Background: Tissue-based h-CGP is increasingly utilized for treatment selection in patients with advanced solid tumors but has high tumor surface area [TSA] requirements (≥25mm^2 for leading commercial tests). P-CGP is recommended when tissue is insufficient for H-CGP. Here we assessed the feasibility and clinical impact on actionable biomarker identification of PCR-CGP. **Methods:** We performed a post-hoc, non-prespecified analysis on 21,743 consecutive subjects with advanced solid tumors who sent TTS for PCR-CGP from 5/17-12/19 as part of an ongoing observational trial at > 20 U.S. health systems (NCT03061305). PCR-CGP was performed using StrataNGS, a single-site laboratory developed test assessing all CGP biomarker classes (including microsatellite instability (MSI) status and tumor mutation burden [TMB]). We predicted actionable biomarker identification rates for PCR-CGP, H-CGP and P-CGP if applied to all U.S. patients with advanced solid tumors through incorporating population incidence, biomarker frequencies, test TSA and tumor content requirements (or cfDNA detection rates), and performance characteristics. Actionable biomarkers were the 30 in 11 tumor types from the MoIDX p-CGP local coverage determination (L38043), pan-tumor NTRK fusions and MSI, and TMB in lung cancer. **Results:** Among TTS from 21,734 patients with advanced cancer, 20,493 (94.3%) met TSA requirements for PCR-CGP (≥2mm^2) vs. 9,281 (42.7%) for H-CGP. PCR-CGP reported results for 98.0% and 95.0% of patients with large (≥25mm^2 TSA) and small (2-24mm^2) TS, respectively, in a median of 7 business days. Compared to 1,882 orthogonal actionable biomarker results, PCR-CGP accuracy was 96.6% and 96.5% in large and small TTS, respectively. Actionable biomarker frequency was highly correlated in PCR-CGP tested large vs. small TTS (r^2= 0.99), as well as in this PCR-CGP cohort vs. a MSKCC institutional pan-cancer H-CGP cohort (r^2= 0.92). If applied to all U.S. patients with advanced solid tumors, PCR-CGP has significantly greater predicted actionable biomarker identification rate (88.5%) compared to P-CGP (77.0%, N-1 chi-squared test, p < 0.0001) or H-CGP (54.3%, p < 0.0001). **Conclusions:** Half of TTS submitted for PCR-CGP did not meet H-CGP tissue requirements. PCR-CGP is feasible for the vast majority of patients and is predicted to expand the actionable biomarker evaluable proportion of patients with advanced solid tumors compared to H-CGP or P-CGP. Clinical trial information: NCT03061305. Research Sponsor: Strata Oncology.

3575 Poster Session (Board #305), Fri, 8:00 AM-11:00 AM

Hyperprogression in cancer patients on immunotherapeutic agents. *First Author: Sumi Dey, University of Michigan, Ann Arbor, MI*

Background: Patients (pts) treated with checkpoint inhibitors (CPI) may uncommonly experience accelerated progression in their tumor burden when compared to their rate of progression prior to receiving CPI. This hyperprogression has been varyingly defined and no biomarker has yet been identified. **Methods:** We reviewed the database from the Tumor Response Assessment Core (TRAC) at University of Michigan to identify these patients. Hyperprogression was defined as increase in tumor burden per specific immune RECIST criteria by at least 40% from baseline on the first follow-up scan with a minimum increase of 10 mm, and at least 2 times rate of growth than observed prior to start of CPI therapy. **Results:** Out of 741 pts who underwent baseline and 1st follow-up assessment enrolled on 118 trials, 302 (34.4%) pts received immunotherapy alone or in combination with chemotherapy/targeted agents across 49 trials. Of them, 15 pts (5%) with 5 females (33%) and median age of 63 years (range, 44 -72) met criteria for hyperprogression. The primary cancers included lung (5), colorectal (2), renal (2), biliary (1), pancreatic (1), esophageal (1), bladder (1), small bowel (1), and melanoma (1). The median time to hyperprogression was 67 (range 42-110) days, and the mean survival was 7.9 months from trial enrollment. We did not identify any clinical factor or specific CPI therapy that associated with hyperprogression. Exploratory biomarker analysis of genomic (gene panel assay) and immune subsets of tissue microenvironment (multiplex staining) is underway. **Conclusions:** This is the largest cohort investigated for hyperprogression across multiple cancers in literature. The rate of hyperprogression observed is less than previously reported in literature, and physicians need to be aware of this possibility while administering CPI to their patients. Research Sponsor: None.

3576 Poster Session (Board #306), Fri, 8:00 AM-11:00 AM

Targetable immune checkpoint molecules may be significantly differentially expressed in minority ethnicities. *First Author: Jacob J. Adashek, University of South Florida, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Studies of immune checkpoint blockade therapy (ICT) outcomes have been largely performed in melanoma and lung cancer patients, both of which are enriched for White patients. For example, a National Cancer Database study found that 97% of first-line ICT treatments in melanoma have been administered to White recipients (Patel, ASCO-SITC 2020). Given expanding indication in tumor types affecting more diverse populations, we sought to study whether minority populations might be projected to have differing checkpoint blockade response rates. **Methods:** Ethnicity information and RNAseq expression profiles and primary site information were obtained for 7087 patients from TCGA. Ethnicity was tested for association with RNA expression of targetable checkpoint genes (*PD1, PDL1, PDL2, CTLA4, IDO1, LAG3, TIM3, TIGIT, OX40, VISTA*, and *GITR*) in 5 tumor histology types by Wilcoxon methods with Benjamini-Hochberg correction for multiple hypothesis testing. A dataset of $>$ 2700 cases was obtained from NantHealth, with paired whole exome/RNAseq data. Ethnicity for 579 patients was assigned using allele-fraction from ~250 single nucleotide polymorphic sites found exclusively in 6 populations within the 1000 Genomes project. Ethnicity/checkpoint associations found in TCGA were tested within this dataset. **Results:** Within the TCGA cohort, ethnicity was not a factor in differential expression of checkpoint molecules in lung cancer. Within melanomas, in Asian patients *PDL1, CTLA4*, and *IDO1* were expressed at lower levels than in White patients (each $p = 0.04$). These associations did not remain significant after correction for multiple hypothesis testing. Breast cancers in Black patients had significantly higher *PD1, CTLA4, IDO1, LAG3, GITR*, and *OX40* expression compared to White patients, all remaining significant after correction (adj. p 3.7e-5 to 6.4e-3). Among White patients, colon cancers showed higher expression of *PDL1/2, IDO1, LAG3, TIM3*, and *GITR* (p 0.04 to 0.0017). *IDO1* was significantly higher in White patients even after correction (adj. $p = 0.03$), and lower in Black patients (adj. $p = 0.03$). **Conclusions:** Ethnicity may represent a significant factor for efficacy checkpoint blockade therapies. White breast cancer patients might be anticipated to exhibit reduced sensitivity to PD1/CTLA4 blockade, while Black colon cancer patients may exhibit reduced sensitivity to IDO1 therapies such as epacadostat. A biomarker-driven approach to patient selection may ameliorate ethnic disparities in ICT outcomes. Research Sponsor: None.

3577 Poster Session (Board #307), Fri, 8:00 AM-11:00 AM

Comparison of recurrence patterns after surgery and radiation therapy with 68Ga-PSMA-11 PET/CT in nonmetastatic castrate-sensitive prostate cancer patients: A single-center post-hoc retrospective analysis in 787 patients. *First Author: Wesley R Armstrong, Ahmanson Translational Theranostics Division, University of California, Los Angeles, CA*

Background: 20 to 50% of prostate cancer (PCa) patients undergoing radical prostatectomy (RP) or definitive radiation therapy (dRT) will experience disease recurrence. However, anatomical recurrence patterns may differ depending on the therapeutic approaches. The aim of this post-hoc retrospective analysis was to investigate if the relapse pattern as assessed by 68Ga-PSMA-11 PET/CT was different depending on the type of local pelvic therapy (RP, dRT, salvage RT (SRT), pelvic lymph node dissection (PLND), pelvic lymph node RT (PLNRT)) in patients with non-metastatic castrate sensitive (nmCS) recurrent disease after primary definitive therapy. **Methods:** Patients who underwent a 68Ga-PSMA-11 PET/CT for nmCS PCa recurrent disease after primary definitive therapy were screened from a database of 4 prospective studies (NCT02940262, NCT03515577, NCT04050215, NCT03582774). Patients who underwent primary staging ($n = 95$), without definitive therapy ($n = 68$), with known metastatic disease (M1) ($n = 68$) or with castrate resistant (CR) disease ($n = 291$) were excluded. We examined the relationship between recurrence patterns as assessed by 68Ga-PSMA-11 PET/CT (PROMISE criteria) and prior local treatments: i) RP, ii) dRT, iii) RP + SRT. **Results:** 787 patients were included in the analysis. Positive scan rates were 60%, 94% and 75% in RP, dRT and RP + SRT populations, respectively. Median pre-scan PSA levels were 0.50 (0.02-72.5) ng/ml, 4.4 (0.1-202) ng/ml, and 1.07 (0.04-33) ng/ml for patients who underwent RP ($n = 464$), dRT ($n = 109$) and post-RP SRT ($n = 214$). Median time to first recurrence was 27.7 after RP and 54.6 months after dRT ($p = < 0.0001$). Patients who underwent RP had lower local recurrence (LR) pattern (T+) rates by PSMA PET than those with dRT (99/464; 21% vs 69/109; 63%; $p = < 0.0001$). Nodal metastasis (N1) positivity rate was similar between RP and dRT (179/464; 39% vs 43/109; 39%; $p = 0.87$). Extrapelvic metastasis (M1) positivity rate was lower for RP than dRT (93/464; 20% vs 51/109; 47%; $p = < 0.0001$). Median time from post-RP SRT to second recurrence was 22.3 months. In patients who had a second recurrence after RP and SRT the positivity rate of LR (T+), N1 disease and M1 disease by PSMA PET/CT was 12% (24/214), 46% (99/214) and 44% (95/214). **Conclusions:** In this cohort of patients with nmCS PCa recurrent disease after primary definitive therapy, the patterns of failure differ based on prior local treatments. Research Sponsor: None.

3578 Poster Session (Board #308), Fri, 8:00 AM-11:00 AM

Highly accurate automated tissue classification using deep learning on digital pathology images: A novel tool for resolving conflicts in diagnosis. *First Author: Stephen Charles Benz, NantOmics, LLC, Santa Cruz, CA*

Background: Pathologist inspection of biopsy slides is the gold-standard for diagnosis and is crucial for effective therapy decisions. However, expert shortage is resulting in turnaround times exceeding College of American Pathologists' (CAP) standards (Alshieban, 2015). Further, discrepancy between diagnoses can exceed 4% (Mukhopadhyay, 2018), and 2% of cases are designated as 'carcinoma of unknown primary' (CUP) negatively affect outcomes due to difficulty selecting therapies (Rassy, 2020). Here we sought to aid in diagnosing patients from whole-slide images (WSIs) using deep neural networks. **Methods:** $>$ 6.3K high-resolution H&E-stained diagnostic WSI of formalin-fixed paraffin-embedded (FFPE) tumor block slices were selected from TCGA sources. Slide images were obtained from 30 different cancer subtypes including 368 Breast (5.6%), 324 Colon (5.12%), 287 Lung Adenocarcinoma (LUAD) (4.5%), Lung Squamous-Cell carcinoma (LUSC) (4.5%), and Stomach Adenocarcinoma (4.3%). Local regions containing tumor tissue were automatically identified by training an *Inception V3* deep-learning network as previously presented. A separate *Inception V3* network was trained to classify the primary tissue of 200mm^2 tumor regions in 60% of the images, which was validated in the remaining 40% testing cohort. **Results:** The proposed deep-learning model was 92.7% accurate in identifying the primary tissue within the test set of WSIs. As expected, most misclassification occurred in highly-related tissue-types: Rectal cancers misclassified as colon (25%) and vice versa (4.8%), uveal melanomas misclassified as cutaneous melanomas (18.6%), cholangiocarcinomas as hepatocellular carcinomas (8.6%), and LUSC misclassified as LUAD (6.0%) and vice versa (3.4%). Combining related tissues, the classifier achieves 94.6% accuracy across 24 primary types. Unexpectedly, cutaneous melanomas samples were misclassified as breast (9.1%) and LUSC (5.6%), suggestive of related molecular phenotypes. **Conclusions:** By focusing machine-vision attention on tumor regions, the automated system approaches pathologist accuracy. Used in conjunction with molecular profiling, rates of CUP or misdiagnosis can feasibly be minimized to improve patient care. This system is currently being validated in an external set of $>$ 4K unselected clinical cases from the NantHealth database. Research Sponsor: ImmunityBio.

3579 Poster Session (Board #309), Fri, 8:00 AM-11:00 AM

A phase Ib study of oral Chk1 inhibitor LY2880070 as monotherapy in patients with advanced or metastatic cancer. *First Author: Wilson H. Miller, Segal Cancer Center, Jewish General Hospital, Rossy Cancer Network, McGill University, Montreal, QC, Canada*

Background: LY2880070 (LY) is an orally-administered, selective adenosine triphosphate-competitive inhibitor of checkpoint kinase 1 (Chk1). LY blocks the checkpoint response, and Chk1 inhibition results in mitotic catastrophe to produce apoptosis. **Methods:** This 2-part, open-label multicenter study explores the safety, pharmacokinetics (PK) and anti-tumor activity of LY in patients with advanced or metastatic cancers. The primary objective of this study was to determine the maximum tolerated dose (MTD) for multiple escalating oral doses of LY. Secondary objectives were to: 1) Characterize the dose-limiting toxicities (DLTs) and overall safety profile for LY; 2) Evaluate the PK of LY; and 3) Evaluate the anti-tumor activity of LY. Patients received LY orally in 21-day cycles in two treatment arms: 1) A multiple ascending dose (MAD) arm in patients with normal/intermediate CYP2D6 metabolism; or 2) An arm with LY administered as monotherapy to CYP2D6 poor metabolizers. **Results:** The MTD in normal/intermediate CYP2D6 metabolizers was 200 mg BID daily. A dose of 400 mg QD was not tolerated even with the use of anti-emetics. However, BID administration (same total daily dose) made LY tolerable. Dose-limiting toxicities were predominantly vomiting, nausea, and fatigue, and appeared to be correlated with C_{max}. The mean half-life was 5.35 (+/- 2.3) hours. BID dosing provided maintenance of the AUC (3271.4 h•ng/mL 200 mg BID vs 3377.9 h•ng/mL 400 mg QD) while lowering C_{max} (350.0 ng/mL 200 mg BID vs 691.9 ng/mL 400 mg QD) and increasing C_{min}, compared to QD dosing of the same total daily dose. Importantly, BID administration of 200 mg LY resulted in a median C_{min} at steady-state that remains above the IC_{80} for 12 h/day and above the IC_{50} for 24 h/day. Five patients had a best response of SD for a duration of $\geq$ 6 cycles. **Conclusions:** LY was tolerated in a daily BID schedule. The toxicity profile can be modulated by changing the dosing frequency from QD to BID while administering the same daily dose. LY may be a potential combination therapy with DNA damaging agents. Study #: NCT02632448. This study is sponsored by Esperas Pharma Inc., 1255 boul. Robert-Bourassa #1610, Montreal, Qc, H3B 3X3. Clinical trial information: NCT02632448. Research Sponsor: Esperas Pharma Inc.

3580 Poster Session (Board #310), Fri, 8:00 AM-11:00 AM

Preclinical evaluation of XPO1 inhibition in Wilms tumors. *First Author: Michael Vincent Ortiz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: XPO1 is a nuclear export protein that selectively transports tumor and growth regulatory proteins out of the nucleus, thereby effectively inhibiting their function. We previously utilized the Virtual Inference of Protein-activity by Enriched Regulon analysis (VIPER) algorithm to discover that malignant rhabdoid tumors were dependent upon XPO1 inhibition and then evaluated a preclinical cohort using selinexor (KPT-330), the first-in-class selective inhibitor of nuclear export, to demonstrate that XPO1 inhibition was sufficient to cause cell cycle arrest, apoptosis, and disease control in multiple cell line and patient derived xenograft (PDXs) models. Our subsequent analysis revealed that the most common childhood kidney tumor, Wilms tumor, has even high higher inferred activity of XPO1 than rhabdoid tumors leading to our hypothesis that XPO1 inhibition is an effective therapeutic strategy to treat Wilms tumors. **Methods:** A panel of 9 Wilms tumor cell lines and 3 Wilms tumor PDXs were genomically characterized and tested to evaluate the pre-clinical efficacy of XPO1 inhibition in Wilms tumors. **Results:** Proliferation rate, increased XPO1 protein expression, and loss of function mutations in TP53 correlated with *in vitro* Wilms tumor cell line sensitivity to selinexor. Evaluation of co-segregation of all single nucleotide variant changes using with inferred activity of XPO1 on VIPER in all TGCA tumors demonstrates a strong association with TP53 alterations. XPO1 inhibition was effective in all Wilms tumor models tested, most significantly in MSKREN-57196, a favorable histology Wilms tumor PDX with somatic 1q gain as well as WTX and MYCN mutations, as well as in MSKREN-31827, a diffusely anaplastic TP53 mutant Wilms tumor PDX. Eltanexor (KPT-8602) is an XPO1 inhibitor with decreased CNS penetration and an improved toxicity profile; this drug was tested in these in vivo models and found to be at least as effective as selinexor. **Conclusions:** Somatic 1q gain in favorable histology Wilms tumors and TP53 mutations in diffusely anaplastic Wilms tumors have a particularly poor prognosis in the relapsed setting. Our study demonstrates that XPO1 inhibition may provide a rational therapeutic option to treat such high-risk Wilms tumors. Future clinical trials evaluating XPO1 inhibitors should evaluate its efficacy in children with relapsed Wilms tumors. Research Sponsor: Cycle for Survival, Other Foundation, U.S. National Institutes of Health, Friends and family of Caroline Bhatt.

3581 Poster Session (Board #311), Fri, 8:00 AM-11:00 AM

A phase Ib study of oral Chk1 inhibitor LY2880070 in combination with gemcitabine in patients with advanced or metastatic cancer. *First Author: Quincy S. Chu, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada*

Background: LY2880070 (LY) is an oral, selective competitive inhibitor of checkpoint kinase 1 (Chk1). Chk1 inhibitors are known to increase the antitumor efficacy of agents such as gemcitabine (GEM), which induce replication stress. Synergy between these two agents has been applied to the clinical setting. **Methods:** This two-part, open-label multi-center study explores the safety, pharmacokinetics (PK), and anti-tumor activity of LY in patients with advanced or metastatic cancers. The primary objective of this study was to determine the maximum tolerated dose (MTD) for multiple escalating oral doses of LY in combination with GEM. Secondary objectives were to: 1) Characterize the dose-limiting toxicities (DLTs) and overall safety profile for LY; 2) Evaluate the PK of LY; and 3) Evaluate the anti-tumor activity of LY. Patients received LY in a variety of different dose regimens, in combination with GEM (50 to 800 mg/m^2) on days 1, 8, and 15 (optional) of a 21-day cycle. **Results:** The combination of LY with GEM required lower doses of both LY (vs 200 mg BID monotherapy RP2D dose) and GEM (vs approved doses). The dose levels explored ranged from LY:GEM of 10 mg QD: 800 mg/m^2 to 50 mg BID:100 mg/m^2. BID dosing of LY was implemented in order to maximize the total daily dose and avoid the adverse events that appeared to correlate with C_{max}. Treatment-emergent adverse events in $>$ 40% of patients included vomiting, nausea, and fatigue. DLTs included reduced platelet count (Gr2), fatigue (Gr3), diarrhea (Gr3), and thrombocytopenia (x2, Gr2). The $t_{1/2}$ of LY was ~ 5 h, and was not significantly affected by combination with GEM. Two patients had a best overall response of SD for a duration of $\geq$ 6 cycles, and a confirmed PR was observed in an ovarian cancer patient who had failed multiple regimens. **Conclusions:** LY was tolerated in combination with lower dose GEM. The toxicity profile can be modulated by changing the dosing frequency from QD to BID while administering the same daily dose. LY may be good candidate for combination therapy with DNA damaging agents. Clinical trial information: NCT02632448. Research Sponsor: Esperas Pharma Inc.

3582 Poster Session (Board #312), Fri, 8:00 AM-11:00 AM

Preclinical evaluation of KZR-261, a novel small molecule inhibitor of Sec61. *First Author: Eric Lowe, Kezar Life Sciences, South San Francisco, CA*

Background: Secreted and transmembrane proteins play key roles in malignant transformation and growth, including in autocrine growth factor expression, receptor oncogene signaling, and immune system evasion. Biogenesis of these proteins involves translocation of the nascent polypeptides into the endoplasmic reticulum (ER) through the Sec61 channel, providing an untapped therapeutic target for a broad spectrum of malignancies. Here we describe preclinical activity of KZR-261 and related inhibitors of Sec61-dependent protein secretion. **Methods:** Sec61 inhibition with KZR-261 and related analog KZR-834 were evaluated using cell lines overexpressing proteins of interest tagged with luciferase. In vitro anti-tumor activity was assessed against a panel of 346 cell lines across 25 tumor types. Quantitative proteomic profiling by mass spec and gene expression profiling by RNAseq were conducted following treatment in multiple solid and heme tumor cell lines. Anti-tumor efficacy was evaluated in athymic nude mice implanted with the cancer cell lines H82 (SCLC), HT29 (CRC), BxPC3 (Pancreatic), 22RV1 (Prostate), H929 (Myeloma) and RL (NHL). Activity was also evaluated in a MC38 syngeneic colon tumor model. **Results:** KZR-261 and KZR-834 exhibited nanomolar potency against many therapeutic targets, including immune checkpoints, VEGF-A, VEGFR and EGFR. Broad in vitro anti-cancer activity was observed with KZR-834, which potently decreased cell viability across both solid and heme tumor types including CRC, Pancreatic, HNSCC, HCC, Lymphoma and Myeloma. Global proteomic analysis observed more than 1.5 fold downregulation of $<$ 10% of detected Sec61 client proteins following treatment, while gene expression profiling revealed upregulation of ER stress response genes in sensitive versus resistant cell lines. Analysis of the TCGA database also found these genes upregulated in a number of different tumor types. In vivo, weekly IV administration was well tolerated and induced a dose dependent anti-tumor response at doses below the MTD in solid and heme xenograft models. In the syngeneic MC38 model, administration of KZR-834 in combination with anti-PD1 antibody resulted in greater anti-tumor activity than either single agent. **Conclusions:** Novel Sec61 inhibitors potently block expression of secreted and membrane proteins, translating into anti-tumor activity against many tumor types in vitro and in vivo, suggesting broad therapeutic potential. Clinical trials are being planned with KZR-261 to understand safety and early efficacy of this novel compound and therapeutic target. Research Sponsor: Kezar Life Sciences.

3583 Poster Session (Board #313), Fri, 8:00 AM-11:00 AM

Results of a completed phase I trial of CBL0137 administered intravenously (IV) to patients (Pts) with advanced solid tumors. *First Author: John Sarantopoulos, Institute for Drug Development, Mays Cancer Center at University of Texas Health San Antonio, San Antonio, TX*

Background: The novel curaxin CBL0137 intercalates into DNA, interfering with histone/DNA binding. Consequent trapping of histone chaperone FACT leads to MYC, NF-kB, and HSF1 inhibition, p53 activation, and an IFN response. CBL0137 shows broad nonclinical antitumor activity (Gasparian et al. Sci Transl Med. 2011; 3(95):95ra74). **Methods:** This dose-ranging study assessed the CBL0137 maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D) and CBL0137 safety, pharmacokinetics (PK), and efficacy in adults with advanced treatment-refractory solid tumors. CBL0137 was administered IV on Days 1, 8, and 15 of repeated 28-day cycles until progressive disease (PD) or unacceptable toxicity. Doses were escalated using a 3+3 design based on Cycle 1 dose-limiting toxicities (DLTs). PK was assessed through 168 hours after Day 1. Efficacy was evaluated every 8 weeks. **Results:** The study enrolled 83 pts (M/F [n] = 49/34; median [range] age = 64 [33-85] years; ECOG status [n] = 1/2 [32/51]), with cancer types (n) of colorectal (23), prostate (7), glioblastoma (6), liver (6), non-small-cell (5), and others (36) across 17 dose levels from 10 to 700 mg/m^2/infusion. Durations of therapy ranged to 24 months. Cycle 1 DLTs (n type) were observed at 240 mg/m^2 (1 Gr 3 photosensitivity), 400 mg/m^2 (1 Gr 3 anemia), 700 mg/m^2 (1 Gr 4 thrombocytopenia, 1 Gr 4 neutropenia/Gr 4 thrombocytopenia), and 650 mg/m^2 (1 Gr 3 thrombocytopenia, 1 Gr 4 neutropenia/Gr 3 thrombocytopenia). Nausea and vomiting were successfully prevented with dexamethasone/serotonin antagonists. Photosensitization was effectively managed with sun protection. Peripheral venous thrombosis required central vein infusion in subjects with glioblastoma. PK showed dose-proportional increases in plasma CBL0137 area under the concentration-time curve (AUC), a high mean (range) volume of distribution (Vd) of 1,030 (655-1460) L/m^2 consistent with extensive tissue distribution and DNA intercalation, and an average mean (range) half-life ($t_{1/2}$) of 24.7 (10.3-40.7) hours without dose dependence. The best response was stable disease: 2 pts with liver cancer had tumor control for 9 and 24 months and a maximum tumor regression of 10%; 2 pts with prostate cancer had tumor regressions by 11% and 22%; 1 pt with uterine cancer had a 20% tumor regression. **Conclusions:** CBL0137 administered IV was generally well tolerated with manageable toxicities The MTD and RP2D were estimated at 540 mg/m^2 due to myelosuppressive DLTs. PK were predictable. Preliminary evidence of antitumor activity supports Phase 2 testing. Clinical trial information: NCT01905228. Research Sponsor: Incuron, Inc.

3584 Poster Session (Board #314), Fri, 8:00 AM-11:00 AM

Selpercatinib (LOXO-292) in patients with *RET*-fusion+ non-small cell lung cancer. *First Author: Koichi Goto, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Selpercatinib (LOXO-292) is a highly selective and potent small molecule RET kinase inhibitor. Here we report an update on the efficacy and safety of selpercatinib in *RET*-fusion+ non-small-cell lung cancer (NSCLC). **Methods:** Patients with *RET*-fusion+ NSCLC were enrolled to the Phase 1/2 LIBRETTO-001 trial (NCT03157128), a global, multicenter trial (16 countries, 89 sites). Following the Phase 1 dose escalation portion of the trial, patients received the recommended dose of 160 mg orally twice daily. Each cycle was 28 days. The primary endpoint was objective response rate (ORR) per RECIST 1.1. Secondary endpoints included duration of response (DoR) and safety. Per health authority agreement, the primary analysis set was defined as the first 105 consecutively enrolled patients previously treated with platinum-based chemotherapy. Treatment-naïve patients were analyzed separately. All analyses were based on a 16-Dec-2019 data cutoff date. **Results:** In the primary analysis set of platinum-treated patients (median of 3 prior systemic regimens; range 1-15), the ORR by investigator assessment was 70% (95% CI 59.8–78.1, n = 73/105). Responses did not differ by fusion partner or number or type of prior therapies, including anti-PD-1/PD-L1 agents and off-label multikinase inhibitor use. The median DoR was 20.3 months (95% CI 15.6–24.0) with 45 of 73 (62%) responders censored at a median follow-up of 14.8 months. Among 39 treatment-naïve patients, the ORR by investigator assessment was 90% (95% CI 75.8–97.1, n = 35/39, including 2 responses pending confirmation). Median DoR was not reached with 27 of 33 (82%) confirmed responses ongoing at a median follow-up of 7.4 months. In the safety analysis set consisting of all selpercatinib dosed patients (N = 702), the most common treatment-related adverse events (TRAEs) that occurred in ≥15% of patients were dry mouth (33.3%), increased AST (24.5%), increased ALT (23.8%), hypertension (23.2%), diarrhea (19.7%), and fatigue (16.8%). Only 2% (14 of 702) of patients discontinued selpercatinib for TRAEs. **Conclusions:** Selpercatinib achieved marked and durable antitumor activity in patients with *RET*-fusion+ NSCLC. Selpercatinib was well tolerated. Efficacy data assessed by independent review committee based on the 16-Dec-2019 data cutoff date will be presented. Clinical trial information: NCT03157128. Research Sponsor: Loxo Oncology Inc., a wholly owned subsidiary of Eli Lilly and Company.

3585 Poster Session (Board #315), Fri, 8:00 AM-11:00 AM

Activity of SY-5609, an oral, noncovalent, potent, and selective CDK7 inhibitor, in preclinical models of colorectal cancer. *First Author: Liv Johannessen, Syros Pharmaceuticals, Cambridge, MA*

Background: Colorectal cancer (CRC) is driven by genetic alterations that result in constitutive activation of oncogenic transcription factors (eg β-catenin, MYC) and of mitogenic signaling and cell cycle progression (driven by oncogenic mutations in KRAS and BRAF). CDK7 is a key regulator of transcription, through phosphorylation of the CTD domain of RNA Polymerase II, and of cell cycle progression, through phosphorylation of the cell cycle kinases CDK1, 2, 4, and 6. This dual role of CDK7 suggests inhibitors of CDK7 may be effective in the treatment of CRC. SY-5609 is an oral, noncovalent, potent and highly selective CDK7 inhibitor in phase 1 clinical development for patients with advanced solid tumors including CRC (NCT04247126). Here we report on the activity of SY-5609 in patient-derived xenograft (PDX) models of CRC. **Methods:** SY-5609 was administered once daily (QD) by oral gavage for 21 days (end of treatment, EOT) to mice bearing PDX models of CRC. The relationship between SY-5609 dose, pharmacodynamic (PD) changes in xenograft tissue, tumor growth inhibition (TGI), and mouse body weight (BW) was evaluated across a range of doses. SY-5609 TGI activity was also evaluated at sub-maximum-tolerated-dose levels across a panel of 30 independent CRC models including BRAF-, KRAS-, and non-BRAF/KRAS-mutant (wild type) models (n = 10 per group). **Results:** SY-5609 induced dose-dependent TGI in BRAF-mutant CRC PDX tumors, with tumor regressions observed at well tolerated doses (no BW loss at EOT), and no tumor regrowth for 2+ weeks after treatment was discontinued. Dose-dependent TGI was associated with dose-dependent PD changes in PDX tumor tissue. Across 30 PDX models, SY-5609 at well-tolerated doses (average BW loss of 0% at EOT across all models) induced ≥50% TGI in 67% (20/30) of models. Deep responses (≥90% TGI or regressions) were observed in 23% (7/30) of models, with enrichment for deep responses in BRAF mutant models (50%, 5/10) relative to KRAS mutant (10%, 1/10), and wild type (10%, 1/10) models. **Conclusions:** Daily oral dosing of the CDK7 inhibitor SY-5609 induces robust TGI, including regressions, in CRC PDX models at well-tolerated doses. Dose-dependent TGI is associated with dose-dependent PD changes in CRC PDX tumor tissue. These results highlight the therapeutic potential of SY-5609 in CRC and support the evaluation of SY-5609 in CRC patients in early phase clinical trials. SY-5609 is in phase 1 clinical development for patients with advanced solid tumors including CRC (NCT04247126). Research Sponsor: Syros Pharmaceuticals.

3586 Poster Session (Board #316), Fri, 8:00 AM-11:00 AM

A phase I, first-in-human, open-label, dose-escalation, safety, pharmacokinetic, and pharmacodynamic study of oral TP-3654 administered daily for 28 days to patients with advanced solid tumors. *First Author: Ignacio Garrido-Laguna, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: TP-3654 is an oral, second generation, potent PIM-1 kinase inhibitor with activity against PIM 2, 3 and favorable selectivity against other kinases. These cytoplasmic serine/threonine kinases are highly expressed in many cancers and their oncogenic potential has been largely attributed to supressing apoptosis downstream of stimuli including inflammatory cytokines and other immune effectors. TP-3654 has efficacy in various hematologic and solid tumor models inducing stromal Pim-1 also has been shown to mediate various aspects of the tumor microenvironment. Thus, Pim kinases are attractive targets for the treatment of many human malignanices. **Methods:** A first in human, multicenter, phase 1, dose escalation study using a standard 3+3 design with a modified Fibonacci scheme to examine the safety and clinical activity of TP-3654 in patients with advanced solid tumors. **Results:** Ten patients were enrolled between 30Apr and 31Dec2019 receiving 480, 720, and 1080 mg respectively. Grade 3 AEs were scrotum wound infection, altered mental status, anemia, fall, and lower extremity edema, none were related to study drug and all were manageable with supportive care. There were no Grade 4 or 5 AEs and no DLTs. Median duration of SD was 5.5 months (6/10) and with prolonged SD > 16wks (4/10). One CRC patient with 4 lines of prior therapy had a 22% reduction in tumor volume (SD > 5+ mos). TP-3654 plasma PK values (C_{max}, AUC) continuously increased through all 3 cohorts. Average C_{max} (ng/mL) and $AUC_{0\text{-}24}$ (ng*hours/mL) were 195, 1965 (480mg); 357, 3310 (720mg); 735, 6922 (1080mg), respectively. PK values increased linearly with higher doses without reaching saturation. Peripheral Blood Mononuclear Cells were isolated from subjects prior and up to 24hours after treatment. Western Blot from protein lysates revealed a decrease in phosphorylation of BAD and p70s6K proteins, both regulated by PIM-1 kinase. **Conclusions:** These findings suggest that TP-3654 is tolerated as a monotherapy in patients with heavily pretreated, relapsed, and resistant solid tumors warranting further clinical development in selected indications. Research Sponsor: Tolero Pharmaceuticals.

3587 Poster Session (Board #317), Fri, 8:00 AM-11:00 AM

AVID200, first-in-class TGF-beta 1 and 3 selective and potent inhibitor: Safety and biomarker results of a phase I monotherapy dose-escalation study in patients with advanced solid tumors. *First Author: Timothy A Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: AVID200 is a rationally designed first-in-class, selective inhibitor of transforming growth factor-beta (TGF-beta) that neutralizes TGF-beta 1 & 3 with pM potency and 4,000 fold selectivity over TGF-beta 2. TGF-beta 1 & 3 signaling has been associated with immune checkpoint inhibitor resistance and immunosuppression in the tumor microenvironment while TGF-beta 2 is required for normal cardiac function and hematopoiesis. **Methods:** NCT03834662 (AVID200-03) is a multicenter Phase 1 study following a standard 3 + 3 dose escalation to evaluate safety and tolerability of AVID200 given IV every 3 weeks to patients (pts) with advanced solid tumors. Peripheral target engagement was assessed in blood by ELISA and a cell-based functional assay, and in skin biopsies by immunohistochemistry (IHC). Pharmacodynamic markers of TGF-beta signal modulation and immune activation were evaluated in serum using the InflammationMAP v 1.0 (Myriad RBM) and in paired tumor biopsies by IHC and Imaging Mass Cytometry. **Results:** Nineteen pts (ECOG 0-1, median age 63 [range 39-77], 52.6% male) received AVID200 at 3 planned dose levels of 180 (N = 7), 550 (N = 6), and 1100 mg/m^2 (N = 6) (~5, 15, and 30 mg/kg). The maximum tolerated dose was not reached. Three Grade (G) 3 treatment-related adverse events (TRAEs) were reported in 2 pts (diarrhea and lipase elevation, anemia); no > G3 TRAEs were observed. Serum exposure was dose-proportional and AVID200 sequestered all active TGF-beta 1 & 3, but not beta 2, in blood across the entire dosing period at all dose levels, providing proof-of-mechanism of AVID200. SMAD2 phosphorylation in skin biopsies was detectably reduced on Day 4 at 15 and 30 mg/kg. Pro-inflammatory markers in serum were increased on Day 8 versus baseline in a dose-dependent manner. Tumor biopsies of pts treated at 15 mg/kg showed modulation of TGF-beta signaling and immune activation. A best response of RECIST stable disease > 12 weeks was observed in 2 pts: 1 with adenoid cystic carcinoma (5 mg/kg; 8.7 months); 1 with breast carcinoma (30 mg/kg; 3.1 months). **Conclusions:** AVID200 was safe and well tolerated at dose levels of 5-30 mg/kg, with peripheral target engagement across the entire dosing period. AVID200 led to TGF-beta target modulation and immune activation. These data provide proof-of-principle that AVID200-mediated selective and potent inhibition of TGF-beta 1 & 3 is feasible in the clinic. The AVID200 monotherapy data warrant exploration of rational combination with a PD-(L)1 inhibitor. Clinical trial information: NCT03834662. Research Sponsor: Forbius.

3588 Poster Session (Board #318), Fri, 8:00 AM-11:00 AM

Correlation between overall response rate and progression-free survival/overall survival in comparative trials involving targeted therapies in molecularly enriched populations. *First Author: Benjamin J. Solomon, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Randomized trials involving agents targeting oncogene addicted tumors have greatly increased over the past decade. Whether clinical response rates can predict or correlate with efficacy measures such as progression-free survival (PFS) or overall survival (OS) has not been established in molecularly enriched patient populations. In this meta-analysis, we investigated whether improvements in objective response rate (ORR) in comparative trials using targeted agents could serve as a potential surrogate endpoint for improvements in PFS or OS in populations with oncogene addicted cancer. **Methods:** CT.gov and MEDLINE databases were queried (using commercial text mining software I2E) for randomized, phase 3 clinical trials based on the following prospectively defined criteria: (1) use of agents targeting EGFR activating mutations (erlotinib, gefitinib, afatinib, dacomitinib, osimertinib), ALK and ROS1 rearrangements (crizotinib, ceritinib, alectinib), BRAF V600E or V600K mutations (dabrafenib), and BCR-ABL fusion protein (imatinib, dasatinib, nilotinib, ponatinib); (2) must include molecularly enriched trial populations (biomarker subgroup data included if available); (3) control arms should not include targeted agents directed towards those molecularly enriched populations. ORR, OS, and PFS data were manually extracted from the relevant studies and correlative analyses (weighted Pearson correlation) were performed. **Results:** 61 trials were identified with 15 ultimately meeting the prespecified criteria. ORR effect size (both the ORR difference and log odds ratio) and the log PFS hazard ratio were strongly correlated (-0.78, p-value = 0.0007). No significant correlation was found between ORR and OS. **Conclusions:** In our analyses, a strong correlation between ORR and PFS was found in randomized clinical trials investigating agents targeting oncogene-driven cancers. Establishing a correlation between ORR and OS was limited, most probably due to confounding factors such as treatment cross-over following progression, number of subsequent therapies and long post-progression survival in this setting. These findings further warrant the use of ORR as a surrogate for PFS in biomarker-driven studies. Research Sponsor: Eli Lilly and Company.

3589 Poster Session (Board #319), Fri, 8:00 AM-11:00 AM

Phase I study of the combination of alisertib (MLN8237) and gemcitabine in advanced solid tumors. *First Author: Jasmine Huynh, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Aurora Kinase A (AKA) is a key mitotic regulator overexpressed in multiple solid tumors. This open-label dose escalation and expansion phase I study evaluated the safety and tolerability of alisertib (MLN8237), an oral AKA inhibitor, in combination with gemcitabine. **Methods:** In dose escalation, patients (pts) > 18y with refractory solid tumors received 28-day cycles of gemcitabine on days 1, 8, 15 and alisertib twice daily on days 1-3, 8-10, and 15-17. Gemcitabine was given at 1000mg/m2. Four dose levels (DL) of alisertib (20-50mg) were given per 3+3 design to investigate dose limiting toxicities (DLT) in cycle 1, to determine maximum tolerated dose (MTD) and recommended phase II dose (RP2D). In dose expansion, advanced pancreatic adenocarcinoma pts received the MTD dose twice daily on a modified dosing schedule to allow for pharmacokinetic (PK) evaluation. Anti-tumor activity was assessed by response rate (RECIST 1.1) and progression-free survival (PFS). PK evaluation of plasma gemcitabine and alisertib was performed on all pts enrolled in the dose expansion. PK sampling was performed before treatment, immediately after gemcitabine infusion, and at other pre-specified post-infusion timepoints. **Results:** Twenty-six pts were treated in total: 21 pts in dose escalation and 5 pts in dose expansion. Overall, median age was 57y [42-82]; 50% male; 62% PS 1 (16 pts); 2 [0-7] median prior therapies. In the dose escalation phase, 9 tumor types were included and NSCLC was most common (7 pts). Maximum administered dose (DL4) achieved 900 mg alisertib per cycle and was tolerated (1 DLT in 6 pts). The dose expansion phase enrolled 5 pts with advanced pancreatic adenocarcinoma; median age 63y [48-82]; 60% male; 60% PS 1 (3 pts); 2 [1-2] median prior therapies. Grade ≥3 TRAEs were observed in 73% of all pts and were predominantly hematologic, including neutropenia (54%), leukopenia (50%), and lymphopenia (31%). Similar TRAEs were seen at DL4; all 14 pts experienced neutropenia with 64% experiencing grade ≥3 neutropenia. Fourteen of 23 evaluable pts (61%) had stable disease and 2 pts (9%) had partial response (PR) as best overall response. Median PFS was 2.9 months (95% CI 2.0-4.2). Analysis of PK data is ongoing and will be reported. **Conclusions:** Alisertib can be safely administered with gemcitabine. RP2D for alisertib is 50 mg PO BID in combination with full dose gemcitabine. Best response was at least stable disease in a majority of pts with PR observed in 9% of this heavily pretreated group of patients. Most grade ≥3 TRAEs were hematologic. Results of PK studies will also be reported. Clinical trial information: NCT01924260. Research Sponsor: Takeda.

3590 Poster Session (Board #320), Fri, 8:00 AM-11:00 AM

Phase I study of IM156, a novel potent biguanide oxidative phosphorylation (OXPHOS) inhibitor, in patients with advanced solid tumors. *First Author: Sun Young Rha, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: IM156, a novel oral potent biguanide OXPHOS inhibitor of Protein Complex 1 (PC1) of the mitochondrial electron transport chain, causes AMPK phosphorylation, the downstream effects of which are detrimental to OXPHOS-dependent cancer cells prone to energy stress. Preclinical experiments with IM156 demonstrated activity in solid tumor and hematologic malignancy models as a single-agent and in combinations. **Methods:** This was an open label, first-in-human, multi-center, dose-escalation study (NCT03272256) using a 3+3 design. The primary endpoint was to determine the maximum tolerated dose and/or recommended Phase 2 dose (RP2D) based on dose limiting toxicities (DLT), safety and tolerability. Secondary endpoints included pharmacokinetics (PK), pharmacodynamics (PD) and preliminary signals of efficacy. Eligible patients were adults with advanced solid tumors refractory to standard therapies with ECOG Performance Status <2, adequate organ function, and measurable disease (RECIST 1.1 or RANO [gliomas]). IM156 was administered orally every other day (QOD) or daily (QD) in 28-day cycles. **Results:** 22 patients (gastric cancer: N = 8; ovarian cancer: N = 3; colorectal cancer: N = 3; endometrial cancer: N = 2; sarcoma: N = 2; other: N = 4) were enrolled in 7 dose cohorts (100, 200, 400, 800, and 1,200 mg QOD; 800 and 1,200 mg QD). The most frequent treatment-related adverse events (TRAEs) were gastrointestinal (nausea [N = 16, 73%], diarrhea [N = 12, 55%], and vomiting N = 11, 50%]). Nausea, reported in 3 (14%) patients, was the only Grade 3 TRAE. No DLTs were reported; the RP2D declared was 800 mg as 1,200 mg QD was associated with Grade 2/3 nausea requiring dose modifications. PK demonstrated dose-proportional increases in C_{max} and $AUC_{0\text{-}last}$ reaching the expected efficacious range. PD demonstrated a decrease in tumor growth rate in 3 patients (1,200 mg QOD: N = 2; 800 mg QD: N = 1), and a decrease in VEGF and tumor markers in a patient with gastric cancer with neuroendocrine differentiation treated at 800 mg QD who remains on study in Cycle 11. Best response was stable disease in 7 (32%) patients. **Conclusions:** IM156 is the first PC1 OXPHOS inhibitor to have been successfully tested in patients with cancer with the identification of a RP2D. It was well tolerated at dose levels active in preclinical models, and demonstrated modest clinical activity in an unselected population of patients. Subsequent development will focus on OXPHOS-dependent tumors and in combinations with agents in which OXPHOS metabolism is a mechanism of resistance. Clinical trial information: NCT03272256. Research Sponsor: Immunomet Therapeutics.

3591 Poster Session (Board #321), Fri, 8:00 AM-11:00 AM

TOOme: A novel computational framework to infer cancer tissue-of-origin by integrating both gene mutation and expression. *First Author: Wei Gao, Departments of Internal Medicine-Oncology, Fujian Provincial Cancer Hospital and Fujian Medical University Cancer Hospital, Fuzhou, China*

Background: Metastatic cancers require further diagnosis to determine their primary tumor sites. However, the tissue-of-origin for around 5% tumors could not be identified by routine medical diagnosis according. With the development of machine learning techniques and the accumulation of big cancer data from TCGA and GEO, it is now feasible to predict cancer tissue-of-origin by computational tools. **Methods:** Developed a computational framework to infer tumor tissue-o. **Results:** Applied TOOme to the TCGA data containing 7,008 non-metastatic samples across 20 solid tumors including BLCA, BRCA, CESC, COAD, GBM and so on. 74 genes by gene expression profile and 6 genes by gene mutation are selected by the random forest process, which can be divided into two categories: (1) cancer type specific genes, which are highly expressed or mutated only in one specific cancer and (2) those expressed or mutated in several cancers with different levels of expression or mutation rates. Function analysis indicates that the selected genes are significantly enriched in gland development, urogenital system development, hormone metabolic process, thyroid hormone generation prostate hormone generation and so on. According to the multiple-label classification method, random forest performs the best with a 10-fold cross-validation prediction accuracy of 96%. We also use the 19 metastatic samples from TCGA and 256 cancer samples downloaded from GEO as independent testing data, for which TOOme achieves a prediction accuracy of 89%. The cross-validation validation accuracy is better than those using gene expression (i.e., 95%) and gene mutation (83%) alone. **Conclusions:** TOOme provides a quick yet accurate alternative to traditional medical methods in inferring cancer tissue-of-origin. In addition, the methods combining somatic mutation and gene expressions outperform those using gene expression or mutation alone. Research Sponsor: None.

3592 Poster Session (Board #322), Fri, 8:00 AM-11:00 AM

Phase Ib/IIa study of GC1118 in combination with irinotecan or FOLFIRI in patients with metastatic solid tumors. *First Author: Keun Wook Lee, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, South Korea*

Background: GC1118 is a novel anti-EGFR monoclonal antibody which has a unique binding epitope and superior ligand inhibition potential. It showed promising antitumor activity as a single agent in the phase I study. This study aimed to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of GC1118 in combination with irinotecan or FOLFIRI in metastatic solid tumors and evaluate the efficacy of GC1118 plus FOLFIRI as a second line therapy for RAS and BRAF wild-type metastatic colorectal cancer. **Methods:** Phase 1b part was designed to evaluate weekly GC1118 (starting from 3 mg/kg) in combination with biweekly irinotecan (180mg/m^2) or FOLFIRI (irinotecan 180mg/m^2, leucovorin 400mg/m^2, 5-FU 400 mg/m^2 bolus, and 5-FU 2400mg/m^2 over 46hrs) in a 3+3 design. In the phase 2a part, the RP2D of GC1118 is administered in combination with FOLFIRI in a Simon's two stage design with objective response rate (ORR) as the primary endpoint. **Results:** 13 pts were enrolled in phase 1b and received 3mg/kg of GC1118 with irinotecan (N = 6) or FOLFIRI (N = 7). DLT occurred in 2 pts (G4 neutropenia, G2 rash) in irinotecan arm and 1pt (G3 neutropenia) in FOLFIRI arm with 3mg/kg of GC1118 and it was determined as MTD and RP2D. Adverse events (AE) of grade $\geq$ 3 included neutropenia (61.5 %), skin rash (15.4 %) and diarrhea (15.4%). Dose reductions due to GC1118-related AE were required in 6 (46.2%) patients. Among 10 response-evaluable pts in phase 1b, best overall response was PR in 3 and SD in 6, and median PFS was 12 months. In stage 1 of phase 2a (N = 9), 4 PR and 5 SD were observed (ORR 44.4%, 95% CI 13.7 – 78.8). We moved to stage 2, and are currently enrolling additional 20 pts. AE of grade $\geq$ 3 included neutropenia (66.7%), skin rash (22.2%) and diarrhea (11.1%). Updated data of the phase 2a part will be presented at the meeting. **Conclusions:** The MTD and RP2D of weekly GC1118 in combination with irinotecan or FOLFIRI was 3mg/kg. Preliminary results of GC1118 and FOLFIRI as a 2nd line treatment in mCRC suggests promising antitumor activity and acceptable safety profile. Clinical trial information: NCT03454620. Research Sponsor: Green Cross Corporation.

3593 Poster Session (Board #323), Fri, 8:00 AM-11:00 AM

Phase I study of regorafenib and sildenafil in advanced solid tumors. *First Author: Andrew Stewart Poklepovic, VCU Massey Cancer Center, Richmond, VA*

Background: Regorafenib (R) is an oral multikinase inhibitor with anti-angiogenic properties approved for use in several solid tumors. Sildenafil (S) is an oral phosphodiesterase-5 (PDE5) inhibitor that interacts synergistically with R in both short-term and colony formation assays to kill multiple cancer cell types. Mechanistic studies identified that PDE5 knockdown enhances R lethality, suggesting a direct target effect for S. **Methods:** A single-center, open-label, dose-escalation study was conducted in adults with advanced solid tumors. Patients (pts) took R (120 or 160 mg) and S (50 or 100 mg) once daily days 1 through 21 of each 28-day cycle. Pts remained on study treatment until progression or excessive toxicity, with response assessments every 8 wks. The maximum tolerated dose (MTD) was defined as the maximum tested dose with $\leq$1/6 pts experiencing dose-limiting toxicity (DLT), with Cycle 1 as the DLT observation period. **Results:** 32 pts were enrolled and 29 treated at 3 dose levels (DLs). Median duration of treatment was 8 (range 2 – 101) wks. One of 6 evaluable pts treated at DL2 (160 mg R + 50 mg S) experienced DLT (grade 4 lipase increase). One of 12 evaluable pts treated at DL3A (160 mg R + 100 mg S, the MTD) experienced DLT (grade 3 rash and grade 3 muscle pain). The toxicity profile was generally consistent with that seen in R monotherapy at FDA-approved doses. 10 pts had a best response of progressive disease (PD). 14 pts had a best response of stable disease (SD), 5 of whom had stable disease duration $>$ 24 wks. 5 treated pts were not evaluable for response. Notably, 2 pts with ovarian cancer and 1 with cervical cancer had stable disease $>$ 24 wks. Analyses of correlative studies to examine pharmacokinetics and drug combination pharmacodynamic effects are underway. **Conclusions:** The combination was well-tolerated. The recommended phase 2 dose is 160 mg R + 100 mg S. Objective responses were not observed, but prolonged stable disease was seen in a subset of pts. Encouraging disease control was seen in gynecologic cancers. Dosing up to 100 mg S is safe concurrently with standard doses of R, and may be considered as an adjunct to R in future trials. Evaluation of R+S in gynecologic cancers warrants further consideration. Clinical trial information: NCT02466802. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Dose Level (mg R + mg S)	# treated pts	# DLT evaluable pts	# pts with DLTs	# Response evaluable pts	# pts with PD	# pts with SD
1 (120 + 50)	4	3	0	4	2	2
2 (160 + 50)	9	6	1	6	2	4
3A (160 + 100)	16	12	1	14	6	8

3594 Poster Session (Board #324), Fri, 8:00 AM-11:00 AM

Selpercatinib (LOXO-292) in patients with *RET*-mutant medullary thyroid cancer. *First Author: Manisha H. Shah, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Selpercatinib (LOXO-292) is a highly selective and potent small molecule RET kinase inhibitor. Here we report an update on the efficacy and safety of selpercatinib in *RET*-mutant medullary thyroid cancer (MTC). **Methods:** Patients with *RET*-mutant MTC were enrolled to the Phase 1/2 LIBRETTO-001 trial (NCT03157128), a global, multicenter trial (16 countries, 89 sites). Following the Phase 1 dose escalation portion of the trial, patients received the recommended dose of 160 mg orally twice daily. Each cycle was 28 days. The primary endpoint was objective response rate (ORR) per RECIST 1.1. Secondary endpoints included duration of response (DoR) and safety. Per health authority agreement, the primary analysis set was defined as the first 55 consecutively enrolled patients previously treated with multikinase inhibitors cabozantinib and/or vandetanib. Patients naïve to cabozantinib and vandetanib treatment were analyzed separately. All analyses were based on a 16-Dec-2019 data cutoff date. **Results:** In the primary analysis set of prior cabozantinib and/or vandetanib-treated patients with MTC (n = 55), the ORR by investigator assessment was 62% (95% CI 47.7–74.6, n = 34/55) and the median DoR was not reached (95% CI 18.4 months–not estimable) despite a median follow-up of 14.8 months. In cabozantinib/vandetanib treatment-naïve patients (n = 88), the ORR by investigator assessment was 69% (95% CI 58.6–78.7, n = 61/88, including 2 responses pending confirmation). Of the 59 confirmed responding patients, with a median follow-up of 8 months, responses were ongoing for 57 responders at the time of the analysis. In the safety analysis set consisting of all selpercatinib dosed patients (N = 702), the most common treatment-related adverse events (TRAEs) that occurred in $\geq$15% of patients were dry mouth (33.3%), increased AST (24.5%), increased ALT (23.8%), hypertension (23.2%), diarrhea (19.7%), and fatigue (16.8%). Only 2% (14 of 702) of patients discontinued selpercatinib for TRAEs. **Conclusions:** Selpercatinib use was associated with marked and durable antitumor activity in prior cabozantinib and/or vandetanib-treated patients and in cabozantinib/vandetanib-naïve patients with *RET*-mutant MTC, with the majority of responses ongoing in both cohorts. Selpercatinib was well tolerated. Efficacy data assessed by independent review committee based on the 16-Dec-2019 data cutoff date will be presented. Clinical trial information: NCT03157128. Research Sponsor: Loxo Oncology Inc., a wholly owned subsidiary of Eli Lilly and Company.

3595 Poster Session (Board #325), Fri, 8:00 AM-11:00 AM

IGM-8444 as a potent agonistic Death Receptor 5 (DR5) IgM antibody: Induction of tumor cytotoxicity, combination with chemotherapy and *in vitro* safety profile. *First Author: Beatrice Wang, IGM Biosciences Inc, Mountain View, CA*

Background: Death receptor 5 (DR5) is a member of the tumor necrosis factor (TNF) receptor superfamily that multimerizes when bound to its ligand, TNF-related apoptosis inducing ligand (TRAIL), to activate the extrinsic apoptotic pathway. DR5 is broadly expressed on solid and hematologic cancers and has been targeted with both recombinant TRAIL and agonistic antibodies in the clinic. However, these therapeutics have generally been unsuccessful due to toxicity or lack of efficacy. We have developed a multivalent IgM DR5 agonist, IGM-8444, that multimerizes DR5 to selectively and potently induce tumor cell apoptosis while maintaining tolerability. **Methods:** IGM-8444 is an engineered, pentameric IgM antibody with 10 binding sites specific for DR5. Human tumor cell lines or hepatocytes were evaluated *in vitro* for dose dependent IGM-8444 induced cytotoxicity. The efficacy of IGM-8444 was evaluated with or without chemotherapy, in cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) mouse tumor models, with IGM-8444 administered at various dose levels and schedules when tumors reached approximately 100 mm^3. Sera and tumors were analyzed for biomarkers of tumor apoptosis. **Results:** *In vitro* cytotoxicity assays identified IGM-8444 activity across cell lines from 18 solid and hematologic malignancies. In IGM-8444 partially resistant cell lines, combination with chemotherapy or a Bcl2 inhibitor enhanced *in vitro* cytotoxicity. IGM-8444 was efficacious as a monotherapy in CDX and PDX tumor models including colorectal, lung, and gastric indications. In a gastric PDX model, IGM-8444 induced complete and durable dose-dependent tumor regressions. *In vivo*, combination of IGM-8444 with standard-of-care chemotherapies, such as irinotecan, led to enhanced efficacy. IGM-8444 administration increased markers of tumor apoptosis, identifying potential clinical pharmacodynamic biomarkers. At doses several log-fold higher than efficacious doses, IGM-8444 demonstrated a favorable single agent *in vitro* safety profile, with little to no *in vitro* cytotoxicity observed using primary human hepatocytes from multiple donors. **Conclusions:** These data support the clinical development of IGM-8444 in both solid and hematological malignancies as a single agent and in combination with standard of care therapy. IGM-8444 is projected for IND filing in 2020. Research Sponsor: IGM Biosciences Inc.

3596 Poster Session (Board #326), Fri, 8:00 AM-11:00 AM

Tumor-targeted oncolytic adenovirus demonstrates high cytotoxicity for human lung and renal cell carcinomas independently of the level of tumor PD-L1 expression. *First Author: Jia Yao, Emory University School of Medicine, Atlanta, GA*

Background: Immuno-checkpoint (IC) inhibitors targeting PD1-PD-L1 pathway have proven highly effective at extending survival of cancer patients. However, the clinical benefits of IC inhibitors are limited to only about 20% patients who have moderate to high levels of tumor PD1 and/or PD-L1 expression. To develop therapeutics that would provide clinical benefits to a larger proportion of cancer patients, we engineered oncolytic adenovirus for targeted infection of human tumor cells via CD46 and integrins of $\alpha 3\beta 1$ or $\alpha 6\beta 4$ classes, overexpressed on many epithelial human cancers. **Methods:** Here, we analyzed the infectivity and cytotoxicity of this novel oncolytic virus in a panel of human non-small cell lung cancers (NCSLC) cell lines, primary patient derived NSCLC xenografts, and tumor surgical explants from patients with renal cell carcinoma (RCC). **Results:** The in vitro analysis of NSCLC cells lines (N = 17) demonstrated that over 60% of them were highly sensitive to virus infection. The genome-wide transcriptional profiling showed that only 3 out of 12 cell lines that were sensitive to oncolytic virus infection, expressed PD-L1 ($>$ 4.5 Log2 RPMK). Furthermore, although the pre-treatment of these cell lines with IFN-I activated PD-L1 expression, IFN-I treatment did not reduce the efficacy of tumor cell infection by the oncolytic virus. The analysis of virus infectivity on primary human tumor cells from patients with NSCLC (N = 4) and RCC (N-24) demonstrated that primary tumors were highly sensitive to oncolytic virus infection. Specifically, tumor-targeted oncolytic virus demonstrated strong cytotoxicity in 22 out of 24 analyzed primary isolated RCC cell samples. Next, we subcutaneously grafted PD-L1-negative NSCLC A549 cells to NSG mice, treated them with oncolytic virus intravenously, and the kinetics of tumor growth and animal survival was monitored. This analysis showed that after intravenous administration, oncolytic virus was able to infect tumor cells and suppress tumor growth. Whereas the median survival in mock-treated group was 26 days, all mice survived up to 100 days post oncolytic virus therapy (endpoint). **Conclusions:** Our study showed that tumor-targeted oncolytic adenovirus infects human tumor cell lines independently of their PD-L1 expression status and is not sensitive to IFN-I inhibition. This novel tumor-targeted oncolytic virus has the potential to provide clinical benefits to cancer patients, who do not respond or became resistant to ICI drugs. RICTOR amplification as a novel therapeutic target for lung cancer brain metastases. *First Author: Haiying Cheng, Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY*

Background: Approximately 20% to 50% of patients with advanced lung cancer develop brain metastases, which are associated with debilitating neurologic impairment and a dismal prognosis. There have been very limited studies investigating the genomics of brain metastases in lung cancer. **Methods:** We comprehensively investigated the frequency of PI3K/AKT/RICTOR/mTOR pathway aberrations in primary and metastatic sites using an extensive database of 11845 cases of lung adenocarcinoma by NGS (FoundationOne). The potential roles of *RICTOR* amplification in the development of brain metastases were studied both in vitro and in vivo in orthotopic mouse models. **Results:** Compared to the primary tumor, *PI3K/AKT/mTOR* gene alterations were more frequent in metastatic sites, with particular enrichment noted in brain metastases. *RICTOR* amplification alone accounted for the observed higher frequency both in brain metastases (brain vs. primary: 9.73% vs 3.50%, P = 2.6E-14; brain vs. other mets: 9.73% vs. 7.3%, P = 0.03) and other metastatic sites (other mets vs. primary: 7.3% vs.3.5%, P = 10E-15), whereas the frequency of *PTEN, AKT1, PK3CA* or *mTOR* genetic alterations was not different in the primary tumor, brain and other metastatic sites. *In vitro*, inducible RICTOR knockdown in H23 lung cancer cells (parental line with *RICTOR* amplification) was associated with reduced cell migration and invasion, whereas upregulation of RICTOR in HCC827 lung cancer cells (parental line with normal *RICTOR* copy numbers) was associated with an increase of both processes. These results were confirmed with pharmacological inhibition using mTOR1/2 inhibitors with known CNS penetration. In vivo, both inducible ablation of RICTOR and the mTOR1/2 inhibitor TAK228 (Sapanisertinib) significantly inhibited lung cancer H23-R4-Luc tumor growth in the brain, including a number of near complete responses. Mechanistic studies suggest that RICTOR may regulate the brain metastasis process through AKT and CXCL12 chemokine-CXCR4 axis. **Conclusions:** *RICTOR* amplification is the first identified actionable target that is markedly enriched in brain metastases. Our study provides a strong rationale for the development of RICTOR-targeted therapeutic strategies for the treatment and/or prevention of these major causes of lung cancer morbidity and mortality. Therapeutic drug monitoring of pazopanib: Using cost-neutral PK-guided interventions to optimize exposure. *First Author: Stefanie L. Groenland, The Netherlands Cancer Institute–Antoni van Leeuwenhoek, Amsterdam, Netherlands*

Background: Pazopanib is an approved treatment for renal cell carcinoma (RCC) and soft tissue sarcoma (STS). At the currently registered fixed dose of 800 mg QD, 20% of patients (pts) do not attain the efficacy threshold of $C_{min} \geq 20.5$ mg/L (Suttle et al, 2014), providing a strong rationale for therapeutic drug monitoring (i.e. individualizing the dose based on measured plasma drug concentrations). Previous studies provided cost-neutral alternatives to absolute dose increments to optimize exposure (i.e. splitting intake moments or concomitant intake with food (Groenland et al, 2020; Lubberman et al, 2019)). This study aimed to investigate the feasibility, tolerability and efficacy of TDM of pazopanib, using cost-neutral interventions. **Methods:** Patients starting treatment with pazopanib at the standard dose of 800 mg QD in modified fasting state were included in the prospective DPOG TDM study (www.trialregister.nl, NL6695). PK sampling occurred 4, 8 and 12 weeks after start of treatment, and every 12 weeks thereafter. Pazopanib concentrations were measured with LC-MS/MS and C_{min} was calculated. In case of $C_{min} < 20.5$ mg/L and acceptable toxicity, a dose intervention was recommended. As a first step, intake moments were split (i.e. 400 mg BID). Secondly, concomitant intake with food was recommended. **Results:** In total, 34 pts were included (19 STS, 15 RCC), of whom 158 PK samples were collected. Eleven pts (32%) were underdosed and had at least 1 PK sample below the target. In 24% of the pts a PK-guided intervention could be performed, which was successful in 6 pts (75%). Median C_{min} increased from 15 mg/L to 32 mg/L (p = 0.027). Eventually, 3 pts went back to 800 mg QD due to toxicity, after which C_{min} remained $\geq$ 20.5 mg/L in 2 pts. In pts with adequate exposure throughout the study, median C_{min} was 32 mg/L (range 23 – 65 mg/L). In 3 pts, a PK-guided intervention could not be performed, due to progression (n = 1) or logistical issues (n = 2). Twelve pts (35%) received a dose reduction due to toxicity (lowest dose was 200 mg QAD), exposure remained adequate at this reduced dose in all pts. For STS pts, median PFS was 19.8 months in pts with $C_{min} < 20.5$ mg/L who did need an intervention vs. 6.4 months in pts with all $C_{min} \geq 20.5$ mg/L (not significant). For RCC pts, this was 15.5 months vs. 7.4 months, respectively (not significant). **Conclusions:** This prospective study shows that PK-guided dose optimization of pazopanib using cost-neutral interventions is feasible in daily practice. A PK-guided intervention was performed in 24% of the patients, which was successful in 75% of these patients. Clinical trial information: NL6695. 3599 Poster Session (Board #329), Fri, 8:00 AM-11:00 AM

Preliminary clinical pharmacokinetics and dose-response to support a phase II dose selection for CX-2009: A masked probody drug conjugate to CD166. *First Author: Mark Stroh, CytomX Therapeutics, Inc., South San Francisco, CA*

Background: PROBODY therapeutics are antibody prodrugs with cleavable peptide masks designed to reduce off-tumor, on-target toxicities. The mask blocks binding in the periphery and is removed by tumor-associated proteases resulting in intratumoral binding. CX-2009 is a PROBODY drug conjugate directed against CD166/ALCAM, which is a target overexpressed in carcinomas but not suitable for traditional ADC targeting because it is expressed in normal epithelium. CX-2009 is conjugated to DM4, a potent microtubule inhibitor. Here we report preliminary clinical pharmacokinetic (PK) and exploratory dose-response (DR) analyses for CX-2009 from the ongoing phase 1/2 PROCLAIM-CX-2009 study (NCT03149549). **Methods:** Human PK and anti-drug antibody (ADA) data were obtained at selected times post-dose following IV 0.25–10 mpk CX-2009 Q3W and of 6 mpk Q2W. Covariates were selected for population PK (POPPK) based on multivariate screening at $P < 0.01$. Preliminary exploratory DR analyses were conducted for selected endpoints including adverse events of special interest and response data (CR, PR, SD, and PD). **Results:** Preliminary CX-2009 PK data from 92 subjects were available as of October 2019. Median free DM4 levels circulated at ≤0.3% of Total CX-2009 (masked + activated CX-2009) levels across the 1–10 mpk dose levels. A two-compartment POPPK model with linear elimination was fit to the Intact (masked form) CX-2009 data. The preliminary CX-2009 POPPK model estimates for Intact CX-2009 clearance (CL), volume of distribution, and half-life were 0.47 L/day, 4.51 L, and 7.14 days, respectively, with 91% of CX-2009 circulating as Intact CX-2009. ADA was not a statistically significant covariate on Intact CX-2009 CL. Evidence of clinical activity was observed at doses of 4 mpk Q3W or higher. DR analysis suggested that the frequency of grade ≥3 ocular toxicity events increased significantly at dose equivalents ≥8 mpk Q3W. POPPK simulations suggested that the targeted 90 nM trough concentration (based on nonclinical data) would be contained within the 90% prediction interval of predicted Intact CX-2009 levels following CX-2009 7 mpk. **Conclusions:** Preliminary CX-2009 PK data following CX-2009 0.25-10 mpk suggest that CX-2009 circulates predominantly as Intact CX-2009, and that Intact CX-2009 PK is not strongly influenced by target-mediated drug disposition or ADA. Preliminary DR and POPPK simulations support further evaluation of 7 mpk CX-2009 Q3W in selected cohort expansions. Clinical trial information: NCT03149549. Research Sponsor: CytomX Therapeutics, Inc.

3600 Poster Session (Board #330), Fri, 8:00 AM-11:00 AM

Prophylactic dihydropyrimidine dehydrogenase (DPYD), and reactive cytidine deaminase (CDA) testing is feasible and reduces severe toxicity in Irish patients receiving 5-fluorouracil (5-FU) based chemotherapy. *First Author: Jake Murphy, Bon Secours Hospital, Cork, Ireland*

Background: 5-Fluorouracil (5-FU) steady state concentrations can vary up to fourfold among cancer patients. 5-FU intolerance and toxicity is associated with reduced activity of the key metabolic enzyme dihydropyrimidine dehydrogenase (DPD) due to polymorphisms of the DPYD gene, as well as mutations in cytidine deaminase (CDA). Since 2012, Bon Secours Hospital, Cork has implemented prophylactic DPYD screening to reduce toxicity. **Methods:** In this retrospective cohort study, 742 adult cancer patients who underwent reactive or prophylactic DPYD testing in our center between 2012 and 2019 were included. Reactively tested patients were screened prior to 2012. 5-FU related toxicities were graded according to Common Terminology Criteria for Adverse Events (CTCAE) and analysed. Frequencies of polymorphisms in DPYD, affecting 5-FU metabolism in patients who experienced severe toxicity are described, in both patients who were retrospectively tested, and in our larger prophylactic patient cohort. Mutations of genes encoding CDA were also analysed. Analysis of type and severity of toxicity, and survival analysis will be presented at the Annual Meeting. **Results:** 742 patients were tested for DYPD in our centre, of which 704 were prophylactic tests. 11.4% of the patients tested prophylactically were found to have polymorphisms in the DYPD gene. Expectedly, a higher proportion of patients tested reactively were found to have polymorphisms in DYPD (21.9%). 21 out of 34 patients who had severe toxicity had CDA mutations present on testing. Further data involving classification and severity of toxicities, along with survival analysis will be presented at the Annual Meeting. **Conclusions:** The prevalence of DPYD mutations in Ireland is estimated to be 7-10%, and is putatively responsible for approximately 20% of all severe 5-FU toxicities suffered by cancer patients. Implementing prophylactic DPYD screening is beneficial in reducing toxicities in this setting. Future work will focus on phenotypic measurements of uracil metabolism and pharmacokinetic 5-FU monitoring to further reduce toxicity in patients who do not have DPYD mutations. 3601 Poster Session (Board #331), Fri, 8:00 AM-11:00 AM

Myelodysplastic syndrome and acute myeloid leukemia as side effect of PARP inhibitors. *First Author: Samip R. Master, Louisiana State University Health Sciences Center, Shreveport, LA*

Background: Acute myeloid leukemia(AML) and myelodysplastic syndrome(MDS) have been rarely noted in patients on PARP inhibitors. The actual incidence is unknown and it has been put has warning/precaution of FDA label for olaparib, niraparib and rucaparib. **Methods:** The FDA has made the data on the adverse effects of various treatments available to the general public through the FDA Adverse Events Reports System (FAERS) public dashboard. We investigated the adverse events reported for PARP inhibitors like olaparib, niraparib and rucaparib for the years 2017-2019 to find out the number of patients who had acute leukemia or myelodysplastic syndrome reported while on those medications. **Results:** A total of 8151 adverse events were reported between 2017 and 2019 for olaparib, niraparib and rucaparib. Out of which, 6077 were serious and 1121 deaths were reported. There were 237 reports of AML and MDS, which compromise 2.9 % of total events reported. We also looked that cyclophosphamide data for comparison purposes during the same period. There were 29,162 adverse events reported for cyclophosphamide, out of which 963 i.e. 3.3% were AML and MDS. For olaparib, 2523 adverse events were reported and 173 (6.8%) were MDS/AML. For niraparib, 5496 adverse events were reported and 41(0.7%) were MDS/AML. For rucaparib, 153 adverse events were reported and 4 (2.6%) were MDS/AML. **Conclusions:** Based on this retrospective data, AML/MDS is an adverse event in pts of PARP inhibitors and needs to be monitored. Pts on olaparib seem to have high risk of AML/MDS compared to other two to PARP inhibitors. Research Sponsor: None.

3602 Poster Session (Board #332), Fri, 8:00 AM-11:00 AM

Preliminary population pharmacokinetics supports phase II dose selection for masked anti-PD-L1 antibody CX-072. *First Author: Mark Stroh, CytomX Therapeutics, Inc., South San Francisco, CA*

Background: PROBODY therapeutics (Pb-Tx) are antibody prodrugs designed to reduce off-tumor, on-target toxicities. The mask inhibits Pb-Tx binding in the periphery yet can be removed by tumor-associated proteases, restricting target engagement to the tumor. This is the first report of preliminary clinical pharmacokinetic (PK) analysis supporting selection of the phase II dose for CX-072, an anti–PD-L1 Pb-Tx, from the ongoing phase I/II PROCLAIM-CX-072 study (NCT03013491). **Methods:** A quantitative systems pharmacology (QSP) model[1] was used to project the CX-072 plasma trough level (C_{min}) corresponding to 95% intratumoral receptor occupancy (RO). Human PK and anti-drug antibody (ADA) data were obtained at selected times postdose following IV administration of 0.03–30 mpk CX-072 in PROCLAIM-CX-072. Population PK (POPPK) modeling was performed with NONMEM v7.3.0. Exploratory analysis and simulations were done with R v3.3.1 or later. Covariates were selected for POPPK using forward addition ($P<0.05$) followed by backward deletion ($P<0.01$). **Results:** The preliminary POPPK analyses were informed using available PK data as of August, 2019 from 135 subjects receiving CX-072 Q2W as monotherapy in the dose-escalation and expansion cohorts of PROCLAIM-CX-072. A mixture model was used to capture time- and dose-dependent apparent ADA effect on clearance (CL). The preliminary POPPK model estimates for CX-072 CL and volume of distribution (Vd) were 0.306 L/day and 4.84 L, respectively. Statistically significant covariate effects included body weight on the central Vd and CL, and albumin on CL. The QSP model predicted a CX-072 C_{min} of 13–99 nM would be required for 95% intratumoral RO. POPPK simulations suggested that >95% of patients receiving CX-072 10 mg/kg Q2W would meet or exceed this targeted C_{min} regardless of ADA. Additional observed data indicated that the majority of patients receiving 10 mpk CX-072 Q3W × 4 with 3 mpk ipilimumab (IPI) Q3W × 4 in the CX-072-IPI combination part of PROCLAIM-CX-072 maintained the targeted C_{min}. Simulations did not suggest there would be a clinically meaningful change in exposure following a fixed dose of CX-072 800 mg relative to the 10 mpk weight-based dose. **Conclusions:** Preliminary PK analysis supports selection of 800 mg CX-072 Q2W as the recommended monotherapy dose and 800 mg Q3W when combined with IPI. The combination of 800 mg CX-072 + 3 mpk IPI Q3W × 4 doses, followed by monotherapy administration of 800 mg CX-072 Q2W is being further explored in phase II. Reference: 1) Stroh M et al. *CPT.* 2019(9):676-84. Clinical trial information: NCT03013491. Research Sponsor: CytomX Therapeutics, Inc.

3603 Poster Session (Board #333), Fri, 8:00 AM-11:00 AM

Final results from the phase I study expansion cohort of the selective FGFR inhibitor Debio 1,347 in patients with solid tumors harboring an FGFR gene fusion. *First Author: James M. Cleary, Dana Farber Cancer Institute, Boston, MA*

Background: Debio 1347 is a selective oral inhibitor of FGFR 1-3 tyrosine kinases. It exhibited high antitumor activity in *in vitro* and *in vivo* tumor models with FGFR1-3 gene fusions. Here we report the results of the expansion portion of a Phase 1 study of advanced solid tumors patients (pts) harboring an FGFR1-3 gene fusion. **Methods:** Pts with advanced refractory solid tumors harboring an FGFR1-3 gene fusion were enrolled. Based on results from the dose escalation portion, pts received Debio1347 80 mg once daily (qd) in 28-day cycles. Pharmacokinetics (PK) and pharmacodynamics were evaluated. The data cut-off was October 8, 2019. **Results:** Among 18 pts enrolled, 5 had primary brain tumors (PBT), 5 had cholangiocarcinoma, 2 had urothelial cancer, 2 had colon cancer, 1 patient each lung neoplasm, gastric cancer, endometrial cancer and squamous cell carcinoma of the chest wall. Tumors harbored fusions with FGFR1 (n = 1), FGFR2 (n = 8), and FGFR3 (n = 9). All had prior systemic therapy (median 3 lines; range 1-4). The most common treatment emergent adverse events were fatigue (50%), hyperphosphatemia (44.4%), anemia (38.9%), alopecia (33.3%), nausea (33.3%), vomiting (33.3%), constipation (33.3%), and palmar-plantar erythrodysesthesia syndrome (22.2%). Blurred vision was reported in 1 pt. There were no findings on ocular exams compatible with retinal detachment. No grade 3 AE related to study drug were reported. One patient needed dose reduction due to grade 2 nails toxicity. In PK analysis, plasma steady-state was rapidly achieved and serum phosphate increase correlated with Debio 1347 plasma exposure, confirming target engagement at 80 mg qd. Median follow-up was 18 weeks. Partial responses were observed in 3 pts harboring an FGFR2 fusion: 1 out of 2 colon cancer and 2 out 5 cholangiocarcinoma. Median duration of response was 16.1 weeks (range: 8.4-22.8+). Overall disease control was observed in 11 out of 14 pts without PBT (79%). Median PFS was 18.3 weeks. No signs of activity were observed in the 5 patients with PBT, all with an FGFR3-TACC3 fusion. **Conclusions:** Debio 1347 at the recommended dose of 80 mg qd was generally well tolerated and showed signs of activity in solid tumors harboring an FGFR fusion. The FUZE phase 2 clinical trial of Debio 1347 is recruiting FGFR fusion-positive advanced solid tumors irrespectively of tumor histology, excluding PBT. Clinical trial information: NCT01948297. Research Sponsor: Debiopharm International SA.

3604 Poster Session (Board #334), Fri, 8:00 AM-11:00 AM

Results of a phase Ib trial evaluating the safety and clinical activity of sapanisertib (TAK 228) in combination with serabelisib (TAK 117) and paclitaxel in patients with advanced ovarian, endometrial, or breast cancer. *First Author: Casey B. Williams, Avera Cancer Institute, Sioux Falls, SD*

Background: The link between taxane resistance and activation of PI3K/AKT/mTOR signaling suggests that by inhibiting this pathway in combination with anti-microtubule agents like paclitaxel may improve treatment outcomes in many malignancies. To investigate this further we combined the TORC 1/2 inhibitor sapanisertib (TAK-228), the PI3Kα isoform inhibitor serabelisib (TAK-117), and paclitaxel in a phase I trial to determine the safety, efficacy, and RP2D. **Methods:** Open label, cohort study using a traditional 3+3 dose escalation design with a maximum of 5 dosing cohorts. A dose expansion of cohort 4, the recommended RP2D, is planned for February 2020. **Results:** Enrollment to the DLT evaluation has been completed and the clinical results are summarized in Table. Sixteen patients have been enrolled; a majority were heavily pretreated and resistant to paclitaxel. Overall, the combination was safe and tolerable. One DLT occurred due to renal dysfunction in cohort 5. 360 adverse events have been reported, but only 28 (8%) grade 3 or 4 events. The most common events were leukopenia and non-febrile neutropenia. Two patients required dose reductions as a result of pneumonitis. The ORR is currently 46% in 13 evaluable patients. CBR is 69% and PFS is currently at 10 months. Two patients achieved a CR and three patients remain on treatment. **Conclusions:** The combination proved to be well tolerated in the doses and schedules used in cohorts 1-4 and exhibited very promising clinical activity in heavily pretreated patients. This regimen could prove to be a highly effective treatment option and a phase 2 study is warranted at the RP2D. Clinical trial information: NCT03154294.Research Sponsor: Takeda.

Pt # and Diagnosis	Cohort	Previous Lines	TAK 228/117 (mg) days 2-4, 9-11, 16-18, and 23-25	Paclitaxel Dose (mg/m2) days 1, 8, and 15	Best Response

Efficacy and safety of entrectinib in patients (pts) with *NTRK*-fusion positive (*NTRK*-fp) solid tumors: An updated integrated analysis. *First Author: Christian Diego Rolfo, University of Maryland School of Medicine, Baltimore, MD*

Background: *NTRK* gene fusions lead to transcription of chimeric TRK proteins with overexpressed kinase function. Entrectinib is a potent inhibitor of TRKA/B/C. In phase 1/2 studies (ALKA, STARTRK-1, STARTRK-2; EudraCT 2012-000148-88; NCT02097810; NCT02568267), entrectinib was effective in pts with *NTRK*-fp solid tumors. We present updated data in a larger population with longer follow-up. **Methods:** In this integrated analysis of adult pts from 3 phase 1/2 trials (data cut-off 31 Oct 2018), tumors were assessed by blinded independent central review (BICR) with RECIST v1.1 (end of cycle 1; then every 8 wks). Primary endpoints were overall response rate (ORR) and duration of response (DOR). Secondary endpoints were progression-free survival (PFS), overall survival (OS), efficacy in pts with/without baseline CNS disease, and safety. **Results:** There were 74 evaluable pts with advanced/metastatic *NTRK*-fp solid tumors (Table). Median duration of survival follow-up in all pts was 14.2 mo (range 0.1–29.7). BICR ORR was 63.5% (95% CI 51.5–74.4), with 5 complete responses (6.8%). Median BICR DOR was 12.9 mo (95% CI 9.3–NE); median BICR PFS was 11.2 mo (95% CI 8.0–15.7); median OS was 23.9 mo (16.0–NE). In pts with no baseline CNS disease (investigator-assessed; n=55), BICR ORR was 65.5% (95% CI 51.4–77.8) and median BICR DOR in responders was 12.9 mo (95% CI 9.3–NE). In pts with baseline CNS disease (investigator-assessed; n=19), BICR ORR was 57.9% (95% CI 33.5–79.8) and median BICR DOR in responders was 6.0 mo (95% CI 4.2–NE). Safety was in line with that previously reported; the most common ≥grade 3 treatment-related AEs were weight gain (8, 7.1%), anemia (8, 7.1%), and fatigue (7, 6.2%). **Conclusions:** In this updated analysis, including more pts and longer follow-up, entrectinib continued to demonstrate clinically meaningful responses in pts with *NTRK*-fp solid tumors, with and without baseline CNS disease. Clinical trial information: NCT02097810, NCT02568267.Research Sponsor: Ignyta/F Hoffmann-La Roche.

Safety and efficacy of pemigatinib plus pembrolizumab combination therapy in patients (pts) with advanced malignancies: Results from FIGHT-101, an open-label phase I/II study. *First Author: Martin Gutierrez, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ*

Background: Pemigatinib (INCB054828) is a selective fibroblast growth factor receptor (FGFR) 1–3 inhibitor with demonstrated efficacy as monotherapy in phase 1/2 (FIGHT-101) and phase 2 (FIGHT-201, -202, -203) trials in pts with advanced cancer. Here, we present preliminary safety, efficacy, and pharmacokinetic (PK) data for pemigatinib (PEMI) combined with pembrolizumab (PEMBRO), a programmed cell death protein-1 (PD-1) inhibitor, in pts with refractory advanced malignancies enrolled in the ongoing FIGHT-101 trial (NCT02393248). **Methods:** FIGHT-101 includes monotherapy (part 1 and 2) and combination therapy (part 3) cohorts. This analysis is based on pts enrolled in the PEMI + PEMBRO combination dose finding (3a) and dose expansion (3b) cohorts. Eligible adults had advanced malignancies who had progressed after prior therapy and for whom PEMBRO treatment was relevant; pts in part 3b had *FGF/FGFR* alterations. Pts received oral PEMI at 9 mg or 13.5 mg QD on an intermittent dosing (ID) schedule (21-day cycle, 14-day on/7-day off), or 13.5 mg QD on a continuous dosing (CD) schedule, plus PEMBRO 200 mg IV on day 1 of each 21-day cycle. **Results:** At data cutoff (August 30, 2019), 23 pts had received PEMI + PEMBRO; 22 (96%) had discontinued therapy (disease progression, 70%). Most frequent tumors were NSCLC (n = 3), bladder (n = 3), pancreatic, testicular, and sarcoma (each n = 2). Of 19 enrolled pts with baseline *FGF/FGFR* data; 5 had *FGFR* mutations or rearrangements. No dose-limiting toxicities occurred with PEMI + PEMBRO. The recommended PEMI dose combined with PEMBRO was 13.5 mg QD. Most frequent all-cause, all-grade (Gr) adverse events for ID (n = 17) were hyperphosphatemia (n = 14 [82%]; Gr ≥3, n = 0), anemia (n = 9 [53%]; Gr ≥3, n = 3 [18%]), and decreased appetite (n = 9 [53%]; Gr ≥3, n = 0); for CD (n = 6), hyperphosphatemia (n = 5 [83%]; Gr ≥3, n = 0), and dry mouth (n = 4 [67%]; Gr ≥3, n = 0). One pt discontinued, 2 reduced dose, and 13 interrupted dose due to AEs (none for hyperphosphatemia; dose interruption mainly for gastrointestinal AEs [n = 5]). One fatal AE occurred (suicide, not treatment-related). PK parameters for PEMI in the PEMI + PEMBRO combination were comparable with those for PEMI monotherapy. Five pts had partial response (3 had *FGFR* rearrangements or mutations); 5 pts had stable disease. **Conclusions:** PEMI + PEMBRO combination therapy was tolerable with no new safety signals, and demonstrated preliminary antitumor activity in pts with advanced malignancies including those with *FGF/FGFR* alterations. Clinical trial information: NCT02393248. Research Sponsor: Incyte Corporation.

3607 Poster Session (Board #337), Fri, 8:00 AM-11:00 AM

Results of a completed first-in-human phase Ib dose-escalation study of oral CBL0137 in patients with advanced solid tumors. *First Author: Mikhail Fedyanin, Federal State Budgetary Institution N.N. Blokhin National Medical Research Center of Oncology of the Ministry of Health of the Russian Federation (N.N. Blokhin NMRCO), Moscow, Russian Federation*

Background: Curaxin CBL0137 is a novel compound with broad anticancer activity in animal models. The drug is a non-genotoxic DNA intercalator that interferes with histone/DNA binding causing decondensation of chromatin in tumor cells, functional inactivation of histone chaperone FACT, activation of p53 and IFN responses, and inhibition of pro-cancer transcriptional factors, MYC, NF-kB, HSF1, and HIF1a. **Methods:** The study enrolled adults with advanced chemorefractory solid tumors, ECOG PS ≤2, and adequate organ function. The primary objective was to find the maximum tolerated dose (MTD) and recommended dosing regimen (RDR). Secondary objectives were to evaluate CBL0137 safety, pharmacokinetics, and efficacy. CBL1037 was given orally once daily (QD) for the first 14 days of repeated 28-day cycles. A 3+3 dose escalation determined the MTD, defined as the highest dose at which ≤1 of 6 pts had Cycle 1 dose-limiting toxicity (DLT). Pharmacokinetics were assessed on Days 1 and 13. Efficacy was evaluated every 8 weeks. **Results:** 60 pts were enrolled (females/males [n]: 42/18; median [range] age 56 [25-76] years; ECOG PS [n] 0/1/2: 8/49/3); cancer types [n]: ovarian cancer [15], colorectal cancer [14], breast cancer [11], others [20]) over 16 dose levels ranging from 4 mg to 200 mg QD. Durations of therapy ranged from 6 to 342 days. Three DLTs were observed: prolongation of QTc Gr 3 (88 mg QD), neutropenia/thrombocytopenia Gr 4 (200 mg QD), and LV dysfunction Gr 3 (200 mg QD). Dose-dependent nausea/vomiting was observed and was Gr 2-4 at 200 mg QD. Gr 1/2 photosensitization occurred in 11 subjects across doses from 48 to 200 mg QD but was successfully managed with sun protection and resulted in no dose modifications or discontinuations. On Day 1, mean (range) plasma CBL0137 T_{max} values were 5.1 (1-10) hrs. Generally linear increases in AUC occurred with increasing CBL0137 dose. Mean (range) $t_{1/2}$ values were 25.6 (0.3-166) hrs, with minor dose dependency. Mean (range) Day 13/Day 1 C_{trough} ratios showed 3.6 (1.7-7.2)-fold accumulations. Disease control was registered in 11 pts who had stable disease (SD). Target lesion regressions up to 21% were documented in 4 patients with breast cancer (2), sarcoma (1), and ovarian cancer (1). Pts with breast cancer (1) and sarcoma (1) had SD for > 36 weeks. **Conclusions:** The Phase 2 RDR for oral CBL0137 was established as 180 mg QD x 14 days in 28-day cycles based on bone marrow and gastrointestinal DLTs at 200 mg QD. CBL0137 showed a manageable safety profile with efficacy signals. Further study as a component of combinations is planned. Clinical trial information: 847. Research Sponsor: Incuron.

3609 Poster Session (Board #339), Fri, 8:00 AM-11:00 AM

CTEP 9557: A dose-escalation trial of combination dabrafenib, trametinib, and AT13387 in patients with BRAF mutant solid tumors. *First Author: Meghan Mooradian, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Combination BRAF and MEK inhibitor therapy is associated with response in patients (pts) with BRAF mutant (mut) solid tumors; however critical limitations for the durable activity of these agents remains. Preclinically, the addition of heat shock protein 90 (HSP90) inhibitors improves the efficacy of BRAF inhibitor (BRAFi) therapy in both BRAFi-sensitive and resistant mutant cell lines. **Methods:** CTEP study 9557 (NCT02097225) is a phase I study designed to determine the safety and efficacy of the small molecule HSP90inhibitor, AT13387, in combination with dabrafenib (dab) and trametinib (tram) in patients with $BRAF^{V600E/K}$ mut solid tumors. Prior chemotherapy, immunotherapy, BRAF and/or MEK exposure was permitted. The primary objective was to determine the maximum tolerated dose (MTD). **Results:** From July 2015 to June 2018, 22 patients with previously treated, metastatic $BRAF^{V600E/K}$ mut solid tumors were enrolled using a 3 + 3 design at four dose levels (DL) (Table). Pts were predominantly female (59%) with a median age of 57.5yrs (37 -75). The most common tumor type was $BRAF^{V600E}$mut colon cancer (N=12). Dose limiting toxicities (DLTs) occurred in one patient in DL3 and one in DL4, specifically grade 3 myelosuppression and fatigue, respectively. The MTD was Dab 150mg [BID/PO], Tram 2mg [QD/PO] and AT1187 260mg/m2 [D1,8,15/IV]. Twenty-one of 22 pts were eligible for efficacy assessment. Best response, per RECIST 1.1, was partial response (PR) in 2 pts – one with colon ca (TKI-naïve), one with melanoma (TKI-resistant) - stable disease (SD) in 8 pts, and disease progression (PD) in 11 with a disease control rate (PR + SD) of 47.6% (90% CI: 29% - 67%). Median time to progression was significantly longer in DL3 (3.9 mths; 1.8-9.2) compared to DL1 (1.6mths; 0.9-1.7) or DL2 (1.5; 0.6-3.6). Median PFS and OS were 1.8mths (90% CI: 1.6 – 3.7mths) and 5.1 mths (90% CI: 2.5 -10.6mths), respectively. Median OS was not reached in DL3/4. Correlative data on the expression of the key signaling proteins relating to response will be presented at the meeting. **Conclusions:** HSP90 inhibition combined with BRAF/MEK inhibition was determined to be safe with evidence of disease control in a heavily pre-treated population of pts with $BRAF^{V600E/K}$ mut solid tumors. Clinical trial information: NCT02097225.Research Sponsor: U.S. National Institutes of Health.

Dose level cohorts.

DOSE LEVEL	DABRAFENIB [BID/PO]	TRAMETINIB [QD/PO]	AT13387 [D1,8,15/IV]
-1	75 mg	1 mg	180 mg/m2
1	150 mg	1 mg	180 mg/m2
2	150 mg	2 mg	180 mg/m2
3	150 mg	2 mg	220 mg/m2
4	150 mg	2 mg	260 mg/m2

3610 Poster Session (Board #340), Fri, 8:00 AM-11:00 AM

Activity and safety of larotrectinib in adult patients with TRK fusion cancer: An expanded data set. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The highly selective TRK inhibitor larotrectinib is approved for the treatment of adult and pediatric cancers that harbor *NTRK* gene fusions; it achieves a 79% overall response rate (ORR) in this population (Hong et al., *Lancet Oncol*, 2020). The activity of larotrectinib in adults alone was further characterized in this update with a larger series of patients and more mature durability data. **Methods:** Adults (aged ≥18 y) with TRK fusion cancer treated in three larotrectinib clinical trials (NCT02122913, NCT02576431, and NCT02637687) were analyzed. Larotrectinib was administered 100 mg BID until disease progression, withdrawal, or unacceptable toxicity. ORR was investigator-assessed (RECIST v1.1). Compared to previously presented data on 74 patients, this expanded data set includes an additional 42 patients (data cutoff: July 15, 2019). **Results:** 116 adults (median age: 56 y, range 19–84 y; 53% female) with TRK fusion cancer were treated. Tumor types included thyroid cancer (22%), salivary gland cancer (19%), soft tissue sarcoma (16%), lung cancer (12%), colon cancer (7%), melanoma (5%), breast cancer (5%), GIST (3%), and 9 other types (≤2% each). *NTRK* fusions involved *NTRK1* (43%), *NTRK2* (3%), and *NTRK3* (54%). 78% of patients had received prior systemic therapy (with 68% of those receiving ≥2 prior therapies). The ORR was 71% (95% CI 62–79): 10% complete response, 60% partial response (2% pending confirmation), 16% stable disease, 9% progressive disease, 3% not determined. In patients with brain metastases, the ORR was 71% (95% CI 42–92; 10 of 14 patients, all partial responses). Median duration of response for the overall data set (n = 116) was 35.2 mo (95% CI 21.6–not estimable [NE]). Median progression-free survival was 25.8 mo (95% CI 15.2–NE). Median overall survival was not reached (range 0.5+ to 51.6+ mo) at a median follow-up of 15.8 mo. Duration of treatment ranged from 0.10 to 51.6+ mo. 12% of patients had dose reductions. One patient (1%) discontinued due to a larotrectinib-related adverse event (AE). AEs were mostly grade 1–2; no new unexpected AEs were reported. **Conclusions:** In an expanded data set of adults with TRK fusion cancer, larotrectinib demonstrated robust and durable tumor-agnostic efficacy and favorable safety, supporting *NTRK* gene fusion testing in patients with solid tumors of any type. Clinical trial information: NTC02122913, NCT02576431, NCT02637687. Research Sponsor: Bayer and Loxo Oncology (a subsidiary of Lilly).

3611 Poster Session (Board #341), Fri, 8:00 AM-11:00 AM

A phase I, first-in-human, open-label, dose-escalation, safety, pharmacokinetic, and pharmacodynamic study of oral TP-1287 administered daily to patients with advanced solid tumors. *First Author: Ben George, Froedtert & The Medical College of Wisconsin, Milwaukee, WI*

Background: TP-1287 is a an orally bioavailable phosphate prodrug of alvocidib, a cyclin dependent kinase 9 (CDK9) inhibitor. TP-1287 exhibits potent inhibition of intracellular kinases including CDK9. Inhibition of CDK9 leads to downregulation of the BCL-2 family member, MCL-1, which in turn inhibits tumor growth in preclinical animal models of prostate, breast, and lung carcinomas. **Methods:** This is a multicenter, Phase 1, dose escalation study using a standard 3+3 design with a modified Fibonacci scheme to examine the safety and clinical activity of TP-1287 in patients with advanced solid tumors. Patients will be added at the maximum tolerated dose (i.e. expansion cohort) to test TP-1287 as a single agent in patients with castrate resistant prostate cancer. **Results:** Twenty-two patients who were enrolled between December 2018 and January 2020 received a range of doses from 1 mg QD to 11 mg BID over 7 cohorts. Data are available for 20 patients as of the data cutoff date. TP-1287 plasma PK C_{max} and AUC increased in near linear fashion over cohorts 1 thru 6, reaching 80 ng/mL and 499.3 ng*h/mL in cohort 6 for C_{max} and AUC, respectively. TP-1287 treatment resulted in dose-dependent reductions of phospho-RNA Pol II, consistent with CDK9 inhibition, as measured by a flow cytometric assay assessing pharmacodynamic changes in phosphorylation state in PBMCs. The most frequently observed Grade 3 AE was unrelated anemia in 2 patients. All other events of Grade 3 (9 events/7 patients) and Grade 4 (1 event/seizure with new CNS mets) were unlikely related or unrelated. Clinical benefit was seen in one sarcoma patient with PR (15+cycles), one RCC patient with SD (7+cycles) and 2 bladder cancer patients with SD (6 and 8 cycles). **Conclusions:** These findings suggest that TP-1287 is tolerated as a monotherapy in patients with heavily pretreated, relapsed, refractory solid tumors and further clinical development in selected indications is warranted. Clinical trial information: NCT03298984. Research Sponsor: Tolero Pharmaceuticals, Inc.

3612 Poster Session (Board #342), Fri, 8:00 AM-11:00 AM

Phase II trial of the MEK 1/2 inhibitor selumetinib (AZD6244, ARRY-142886 Hydrogen Sulfate) in adults with neurofibromatosis type 1 (NF1) and inoperable plexiform neurofibromas (PN). *First Author: Geraldine Helen O'Sullivan Coyne, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: NF1-related PN are locally invasive tumors characterized by increased activation of the RAS pathway causing significant morbidity including disfigurement, pain and functional limitations. Selumetinib has received breakthrough designation for NF1 PN based on phase I / II trials in children. We present results for the ongoing phase II study of selumetinib in adults with NF1 PN, which includes pharmacodynamic (PD) evaluation of serial tumor biopsies as well as functional/patient-reported outcomes (PROs). **Methods:** Open-label Simon 2-stage design. Eligibility: NF1 patients (pts) ≥18 years old with inoperable/symptomatic/progressive PN. First 2 pts received selumetinib 75 mg BID; subsequent pts received selumetinib 50 mg BID. Primary objective: response rate by volumetric MRI analysis (partial response [PR]; ≥20% volume decrease). Secondary objectives: PD studies on pre/on-treatment biopsies of PN and cutaneous neurofibromas, assessment of clinical benefit using PROs (Numeric Rating Scale-11, Pain Interference Index), and PN-specific functional assessments. Validated, fit-for-purpose, isozyme-specific measurements of pERK/ERK/pMEK/MEK performed using SOPs designed for labile phosphoproteins (PMID 27001313). **Results:** As of February 2020, 27 pts have enrolled. Outcomes are reported for 23 pts (74% male; median age 33 years, range 18-60). Most common PN-related morbidity: pain (19 pts). Sixteen pts achieved PR (69%), with 13/16 confirmed; no disease progression. Time to response: 11 months (range 5-25); median change in PN volume at best response: -22% (range -41% to +5.5%); median duration of treatment: 28 months (range 2-50). Selumetinib suppressed tumor pERK1,2/ERK1,2 but not pMEK1,2/MEK1,2 ratios from 1-10 hours following oral dosing (one $t_{1/2}$). Pt-reported target tumor pain intensity and pain interference scores significantly improved (both $p < 0.03$). Pts 1 and 2 were dose-reduced due to grade 3 intolerable rash (n = 2) and pain (n = 1). Grade ≥3 drug-related toxicities on 50 mg (21 pts) include transaminitis (5 pts), rash (1 pt) and pancreatic enzyme elevation (1 pt). Two pts were dose reduced (rash = 1 pt, transaminitis = 1 pt). Two pts discontinued by choice, 2 pts withdrawn by PI (best interest of patient), and 1 pt each removed for transaminitis, surgical resection, serious concurrent medical illness, and noncompliance. **Conclusions:** Selumetinib shrinks the majority of adult PN and results in molecular target suppression and clinical benefit. Clinical trial information: NCT02407405. Research Sponsor: U.S. National Institutes of Health.

3613 Poster Session (Board #343), Fri, 8:00 AM-11:00 AM

Phase I study of afatinib plus selumetinib in patients with KRAS mutation-positive colorectal, non-small cell lung and pancreatic cancer. *First Author: Sanne Huijberts, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Mutations in the *KRAS* gene result in a constitutively activated RAS-RAF-MEK-ERK (MAPK) pathway. In KRAS mutant tumors, the antitumor activity of MEK inhibitors is limited due to intrinsic resistance caused by feedback activation of upstream epidermal growth factor receptors (HER). This upstream activation not only reactivates MAPK, but also the phosphoinositide 3-kinase (PI3K)-AKT pathway in preclinical research. Based on these data, a phase I clinical trial was initiated with the combination of the orally administered pan-HER inhibitor afatinib and the MEK inhibitor selumetinib in patients with *KRAS* mutant and *PIK3CA* wildtype colorectal cancer (CRC), non-small cell lung cancer (NSCLC), or pancreatic cancer to determine the recommended phase 2 regimen (RP2R). **Methods:** In this multicentre study, patients received escalating doses of afatinib and selumetinib according to a 3+3 design starting with 20 mg afatinib once daily (QD) continuously and 25 mg selumetinib twice daily (BID) in a 21 days on/7 days off schedule. Continuous and intermittent dosing were explored to assess optimal exposure and tolerability. The primary aim was determining the RP2R. Secondary objectives included assessment of anti-tumor activity and the analyses of pharmacokinetic and pharmacodynamic parameters for target inhibition. Clinicaltrials.gov identifier: NCT2450656. **Results:** In total, 26 mostly heavily pretreated patients with CRC (n=19), NSCLC (n=6) and pancreatic cancer (n=1) were enrolled among 5 dose-levels. Dose-limiting toxicities (DLTs) occurred in 6 patients and consisted of grade 3 diarrhea (n=3), decreased appetite (n=1), nausea/vomiting (n=1), dehydration (n=2) and mucositis (n=1). Clinical efficacy was limited with no responses according to RECIST v1.1 and stable disease for 221 days in a patient with NSCLC as best response. **Conclusions:** The RP2R was determined at 20 mg afatinib QD continuously and 25 mg selumetinib BID 21 days on/7 days off for continuous dosing. The 3 patients treated in the escalation cohort of the ongoing intermittent dose-level with 20 mg afatinib QD and 25 mg selumetinib BID 5 days on/2 days off, experienced no DLTs. Pending the latest safety results of the expansion cohort for this ongoing dose-level, the RP2R of intermittent dosing has not been established at the moment. Clinical trial information: NCT2450656. Research Sponsor: Boehringer Ingelheim Inc., AstraZeneca Inc.

3614 Poster Session (Board #344), Fri, 8:00 AM-11:00 AM

Quality of life of adults and children with TRK fusion cancer treated with larotrectinib compared to the general population. *First Author: Shivaani Kummar, Stanford Cancer Institute, Stanford University, Palo Alto, CA*

Background: *NTRK* gene fusions occur in diverse tumor types in adults and children. The selective TRK inhibitor, larotrectinib, has shown high response rates, durable disease control, and a favorable safety profile in patients (pts) with TRK fusion cancer. We report an expanded quality of life (QoL) analysis for pts treated with larotrectinib. **Methods:** QoL data were collected in two trials of larotrectinib in pts with TRK fusion cancer using EORTC QLQ-C30 (adults) and PedsQL (children) questionnaires, and were analyzed descriptively and longitudinally. EORTC QLQ-C30 global health scores (GHS) and PedsQL total scores range from 0 to 100, with higher scores indicating better QoL. We calculated the proportion of pts with normal/above and below normal QoL scores compared to values in the literature for the US general population. **Results:** By July 2019, 126 pts with TRK fusion cancer (74 adults, 24 children ≥2 yrs, and 28 infants <2 yrs) had received larotrectinib and completed baseline (BL) and ≥1 post-BL questionnaire. Most pts had clinically meaningful QoL improvements that reached or exceeded the minimally important difference (Table); a positive change from BL was also seen in infants: mean best change of 12.0 (SD 13.8). Of 52 adults with BL EORTC QLQ-C30 GHS at or above the population norm, 51 remained in this category on treatment and 1 moved into the below normal category. Of 22 adults with BL scores below the population norm, 20 moved into the normal/above normal category. All 9 children aged ≥2 yrs with BL PedsQL scores at or above the population norm remained in this category on treatment. Of 15 children with BL scores below the population norm, 10 moved into the normal/above normal category. Sustained QoL improvements (change from BL ≥0) occurred by 2 months of treatment in 69% of adults and 75% of children. Median duration of sustained improvement in EORTC QLQ-C30 GHS and PedsQL total score was 12.0 months (range 1.7–20.3) and not estimable (range 1.1–23.0), respectively. **Conclusions:** Adults and children with TRK fusion cancer treated with larotrectinib had rapid, clinically meaningful, and sustained improvements in QoL. Clinical trial information: NCT02576431, NCT02637687.Research Sponsor: Bayer HealthCare and Loxo Oncology, Inc., a wholly owned subsidiary of Eli Lilly.

	EORTC QLQ-C30 GHS	PedsQL total score (≥2 yrs old)
BL and ≥1 post-BL measurement, n	74	24
Best change in total score from BL, mean (SD)	17.5 (20.0)	20.7 (17.2)
Best post-BL score above BL score, % (n)	69 (51)	88 (21)
MID* improvement, % (n)	59 (44)	79 (19)
BL and ≥2 post-BL measurements, n	64	24
Sustained improvement for ≥2 consecutive cycles, % (n)	47 (30)	75 (18)

*Minimally important difference: ≥10 points for EORTC QLQ-C30; ≥4.5 points for PedsQL

3615 Poster Session (Board #345), Fri, 8:00 AM-11:00 AM

Single-agent ONC201 in recurrent H3 K27M-mutant diffuse midline glioma. *First Author: Isabel Arrillaga-Romany, Massachusetts General Hospital, Boston, MA*

Background: Recurrent H3 K27M-mutant diffuse midline glioma is a lethal brain tumor that predominantly affects children and young adults and has no effective therapy. ONC201 is a first-in-class orally administered, anti-cancer small molecule that selectively antagonizes the dopamine receptors DRD2/DRD3 and agonizes ClpP, a mitochondrial protease. Prior studies have indicated dysregulated dopamine receptor expression and enhanced ONC201 sensitivity among H3 K27M-mutant gliomas. **Methods:** Adults with midline H3 K27M-mutant glioma patients were enrolled to a dedicated Phase II clinical trial (NCT03295396), a multi-arm Phase II clinical trial (NCT02525692), and expanded access protocols under the Sponsor's IND. Results were pooled among patients treated with ONC201 monotherapy through any of these trial with H3 K27M confirmed glioma, progressive and measurable disease by RANO, > 90 days from completion of prior radiation, no evidence of leptomeningeal dissemination, midline location other than primarily pons or spinal cord, and baseline KPS > 60. Using an enrollment cutoff of February 15, 2019 and data cutoff of July 31, 2019, there were 20 patients (NCT03295396, 12; NCT02525692, 7; expanded access, 1). Dosage was 625 mg weekly in 19 and once every 3 weeks in 1. **Results:** No DLTs or treatment discontinuations due to toxicity occurred. Midline gliomas can exhibit minimal contrast enhancement or exhibit a mixture of contrast-enhancing and non-contrast enhancing regions in the tumor. As a result, blinded independent central review (BICR) of tumor response by MRI was assessed by RANO-HGG and RANO-LGG for each patient to capture contrast-enhancing lesions by T1 post-contrast and non-contrast-enhancing assessments by T2/FLAIR, respectively, in the object response rate. The best response by RANO-HGG or RANO-LGG is 30% (95% CI, 11.9-54.3%). Duration of response by RANO-HGG is median 52.7 weeks (range 15.9-138.3). One patient with stable disease as of this data cutoff has continued on treatment beyond 12 months and recently underwent an investigator-reported PR by RANO-HGG that is pending confirmation. **Conclusions:** Single agent ONC201 is well tolerated and clinically active in recurrent H3 K27M-mutant diffuse midline glioma patients. Clinical trial information: NCT03295396, NCT02525692. Research Sponsor: U.S. National Institutes of Health.

3616 Poster Session (Board #346), Fri, 8:00 AM-11:00 AM

The next-generation RET inhibitor TPX-0046 is active in drug-resistant and naïve RET-driven cancer models. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *RET* fusions/mutations drive oncogenesis in lung and thyroid cancers, and several other malignancies. Selective RET inhibitors (selpercatinib/pralsetinib) are active in patients with these cancers; unfortunately, resistance often occurs. On-target resistance includes the acquisition of solvent front mutations (SFMs i.e. *RET* G810 substitutions). TPX-0046 is a structurally differentiated RET inhibitor that is potent against a range of RET fusions and mutations including SFMs. **Methods:** The rationally-designed, compact, macrocyclic RET/SRC inhibitor TPX-0046 was characterized in RET-driven *in vitro* and *in vivo* tumor models. **Results:** In enzymatic assays, TPX-0046 showed low nanomolar potency against wild-type RET and 18 *RET* mutations/fusions. It was potent against SRC and spared VEGFR2/KDR. TPX-0046 inhibited RET phosphorylation ($IC_{50} < 10$ nM) in tumor cell lines (LC2/ad, *CCDC6-RET*; TT, *RET* C634W) and Ba/F3 engineered RET models (WT, G810R). In cell proliferation assays, TPX-0046 inhibited *KIF5B-RET* Ba/F3, LC2/ad, and TT cells with IC_{50} values ~1 nM. Ba/F3 RET engineered cells with SFMs (e.g. G810C/R/S) were potently inhibited by TPX-0046 (mean proliferation IC_{50} 1–17 nM). TPX-0046 demonstrated marked *in vivo* anti-tumor efficacy in RET-driven cell-derived and patient-derived xenograft tumor models. In a Ba/F3 *KIF5B-RET* xenograft model, a single dose of 5 mg/kg TPX-0046 inhibited > 80% of RET phosphorylation (corresponding mean free plasma concentration: 51 nM). At 5 mg/kg BID, tumor regression was observed in RET-dependent xenograft models, including those that harbor RET SFMs: TT, CTG-0838 PDX (NSCLC, *KIF5B-RET)*, CR1520 PDX (CRC, *NCOA4-RET*), Ba/F3 *KIF5B-RET*, and Ba/F3 *KIF5B-RET* G810R. **Conclusions:** TPX-0046 is a unique next-generation RET inhibitor that possesses potent *in vitro* and *in vivo* activity against a diverse range of *RET* alterations, including SFM-mediated resistance. A phase 1/2 trial for RET inhibitor-resistant and naïve RET-driven cancers is on-going (NCT04161391). Research Sponsor: Turning Point Therapeutics.

3617 Poster Session (Board #347), Fri, 8:00 AM-11:00 AM

Clinical efficacy of ONC201 in thalamic H3 K27M-mutant glioma. *First Author: Abed Rahman Kawakibi, Michigan Medicine, Ann Arbor, MI*

Background: Diffuse midline gliomas, H3 K27M-mutant are associated with a poor prognosis compared to H3 wild-type gliomas and have no effective therapy following first-line radiation. ONC201 is a bitopic DRD2 antagonist and allosteric ClpP agonist that has shown encouraging single agent efficacy in recurrent H3 K27M-mutant gliomas located in various midline structures of the brain. In addition to tumor and immune cells, the pharmacodynamics of ONC201 extend to stromal cells that can mediate a bystander antitumor response in preclinical models. Given this observation and that the thalamus has the highest extrastriatal expression of DRD2, we report the clinical experience of ONC201 in a subgroup of H3 K27M-mutant glioma patients with primary tumors located in the thalamus. **Methods:** We analyzed 29 thalamic H3 K27M-mutant glioma patients treated with ONC201 in clinical trials enrolled as of 5/22/19. Nineteen enrolled with recurrent disease whereas 10 enrolled following radiation prior to recurrence. Twelve patients enrolled on NCT03295396, 10 NCT03416530, 4 NCT02525692, and 3 expanded access. Median age was 22 years old (range: 5-70) and baseline KPS was 80 (range: 60-90). Median time from radiation to start of ONC201 was 1.8 months (range: 0.2-8.7) for non-recurrent patients and 7.2 months (range: 1.4-102.0) for recurrent patients. **Results:** As of 12/18/2019, PFS6 and OS12 measured relative to initiation of ONC201 are 26.3% and 36.8%, respectively, in the recurrent group. For patients initiating ONC201 post-radiation prior to recurrence, median PFS or OS have not been reached with a median follow up of 21.9 months (8.6-26.6) from diagnosis, which surpass historical OS of 13.5 months. Best response for evaluable recurrent patients by RANO: 1 CR, 3 PR, 4 SD, 8 PD, 3 not reported; for non-recurrent patients: 2 PR, 4 SD, 1 PD, 3 not reported. Median duration of response for recurrent patients is 14.0 months (2.0-33.1). ONC201 was well tolerated and no dose-limiting toxicities or treatment discontinuations due to toxicity occurred. Furthermore, H3 K27M cell-free tumor DNA in plasma and CSF correlated with MRI response. **Conclusions:** In summary, single agent ONC201 administered at recurrence or following radiation, demonstrates promising clinical efficacy in thalamic H3 K27M-mutant glioma patients. Investigations are ongoing to assess whether micro-environmental DRD2 expression correlates with responses of thalamic H3 K27M-mutant glioma to ONC201. Clinical trial information: NCT03295396, NCT03416530, NCT02525692. Research Sponsor: None.

BET inhibitor molibresib for the treatment of advanced solid tumors: Final results from an open-label phase I/II study. *First Author: Sophie Cousin, Medical Oncology, Institute Bergonié, Bordeaux, France*

Background: Molibresib is an orally available, small molecule bromodomain and extra-terminal domain (BET) protein inhibitor under investigation for treatment of advanced solid tumors. **Methods:** This was an open-label, single- and repeat-dose, 2-part, Phase 1/2 study including patients (aged ≥16 years) with advanced solid tumors. Part 1: patients received different oral doses of molibresib (2–100mg QD; amorphous free-base formulation) to determine recommended Phase 2 dose. Part 2 (expansion cohort): patients with various tumor types received the bioequivalent besylate formulation (75mg) to explore clinical activity at recommended dose. Safety and efficacy (response rate [RR] based on RECIST 1.1 criteria, progression-free survival [PFS], and overall survival [OS]) were evaluated for the total cohort (patients from Part 1 and 2). Safety, pharmacokinetic, pharmacodynamic, and efficacy per tumor type were evaluated in Part 2. **Results:** Part 1 only data have previously been reported. Overall, 196 patients were included in the total cohort (1 patient in Part 1 was counted twice). In the all treated population, 195 patients (median age 58 years; 46% male) received ≥1 dose of molibresib (Part 1: n = 93; Part 2: n = 102). Adverse events (AEs) were experienced by 193/196 (98%) patients; 180/196 (92%) had a treatment-related AE (TRAE). AEs led to permanent treatment discontinuation in 38/196 (19%) patients. Of different tumor types in Part 2, NUT carcinoma (NC) had the lowest frequency of TRAEs (10/12 [83%]) and AEs leading to permanent treatment discontinuation (1/12 [8%]). In total cohort, 3/31 NC patients and 1/35 with castration-resistant prostate cancer (CRPC) achieved a confirmed partial response. A further 67/196 (34%) achieved stable disease (SD). In Part 2, RR in 12 NC patients was 8% (CI: 0.2–38.5); 50% had SD and median PFS was 4.8 months with median OS of 5.0 months. In CRPC patients, RR was 4% (CI: 0.1–21.9); 22% had SD; median PFS was 8.0 months with median OS of 9.1 months. Plasma concentrations for molibresib and active metabolites were similar between different tumor types. Gene expression analysis from pre- and post-dose biopsy samples collected from 10 mCRPC patients showed transcriptional downregulation of Myc target genes upon treatment with molibresib. **Conclusions:** Molibresib demonstrated a manageable safety and tolerability profile with single agent activity observed in selected patients with NC and CRPC. Clinical trial information: NCT01587703. Research Sponsor: GSK, Other Foundation.

3619 Poster Session (Board #349), Fri, 8:00 AM-11:00 AM

ONC201 in previously irradiated pediatric H3 K27M-mutant glioma or newly diagnosed DIPG. *First Author: Sharon L. Gardner, New York University School of Medicine, New York, NY*

Background: ONC201 is a first-in-class DRD2 antagonist and ClpP agonist that has demonstrated promising activity in high-grade glioma preclinical models and radiographic regressions with single agent ONC201 in recurrent H3 K27M-mutant glioma patients . The recommended phase 2 dose (RP2D) of 625mg ONC201 orally once a week has been established in adult patients as well tolerated and biologically active. ONC201 efficacy has been shown in high-grade glioma preclinical models and radiographic regressions with single agent ONC201 have been reported in adult recurrent H3 K27M-mutant glioma patients. We report results from the first Phase I pediatric clinical trial of ONC201. **Methods:** This open-label, multi-center trial for pediatric H3 K27M-mutant glioma or non-biopsied DIPG employed a 3+3 dose-escalation and dose-expansion design with 6 arms. Arms A and E, which have completed accrual, determined the RP2D of ONC201 using oral capsule and liquid formulations in post-radiation pediatric H3 K27M-mutant glioma patients ONC201, respectively. Arm B aims to determine the RP2D for ONC201 in combination with radiotherapy in patients with newly diagnosed DIPG. Arms C and D aim to measure intratumoral ONC201 concentrations in midline glioma patients and the impact of ONC201 on H3 K27M DNA levels in CSF, respectively. Arm F was recently opened to study ONC201 as a single agent in patients with progressive H3 K27M-mutant tumors (excluding DIPG and spinal cord tumors) following radiotherapy. After determining the RP2D, a dose-expansion cohort will evaluate the safety, radiographic response, and activity of ONC201. **Results:** An RP2D of weekly 625mg ONC201 scaled by body weight as a capsule or in liquid formulation was established in the primary endpoints of arms A, B and E alone or in combination with radiation, without incidence of dose-limiting toxicity (DLT). Pharmacokinetic profiles were similar to those observed in adults ($T_{1/2}$: 8.4h; T_{max}: 2.1h; C_{max}: 2.3ug/mL; $AUC_{0\text{-tlast}}$: 16.4ug/mL), with similar exposure across body weights. **Conclusions:** ONC201 was well tolerated without DLTs at the same adult RP2D scaled by body weight as monotherapy or in combination with radiotherapy in pediatric H3 K27M-mutant glioma patients. Further investigation of ONC201 to treat H3 K27M-mutant glioma and DIPG is warranted. Clinical trial information: NCT03416530. Research Sponsor: U.S. National Institutes of Health.

3620 Poster Session (Board #350), Fri, 8:00 AM-11:00 AM

Pan-cancer analysis of FGFR1-3 genomic alterations to reveal a complex molecular landscape. *First Author: Melanie A. Krook, The Ohio State University Comprehensive Cancer Center, Ohio State University, Columbus, OH*

Background: Activating genomic alterations (GAs) in the fibroblast growth factor receptor (FGFR) gene family occur in many tumor types. *FGFR1-3* mutations and rearrangements are of particular interest given evidence of clinical activity of selective FGFR inhibitors in patients (pts) with susceptible alterations. We queried *FGFR1-3* GAs in patient tumor samples analyzed using comprehensive genomic profiling (CGP) and performed *in vitro* characterization of select novel alterations. **Methods:** Tumor samples were assayed by hybrid capture based CGP on 0.8-1.2 Mb of the genome to identify GAs in exons and select introns in up to 404 genes (Foundation Medicine, Inc, Cambridge MA). Cell lines were stably transduced with alterations of interest and transformation assays and drug sensitivity assays were performed to determine oncogenic potential and sensitivity to FGFR inhibition by pemigatinib. **Results:** GAs in *FGFR1-3* were present in 6314 of 274,694 pt specimens (2.3%), of which 4091 (64.8%) were short variants and 2269 (35.9%) were rearrangements. Tumor types with the highest frequency of *FGFR1-3* alterations were bladder cancer (17.9%), cholangiocarcinoma (11.1%), endometrial cancer (7.9%), and glioma (5.5%) (Table). We identified 270 unique *FGFR1-3* short-variants, including 144 missense mutations and 94 truncating alterations. Of short variants, the most frequent were *FGFR3* p.S249C (18.3%), *FGFR2* p.S252W (9.9%) and *FGFR1* p.N546K (6.9%). Truncating alterations were largely identified in exon 18, downstream of the kinase domain. We identified 476 unique *FGFR1-3* rearrangement pairs (*FGFR1*; n=77, *FGFR2*; n=338, *FGFR3*; n=61). *FGFR3-TACC3* was the most prevalent *FGFR* rearrangement (29.0%), followed by *FGFR2-BICC1* and *FGFR2*-N/A (both 9.7%). *In vitro* analysis of the transforming potential and drug sensitivity for select alterations will be reported. **Conclusions:** *FGFR1-3* mutations and rearrangements are highly diverse and present at low to moderate frequencies across many cancers. Therefore, cataloging and characterizing these diverse alterations has the potential to facilitate precision medicine. Tumor-specific and -agnostic trials of selective FGFR inhibitors in pts with susceptible alterations are ongoing. Research Sponsor: Incyte Corporation.

3621 Poster Session (Board #351), Fri, 8:00 AM-11:00 AM

Identifying pan-cancer transcriptomic determinants of perineural and lymphovascular invasion using machine learning. *First Author: Jimmy Guo, Broad Institute, Cambridge, MA*

Background: Tumor invasion of nerves, blood vessels, and lymphatics are a primary means of local recurrence and escape from the local microenvironment, resulting in metastases and poor clinical outcomes. However, the genetic drivers that are most pertinent to these malignant processes are not well understood, and few therapeutics successfully target perineural invasion (PNI) and lympho-vascular invasion (LVI). Identifying genetic drivers and biomarkers can be valuable for therapeutic targeting and prognostication. **Methods:** We analyzed surgical pathology reports and bulk RNA-seq data of 1,624 patients across 12 cancer types from The Cancer Genome Atlas (TCGA). Differential gene expression analysis between patients with and without PNI/LVI was performed using DEseq2 in Python while adjusting for age, sex, race, and cancer type. Genes with an adjusted p-value < 0.001 were then used to derive parsimonious signatures using random forest classifier and recursive feature selection algorithms. **Results:** To assess whether these invasive histological phenotypes have clinical ramifications, we examined outcomes data and found that patients with PNI or LVI have reduced overall (OS) and disease-free survival (DFS) ($p < 0.05$) relative to those without. In addition, patients with both PNI and LVI have the lowest DFS from our pan-cancer analysis, suggesting that each may have non-redundant contributions to poor outcomes. From the differential gene expression analysis, we identified a set of 621 and 606 genes that were highly associated with PNI and LVI, respectively ($p_{adj} < 0.001$). Many of these genes such as TEKT5 ($p_{adj} = 3.18 \times 10^{-64}$), which is canonically associated with ciliary and flagellar microtubules, and SCRIB ($p_{adj} = 1.60 \times 10^{-21}$), which helps establish apico-basal cell polarity, have not been described previously in relevance to PNI and LVI, and warrant further scientific and clinical investigation. These genes were ultimately condensed into a signature that optimizes for both model simplicity and goodness of fit with up to 90% accuracy as determined by trials on both a logistic regression and neural network model. **Conclusions:** We concluded from a pan-cancer analysis that PNI and LVI are associated with poor outcomes, and we were able to robustly identify sets of genes that characterize each invasive mechanism for further functional investigation. Research Sponsor: None.

3622 Poster Session (Board #352), Fri, 8:00 AM-11:00 AM

Increased tumor purity and improved biomarker detection using precision needle punch enrichment of pathology specimen paraffin blocks: Method validation and implementation in a prospective clinical trial. *First Author: Jonathan Keith Killian, Foundation Medicine, Cambridge, MA*

Background: While many sequencing assays may be geared for short variants (SV), more complex biomarkers such as genomic loss of heterozygosity (gLOH) score, also referred to as homologous recombination deficiency (HRD) score, require higher tumor purity for confident detection. Practical methods to increase tumor nuclei percentage (TN%) from pathology specimens are needed to achieve biomarker results to maximize patient matching to approved therapies and/or clinical trial enrollment. **Methods:** Tumor purity of specimens was determined by the computational analysis pipeline component of the FDA-approved NGS assay, FoundationOneCDx. In the validation study, specimen purities for each tissue block were compared following either no enrichment (UnE, n=46), pathologist-directed enrichment by straight razor blade (RBE, n=30) or precision needle punch (NPE, n=47). Post-enrichment H&E slides confirmed target region sampled for the NPE arm. Based upon validation data, the needle punch process was implemented for the Lung-MAP prospective clinical trial (LM-NPE). TN% was compared between the first 55 tested LM-NPE specimens and the validation study to assess performance on real-world samples outside of a controlled validation experiment. **Results:** The mean computational TN% in the 4 groups were: UnE: 33%; RBE: 30%; NPE: 52%; and LM-NPE: 48%. In the validation study, NPE had significantly higher purity than both UnE and RBE ($p<0.001$); in the trial arm, LM-NPE performed equivalently to NPE ($p=0.344$). Based upon a 30% tumor purity cutoff, gLOH could be determined for 52% UnE, 50% RBE, 89% NPE and 71% LM-NPE. Comparing NPE and LM-NPE groups reveals no statistical difference in Pass/Fail rates for gLOH determination ($p=0.883$; Fisher's Test). **Conclusions:** Precision needle punch cores from tissue blocks have elevated tumor purity, and consequently, a greater number of successful gLOH determinations. Moreover, this process is rapid and inexpensive. Precision punches may constitute best practice with respect to enriching tumor cells from low-purity specimens for biomarker detection in a routine laboratory specimen-processing setting. Research Sponsor: Foundation Medicine Inc.

Comparison	p-value Abs tumor purity	p-value gLOH Pass rate	Abs Diff in mean tumor purity	Abs Diff in gLOH Pass Rate
UnE (n=46) vs RBE (n=30)	0.491	0.853	3%	2%
UnE (n=46) vs NPE (n=47)	<0.001	<0.001	19%	37%
RBE (n=30) vs NPE (n=47)	<0.001	<0.001	22%	39%
LM-NPE (n=55) vs NPE (n=47)	0.344	0.883	4%	18%

3623 Poster Session (Board #353), Fri, 8:00 AM-11:00 AM

Targeting G1-S phase cell-cycle alterations with CDK4/6 inhibitor-based genomically matched personalized therapy approach. *First Author: Jacob J. Adashek, University of South Florida, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Although CDK4/6 inhibitors are established as a standard treatment option for hormone receptor-positive, HER2-negative metastatic breast cancer patients, its benefit in other solid tumors is unclear. Moreover, no clear biomarker exists that predicts the response to CDK4/6 inhibitors. Herein, we investigated the factors associated with clinical outcomes from CDK4/6 inhibitor-based therapy, used alone or in combination with other therapies targeting genomic co-alterations, among diverse cancer patients with potentially sensitizing alterations in G1-S phase cell-cycle alterations (defined as *CDK4/6* amplifications, *CCND1/2/3* amplifications or *CDKN2A/B* alterations). **Methods:** We interrogated molecular profiles of 2,457 patients with diverse solid tumors for G1-S phase cell-cycle alterations and co-altered genes using clinical-grade next generation sequencing (182-465 genes). **Results:** G1-S phase cell-cycle alterations occurred in 20.6% (507/2,457) of patients with 99% of those with cell cycle alterations (N = 501/507) harboring at least one characterized co-alteration (median, 4; range, 0-24). Significant improvement in median PFS was observed when CDK4/6 inhibitor-based therapies matched a larger proportion of tumor alterations, often by being given together with other drugs that were matched to genomic co-alterations, hence achieving a high Matching Score (high Matching Score [≥50%] vs. low Matching Score [< 50%]: all cohorts including breast cancer [N = 58]: PFS: 6.2 vs. 3.2 months, P = 0.001; non-breast cancer cohort [N = 40]: PFS 6.2 vs. 2.0 months, P < 0.001 [multivariate]). (Matching Score roughly equivalent to number of alterations targeted divided by total number of characterized alterations). In contrast, targeting CDK4/6 alone in patients harboring cell-cycle pathway alterations along with other co-alterations, without targeting the genomic co-alterations, did not improve PFS even in patients who received matched CDK4/6 inhibitors as part of a combination regimen. Representative cases that were successfully treated with a matched combination strategy will also be presented. **Conclusions:** Most patients with G1-S phase cell-cycle alterations harbored co-genomic alterations. Our current study suggests that targeting co-alterations along with cell cycle molecular alterations may be necessary to achieve better clinical outcome. Further clinical investigation with larger numbers of patients are required. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

3624 Poster Session (Board #354), Fri, 8:00 AM-11:00 AM

Tumor genomic analysis for biomarker identification in a phase I trial of the Wee 1 inhibitor adavosertib (AZD1775). *First Author: Abdul Rafeh Naqash, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: Adavosertib, a first-in-class Wee1 kinase inhibitor, abrogates G2/M cell cycle arrest causing premature mitosis and DNA replication stress, yielding enhanced DNA damage. Here we report on potential biomarkers of response from tumor genomic analysis in patients (pts) with solid tumors treated with adavosertib. **Methods:** Adavosertib was administered once daily on days 1-5 and 8-12 of a 21-day cycle. RECIST 1.1 was used to evaluate clinical response. Paired tumor biopsies were obtained for RNASeq gene expression profiling (GEP) and for whole-exome sequencing (WES) to evaluate gene mutation and copy number amplification (CNA). Fold change (FC) was calculated to define gene overexpression. To identify the frequency of CNA and mRNA overexpression for the genomic biomarkers of interest, cBioPortal analysis using TCGA and MSK-IMPACT datasets was performed. Differential GEP analysis of tumor and paired normal tissue was performed using the gene expression profiling interactive analysis (GEPIA) interface (Tang et al. 2017). **Results:** Out of 35 pts evaluable for response, 6 (17%) had partial response (PR; 4 ovarian carcinoma [OVC], 2 endometrial carcinoma [EC]). The median duration of response was 5.2 months (range 4.0-23.1). Eighteen pts (51.4%) had stable disease. Genomic analysis of tumor biopsies was available for 9 pts; 7 of these pts were evaluable for response, and 3 had PR (2 OVC, 1 EC). WES revealed TP53 mutations in 6 pts (66.6%; 3 pts with PR, 2 with progressive disease,1 not evaluable). On WES, tumor Cyclin E1 (*CCNE1*) CNA was present in 1 of 3 PR pts while tumors from all 3 PR samples showed relatively high *CCNE1* expression by RNAseq (FC = 4.07). In the MSK-IMPACT 2017 dataset, *CCNE1* CNA was identified in 1.8% of pts (194 of 10336); of which, OVC (10.3%) and EC (8.7%) had the highest incidence of *CCNE1* CNAs. In separate tumor-specific (OVC, EC) TCGA datasets having *CCNE1* overexpression and/or CNA, overlap in *CCNE1* overexpression with *CCNE1* CNA was 35.5% (OVC) and 25.2% (EC). Compared to normal ovarian/ endometrial tissues, GEPIA analysis revealed significantly higher *CCNE1* mRNA expression in OVC (FC = 3.5) and EC (FC = 3.8). **Conclusions:** *CCNE1*alterations (overexpression and/or CNA) tend to be enriched in OVC and EC with a limited fraction showing both overexpression and CNA. Tumor genomic analysis of additional OVC and EC pts treated with adavosertib is required to determine whether *CCNE1* mRNA overexpression, regardless of *CCNE1* CNA, is a potential biomarker of response to this drug in these tumor types. Funded by NCI contract No. HHSN261200800001E. Clinical trial information: NCT01748825. Research Sponsor: U.S. National Institutes of Health, Funded by NCI contract No. HHSN261200800001E.

3625 Poster Session (Board #355), Fri, 8:00 AM-11:00 AM

Therapeutic vulnerabilities among KRAS G12C mutant (mut) advanced cancers based on co-alteration (co-alt) patterns. *First Author: Maliha Nusrat, Gastrointestinal Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Oncogenic *KRAS* mut drive cancers and confer therapeutic resistance by activating MAPK signaling. Inhibiting *KRAS* has been elusive until the recent promising phase I trials with KRAS G12C inhibitors (i). We characterized frequencies of *KRAS* G12C mut and gene co-alt among advanced cancer patients (pts) to identify therapeutic vulnerabilities for combination development. **Methods:** We analyzed next generation sequencing datasets from MD Anderson Cancer Center (MDACC, n = 42,316) and AACR GENIE (n = 56,970). Genes and individual alterations were annotated for potential actionability with approved or investigational drugs and grouped into 12 oncogenic pathways. Frequencies of potential drug combinations with KRAS G12Ci were estimated per tumor type based on co-occurrence of potentially actionable alterations. **Results:** *KRAS* G12C was present in 850/34,801 (2.4%) advanced solid tumor and 22/7698 (0.3%) hematologic malignancy pts in MDACC dataset; and 1422 (2.5%) pts in AACR GENIE. Among solid tumor pts, 798 had histology data and 640 had ≥46 gene profiling. Most common cancers were non-small cell lung (NSCLC, 67%), colorectal (CRC, 24%), other gastrointestinal (oGI, 4%) and gynecologic (gyn, 2%). KRAS G12C prevalence was 19.5% (441/2265) in NSCLC and 4.2% (146/3469) in CRC. Genes most commonly co-altered were *TP53* (42%), *STK11* (17%) and *MET* (11%) in NSCLC; *TP53* (58%), *APC* (54%) and *PIK3CA* (24%) in CRC; *TP53* (42%), *APC* (21%) and *ATM* (21%) in oGI; *TP53* (56%), *PIK3CA* (25%), and *PTEN* (19%) in gyn cancers. These co-alt did not impact overall survival. In both datasets, as compared to *KRAS* wild, *KRAS* G12C was significantly co-altered with *STK11* in NSCLC; *PIK3CA* and *SMAD4* in CRC ($P < 0.05$ for all). *EGFR* mut in NSCLC and *BRAF* mut in CRC rarely co-occurred with *KRAS* G12C ($P < 0.01$). Most frequently co-altered oncogenic pathways in NSCLC, CRC, oGI and gyn cancers respectively included PI3K (27, 32, 33, 44 %), receptor tyrosine kinases (13, 16, 42, 13 %) and DNA damage repair (12, 10, 38, 19 %). Potentially actionable co-alt frequencies suggest that combining KRAS G12Ci with mTORi or PI3Ki would be indicated most frequently, in 24% and 13% of all pts respectively. **Conclusions:** KRAS G12Ci development is most relevant for NSCLC, gastrointestinal and gyn cancers. The co-alt patterns highlight relevant oncogenic pathways and candidate drugs for future combination therapies. Co-inhibition of PI3K-mTOR and MAPK pathways has shown synergism in prior pre-clinical studies but had poor tolerance in pts. There is opportunity to revisit this approach with the new KRAS G12Ci. 3626 Poster Session (Board #356), Fri, 8:00 AM-11:00 AM

The landscape of predictive biomarkers for ATR inhibition in Chinese solid-tumor patients. *First Author: Rong Shen, Department of Chemotherapy, Shandong Provincial Hospital Affiliated to Shandong University, Jinan, China*

Background: Ataxia Telangiectasia and Rad3-related (ATR) is one of the core regulators participating in DNA damage response as a sensor of replication stress. Besides, ATR also plays a role in cell cycle checkpoint activation and DNA replication regulation. Several ATR inhibitors (ATRi) have been demonstrated in anti-cancer clinical trials. Herein, we describe the distribution of selected biomarkers, which have been shown to predict a higher sensitivity to ATRi according to preclinical data, in Chinese cancer population. **Methods:** FFPE tumor tissues and matched blood samples from 10,194 Chinese patients with 25 different types of solid tumors were collected. NGS based 450 cancer genes panel assay were performed to detect genomic alterations, including SNV, short and long insertions/deletions, CNV and rearrangements/fusions. The testing was carried out by a CAP accredited and CLIA certified laboratory. **Results:** The prevalence of *ARID1A* mutations, *ATM* mutations, *BRCA1/BRCA2* mutations, *MYC* amplification, and *CCNE1* amplification accounted for 9.5%, 4.7%, 6.0%, 3.5% and 3.3% of this cohort respectively. The most common tumors with *ARID1A* mutations were endometrial carcinoma (EC, 34.4%), gastric carcinoma (GC, 19.4%), small bowel carcinoma (SBC, 19.3%), intrahepatic cholangiocarcinoma (19.3%), extrahepatic cholangiocarcinoma (17.7%) and urothelial carcinoma (UC, 16.7%). For *ATM* mutations, the prevalence was colorectal carcinoma (CRC, 8.9%), SBC (8.8%), pancreatic cancer (7.8%), UC (7.3%), gallbladder carcinoma (GBC, 7.1%) and GC (6.8%). For *BRCA1/BRCA2* mutations, the prevalence was ovarian carcinoma (29.5%, Germline 23%), breast carcinoma (13.3%, Germline 7.1%), EC (11.5%, Germline 3.3%), UC (10.4%), melanoma (8.5%) and CRC (7.9%). For *MYC* amplification, the prevalence was breast carcinoma (10.2%), ovarian carcinoma (9.2%), esophageal carcinoma (7.2%), thymic tumor (6.1%), cancer of unknown primary (CUP, 5.8%) and gastrointestinal neuroendocrine tumor (GI-NET, 5.4%). For *CCNE1* amplification, the prevalence was GC (11.9%), GBC (8.8%), bone sarcoma (7.7%), ovarian carcinoma (6.9%), CUP (4.2%) and GI-NET (4.1%). **Conclusions:** Our study reported the prevalence of gene mutations of ATRi sensitivity determinants in a large cohort of Chinese cancer patients. The results revealed the high prevalence and different distribution of these biomarkers across a wide spectrum of cancers. The genomic profile study also provided information for ATRi sensitivity assessment and the drug combinations with ATR inhibition. Research Sponsor: None.

3627 Poster Session (Board #357), Fri, 8:00 AM-11:00 AM

Modeling differentially expressed genes in patient tumors to guide expression-based biomarker development. *First Author: Derek Liu, Dana–Farber Cancer Institute, Boston, MA*

Background: Differential gene expression (DGE) methods, initially developed for analyzing bulk RNA changes in pure tumor cell lines under experimental settings, are commonly used to identify biomarkers in and infer biological differences between patient tumor samples, which are admixtures of tumor and non-tumor components. Methods to sensitively and accurately detect cell type-specific expression differences in admixed patient samples are not well characterized but may greatly affect emerging targeted and immunotherapy biomarker strategies. To address this issue, we developed a simulation framework to benchmark our ability to detect changes in tumor-intrinsic gene expression. **Methods:** Pseudobulk RNAseq melanoma cohorts were simulated by sampling from melanoma single cell RNAseq data. Simulation parameters were optimized to maximize concordance of gene expression means and variances (Spearman r = 0.81, 0.68, respectively) between the TCGA SKCM cohort (n = 462) and matched simulated cohort, and then validated in two independent melanoma cohorts (n = 42, 129; means Spearman r = 0.80, 0.78; variances Spearman r = 0.68, 0.63). Using this simulation framework, we benchmarked the effect of sample size, magnitude of differential expression, and differences in cell type proportions on the sensitivity and positive predictive value (PPV) of detecting true differentially expressed genes in the tumor-intrinsic compartment. **Results:** Reference cohorts of 50 total tumors (n = 10) were simulated to contain a 2 standard deviation tumor-intrinsic expression change in 50 randomly selected genes and a 11% difference in mean purity between two equally sized 25-tumor subgroups. DGE analysis using DESeq2 with an FDR q-value threshold of 0.1 yielded a sensitivity of 0.37 and PPV of 0.29. DGE analysis of the same simulated cohorts using a non-parametric Mann-Whitney U test with an FDR q-value threshold of 0.1 yielded a sensitivity of 0.13 and PPV of 0.76. **Conclusions:** Commonly used DGE methods for existing expression-based biomarker strategies have poor sensitivity and PPV in admixed tumor samples, limiting our ability to find meaningful transcriptional biomarkers in clinical cohorts. We are currently developing methods to more accurately detect true differentially expressed genes in admixed bulk RNAseq samples and applying these approaches for biomarker discovery in immunotherapy-treated patient cohorts and other clinical tumor cohorts. Research Sponsor: U.S. National Institutes of Health.

3628 Poster Session (Board #358), Fri, 8:00 AM-11:00 AM

Employing RNA sequencing to enhance treatment options for cancer patients. *First Author: Gargi D. Basu, Ashion Analytics, Phoenix, AZ*

Background: Fusions and translocations account for 20% of cancer mortality globally. Maximizing their detection enhances the utility of precision medicine for various solid and hematologic cancers. Practice guidelines stress the importance of RNA sequencing. Novel assay techniques employing a comprehensive genomic profiling approach, including RNA sequencing, yield information beyond conventional DNA next generation sequencing (NGS) alone. **Methods:** Tumor samples (N = 1517) were assayed combining whole transcriptome (RNA) sequencing, whole exome (DNA) sequencing, and comparison of tumor sequence vs. paired normal DNA. Results were analyzed to determine the frequency of rare and common RNA fusion and variant detection. Findings were mapped to a knowledge-base of targeted treatment options. **Results:** Analysis detected 79 (5.2%) actionable fusions and 15 (1%) transcript variants across major solid and heme-based malignancies. Notably, we observed actionable transcript variants that are not detectable at the DNA level including: EGFRvIII, EGFRvIVa and EGFRvIVb in GBM; ARv7 in prostate, and METe14 in TNBC. Many fusion cases (42%, n = 33) had no other actionable molecular abnormalities. Novel fusions included: SLC12A/ROS1 in low-grade spindle cell neoplasm with myogenic differentiation, KANK1/NTRK2 in ganglioneuroblastoma, ETV6/NTRK3 in metastatic mammary analogue secretory carcinoma, FGFR1/SCT in germ cell tumor, ZNF33B/RET fusion in GBM, SH3BP4/ERBB4 and EML4/ALK in RCC, VTCN1/NRG1 in pancreatic cancer, and AGRN/NRG1 in cholangiocarcinoma. More common actionable fusion events included: EML4/ALK in NSCLC, KIAA1549/BRAF in pilocytic astrocytoma, FGFR2 and FGFR3 in cholangiocarcinoma and urothelial cancers and ESR1 in endocrine therapy-resistant breast cancers. The fusion events detected in heme-based malignancies included MLLT10 and MLLT4 in AML, BCR/ABL in leukemias, TCF3/PBX1 in B cell ALL, NPM1/ALK in ALCL, and novel fusion CIITA/CD274 in DLBCL. All RNA fusions and transcript variants found were matched to FDA-approved or investigational treatment options. **Conclusions:** Maximizing the rate of variant detection for targeted therapy relies on precise identification of common and rare fusion events. Without the addition of RNA sequencing, 15 transcript variants in our cohort would have been missed and 33 of the fusions may have gone undetected by conventional DNA NGS testing, resulting in zero targeted treatment options for this vulnerable population. Further use of comprehensive genomic profiling is vital to optimizing cancer care. Research Sponsor: None.

3629 Poster Session (Board #359), Fri, 8:00 AM-11:00 AM

Identifying functional loss of *ATM* gene in patients with advanced cancer. *First Author: Patrick Glen Pilie, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *ATM* is frequently mutated in cancer, and defects may serve as a putative predictive biomarker. However, the functional impact of most *ATM* variants is not well known. In this study, we examined the relationship between *ATM* variants and ATM protein expression to better discern ATM functional defects in patients (pts) with advanced cancer. **Methods:** We retrospectively identified pts seen at MD Anderson Cancer Center who had *ATM* variants detected on CLIA-certified next generation sequencing (NGS) assays. ATM immunohistochemistry (IHC) was performed on available tumors. We then prospectively assessed ATM IHC on tumors from pts who were referred for DNA damage repair inhibitor (DDRi) trials. Functional classification of the variants was performed via published in silico tools and/or precision oncology decision support (PODS). An IHC cut-off of 100% loss in tumor cell nuclei defined ATM loss of protein (LOP). **Results:** Of 1394 *ATM*-mutant tumors identified retrospectively, *ATM* alterations were classified as 16% (N = 216) inactivating, 12% (N = 163) potentially inactivating, 71% (N = 993) variant of unknown significance (VUS), and 2% (N = 22) benign. Coding variants were seen across the *ATM* exonic structure/splice sites, and 20 individual variants were shared in > 10 pts. 263/297 available retrospective tumor samples had interpretable IHC results; 27% (N = 72) had ATM LOP. LOP was most prevalent in tumors with inactivating *ATM* variants (39/100, 39%); but, importantly, LOP was seen in 20% (N = 33/162) of potentially inactivating/VUS, thus better clarifying their functional impact. In the prospective cohort of 217 pt tumors, 17% (N = 37) had ATM LOP. 29% (N = 62/217) of this cohort also had *ATM* variants. ATM LOP was seen in 48% of tumors with inactivating variants (N = 14/29), 25% of tumors with potentially/VUS(N = 9/36), and 9% (N = 14/156) of tumors without *ATM* variants identified. ATM LOP was detected most commonly in colorectal (24%; N = 8/34), cholangiocarcinoma (20%; N = 6/30), prostate (16%; N = 16/104) and pancreatic (9%; N = 1/11) cancers among this cohort of pts referred for DDRi trials. **Conclusions:** *ATM* coding variants occurred across the gene, with certain variants shared across tumor types. The functional impact of most *ATM* variants was VUS, and ATM LOP can help clarify function in up to 25% of these VUS. Also, ATM LOP can be seen even in tumors without *ATM* variants identified, suggesting epigenetic or post-translational loss. Future prospective studies assessing predictive capability of paired DNA and protein-level profiling of ATM are warranted. Research Sponsor: MD Anderson internal departmental funding.

3630 Poster Session (Board #360), Fri, 8:00 AM-11:00 AM

Predictive value of a CLIA-approved organoid based drug sensitivity test. *First Author: Astrid Margossian, Sengine Precision Medicine, Seattle, WA*

Background: Precision medicine integrates genetic, molecular, and clinical information to optimize therapy selection for cancer patients. *Ex vivo* drug testing has the potential to match the right drug to the right patient. We developed a CLIA-certified functional drug assay for all solid tumors which provides an actionable report of organoid sensitivity to targeted, endocrine and chemotherapy agents as a tool for therapeutic decisions. Objectives: To establish the predictive power of the test in relation to well-known genomic biomarkers as well as prior treatments to identify drug sensitivity. To demonstrate that functional drug testing increases the actionability of genomic reports. **Methods:** From 2016 to 2019, 240 organoids from cancer patients were subjected to functional testing at SEngine Precision Medicine. Patients with advanced primary or metastatic cancer (solid tumors) who were treatment naïve or had previous therapies fail. Fresh samples of tumor cells from core biopsies, surgical excisions, or fluids arrived <48 hrs following collection and were cultured as 3D organoids. They were evaluated using a multi-dose response format with a library of up to 130 compounds. Drug sensitivity was quantified using a score that combines sensitivity and personalization of each patient's response relative to a reference population. Known genomic actionability from levels of evidence 1-2 from MSKCC OncoKB were queried against results for correlation. **Results:** Organoids were derived from breast (18.7%), ovarian (18.3%), colorectal (17.9%), pancreatic (6.7%), and others solid tumors (38,3%). Median age of patients was 53 (r5-83). 68 drugs on average were tested per patient with a mean turnaround time of 18 days (r9 -37). A mean of 7 drugs per patient were identified as top scoring drugs. In 75 patients with genomic data, we found high concordance of drug sensitivity with known genomic anchors (e.g., inhibitors of BRCA1/ PARP, ERBB2/HER2, FGFR1-2/FGFR, KRAS, PIK3CA/PI3K), measured as sensitivity to drugs among this targeted groups. However, several patient samples demonstrated sensitivity to targeted agents in the absence of known genomic biomarkers. Most important, analysis of previous treatments indicated >90% of retrospective concordance. **Conclusions:** Organoid based drug testing exhibits strong concordance with genomic and retrospective clinical evidence. In addition, functional testing identifies candidate therapies in patients with no known biomarkers and can identify the significance of variants currently not validated. Research Sponsor: Sengine Precision Medicine.

3631 Poster Session (Board #361), Fri, 8:00 AM-11:00 AM

Comprehensive molecular analysis of microsatellite-stable (MSS) tumors with high mutational burden in gastrointestinal (GI) cancers. *First Author: Jingyuan Wang, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Mutational signatures contributing to high tumor mutation burden (TMB-H) independent from microsatellite instability-high (MSI-H) status are not well-studied. We aimed to characterize specific molecular features of a large cohort of GI tumors with TMB-H & MSS. **Methods:** We sequenced23392 GI tumors, including 2707 gastroesophageal (GE), 11616 colorectal (CRC), and 9069 others. Samples were analyzed using Next-generation sequencing (NGS) and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ). MMR/MSI status was evaluated by a combination of IHC, Fragment Analysis and NGS. Tumors with TMB ≥ 17 mutations/Mb were defined as TMB-H. PD-L1 was tested by IHC [22C3 (CPS score, positivity: CPS ≥ 1%) in GE tumors and SP142 (Positivity: TPS ≥ 5%) in other cancers]. Findings were compared in four groups (TMB-H/L & MSI-H/MSS) using Fisher-Exact or Chi-square and adjusted for multiple comparison by Benjamini-Hochberg. Significance was determined by adjusted (adj) $p < .05$. **Results:** Overall, TMB-H & MSS was observed in 1% of patients (pts) (n = 237, including 45 GE, 124 CRC, 68 others), while TMB-H & MSI-H, TMB-L & MSS, TMB-L & MSI-H were observed in 4% (n = 936), 94.4% (n = 22089) and 0.6% (n = 130) respectively. Compared to other groups, TMB-H & MSS showed the most prevalent amplifications (AMPs), including *CCND1* (5.6%), *FGF3/4/19* (4.9%, 4.3%, 4.4%), *MYC* (4.3%) (Top 5, adj $p < .05$), and the highest mutation rates in *POLE* (21.6%), *RB1* (13.1%), *CDC73* (10.3%), *RUNX1* (6.5%), and genes involved in PI3K & MAPK (*PIK3R1* 17%, *mTOR* 3.4%, *MAP2K1* 3.8%, *MAP2K4* 5.6%) and Wnt (*APC* 48.5%, *SMAD2* 6.5%, *TCF7L2* 3.8%) pathways (adj $p < .05$). The rates of HER2 AMP and high-expression (IHC) were the highest in TMB-H & MSS, followed by TMB-L & MSS, TMB-H & MSI-H, TMB-L & MSI-H (adj $p < .0001$); PD-L1 positive rate was similar between TMB-H & MSS and TMB-L & MSI-H, while the highest and lowest in TMB-H & MSI-H and TMB-L & MSS respectively in GE and other GI cancers (adj $p < .01$) (Table). **Conclusions:** This is the largest study to investigate the special molecular landscape of pts with TMB-H & MSS in GI cancers. Our data may provide novel insights for pt selection and more effective targeted combination immunotherapies (e.g. HER2, PI3K inhibitors) in GI cancers. Research Sponsor: National Cancer Institute (grant number P30CA014089), The Gloria Borges WunderGlo Foundation-The Wunder Project, Dhont Family Foundation, San Pedro Peninsula Cancer Guild, Daniel Butler Research Fund and Call to Cure Fund, Fong research project.

The status of HER2 and PD-L1 among four groups (TMB-H/L & MSI-H/MSS).

3632 Poster Session (Board #362), Fri, 8:00 AM-11:00 AM

Comprehensive analysis of HER2 status through genomic, transcription, and translation among 5,305 patients with diverse malignancies. *First Author: Akram Mesleh Shayeb, University of California San Diego, Moores Cancer Center, La Jolla, CA*

Background: HER2 alterations is a predictive biomarker for anti-HER2 regimen. Success in breast and gastric cancers with anti-HER2 therapies translated to explore their efficacy in other tumors. Currently, measurement of HER2 can be done by assessing the expression of protein [e.g. immunohistochemistry (IHC)] or gene amplification of copy number variation (CNV) [e.g. fluorescence in situ hybridization or next-generation sequencing (NGS)]. But little is known about the transcription level (mRNA) of HER2. Herein, we investigated HER2 mRNA expression and its association with gene and protein expressions among diverse cancer types. **Methods:** Between 2015-2019, HER2 status was evaluated using IHC, qRT-PCR and NGS by Paradigm Diagnostics (CLIA-certified laboratory). All tumors in the database were included for analysis. Correlations between all 3 tests were done. An illustrative patient who was treated with anti-HER2 therapy base on the mRNA testing is presented. **Results:** HER2 testing was performed on 5305 patients (pts) with diverse cancers including NSCLC (n=1175), breast (n=1040) and colon (n=566); 4.1% (161/3926) had amplification through NGS, 33.3% (615/1848) had mRNA overexpression and 9.3% (236/2533) had overexpression by IHC. Of 723 pts who had all three tests performed, we found 7.5% (54/723) of pts with all three HER2 markers being positive (CNV [+]/mRNA [+]/ IHC [+]). Meanwhile, variety of amplification/ expression patterns were seen (see Table). CNV positivity translated to protein expression in 95% of cases. While only 4% of pts were IHC positive when CNV and mRNA were negative. 20% (144/723) of pts had mRNA overexpression alone among diverse cancer types. Representative case of 70yo female with metastatic cholangiocarcinoma harboring mRNA overexpression (but negative for CNV, IHC unclear due to sample insufficiency) who had near complete response to anti-HER2 therapy with progression-free survival of 24+ months is presented. **Conclusions:** HER2 status can be discordant with different assays but NGS positivity has excellent correlation with mRNA and protein expression. Of importance, HER2 mRNA can be overexpressed in 20% of pts even when gene amplification and protein expression are negative. Further studies are warranted to determine the clinical utility of mRNA as a biomarker for HER2 and potential use for anti-HER2 targeted therapies. Research Sponsor: None.

Olaparib monotherapy in pretreated patients with *BRCA1/2* alterations: Results of a DRUP trial cohort. *First Author: Hanneke van der Wijngaart, Department of Medical Oncology, Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Extensive molecular profiling in cancer regularly reveals targets for which approved drugs are available in tumor types outside the registered label. Efficacy of off-label use of these drugs is unavailable. Access to these drugs for pts is challenging. In the Drug Rediscovery Protocol (DRUP, Van der Velden et al, Nature 2019), pts are treated based on their tumor molecular profile. Here, we present the results of the successful cohort "Olaparib for tumors with *BRCA1/2* alterations". **Methods:** Twenty five adult cancer patients (pts) who exhausted all treatment options and had *BRCA1/2* loss of function (LoF) mutations (found in routine diagnostics) were included. No pts were eligible for on-label treatment with PARP inhibitors. Pts were treated with olaparib until disease progression or unacceptable toxicity. The primary endpoint was clinical benefit (CB: objective response or stable disease (SD) $\geq$ 16 weeks). Pts were enrolled using a Simon-like two-stage model, with 8 pts in stage 1 and up to 24 pts in stage 2 if at least 1 pt had CB in stage 1. A fresh frozen biopsy was obtained from each pt for whole genome sequencing (WGS) and target confirmation. **Results:** Fourteen pts (56%) had CB. The objective response rate was 32%. Nine different cancer types were included: prostate (n=11), breast (n=4), ovarian (n=2), pancreatic (n=3), colorectal (n=2), biliary tract (n=2), kidney (n=1), adrenal gland (n=1) and endometrial (n=1). WGS could be performed on 58% of baseline tumor biopsies, confirming the original *BRCA1/2* mutations in 86%. CB was observed in pts with both somatic and germline *BRCA* alterations and across tumor types. CB was only observed in cases with biallelic loss of *BRCA1/2* in the tumor and when classified as HRD by a pan-cancer homologous recombination deficiency classifier (CHORD), which relies on genome-wide SNV, indel, and SV mutational footprints for HRD detection. No evidence of complete *BRCA* loss and HRD was observed in 5 pts with PD, while 4 patients with effective *BRCA* complete loss and HRD also had PD. WGS analysis of these pts suggested resistance mechanisms due to other oncogenic drivers (e.g FGFR1 amplification, CTNNB1 stabilization, KEAP1 inactivation). **Conclusions:** Olaparib seems to be an effective treatment option for pts with *BRCA1/2* LoF mutated malignancies, regardless of histology, for both germline and somatic alterations, which needs confirmation in an independent cohort. CB of olaparib was observed in malignancies showing biallelic loss of *BRCA1/2* and when classified as HRD, indicating the importance of the *BRCA*/HRD signature status. Clinical trial information: NCT02925234. Research Sponsor: KWF Cancer Society, Pharmaceutical/ Biotech Company.

3634 Poster Session (Board #364), Fri, 8:00 AM-11:00 AM

A randomized, controlled trial of structured palliative care versus standard supportive care for patients enrolled on phase I clinical trials. *First Author: Michelle Elizabeth Treasure, Cleveland Clinic Foundation, Cleveland, OH*

Background: Phase 1 clinical trials are the first step in developing new cancer therapeutics. Patients enrolled in these studies have typically exhausted standard therapies and are at a point in their disease trajectory where they often are choosing between a phase 1 clinical trial and hospice care. These patients may have significant symptom burden, which can result in early trial discontinuation and confound phase 1 trial outcomes, including toxicity profiles, which may influence further drug development. This study aimed to determine the palliative care needs of patients enrolled on phase 1 clinical trials and their caregivers (CGs), along with differences in study duration, adverse event (AE) and symptom profiles, and quality of life (QOL) between those receiving structured palliative care vs usual supportive care. **Methods:** 68 patients enrolled on phase 1 clinical trials were randomly assigned to receive structured palliative care or usual supportive care. 39 of their CGs were enrolled and assigned to the same arm as the patient. Quality of life metrics were obtained monthly: the Functional Assessment of Cancer Therapy-General and Memorial Symptom Assessment Scale -Short Form for patients, and The Quality of Life in Life Threatening Illness - Family Carer Version and Caregiver Reaction Assessment for CGs. Palliative care resources utilized were assessed for those in the palliative care arm, and referrals to supportive care services assessed in those in the usual care arm. AEs recorded on the Phase 1 trials were evaluated & compared between arms. **Results:** Mean duration on phase 1 study was 132 days in the palliative care arm vs 114 days in the usual care arm ($p = 0.55$). Total weighted AE rate (# of AE [x] AE grade per month) was 26.9 in the palliative care arm vs 34.0 in the usual care arm ($p = 0.53$). Patients in the palliative care arm experienced better QOL and lower symptom burden, as did their CGs, compared to those in the usual care arm. While the differences in outcomes were not statistically significant, all results favored structured palliative care. **Conclusions:** Phase 1 patients and their CGs have physical and psychosocial needs which warrant palliative care services. Preliminary results suggest structured palliative care is associated with increased duration on study (by nearly 3 weeks), improved patient and CG QOL, and reduced patient symptom and CG burden. A larger study is warranted to confirm these results and further develop the ideal palliative care intervention in these populations. Clinical trial information: NCT02543541. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

3635 Poster Session (Board #365), Fri, 8:00 AM-11:00 AM

Pooled safety analysis of single-agent lurbinectedin versus topotecan (Results from a randomized phase III trial CORAIL and a phase II basket trial). *First Author: Alexandra Leary, Institut de Cancérologie Gustave Roussy, Villejuif, France*

Background: Lurbinectedin (L), an inhibitor of active transcription, has shown activity in second-line (2L) small cell lung cancer (SCLC) (ASCO 2019). Topotecan (T) is the only approved drug in 2L SCLC and is also used in platinum resistant ovarian cancer (PROC). **Methods:** This pooled safety analysis includes data from 554 patients (pts) treated with L at 3.2 mg/m^2 Day 1 q3wk 1-h (no primary prophylaxis with G-CSF required): 335 with selected solid tumors (9 indications, including 105 pts with SCLC) from a phase II Basket study and 219 with PROC in the phase III CORAIL study. An indirect exploratory comparison (pooled data from CORAIL + Basket) and a direct comparison (data from CORAIL) of L *vs.* T are presented. **Results:** Most common adverse events with L were grade 1/2 fatigue, nausea and vomiting. Treatment-related (L/T): dose reductions: 22.9/48.3%, delays: 25.8/52.9%, grade $\geq$3 serious adverse events (SAEs): 15.0/32.2%, discontinuations: 3.2/5.7%, deaths: 1.3/1.5%, G-CSF use: 23.8/70.1%, and transfusions: 15.9/52.9%. **Conclusions:** Lurbinectedin has a predictable and manageable safety profile. A significant safety advantage was observed when lurbinectedin was compared with topotecan in the CORAIL trial in terms of hematological toxicities. With the limitations of indirect comparisons, in the pooled safety analysis, fewer lurbinectedin-treated pts had severe hematological toxicities, SAEs, dose adjustments, treatment discontinuations and use of supportive treatments than topotecan-treated pts. Clinical trial information: NCT02421588 and NCT02454972. Research Sponsor: PharmaMar SA.

Safety profile (L *vs.* T): grade 3/4 adverse events (related or unknown) and laboratory abnormalities (regardless of relationship).

The skin types closely related to development of the facial acneiform rash and the therapeutic effects of EGFR inhibitors in RAS wild-type metastatic colorectal cancer: Ancillary analysis of FAEISS study. *First Author: Syusuke Yoshikawa, Shizuoka Cancer Center, Shizuoka, Japan*

Background: At ESMO2019, we reported the primary results of a randomized controlled trial (FAEISS study) investigating the efficacy of topical corticosteroid treatment to facial acneiform rash (AR) by EGFR inhibitors comparing groups starting with a very strong topical corticosteroid and the standard weak topical corticosteroid. As an ancillary analysis, we investigated the association between AR and the pre-treatment skin types, as well as between the skin types and therapeutic effects of EGFR inhibitors on the primary disease. **Methods:** Utilizing pre-treatment clinical photos of the face taken according to the method determined by FAEISS study protocol, we divided the skin types into categories including enlarged pore, oiliness, xerosis, wrinkles, skin color/redness, and allocated the score (1-3) by central review. The severity of AR occurred during the study was graded and was evaluated the association with the specific skin type by Fisher's exact test. We also investigated the association between the skin types and the best overall response (RECISTv1.1) to EGFR inhibitor therapy on the primary disease using the Cochran-Armitage trend test. **Results:** Of the registered 172 cases of RAS wild-type metastatic colorectal cancer [104 men and 68 women, median age = 68 (26-79)], omitting the cases with unevaluable data, finally we analyzed 146 cases for associations between the skin types and AR and 147 cases for best overall response. Interestingly, AR developed 13.6% of enlarged pore score 1, 29% of score 2 and 45.8% of score 3, and patients with enlarged pore tended to have more AR ($p = 0.058$). Surprisingly, the response(CR/PR/SD) of the primary disease were 59.1% of the enlarged pore score 1, 70.6% of score 2 and 87.0% of score 3, and showed statistically significant trend($p < 0.038$). **Conclusions:** This study suggested that a skin type (enlarged pore) is a possible marker predicting AR risk in EGFR inhibitor therapy for RAS wild-type metastatic colorectal cancer, and better therapeutic effects of EGFR inhibitors. Research Sponsor: None.

3638 Poster Session (Board #368), Fri, 8:00 AM-11:00 AM

Safety, tolerability, and preliminary pharmacokinetic/pharmacodynamic profile of JMT103 in patients with bone metastases from solid tumors: A multicenter, open-label, dose-escalation, phase I clinical study. *First Author: Jin Li, Department of Medical Oncology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China*

Background: Bone is one of the most common metastatic sites of malignancies. The metastatic tumor cells activate osteoclast activity and promote bone resorption via RANKL/RANK signaling pathway, and lead to osteolytic destruction. JMT103 is an innovative fully human IgG4 monoclonal antibody targeting RANKL. It can block RANKL/RANK signaling pathway, inhibit bone resorption, and protect bones from tumor metastasis. This study aimed to evaluate the safety and tolerability of JMT103 in patients with bone metastasis. **Methods:** This is a multicenter, open label, dose escalation, phase I clinical trial. The patients (ECOG score: 0-1) with bone metastasis from solid tumor who had not received bisphosphonates within 6 weeks before enrollment and were naïve to denosumab were enrolled. The initial dose was 0.5 mg/kg, sequentially escalated to 1.0, 2.0, and 3.0 mg/kg. JMT103 was injected subcutaneously by accelerated titration in 0.5 and 1.0 mg/kg dose groups, but via traditional "3+3" dose-escalation design in 2.0 and 3.0 mg/kg dose groups. Expansion study was conducted for subjects in 1.0, 2.0, and 3.0 mg/kg dose groups. Specifically, 3 additional doses (q4w) were injected after the end of 12-week single-dose study. The primary endpoints were maximum tolerated dose and safety. The secondary outcome measures included PK profile, preliminary efficacy biomarkers, immunogenicity, and bone mineral density (BMD). **Results:** From May 2018 to January 2020, 56 patients (13 males, 43 females, mean (SD) age: 55.57 (11.42) years) were enrolled, including bone metastasis from breast cancer (n = 36), gastric cancer (n = 5), lung cancer (n = 4), rectal cancer (n = 3), colorectal cancer (n = 2), or other solid tumors (n = 6). Nineteen patients participated in the dose-escalating study and 37 patients participated in the expansion study. JMT103 showed overall good safety. There were 74 drug-related AEs in all, including grade 3 (DLT hypocalcemia, n = 1; hypophosphatemia, n = 3), grade 2 (n = 15), and grade 1 (n = 55) AEs. The most common drug-related AEs were hypophosphatemia (n = 15), hypocalcemia (n = 12), and hypermagnesemia (n = 6). Median uNTx/Cr decrease from baseline was 76.6% (n = 20). **Conclusions:** JMT103 shows good safety and tolerability in patients with bone metastasis. Clinical trial information: NCT03550508. Research Sponsor: JMT-Bio Technology Co., Ltd.

3639 Poster Session (Board #369), Fri, 8:00 AM-11:00 AM

BXQ-350 to target to the lysosome and kill glioblastoma (GBM) cells via activation of apoptotic caspases in vitro. *First Author: Laura Felix, Student, Covington, KY*

Background: Apoptosis is a programmed cell death mechanism where cells respond to internal or external stimuli by initiating a cascade of events and enzymes leading to cell death. One of the hallmarks of cancer is the ability of tumor cells to resist these apoptotic stimuli. This allows tumor cells to have aberrant metabolisms, such as sphingolipid metabolism in tumor cell lysosomes, or mutations which would normally commit cells to death. Saposin C, the protein component of BXQ-350, Bexion Pharmaceuticals' proprietary biotherapeutic, is involved in normal lysosomal sphingolipid metabolism. Removing resistance, shortcutting steps leading to apoptosis, or correcting sphingolipid metabolism can result in the death of these tumor cells. **Methods:** The GBM cell line Gli36ΔEGFR was plated in 96 well plates at a density of $1x10^4$ cells per well in Dulbecco's Modified Eagle Media with 10% FBS overnight at 37°C for caspase and cytotoxicity assays. Cells were treated with 9uM to 30uM BXQ-350 in triplicate and incubated for 24 hours at 37°C. Promega's Caspase-Glo 9 or Caspase-Glo 3/7 reagent was added to appropriate wells and the plates were incubated at room temperature in the dark for 3 hours then luminescence was read. The parallel cytotoxic assay was run under the same conditions except Roche's MTT labeling reagent was added to the appropriate wells after 24 hours and incubated at 37°C for 4 hours. Solubilization solution was added to each well and the plate was incubated at 37°C overnight then absorbance was read. The GBM cell line U87 MG was used to determine lysosomal targeting. U87 MG cells were treated with 10uM BXQ-350 and incubated at 37°C overnight. They were stained with anti-SapC (RFP) and anti-LAMP1 (GFP) antibodies and images were taken. **Results:** BXQ-350 mediated cell death is correlated with a rise in Caspase 3, Caspase 7 and Caspase 9 activity. The caspase activity levels did not rise until after BXQ-350 passed its IC50 and stayed elevated. Caspases 3/7 levels showed higher activity compared to untreated than Caspase 9. In addition to this, BXQ-350 was seen to colocalize to LAMP1, a lysosomal membrane protein. **Conclusions:** BXQ-350 tracks to the lysosomal membrane where it initiates the cascade of enzymes necessary to cause apoptosis. Caspases 3/7 are the effector caspases and are necessary for the completion of the apoptotic pathway. The higher activity levels of these caspases show the cells are committed to cell death not allowing these cells to subvert apoptosis. This removes one of the major barriers to fighting cancer. Research Sponsor: Bexion Pharmaceuticals.

3640 Poster Session (Board #370), Fri, 8:00 AM-11:00 AM

Phase I dose-finding study of oral ERK1/2 inhibitor LTT462 in patients (pts) with advanced solid tumors harboring MAPK pathway alterations. *First Author: Filip Janku, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX*

Background: LTT462 is an investigational small molecule inhibitor of ERK1/2, which has demonstrated preclinical activity in multiple MAPK activated cancer cells and xenograft models. This first-in-human study was designed to evaluate the safety and tolerability of LTT462 in advanced solid tumors harboring MAPK pathway alterations (NCT02711345). **Methods:** The dose-escalation part of this Phase I, open-label study, enrolled adult and adolescent pts with advanced solid tumors harboring ≥1 documented MAPK pathway alteration with progressive disease (PD) despite standard therapy, or for whom there is no effective standard treatment. Oral LTT462 was given once daily (QD) at 45–600 mg or twice daily (BID) at 150 mg or 200 mg. Objectives were to determine the maximum tolerated dose (MTD) using a Bayesian hierarchical logistic regression model guided by escalation with overdose control, and characterize safety, pharmacokinetics, pharmacodynamics, and preliminary efficacy of LTT462. **Results:** Sixty-five pts (median age 60 years) including 1 pt aged 15 were enrolled in the dose-escalation; most pts (22%) had 3 prior therapies. Most common primary sites for cancer were in the colon (n = 21; 32%), ovary (n = 9; 14%), and pancreas (n = 7; 11%). All pts discontinued, the majority due to PD (n = 44; 68%). Eleven pts experienced DLTs; 6 pts experienced Grade 3 eye disorder DLTs (4 pts retinopathy, 2 pts chorioretinopathy). Treatment-related adverse events (TRAEs) were reported for 89% of pts, most commonly (> 30%) diarrhea (n = 25; 38%) and nausea (n = 22; 34%). Grade 3/4 TRAEs were reported in 29% of pts; most common was retinopathy (n = 4; 6%). MTD of LTT462 was 400 mg QD and 150 mg BID. Overall, 8 pts (12%) had stable disease (SD) and 35 pts (54%) had PD. An unconfirmed partial response was reported in a pt with cholangiocarcinoma with *BRAF* mutation; best change in sum of target lesions per RECIST 1.1 was -33.9%. LTT462 increased plasma peak drug concentration and drug exposure at increasing doses between 45–450 mg QD. Exposure at LTT462 600 mg QD was lower than anticipated, indicating potential saturation of absorption at this dose. LTT462 inhibited ERK1/2 and reduced *DUSP6* expression relative to baseline in most pts evaluated. **Conclusions:** LTT462 is well tolerated. Limited clinical activity was reported with single agent LTT462; best overall response was SD. An ongoing study is investigating LTT462 in combination with the RAF inhibitor, LXH254, in NSCLC and melanoma. Clinical trial information: NCT02711345. Research Sponsor: Novartis.

3641 Poster Session (Board #371), Fri, 8:00 AM-11:00 AM

The incidence of myelodysplastic syndrome in patients receiving poly-ADP ribose polymerase inhibitors for treatment of solid tumors: A meta-analysis. *First Author: Roni Nitecki, MD Anderson Cancer Center, Houston, TX*

Background: Clinical trials have reported improved outcomes with PARPi (poly [adenosine diphosphate–ribose]-ADP polymerase inhibitor) therapy in ovarian, breast, pancreatic and lung cancers. There is concern that PARPi therapy may cause myelodysplastic syndrome (MDS). In this meta-analysis we seek to quantify the risk of MDS among patients treated with PARPi for solid tumor malignancies. **Methods:** We searched Medline, Embase, and Cochrane databases (up to January 6, 2020) to abstract randomized controlled trials that include a PARPi in the experimental arm in solid tumors. Combinations included PARPi versus (vs.) placebo, PARPi vs. cytotoxic treatment, and PARPi with cytotoxic treatment vs. cytotoxic treatment. We used to time-to-event curves to estimate person-time and calculated the incidence of MDS among all studies. We used random-effects Poisson regression models to estimate pooled incidence risk ratio (RR) for developing MDS. **Results:** We identified 14 studies, 10 in ovarian, 3 in breast, and 1 in pancreatic cancer patients. Of 5,646 patients, 62.3% received a PARPi alone or in combination with chemotherapy or bevacizumab, and 37.8% received treatment consisting of placebo alone or with chemotherapy or bevacizumab. PARPi were investigated as an upfront treatment in 2,827 patients, and as treatment for recurrence in 2,819 patients. The incidence of MDS was 6.73 cases vs. 3.85 per 1000 person-years in patients receiving PARPi as compared to control corresponding to a 3-year cumulative incidence of 2.0% and 1.1%. Accounting for intra-study clustering, PARPi use was associated with a 60% increase in risk (incidence RR 1.60, 95% Confidence Interval [CI] 0.89-2.87) of MDS compared to control. In the upfront setting, patients randomized to PARPi were twice as likely to develop MDS (RR 2.08, 95%, CI 1.39-3.64). Among patients treated for recurrence, the risk of MDS appeared to be similar among patient randomized to PARPi or control treatment (RR 1.13, 95% CI 0.35-3.64). In studies that compared PARPi in combination with other cytotoxic treatment vs. cytotoxic treatment alone, PARPi was associated with a large risk of MDS (RR 5.08, 95% CI 1.36-19.03). **Conclusions:** In pooled estimates from randomized controlled trials in solid tumors PARPi treatment appears to be associated with an increased incidence of MDS particularly in the upfront setting and when combined with cytotoxic treatment. Despite pooling 14 randomized trials our estimates remain imprecise due to the rarity of MDS. Research Sponsor: U.S. National Institutes of Health.

3642 Poster Session (Board #372), Fri, 8:00 AM-11:00 AM

Evaluation of a computational decision support system for molecularly targeted treatment planning by the clinical outcome data of the randomized trial SHIVA01. *First Author: Anna Dirner, Oncompass Medicine Hungary Ltd, Budapest, Hungary*

Background: Precision oncology requires the identification of individual molecular pathomechanisms to find optimal personalized treatment strategies for every cancer patient. Incorporation of complex molecular information into routine clinical practice remains a significant challenge due to the lack of a reproducible, standardized process of clinical decision making. **Methods:** To provide a standardized process for molecular interpretation, we develop a precision oncology decision support system, the Realtime Oncology Molecular Treatment Calculator (MTC). MTC is a rule-based medical knowledge engine that dynamically aggregates and ranks relevant scientific and clinical evidence using currently 26,000 evidence-based associations and reproducible algorithm scoring of drivers, molecular targets to match molecular alterations to efficient therapies. To validate this novel method and system, we used data of the SHIVA01 trial of molecularly targeted therapy (Lancet Oncol 2015 16:1324-34). Molecular profiles of participants were uploaded to MTC and aggregated evidence level (AEL) values of associated targeted treatments were calculated, including those used in the SHIVA01 trial. **Results:** The MTC output provided a prioritized list of drugs associated with the driver alterations in the patient molecular profile, where ranking is based on AEL values. Of 113 patients who received targeted therapy with available clinical best response data, disease control was experienced in 63 cases (PR: 5, SD: 58), while disease progression occurred in 50 cases. The average AEL score for the therapies applied was significantly higher in the responsive group than in the non-responsive group (1512 and 614, respectively ($p = 0.049$)). In 94 cases, drugs other than those used for therapy were ranked higher by the MTC. The average AEL difference between the top-ranked and the used drugs was in an inverse correlation with clinical response, i.e. smaller differences associated with a better outcome. **Conclusions:** Results indicate that the aggregation of evidence-based tumor-driver-target-drug associations using standardized mathematical algorithms of this computational tool is a promising novel approach to improve clinical decisions in precision oncology. Further validation based on the results of other targeted clinical trials and real-life data using more detailed molecular profiles is warranted to explore the full clinical potential of this novel medical solution. 3643 Poster Session (Board #373), Fri, 8:00 AM-11:00 AM

Survival associated with mutations in SWI/SNF chromatin remodeling complex genes. *First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA*

Background: The SWI/SNF (SWitch/Sucrose NonFermentable) chromatin remodeling complex (CRC) - a combinatorial assembly of products from multiple genes - alters histone/DNA interactions and thereby impacts transcription, DNA replication/repair, and cell division. Studies suggest that over 20% of human cancers contain mutations in at least one SWI/SNF gene, implying that it is the most highly mutated CRC in human cancer. To address existing knowledge gaps, we sought to evaluate the association between SWI/SNF mutations and overall survival (OS). **Methods:** We identified adult cancer patients who consented to have OncoPanel testing (Dana-Farber/Brigham & Women's Hospital's next generation sequencing platform) from June 2013-August 2019. These data were merged with institutional electronic health records and National Death Index vital status. We determined mutation frequency and co-occurrence for the nine SWI/SNF genes included in OncoPanel (ARID1A, ARID1B, ARID2, BCL11B, PBRM1, SMARCA4, SMARCB1, SMARCE1, and SS18). We assessed the association between mutation and OS (from time of OncoPanel testing) for cancers with at least 500 analyzed and 20 mutated cases, controlling for age and TP53 status. Exploratory analyses were conducted using cBioPortal and SAS (no multiple comparison adjustment). **Results:** Among 25,434 samples from 24,648 patients, a mutation in at least one evaluated SWI/SNF gene was identified in 26% of cases (ARID1A 10.5%, ARID1B 7.2%, SMARCA4 5.5%, PBRM1 4.9%, ARID2 4.8%, BCL11B 3.5%, SMARCE1 1.1%, SMARCB1 1.0%, and SS18 0.7%). The most frequently mutated cancers included small bowel (52%), endometrial (49%), ampullary (48%) and bladder (45%). Co-occurrence was common (30 of 36 potential gene-pairs), with the largest associations (odds ratio; all $P < .05$) seen for SMARCB1:BCL11B (4.19), ARID1B:BCL11B (3.87), ARID2:BCL11B (3.85), and SMARCA4:BCL11B (3.78). Associations between having a mutation and OS were seen for the following cancers/genes (odds ratio; all $P < .05$): ARID1A (colorectal 0.72, pancreatic 1.46), ARID1B (melanoma 0.32), SMARCA4 (esophagogastric 1.48, non-small cell lung 1.89, ovarian 0.43), SMARCB1 (non-small cell lung 2.04), and SS18 (soft tissue sarcoma 2.06). **Conclusions:** Mutations in SWI/SNF genes are widespread, with mutation rates varying by cancer type. Co-occurrence was common, especially with BCL11B. Associations with OS were both favorable and unfavorable, with variability seen by gene and cancer type. Future research should explore the mechanisms by which mutations in SWI/SNF genes influence treatment response/OS. Research Sponsor: Institutional.

TPS3645 Poster Session (Board #375), Fri, 8:00 AM-11:00 AM

A phase I trial of aerosol gemcitabine for the treatment of patients with solid tumors and lung metastases. *First Author: Nancy Beatriz Gordon, UT MD Anderson Cancer Ctr, Houston, TX*

Background: Pre-clinical studies of aerosol gemcitabine (GCB) in mice and dogs with osteosarcoma (OS) lung metastases demonstrated therapeutic efficacy. Aerosol GCB administered once weekly proved to be safe in adults with lung cancer. Direct delivery of GCB to the lungs via inhalation may offer higher drug concentration in the tumor with fewer side effects. We initiated a Phase I study to evaluate the feasibility and safety of aerosol GCB treatment in patients>12 years with solid tumors and lung metastases (2015-0720- NCT03093909). **Methods:** Eligibility criteria: 1) Diagnosis of solid tumor with lung metastases, 2) willing to comply with protocol therapy, 3) adequate organ function, 4) patient age > 12 and < 50 years, 5) good performance status, 6) resolution of all acute toxic effects of any prior anti-cancer therapy, and 7) no radiotherapy within 2 weeks. Patients who previously received systemic GCB are eligible. Objectives: To determine the maximum tolerated dose (MTD) and toxicities of aerosol GCB, to evaluate for drug spillover into the circulation, and to preliminarily assess the anti-tumor activity. Correlative studies include effect of aerosol GCB on immune cell infiltration in the lung, autophagy, apoptosis, heat shock protein 27, evidence of DNA strand breaks (gH2AX) and expression of human equilibrative nucleoside transporter-1.Aerosol GCB is administered via a breath-induced nebulizer twice a week in 28-day cycles. A maximum of 6 dose levels will be studied; the starting dose is 0.75 mg/kg twice weekly. If no progressive disease or unacceptable treatment-related toxicity, patients may continue for 12 cycles. The study uses the accelerated titration method for the first 2 dose levels then the 3+3 design for the remaining dose levels. After determining the MTD, we will evaluate the defined MTD in an expansion cohort of 14 patients with relapsed OS. Symptoms, pulse oximetry, and pulmonary function are assessed prior to each nebulized dose using remote spirometry that allows raw numbers and flow-volume curves to be uploaded and transmitted via bluetooth to an android tablet provided to patients. Data is transmitted to a web portal and captured in a HIPAA-compliant web-based database (REDCap) that is accessible to the research team. **Results:** To date, the study enrolled 4 patients and accrual is ongoing at dose level 3. **Conclusions:** This study will provide information on the feasibility and safety of aerosol GCB. If proven to be feasible and safe, it can potentially offer a novel approach to treat metastatic OS to the lungs while minimizing systemic toxicity. Clinical trial information: NCT03093909. Research Sponsor: The Gateway for Cancer Research and Archer Charitable Foundation.

TPS3646 Poster Session (Board #376), Fri, 8:00 AM-11:00 AM

A phase I/II, two-part, multicenter, first-in-human study of DS-7300a in patients with advanced solid malignant tumors. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: B7 homologue 3 (B7-H3) is a protein that is overexpressed in various cancer types, including lung, head and neck squamous cell carcinoma, prostate, esophageal, and breast. B7-H3 overexpression is associated with poor prognosis because it promotes increased invasive and metastatic potential of cancer cells (Dong P, et al. *Front Oncol.* 2018;8:264). Currently, no B7-H3–targeted cancer therapies are approved. DS-7300a is an antibody-drug conjugate composed of a humanized anti–B7-H3 IgG1 monoclonal antibody (MABX-9001a) conjugated to a drug linker that releases its payload upon internalization by cancer cells. The payload, DXd, is an exatecan derivative that inhibits topoisomerase I, an enzyme that relaxes supercoiled DNA for replication and transcription. DS-7300a induced apoptosis in cancer cells in vitro and showed potent antitumor activity in xenograft models of various types of solid tumors in vivo. **Methods:** This phase 1/2, multicenter, nonrandomized, open-label, first-in-human study of DS-7300a is ongoing in the United States and Japan in patients with selected advanced solid tumors (NCT04145622). This study has 2 parts: dose escalation (part 1) and dose expansion (part 2). Primary objectives are to evaluate the safety, tolerability, and antitumor activity of DS-7300a and to determine the maximum tolerated dose or recommended dose for the expansion part. Secondary objectives include the pharmacokinetic characterization of DS-7300a, determination of the total levels of anti–B7-H3 antibody and the drug component (DXd), and assessment of the incidence of anti-drug antibodies against DS-7300a. Key inclusion criteria are age $\geq$ 18 years (United States) or $\geq$ 20 years (Japan), an ECOG performance status of 0 or 1, $\geq$ 1 measurable lesion according to RECIST 1.1 as assessed by the investigator, and consent to provide pre- and on-treatment tissue samples (mandatory if clinically allowed and not contraindicated). Key exclusion criteria include prior treatment with orlotamab, enoblituzumab, other B7-H3–targeted agents, or an antibody-drug conjugate that is conjugated with a topoisomerase I inhibitor. Dose expansion will start with 3 cohorts, including patients with selected advanced solid tumors. In both parts, DS-7300a will be administered intravenously on day 1 of each 21-day cycle. During dose escalation, the starting dose of DS-7300a is 0.8 mg/kg. This trial is currently in the dose-escalation part. Clinical trial information: NCT04145622. Research Sponsor: Daiichi Sankyo Co., Ltd.

TPS3647 Poster Session (Board #377), Fri, 8:00 AM-11:00 AM

EV-202: A phase II study of enfortumab vedotin in patients with select previously treated locally advanced or metastatic solid tumors. *First Author: Justine Yang Bruce, Carbone Cancer Center, University of Wisconsin, Madison, WI*

Background: Nectin-4, a transmembrane cell adhesion protein, is highly expressed in urothelial carcinoma (UC), breast cancer (BC), non-small cell lung cancer (NSCLC), and gastroesophageal cancers (GEC); targeting Nectin-4 on these tumors may provide a novel treatment approach. Enfortumab vedotin (EV), an investigational human monoclonal antibody-drug conjugate, binds to Nectin-4 and upon internalization releases MMAE resulting in cell cycle arrest and cell death. Recently, EV received accelerated approval by the FDA for the treatment of adults with locally advanced/metastatic UC who previously received a PD-1 or PD-L1 inhibitor, and a platinum-containing chemotherapy in the neoadjuvant/adjuvant, locally advanced or metastatic setting. Use of EV in this study is investigational. **Methods:** This open-label phase 2 study (NCT04225117) will assess the efficacy and safety/tolerability of EV in patients (pts) with previously treated locally advanced/metastatic malignant solid tumors. Adult pts (~240) with histologically or cytologically confirmed disease and an ECOG $\leq$1 will be enrolled into 1 of 6 tumor-specific cohorts (Table), with ~40 pts each. While Nectin-4 expression is not required for enrollment, it is being tested retrospectively. Patients with active CNS metastases, grade $\geq$2 preexisting sensory or motor neuropathy, grade $\geq$3 immunotherapy-related hypothyroidism or panhypopituitarism, ongoing grade $>$3 immunotherapy-related AEs requiring high-dose steroids, or a history of uncontrolled diabetes mellitus within 3 months of the study will be excluded. All pts will receive EV 1.25 mg/kg IV on Days 1, 8, and 15 of each 28-day cycle until treatment discontinuation criteria are met; dose reductions/interruptions will be permitted. For all cohorts, the primary endpoint is investigator-assessed confirmed objective response rate (RECIST v1.1); secondary endpoints include duration of response, disease control rate, progression-free and overall survival, and safety/tolerability of EV. This study is recruiting as of February 2020. Clinical trial information: NCT04225117.Research Sponsor: Astellas Pharma, Inc.

Cohort	Tumor Type
1	Hormone receptor–positive/human epidermal growth factor receptor 2–negative BC
2	Triple-negative BC
3	Squamous NSCLC
4	Nonsquamous NSCLC
5	Head and neck cancer
6	GEC, including gastroesophageal junction adenocarcinoma

TPS3648 Poster Session (Board #378), Fri, 8:00 AM-11:00 AM

TROPiCS–03: A phase II open-label study of sacituzumab govitecan (SG) in patients with metastatic solid tumors. *First Author: Ashish Saxena, Weill Cornell Medicine, New York-Presbyterian Hospital, New York, NY*

Background: Trophoblast cell surface antigen (Trop-2) is highly expressed in many epithelial cancers (non–small-cell lung cancer [NSCLC], endometrial cancer, urothelial carcinoma [UC], and triple-negative breast cancer [TNBC]) and has been linked to aggressive disease and poor prognosis. SG is a Trop-2–directed antibody drug conjugate containing SN-38 (active metabolite of irinotecan) with a 7.5:1 drug-to-antibody ratio and unique hydrolyzable linker that allows for extracellular bystander effect. The phase 1/2 IMMU-132-01 basket study reported clinical activity with SG in patients with multiple tumor types not selected for Trop-2 expression including NSCLC (objective response rate [ORR]: 17%), TNBC (ORR: 33%), and UC (ORR: 31%).1-3 Results from the overall safety population (N=420) from this study found that SG was tolerable, with a predictable and manageable safety profile, and low discontinuation rates due to AEs. **Methods:** To test a biomarker-enrichment strategy with Trop-2, the TROPiCS-03 (TROP-2 Investigations in Cancer with SG) study was initiated. TROPiCS-03 (NCT03964727) is a multi-cohort, open-label, phase 2 study in patients with metastatic solid tumors - presently NSCLC (adenocarcinoma and squamous cell carcinoma), head and neck squamous cell carcinoma, and endometrial cancer - selected based on elevated Trop-2 expression by a validated IHC assay. Patients receive SG (10 mg/kg IV, days 1 and 8 every 21 days) and continue treatment until lack of clinical benefit or unacceptable toxicity. The primary endpoint is objective response rate (local assessment) and additional endpoints include clinical benefit rate, duration of response, progression-free survival, and safety. Females or males $\geq$18 years old who are histologically documented to have locally advanced or metastatic (M1, stage 4) solid tumors of the above types are eligible. Patients must have ECOG 0 or 1 and adequate clinical laboratory results to be enrolled. All subjects will have progressed after prior platinum-based chemotherapy and programmed death-ligand 1 (PD-L1) or programmed cell death protein 1 (PD-1) directed therapy. Patients who have previously received topoisomerase I inhibitors and those with known active CNS metastases are excluded. Approximately 160 patients will be enrolled in the trial overall; enrollment in the NSCLC cohort is currently in progress. Clinical trial information: NCT03964727. Research Sponsor: Immunomedics, Inc.

TPS3649 Poster Session (Board #379), Fri, 8:00 AM-11:00 AM

Phase I study of the antibody-drug conjugate ABBV-321 in patients with non-small cell lung cancer and squamous head and neck cancer with overexpression of the epidermal growth factor receptor. *First Author: Benedito A. Carneiro, The Warren Alpert Medical School, Brown University, Providence, RI*

Background: ABBV-321 (serclutamab talirine) is an epidermal growth factor receptor (EGFR)-targeted antibody-drug conjugate that consists of a humanized immunoglobulin G1 anti-EGFR monoclonal antibody conjugated to a pyrrolobenzodiazepine (PBD) dimer via a maleimidocaproyl-valine-alanine linker. Once bound, ABBV-321 is internalized, the maleimidocaproyl-valine-alanine linker undergoes proteolytic cleavage, and the cytotoxic PBD is released, causing DNA cross-links and cell death. Preclinical studies have shown cytotoxicity in numerous human xenograft and patient (pt)-derived tumor models. This first-in-human trial is assessing the safety, pharmacokinetic (PK), and preliminary antitumor activity of ABBV-321 in pts with advanced solid tumor types likely to exhibit elevated levels of EGFR. **Methods:** This is a 2-part, multicenter phase 1 study (NCT03234712) of ABBV-321 monotherapy in pts ($\geq$18 years; Eastern Cooperative Oncology Group performance status 0–1) with advanced solid tumors associated with overexpression of EGFR. EGFR overexpression will be determined by centralized testing using an RNA-based assay. Primary objectives of the completed part 1 (dose escalation) were to determine the maximum tolerated dose (MTD)/recommended phase 2 dose (RP2D) of ABBV-321 and assess the PK and toxicity and safety profile; part 2 (dose expansion) will evaluate safety and PK profile at the RP2D in specific cohorts (NSCLC and HNSCC). Secondary objectives include assessment of preliminary antitumor activity. Pts will receive escalating doses of ABBV-321 until the MTD/RP2D is determined. Dose-limiting toxicities will be assessed during the first cycle of dosing. Adverse events (AEs) will be evaluated per National Cancer Institute Common Terminology Criteria for AEs (version 4.03). Blood samples for PK analysis (ABBV-321, total antibody, unconjugated PBD) will be collected at designated time points throughout the study. The multinational trial is active, with the first pt screened on 1 Feb 2018. The dose-escalation phase has been completed; screening and enrollment for the expansion phase of the study in NSCLC and HNSCC is underway. Clinical trial information: NCT03234712. Research Sponsor: AbbVie, Inc.

TPS3650 Poster Session (Board #380), Fri, 8:00 AM-11:00 AM

A basket trial of trastuzumab deruxtecan, a HER2-targeted antibody-drug conjugate, for HER2-amplified solid tumors identified by circulating tumor DNA analysis (HERALD trial). *First Author: Masataka Yagisawa, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Trastuzumab deruxtecan, a new HER2-targeting antibody-drug conjugate, has been approved for unresectable or metastatic HER2-positive breast cancer by the Food and Drug Administration. In a phase I/II trial, trastuzumab deruxtecan showed a manageable safety profile and antitumor activity in HER2-positive various cancer types. In addition, a tissue-based HER2 test occasionally cannot identify accurate HER2 status due to spatial and temporal intratumoral heterogeneity, leading to potentially missing an opportunity for responders to receive benefit from anti-HER2-targeted therapy. Circulating tumor DNA (ctDNA) analysis can detect comprehensive somatic genome alterations by assessment of spatial and temporal intratumoral heterogeneity with minimal invasiveness. **Methods:** We designed an investigator-initiated multicenter phase II basket trial to evaluate efficacy and safety of trastuzumab deruxtecan in advanced solid tumor malignancies with *HER2* amplification identified by Guardant360, a 74-gene sequencing ctDNA panel, as a part of the Nationwide Cancer Genome Screening Project (GOZILA study, UMIN000029315). The key eligibility criteria are as follows: 1) Histopathologically confirmed advanced solid tumor malignancy; 2) Identified *HER2* amplification by Guardant360; 3) Failed prior standard therapy. The participants will receive intravenously 5.4 mg/kg of trastuzumab deruxtecan every 3 weeks. The primary endpoint is objective response rate (ORR). The planned sample size is 55-65. A Bayesian model considering the potential heterogeneity across cancer types will be applied to detect ORR of 5% versus 25% to a certain level while maintaining the false-positive error rate in each cancer type at 10%. Furthermore, tumor tissue, ctDNA and circulating tumor cells are serially collected and analyzed to investigate the predictive biomarkers and resistance mechanisms. The trial was activated in late 2019. At the time of the abstract submission, 2 patients have been enrolled. This trial is granted by AMED under Grant Number JP18lk0201084. Clinical trial information: JapicCTI-194707. Research Sponsor: Japan Agency for Medical Research and Development.

TPS3651 Poster Session (Board #381), Fri, 8:00 AM-11:00 AM

A phase I, open-label, dose-escalation trial of BI 1701963 as monotherapy and in combination with trametinib in patients with KRAS mutated advanced or metastatic solid tumors. *First Author: Eelke Gort, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Activating mutations of *KRAS* drive many types of cancer. Activation of KRAS relies on guanine nucleotide exchange factors, such as SOS1, to mediate exchange of GDP for GTP. BI 1701963 is a small-molecule protein–protein interaction inhibitor that prevents the interaction between KRAS and SOS. Binding of BI 1701963 to the catalytic site of SOS1 inhibits binding of SOS1 to RAS–GDP, thereby hindering the exchange from RAS–GDP (inactive form) to RAS–GTP (active form). In preclinical studies this has been shown to lead to cytostasis in cancer cells addicted to KRAS signaling. **Methods:** NCT04111458 is a first-in-human trial of BI 1701963 in patients aged ≥18 years with tumors harboring *KRAS* mutations. Primary objectives are to determine the maximum tolerated dose (MTD) and recommended Phase II dose of BI 1701963 as monotherapy and in combination with trametinib, based on dose-limiting toxicities (DLTs). Secondary objectives are to evaluate safety, tolerability, pharmacokinetics/-dynamics and preliminary efficacy. The study will have two arms (mono- and combination therapy), and be divided into dose escalation (Part A), confirmation (Part B) and expansion (Part C, combination only) phases. Inclusion criteria include activating *KRAS* mutation, ≥1 evaluable lesion (RECIST 1.1), ECOG PS ≤1 and adequate organ function. Exclusion criteria include history of: RAS, MAPK or SOS1 targeting therapies; retinal vein occlusion; retinal pigment epithelial detachment; and decreased cardiac function. Parts B and C will be conducted in patients with advanced NSCLC. Treatment will continue until confirmed clinical benefit, defined toxicities, or withdrawal of consent. The primary endpoints are: Part A, the MTD, and the number of patients with DLTs during Cycle 1; Part B (monotherapy), the number of patients with DLTs; Part C, objective response (OR, RECIST 1.1). Starting doses of BI 1701963 in Part A will be 50 mg once daily (QD) orally (monotherapy) and 100 mg QD (combination, once proved safe as monotherapy) and will be escalated until the MTD is reached. The starting dose of trametinib will be 1 mg QD, escalated to the MTD or a max. of 2 mg QD. Dose cohorts will include ≥3 patients, with two therapeutic relevant doses (TRDs) established in each arm. In Part B, patients will be randomized to groups receiving one of the TRDs. If an OR is observed at a TRD in the combination arm, additional patients will be recruited into expansion cohorts receiving the relevant dose. As of Feb 11, 2020 three patients have been treated. Clinical trial information: NCT04111458. Research Sponsor: Boehringer Ingelheim.

TPS3652 Poster Session (Board #382), Fri, 8:00 AM-11:00 AM

SGN228-001: A phase I open-label dose-escalation, and expansion study of SGN-CD228A in select advanced solid tumors. *First Author: Amita Patnaik, START, San Antonio, TX*

Background: SGN-CD228A is an investigational antibody-drug conjugate (ADC) that targets CD228, a cell-surface oncofetal protein with prevalent expression in several types of cancer and limited expression on normal tissues. SGN-CD228A consists of a humanized IgG1 anti-CD228 monoclonal antibody conjugated to an average of 8 molecules of monomethyl auristatin E (MMAE) via a PEGylated β-glucuronidase cleavable linker. MMAE is a well-studied and highly active chemotype with an established safety profile. The proposed mechanism of action involves binding CD228 on cell surfaces, ADC internalization, and trafficking to lysosomes. MMAE is then released through β-glucuronidase cleavage of the glucuronide MMAE linker. MMAE then binds tubulin, which disrupts microtubule networks and causes cell cycle arrest and apoptosis. **Methods:** SGN228-001 (NCT04042480) is a phase 1, open label, multicenter, dose escalation, and expansion study enrolling up to 240 subjects to evaluate the safety, tolerability, PK, and antitumor activity of SGN-CD228A in select advanced solid tumors. Eligible subjects are ≥18 years of age and have metastatic cutaneous melanoma, malignant pleural mesothelioma, human epidermal growth factor receptor 2-negative metastatic breast cancer, advanced non-small cell lung cancer, metastatic colorectal cancer, or advanced pancreatic ductal adenocarcinoma. Subjects must have relapsed, refractory, or progressive disease, and should have no appropriate standard therapy available. Measurable disease per Response Evaluation Criteria in Solid Tumors Version 1.1 (RECIST v1.1), Eastern Cooperative Oncology Group (ECOG) performance status score of ≤1, and adequate renal, hepatic, and hematologic function are required. The study includes dose escalation and dose expansion, with multiple disease-specific dose expansion cohorts and a biology cohort. Dose escalation will be conducted using the modified toxicity probability interval method (Ji 2010) to evaluate the safety and identify the maximum tolerated dose of SGN-CD228A. Following dose escalation, disease-specific expansion cohorts and a biology cohort (to evaluate exploratory biomarkers) are planned. Response assessments will be conducted every 6 weeks per RECIST v1.1 and all subjects will be followed for safety. Pharmacokinetics and markers of pharmacodynamics will be assessed regularly. Key efficacy endpoints include objective response rate, progression-free survival, and duration of objective response. Enrollment is ongoing in the US and planned in Europe. Clinical trial information: NCT04042480. Research Sponsor: Seattle Genetics Inc.

TPS3653 Poster Session (Board #383), Fri, 8:00 AM-11:00 AM

Randomized phase II trial of topotecan plus M6620 (VX-970) versus topotecan alone in patients with relapsed small-cell neuroendocrine cancers including small cell lung cancer. *First Author: Nobuyuki Takahashi, National Cancer Institute, Bethesda, MD*

Background: Ataxia telangiectasia and Rad3-related (ATR) is an essential kinase that senses stressed replication forks and orchestrates the multifaceted replication stress response. Cancer cells under replication stress are particularly susceptible to ATR inhibition. Small-cell neuroendocrine cancers (SCNCs) are highly aggressive and arise in multiple tissues, most commonly lung (SCLC). We hypothesized that SCNCs are under replication stress and that exacerbating this stress could selectively kill SCNC by replicative damage. Based on promising data from a single-arm study, this study seeks to evaluate the improvement of progression free survival (PFS) by adding M6620 to topotecan in patients with SCNC. **Methods:** This study is an investigator-initiated, multicenter, open-label randomized phase 2 clinical trial. Key inclusion criterion are patients at age ≥18 with SCNCs that had relapsed after at least one prior chemotherapy, ECOG PS ≤ 2, and adequate organ function. Patents with asymptomatic brain metastasis, irrespective sensitivity with prior platinum-based chemotherapy, and previously treated with immune checkpoint inhibitors are eligible. The primary cohort consists of 54 patients with SCLC randomized 2:1 to receive either topotecan in combination with M6620 or topotecan alone. Topotecan is administered 1.25 mg/m^2 intravenously over 30 minutes every 23 hours on day 1 through 5, pegfilgrastim 6 mg subcutaneously on day 6 and M6620 is administered at 210 mg/m^2 intravenously over 60 minutes on day 2 and day 5 if the patient is randomized to the combination arm, in 21-day cycles. Patients randomized to the topotecan alone arm can cross-over to the combination arm at disease progression. An exploratory cohort will enroll 20 patients with SCNC. Primary endpoint is PFS improvement with the combination compared with topotecan alone. Secondary endpoints are ORR and overall survival. To evaluate the genomic features associated with clinical outcomes and to gain insight into the underlying mechanisms of ATR inhibitor response, we require mandatory biopsy before starting treatment. Clinical trial information: NCT03896503. Research Sponsor: U.S. National Institutes of Health.

TPS3654 **Poster Session (Board #384), Fri, 8:00 AM-11:00 AM**

A phase II basket study of MCLA-128, a bispecific antibody targeting the HER3 pathway, in NRG1 fusion-positive advanced solid tumors. *First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *NRG1* fusions are oncogenic drivers across various cancers. NRG1 fusion proteins bind to HER3, leading to HER2/HER3 heterodimerization, increased downstream signaling, and tumor growth. Clinical responses to anti-HER3 antibodies or HER2 tyrosine kinase inhibitors have been reported. In contrast to these agents, MCLA-128 is a HER2/HER3 bispecific antibody that blocks both NRG1 binding and HER2/3 dimerization. Two patients with chemotherapy-resistant *ATP1B1-NRG1*-positive pancreatic *KRAS*-wild-type adenocarcinomas who received MCLA-128 through FDA-approved single-patient Investigational New Drug (IND) applications showed significant tumor shrinkage and durable tumor marker (CA-19-9) response. These data support the evaluation of MCLA-128 in *NRG1* fusion-positive tumors using a basket approach. **Methods:** This is a global, open-label, multicenter phase 2 basket trial of MCLA-128 in patients with solid tumors harboring *NRG1* gene fusions. Main eligibility criteria are locally advanced unresectable or metastatic cancers harboring an *NRG1* fusion, and failure under prior standard therapy appropriate for the tumor type and disease stage. Genomic screening of tumor tissue is done at a local laboratory (with post-hoc central confirmation) or central laboratory (RNA sequencing). Three *NRG1* fusion-positive tumor cohorts are being evaluated: pancreatic cancer, NSCLC, and other solid tumors. The sample size for the first two cohorts is up to 25 patients; the basket group may enroll up to 40 patients. The primary endpoint for all cohorts is investigator-assessed objective response rate (RECIST v1.1). The key secondary endpoint is duration of response. Other secondary endpoints include progression-free and overall survival. Eligible patients receive a bi-weekly dosing regimen of 750 mg of MCLA-128 (2-hour infusion), every 2 weeks, in 4-week cycles. The study is actively accruing patients in North America, Europe, and Asia. *Previously presented at ESMO 2019, 685TiP, Schram et al.-Reused with permission.* Clinical trial information: NCT02912949. Research Sponsor: Merus NV.

TPS3655 **Poster Session (Board #385), Fri, 8:00 AM-11:00 AM**

BT5528-100 phase I/II study of the safety, pharmacokinetics, and preliminary clinical activity of BT5528 in patients with advanced malignancies associated with EphA2 expression. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: BT5528 is a Bicycle Toxin Conjugate (BTC), comprising a bicyclic peptide targeting the tumor antigen EphA2, linked to a cytotoxin (monomethyl auristatin E [MMAE]) via a tumor microenvironment cleavable linker. *Bicycles* are a novel class of chemically synthesized constrained peptides, developed by Bicycle Therapeutics. EphA2 is reported to be overexpressed in a range of solid tumors, contributes to oncogenesis, tumor-associated angiogenesis and metastasis. Intracellular EphA2 signaling converges on pathways that are integral to cell growth, proliferation, migration and invasion. Increased EphA2 expression has been identified as a resistance mechanism to EGFR Tyrosine Kinase Inhibitor based therapy. BT5528 mechanism of action is dependent on tumor penetration, target binding and release of MMAE toxin payload. BTCs offer advantages over antibody-toxin conjugates exhibiting rapid penetration of dense tumors and decreased extra-tumor exposure. BT5528 exhibited a favorable preclinical profile supporting the initiation of a first-in-human study to investigate safety and efficacy of BT5528 in indications with evidence of EphA2 expression including non-small-cell lung cancer (NSCLC), ovarian cancer, triple-negative breast cancer (TNBC), gastric/upper gastrointestinal (GI), pancreatic and urothelial cancers. **Methods:** BT5528-100 (NCT04180371) is a Ph I/II study to evaluate safety and tolerability of weekly BT5528 alone and in combination with Q4W nivolumab. Each dose escalation utilizes a 3+3 design which converts to a Bayesian design to determine MTD or MAD and RP2D for BT5528 with and without nivolumab. Eligible patients must have advanced solid tumors associated with EphA2 expression which have recurred after exhausting standard treatment options. Patients must have available tumor tissue and acceptable hematologic and organ function, with exclusions for uncontrolled brain metastases, thromboembolic events, bleeding disorders, uncontrolled hypertension, CYP3A4 inhibitors/inducers or, for the nivolumab cohorts, autoimmune disease. On-study tumor and blood samples will be collected for biomarker evaluations including tumor EphA2 expression, ADA, and candidate response biomarkers for BT5528 alone and combination with nivolumab. Pharmacokinetic data will be reported for C1D1 and D15 for BT5528 and MMAE. The expansion phase will enroll specific tumor types to evaluate clinical activity of BT5528. Enrollment is ongoing. Clinical trial information: NCT04180371. Research Sponsor: Bicycle Tx Limited.

TPS3656 **Poster Session (Board #386), Fri, 8:00 AM-11:00 AM**

An open-label, first-in-human, phase I trial of the safety and efficacy of daily PCLX-001. *First Author: Randeep S. Sangha, Cross Cancer Institute, Edmonton, AB, Canada*

Background: Myristoylation regulates numerous membrane-bound signal transduction pathways important in cancer biology. This modification is catalyzed by N-myristoyltransferases 1 and 2 (NMT1 and NMT2). PCLX-001 is an oral small molecule with high affinity for both NMT proteins (IC50 of 5nM and 8nM, respectively) with high bioavailability and drug-like pharmacokinetic properties. In *ex vivo* sensitivity screening cell lines of hematologic cancer origin were exquisitely sensitive to PCLX-001, although high sensitivities and cell killing were also seen in some solid tumor lines derived from lung, pancreas, breast, colon, and bladder carcinomas. PCLX-001 demonstrated strong preclinical single-agent antitumor activity and tolerability *in vivo* in subcutaneous tumor xenograft models derived from lymphoma cell lines, lung cancer cell lines, a breast cancer cell line, as well as in a patient derived xenograft model from a patient with refractory DLBCL. The primary objective of this study is to determine the MTD and/or recommended phase II dose, safety, tolerability, and pharmacokinetics of PCLX-001 as a single agent, in patients with refractory lymphomas and advanced solid tumors. The secondary objective of the study is to evaluate the preliminary single agent antitumor activity of PCLX-001 in the patient populations studied. **Methods:** This is a multicenter, open-label, phase I dose-escalation study of oral PCLX-001 comprised of two parts (dose escalation and dose expansion). Eligible patients will have: histologically-confirmed advanced solid tumor or B-cell lymphomas who have failed prior therapy and/or are not eligible for therapies; ages $\geq$ 18 years; adequate organ function; life expectancy of at least 12 weeks; and measurable disease. Part A (dose-escalation) patients will be accrued in cohorts of 3 to 6 patients to each dose level, starting at 20 mg daily on a 28 day cycle. Dose escalation will follow a modified Fibonacci design such that the magnitude of escalation decreases as the dose level nears the human equivalent dose of the highest non-severely toxic dose in dogs and then escalate at 1.4 times the previous dose. Dose escalation and determination of the maximum tolerated dose will be based on the occurrence of dose limiting toxicities in cycle 1. Part B will have two single agent expansion cohorts (n = 20 each) in advanced solid malignancies and relapsed/refractory B-cell lymphoma, to determine the preliminary clinical activity of PCLX-001 to determine the recommended phase II dose. The first patient on study is planned for Q3 2020. Research Sponsor: Pacylex, Other Foundation.

TPS3657 **Poster Session (Board #387), Fri, 8:00 AM-11:00 AM**

A phase I/II, open-label, dose-escalation, and cohort-expansion study evaluating the safety, pharmacokinetics, and therapeutic activity of OBI-999 in patients with advanced solid tumors. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Aberrant glycosylation is a hallmark of cancer. Glycosphingolipids (GSLs), glycans conjugated to a lipid (ceramide) core, are essential for the recruitment of immune-related proteins to specific membrane microdomains. Globo H (GH) is a GSL found on normal cells but highly overexpressed on various epithelial tumors playing a role in tumor development and progression. GH is a promising target for immunotherapy. OBI-999 is an ADC composed of a human recombinant immunoglobulin G (IgG) monoclonal antibody that selectively and specifically binds to GH, attached by a linker to the antimitotic agent monomethyl auristatin E (MMAE). Its mechanism of action is based on tumor-selective delivery of MMAE to GH-expressing tumors with subsequent tumor cell death. Preclinical studies demonstrated that OBI-999 antibody binds specifically to the GH antigen, and antitumor efficacy was noted in breast, gastric, pancreatic, and lung cancer xenograft models. The pharmacokinetics (PK) of OBI-999 were determined in normal and tumor-bearing mice, rats, and monkeys. Exposure of OBI-999 increased proportionally with dose. No sex difference or accumulation was seen. The primary objectives are to determine dose limiting toxicities (DLTs), the maximum tolerated dose (MTD), and the phase 2 recommended dose (P2RD). The secondary objectives are to assess the rates of objective response and clinical benefit, the duration of progression-free survival, the immunogenicity of OBI-999, and the PK and pharmacodynamics (PD) of OBI-999 and MMAE. **Methods:** In Part 1, a "3+3" dose-escalation part of the study, up to 30 patients with advanced solid tumors refractory to $\geq$1 line of systemic therapy, who cannot tolerate standard therapy, or for whom no standard treatment is available, regardless of GH status will be treated. OBI-999 will be administered as a 60-minute IV infusion using a dose range of 0.4, 0.8, 1.2, 1.6, and 2.0 mg/kg on day 1 of every 21-day cycle. In Part 2, the cohort-expansion portion of the study, patients will be treated at the MTD or at a lower RP2D as determined by cumulative toxicities and tolerability profile. The study will determine the preliminary clinical activity and safety of OBI-999 in up to 155 patients with advanced solid tumors, pancreatic, gastric, esophageal, and colorectal cancer according to a Simon two-stage phase 2 design. Patients must have GH overexpression defined as an H-score of $\geq$100 according to an FDA Investigational Device Exempt (IDE) validated IHC assay. Clinical trial information: NCT04084366. Research Sponsor: OBI Pharma Inc.

TPS3658 Poster Session (Board #388), Fri, 8:00 AM-11:00 AM

A first-in-man phase I/II study of OBI-3424, an AKR1C3-selective bis-alkylating agent prodrug, in subjects with advanced cancer, including hepatocellular carcinoma (HCC) and castrate-resistant prostate cancer (CRPC). *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Aldo-keto reductase family 1 member C3 (AKR1C3) modulates cellular differentiation and proliferation through indirect regulation of ligand access to hormone and nuclear receptor signaling. AKR1C3 is expressed at high levels in various human cancers, including HCC. In prostate cancer cells exposed to anti-androgen therapies, AKR1C3 is adaptively upregulated. CRPC is a potential indication for this targeted alkylating agent. AKR1C3 tumor expression is associated with poor patient survival and resistance to cancer therapies. OBI-3424 is a nitro-benzene prodrug of a nitrogen mustard that can be selectively cleaved in the presence of AKR1C3 enzyme into a bis-alkylating agent capable of forming intra- and inter-strand crosslinks with DNA, thereby resulting in cell death. The selectivity of OBI-3424 for AKR1C3 distinguishes it from traditional alkylating agents, which are nonselective. The primary objectives of the study are to evaluate the safety and tolerability of single-agent OBI-3424. The dose-escalation phase will determine the dose-limiting toxicities (DLT), maximum tolerable dose (MTD), and recommended Phase 2 dose (RP2D) of OBI-3424 through assessment of PK of OBI-3424 and OBI-2660 in plasma and urine. After determining the maximum tolerated dose (MTD), the study will enroll subjects with advanced HCC or CRPC, two tumor types with a high likelihood of over-expression of AKR1C3, into the dose expansion portion of the study according to a Simon two-stage phase 2 design. This phase is designed to assess the objective response rate, and progression-free survival in patients with HCC and CRPC. Immunohistochemistry assays are being developed to assess tumor expression of AKR1C3 for this study. The clinical safety and relationship of efficacy to AKR1C3 tumor expression will serve to guide further clinical development of OBI-3424 in these two unmet need settings. **Methods:** Based on the toxicology and PK results in cynomolgus monkeys, the starting dose is one sixth of the human equivalent dose of the highest non-severely toxic dose observed. Doses of 1, 2, 4, 6, 8, 12, and 14 mg/m^2 will be used. OBI-3424 is administered intravenously (IV) over 30 minutes on days 1 and 8 of each 21-day cycle. Subjects without clinically significant disease progression may continue on treatment for up to 2 years, if they do not experience a DLT or other significant toxicity. Clinical trial information: NCT03592264. Research Sponsor: OBI Pharma Inc.

TPS3659 Poster Session (Board #389), Fri, 8:00 AM-11:00 AM

SKB264 ADC: A first-in-human study of SKB264 in patients with locally advanced unresectable/metastatic solid tumors who are refractory to available standard therapies. *First Author: Yongheng Liu, Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd., Chengdu, China*

Background: Elevated expression of trophoblast antigen 2 (TROP2) is often associated with invasion/aggression, progression, and metastasis of many different tumor types. Efficacies of anti-TROP2 ADC have been demonstrated both preclinically and in the clinical trials. SKB264 is being developed as a further optimized TROP2-targeting ADC with a proprietary cytotoxic, belotecan-derived payload and novel stable conjugation chemistry to achieve average DAR (Drug Antibody Ratio) of 7.4. Release of payload upon SKB264 internalization is in a TROP2 expression dependent manner. Extensive preclinical studies demonstrated antitumor activity of SKB264 in vitro, in xenograft and patient-derived xenograft (PDX) animal models. In addition, safety studies have demonstrated a good safety profile to allow SKB264 to be studied in clinical trials. **Methods:** SKB264-01 is a global open label multicenter study. The study is divided into 2 parts, the phase I is to determine the safety profile, define MTD and/or the RP2D, and characterize DLTs of SKB264. Dose escalation and MTD identification will be directed using a Bayesian logistic regression model (BLRM) with overdose control. The phase II is to evaluate efficacy and obtain clinical activity data of SKB264 as a monotherapeutic agent at the RP2D in each of the designated Phase II cohorts and overall (n = 16 per cohort; n = 48 for entire Phase II part). Objective response rate (ORR) will be continuously evaluated in each cohort using a Bayesian hierarchical model. TROP2 assessments will not be performed prior to enrollment but it will be assessed retrospectively. Confirmation of TROP2 expression by immunohistology or other methods is not required, but the Sponsor will request tissue specimens from archived materials for determination of TROP2 expression. The patient must have, in the judgment of the investigator, historically documented, incurable, locally advanced or metastatic cancer that are refractory to standard therapies of one of the following types: i. ovarian epithelial cancer, ii. gastric adenocarcinoma, iii. pancreatic adenocarcinoma, iv. triple negative breast cancer, v. bladder cancer. Patient will receive study drug as a single IV infusion at the prescribed dose level at each administration. Cycles will continue until disease progression or unacceptable toxicity. Adverse Events (AE) will be graded according to CTCAE V.5.0. Responses will be evaluated according to RECIST V1.1. The enrollment will began in Mar 2020 in USA sites. Clinical trial information: NCT04152499. Research Sponsor: KLUS Pharm Inc.

TPS3660 Poster Session (Board #390), Fri, 8:00 AM-11:00 AM

A phase Ia/Ib, dose-escalation/expansion study of BI 907828 in combination with BI 754091 and BI 754111 in patients (pts) with advanced solid tumors. *First Author: Anthony W. Tolcher, NEXT Oncology, San Antonio, TX*

Background: Preclinical data show that the combination of a murine double minute 2–tumor protein 53 (MDM2–TP53) antagonist with anti-PD-1 and anti-LAG3 antibodies produces an anti-tumor effect in multiple tumor types. This Phase Ia/Ib study aims to determine the safety, recommended dose for expansion (RDE), and preliminary efficacy of BI 907828, a MDM2–TP53 antagonist, with BI 754091, an anti-PD-1 antibody, and BI 754111, an anti-LAG-3 antibody, in a variety of *TP53* wild-type cancers. **Methods:** In Phase Ia (dose escalation), ~30 pts with a confirmed diagnosis of any unresectable, advanced/metastatic solid tumor, irrespective of *TP53* mutation status, will be enrolled. Pts will receive one dose of BI 907828 every 21 days (Q3W), at a starting dose of 10 mg orally, plus BI 754091 and BI 754111 (240 mg and 600 mg, respectively, Q3W, intravenously). Dose escalation will be guided by a Bayesian Logistic Regression Model with overdose control. The primary endpoint is the maximum-tolerated dose of BI 907828 based on dose-limiting toxicities (DLTs) during the first treatment cycle. Secondary endpoints include pharmacokinetics and DLTs in the treatment period (to determine the RDE). In Phase Ib (dose expansion), pts with previously treated, unresectable, advanced/metastatic *TP53* wild-type tumors with ≥1 measurable target lesion will be enrolled into four expansion cohorts (1: NSCLC; 2: melanoma; 3: well-differentiated/dedifferentiated liposarcoma or undifferentiated pleomorphic sarcoma; 4: hepatocellular carcinoma). The RDE of BI 907828 will be administered with fixed doses of BI754091 and BI 754111 (Q3W). In the NSCLC cohort only, pts will be randomized to one of three arms: RDE of BI 907828 + 240 mg BI 754091 + 600 mg BI 754111 (arm A, 32 pts); 240 mg BI 754091 + 600 mg BI 754111 (arm B, 32 pts); RDE of BI 907828 + 240 mg BI 754091 (arm C, 16 pts). The primary endpoint is objective response (OR, per RECIST 1.1). Secondary endpoints include OR (per iRECIST), disease control (per RECIST 1.1 and iRECIST), progression-free survival (PFS), PFS rate at 12 and 24 weeks (cohort 3), and safety. Phase Ib will include at least 140 evaluable pts (80 pts in cohort 1 and 20 pts each in cohorts 2–4). Clinical trial information: NCT03964233. Research Sponsor: Boehringer Ingelheim.

TPS3661 Poster Session (Board #391), Fri, 8:00 AM-11:00 AM

Trial in progress: A phase Ib study of AMG 510, a specific and irreversible KRAS^{G12C} inhibitor, in combination with other anticancer therapies in patients with advanced solid tumors harboring *KRAS* p.G12C mutation (CodeBreak 101). *First Author: Marwan Fakih, City of Hope National Medical Center, Duarte, CA*

Background: Kirsten rat sarcoma viral oncogene homolog *(KRAS)* p.G12C mutation has been identified as a driver oncogenic mutation in several solid tumors (eg, non-small cell lung cancer [NSCLC], colorectal cancer [CRC]). Development of therapies targeting KRAS^{G12C} has been unsuccessful. AMG 510 is a specific and irreversible small molecule inhibitor of KRAS^{G12C}. A first-in-human clinical trial of AMG 510 monotherapy in patients with *KRAS* p.G12C mutant solid tumors is currently ongoing. AMG 510 in combination with additional anticancer therapies may lead to enhanced antitumor efficacy. This study is a master protocol designed to evaluate multiple investigational regimens of AMG 510 in patients with *KRAS* p.G12C mutant solid tumors. Here, we present two combination cohorts of AMG 510 with a mitogen-activated protein kinase kinase (MEK) inhibitor and an investigational anti-programmed cell death protein-1 (PD-1) therapy, respectively. Additional combination cohorts will be presented at the meeting. **Methods:** This is a phase 1b, open-label study evaluating AMG 510 in combination with a MEK inhibitor or an investigational anti-PD-1 therapy in pts with *KRAS* p.G12C mutant solid tumors. The dose exploration phase (part 1; n=20) will evaluate the safety and tolerability of AMG 510 in combination with the MEK inhibitor or anti-PD-1 therapy; this will be followed by a dose expansion phase (part 2; n=40) to verify the safety and tolerability profile of AMG 510 combination therapies and assess antitumor efficacy. Key eligibility criteria include locally-advanced or metastatic malignancy with *KRAS* p.G12C mutation identified through molecular testing and at least one or multiple lines of prior systemic therapy (eg, ≥2 for advanced/metastatic colorectal cancer). Primary endpoints include dose-limiting toxicities, treatment-emergent or -related adverse events. Secondary endpoints include pharmacokinetic parameters of combination regimens, disease control rate, duration of response, progression-free survival, and duration of stable disease (measured by computed tomography or magnetic resonance imaging and assessed per RECIST 1.1). The study began enrolling pts in December 2019 and is ongoing. For more information, please contact Amgen Medical Information: medinfo@amgen.com. Clinical trial information: NCT04185883. Research Sponsor: Amgen Inc.

TPS3662 Poster Session (Board #392), Fri, 8:00 AM-11:00 AM

First-in-human phase I study of SY-5609, an oral, potent, and selective noncovalent CDK7 inhibitor, in adult patients with select advanced solid tumors. *First Author: Kyriakos P. Papadopoulos, South Texas Accelerated Research Therapeutics, LLC, San Antonio, TX*

Background: SY-5609 is an oral, noncovalent, highly selective and potent inhibitor of cyclin-dependent kinase 7 (CDK7), a key regulator of 2 biological processes that play critical roles in driving tumor development: transcription and cell cycle control. Evaluation of SY-5609 as a single agent in PDX models from a range of solid tumors, including breast, ovarian, lung and colorectal tumors, revealed robust antitumor activity including complete regressions, and activity in models known to be resistant to standard of care therapy. Models with genetic alterations in RB pathway genes demonstrated deep ($>$ 90% TGI) and sustained SY-5609-induced tumor regressions following treatment discontinuation, in contrast to models without genetic alteration in RB pathway genes, suggesting that tumor cells with aberrant cell-cycle control may be particularly sensitive to SY-5609 treatment. The study is designed to evaluate the safety, tolerability, and maximum tolerated dose (MTD) of SY-5609, to characterize the pharmacokinetic (PK), pharmacodynamic (PD), and preliminary antitumor activity of SY-5609, and to explore candidate biomarkers predictive of response to SY-5609. **Methods:** This is a multi-center, open-label Phase 1 trial expected to enroll approximately 60 adult patients with select advanced solid tumors for which standard treatment is no longer effective. The dose escalation phase of the trial is open to adult patients with ovarian, breast, colorectal, or lung cancer, and patients with any solid tumor histology with molecular evidence of deregulated RB cell cycle control. SY-5609 is being administered orally once daily, for each 4-week cycle. Initially, patients will be enrolled into single-patient accelerated titration cohorts; subsequent cohorts will transition to a 3 + 3 design. Following completion of DLT evaluation at a given dose level, additional patients may be enrolled at that dose to further characterize safety, PK, PD, and early clinical activity. Data from this trial will support dose selection for planned evaluations of antitumor activity of SY-5609 as a single agent and in combination. Clinical trial information: NCT04247126. Research Sponsor: Syros Pharmaceuticals.

TPS3663 Poster Session (Board #393), Fri, 8:00 AM-11:00 AM

A phase I, open-label, multicenter, first-in-human study of the safety, tolerability, pharmacokinetics, and antitumor activity of TPX-0022, a novel MET/CSF1R/SRC inhibitor, in patients with advanced solid tumors harboring genetic alterations in MET. *First Author: David S. Hong, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Alterations in the MET gene, including amplifications, chromosomal translocations, and activating mutations (kinase domain [KD] or exon 14 [Δex14]), occur across various tumors and may function as oncogenic drivers. SRC family kinases function as a key downstream node for MET signaling. CSF1R is a receptor tyrosine kinase associated with tumor progression and suppression of the immune response in the tumor microenvironment. TPX-0022 is a type I kinase inhibitor with a novel macrocyclic structure that potently inhibits MET, CSF1R and SRC to simultaneously target oncogenic MET signaling, its key downstream mediators, and the tumor microenvironment. **Methods:** This is a multicenter phase 1 first-in-human, open-label study to determine the safety, tolerability, PK, and preliminary efficacy of TPX-0022 in adults with advanced solid tumors harboring genetic alterations in MET. TPX-0022 will be administered orally in continuous 28-day cycles. The primary endpoint is the incidence of DLTs and determination of recommended phase 2 dose (RP2D). Secondary endpoints include ORR by blinded independent central review, intra-cranial response rate, PFS and OS (dose expansion only). In the dose escalation portion, ~30 subjects age $\geq$18 with solid tumors harboring MET gene amplifications, Δex14, fusions or KD mutations as determined by local tissue-based or liquid biopsy will be enrolled in a 3+3 design. Intrasubject dose escalation will also be allowed. Once the RP2D has been determined, a food effect sub-study will be conducted and ~80 subjects will be enrolled in a dose expansion portion of the study into the following cohorts: I: non-small cell lung cancer (NSCLC) Δex14 (MET therapy naïve), II: NSCLC Δex14 (MET therapy pre-treated), III: MET amplified NSCLC, gastric, or hepatocellular carcinoma, IV: solid tumors with MET KD mutations or fusions. Correlative studies will include analysis of circulating cell-free DNA to identify genomic alterations that may predict activity of TPX-0022 as well as circulating protein biomarkers such as s-MET, HGF, CSF1 and serum cytokines. The study is open and enrolling in the dose escalation portion at the time of submission. Clinical trial information: NCT03993873. Research Sponsor: Turning Point Therapeutics.

TPS3665 Poster Session (Board #395), Fri, 8:00 AM-11:00 AM

Masterkey-01: Phase I/II, open-label multicenter study to assess safety, tolerability, pharmacokinetics, and antitumor activity of BDTX-189, an inhibitor of allosteric ErbB mutations, in patients with advanced solid malignancies. *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: A significant unmet need exists for drugs targeting allosteric ErbB mutations (non-canonical mutations outside the ATP binding site). Current EGFR and HER2 tyrosine kinase inhibitors or mAbs have limited antitumor activity against allosteric mutations, resulting in toxicity before adequate drug exposure (Connell and Doherty, 2017). BDTX-189 is a potent and selective orally available irreversible inhibitor targeting unique oncogenic driver mutations of ErbB kinases in EGFR and HER2, while sparing WT EGFR. Preclinical studies demonstrated antitumor activity across a range of allosteric ErbB mutants, including extracellular domain allosteric mutations of HER2 as well as EGFR and HER2 kinase domain exon 20 insertions (Buck, 2019). This first-in-human trial (NCT04209465) is aimed to determine the recommended phase 2 dose (RP2) and schedule (Phase 1, P1), and evaluate the efficacy (Phase 2, P2) of BDTX-189. P1 primary objective is to determine the RP2 dose and schedule of monotherapy BDTX-189. Secondary objectives include assessment of safety, tolerability, pharmacokinetics (PK), pharmacodynamic (PD) effects in tumor, and preliminary efficacy. The P2 primary objective is to assess antitumor activity of monotherapy BDTX-189. **Methods:** The study will enroll patients (pts) $\geq$18 yrs with histologically or cytologically confirmed locally advanced or metastatic solid tumors with no standard therapy available or for whom standard therapy is unsuitable or intolerable. P1 dose-escalation will use a BOIN design (Yuan, 2016) and will enroll $\leq$ 88 pts with allosteric HER2 or HER3 mutation; EGFR or HER2 exon 20 insertion mutation; HER2 amplified or overexpressing tumor; or EGFR exon 19 deletion or L858R mutation. BDTX-189 will be dosed orally (PO) initially QD in 3 wk cycles. Regimen optimization will use PK, PD and safety data and may explore a BID schedule. An expansion cohort of $\leq$12 pts will further evaluate safety and preliminary efficacy of BDTX-189 prior to P2. P2, utilizing a Simon 2-stage design, will enroll $\leq$100 pts with NSCLC with EGFR or HER2 exon 20 insertion mutations (cohort 1); breast cancer with an allosteric ErbB mutation (cohort 2); tumors (except breast) with S310F/Y mutation (cohort 3); and other allosteric ErbB mutations not defined in cohorts 1-3 (cohort 4). Assessments include safety, tolerability, DLTs, evaluation of MTD, PK, PD, and preliminary antitumor activity. Enrollment began 1/2020. Clinical trial information: NCT04209465. Research Sponsor: Black Diamond Therapeutics.

4000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase II, multicenter, open-label study of trastuzumab deruxtecan (T-DXd; DS-8201) in patients (pts) with HER2-expressing metastatic colorectal cancer (mCRC): DESTINY-CRC01. *First Author: Salvatore Siena, Department of Oncology and Hemato-Oncology, Università degli Studi di Milano and Niguarda Cancer Center, Grande Ospedale Metropolitano Niguarda, Milan, Italy*

Background: T-DXd is an antibody-drug conjugate composed of an anti-HER2 antibody, cleavable tetrapeptide-based linker, and topoisomerase I inhibitor payload. Early studies have shown promising activity in advanced HER2-expressing tumors. DESTINY-CRC01 (DS8201-A-J203; NCT03384940) is a phase 2, open-label, multicenter study of T-DXd in pts with HER2-expressing mCRC. **Methods:** Pts with centrally confirmed HER2-expressing, *RAS*–wild type mCRC that progressed on ≥ 2 prior regimens received T-DXd 6.4 mg/kg every 3 weeks (q3w) in 3 cohorts (A: HER2 IHC 3+ or IHC 2+/ISH+; B: IHC 2+/ISH−; C: IHC 1+). The primary endpoint was confirmed objective response rate (ORR) by independent central review in cohort A; secondary endpoints included, disease control rate (DCR; CR + PR + SD), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and ORR in cohorts B and C. **Results:** At data cutoff (Aug 9, 2019), 78 pts (A, 53; B, 7; C, 18) had received T-DXd. Median age was 58.5 y (range, 27-79 y), 52.6% of pts were male, and 89.7% had left colon or rectum cancer; median number of prior regimens was 4 (range, 2-11); all pts had prior irinotecan. Median treatment duration was 3.5 mo (95% CI, 2.1-4.3 mo; cohort A, 4.8 mo [95% CI, 3.9-5.8 mo]); 38.5% of pts remained on T-DXd treatment. The confirmed ORR was 45.3% (24/53 pts; 95% CI, 31.6%-59.6%) in cohort A, including 1 CR and 23 PRs; median DOR was not reached (95% CI, 4.2 mo-NE). The ORR in pts with prior anti-HER2 treatment was 43.8% (7/16 pts; 95% CI, 19.8%-70.1%). The DCR was 83.0% (44/53 pts; 95% CI, 70.2%-91.9%); median PFS was 6.9 mo (95% CI, 4.1 mo-NE); median OS was not reached. No responses were observed in cohorts B or C. Grade ≥ 3 treatment-emergent adverse events (TEAEs) occurred in 61.5% of pts (48/78); the most common (≥10%) were decreased neutrophil count (21.8%) and anemia (14.1%). Seven pts (9.0%) had TEAEs leading to drug discontinuation. Five pts (6.4%) had interstitial lung disease (ILD) adjudicated by an independent committee as related to T-DXd (2 grade 2; 1 grade 3; 2 grade 5 [the only drug-related deaths]). **Conclusions:** Overall, T-DXd 6.4 mg/kg q3w demonstrated remarkable activity in pts with HER2-expressing mCRC refractory to standard therapies, with a safety profile consistent with previous results. ILD is an important risk and requires careful recognition and intervention. Clinical trial information: NCT03384940. Research Sponsor: Daiichi Sankyo Co., Ltd.

4001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Encorafenib plus cetuximab with or without binimetinib for *BRAF* V600E metastatic colorectal cancer: Updated survival results from a randomized, three-arm, phase III study versus choice of either irinotecan or FOLFIRI plus cetuximab (BEACON CRC). *First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BEACON CRC is a randomized, phase 3 study which evaluated the triplet of encorafenib (ENCO) + binimetinib (BINI) + cetuximab (CETUX) and the doublet of ENCO + CETUX vs. investigator's choice of irinotecan + CETUX or FOLFIRI + CETUX in patients (pts) with *BRAF*V600E metastatic colorectal cancer (mCRC) whose disease had progressed after 1-2 prior regimens in the metastatic setting. Primary endpoints were overall survival (OS) and objective response rate (ORR; by blinded central review) for triplet vs control. In a previous interim analysis, triplet and doublet improved OS and ORR versus standard of care. Here we report on an updated analysis. **Methods:** Updated analysis includes 6 months of additional follow-up and response data for all randomized pts. The study is ongoing. **Results:** Pts received triplet (n=224), doublet (n=220), or control (n=221). Median OS was 9.3 months (95% confidence interval [CI]:8.2, 10.8) for triplet and 5.9 months (95% CI:5.1-7.1) for control (hazard ratio [HR] (95% CI): 0.60 (0.47-0.75)). Median OS for doublet was 9.3 months (95% CI: 8.0-11.3) (HR vs. control: 0.61 (0.48-0.77). Confirmed ORR was 26.8% (95% CI: 21.1%-33.1%) for triplet, 19.5% (95% CI: 14.5%-25.4%) for doublet, and 1.8% (95% CI: 0.5%-4.6%) for control. Retrospective subgroup analyses suggested some pts may benefit more from triplet than doublet therapy (Table). Both triplet and doublet showed improved OS compared to control in all subgroups. Adverse events were consistent with prior analysis, with grade ≥3 adverse events in 65.8%, 57.4%, and 64.2% for triplet, doublet and control, respectively. **Conclusions:** The updated analysis of the BEACON CRC study confirmed that encorafenib + cetuximab with or without binimetinib improved OS and ORR in previously treated pts with *BRAF* V600E mCRC compared with standard chemotherapy. Clinical trial information: NCT02928224. Research Sponsor: Pfizer Inc.

OS in select subgroups, triplet vs. doublet.

		Events/Patients	Triplet vs Doublet Medians (months)	HR (95% CI)*
All Patients		265/444	9.3 vs 9.3	0.95 (0.74-1.21)
CRP	**High**	139/174	6.5 vs 5.1	0.76 (0.54, 1.06)
	Normal	120/261	13.8 vs 14.0	1.09 (0.76, 1.56)
ECOG PS	**1**	153/216	8.1 vs 6.1	0.81 (0.59, 1.11)
	0	112/228	10.4 vs 13.9	1.28 (0.88, 1.86)
No. of organs	**3+**	141/214	8.5 vs 6.7	0.69 (0.49, 0.96)
	<=2	124/230	10.0 vs 12.3	1.34 (0.94, 1.91)
Tumor Status	**Partially/Not Resected**	123/188	8.5 vs 8.3	0.80 (0.56, 1.14)
	Resected	142/256	9.5 vs 12.3	1.20 (0.86, 1.68)

*HR<1 favors triplet; HR>1 favors doublet

4002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

First-line FOLFOX plus panitumumab versus 5FU plus panitumumab in RAS-BRAF wild-type metastatic colorectal cancer elderly patients: The PANDA study. *First Author: Sara Lonardi, Veneto Institute of Oncology (IOV)-IRCCS, Padua, Italy*

Background: Data on first-line treatment efficacy in elderly patients are limited. Many analyses adopt a questionable cut-off of 65 years and specific evidence with anti-EGFRs is low. FOLFOX-panitumumab (pan) is an option for RAS wild-type (wt) untreated mCRC patients. Guidelines recommend considering fluoropyrimidine monotherapy as an option for elderly patients, but no randomized studies have ever explored the role of the combination with an anti-EGFR. **Methods:** This is a prospective, open-label, multicenter phase II randomized trial. Unresectable and previously untreated *RAS-BRAF* wt mCRC patients aged ≥70 were randomized to receive FOLFOX-pan (arm A), or 5FU/LV-pan (arm B) for up to 12 cycles followed by pan maintenance until PD. The primary EP was PFS in both arms. Stratification criteria were age (≤75 vs > 75 years), ECOG PS (0–1 vs 2) and geriatric assessment with G8 Score (≤14 vs > 14). In each treatment arm, the null hypothesis for median PFS was set at ≤6 months. Assuming an expected median PFS time ≥9.5 months with both experimental regimens, a sample size of 90 patients in each arm granted to the study a power of 90%, with a type I error rate equal to 5% (1-sided Brookmeyer-Crowley test) for rejecting the null hypothesis. No formal comparison between the two arms was planned. **Results:** From Jul 2016 to Apr 2019 a total of 394 patients were screened, 211 were deemed eligible for inclusion and 185 were randomized (92 arm A and 93 arm B). Main pts' characteristics were (arm A/B): males 66%/61%; median age 77/77y; PS≥1 49%/55%; right colon 23%/21%; G8 > 14 31%/30%. At a median follow up of 20.5 mos, 135 (arm A/B: 64/71) PD events were collected. Median PFS was 9.6 (95% CI 8.8-10.9) in arm A with FOLFOX-pan and 9.1 (95% CI 7.7-9.9) in arm B with 5FU/LV-pan. Response rates were (arm A/B): 65%/57%. Grade 3-4 toxicities were (arm A/B): neutropenia 9.8%/1.1%; diarrhea 16.3%/1.1%; stomatitis 9.8%/4.4%; neurotoxicity 3.3%/0%; fatigue 6.5%/4.4%; skin rash 25%/24.2%, hypomagnesemia 3.3%/7.7%. **Conclusions:** Large prospective randomized studies in molecularly selected elderly mCRC are feasible with multicenter collaborative efforts. Primary EP was met in both treatment arms. 5FU/LV plus panitumumab for up to 12 cycles followed by panitumumab maintenance until PD might be a reasonable option in elderly mCRC patients with RAS/BRAF wt tumors deserving further investigations in phase III trials. Clinical trial information: NCT02904031. Research Sponsor: GONO Group, Pharmaceutical/Biotech Company.

4003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Celecoxib in addition to standard adjuvant therapy with 5-fluorouracil, leucovorin, oxaliplatin (FOLFOX) in stage III colon cancer: Results from CALGB/SWOG 80702. *First Author: Jeffrey A. Meyerhardt, Dana-Farber Cancer Institute, Boston, MA*

Background: Aspirin and cyclooxygenase-2 (COX-2) inhibitors have been associated with a reduced risk of colorectal polyps and cancer in observational and randomized studies. CALGB/SWOG 80702 tested the effect of celecoxib, a COX-2 inhibitor, on reducing the risk of recurrence in stage III CC. **Methods:** CALGB/SWOG 80702 is a 2x2 randomized controlled phase III trial of 3 v 6 months of adjuvant FOLFOX (data previously reported as part of the IDEA collaboration) with concurrent celecoxib (400 mg daily) v placebo x 3 yrs for patients (pts) with resected stage III CC. The primary endpoint of the trial is disease-free survival (DFS), defined as time from randomization to recurrence or death from any cause. The trial was designed to provide 91% power to detect a hazard ratio (HR) of 0.79 in favor of celecoxib with 2-sided alpha = 0.05 (775 events required); due to slowing accumulation of events 4 years after complete accrual, power was lowered to 85% with same HR and alpha assumptions (696 events required). The DSMB released data on February 24, 2020 at median f/u of 5.6 yrs with 689 DFS events. **Results:** Between June 2010 and November 2015, 2,526 pts were consented and randomized to the trial. Treatment arms were well balanced by patient and tumor prognostic features, as well as low-dose aspirin use. Baseline characteristics included 45% female, 18% non-White, 8% Hispanic, 15% T4, 26% N2. 3-yr DFS for celecoxib was 76.3% v 73.3% for placebo (HR 0.89 [95% CI 0.77-1.04]; P = 0.14). 5-yr overall survival (OS) was 83.9% for celecoxib v 81.7% for placebo (HR 0.87 [95% CI 0.72-1.05]; P = 0.14). When considering the 4 treatment arms separately, 3-yr DFS was 77.0% for 12 months FOLFOX + celecoxib, 74.9% for 12 months FOLFOX + placebo, 75.5% for 6 months FOLFOX + celecoxib, and 71.9% for 6 months FOLFOX + placebo (log rank P = 0.22; P interaction = 0.64). There were no significant differences in grade 3-4 toxicity with celecoxib v placebo. Compliance with protocol celecoxib treatment, defined as 3 yrs of therapy completion or recurrence/death while on treatment, was 58.1% pts on celecoxib and 60.2% pts on placebo. **Conclusions:** The addition of celecoxib to standard chemotherapy did not significantly improve DFS or OS. Clinical trial information: NCT01150045. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

4004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Overall survival (OS) and long-term disease-free survival (DFS) of three versus six months of adjuvant (adj) oxaliplatin and fluoropyrimidine-based therapy for patients (pts) with stage III colon cancer (CC): Final results from the IDEA (International Duration Evaluation of Adj chemotherapy) collaboration. *First Author: Alberto F. Sobrero, Ospedale Policlinico San Martino IRCCS, Genoa, Italy*

Background: In overall population, IDEA pooled analysis did not demonstrate non-inferiority (NI) regarding 3y DFS in pts with stage III CC receiving 3m vs. 6m of adj FOLFOX/CAPOX. However, in pts treated with CAPOX (especially in low-risk pts), 3m of therapy was as effective as 6m. Results of OS and 5y DFS are reported. **Methods:** OS was defined as time from enrollment to death due to all causes. OS NI margin was conservatively set to be Hazard Ratio (HR) = 1.11, which is equivalent to: the maximum acceptable loss of OS efficacy, by shortening treatment to 3m, was half of the OS efficacy gained in MOSAIC trial (i.e., 2.26% absolute reduction in 5y OS rate). Pre-planned sub-group analyses included by regimen and risk group for both OS and 5y DFS. NI was to be declared if the one-sided false discovery rate adjusted (FDRa) NI p-value < 0.025. **Results:** With an overall median survival follow-up of 72 m (range per study, 62 to 84 m), 2584 deaths and 3777 DFS events among 12,835 pts from six trials were observed. Across 6 studies, 39.5% of pts received CAPOX (rate by study, 0% to 75.1%). Overall, the 5y OS rate was 82.4% (3m) and 82.8% (6m), with estimated OS HR of 1.02 (95% confidence interval [CI], 0.95-1.11; FDRa NI p, 0.058) and absolute 5-y OS rate difference of -0.4% (95% CI, -2.1 to 1.3%). Overall, the 5y DFS rate was 69.1% (3m) and 70.8% (6m), with estimated DFS HR of 1.08 (95%CI, 1.01-1.15, FDRa NI p, 0.22). HRs (95% CI) within subgroups see table. **Conclusions:** 5y OS rate reported in IDEA trials was higher than historical rates, regardless of duration of therapy. While overall survival in IDEA did not meet prior statistical assumptions for NI in overall population, the 0.4% difference in 5y OS should be placed in clinical context. OS and 5y DFS results continue to support the use of 3m adjuvant CAPOX for the vast majority of stage III colon cancer pts. This conclusion is strengthened by the substantial reduction of toxicities, inconveniencies and cost associated with shorter treatment duration. Clinical trial information: NCT01150045; 2009-010384-16; NCT00749450; ISRCTN59757862; 2007-003957-10; UMIN000008543; 2007-000354. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

	OS	Long-term DFS
CAPOX	0.96 (0.85, 1.08)	0.98 (0.88, 1.08)
FOLFOX	1.07 (0.97, 1.18)	1.16 (1.06, 1.26)
Low Risk (T1-3 N1)	0.95 (0.84, 1.08)	1.04 (0.94, 1.14)
High Risk (T4 or N2)	1.08 (0.98, 1.19)	1.12 (1.03, 1.22)

4005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A randomized phase II/III trial comparing hepatectomy followed by mFOLFOX6 with hepatectomy alone for liver metastasis from colorectal cancer: JCOG0603 study. *First Author: Yukihide Kanemitsu, Department of Colorectal Surgery, National Cancer Center Hospital, Tokyo, Japan*

Background: The role of adjuvant chemotherapy after hepatectomy is controversial for liver only metastases from colorectal cancer (LM). Current recommendations for oxaliplatin-containing adjuvant regimen (FOLFOX) for LM are based on extrapolation of the results of the EORTC intergroup trial 40983, which showed that perioperative FOLFOX confirmed a progression-free survival benefit but did not affect overall survival (OS) in LM patients. We conducted a randomized controlled trial to determine if adjuvant modified FOLFOX (mFOLFOX) is superior to hepatectomy alone for LM. **Methods:** Eligible patients aged 20-75 years who had histologically proven colorectal adenocarcinoma with an unlimited number of LM were randomly assigned (1:1) to receive either adjuvant mFOLFOX6 (oxaliplatin 85mg/m^2, l-LV 200 mg/m^2, 5-FU bolus 400 mg/m^2 and 2400mg/m^2 over 48 h), for 12 cycles after surgery (CTX arm), or surgery alone (S alone arm). When treatment compliance after 9 courses of CTX was as high as expected in phase II, the registration was continued in phase III. The primary endpoint of phase III was disease-free survival (DFS), and the secondary endpoints were OS, toxicity, and sites of relapse. The planned sample size was 150 patients (pts) per arm, with a one-sided alpha of 5%, and 80% power detecting a 5y-DFS difference of 12% (25% with S alone vs. 37% with CTX). **Results:** Between Mar. 2007 and Jan. 2019, 300 patients were randomized. 151 pts were allocated to CTX, and 149 pts to S alone. When the third interim analysis of phase III was performed in Dec. 2019, the DSMC recommended the early termination of the trial because a statistically significant difference in terms of DFS but the futility in terms of OS was found. With a median follow-up period of 54 months for disease-free surviving patients, the 3y-DFS was 52.1% (95% CI 43.2 – 60.2) with CTX and 41.5% (33.2 – 49.6) with S alone (hazard ratio 0.63 [0.45 – 0.89], one-sided $p = 0.002 < 0.0163$ for the one-sided alpha level at the interim analysis). However, the 3y-OS was 86.6% (79.2-91.4) with CTX and 92.2% (86.0 – 95.8) with S alone (hazard ratio 1.35 [0.84 – 2.19]). The 5y-OS was 69.5% (59.6-77.5) with CTX and 83.0% (74.5-88.9) with S alone. Median OS after recurrence was 38.4 months in the CTX arm and 87.6 in the S alone arm. **Conclusions:** DFS did not correlate with OS for LM. Postoperative chemotherapy with mFOLFOX6 improves DFS but worsens OS over surgery alone due to more deaths after recurrence in the CTX arm. Adjuvant mFOLFOX is not beneficial to patients after hepatectomy for LM. Clinical trial information: UMIN000000653. Research Sponsor: National Cancer Center Research and Development Fund and Grants-in-Aid for Cancer Research.

4006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Short-course radiotherapy followed by chemotherapy before TME in locally advanced rectal cancer: The randomized RAPIDO trial. *First Author: Geke Hospers, University of Groningen, University Medical Center Groningen, Department of Medical Oncology, Groningen, Netherlands*

Background: Local control in locally advanced rectal cancer (LARC) has improved. However, systemic relapses remain high even with postoperative chemotherapy, possibly due to low compliance. Short-course radiotherapy (SCRT) followed by delayed surgery with, in the waiting period, chemotherapy, may lead to better compliance, downstaging and fewer distant metastases. The main objective of the international multicenter phase III RAPIDO trial is to decrease Disease-related Treatment Failure (DrTF), defined as locoregional failure, distant metastasis, a new primary colon tumor or treatment-related death, by reducing the risk of systemic relapse without compromising local control. **Methods:** MRI-diagnosed LARC patients with either cT4a/b, extramural vascular invasion, cN2, involved mesorectal fascia or enlarged lateral lymph nodes considered to be metastatic were randomly assigned to SCRT (5x5 Gy) with subsequent six cycles of CAPOX or nine cycles of FOLFOX4 followed by total mesorectal excision (TME) (experimental arm) or, capecitabine-based chemoradiotherapy (25-28 x 2.0-1.8 Gy) followed by TME and optional, predefined by hospital policy, postoperative eight cycles of CAPOX or twelve cycles of FOLFOX4 (standard arm). **Results:** Between June 2011 and June 2016, 920 patients were randomized. Pathological complete response rates were 27.7% vs 13.8% (OR 2.40 [1.70 – 3.39]; $p < 0.001$) in the experimental and standard arms, respectively. At three years, cumulative probability of DrTF was 23.7% in the experimental arm and 30.4% in the standard arm (HR 0.76 [0.60 – 0.96]; $p = 0.02$). Probability at three years of distant metastasis and locoregional failure were, in the experimental and standard arms, 19.8% vs 26.6% (HR 0.69 [0.53 – 0.89]; $p = 0.004$) and 8.7% vs 6.0% (HR 1.45 [0.93 – 2.25]; $p = 0.10$), respectively. No differences in DrTF between hospitals with or without policy for postoperative chemotherapy were found ($p = 0.37$). Overall health ($p = 0.192$), quality of life ($p = 0.125$) and low anterior resection syndrome score ($p = 0.136$) were comparable between the two treatment arms. **Conclusions:** A lower rate of DrTF, as a result of a lower rate of distant metastases, in high-risk LARC patients can be achieved with preoperative short-course radiotherapy, followed by chemotherapy and TME than by conventional chemoradiotherapy. In addition, the high pCR rate, achieved with the experimental treatment regimen can contribute to organ preservation. This treatment can be considered as a new standard of care. Clinical trial information: NCT01558921. 4007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Total neoadjuvant therapy with mFOLFIRINOX versus preoperative chemoradiation in patients with locally advanced rectal cancer: Final results of PRODIGE 23 phase III trial, a UNICANCER GI trial. *First Author: Thierry Conroy, Institut de Cancérologie de Lorraine, Vandoeuvre-Les-Nancy, France*

Background: PRODIGE 23 investigated the role of neoadjuvant mFOLFIRINOX before preoperative (preop) chemoradiation (CRT), with TME-surgery and adjuvant chemotherapy (CT) in resectable locally advanced rectal cancer. **Methods:** PRODIGE 23 is a phase III multicenter randomized clinical trial. Eligible pts had cT3 or cT4, M0 rectal adenocarcinomas <15 cm from the anal verge, age 18-75 years, and WHO PS ≤ 1. Randomization was stratified by center, T stage, N status, tumor location, and perirectal fat extramural extension. Primary endpoint was 3-yr disease-free survival (DFS). Main secondary endpoints were ypT0N0 rate, overall survival (OS) and metastasis-free survival (MFS). 460 pts were required to observe 136 events to show a gain in 3-year DFS from 75% to 85% (HR=0.56) with a 2-sided α=0.05 and 90% power. HR and 95% CI were estimated by a stratified Cox proportional hazard model. Arm A pts received preop CRT (50 Gy, 2 Gy/fraction [fr]; 25 fr + capecitabine), surgery, then adjuvant CT for 6 months (mos). Arm B pts received 6 cycles of mFOLFIRINOX (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2, irinotecan 180 mg/m^2 D1, and 5-FU 2.4 g/m^2 over 46 h) every 14 days, followed by the same preop CRT, surgery and 3 mos of adjuvant CT. Adjuvant CT consisted of mFOLFOX6 or capecitabine, depending on the centre's choice for all pts. Imaging work-up, operative and pathology reports were centrally reviewed. **Results:** (ITT) Between 6/2012 and 6/2017, 230 and 231 pts were randomly assigned in Arm A/B, respectively by 35 participating centers. Pts characteristics were well balanced. Neoadjuvant mFOLFIRINOX and CRT in both arms were well tolerated. Compliance to CRT and to adjuvant CT was not hampered by neoadjuvant CT. Surgical morbidity did not differ between the 2 arms. The ypT0N0 rate was 11.7 vs 27.5% in Arm A/B ($p<0.001$). Median follow-up was 46.5 mos. 136 DFS events was reported. 3-yr DFS was significantly increased in arm B (HR 0.69, 95% CI 0.49-0.97, p=0.034): 68.5% (CI: 61.9-74.2) vs 75.7% (CI: 69.4-80.8) in arm A/B. The subgroup analysis showed no evidence of heterogeneity of the effect size of treatment on DFS. 3-yr MFS was also significantly higher in arm B: 71.7 in arm A vs 78.8% (HR 0.64, CI 0.44-0.93, $p<0.02$) in arm B. 3-yr OS was 87.7 vs 90.8% (HR 0.65, CI 0.40-1.05, p=0.077) in arm A/B, with 54.2% of the pts with recurrence being alive. **Conclusions:** Neoadjuvant mFOLFIRINOX plus CRT is safe, and significantly increased ypCR rate, DFS and MFS. OS data are not mature. Clinical trial information: NCT01804790. Research Sponsor: FRENCH CANCER INSTITUTE - INCA - PHRC, Other Foundation.

4008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Preliminary results of the organ preservation of rectal adenocarcinoma (OPRA) trial. *First Author: Julio Garcia-Aguilar, Colorectal Service, Department of Surgery, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: Organ preservation (OP) with a watch and wait strategy (WW) and total neoadjuvant therapy (TNT) are new treatment paradigms for patients with locally advanced rectal cancer. The safety and efficacy of WW and of TNT have not been studied prospectively. **Methods:** Patients with MRI stage II and III rectal adenocarcinoma were randomized to 4 months of FOLFOX or CAPEOX before (Induction) or after (Consolidation) fluorouracil or capecitabine based chemoradiotherapy (CRT). Patients were re-staged 8-12 weeks after finishing TNT with digital rectal exam, flexible sigmoidoscopy and MRI. Patients with complete or near-complete clinical response were offered WW. Those with incomplete response had total mesorectal excision. The trial was designed so that each arm served as its own single-stage study that discriminates between 3-year disease-free survival (DFS) rates of 75% (historical null) and 85%, with 86% power, and a two-sided type I error of 5%. Secondary objectives included comparing DFS, OP, and distant metastasis-free survival (DMFS) rates between the two arms using the log-rank test. **Results:** Of 324 patients enrolled, 307 (152 I, 155 C) are currently evaluable for the time-to-event analysis as of 2/1/2020. Median follow-up is 2.1 years; 52 DFS events were observed. Patient demographics and tumor characteristics were generally balanced across the two arms. Full compliance with systemic chemotherapy was 82% and 81% for the I- and C-arms, respectively. The median radiation dose was 5400 cGy for both arms. Table shows 3-y DFS, DMFS, and OP rates. **Conclusions:** A WW strategy for patients with locally advanced rectal cancer that achieve a clinical complete response to TNT results in organ preservation for a high proportion of patients without compromising survival. Up-front CRT followed by consolidation chemotherapy resulted in a numerically higher WW rate compared to induction chemotherapy followed by CRT. Clinical trial information: NCT02008656. Research Sponsor: U.S. National Institutes of Health.

3-year rates with 95% CI.

	Induction		Consolidation		p*
DFS	78%	(70%,87%)	77%	(69%,86%)	0.90
DMFS	81%	(74%,90%)	83%	(76%,91%)	0.86
OP	43%	(35%,54%)	58%	(49%,69%)	0.01

Circulating tumor DNA to detect minimal residual disease, response to adjuvant therapy, and identify patients at high risk of recurrence in patients with stage I-III CRC. *First Author: Noelia Tarazona, Department of Medical Oncology, INCLIVA Biomedical Research Institute, University of Valencia, Instituto de Salud Carlos III, CIBERONC, Valencia, Spain*

Background: The clinical utility of tracking circulating tumor DNA (ctDNA) as a non-invasive biomarker for detecting minimal residual disease (MRD) and stratifying patients based on their risk of developing relapse has been well established in colorectal cancer (CRC). This study evaluates the detection and longitudinal monitoring of ctDNA in CRC patients pre- and post-operatively, during and after adjuvant chemotherapy (ACT). **Methods:** The prospective, multicenter cohort study recruited patients (n = 193) diagnosed with resected stage I-III CRC. Plasma samples (n = 1052) were collected at various timepoints with a median follow up of 21.6 months (4.6-38.5 months). Individual tumors and matched germline DNA were whole-exome sequenced and somatic mutations identified. Multiplex PCR assays were designed to 16 tumor-specific single-nucleotide variants to track ctDNA in plasma samples. The study evaluated the relationship between ctDNA status and clinical outcomes including radiologic imaging. Cox regression was used to calculate recurrence-free survival (RFS) in patients stratified by ctDNA status postoperatively and post-ACT. Multivariable analysis was performed with all clinical variables. Best model was selected according to Akaike Information Criterion. **Results:** Pre-operatively ctDNA was detected in 90% (n = 166/185) of the patients. Post-operative ctDNA status prior to ACT was assessed in 152 patients, of which 9.2% (14/152) were identified to be MRD-positive and 78.5% (11/14) eventually relapsed. In contrast, 10.1% (14/138) of MRD-negative cases relapsed (HR: 16.53; 95% CI: 7.19-38.02; $p < 0.001$). Longitudinal ctDNA-positive status, post-ACT (n = 84) and post definitive therapy (n = 139) was associated with a 27.92 HR (95% CI: 9.16-85.11; $p < 0.001$) and a 47.52 HR (95% CI: 17.34-130.3.; $p < 0.001$), respectively. In the multivariable analysis, longitudinal ctDNA status was the only significant prognostic factor associated with RFS (HR: 53.19, 95% CI: 18.87-149.90; $p < 0.001$). Serial ctDNA analysis detected MRD up to a median of 9.08 months (0.56-16.5 months) ahead of radiologic relapse with a sensitivity of 79.1% and specificity of 99%. **Conclusions:** Postoperative ctDNA analyses detect patients with high-risk of recurrence, with near 100% specificity. Early detection of MRD and longitudinal monitoring of ctDNA could guide treatment decisions. Intervention trials to assess the clinical benefit of ctDNA use are underway. A new prognostic and predictive tool to enhance shared decision making in stage III colon cancer. *First Author: Alberto F. Sobrero, Ospedale Policlinico San Martino IRCCS, Genoa, Italy*

Background: Survival outcomes in patients with stage III colon cancer varies widely according to T-N sub-stages. The ability to estimate the benefit of each therapeutic option (surgery alone, fluoropyrimidines alone, oxaliplatin-based doublet for either 3 or 6 months) in each T-N subgroup within stage III, may provide more accurate information helping doctors and patients in the complex shared decision-making process surrounding adjuvant therapy. **Methods:** Theoutcomedata of 12,834 patients with stage III colon cancer enrolled in the IDEA trial served as our database. Patients were categorized in 16 sub-stages, based on the T-N categories. We created a meta-regression model to predict the expected 3-year DFS within each T-N sub-stage and hence the 5-year DFS rates were projected. We then evaluated the efficacy of each therapeutic option in every sub-stage, working backward by subtraction, using an average of the HRs reported in the pertinent trials publication as conversion factor. **Results:** Large differences in 3-year DFS rate were observed among the subgroups, ranging from 95% (T1N1a) to 29% (T4N2b) in the overall population. The contribution to outcome of each therapeutic option in this setting varied widely across sub-stages. According to our model, patients with T1N1a cancers have a projected 5-year DFS of 85% with surgery alone. Adjuvant fluoropyrimidine alone results in 4.2% absolute DFS gain; an additional 1.7% and 0.6% gain is seen with oxaliplatin for 3 and 6 months, respectively. Patients with T4N2b cancers show a 4.7% 5-year DFS with surgery alone, and a 7.1%, 5.0%, 2.1% increase with the aforementioned adjuvant options, respectively. **Conclusions:** The resulting overlay bar graph gives patients and doctors the projected relative benefit of each treatment option and may substantially help the shared decision-making process. Impact of high-risk features on disease-free survival (DFS) in patients (pts) with high-risk stage II colon cancer (CC) in ACHIEVE-2 trial as part of the IDEA collaboration. *First Author: Dai Manaka, Kyoto Katsura Hospital, Kyoto, Japan*

Background: The IDEA collaboration for high-risk stage 2 colorectal cancer patients (pts) demonstrated that for CAPOX, 3 months was non-inferior to 6 months treatment, while for FOLFOX, 6 months was superior to 3 months treatment. We investigated the impact of high risk features on disease-free survival (DFS). **Methods:** ACHIEVE-2, one of the 4 IDEA studies (SCOT, TOSCA, ACHIEVE-2, HORG), was an open-label, multicenter randomized trial for high-risk stage II colon cancer. High risk features are defined as one or more: T4, inadequate nodal harvest < 12, poorly differentiated, clinical sign of obstruction and perforation or vascular invasion. The association of high risk features with DFS were measured by Cox regression analyses. **Results:** Between 2014 and 2017, ACHIEVE-2 enrolled 525 pts, out of whom 514 pts were the modified ITT (mITT) population; 432 received CAPOX (84.0%) and 82 did mFOLFOX6 (16.0%). High-risk features included 35.8% of T4, 12.8% of inadequate nodal harvest, 11.5% of poorly differentiated, 19.3% of obstruction, 6.4% of perforation and 87.5% of vascular invasion; 47.3% had one features, 35.2% had two, 14.6% had three, and 2.9% had four or more. With a median follow-up of 36.1 months, 3-year DFS rates were 88% in both arms, with a hazard ratio (HR) of 1.12 (95% CI, 0.67-1.87, p=0.67). In multivariate analysis, T4 (HR 3.77 [2.18-6.53], $p< 0.0001$) and inadequate nodal harvest (HR 2.98 [1.59-5.59], p= 0.0006) remained independent significant negative prognostic factors. The 3-year DFS rates in T4 and Non-T4 diseases were 78% and 94% ($p<0.0001$), while 3-year DFS rate in pts with inadequate and adequate nodal harvest were 77% and 90% (p=0.0059). No interaction was observed between treatment duration and T4 or inadequate nodal harvest. **Conclusions:** Our findings indicated the relative impact of high risk features on DFS varies across factors; T4 and inadequate nodal harvest < 12 were more significant than the others. Our results must be interpreted within the combined analysis as well as within the reproducibility of results across the 4 trials. Clinical trial information: 000013036. Research Sponsor: None.

Improving the AJCC/TNM staging classification for colorectal cancer: The prognostic impact of tumor deposits. *First Author: Oliver Peacock, Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Identification of tumor deposits (TD) currently plays a limited role in staging for colorectal cancer (CRC) other than for N1c designation. The aim of this study was to determine the prognostic impact, beyond AJCC N1c designation, of TD among primary CRC patients. **Methods:** Patients with stage 1 to 3 primary CRC diagnosed between 2010 and 2015 were identified from the Surveillance, Epidemiology and End Results (SEER) database. Cancer specific survival (CSS) stratified by TDs and nodal status was calculated, and Kaplan-Meier method and multivariable COX proportional hazards regression analyses were performed. **Results:** A total of 74,494 patients with primary CRC were identified. Mean age was 66.4 (SD+/-13.2) years, 36,988 (49.7%) were female and 40,651 (54.6%) were right-sided. TDs were present in 4,481 patients (6.0%) and 26,603 (35.7%) had lymph node metastases. The presence of TDs were significantly associated with adverse tumor characteristics including advanced pathological stage, nodal and metastasis status, higher grade and perineural invasion. Incorporating TDs into each nodal status was independently associated with worse CSS and supported reclassification of nodal status to incorporate TDs following multivariable regression analysis as outlined in the table. Following multivariable regression analysis, the proposed AJCC nodal reclassification incorporating TDs, in combination with tumor stage was a strong predictor of CSS, and also represents a new summary staging. **Conclusions:** TDs are an independent predictor of worse outcome in CRC. The presence of TDs have distinctly different CSS and these data support modification of the current N classification. This study proposes a reclassification of the AJCC system for CRC to incorporate TDs and informs an updated node and summary stage. Research Sponsor: None.

Proposed AJCC Reclassification	Includes current & modification	Adjusted HR (95% CIs)
N0	N0	1.00
N1a	N1a TD-ve	1.90 (1.78-2.05)
N1b	N1b TD-ve, N1c	2.63 (2.48-2.80)
N1c	Removed	-
N2a	N2a TD-ve, N1a-b TD+ve	3.73 (3.50-3.98)
N2b	N2a TD +ve, N2b TD-ve	6.12 (5.73-6.54)
N3	N2b TD+ve	7.91 (6.94-9.01)

FOxTROT: neoadjuvant FOLFOX chemotherapy with or without panitumumab (Pan) for patients (pts) with locally advanced colon cancer (CC). *First Author: Jenny F. Seligmann, University of Leeds, Leeds, United Kingdom*

Background: FOxTROT has reported marked down-staging, reduced perioperative morbidity and a trend towards fewer recurrences with 6 wks of oxaliplatin-fluoropyrimidine neoadjuvant chemotherapy (NAC) in CC (Seymour, ASCO 2019 abstract 3504). Using updated data, we investigate the contribution of panitumumab (Pan) and tumour markers to efficacy of NAC. **Methods:** 1053 pts with radiologically-staged T3-4, N0-2, M0 CC were randomly allocated (2:1) to either 6 wks of NAC and 18 wks of postoperative adjuvant chemotherapy (AC) or 24 wks of AC. 279 pts with *RAS*-wt tumours were also randomised 1:1 to receive Pan or not with NAC. The primary endpoint was freedom from recurrence or residual disease at 2 years for NAC vs AC, and depth of extramural spread for the Pan randomisation; secondary endpoints include safety, histological downstaging, CC-specific survival and OS. **Results:** Of 699 allocated pre-and-postoperative chemotherapy, 674 (97%) started and 612 (88%) completed NAC. 684/699 (97.8%) pre-and-postoperative and 349/354 (98.6%) control patients underwent tumour resection. There was marked T- and N-down-staging and tumour regression with NAC (all $p<0.001$). There were fewer disease recurrences within 2 years in the NAC than AC group: 15.6% (109/698) vs 19.5% (69/354), RR=0.76 (95%CI 0.56-1.02), P=0.07. Response to NAC was significantly ($p<0.001$) less in MMR-deficient (dMMR) than MMR-proficient (pMMR) tumours: 7%(8/115) vs 23%(128/553) moderate or greater histological tumour regression. Reductions in 2-year recurrence were also seen only in pMMR tumours [RR=0.72 (0.52-1.00), p=0.05], with no apparent benefit in dMMR tumours: RR=0.94 (0.43 to 2.07), p=0.9]. Analyses of panitumumab will be presented. **Conclusions:** Six weeks of NAC for operable CC can be delivered safely, with marked histopathological down-staging, and may result in better disease control at 2 years in pMMR disease. Clinical trial information: 87163246. Research Sponsor: Cancer Research UK, Pharmaceutical/Biotech Company.

Tailored treatment strategy for locally advanced rectal carcinoma: Five-year results of the French phase II, randomized, multicenter GRECCAR4 trial. *First Author: Philippe Rouanet, Institut Régional du Cancer de Montpellier, Montpellier, France*

Background: Preoperative radiochemotherapy and total mesorectal excision are the standard-of-care for locally-advanced rectal carcinoma, but some patients are over- or undertreated. Our phase II study assessed the feasibility of tailored radiochemotherapy, based on tumor response to induction high-dose chemotherapy (FOLFIRINOX). **Methods:** We enrolled 206 patients; good responders after chemotherapy (≥75% tumor volume reduction) were randomly assigned to immediate surgery (arm A) or standard radiochemotherapy (Cap 50: 50 Gy and oral capecitabine daily) plus surgery (arm B). Poor responders were randomly assigned to Cap 50 (arm C) or intensive radiochemotherapy (Cap 60 (60 Gy irradiation), arm D) before surgery. **Results:** After induction treatment, 194 patients were classified as good (n=30, 15%) or poor (n=164, 85%) responders, and included in arms A and B (16 and 14 patients) or C and D (113 and 51 patients). The primary objective was obtained: (90% CI) R0 resection rates in the four arms respectively were 100% (74–100), 100% (85–100), 83% (72–91), and 88% (77–95). At 5 years: overall survival 90% (CI: 47.3-98.5), 93.3% (CI: 61.3-99.0), 84.3% (CI: 71.0-91.8), 86.1% (CI: 71.6-93.5); disease-free survival 80% (CI: 40.9-94.6), 89.5% (CI: 64.1-97.3), 72.9% (CI: 58.5-82.9), 72.8% (CI: 57.7-83.2); local recurrence 0, 0, 2.1% (CI: 0.3-13.9), 9.3% (CI: 3.6-23.0); metastasis 20% (CI: 5.4-59.1), 10.5% (CI: 2.7-35.9), 18% (CI: 31.8-94.6), 18.8% (CI: 10.2-33.0). Late morbidity and quality of life evaluations showed no significant difference between arms. **Conclusions:** Tailoring preoperative radiochemotherapy based on induction treatment response is safe and promising. Early tumoral response to induction chemotherapy can discriminate tumor prognosis. Clinical trial information: NCT01333709. Research Sponsor: Grant INCa-DGOS_5506: PHRC-K 2012–112.

FOLFOXIRI/bevacizumab (bev) versus doublets/bev as initial therapy of unresectable metastatic colorectal cancer (mCRC): A meta-analysis of individual patient data (IPD) from five randomized trials. *First Author: Chiara Cremolini, Department of Translational Research and New Technologies in Medicine and Surgery, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy*

Background: Several randomized trials demonstrated that intensifying the upfront chemotherapy in combination with bev is beneficial for mCRC patients with an increased incidence of some adverse events. All trials had primary endpoints other than OS, and a proper estimation of the magnitude of the OS benefit from FOLFOXIRI/bev versus doublets (FOLFIRI or FOLFOX)/bev is currently lacking. Within each trial, subgroup analyses failed to identify predictors of benefit from the intensified therapy. To test OS with higher power compared to single trials, and to explore interaction of treatment effect with main patients' and disease characteristics, we performed an IPD meta-analysis. **Methods:** IPD were collected from 5 randomized trials: CHARTA (NCT01321957), OLIVIA (NCT00778102), STEAM (NCT01765582, only combined FOLFOXIRI/bev and FOLFOX/bev arms), TRIBE (NCT00719797) and TRIBE2 (NCT02339116). Primary endpoint was OS. Secondary endpoints included PFS, objective response rate (ORR), R0 resection rate, G3/4 adverse events, and subgroup analyses. All statistical analyses were by intention-to-treat, stratified by trial. **Results:** 1697 pts randomized to FOLFOXIRI/bev (N=846) or doublets/bev (N=851) were included. Among pts in the doublets/bev group, 595 (70%) received FOLFOX/bev and 256 (30%) FOLFIRI/bev. At a median follow up of 39.9 mos, pts assigned to FOLFOXIRI/bev reported significantly longer OS than those assigned to doublets/bev (median OS 28.9 vs 24.5 months; HR 0.81 [95%CI 0.72-0.91], $p<0.001$), with no significant heterogeneity among trials ($p=0.39$; $I^2=2\%$). The estimated 5-yr OS was 22.3% vs 10.7% ($p<0.001$). No significant interaction effect between treatment arm and OS was demonstrated in terms of metastatic spread (liver-limited vs. not liver-limited p=0.665), primary side (p=0.656), and *RAS/BRAF* status (p=0.337). Pts assigned to FOLFOXIRI/bev achieved longer PFS (median PFS 12.2 vs 9.9 months; HR 0.74 [95%CI 0.67-0.82], $p<0.001$), higher ORR (64.5% vs 53.6%, $p<0.001$), higher R0 resection rate (16.4% vs 11.8%, p=0.007), and experienced higher rates of G3/4 neutropenia ($p<0.001$), febrile neutropenia (p=0.019), mucositis (p=0.024), nausea (p=0.016), and diarrhea ($p<0.001$). **Conclusions:** FOLFOXIRI/bev determines a clinically and statistically significant improvement of mCRC patients' OS vs doublets/bev with a meaningful effect also on 5-yr OS, PFS, ORR and R0 resection rate. No significant heterogeneity among explored subgroups was found. Research Sponsor: None.

Consensus molecular subtypes and CRCassigner classifications in metastatic colorectal cancer (mCRC): Prognostic and predictive impact in the TRIBE2 study. *First Author: Beatrice Borelli, Department of Translational Research and New Technologies in Medicine and Surgery, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy*

Background: The TRIBE2 study (NCT02339116) recently demonstrated the superiority of upfront FOLFOXIRI/bevacizumab (bev) when compared to a pre-planned strategy of doublets/bev in molecularly unselected but mostly (74%) *RAS*/*BRAF* mutant mCRC patients. The Consensus Molecular Subtypes (CMS) and CRCAssigner (CRCA) demonstrated prognostic value in multiple studies, but their predictive role has not been established so far. Given the poor prognosis associated with early stage mesenchymal/stem-like subtypes, we hypothesized that the CMS/CRCA classifiers could predict benefit from the upfront intensified strategy in patients included in the TRIBE2 study. **Methods:** Untreated formalin-fixed paraffin-embedded samples were classified into CMS/CRCA subtypes using a custom nCounter assay (NanoString Technologies). The impact of subtypes on progression free survival (PFS), progression free survival 2 (PFS2, defined as the time from randomization until the second evidence of disease progression) or overall survival (OS) was evaluated in the profiled population. **Results:** 426 and 428 (63%) patients enrolled in the TRIBE2 study were profiled according to CMS and CRCA classifications, respectively. The distribution of CMS/CRCA subtypes differed according to primary tumour site (both $p < 0.001$ for CMS/CRCA) and *RAS*/*BRAF* mutational status (both $p < 0.001$ for CMS/CRCA). Significant associations of both CMS/CRCA classifiers with PFS, PFS2 and OS were demonstrated (Table). The effect of treatment intensification was independent of CMS subtypes (p for interaction for PFS/PFS2/OS: ns). Significant interaction effect between CRCA subtypes and treatment arm was reported in terms of PFS ($p = 0.017$), PFS2 ($p = 0.010$) and OS ($p = 0.008$). The benefit from the intensification of the upfront chemotherapy seemed more relevant in the stem-like (PFS, HR = 0.60; p = 0.03) and mixed subtypes (HR = 0.44; p = 0.002). **Conclusions:** CMS subtypes have a prognostic role in mCRC independently of *RAS*/*BRAF* status. CRCA classification may help identifying subgroups of patients who may derive a more substantial benefit from upfront FOLFOXIRI/bev. Research Sponsor: GONO Foundation.

First-line biological agents plus chemotherapy in elderly patients with metastatic colorectal cancer: A retrospective pooled analysis. *First Author: Pilar Garcia-Alfonso, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: Biological agents, in combination with chemotherapy, are recommended as first-line treatment of metastatic colorectal cancer (mCRC); however, evidence guiding appropriate management of elderly patients with mCRC is lacking. This study compared the efficacy and safety outcomes in older versus younger patients with mCRC who received first-line biological therapy. **Methods:** This retrospective analysis used pooled data from five Spanish TTD collaborative group studies of adults with advanced CRC who received first-line treatment with bevacizumab, cetuximab or panitumumab, stratified by age (≥65 vs < 65 years). Endpoints included progression-free survival (PFS), overall survival (OS), overall response rate (ORR) and safety. **Results:** In total, 999 patients from five studies were included in the analysis; 480 (48%) were aged ≥65 years and 519 (52%) were aged < 65 years; 733 (73.37%) were treated with bevacizumab, 189 (18.92%) received cetuximab and 77 (7.71%) received panitumumab. Median PFS did not significantly differ between patients aged ≥65 versus < 65 years (9.9 vs 9.4 months; hazard ratio [HR] 1.01; 95% confidence interval [CI] 0.88–1.17). Median OS was significantly shorter in older versus younger patients (21.3 vs 25.0 months; HR 1.21; 95% CI 1.04–1.41; P = 0.0132). There was no significant difference between older versus younger patients in ORR (59% vs 62%). Older patients experienced more treatment-related grade ≥3 adverse events. **Conclusions:** Biological agents are an effective first-line treatment option for elderly patients with mCRC, with comparable efficacy in PFS and ORR to that observed in younger patients and a manageable safety profile. Research Sponsor: Roche Farma SA.

CodeBreak 100: Activity of AMG 510, a novel small molecule inhibitor of $KRAS^{G12C}$, in patients with advanced colorectal cancer. *First Author: Marwan Fakih, City of Hope National Medical Center, Duarte, CA*

Background: Kirsten rat sarcoma viral oncogene homolog *(KRAS)* p.G12C mutation is associated with poor prognosis in colorectal cancer (CRC). AMG 510 is a first-in-class small molecule that specifically and irreversibly inhibits $KRAS^{G12C}$ by locking it in the inactive guanosine diphosphate-bound state. In a previous interim analysis of the phase 1, first-in-human trial of AMG 510, we observed a favorable safety profile and preliminary antitumor activity in patients (pts) with advanced solid tumors harboring *KRAS* p.G12C. Here, we present updated data in pts with CRC. **Methods:** Key inclusion criteria were *KRAS* p.G12C mutation identified through molecular testing, measurable disease, and progression on standard therapy. Primary endpoint was safety. Secondary endpoints were objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), as assessed per RECIST 1.1, and overall survival (OS). Oral daily doses of 180, 360, 720, and 960mg were tested in the dose escalation phase, and 960mg dose was selected for the expansion phase. **Results:** As of Jan 8, 2020, 42 pts with CRC (21 female [50%], median age: 57.5 years [range: 33–82]) were enrolled and dosed (25 on 960mg). All pts received prior systemic therapies; 19 pts (45.2%) received > 3 prior lines. Median follow-up was 7.9 months (mos) (range: 4.2–15.9). 13 pts (31.0%) died, and 8 pts (19.0%) remained on treatment (tx). 22 (52.4%) and 8 (19.0%) pts had remained on tx for more than 3 and 6 months, respectively. Progressive disease was the most common reason for tx discontinuation. 20 pts (47.6%) had tx-related adverse events (TRAEs): 18 (42.9%) had grade 2 or lower TRAEs; 2 (4.8%) had grade 3 TRAEs, which were diarrhea (2.4%) and anemia (2.4%). There were no dose-limiting toxicities, fatal TRAEs, or TRAEs leading to tx discontinuation. Overall, ORR and DCR were 7.1% (3/42) and 76.2% (32/42), respectively. At 960mg, ORR and DCR were 12.0% (3/25) and 80.0% (20/25). 3 pts with PR had duration of response of 1.5, 4.2, and 4.3 months, respectively, and their responses were still ongoing at data cutoff. In all pts treated with all doses, median duration of stable disease was 4.2 mos (range: 2.5[+]–11.0). PFS/OS will be reported. **Conclusions:** In pts with heavily pretreated *KRAS* p.G12C mutant CRC, AMG 510 monotherapy was well tolerated, with the majority of pts achieving disease control. Study is ongoing. Clinical trial information: NCT03600883. Research Sponsor: Amgen Inc.

REGOMUNE: A phase II study of regorafenib plus avelumab in solid tumors—Results of the non-MSI-H metastatic colorectal cancer (mCRC) cohort. *First Author: Sophie Cousin, Department of Medicine, Institut Bergonié, Bordeaux, France*

Background: Regorafenib (R) has been shown to modulate anti-tumor immunity by different mechanisms including reduction of tumor-associated macrophages (TAMs). Synergy between R and anti–PD-1/PD-L1 antibodies has been shown in pre-clinical models. **Methods:** This is a single-arm open-label multicentric phase II trial assessing the efficacy and safety of R (160 mg QD 3weeks/4) + Avelumab (A) (10 mg/kg every 2 weeks) combination in non MSI-H mCRC patients (pts). The primary endpoint was the confirmed objective response rate, based on central review according to RECIST 1.1. Secondary endpoints included: 1-year progression free survival (PFS), 1-year overall survival (OS), and Safety using NCI-CTCAE v5.0. Correlative studies were planned from pts tumor samples obtained at baseline and C2D1. **Results:** Between Nov. 2018 and Oct. 2019, 48 pts were enrolled in 4 centers. Median age was 61.8 (range: 26.3-78.7). Median follow-up was: 7.2 months. Median number of previous treatment lines was: 3 (range: 1-7). 41 (87.2%) pts experienced at least 1 dose modification or treatment interruption. The most common grade 3/4 adverse events were palmar-plantar erythro-dysesthesia syndrome (29.8%), hypertension (23.4%) and diarrhea (12.8%). No death was related to the treatment. Among 40 pts who had at least one imaging tumor assessment, 12 (30%) had reduction in tumor burden. Best response was stable disease for 23 pts (57.5%) and progressive disease for 17 pts (42.5%). The median PFS and OS were 3.6 months ($CI_{95\%}$: [1.8 – 5.4]) and 10.8 months ($CI_{95\%}$: [5.9 – NA]) respectively. Baseline tumor samples and paired biopsies were available for 24 and 15 pts respectively. High infiltration by TAMs at baseline was significantly associated with adverse outcome (PFS: 1.9 vs 3.7 months, p=0.045; OS: 4.8 months vs NR, p=0.027). Increased tumor infiltration by CD8+ at C2D1 compared to baseline was significantly associated with better PFS (p=0.011). Combining low TAMs infiltration and low tumor cells to CD8+ T cells distance enabled the identification of a subgroup of pts (n= 6/24, 25%) more likely to benefit from R+A combination: median PFS: 5.3 vs 1.9 months (p=0.037); median OS: NR vs 5.3 months (p=0.02). **Conclusions:** The R+A combination achieved PFS and OS that compared favourably with historical data of R alone in this clinical setting. High-resolution analysis of tumor samples identified a composite score based on TAMs infiltration and tumor cell to CD8+ T cells distance which could be used as a biomarker in further studies investigating this approach in mCRC pts. Clinical trial information: NCT03475953. Research Sponsor: Bayer and Merck.

Pembrolizumab for previously treated advanced anal squamous cell carcinoma: Pooled results from the KEYNOTE-028 and KEYNOTE-158 studies. *First Author: Aurelien Marabelle, Gustave Roussy, Université Paris-Saclay, Villejuif, France*

Background: Patients (pts) with anal squamous cell carcinoma (ASCC) have poor outcomes and few treatment options. We report a pooled analysis of pembrolizumab (pembro) antitumor activity and safety in the ASCC cohorts of the multicohort studies KEYNOTE-028 (NCT02054806; phase 1b) and KEYNOTE-158 (NCT02628067; phase 2), providing a robust sample size and longer follow-up. **Methods:** Eligible pts were aged ≥18 y with histologically/cytologically confirmed metastatic/unresectable ASCC, had prior failure of/intolerance to standard therapy or no standard therapy options, measurable disease (RECIST v1.1), ECOG PS 0/1, and a tissue sample evaluable for PD-L1/biomarkers (KEYNOTE-028 required PD-L1 positivity). Baseline PD-L1 expression was assessed using a prototype IHC assay (QualTek) in KEYNOTE-028 and the PD-L1 IHC 22C3 pharmDx assay (Agilent Technologies) in KEYNOTE-158. Pts received pembro 10 mg/kg Q2W (KEYNOTE-028) or 200 mg Q3W (KEYNOTE-158) for 2 y or until PD/unacceptable AEs. The primary endpoint in both studies was ORR (per RECIST v1.1). Secondary endpoints were duration of response (DOR), PFS, OS, and safety. **Results:** 137 pts with ASCC were treated in KEYNOTE-028 (n = 25) or KEYNOTE-158 (n = 112) and were included in this analysis (median age, 61 y; 83.2% women; 73.0% had PD-L1–positive tumors). Median follow-up was 11.7 mo; 124 pts (90.5%) had discontinued treatment. ORR (95% CI) was 10.9% (6.3%–17.4%). 8 pts had CR and 7 had PR. ORR (95% CI) by PD-L1 status was 14.0% (7.9%–22.4%) in the PD-L1 positive group and 3.3% (0.1%–17.2%) in the PD-L1 negative group. Among all treated pts, median DOR was not reached (range, 6.0+ to 57.5+ mo). By Kaplan-Meier estimation, 84.6% of responders had a DOR ≥24 mo. Median PFS was 2.1 mo (95% CI, 2.0–2.1) and median OS was 11.7 mo (95% CI, 8.8–14.5). The 12-mo PFS and OS rates were 14.5% and 47.4%. 85 pts (62.0%) had +1 treatment-related AE, 24 pts (17.5%) with grade 3–4 events (no grade 5 events). 32 pts (23.4%) had immune-mediated AEs; 2 pts (1.5%) had infusion related reactions. **Conclusions:** In pts with previously treated advanced ASCC, pembro showed durable antitumor activity, particularly in pts with PD-L1–positive tumors, and manageable toxicity. Clinical trial information: NCT02054806 (KEYNOTE-028), NCT02628067 (KEYNOTE-158). Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4021 Poster Session (Board #13), Fri, 8:00 AM-11:00 AM

Pre- versus postoperative CAPOX plus bevacizumab (CAPOX-Bev) for resectable liver metastases from colorectal cancer (CLM): A randomized phase II/III trial (HiSCO-01). *First Author: Yuji Takakura, Department of Gastroenterological and Transplant Surgery, Hiroshima University, Hiroshima, Japan*

Background: The role of neoadjuvant chemotherapy, particularly for those with initially resectable CLM, is controversial. And the optimal regimen and duration to be used in the neoadjuvant setting is not established. We conducted prospective, multicenter, randomized phase II/III study to assess pre-operative 8 cycles of CAPOX-Bev (arm A) plus radical surgery compared with post-operative 8 cycles of CAPOX-Bev (arm B) for patients (pts) with resectable CLM. **Methods:** The primary endpoint in the Phase II was completion rate of protocol treatment (more than 6 cycles of CAPOX-Bev plus R0 surgical resection) and PFS in the Phase III. The secondary endpoints were OS, ORR (arm A), liver damage (arm A), safety. The Phase III part was terminated due to slow enrollment. **Results:** 81 pts were enrolled from 10 centers between November 2010 and November 2017. The full analysis set consisted of 76 pts who started protocol treatment (arm A 37 vs. arm B 39). 76 pts had the following characteristics: median age 66 (27-80), median number of liver metastases 2 (1-14), 69.7% male, 67.1% synchronous and 94.7% primary resected. Completion rate of protocol treatment was 89.2% in arm A and 71.8% in arm B (p = .06). ORR was 63.9%, including 2 pts who had pathologically complete response (5.6%). Only 1 pts in arm A could not undergo surgery due to progression of disease. In the chemotherapy safety population, arm B was associated with more grade 3 neutropenia and grade 3 gastrointestinal disorder than arm A. The most frequent surgical adverse event was biliary fistula, with an incidence of 0% in arm A and 10.3% in arm B (p = .02). No patient died from treatment-related adverse events. The median follow-up time was 40 months. The rate of PFS at 3 years was 32.2% in arm A versus 38.5% in arm B (p = .99). **Conclusions:** Pre-operative 8 cycles of CAPOX-Bev is compatible with radical surgery, but may have no impact on progression-free survival compared with post-operative chemotherapy. Clinical trial information: UMIN000003783. Research Sponsor: None.

4022 Poster Session (Board #14), Fri, 8:00 AM-11:00 AM

Impact of empirically eliminating 5-fluorouracil (5-FU) bolus and leucovorin (LV) in patients with metastatic colorectal cancer (mCRC) receiving first-line treatment with mFOLFOX6. *First Author: Alexa Basilio, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Systemic chemotherapy with a 5-FU-based regimen, such as mFOLFOX6, is the preferred first line treatment option for mCRC. Due to hematologic toxicities associated with the 5-FU bolus component, providers may choose to eliminate it empirically in patients receiving palliative therapy. This study aimed to assess the impact of empirically eliminating the 5-FU bolus and LV from first line treatment with mFOLFOX6 in mCRC. **Methods:** This was a retrospective chart review of patients ≥ 18 years old with mCRC receiving palliative first line mFOLFOX6 chemotherapy with (bolus) or without (non-bolus) the 5-FU bolus and LV components from January 1, 2015 through August 31, 2019 at Moffitt Cancer Center. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), disease control rate (DCR) defined as partial response and stable disease at first scan, utilization of growth factor support and safety. **Results:** Data analysis cutoff was December 31, 2019, with 61 patients included in the bolus arm and 72 in the non-bolus arm. Median follow-up time was 21.8 months. No difference was found in median PFS (8.12 vs. 6.64 months, p=0.787) or OS (29.36 vs. 21.6 months, p=0.395) between the bolus and non-bolus arms, respectively. Observed DCR at first scan was similar between both arms (47.3% vs. 52.7%, p=0.44). Utilization of growth factor support was significantly higher in the bolus arm (73.7% vs. 26.3%, p=0.012). Fewer grade ≥ 3 treatment-related hematologic adverse events (AE) were seen in the non-bolus arm (37.7% vs. 22.2%, p=0.058) (table). **Conclusions:** This is the only study to date that analyzed the impact of empirically eliminating 5-FU bolus and LV from first line palliative therapy with mFOLFOX6 in mCRC. Results showed no significant difference in median PFS or OS. Despite reduced growth factor utilization, the non-bolus arm demonstrated a favorable safety profile with less treatment-related hematologic grade ≥ 3 AE. The results of this study warrant consideration of empirically eliminating 5-FU bolus and LV from the mFOLFOX6 regimen to avoid additive toxicities without negatively impacting efficacy. Research Sponsor: None.

Hematologic AE grade ≥ 3, n (%)	Bolus (n=61)	Non-bolus (n=72)
Neutropenia	12 (20)	9 (13)
Anemia	12 (20)	8 (11)
Thrombocytopenia	3 (5)	2 (3)

4023 Poster Session (Board #15), Fri, 8:00 AM-11:00 AM

Differential association of proton pump inhibitors with efficacy of capecitabine and 5-fluorouracil in metastatic colorectal cancer: A post-hoc analysis from AXEPT phase III trial. *First Author: Sun Young Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Proton pump inhibitors (PPIs) reportedly can impair the absorption of oral anticancer agents by potent acid suppression. Concomitant use of a PPI with capecitabine (Cap) was suggested to be associated with poor outcome in gastrointestinal cancers, however, the potential interaction has not been studied yet in a prospective randomized clinical trial comparing Cap with 5-fluorouracil (FU). We analyzed the differential impact of PPI use on Cap and FU using dataset from AXEPT trial, a phase III randomized trial that demonstrated non-inferiority of a modified XELIRI (mXELIRI; Cap plus irinotecan) with FOLFIRI (FU, leucovorin and irinotecan), both either with or without bevacizumab in patients (pts) with metastatic colorectal cancer (mCRC). **Methods:** From the per-protocol set (n = 620), pts with available information on concomitant medications (n = 482) were eligible for this sub-study. PPI use was defined as concomitant exposure of Cap and any PPI for 20% or more of the study period. The treatment-by-PPI-use interaction was examined adjusting to stratification factors including age, sex, country, performance status, number of metastatic sites, previous use of oxaliplatin, and concurrent bevacizumab treatment. **Results:** 49 (10.1%) pts were PPI users. Clinical characteristics were well balanced between the two groups differing in PPI use. In PPI users, the mXELIRI group tended to have poorer OS (hazard ratio [HR], 1.83; 95% confidence interval [CI], 0.96–3.48; p = 0.0644) compared with the FOLFIRI group. In contrast, within PPI non-users, OS of mXELIRI was better than that of FOLFIRI (HR, 0.76; 95% CI, 0.61- 0.95; p = 0.0162). Similarly, a trend of worse PFS with mXELIRI than with FOLFIRI was observed in PPI users (HR, 1.73; 95% CI, 0.94-3.21; p = 0.0798), but not in PPI non-users (HR, 0.90; 95%CI, 0.73 – 1.10; p = 0.2871). Treatment-by-PPI-use interaction was significant for OS (p = 0.0116) and PFS (p = 0.0415). No significant interactions were found between treatment and PPI use in terms of treatment failure, overall response, disease control, and grade 3–4 toxicities. **Conclusions:** There was a significant interaction between PPI use and treatment (Cap vs FU) in terms of OS and PFS in AXEPT dataset. This suggests that PPI use could impair the efficacy of Cap, but not that of FU. PPIs should be used with caution in pts with mCRC taking Cap. Clinical trial information: NCT01996306. Research Sponsor: Chugai Pharmaceutical and Hoffmann-La Roche.

4024 Poster Session (Board #16), Fri, 8:00 AM-11:00 AM

Cetuximab/irinotecan/5-FU +/-oxaliplatin or FOLFOXIRI +/- bevacizumab in patients with colorectal cancer and nonresectable liver metastases (AIO CELIM2-study). *First Author: Gunnar Folprecht, University Hospital Carl Gustav Carus, Dresden, Germany*

Background: EGFR based combinations and the triplet combination FOLFOXIRI are known to increase response rates compared to doublet combinations. **Methods:** Patients with colorectal cancer and non-resectable liver metastases were enrolled into the trial. RAS wild type patients were randomised to cetuximab/FOLFIRI or cetuximab/FOLFOXIRI, RAS/BRAF mutant patients were randomised to FOLFOXIRI with or without bevacizumab. The primary endpoint was response. Secondary endpoints included progression free and overall survival. The trial was closed early due to poor recruitment. **Results:** Between 2014 and 2018, ninety-two pts were enrolled into the study. 54 wild type pts were randomised into cetuximab based treatment with (28 pts) or without (26 pts) oxaliplatin, 38 RAS/BRAF mutant pts were randomised to receive FOLFOXIRI alone (18 pts) or plus bevacizumab (16 pts). Objective response was achieved in 21/26 pts (81 % [95 CI: 61 – 93 %]) with cet/FOLFIRI, 24/28 pts (86 % [95 CI: 67 – 96 %]) with cet / FOLFOXIRI, 13/1 8 pts (72 % [95 CI: 46 – 90 %]) with FOLFOXIRI and 14/ 20 pts (70 % [95 CI: 46 – 88 %]) with bev/FOLFOXIRI. Two pts with cet/ FOLFOXIRI and one pat with FOLFOXIRI achieved CR according to imaging. The median PFS was 12.7 [95 % CI: 7.2 – 18.2], 15.0 [95 % CI: 11.3 – 18.7], 17.5 [95 % CI: 8.0 – 27.1] and 15.0 [95 % CI: 11.4 – 18.5] months with cet/FOLFIRI, cet/FOLFOXIRI, FOLFOXIRI and bev/FOLFOXIRI. The median overall survival was 42 mo. [95 % CI: 28 – 55], 55 [95 % CI:41 – 68], 28 [95 % CI: 22 – 36] and 44 [95 % CI: 0 – 94] months with cet/ FOLFIRI, cet/FOLFOXIRI, FOLFOXIRI and bev/FOLFOXIRI. The frequency of grade $\geq$ 3 toxicity per arm (cet/FOLFIRI, cet/FOLFOXIRI, FOLFOXIRI and bev/FOLFOXIRI) was 29 %, 46 %, 56 %. 45 % for neutropenia/leukopenia, 11 %, 12 %, 28 %, 25 % for diarrhea and 29 %, 19 %, 6 % and 5 % for skin toxicities. **Conclusions:** High response rates were observed in patients with colorectal liver metastases with all regimens. The numerically highest response rate was observed in RAS wild type patients treated with cetuximab/ FOLFOXIRI. Clinical trial information: NCT01802645. Research Sponsor: Merck-Serono.

4025 Poster Session (Board #17), Fri, 8:00 AM-11:00 AM

Skeletal muscle loss under chemotherapy and its association with survival and systemic treatment toxicity in metastatic colorectal cancer: An AGEO prospective multicenter study. *First Author: Claire Gallois, Hopital Européen Georges Pompidou, Paris, France*

Background: We showed in a previous work that "Patient Generated-Subjective Global Assessment" (PG-SGA) was independently associated with survival and treatment toxicities in non-pretreated metastatic colorectal cancer (mCRC) patients. We have evaluated here if muscle mass in these patients can provide useful additional information for clinical practice. The objective of the present work was to evaluate the association between baseline sarcopenia, and the variation of the Skeletal Muscle Index (SMI) under treatment with survival and chemotherapy-related toxicities in our population of non-pretreated mCRC patients. **Methods:** This prospective multicenter observational study enrolled non-pretreated mCRC patients. Measurement of SMI was performed on routine CT scan at day 0 (D0) and day 60 (D60). PG-SGA score and other nutritional factors were collected at D0. Progression-free survival (PFS) and overall survival (OS) were calculated from treatment start. Treatment related toxicities were registered according to the NCI CTCAE v4.0. **Results:** 149 patients were included in eight French centers from 7/2013 to 11/2016. Sarcopenia at baseline was not significantly associated with survival outcomes or chemotherapy-related toxicities. The best cut-point value of SMI variation (between D0 and D60) for OS prediction obtained with a log-rank maximisation method was -14%. The decrease in SMI $>$ 14%, with a median follow-up of 23 months, was significantly associated with shorter PFS (6 vs 9 mo; HR 1.8, 95%CI 1.1-3.1, p = 0.02) and OS (8.5 vs 26 mo; HR 2.4, 95%CI 1.3-4.4, p = 0.004), independently of hypoalbuminemia and malnutrition defined by PG-SGA, in multivariate analysis. 40% of patients with a SMI decrease $>$ 14%, and 22% of patients with a SMI increase or stable or decrease $<$ 14% developed grade $\geq$ 2 clinical toxicities (OR 3.0, 95%CI 1.2-7.7, p = 0.02), but the difference was not statistically significant in multivariate analysis (OR 2.3. 95%CI 0.8-6.7, p = 0.1). **Conclusions:** To our knowledge, this study is the first study assessing the association of skeletal muscle loss with survival and treatment toxicities in patients with mCRC prospectively. In our population of non pre-treated mCRC patients, baseline sarcopenia was not associated with poor survival outcomes, but the decrease in SMI $>$ 14% during the first two months of treatment was significantly associated with decreased PFS and OS, independently of other prognostic and nutritional factors. High amphiregulin mRNA expression is a strong prognostic biomarker with response to cetuximab in FIRE-1, CIOX, and FIRE-3. *First Author: Arndt Stahler, Department of Medicine III, University Hospital, LMU Munich, Munich, Germany*

Background: Amphiregulin (*AREG*) and epiregulin (*EREG*) were discussed as biomarkers for treatment of metastatic colorectal cancer (mCRC). Data from randomized controlled trials (RCT) are limited. **Methods:** *AREG* and *EREG* mRNA expression by RTqPCR in relation to housekeeping genes were available from 688 patients of three RCT (FIRE-1, n = 192, FUFIRI vs. mIrOx; CIOX, n = 113, cetuximab + CAPIRI/CAPOX; FIRE-3, n = 383, FOLFIRI+cetuximab/bevacizumab) and were normalized to their respective range of each trial with median and 3rd quartile as threshold values. Kaplan-Meier estimated overall survival (OS) and progression-free survival (PFS). Cox regression analysis calculated hazard ratio (HR) and 95% confidence interval (95% CI). Overall response rate (ORR) was compared by chi square test. **Results:** Across all trials, high *AREG* mRNA expression appeared as strong prognostic biomarker for OS, PFS and ORR for all threshold values. In *RAS* wildtype patients, high *AREG* expression was associated with better OS and PFS for cetuximab but not bevacizumab treatment. (Table) No effects were seen for epiregulin when all trials were analysed together. **Conclusions:** High *AREG* mRNA expression appeared as strong prognostic biomarker in mCRC. Positive predictive information might exist for cetuximab treatment. Research Sponsor: None.

Prognostic characteristics of patients with benign mesenteric lymph node enlargement after surgical resection for colorectal cancer. *First Author: Fei Tian, Massachusetts General Hospital, Boston, MA*

Background: Patients with lymph node metastasis of colorectal cancer (CRC) have a greater risk of recurrence. However, the characteristics of benign mesenteric lymph node enlargement (BLNE) are not well documented. The aim of this study is to assess clinical and prognostic significance of BLNE in patients with CRC. **Methods:** 601 patients who underwent surgery for stage 0, I, II CRC from January 2010 to April 2014 were included and separated into two groups by presence of BLNE. Univariate and multivariate analyses were constructed to demonstrate prognostic factors between BLNE group (n = 275) and control group (n = 326). **Results:** The risk of recurrence in BLNE group after curative resection was significantly lower than control group, with the 1-, 3-, and 5-year disease-free survival rates being 98.2, 91.6, and 86.9 %, in BLNE group and 95.7, 86.2, and 78.2 %, in control group respectively (p = 0.004). The mortality in BLNE group was lower compared with non BLNE group (mean overall survival: 95.7$\pm$1.2 vs. 89.5$\pm$1.4 months, p = 0.001). Patients of BLNE group also had a higher percentage of younger age, family tumor history, left sided tumors and tumor size $\geq$4cm. Adjusted Cox regression showed BLNE was an independent prognostic factor for both disease free survival and overall survival (P= 0.003 and 0.001). **Conclusions:** The study indicates that BLNE can be a useful positive factor in predicting recurrence and long-term survival concerning CRC patients. This conclusion offers a new viewpoint about CRC genesis and progression. Research Sponsor: None.

Fruquintinib combination with sintilimab in refractory metastatic colorectal cancer patients in China. *First Author: Miaomiao Gou, PLA General Hospital, Beijing, China*

Background: Fruquintinib, a vascular endothelial growth factor receptor (VEGFR) inhibitor, is a new anti-cancer targeting drug independently developed in China for refractory metastatic colorectal cancer (mCRC). Because Regorafenib combined with nivolumab has a promising future in patients with refractory mCRC, we aim to evaluate the efficiency of combination of Fruquintinib with Sintilimab (a highly selective, fully human monoclonal antibody PD-1 mAb) in these patients. **Methods:** Fifty-two patients with refractory mCRC were given fruquintinib (3mg orally, once daily for 3 weeks, followed by 1 weeks off in 4 weeks cycles) and sintilimab (200mg intravenously, once every 3 weeks). Before treatment, peripheral blood samples were collected and next-generation sequencing was performed to detect the gene profile of patients. **Results:** The ORR was 15.38% (8/52), DCR was 57.6% (30/52), and mPFS was 108 days. The patients was divided into two groups according to their PFS: PFS $\geq$ 90 days and PFS $<$ 90 days. PFS was significantly worse in patients with the following mutations: AMER1 (p=0.0073), DNMT3A (p=0.0075), ETV5 (p=0.012), EWSR1 (p=0.016), FANCA (p=0.019), IKBKE (p=0.0073), NOTCH1 (p=0.015), STAG2 (p=0.012) and TCF7L2 (p=0.0073). It was also significantly worse in the patients had the abnormalities of complexity and coagulation cascades (p = 0.026) and pancreatic cancer pathway (p = 0.0098). **Conclusions:** Fruquintinib combined with Sintilimab seemed not resulted in a significant increase in ORR, DCR and OS in refractory mCRC. Certain mutational genes and abnormal pathway caused by some frameshift mutations may affect the efficacy. It is suggested that targeting these mutational genes and signaling pathway may be helpful to improve the efficacy of Fruquintinib combination with Sintilimab. Research Sponsor: None.

4029 Poster Session (Board #21), Fri, 8:00 AM-11:00 AM

Sex differences in efficacy and toxicity of first-line treatment of metastatic colorectal cancer (CRC): An analysis of 18,399 patients in the ARCAD database. *First Author: Anna Dorothea Wagner, Lausanne University Hospital, Lausanne, Switzerland*

Background: The clearance of 5-FU differs significantly between men (M) and women (W). Adjuvant chemotherapy (CT) for CRC has a higher toxicity in W. The impact of sex on efficacy and toxicity in first-line trials of metastatic CRC (mCRC) is unknown. **Methods:** We analyzed patient (pt) and tumor characteristics, toxicities (nausea (AE1), vomiting (AE2), diarrhea, neutropenia (AE3)) and efficacy (overall survival (OS), progression-free survival (PFS)) according to sex in the following treatment groups: A: CT alone, B: CT + bevacizumab, C: CT + EGFR-antibodies, with subgroup analyses in the CT alone group for single-agent, doublets and triplets, as well as irinotecan- and oxaliplatin-based regimens. Pts from trials with treatments still used today and all relevant data available were eligible. OS and PFS were assessed using Kaplan-Meier and Cox models adjusted for primary tumor location and performance status (PS). **Results:** We included 28 trials with 18.399 pts (11.352 M and 7.047 W). W were younger (61 vs. 63 years), had more often a PS of 1 (49 vs 45%), BRAF mutations (10 vs. 7%), right-sided tumors (42 vs. 35%) and less often rectal tumors (26 vs. 32%). Significant differences in toxicity are reported in table. Rates of diarrhea were similar. There was no sex disparity in OS in the predefined subgroups except for pts receiving triplets where OS was better in M (HR_{adj}=1.39 (1.05 - 1.85)). Median (interquartile range) OS in months for M and W was 16.7 (9.2-27.4) and 16.2 (8.9-27.2) in group 1, 21.9 (12.7-37.5) and 22.3 (12.9 – 39.0) in group 2, and 26.8 (14.6-45.3) and 24.8 (12.3-49.2) in group 3. HRs_{adj} (W vs M) (95% CI), p values for OS were 1.02 (0.96-1.09), .557, 0.92 (0.83-1.03), .142, 0.99 (0.85-1.14), .866. **Conclusions:** M and W with mCRC differ significantly regarding patient and tumor characteristics. The significant higher toxicity in W does not translate in a higher treatment efficacy. Apart from known sex differences in pharmacokinetics of 5-FU, differences in pharmacodynamics must be postulated. Research Sponsor: Fondation ARCAD.

4030 Poster Session (Board #22), Fri, 8:00 AM-11:00 AM

Real-world outcomes of patients with BRAF-mutated mCRC treated in the United States. *First Author: Matthew Braithwaite, University of Utah, Salt Lake City, UT*

Background: BRAF mutations portend a poor prognosis in metastatic colorectal cancer (mCRC). Recent trials have hypothesized that using more aggressive triplet-based chemotherapy regimens such as FOLFOXIRI in the frontline setting may improve outcomes in this patient population. In this study, we utilized real-world data to assess whether FOLFOXIRI is being used in the United States (US) and compared survival outcomes in BRAF mutated (BRAFmt) mCRC stratified by first line (1L) therapy. **Methods:** The nationwide Flatiron Health EHR-derived de-identified database was reviewed for patients diagnosed with mCRC between 2013 and 2018. Patients who had documented BRAF mutation testing and received a standard 1L therapy were included for analysis. Patients who did not have a visit or medication order within 90 days of metastatic diagnosis were excluded to ensure patients were engaged with care at the data-providing institution. Kaplan-Meier and Cox proportional hazard modeling were used to compare survival outcomes stratified by BRAF mutation status and 1L therapy received. **Results:** A total of 4,454 patients with documented BRAF mutational status were included, of which 3,988 (89.5%) were BRAF wild type (BRAFwt) and 466 (10.5%) were BRAFmt. Median OS was 15.4 months (mo) in the BRAFmt group compared to 28.1 mo in the BRAFwt group (HR 0.48, 95% CI 0.41- 0.56, p $<$ 0.001). Only 3% (n = 16) of BRAFmt patients received 1L FOLFOXIRI +/- bevacizumab with a median OS of 13.8 mo compared to 15.5 mo in patients receiving a chemotherapy doublet (FOLFOX, CAPEOX, or FOLFIRI) +/- bevacizumab (95% CI 4.9 – not reached vs 14.3 – 19.0, p = 0.38). In BRAFmt patients, multivariate analysis (MVA) did not detect a significant improvement in OS with the use of FOLFIRI plus bevacizumab (HR 0.88, 95% CI 0.50-1.56, p = 0.67) or FOLFOX/CAPEOX plus bevacizumab (HR 0.89, 95% CI 0.59 – 1.34, p = 0.58) when compared to chemotherapy doublet alone. A MVA comparing 1L therapies in the BRAFwt group did not detect a significant improvement in OS with bevacizumab plus chemotherapy doublet compared to chemotherapy doublet alone. When stratified by 1L treatment regimen, similar proportions of BRAFmt patients received second line therapy. **Conclusions:** This analysis of real-world data confirms the negative prognostic impact of BRAF mutations in mCRC and suggests that FOLFOXIRI has not been widely adopted in the management of these patients in the US. We were unable to demonstrate any significant difference in OS of patients with BRAFmt mCRC based on type of 1L therapy received. Research Sponsor: None.

4031 Poster Session (Board #23), Fri, 8:00 AM-11:00 AM

Results from the safety lead-in for a phase II study of pembrolizumab in combination with binimetinib and bevacizumab in patients with refractory metastatic colorectal cancer (mCRC). *First Author: Christopher Hanyoung Lieu, University of Colorado Comprehensive Cancer Center, Aurora, CO*

Background: The majority of pts with mCRC have microsatellite stable (MSS) tumors with minimal response to PD-L1/PD-1 blockade. MEK inhibition and VEGF inhibition have immunomodulatory effects (upregulation of tumor major histocompatibility complex-I expression, enhanced T-cell infiltration, reduced MDSCs and Tregs in tumors) supporting clinical evaluation of combined MEKi (B), anti–PD-1 (P), and anti-VEGF (BV) in pts with mCRC. We hypothesize that the combination of binimetinib, pembrolizumab, and bevacizumab (BPBV) will result in greater clinical benefit than pembrolizumab alone. **Methods:** Patients with chemotherapy-refractory mCRC were evaluated (20 planned in the safety lead-in and 50 planned for total accrual). B was dosed at 45mg PO BID, P was administered at 200mg IV Q21 days, and BV was administered at 7.5mg/kg IV Q21 days. Primary objectives were safety, tolerability, and investigator-assessed ORR by RECIST 1.1. Clinical benefit rate (CR+PR+SD) and progression-free survival were secondary endpoints. Descriptive statistics were used to summarize safety and clinical activity. **Results:** As of January 9, 2020, 21 pts (10 KRAS/NRASmt, 11 RASwt, 21 MSS) were enrolled into the safety lead-in and were evaluable. The median number of prior therapies was 6. The BPBV combination was tolerable. Treatment-related Gr 1-2 and Gr 3-4 AEs occurred at 60% and 38%, respectively. The most frequent related Gr 3-4 AEs were aceniform rash, diarrhea, and hypertension (19%, 14%, 14% respectively). No treatment-related Gr 5 AEs occurred. A total of 17 patients were evaluable for response. Confirmed PR was observed in 2 pts (12%). SD was noted in 14 patients (82%) leading to a clinical benefit rate of 94%. 1 patient had PD as the best response to treatment. Median PFS was 6.4 months (95% CI 4.2-8.9). Molecular determinants, immune biomarkers, and updated tumor assessments of response will be presented. **Conclusions:** B + P + BV demonstrated a tolerable safety profile and improvements in ORR and clinical benefit rate compared to those reported with SOC in heavily pretreated pts with mCRC. Objective responses observed in pts were durable, suggesting benefit of this novel combination in a patient population refractory to immune therapies. Clinical trial information: NCT03475004. Research Sponsor: Merck, U.S. National Institutes of Health.

4032 Poster Session (Board #24), Fri, 8:00 AM-11:00 AM

Pembrolizumab monotherapy for patients with advanced MSI-H colorectal cancer: Longer-term follow-up of the phase II, KEYNOTE-164 study. *First Author: Luis A. Diaz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pembrolizumab provides effective antitumor immunity and durable responses in patients (pts) with advanced, colorectal cancer (CRC) with microsatellite instability-high (MSI-H) tumors. We present data on antitumor immunity with pembrolizumab in pts from the phase 2, KEYNOTE-164 study who had approximately 3 years of follow-up, and in pts re-treated after disease progression. **Methods:** KEYNOTE-164 enrolled pts with metastatic MSI-H CRC, MSI-H status confirmed locally by IHC or PCR, and ≥2 (cohort A) or ≥1 (cohort B) prior lines of therapy (fluoropyrimidine, oxaliplatin, irinotecan, or anti VEGF/EGFR). Eligible pts received pembrolizumab 200 mg Q3W for 2y (35 administrations) or until progression, unacceptable toxicity, or withdrawal. Pts who stopped pembro due to a confirmed CR or after completing 2y of treatment and who progressed after stopping were eligible for re-treatment with up to 17 administrations in the second-course phase, at investigator discretion. Tumor response was assessed Q9W per RECIST v1.1 by independent review. The primary endpoint was ORR. Secondary endpoints included DOR, PFS, OS, and safety. The data cutoff date was Sep 9, 2019. **Results:** At data cutoff, the median follow-up was 31.4 mo (range, 0.2-47.8) for 61 pts in cohort A and 36.1 mo (0.1-39.3) for 63 pts in cohort B. ORR was 32.8% (3CR, 17PR; 95% CI% 21.3-46.0) for cohort A and 34.9% (8CR, 14PR; 95% CI 23.3-48.0) in cohort B. Median DOR was not reached (NR [range, 6.2-41.3+]) and not reached (range, 3.9+ to 37.1+), respectively. Fifteen pts in cohort A and 17 in cohort B had ongoing responses at data cutoff. Median PFS was 2.3 mo (95% CI 2.1-8.1) with 3-yr PFS rate of 31% in cohort A and was 4.1 mo (2.1-18.9) with 3-yr PFS rate of 34% in cohort B. Median OS was 31.4 mo (21.4-NR) with 3-yr OS rate of 49% in cohort A and was not reached (19.2-NR) with 3-yr OS rate of 52% in cohort B. Nine pts (6 in cohort A, 3 in cohort B) had a second course of treatment. The best response in second course was PR in 1 patient each in cohort A and B. Grade 3-4 drug-related adverse events occurred in 10 (16%) pts in cohort A and 8 (13%) pts in cohort B. No grade 5 drug-related events occurred. **Conclusions:** After approximately 3 y of follow-up, pembrolizumab continues to provide effective long-term antitumor immunity with durable responses, with small numbers of drug-related adverse events and no drug-related deaths in pts with advanced, MSI-H CRC. Clinical trial information: NCT02460198. Research Sponsor: Merck & Co., Inc.

4034 Poster Session (Board #26), Fri, 8:00 AM-11:00 AM

Outcomes and prognostic factors of patients (pts) with metastatic colorectal cancer (mCRC) who underwent pulmonary metastasectomy (PM) with curative intent. *First Author: Gustavo Cartaxo de Lima Gössling, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

Background: Indications for PM in pts with mCRC are often based on the presence of favorable prognostic factors. We aimed to analyze the prognostic factors and outcomes of pts treated with PM for mCRC. **Methods:** We retrospectively identified pts with mCRC who underwent PM with curative intent between Jan 1985 and Dec 2019 at Hospital de Clínicas de Porto Alegre. Demographics, clinicopathological features and previously described prognostic factors were collected. Univariate Cox regression was performed and followed by Kaplan-Meier (KM) curves with log-rank test when significant. **Results:** Fifty-eight pts underwent PM. Demographics are described in Table. Wedge resection was performed in 87.9% and margins were negative in 89.1%. Mean number of lesions was 2.4 ± 1.7, with the largest measuring 1.7 ± 0.9 cm. Two or more resections were performed in 36.2%, nodal sampling in 27.3%, and nodal disease was found in 5.2%.Thirty-day readmission rate was 5.2%. One pt had a Clavien-Dindo grade IIIb complication. RAS/RAF/MMR and CK20/CDX2 were available for 13.8% and 58.6% of the sample. Median PFS 14 months (m) (95% CI 10.4 - 17.5), median OS 58 m (95% CI 33.5 - 82.4) and 5-year survival 49.8%. Unfavorable prognostic factors for OS included disease-free interval (DFI) < 24 m (40 m, 95% CI 31.8 - 48.1 vs 85 m, 95% CI 75.7 -96.2; P < 0.005), synchronous presentation (33 m, 95% CI 23.9 - 42.0 vs 77 m, 95% CI 50.7 - 103.2; P < 0.001), largest lesion size ≥ 2cm (37 m, 95% CI 22.9 - 51.0 m vs 81 m, 95% CI - 33.7 - 128.2, P = 0.019) and lack of CK20 expression (19 m, 95% CI 12.1 - 27.2 vs. 83 m, 95% CI 46.9 - 119.0; P < 0.001). More than one lesion at presentation was prognostic for PFS (11 m, 95% CI 7.6 - 14.3 vs 23 m, 95% CI 0.1 - 59.2; P = 0.003) but not OS (P = 0.11). Grade was significant at Cox regression but showed no effect in further analysis. Neither CEA at baseline or relapse, resection margins, Charlson comorbidity index (CCI) or adjuvant chemotherapy were prognostic. **Conclusions:** Our results suggest a benefit for select pts and PM. Lack of CK20 expression may be associated with more aggressive disease and shorter OS. Additional molecular prognostic factors after PM should be further explored. 4035 Poster Session (Board #27), Fri, 8:00 AM-11:00 AM

Genomic aberration of chromatin regulatory BAF complex as predictive biomarker for immunotherapy in gastrointestinal adenocarcinoma. *First Author: Changsong QI, Department of Gastrointestinal Oncology, Beijing Cancer Hospital, Beijing, China*

Background: SNF/SWI, a large ATP-dependent chromatin remodeling complex, is required for transcriptional activation of genes normally repressed by chromatin, and critical to tumor initiation and progression. Here, we analyzed the predictive utility of the mutations of the SNF/SWI members involved in BAF and PBAF complexes, and sought to explore the potential mechanisms. **Methods:** Clinical, genomic, transcriptional, and immunohistochemical data from immunotherapeutic cohort (MSKCC, n=185), Cancer Cell Line Encyclopedia (CCLE, n=92), The Cancer Genome Atlas (TCGA, n=925), and 3D Medicines database (3DMed, n=1812) were analyzed to explore the predictive effect of genomic aberration of BAF complex on the benefit from immunotherapy in patients with gastrointestinal adenocarcinoma. **Results:** In the MSKCC cohort involving 185 patients with gastrointestinal adenocarcinoma, the mutation of any member involved in BAF complex (*ARID1A*, *ARID1B*, *SMARCA4*, *SMARCB1*, and *SMARCD1*) was significantly associated with prolonged OS of ICI treatment (HR 0.53, 95%CI 0.31-0.90, P=0.019), instead of the mutations of PBAF members including *PBRM1* and *ARID2*. In addition, BAF mutation was not linked with better prognosis in TCGA database, indicating its predictive, not prognostic efficacy of immunotherapy. BAF-mutated samples exhibited higher tumour mutational burden (TMB, P<0.05, Table), and increased mRNA expression of immune-related genes including chemokines and granzyme A. In the 3DMed cohort where tumour samples received both genomic sequencing and PD-L1 immunohistochemical staining, BAF mutation was associated with higher PD-L1 positive rate in tumour cells (P<0.05, Table). **Conclusions:** Genomic aberration of members in chromatin regulatory BAF complex may serve as a predictive, not prognostic biomarker of ICI benefit in patients with gastrointestinal adenocarcinoma, partially underlying the mechanisms including higher mutational burden, transcription of immune-related genes, and protein-level PD-L1 expression. Research Sponsor: Beijing Cancer Hospital.

4036 Poster Session (Board #28), Fri, 8:00 AM-11:00 AM

Trifluridine/tipiracil or regorafenib in refractory metastatic colorectal cancer patients: An AGEO prospective "real life" study. *First Author: Clélia Coutzac, Centre Léon Bérard, Lyon, France*

Background: Regorafenib (R) and trifluridine/tipiracil (T) have proved their efficacy in patients (pts) with metastatic colorectal cancer (mCRC) refractory to standard chemotherapy and targeted therapies. However, it remains unclear which drug should be administered first. **Methods:** This observational study was prospectively conducted in 13 centers between 6/2017 and 9/2019 in France. All consecutive pts with chemoresistant mCRC and receiving T and/or R were eligible. The aim of this study was to describe efficacy and tolerability of T and/or R. Overall survival (OS) and progression-free survival (PFS) of pts receiving T then R (T/R) and the opposite sequence (R/T) were also assessed. **Results:** A total of 237 pts (25% R and 75% T) were enrolled (109 male, median age: 67 years (32-91), mean previous lines of treatment: 2.5 (1-7)). Baseline ECOG PS was 0-1 in 77% of pts. As compared to R pts, T pts were significantly older (68 years vs 63; p = 0.033) and with > 3 metastatic sites (44% vs 30%, p = 0.018). Median OS were 6.6 and 6.2. months in the T and R group, respectively (NS). Median PFS were 2.4 and 2.1 months in the T and R group, respectively (NS). After matching 46 paired pts according to primary tumor resection, age and number of metastatic sites, a trend to a longer OS (9.5 vs 6.8 months; p = 0.17) and a significantly longer PFS (2.8 vs 2 months; p = 0.048) were observed in the T group. Among the overall population, 24% of pts received R/T or T/R sequence. Median OS from first treatment were 10.7 months in the R/T group and 9.8 months in the T/R (NS). Treatment sequence was not an independent prognostic factor for OS or PFS in multivariable analysis. Tolerability profiles were similar to previously published data, but dose reductions were more frequent in the R group (44 vs 27%, p = 0.008). **Conclusions:** Efficacy and safety results in this real life prospective study are in line with those published phase III trials. Both treatments seem similar in term of efficacy favoring T for clinical use as shown by the higher number of patients receiving this drug. Research Sponsor: None.

4038 Poster Session (Board #30), Fri, 8:00 AM-11:00 AM

FOLFIRI versus irinotecan monodrug as second-line treatment in metastatic colorectal cancer patients: An open, multicenter, prospective, randomized controlled phase III clinical study. *First Author: Weijian Guo, Shanghai Medical College, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The most commonly used treatment methods for metastatic colorectal cancer (mCRC)are systemic chemotherapy, molecular targeted therapy and local treatment. The main chemotherapy drugs for mCRC include Irinotecan, Oxaliplatin and 5-Fu. V308 Research shows that FOLFOX and FOLFIRI can be standard first or second-line of each other in the treatment of metastatic colorectal cancer. However if the first-line treatment regimen containing 5-FU fails, whether it is necessary to re-challenge 5-FU when Irinotecan is applied in the second line is unknown. There is no head-to-head comparative study to answer whether the FOLFIRI regimen is better than the Irinotecan monodrug. Therefore, it is necessary to carry out a comparative study of FOLFIRI Versus Irinotecan monodrug to observe whether adding 5-Fu on the basis of Irinotecan can improve the therapeutic effect. **Methods:** This was a randomized phase III trial. Patients from 5 centers in China with metastatic colorectal adenocarcinoma, for whom first-line of chemotherapy including oxaliplatin combined with fluorouracil drugs (combined or not combined with targeted therapy) had failed, were enrolled. 172 patients with mCRC were randomly treated with FOLFIRI or Irinotecan monodrug were included in this study. FOLFIRI group : Irinotecan 180mg/m^2 ; Lecovorin 400mg/m^2 ; 5-Fu 400mg/m^2 ; 5-Fu 2400mg/m^2 CIV 46h. Irinotecan monodrug group 180mg/m^2, The regimen was repeated every 2 weeks. The primary endpoint is PFS , and this clinical trail is a superiority trial. **Results:** ITT (Intention-To-Treat) analysis: Among 172 patients, 10 had PR, 93 had SD, and 63 had PD , 6 patients have not received efficacy evaluation yet. The ORR was 5.68% VS. 5.95%, and the DCR was 61.36% and 54.76% in FOLFIRI group and Irinotecan monodrug group, respectively. Adverse reactions included neutropenia, stomatitis, diarrhea, fatigue, abnormal liver enzymes, pyrexia, arrhythmia, nausea and most of these were grade 1-2. The dose reduction rate induced by drug tocixity of was 13.64% and 7.14% in FOLFIRI group and Irinotecan monodrug group, respectively. **Conclusions:** These data show that Irinotecan monodrug has the similar ORR and DCR with FOLFIRI regimen in second-line treatment of mCRC. Irinotecan monodrug has lower adverse effect. Clinical trial information: NCT02935764. Research Sponsor: None.

4039 Poster Session (Board #31), Fri, 8:00 AM-11:00 AM

Encorafenib plus cetuximab with or without binimetinib for *BRAF* V600E-mutant metastatic colorectal cancer: Quality-of-life results from a randomized, three-arm, phase III study versus the choice of either irinotecan or FOLFIRI plus cetuximab (BEACON CRC). *First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In the BEACON CRC study, the triplet regimen of encorafenib (ENCO) + binimetinib (BINI) + cetuximab (CETUX) significantly improved overall survival (OS, HR:0.52, $P < 0.0001$) and objective response rates (ORR, 26% vs 2%, $P < 0.0001$) in patients (pts) with *BRAF*V600E metastatic colorectal cancer (mCRC) compared with current standard of care. This analysis focuses on the patient-reported quality of life (QOL) assessments from this study. **Methods:** The BEACON CRC study was a randomized, open-label, 3-arm, phase 3 global study which evaluated triplet (ENCO+BINI+CETUX) or doublet (ENCO+CETUX) vs. investigator's choice of irinotecan + CETUX or FOLFIRI + CETUX in pts with *BRAF*V600E mCRC. QOL assessments (secondary endpoints in the trial) included the EORTC QOL Questionnaire (QLQ C30), Functional Assessment of Cancer Therapy Colon Cancer (FACT C), EuroQol 5D 5L, and Patient Global Impression of Change (PGIC). The primary assessment for the QOL variables was the time to definitive 10% deterioration. The study is ongoing. **Results:** 665 pts were randomly assigned to receive either triplet (n = 224), doublet (n = 220), or control (n = 221). Reduction in the risk of QOL deterioration was an estimated 45% (HR 0.55, 95% CI: 0.43, 0.70) and 52% (HR 0., 9485% CI: 0.38, 0.62) in EORTC QLQ C30 and FACT C assessments, respectively, in favor of the triplet regimen over control. For the doublet vs. control, reduction in risk of QOL deterioration was an estimated 46% (HR 0.54, 95% CI: 0.43, 0.69) and 54% (HR 0.46, 95% CI: 0.36, 0.59) in EORTC QLQ C30 and FACT C, respectively in favor of the doublet. Similar results were observed in EuroQol 5D 5L and PGIC assessments. There were no overall differences in QOL between triplet and doublet across the 4 instruments. **Conclusions:** In BEACON CRC, triplet and doublet demonstrated substantial improvement in patient-reported QOL assessments over the current standard of care in pts with *BRAF*V600E-mutant metastatic CRC whose disease had progressed after 1 or 2 prior regimens. Clinical trial information: NCT02928224. Research Sponsor: Pfizer Inc.

4040 Poster Session (Board #32), Fri, 8:00 AM-11:00 AM

Nivolumab (NIVO) + low-dose ipilimumab (IPI) as first-line (1L) therapy in microsatellite instability-high/mismatch repair-deficient (MSI-H/dMMR) metastatic colorectal cancer (mCRC): Two-year clinical update. *First Author: Heinz-Josef Lenz, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: In the phase 2 CheckMate 142 trial, NIVO + low-dose IPI had robust, durable clinical benefit and was well tolerated as 1L therapy for MSI-H/dMMR mCRC (median follow-up 13.8 months [mo; range, 9–19]; Lenz et al. *Ann Oncol* 2018;29:LBA18). Longer follow-up is presented here. **Methods:** Patients (pts) with MSI-H/dMMR mCRC and no prior treatment for metastatic disease received NIVO 3 mg/kg Q2W + low-dose IPI 1 mg/kg Q6W until disease progression or discontinuation. The primary endpoint was investigator-assessed (INV) objective response rate (ORR) per RECIST v1.1. **Results:** In 45 pts with median follow-up of 29.0 mo, ORR (95% CI) increased to 69% (53–82) (Table) from 60% (44.3–74.3); complete response (CR) rate increased to 13% from 7%. The concordance rate of INV and blinded independent central review was 89%. Median duration of response (DOR) was not reached (Table). Median progression-free survival (PFS) and overall survival (OS) were not reached, and 24-mo rates were 74% and 79%, respectively (Table). Nineteen pts discontinued study treatment without subsequent therapy. An analysis of tumor response post discontinuation will be presented. Ten (22%) pts had grade 3–4 treatment-related adverse events (TRAEs); 3 (7%) had grade 3–4 TRAEs leading to discontinuation. **Conclusions:** NIVO + low-dose IPI continued to show robust, durable clinical benefit with a deepening of response, and was well tolerated with no new safety signals identified with longer follow-up. NIVO + low-dose IPI may represent a new 1L therapy option for pts with MSI-H/dMMR mCRC. Clinical trial information: NTC02060188. Research Sponsor: Bristol-Myers Squibb.

4041 Poster Session (Board #33), Fri, 8:00 AM-11:00 AM

Metastases resection in colorectal cancer patients with mutation in oncogene BRAF or tumors located on the right side: Experience at the HGUGM. *First Author: Laura Ortega, Hospital General Universitario Gregorio Marañón, Instituto De Investigación Sanitaria Gregorio Marañon, Madrid, Spain*

Background: Approximately 25% of patients with colorectal cancer (CRC) debut with metastatic disease. In addition, 25-35% of patients with localized disease at diagnosis develop metastatic lesions during the evolution of their disease. Consequently, approximately 50-60% of patients with CRC will present metastatic lesions at some point in their lives. Metastasis resection has improved the prognosis of these patients, achieving overall survival (OS) that exceed 40 months. However, there are doubts about the benefit of this approach in patients with mutations in oncogene BRAF or tumors located on the right-side, due their poor prognosis. The aim of the study is to analyze the impact of metastases resection on OS of these populations. **Methods:** We conducted a retrospective analysis of patients with mCRC attended in the Medical Oncology Department of the Hospital General Universitario Gregorio Marañón (Spain) between January 2010 and 2018. **Results:** 487 patients were identified and included in the analysis. Median age was 71 years (62-81). Most patients were males (62.4%). 55.2% had metastatic lesions at diagnosis. Most patients had ECOG 0-1 at diagnosis of metastatic disease (91.0%). 8.9% of patients had BRAF mutations (n = 21) and 31.8% of patients had primary tumors located on the right-side (n = 152). 474 patients received first-line chemotherapy (97.3%). OS of the entire cohort was 29.67 months; 30.69 months in BRAF mutated patients vs 35.89 in wild-type patients (p = 0.161); 25.29 months in right-side tumors vs 31.02 in left-side tumors (p = 0.044). 306 patients (62.8%) underwent metastases resection. Most common location was liver (51.4%). 147 patients (30.2%) underwent a second metastases resection. Mean number of metastases surgeries was 1.35 (+/-1.40). OS since metastases resection was 24.83 months in BRAF mutated patients vs 41.55 months in wild-type patients (p = 0.020). According to location, it was 35.49 months in right-side tumors vs 43.78 months in left-side tumors (p = 0.106). In BRAF mutated patients, OS was 38.19 months in patients underwent metastases resection vs 18.52 months in non-surgical patients (p = 0.043); 41.51 months vs 16.18 months respectively in patients with tumors located on the right-side ($p < 0.001$). **Conclusions:** Metastases resection has a positive impact on overall survival of patients with mutations in oncogene BRAF or right-side tumors, even though their prognosis is still poor compared to patients without these alterations. Research Sponsor: None.

4042 Poster Session (Board #34), Fri, 8:00 AM-11:00 AM

Rectal cancer in young patients: Clinicoepidemiologic profile and treatment outcomes. *First Author: Pankaj. Goyal, Rajiv Gandhi Cancer Institute and Research Centre, New Delhi, India*

Background: Colorectal cancers are 3rd most common cause of cancer globally however studies of rectal cancers alone in younger patients are scarce. Rectal cancers in Asian patients present at a younger age and has an aggressive tumor biology. This study looks at rectal cancer in young patients, ≤30 years old, with the aim to report clinico-epidemiologic profile and treatment outcomes in this subgroup. **Methods:** Retrospective analysis was conducted at a tertiary care centre. Of total 845 rectal cancer patients between 2012-2017, 103 patients of young rectal cancers were enrolled. Kaplan Meier method was used for survival analysis and cox regression analysis was done to identify factors affecting survival. **Results:** Young rectal cancer patients constituted 12.2% of the total rectal cancer patients. Male: Female ratio was 2.3:1 and the mean age was 24.7 ± 3.9 years. Around 73.8 % patients had locoregional disease (stage I/II/III) at presentation.CEA levels were elevated in 36.9% of patients, while most common histology was signet ring cell histology which was present in 51.5% of patients. Of 76 patients with locoregional disease, 75% received neoadjuvant chemo-radiotherapy, 7.9% received neoadjuvant chemotherapy alone while 3.9% received neoadjuvant radiotherapy alone. Of 76 patients with locoregional disease, 55 patients underwent surgery of which 53.9% underwent low anterior resection while 18.4% underwent abdomino-perineal resection. Pathologic CR rates were seen in 13.3%, while recurrences were seen in 55.4% of non-metastatic patients. Overall 5-year survival for the whole study group was 19.5%, while 1-year PFS and 3-year DFS for metastatic and non-metastatic disease were 5% and 43.8% respectively. On regression analysis elevated CEA levels and not achieving a pathologic CR (pCR) with neo-adjuvant therapy had a trend towards worse overall survival (HR 2, 95% CI 1-4, p = 0.063), (HR 4.7, 95% CI 0.64-35.1, p = 0.125) respectively. **Conclusions:** Rectal cancers in Asia present at younger age and this younger population is associated with advanced stage, increased CEA at presentation, aggressive histology and poor survival. CEA raise and not achieving pCR were associated with trend towards worse survival. Research Sponsor: None.

4043 Poster Session (Board #35), Fri, 8:00 AM-11:00 AM

Recurrence after surgery for concurrent metastatic colorectal cancer: The perspective of bioinformatics and machine learning. *First Author: Zhiwen Luo, Department of Hepatobiliary Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Recurrence of concurrent metastatic colorectal cancers (mCRCs) after surgery is still a challenge. But mCRCs' outcomes are heterogeneous, and no clinicopathological methods can predict its recurrence and guide postoperative treatment from an intrinsic cell activities and extrinsic immune microenvironment perspective. We aimed to identify such gene models. **Methods:** Gene expression analysis on CRCs. Based on metastasis-related genes, a metastatic evaluation model (MEM) was developed, dividing mCRCs into high and low recurrence risk clusters. Machine learning tested MEM's importance to predict recurrence. Further investigating MEM's two clusters made an immune prognostic model (IPM) with immune genes differentially expressed between MEM clusters. The predictive performance of MEM and IPM on prognosis was comprehensively analyzed and validated. The mechanism of IPM on the immune microenvironment and response to immuno/chemotherapy was analyzed extensively. **Results:** RNA data of 998 CRCs were analyzed. High postoperative recurrence risk in mCRCs was owing to immune response's down-regulation, which was influenced by 3 MEM genes (*BAMBI, F13A1, LCN2*) and their related 3 IPM genes (*SLIT2, CDKN2A, CLU*). MEM and IPM were developed and validated on 239 mCRCs to differentiate a low and high recurrence risk (AUCs > 0.7). Functional enrichment analysis showed immune response and immune system diseases pathway represented the major function and pathway related to IPM gene. IPM high-risk group (IPM-high) had higher fractions of Tregs (P= 0.04), lower fractions of resisting memory CD4+ T cells (P= 0.02) than IPM-low. And stroma and immune cells in IPM-high samples were scant (P= 0.0002, 0.001, respectively). In IPM-high, MHC class II molecules all down-expressed, and DNA methylation disordered. TIDE algorithm and GDSC analysis discovered IPM-low was more promising to respond to both anti-CTLA4 therapy (P= 0.005) and common FDA targeted drugs (P< 0.05), while IPM-high had nonresponse to both of them. But anti-CDKN2A agent with activation of MHC class II response might reverse the dilemma of this refractory mCRCs subgroup. **Conclusions:** Postoperative recurrence of mCRC is strongly related to immune microenvironment. Our two relative gene models could identify subgroups of mCRC with different recurrence risk, and stratify mCRCs sensitive to immune/chemotherapy, even highlight the ignored importance of MHC class II molecules on immunotherapy in mCRCs for the first time. Research Sponsor: Capital's Funds for Health Improvement and Research [grant number 2018-1-4021].

4044 Poster Session (Board #36), Fri, 8:00 AM-11:00 AM

TAS-116, an oral HSP90 inhibitor, in combination with nivolumab in patients with colorectal cancer and other solid tumors: An open-label, dose-finding, and expansion phase Ib trial (EPOC1704). *First Author: Akihito Kawazoe, National Cancer Center Hopital East, Kashiwa, Japan*

Background: Regulatory T cells (Tregs) potentially induce the resistance of anti-PD1/PD-L1 inhibitors (A-PD1). TAS-116, a novel HSP90 inhibitor, enhanced antitumor immunity via reducing Tregs *in vitro* and *in vivo*. Combination of TAS-116 plus A-PD1 showed a superior tumor growth suppression compared with either treatment alone *in vivo*. Based on the above, we investigated safety and efficacy of TAS-116 in combination with nivolumab in patients with solid tumors. **Methods:** Enrolled patients received TAS-116 plus nivolumab in a dose-finding part to estimate the maximum tolerated dose and the recommended phase 2 dose (RP2D). Additional patients were enrolled in a dose-expansion part. TAS-116 monotherapy (orally once daily, 80mg on level 1, 120mg on level 2, and 160mg on level 3) was administrated for 2 weeks followed by the combination with nivolumab (intravenously every 2 weeks, 3 mg/kg). The primary endpoint was dose-limiting toxicities (DLTs) during the first cycle (4 weeks). PD-L1 combined positive score (CPS) and tumor mutation burden (TMB) were assessed. We also conducted biomarker research using paired samples from repeated tumor biopsies and blood collections. **Results:** A total of 44 patients with colorectal cancer (CRC, n = 29), gastric cancer (GC, n = 8), sarcoma (n = 5), non-small cell lung cancer (NSCLC, n = 1) and melanoma (n = 1) after standard of cares were enrolled. One patient had MSI-H CRC, but all other patients had MSS tumors. No DLTs were observed at all levels and TAS-116 160 mg was determined as RP2D. The common grade 3 or worse treatment-related adverse included AST/ALT increased (7%), creatinine increased (5%) and platelet count decreased (5%). Objective tumor response was observed in 6 patients including 4 MSS CRC, 1 MSI-H CRC and 1 sarcoma, resulting in objective response rate (ORR) of 16% in MSS CRC without prior A-PD-1. PD-L1 CPS and TMB could be evaluated in 18 and 17 MSS CRC without prior A-PD-1, respectively. ORR was 27% in patients with CPS ≥1 and 0% in patients with CPS < 1. ORR was 33% with TMB-high (median as the cut-off) and 12% with TMB-low. Analysis of tumor-infiltrating lymphocytes before treatment and after TAS-116 monotherapy demonstrated reduction of $FoxP3^{hi}CD45RA^{-}$Tregs fraction in the tumor microenvironment. **Conclusions:** The combination of TAS-116 160mg plus nivolumab had manageable safety profiles and anti-tumor activity especially for MSS CRC patients, which warrants further investigations in a large cohort. Clinical trial information: UMIN000032801. Research Sponsor: Taiho, Ono.

4045 Poster Session (Board #37), Fri, 8:00 AM-11:00 AM

Inpatient outcomes and predictors of mortality in patients with gastrointestinal malignancies presenting with sepsis: A nationwide analysis. *First Author: Parth Desai, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Sepsis is a frequent cause of morbidity and mortality in patients with malignancy. However, there is paucity of literature on mortality, hospital charges and overall healthcare utilization among patients with GI malignancy, which we hope to characterize in this study. **Methods:** We queried retrospective data from the Nationwide Inpatient Sample (NIS) database for the year 2016. Sepsis (Dx1) was identified using ICD-10 code as primary diagnosis in patients with known GI malignancies (Dx2). Univariate and multivariate Poisson regression analysis was done to study outcomes. Propensity score matching was done to minimize confounding factors. Primary outcome was inpatient mortality. Secondary outcomes were Length of Stay (LOS), Total Charge (TOTCHG) and ICU admission. **Results:** A total of 43,240 patients with GI malignancy were admitted in 2016 with sepsis. Two most common GI malignancies admitted with sepsis were colorectal (35%) and hepatocellular cancer (HCC) (28.2%). Overall mortality in GI cancer was 19.8% vs 10.2% in all cancers (p<0.01). There was male (59%) and Caucasian (63%) preponderance. Out of all hospital admissions for GI malignancy, 41.4% were secondary to sepsis. E. coli (31%) infection and gram-negative bacteremia (15%) were the most common causes of sepsis. Sepsis with GI malignancy was associated with length of stay of 7.4 days vs 5.4 days (coef 2.44, 95% CI 2.3-6.7 p=0.04) and a mean hospital charge of $88,728 vs $ 54, 668 (coef 34,140, 95% CI 44,264-90,646, p<0.01) as compared to without sepsis. After adjusting for demographic and patient related variables, independent predictors of mortality were old age, uninsured, African Americans, septic shock requiring pressor support, AKI, inpatient hemodialysis, metabolic encephalopathy and acute respiratory failure. **Conclusions:** Sepsis poses a substantial healthcare burden in patients with GI malignancy and is a major cause of mortality. Early antibiotic treatment is necessary for sepsis control in patients with GI malignancy. Research Sponsor: None.

Pembrolizumab (Pem) in combination with stereotactic body radiotherapy (SBRT) for resectable liver oligometastatic MSS/MMR proficient colorectal cancer (CRC). *First Author: Dustin A. Deming, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: SBRT is used to treat liver metastatic CRC, causing an increase in immunogenic antigen release and influx of responding immune cells. We hypothesize that radiation enhances the immunogenicity of MSS CRC and potentiates the effectiveness of PD-1 blockade. This phase Ib study examines the safety and efficacy of the sequential combination of SBRT and Pem in patients (pts) undergoing resection of their disease. **Methods:** Eligibility criteria include MSS CRC with resectable liver-confined metastatic disease. Prior surgery and systemic chemotherapy are allowed. Subjects receive sequential SBRT and cycle 1 of Pem prior to operative management and adjuvant Pem. The primary objectives are to determine the safety/tolerability of this regimen and the recurrence free survival (RFS) at 1 year following clearance of metastatic disease. Correlative studies examined tumor infiltrating CD8+ T lymphocytes (TILs) and the accumulation and proteolysis of versican (VCAN), an immunoregulatory tumor matrix proteoglycan. Proteolysis of VCAN results in the release of an immunostimulatory fragment, versikine. Cancers with low VCAN and high versikine (VCAN proteolysis predominant (VPP)) are hypothesized to respond better to immunotherapies. **Results:** 15 pts (median age 58.2 [range 38-69]) have been enrolled. All pts had prior FOLFOX. SBRT median dose was 50 Gy (40-60 Gy) to a single lesion targeted in all pts. No DLTs were observed. AEs included one case of biliary tract injury and biloma, not related to immunotherapy. No grade 3/4 immunotherapy-related AEs have occurred. 10 pts have completed a minimum follow-up of 1 year post resection. In the intention to treat analysis, the 1 year RFS was 70% (historic control 50%). 2 of 3 pts with BRAF V600E mutations have had early recurrences. 2 pts had VCAN high tumors and both recurred prior to 1 year. 4 pts had VPP cancers and all were recurrence free at 1 year. TILs in the radiated lesions were $>$ 2 times as abundant as in the pre-treatment (tx) tissue for 50% of pts. 3 of 4 pts who had non-radiated lesions available for analysis had TILs $>$ 2 times pre-tx in the non-radiated lesions indicating a potential abscopal effect. **Conclusions:** The combination of SBRT with Pem and surgical resection is well tolerated with no signal of increased immunotherapy-related toxicity and preliminary evidence of potential enhanced efficacy. Clinical trial information: NCT02837263. Research Sponsor: Merck.

4047 Poster Session (Board #39), Fri, 8:00 AM-11:00 AM

Clinical and pathologic factors associated with survival in BRAFV600E colorectal cancers. *First Author: Van K. Morris, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: $BRAF^{V600E}$ mutations occur in fewer than 10% of all patients (pts) with metastatic colorectal cancer (mCRC) and arise from sessile serrated adenomas. Despite efficacy with targeted therapies against MAPK signaling and with immunotherapies in this population, survival outcomes for pts with $BRAF^{V600E}$ mCRC in general are poor. Characteristics distinguishing pts with $BRAF^{V600E}$ mCRC with favorable versus unfavorable outcomes have not been well annotated. **Methods:** Records of 188 pts with $BRAF^{V600E}$ mCRC evaluated at MD Anderson Cancer Center between 3/2010-1/2020 were reviewed. Pts with the shortest and longest metastatic survival (N = 25 for each group) were compared. Associations between prognostic group and clinical/pathologic features were measured by odds ratio and for median survival by log-rank testing. **Results:** Median metastatic survival differed between the 2 $BRAF^{V600E}$ mCRC populations (8.6 vs 84 months, $p < .0001$). Pts with poor survival more commonly had primary tumors arising from the hepatic flexure/proximal transverse colon (44% vs 16%, p = .04) and more frequent hepatic involvement (75% vs 28%, p = .001). Pts with favorable survival were more likely to develop metachronous metastases (52% vs 16%, p = .01), have fewer distant organ involvement (median 1 vs 2, p = .02), and undergo definitive locoregional therapy to metastatic disease (44% vs 0%, p = .01). Microsatellite instability (36% vs 4%, p = .008) and a history of tobacco use (44% vs 16%, p = .04) were associated with a favorable prognosis. Durable responses to MAPK-targeted therapies (5/25) and immunotherapy (3/25) were noted in the favorable group. **Conclusions:** Pts with $BRAF^{V600E}$ mCRC can achieve excellent long-term survival which belies conventional context and is driven by locoregional and systemic treatment options alike. Anatomic localization of the primary tumor and prior exposures may highlight environmental influences on tumor biology which account for the clinical heterogeneity of pts with $BRAF^{V600E}$ mCRC. 4048 Poster Session (Board #40), Fri, 8:00 AM-11:00 AM

Evaluation of safety, immunogenicity, and preliminary efficacy of PolyPEPI1018 off-the-shelf vaccine with fluoropyrimidine/bevacizumab maintenance therapy in metastatic colorectal cancer (mCRC) patients. *First Author: Joleen Marie Hubbard, Mayo Clinic, Rochester, MN*

Background: PolyPEPI1018 is an off-the-shelf, multi-peptide vaccine containing 12 immunogenic epitopes derived from 7 cancer testis antigens (CTAs) frequently expressed in patients with CRC. Here we report the final results of the phase I study of PolyPEPI1018 vaccine as an add-on to maintenance therapy in mCRC patients. **Methods:** 11 patients with MSS mCRC were vaccinated with PolyPEPI1018 just after the transition to maintenance therapy with fluoropyrimidine/bevacizumab after first-line combo chemotherapy and bevacizumab. Part A: n = 5, single dose; Part B: n = 6, 3 doses, Q12W. Primary endpoint was safety. Immunomonitoring was performed at both blood and tumor levels, as well as prospectively predicted. **Results:** The vaccine was well tolerated; most common side effects were transient skin reactions. No vaccine-related SAE occurred. Pre-existing immune responses were boosted by the vaccine for 7/10 patients. *De novo* responses were also induced, overall, 80% of patients had CD8+ T cell responses against at least 3 CTAs. The magnitude of immune responses as well as the density and the ratio of CD8+/CD3+ tumor infiltrating T cells increased with multiple vaccine doses. Three patients had objective tumor response according to RECIST v1.1: one of them in the single dose group and two of them in the 3 doses group. Both patients in the 3 doses group qualified for curative surgery. One of them had no viable tumor cells in his primary tumor at the time of surgery. Post-trial follow-up revealed PFS of at least 12 months for 3 patients. mPFS was longer for patients receiving multiple doses (9.9 months) compared to single dose (6.1 months). Both measured and predicted multiantigenic immune responses tend to correlate with PFS and tumor volume reduction. **Conclusions:** PolyPEPI1018 was effective in restoring immunological responses to CTAs in patients' with spontaneous immunity against. Treatment with PolyPEPI1018 vaccine and maintenance therapy was safe and demonstrated evidence of early clinical activity in MSS mCRC tumors. Data support further randomized trials with PolyPEPI1018. Clinical trial information: NCT03391232. Research Sponsor: Treos Bio.

4049 Poster Session (Board #41), Fri, 8:00 AM-11:00 AM

Sequencing of treatment matters in synchronous liver or lung only metastatic colon cancer. *First Author: Saurabh Parasramka, University of Kentucky, Lexington, KY*

Background: Per SEER database, approximately 21% of patients have synchronous metastatic disease at presentation with a median 5 year survival of 14%. Liver is by far the most common site of metastatic disease followed by lung. Metastatectomy of appropriate lesions have achieved a 5 year survival ranged between 40%-70% depending on the extent of the metastasis. For liver or lung only metastatic disease, practice varies from surgery followed by adjuvant chemotherapy to perioperative chemotherapy. Benefit of one approach versus the other has not been demonstrated. We decided to study this using the National Cancer Database (NCDB) database available from the 2010-2015 period. **Methods:** Adults $>$ 20 years with primary colon cancer (excluding rectal and recto sigmoid junction) with single organ metastatic disease to liver and/or lung at diagnosis were identified. All patients had received surgery to the primary site, resection of the distant site and chemotherapy in the neoadjuvant setting (NAC) or adjuvant setting (AC) within 1 year of diagnosis. Histology except for adenocarcinoma and variants were excluded. Patients who died within 90 days of surgery were excluded. Descriptive analysis, Kaplan-Meier plots, Log-Rank tests for univariate and proportional hazards models for multivariate survival analyses were performed. To reduce biases, a sensitive analysis was also performed based on the intention to treat principle by including additional surgery only and chemotherapy only cases. **Results:** A total of 3175 colon cancer patients with liver or lung only metastatic disease were identified. 2487 (78%) had AC and 688 (22%) had NAC. Approximately 54% were males with 90% less than 75 years of age. More patients had private insurance and were treated in academic centers in the NC group (62 Vs 51%) and (58 Vs 42%) respectively. Both groups had similar Charlson comorbidity index. NC approach had better OS with HR of 0.75 (CI 0.65-0.85; $p < 0.0001$) on univariate analysis and 0.86 (0.74-0.98; $P < 0.0281$) on multivariate analysis. On multivariate analysis, age group $>$ 75 years, black race, treatment outside academic research program had worse survival ($p <$ 0.0001, 0.0139, 0.0001) respectively. The sensitive analysis showed the similar effects. **Conclusions:** Within the limitations of database review, our analysis suggests survival advantage of neoadjuvant chemotherapy approach over surgery first. 4050 Poster Session (Board #42), Fri, 8:00 AM-11:00 AM

Prognostic effect of specific *RAS/BRAF* mutations in patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Ben George, Froedtert & The Medical College of Wisconsin, Milwaukee, WI*

Background: Somatic mutations in *KRAS, HRAS, NRAS* (extended *RAS*) and *BRAF* have prognostic and predictive impact in pts with mCRC. We analyzed the prognostic impact of specific somatic mutations in extended *RAS* and *BRAF*. **Methods:** We retrospectively reviewed the electronic medical records of pts with mCRC at our institution who underwent comprehensive genomic profiling (CGP) utilizing the Foundation One assay. DNA was extracted from clinical specimens and CGP was performed on hybrid-capture, adaptor ligation-based libraries for up to 315 genes plus 47 introns from 19 genes frequently rearranged in cancer. BRAF mutations were classified as class I, II and III according to accepted nomenclature. Fisher's exact test and Kaplan Meier estimates were used for statistical analyses. This project was approved by the Medical College of Wisconsin Institutional Review Board. **Results:** 273 pts were identified - median age at diagnosis was 57, 48% were male. Somatic mutations in extended RAS were found in 138 (50%) pts, majority being mutations in *KRAS* (46%). Among pts with *KRAS* mutations, codon 12, 13, 61 and 146 mutations accounted for 73%, 11%, 4% and 6% respectively while *KRAS* G12C mutations accounted for 9%. *BRAF* mutations were detected in 22 (8%) pts - *BRAF* V600E and non–V600E mutations accounting for 4.4% and 3.6% respectively. Among pts with BRAF mutations, 17 (77%) were kinase domain mutations, 16 of which could be further classified as class I (12/16), II (1/16) and III (3/16). Median overall survival (mOS) for the entire cohort was 26.4 months (mo). *KRAS* mutated pts had a mOS of 25.8 mo; pts with *KRAS* G12C mutation had a mOS of 23 mo compared to 27.1 mo for pts with other *KRAS* mutations ($p < 0.001$).Pts with *BRAF* mutation had a mOS of 26.2 mo; pts with *BRAF* V600E mutation had a mOS of 14.1 mo compared to 30.6 mo for pts with *BRAF* non-V600E mutations ($p = 0.1$). **Conclusions:** The poor prognosis of pts with *KRAS* G12C and *BRAF* V600E mutations compared to pts with other *KRAS* and *BRAF* mutations merit further biologic characterization with functional assays. Individualized therapeutic strategies must be conceptualized for mCRC pts with specific *RAS/BRAF* mutations, considering their widely disparate prognosis and putative downstream signaling mechanisms. Dynamic molecular simulation to understand conformational changes in proteins associated with specific mutations will be pivotal to optimizing precision therapeutic strategies. Research Sponsor: None.

4051 Poster Session (Board #43), Fri, 8:00 AM-11:00 AM

Randomized phase II trial of avelumab alone or with cetuximab for unresectable, locally advanced or metastatic squamous cell anal carcinoma progressed to at least one line of treatment: The CARACAS study. *First Author: Sara Lonardi, Veneto Institute of Oncology (IOV)-IRCCS, Padua, Italy*

Background: Advanced squamous cell anal carcinoma (advSCAC) is a rare disease with poor prognosis. No standard therapies beyond first line are currently available, yet a promising activity was documented for the anti-EGFR cetuximab (CET) and for anti-PD-1 agents in previous retrospective case series and phase I-II studies, respectively. In experimental models combination of EGFR and PD-L1 blockade was synergistic as PD-L1 blockade led to NK cells activation enhancing cetuximab ADCC. In this trial we aimed to evaluate safety and activity of the anti-PD-L1 avelumab (AVE) alone or in combination with CET in pretreated advSCAC. **Methods:** This was an open-label, prospective, multicenter randomized phase 2 trial (NCT03944252). Patients (pts) with advSCAC progressed after at least 1 line of treatment were randomized 1:1 to receive either AVE 10 mg/kg (arm A) or AVE + CET 500 mg/sqm (arm B) as bi-weekly regimens. A Simon's two-stage Mini-Max design was used. The null hypothesis of a true response rate 5% was tested against the one-sided alternative of a true response rate 20% in each arm. Setting type I error at 0.05 and power at 80%, 30 pts per arm had to be randomized. No formal comparison between the two arms was planned. Primary endpoint was overall response rate (ORR); secondary endpoints were Progression-Free Survival (PFS), Overall Survival (OS) and safety. **Results:** Sixty pts were enrolled, 30 in each arm. All baseline characteristics were well balanced between the two arms. Median age was 63 years; M/F was 19/41; 12 out of 30 pts in each arm had distant metastases; 7 in arm A and 10 in arm B received > 1 previous lines of treatment. At a median follow up of 8.7 months, 3 out of 30 pts in each arm obtained PR (ORR 10%); SD was observed in 12 pts in arm A (40%) and 14 in arm B (47%). Disease control rate was thus 50% in arm A and 57% in arm B. Duration of disease control was 6.1 (95%CI 3.7–11.0) and 6.1 (95%CI 4.1–9.6) months in arm A and B, respectively. Median PFS was 2.1 (95%CI 1.8–4.0) in arm A and 3.9 months (95%CI 2.1–5.6) in arm B. Grade 3-4 adverse events were 13.3% in arm A and 33.3% in arm B: anemia 10% vs 13.3%, fatigue 0 vs 6.7%, skin toxicity 0 vs 6.7%. Treatment interruption due to AE occurred in 3 pts, 1 in arm A and 2 in arm B. Translational analyses will be performed on tissue and blood samples for exploratory purpose. **Conclusions:** The CARACAS trial was the first clinical study to test dual EGFR and PD-L1 blockade in advSCAC. Both AVE monotherapy and AVE-CET showed promising activity with manageable safety profile. Clinical trial information: NCT03944252. Research Sponsor: Veneto Institute of Oncology IRCCS, Pharmaceutical/Biotech Company.

4052 Poster Session (Board #44), Fri, 8:00 AM-11:00 AM

Characterization of sociodemographic and clinicopathological features and associated outcomes of patients (Pts) with anal squamous cell cancer (ASCC): Analysis of 44,084 pts in the National Cancer Database (NCDB). *First Author: Joanna Alyse Young, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: ASCC incidence is rising. There are limited data on the relationships between sociodemographic & clinicopathological features and outcomes of ASCC pts. **Methods:** Pts diagnosed with ASCC between 2004 and 2016 were retrospectively reviewed. Data obtained from the NCDB were used to examine the impact of sociodemographic status on clinicopathological features and outcomes. Pts were categorized based on low (median $<$ \$38,000) or high ($\geq$\$68,000) income and low ($>$ 21% with no high school diploma) or high ($<$ 7% with no high school diploma) education areas based on zip code at time of diagnosis. Logistic regression and chi-square were used to examine differences between groups. **Results:** In total, 44,084 pts with ASCC were identified: median age, 59 yrs, 86% white; 11% black; 64% female. Most pts (84%) resided in metro areas; 29.7% vs 19.8% lived in high vs low income areas; 22.9% vs 17.8% lived in high vs low education areas. Seven percent were uninsured, 50% had government (Gov), and 43% had private insurance. Male gender (HR 1.62, CI 1.41-1.85, $p < 0.001$), low income area (HR 1.28, CI 1.19-1.37, $p = 0.014$), and insurance status (Gov, HR 1.55, CI 1.32-1.82, $p < 0.001$ and uninsured, HR 1.37, CI 1.37-1.85, $p = 0.039$) were associated with a higher risk of death. After adjusting for age, sex, race, stage, grade, insurance status, and comorbidity, pts from low income/education (n = 6695) vs high income/education (n = 4316) areas had a 33 % increased risk of death (HR: 1.33, $p < 0.001$). Pts with stage IV ASCC in the low income/education (n = 227) vs high income/education (n = 295) groups had worse overall survival (mOS, 1.4 vs 1.9 yrs, $p < 0.020$). Of the 44,084 pts, 5461 (12.4%) had confirmed HPV status. Of these, 2658 (48.7%) were HPV+ (high risk subtypes) and 2803 (51.3%) were HPV-. Compared to the HPV- pts, HPV+ pts were more likely to be women (71.8% vs 67.8%, $p = 0.001$), have stage 3 (38.1% vs 33.6%) or 4 (7.9% vs 5.9%, $p < 0.001$) cancer, and have poorly differentiated (29.5% vs 25.6%, $p < 0.001$) tumors. There were no significant differences in race, education, income, metro area, insurance status, or comorbidity between the HPV+ and HPV- pts. Moreover, HPV status did not impact OS (HR 0.92, CI 0.81-1.04, $p = 0.195$). **Conclusions:** HPV status was not correlated to income, education or insurance status, and did not impact OS in ASCC pts. Male gender and insurance status were associated with increased risk of death. Pts living in low income and low education areas were associated with worse survival. Research Sponsor: None.

4053 Poster Session (Board #45), Fri, 8:00 AM-11:00 AM

Prospective study of biomarkers in squamous cell carcinoma of the anal canal (SCCAC) and their influence on treatment outcomes: Five-year long-term results. *First Author: Camila Motta Venchiarutti Moniz, Instituto do Câncer do Estado de São Paulo, Universidade de São Paulo, São Paulo, Brazil*

Background: Chemoradiation (CRT) is a curative treatment for SCCAC. However, some patients (pts) present primary CRT resistance. As a rare tumor, there is a lack of prospective studies of prognostic factors in this setting. **Methods:** This prospective cohort study was aimed to evaluate predictive biomarkers (Ki-67, PD-L1, Human papillomavirus (HPV), HIV status, and tumor DNA mutations) in SCCAC. We published the 6 months (m) response rate (RR) of this cohort showing that HIV- were 5.7 times more likely to achieve response 6m post CRT (OR 5.72, CI 95% 2.5-13.0, $P < 0.001$). Now we report the long-term follow-up results of 5-year progression-free survival (PFS) and overall survival (OS). Eligible pts had T2-4/N0-3/M0 disease and were candidates to standard CRT. DNA mutations were analyzed by next-generation sequencing (NGS). HPV positivity was tested by PapilloCheck Test. KI-67 and PD-L1 were evaluated by immunohistochemistry. **Results:** 78 pts were recruited from Jan/2011 to Dec/2015. 75 were evaluable for PFS and OS. The median age was 57 years; 49 (65%) were stage III, and 9 (12%) were HIV+. HPV was evaluated in 67 and found in 47 (70.1%); HPV16 was the most common. PD-L1 was tested in 61; 10 (16.4%) had positive expression $> 1\%$. Ki-67 was performed in 65, with a median of 50% (range 1-90%). The median follow up is 66m. 5-year PFS and OS rates were 63.3% (95% CI 51.2-73.2%) and 76.4% (95% CI 64.8-84.6%), respectively. In a multivariate analysis, age (HR 1.06, P = 0.022, IC 95% 1.01-1.11) and absence of complete response at 6m (HR 3.36, P = 0.007, IC 95% 1.39-8.09) was associated with inferior OS. The OS rate was 62.5% in HIV+ group (95% CI 22.9-86%) in comparison with 78% (95% CI 65.7-86.3%) among HIV- pts, although this difference was not statistically significant (P = 0.400). A tendency to inferior OS was observed among pts with p53 codon 72 polymorphism (HR 2.83, P = 0.181, 95% CI 0.61-13.02). Other tumor mutations, HPV, Ki-67 expression, and PD-L1 expression, were not associated with PFS and OS. **Conclusions:** HIV- pts were 5.7 times more likely to achieve response 6m post CRT. The absence of complete response at 6m was the main factor associated with poor 5-year OS. New strategies of follow up and complementary treatment should be studied in late responders and HIV+ pts to ensure the success of curative treatment. Clinical trial information: 36211. Research Sponsor: FAPESP- Fundação de Amparo a Pesquisa do Estado de São Paulo (Sao Paulo State Research Support Foundation).

4054 Poster Session (Board #46), Fri, 8:00 AM-11:00 AM

PDL1 expression predicts therapeutic outcome in non metastatic anal squamous cell carcinoma (NMASCC). *First Author: Ilma Soledad Iseas, Oncology Unit, Hospital de Gastroenterologia Bonorino Udaondo, Buenos Aires, Argentina*

Background: NMASCC is a rising incidence disease with up to 30% of treatment failure to achieve complete response (CR) after standard chemoradiotherapy (CRT) leading to severe morbidity and death. Stage III-TNM, p53 mutations, HPV negativity, HIV infection are linked to treatment failure. We investigated the predictive/prognostic role of TNM, CR, HPV, PDL1 positivity and CD3/CD8 densities in NM-ASCC from a single institution. **Methods:** All 79 eligible consecutive NMASCC pts (available FFPE pre-treatment samples) seen from October-2009 to April-2019 having completed definitive CRT (50.4 Gy Pelvic Radiotherapy with Mitomycin-C 12mg/m2/IV/d1-5 / FU 1000mg/m2/d1-4 d29-32 (28%), Mitomycin-C/Capecitabine 825 mg/m2/bid (38%), Cisplatin 60 mg/m2/IV d1-29 and 5FU (34%) were analyzed. Mean age: 59 (range 26-87), 72% female, Stage III: 59%, HPV positive: 86% (HPV-16: 80%);14% HIV positive. IHC assessed by two pathologist for PD-L1 expression (ClonSP263) and CD3-CD8+ TILS densities (Clone 2GV6, Clone SP57). HPV-DNA assessed by PCR (BSGP5+/6+ multiplexed with beta-globin). Kaplan-Meier survival, CR, DFS, OS and Univariate analyses were performed using Cox proportional hazard model. **Results:** CR achieved within 6 months of treatment completion was 68%(53pts). Median follow-up after treatment completion: 35 months (range 6 –149). As of February 2020, 82% (65 pts) are alive, no evidence of disease:(57%) 46 pts, recurrence rate: 26%(22 pts), cancer death: 18% (14 pts). PDL1+ tumors ($>$ 1% positivity-CPS score): 56%, expression levels: 1-5% (57%,26p), $>$ 10%-100% (43%,19p). PDL1+ had a strong association with CR (p = 0.021); higher PDL1+ levels had 8-fold of CR-likelihood than PDL1 negative.(OR 8.50 vs. 1.12). Significative Spearman correlation between PDL1 tumors with CR and CD3-CD8 TILS density was observed (R = 0.43,p = 0.0017 and R = 0.36,p = 0.00094 respectively), albeit CD3-CD8 failed to reach significance as prognostic factors for either CR, DFS or OS. Only CR and PDL1 positive were strongly significantly associated to DFS (HR 0.10 [IC 95% 0.04-0.28] p $<$ 0.001 and HR 0.28 [IC 95% 0.11-0.73] p = 0.006) and OS (HR 0.12 [IC 95% 0.03-0.45] p $<$ 0.001 and HR 0.15 [IC 95% 0.03-0.68] p $<$ 0.004). Low prevalence of HPV negative, early tumors, HIV positive cases in our series probably impacted in statistical power for prognosis correlation. **Conclusions:** PDL1 positivity was the strongest predictive/prognostic factor in NM-ASCC. Alternative therapeutics options to standard CRT should be explored on poor-risk patients as HPV-negative, P53-mutated and PDL1 negative patients. Research Sponsor: None.

4055 Poster Session (Board #47), Fri, 8:00 AM-11:00 AM

Patient-reported gastrointestinal outcomes in patients with anal cancer. *First Author: Ramez Kouzy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Among patients with anal cancer, chemoradiotherapy tends to offer an excellent prognosis but is often associated with undesirable toxicities that diminish quality of life. We sought to quantify the gastrointestinal-related patient-reported outcomes (PROs) of anal cancer patients receiving chemoradiotherapy in order to improve patient-physician communication and shared decision making. **Methods:** We prospectively followed patients with non-metastatic squamous cell carcinoma of the anal canal who received definitive chemoradiotherapy. Patients reported outcomes were collected using the bowel subdomain of the Expanded Prostate Cancer Index Composite (EPIC) questionnaire before treatment and at 4 subsequent timepoints. We used descriptive statistics to summarize the patients' characteristics and EPIC scores, then used the paired Wilcoxon test to compare EPIC scores at different timepoints. **Results:** The study included 21 patients (16 women and 5 men), whose median age was 57 years. Most patients (52%) had T2, and either N0 (38%) or N1 (43%) disease. Most patients (91%) received standard of care chemoradiotherapy. Compared with the patients' median overall summary score at baseline (66), their median score at 1 week (82) was significantly higher (p = 0.009), whereas their median score at 5 weeks (54) was significantly lower (p = 0.025). However, the patients' median overall summary score at baseline and at 3 months did not differ significantly (p = 0.919). Three months after radiotherapy, most patients (73%) reported rarely or never having bloody stools, and most (82%) reported rarely or never being bothered by bloody stools. Overall, EPIC scores show initial improvement of all domains, followed by some worsening of symptoms before returning to baseline levels. **Conclusions:** Anal cancer patients' gastrointestinal-related PROs tend to fluctuate during radiotherapy but return to baseline by 3 months, at which time most patients report few or no residual side effects. Our data provide a clear timeline of gastrointestinal acute toxicity using sequential PRO measurements that will improve patient-physician communication regarding expectations for cancer treatment and help in shared decision making. Research Sponsor: None.

4056 Poster Session (Board #48), Fri, 8:00 AM-11:00 AM

Socioeconomic status based on race in early-stage anal squamous cell carcinoma undergoing locoregional therapy. *First Author: Suleyman Yasin Goksu, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Anal Squamous Cell Cancer (ASCC) is a highly curable cancer. Underserved and vulnerable populations are particularly at risk of developing this disease. We aimed to study racial disparities and overall survival (OS) in patients with ASCC who received radiation therapy (RT) or chemo-RT (CRT) using the National Cancer Database. **Methods:** We identified adult patients with early-stage (stage I-II) ASCC diagnosed between 2004-2016 who underwent RT or CRT. We compared the clinical and treatment characteristics of white and black patients. The chi-square test was used for categorical variables. Kaplan-Meier and Cox regression method performed for survival analyses. We used 1:1 nearest neighbor propensity score matching to eliminate selection bias. **Results:** A total of 10,014 patients; 90.2% were white and 9.8% were black. White patients were more likely to be female, older age, have higher rate high-school education, private insurance, higher income, and travel a longer distance (all $p < .001$). Black patients were more likely to be higher comorbidity score and be treated at an academic/research facility. White patients had a higher rate of CRT and significantly better overall survival (OS) as compared to black patients (5-year survival 76% vs. 70%, $p < .001$) which persisted after propensity score matching (5-year survival 76% vs. 70%, $p = .002$). This difference continued after adjusting for clinically important factors, including HPV status (unmatched $p < .03$, matched $p = .008$). In the patients who received CRT, white patients were associated with improved OS versus black patients (unmatched 77% vs. 71%, $p < .001$; matched 77% vs. 71%, $p = .011$), and even after multivariate Cox analysis (unmatched $p < .001$; matched .014) (Table). **Conclusions:** White patients had significantly better OS as compared to black patients with early-stage ASCC as well as in the patients who received CRT. White patients were associated with high education level, higher income, and private insurance. The rate of HPV positive was similar among groups. Further investigations are needed to enlighten these disparities and target the increase education of the population at risk. Research Sponsor: None.

17-year incidence trends of anal squamous cell carcinoma. *First Author: Khushali Jhaveri, MedStar Washington Hospital Center, Washington, DC*

Background: Anal Cancer is a rare neoplasm with 9 out of 10 cases being Anal Squamous Cell Carcinoma (SCCA). We did a population-based analysis to assess the incidence trends in patients with SCCA and identify any significant change in the direction of trends using the Surveillance, Epidemiology, and End Results (SEER) database. **Methods:** Data was extracted from SEER database for the years 2000-2016 for the US population, across all gender, ages, and races. Joinpoint regression models of SCCA incidence were fitted to identify any discrete joints (year) that represent statistically significant changes in the direction of the trend. The average annual percentage change (APC) in the age-adjusted incidence rate in the pre- and post-joinpoint era were measured. Subgroup analysis for gender, ages, and races was also done. **Results:** 27,721 new adult cases of SCCA were identified from 2000 to 2016. The incidence was higher amongst females (62.44%) compared to males (37.56%) with the white population contributing 85.41% to incidence compared to black (11.84%) and other (2.75%) population. The age-based incidence rate for different groups has been mentioned in Table. A significant jointpoint for SCCA incidence was observed in 2009. The APC was 4.6% (3.5-5.6 95% CI) in 2000-2009 which reduced to 2.1% (0.7-3.4 95% CI) in 2009-2016 indicating a 54% relative reduction in the average annual APC in the US population after 2009. Subgroup analysis revealed significant joinpoints for incidence decrease in Ages 40-59, 80 and above and females of all ages. No significant changes in APC were seen when stratified by race (Refer to Table). **Conclusions:** Our study, in our knowledge, is the first study assessing incidence trends of SCCA over 17-years. The overall incidence of SCCA is increasing but a statistically significant trend towards decreasing rate of growth in incidence was observed in 2009 and later. Further studies are needed to analyze the causality of such changes in the trend of SCCA. Research Sponsor: None.

Gender	Age	Race	Incidence(N)	Joinpoint year	APC pre-joinpoint year (95% CI)	APC post-joinpoint year (95% CI)	APC reduction
Both	All	White	23,677(85.41%)	No trend change			
Both	All	Black	3,281(11.84%)	No trend change			
Both	All	Other	763(2.75%)	No trend change			
Both	20-39 years	All	1,056(3.81%)	No trend change			
Both	40-59 years	All	12,705(45.83%)	2009	5.7% (4.3- 7.0)	-0.3% (-1.8- 1.3)	105%

Utilization and trends in palliation-directed treatments for stage II-IV anal squamous cell carcinoma patients. *First Author: Srinidhi Radhakrishnan, UT Southwestern, Dallas, TX*

Background: Anal squamous cell carcinoma (ASCC) is associated with significant symptom burden including pain, bleeding, and obstructive symptoms. However, the proportion of patients requiring palliation-directed treatments in ASCC is unknown. Palliation-directed treatments can control and improve symptoms and affect quality of life. We aimed to study trends, factors, and outcomes associated with utilization of palliation-directed treatment in ASCC. **Methods:** Using the National Cancer Database (NCDB), adult patients with stage II-IV ASCC diagnosed 2004-2015 were identified and stratified by receipt of palliation-directed treatments. Using chi-square test and logistic regression, we evaluated the associations of demographic, clinical, and pathological factors with palliation-directed treatment utilization. **Results:** Out of 17,988 ASCC patients in this study, palliation-directed treatments were used by 504 patients (2.8%) with stages II-IV ASCC as first line treatment. Two percent received palliation-directed surgery, chemotherapy, and radiotherapy, 0.3% received pain management, and 0.4% utilized combination therapy approach. On univariable analysis, palliation-directed treatments were associated with older age, lower income level ($p=0.004$), Medicare insurance, and higher comorbidity score (*all other* $p<0.001$). Palliation-directed treatments were also more frequent in academic/research facilities ($p=0.01$), in East North Central USA ($p=.001$), and in stage 4 versus stage 2/3 ASCC ($p<.001$). Palliation-directed treatments have increased in recent years (2004-06 vs. 2013-15; $p=.005$) and were more frequently used within 6 months of patient death ($p<.001$). On multivariable analysis stage 4 disease and life expectancy $<$ 6 months were the only variables that maintained significance. **Conclusions:** In our study, palliation-directed treatments were used by 2.8% of the patients as codified by NCDB. Its use was higher in stage 4 ASCC and within the last six months of life. Palliation-directed treatment utilization has incrementally increased in recent years. Additional research is warranted in determining the phase of care wherein palliation-directed treatments are utilized in ASCC. Research Sponsor: None.

4060 Poster Session (Board #52), Fri, 8:00 AM-11:00 AM

The role of fibroblast growth factor receptor 4 (FGFR4) signaling in anti-EGFR resistance in colon cancer. *First Author: Sang Hee Cho, Department of Hematology-Oncology, Chonnam National Univeristy Hwasun Hospital, Hwasun, South Korea*

Background: Anti-EGFR therapy has been used as a standard treatment for metastatic colon cancer, but the innate resistance is still issues of increasing significance. Fibroblast growth factor receptor 4 (FGFR4) plays an important role in cell proliferation, invasion and anti-apoptosis, through the pathway of MAPK-ERK and PI3K-AKT. We investigated potential crosstalk between FGFR4 and EGFR signaling to identify new resistant mechanism of anti-EGFR therapy and how to overcome it in colon cancer. **Methods:** RNA-Seq was used to identify the associated signal pathway and down targets induced by FGFR4. Molecular studies including RTK array, RT-qPCR, western blotting were performed to validate the interaction between FGFR4 and EGFR signaling *in vitro* and *in vivo*. Next, the effect of FGFR4 in cetuximab resistance was investigated *in vitro* and in colon cancer patients. **Results:** FGFR4 overexpression in colon cancer cells activates downstream signaling, such as, PI3K/Akt and RAS/RAF/Erk pathway. Gene Ontology (GO) analysis from RNA-seq revealed that differentially expressed genes (DEGs) altered by expression of FGFR4 were related to biological functions, including cell proliferation, epidermal growth factor receptor signaling, NIK/NF-kB signaling, interferon-gamma signaling, wound healing. RT–qRCR showed that FGFR4 promotes the EGFR and ErbB3 by inducing the expression of EGFR ligands such as AREG, BTC, EREG, HBEGF. In vivo tumorigenesis, we found that FGFR4 promotes tumor growth and high expression of AREG in xenograft tumors. FGFR4 expression reduced the sensitivity to cetuximab in colon cancer cells and synergistic effect was shown when treated with FGFR4 inhibitor with cetuximab. A positive correlation between FGFR4 and AREG expression was observed in cancer, but not in normal tissues and high FGFR4 or AREG expression showed significantly inferior overall survival than low expression in patients treated with cetuximab for metastatic colon cancer. **Conclusions:** We demonstrated a pivotal mechanism of FGFR4 in colon cancer progression and cetuximab resistance through inducing AREG. Our data point to FGFR4 as a new biomarker to predict cetuximab response and dual targeting of FGFR4 and EGFR may be a promising treatment modality for colon cancer. 4061 Poster Session (Board #53), Fri, 8:00 AM-11:00 AM

Consensus molecular subtypes in colorectal cancer differ by geographic region. *First Author: Krittiya Korphaisarn, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkoknoi, Thailand*

Background: The consensus molecular subtypes (CMS) have emerged as a novel classification in colorectal cancer (CRC). However, these subtypes, were mostly derived from a US/European population, and have scant data in other ethnic groups. This study aimed to demonstrate molecular subtypes of CRC across geographic regions. **Methods:** Formalin fixed paraffin embedded (FFPE) tissue from untreated patients with stage II-III colon cancer from Brazil, Canada, Mexico, Thailand, and the US were evaluated. Gene expression profiling was performed at the University of Texas MD Anderson Cancer Center using NanoString's nCounter technology and an optimized classifier for FFPE. **Results:** A total of 366 samples were included in this study, evenly distributed between the 5 international sites. While the US population matched previously reported distributions, the distribution of CMS subtypes varied substantially by region ($P < 0.0001$). While CMS1 was still associated with right-sided tumors ($P < 0.001$) and deficient mismatch repair (dMMR) ($P < 0.001$), the prevalence varied between 8% in Brazil to 30% in Mexico. CMS2 was found vary from 14% in Mexico to 47% in Brazil. The metabolic CMS3 subtype was present in only 3% in Thailand, but as high as 19% in Brazil. CMS4 was confirmed to be associated with higher stage ($P = 0.047$), and the prevalence was lowest in Brazil (14%) compared to 44% and 49% in US and Mexico, respectively. Expansion of study cohort is ongoing. **Conclusions:** CMS subtype prevalence differs substantially by geographic region in CRC. These variations suggest that transcriptomic-defined disease biology in international populations may be more heterogeneous than previously appreciated. Further studies in global populations are required to validate and extend these findings, which may have important impact for novel therapeutic development. Research Sponsor: Moon Shot funding.

4062 Poster Session (Board #54), Fri, 8:00 AM-11:00 AM

Initial correlative studies from a trial of cetuximab and pembrolizumab in metastatic colorectal cancer (mCRC). *First Author: Patrick M Boland, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Cetuximab is an EGFR-targeting IgG1 mAb. Pre-clinical data suggests cetuximab induces $CD8^+$ cytotoxic T-cell (CTL) infiltration of tumors. We hypothesized that augmentation of CTLs in the tumor microenvironment (TME) may provide the proper milieu for effective PD-1 inhibition in metastatic colorectal cancer (mCRC). We conducted a phase Ib/II study of cetuximab with the PD-1 antibody, pembrolizumab, in mCRC. Correlative blood and tissue samples were collected to assess the impact of this treatment on CTLs, as well as potential compensatory alterations in regulatory T-cells (Tregs) and suppressive MDSCs (NCT02713373). **Methods:** 3 week treatment cycles included pembrolizumab at 200 mg on day 1 and cetuximab 250 mg/m2 following the 400 mg/m2 loading dose. Tumor biopsies were obtained at baseline and at c4d1 (Day 64). Peripheral blood (PB) was drawn at baseline, c2d1 (day 22) and c4d1 (Day 64). Flow cytometry was performed within 24 hours with additional samples stored for future analysis. In the present analysis, we assessed changes in levels of the cellular populations of interest between cycle 4 and cycle 1. **Results:** Forty-two RAS-wt patients were enrolled through October 2019. Paired tumor tissues were successfully analyzed for 16 patients and PB for 38. Intratumoral CTLs ($CD3^+CD8^+$) increased significantly (+47%, $p < .05$). In PB, there was a slight overall decrease in PB CTLs (-5%, p = NS) and a significant decrease in $CD8^+CD45RO^+PD1^+$ cells (-42%, $p < .05$). We saw simultaneous decreases in PD-1^+ CTLs in the tumor and PB. There was a trend for increase in Tregs (CD4+ Cd25+ FoxP3+) in PB (+11%, p = NS), but an overall increase in the Teff:Treg ratio (+30%, p = NS). $CD4^+CTLA4^+$ cells significantly increased (+37%, $p < .05$). Granulocytic MDSCs ($CD11b^+CD14^-CD33^+HLADR^-$) in PB decreased significantly on-treatment (-30%, $p < 0.5$). The sample size and tissue limitations prohibited meaningful evaluation of tissue Tregs and MDSCs via the present methods. **Conclusions:** Cetuximab and pembrolizumab induced dynamic changes in the TME and PB. The treatment associated increase in intratumoral CTLs was particularly pronounced, consistent with their local expansion and/or influx. This was accompanied by a decrease in PB CTLs. Decreases in multiple PD-1^+ lymphoid populations were observed in both tumor and PB, notably PD-1^+ CTLs. Of note, we saw a synchronous increase in immunosuppressive $CD4^+CTLA4^+$ T-cells in PB. Patient outcomes are pending maturation. Further analyses are planned, coupled with integration of clinical data. Clinical trial information: NCT02713373. Research Sponsor: Merck.

4063 Poster Session (Board #55), Fri, 8:00 AM-11:00 AM

Development of drug resistance in colon cancer patients following chemotherapy, a contributing factor in the failure of oxaliplatin-based HIPEC to improve survival in the Prodige 7 trial. *First Author: Robert Alan Nagourney, Nagourney Cancer Institute, Long Beach, CA*

Background: Numerous studies suggest benefit for heated intra-peritoneal chemotherapy (HIPEC) in colon cancer but the Prodige 7 trial in 265 colon cancer patients randomized to HIPEC or observation after neo-adjuvant chemotherapy (NACT) didn't confirm benefit with median OS of 41.7 vs. 41.2 mos. (p = 0.99) (Proc. ASCO, 2018). One concern is that prior drug exposure selects for drug resistance blunting HIPEC effect. To test the hypothesis we examined the impact of prior chemotherapy on drug resistance in human tumor organoids isolated from colon cancer patients. **Methods:** Data query identified 111 colorectal cancers (87 colon & 24 rectal) tested for Oxaliplatin sensitivity by ex vivo analysis of programmed cell death (EVA/PCD), a primary culture platform that examines drug induced cell death (apoptotic & non-apoptotic) by morphology, metabolism & histology. Five-point dose response curves interpolated to provide lethal concentration 50% (LC50) were compared by Z score to distribute Oxaliplatin LC50 values around the mean using standard deviation units as the metric of sensitivity or resistance. Of 87 colon 54(62%) were untreated and 33 (38%) treated with 21/33 (64%) having received FOLFOX. To approximate Prodige 7, treated patients were separated by having received FOLFOX $< 2 >$ months before EVA/PCD analysis and also compared Mitomycin (14 vs 41), Irinotecan (18 vs 47) & 5-FU (19 vs. 52) activity to assess cross-resistance. **Results:** Compared to chemo-naïve, FOLFOX-treated patients were significantly more resistant to Oxaliplatin ($P < 0.01$) with the degree of resistance increasing significantly for patients who received treatment < 2 months prior to EVA/PCD compared to those with chemotherapy > 2 months prior to EVA/PCD ($P < 0.01$). Activity for Mitomycin & Irinotecan was not significantly different for chemo-naïve vs. treated patients, but 5 FU was more resistant (P = 0.048) in previously treated. **Conclusions:** The failure of Prodige 7 to improve survival with HIPEC following NACT may reflect diminished Oxaliplatin activity in patients whose residual disease has been selected for Oxaliplatin & 5FU resistance. Resistance was not observed for Mitomycin or Irinotecan. This suggests that those using HIPEC may i) examine other classes of drugs or drug combinations for IP administration ii) improve the selection of candidates for HIPEC administration or iii) consider HIPEC administration earlier in the course of therapy when chemotherapy-induced drug resistance may be less evident. Research Sponsor: None.

4064 Poster Session (Board #56), Fri, 8:00 AM-11:00 AM

The landscape of DNA damage response (DDR) pathway in colorectal cancer (CRC). *First Author: Hiroyuki Arai, Chiba Cancer Center, Chibashi, Japan*

Background: Abnormal DDR is a hallmark of cancer, relating to genome instability, anti-tumor immunity, and sensitivity to chemotherapeutic agents and radiation. We conducted a large-scale investigation to clarify the alteration of DDR pathway in CRC. **Methods:** Tumor samples from 9321 CRC patients were retrospectively reviewed. Next-Generation Sequencing (NGS) on a custom-designed panel enriching 592 gene targets was performed. Samples with mutations detected in any of 29 DDR-related genes were deemed DDR-mutant (DDR-MT); the rest DDR-wild type (DDR-WT). Microsatellite instability (MSI) status was tested with a combination of immunohistochemistry (IHC), fragment analysis and NGS. Tumor mutational burden (TMB) was calculated based on somatic nonsynonymous missense mutations. PD-L1 was tested by IHC (SP142). Consensus molecular subtype (CMS) was developed using RNA sequencing data. **Results:** Of 9321 cases, 1290 (13.8%) were DDR-MT. DDR-MT frequency was higher in right vs. left sided (20.9% vs 10.8%, $p < 0.001$) and MSI-H vs. MSS (76.4% vs 9.5%, $p < 0.001$) cases. In the MSS cases, right-sided had marginally higher frequency of DDR-MT than left-sided (10.6% vs 9.1%, p = 0.055), with much higher frequency of Fanconi anemia pathway alteration in right-sided (1.5% vs 0.7%, $p < 0.01$). CMS1 subtype had the highest frequency of DDR-MT (34.8%); CMS2 had the lowest (7.1%). DDR-MT cases (vs. DDR-WT) had higher mutation rate of *ARID1A* (55.0% vs 19.1%, $p < 0.0001$), *PIK3CA* (22.6% vs 15.8%, $p < 0.0001$) and *BRAF* (20.4% vs 7.3%, $p < 0.0001$), and lower mutation rate of *TP53* (48.2% vs 76.1%, $p < 0.0001$), *APC* (60.5% vs 74.5%, $p < 0.0001$) and *KRAS* (44.0% vs 49.8%, $p < 0.001$). Mean TMB was much greater in DDR-MT than DDR-WT (All: 20.9/Mb vs 7.7/Mb, $p < 0.0001$; MSS: 13.7/Mb vs 7.6/Mb, $p < 0.05$). *PD-L1* positivity was also higher in DDR-MT compared to DDR-WT (All: 10.1% vs 2.7%, $p < 0.0001$; MSS: 4.8% vs 2.4%, $p < 0.0001$). **Conclusions:** Alteration of the DDR pathway was strongly associated with MSI status in CRC. The primary tumor sidedness might also be related, as DDR-MT was more prevalent in right-sided tumors. Elevated TMB and PD-L1 expression in DDR-MT CRC indicate more activated anti-tumor immune profiles compared to DDR-WT, regardless of MSI status, suggesting possible therapeutic benefit from immune checkpoint inhibitors in DDR-MT CRC. Research Sponsor: None.

4065 Poster Session (Board #57), Fri, 8:00 AM-11:00 AM

Tumor-infiltrating lymphocytes and tumor budding refine prognostication in patients with low- and high-risk stage III colon cancers (NCCTG N0147) [Alliance]. *First Author: Dan Sha, Mayo Clinic, Rochester, MN*

Background: Tumor infiltrating lymphocytes (TILs) and tumor budding (linked to epithelial mesenchymal transition) may influence metastatic potential and patient prognosis. We analyzed these features and their relative contribution to survival among low ($T_{1\text{-}3}$ N_1) and high (T_4 and/or N_2) risk groups, defined by the IDEA study, used to inform the duration of adjuvant chemotherapy in stage III colon cancer. **Methods:** Among 1,532 patients (low risk n=804; high risk n=728) treated in a phase III adjuvant trial of FOLFOX + cetuximab (x 6 months), intraepithelial TIL densities and tumor budding were quantified at microscopy in routine histologic sections. Optimal cutpoints were determined in association with 5-yr disease-free survival (DFS). Relative contribution of variables to DFS was calculated using $\chi 2$ from Harrell's rms R package based on multivariable Cox regression models. **Results:** In the overall cohort, the tumor budding/TILs combined variable was more robust for predition of DFS than either alone. Budding/TILs was significantly associated with DFS in both low (HR_{adj}, 1.59; 95% CI, 1.02-2.48; p=.0273) and high (HR_{adj}, 2.82; 95% CI, 1.72-4.63; p<.0001) risk patients. We then determined its relative contribution (%) to DFS (Table). Among low risk, budding/TILs ranked second (24.4%) behind *KRAS* status (45.5%) and ahead of treatment arm (7.2%) and mismatch repair (MMR) status (6.1%). Among high risk, budding/TILs contributed the most to DFS (45.4%) followed by primary tumor sidedness (13.0%), performance status (12.0%), and MMR (10.4%). **Conclusions:** Tumor budding/TILs provides robust prognostic stratification by risk group to improve anatomic tumor staging. The relative contribution of budding/TILs to DFS was second only to *KRAS* status in low risk patients, and was the most important predictor of DFS in high risk patients. Evaluation in patients treated with 3 vs 6 mos of adjuvant chemotherapy is warranted. Research Sponsor: U.S. National Institutes of Health.

Relative contribution to patient DFS.

Low Risk (T1-3N1)	Percent (%)	High Risk (T4 and/or N2)	Percent (%)
KRAS	45.5	Budding/TILs	45.4
Budding/TILs	24.4	Sidedness	13.0
Treatment	7.2	Performance Status	12.0
MMR	6.1	MMR	10.4
Performance Status	5.0	*KRAS*	9.1
BRAF	5.0	Treatment	5.1
Age	3.8	Histologic Grade	2.8
Sidedness	2.3	Other	2.2
Histologic Grade	0.8		

4066 Poster Session (Board #58), Fri, 8:00 AM-11:00 AM

Somatic alterations of *NF1* in colorectal cancer. *First Author: Hiroyuki Arai, Chiba Cancer Center, Chibashi, Japan*

Background: *NF1* encodes neurofibromin, which is a key GTPase-activating protein that downregulates RAS activation. Inactivating mutations in *NF1* result in sustained activation of RAS signaling, a key driver for development of colorectal cancer (CRC), and have been suggested to be a potential mechanism of resistance to EGFR inhibition in *RAS*-wild type (WT) CRC. Little is known about molecular characteristics of *NF1*-mutated (MT) CRC. **Methods:** Tumor profiles from 8150 CRC patients (pts) with available *NF1* mutation status were retrospectively reviewed. NextGen sequencing by a customized 592-gene panel was performed. Microsatellite instability (MSI) / mismatch repair (MMR) status, tumor mutational burden (TMB) and PD-L1 expression were tested. Molecular profiles between *NF1*-MT and *NF1*-WT pts were compared. **Results:** Out of 8150 pts, 176 (2.2%) had somatic *NF1* mutations with pathogenic or presumed pathogenic function. A higher *NF1*-MT frequency was observed in MSI-H/dMMR vs MSS/pMMR (13.5% vs 1.4%, $p < 0.0001$), in right-sided vs left sided (2.9% vs 1.8%, $p < 0.01$), and in *RAS*-WT vs *RAS*-MT (3.0% vs 1.4%, $p < 0.0001$). In MSS/pMMR tumors, no association with sidedness was observed (right: 1.3% vs left: 1.2%, NS). The most prevalent co-mutations with *NF-1* were *APC* (63.2%), *ARID1A* (57.5%), *TP53* (51.5%), *KMT2D* (32.9%) and *KRAS* (32.4%) in all cases, and *APC* (76.2%), *TP53* (69.5%), *KRAS* (38.8%), *ARID1A* (34.4%) and *FBXW7* (21.5%) in MSS/pMMR cases. *POLE* mutation was observed in 18.4% of *NF1*-MT/MSS/pMMR pts. Compared to *NF1*-WT pts, *NF1*-MT pts had more frequent mutations in *ARID1A* (All: 57.5% vs 23.3%, $p < 0.0001$; MSS/pMMR: 34.4% vs 15.2%, $p < 0.05$), and less frequent mutations in *KRAS* (All: 32.4% vs 49.0%, $p < 0.0001$; MSS/pMMR: 38.8% vs 50.3%, $p < 0.05$). Also, *NF1*-MT pts had more frequent alterations in homologous recombination pathway compared to *NF1*-WT pts (All: 39.8% vs 7.5%, $p < 0.0001$; MSS/pMMR: 17.5% vs 4.4%, $p < 0.0001$). Mean TMB was significantly greater in *NF1*-MT than *NF1*-WT (All: 48.9/Mb vs 10.0/Mb, $p < 0.0001$; MSS/pMMR: 48.3/Mb vs 8.2/Mb, $p < 0.0001$). Also, PD-L1 positivity was higher in *NF1*-MT compared to *NF1*-WT (All: 12.9% vs 3.6%, $p < 0.0001$; MSS/pMMR: 7.1% vs 2.6%, $p < 0.05$). **Conclusions:** While more frequent than in *RAS*-MT pts, *NF1*-MT CRC was a small subset in *RAS*-WT pts. *NF1*-MT was associated with alterations in chromatin remodeling and DNA damage response pathways, as well as elevated TMB and PD-L1 expression, which may provide alternative therapeutic strategies beyond EGFR inhibition. Research Sponsor: None.

4067 Poster Session (Board #59), Fri, 8:00 AM-11:00 AM

Prognostic differences of RAS mutations: Results from South Australian (SA) metastatic colorectal (mCRC) registry. *First Author: Timothy Jay Price, Queen Elizabeth Hospital, University of Adelaide, Adelaide, Australia*

Background: Effective targeting of RAS mutations has proven elusive until recently. AMG 510, a novel agent which targets KRAS G12C mutations (G12C MT), has shown promise in early phase clinical trials that included patients with mCRC. Prior reports have suggested that G12C MT may be predictive of poor outcome. **Methods:** We aimed to assess the prognostic implications of individual RAS in a population-based registry. The SAmCRCR collects data from all patients diagnosed with mCRC in South Australia prospectively. Individual RAS mutation data from patients entered into the SAmCRCR between February 2006 and December 2018 was reviewed. Survival was analysed for the more frequent mutations using Kaplan Meier method. **Results:** 1605 (33%) of the 4905 patients entered onto the registry had RAS mutation results available. Of these, 658 (41%) had RAS MT. The nature of the RAS MT was available in 563 (85.7% of those with RAT MT). Patient characteristics, frequency of individual RAS MT and median overall survival (OS) per RAS MT are noted in table. Low frequency MT made up an additional 16.3%. There were numerical differences in survival however there was no statistical difference in survival when comparing the various RAS MT, including the comparison of G12C to G12S (p = 0.38). **Conclusions:** Whilst the G12S mutation was associated with the longest survival numerically, the observed survival for patients with the most common RAS mutations (G12C, G12V, G12A, G12D and G13D) did not significantly differ. Research Sponsor: None.

RAS MT (percentage)	G12C (9.6%)	G12A (10.7%)	G12D (22%)	G12S (4.4%)	G12V (23.6%)	G13D (13.3%)

4068 Poster Session (Board #60), Fri, 8:00 AM-11:00 AM

Impact of tumor side on clinical outcomes in stage II and III colon cancer with known microsatellite instability status. *First Author: Katerina Mary Zakka, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Microsatellite instability high (MSI-H) status indicates better prognosis in early stage colon cancer (CC) compared to microsatellite stable (MSS). However, the impact of tumor side, left side (L) versus right side (R), is not described on clinical outcomes based on MSI status. **Methods:** Patients with pathological stage II and III primary adenocarcinoma of the colon between 2010 and 2015 were identified in the National Cancer Database (NCDB) using ICD-O-3 morphology and topography codes: 8140-47, 8210-11, 8220-21, 8260-63, 8480-81, 8490 and C18.0, 18.2,18.3, 18.5,18.6, 18.7. Univariate (UVA) and multivariable (MVA) survival analyses were conducted, and Kaplan-Meier Curves were used to compare overall survival (OS) based on tumor location and treatment received with Log-rank test. **Results:** A total of 35,071 patients with stage II (n = 17,629) and III (n = 17,442) CC were identified. 51.3% female; 81.5% Caucasian; median age 66 (range, 18-90). Majority of stage II and III tumors were R, 61.2% (n = 10,794) and 56.0% (n = 9,763). MSI-H was more common in stage II compared to III, 23.3% (n = 4,115) vs 18.2% (n = 3,171) ($p < 0.0001$). Survival was better in stage II MSI-H compared to MSS, 5 year-OS 75.1% vs 71.8% (p = 0.0057). However, stage III CC survival was better in MSS compared to MSI-H, 5-year OS 60.5% vs 58.0% ($p < 0.001$). In stage II MSI-H CC R was more common than left, 78.3 % (n = 3223) vs 21.7% (n = 892). There was no significant difference in survival between stage II MSI-H L vs R (5-year OS 76.2% vs 74.7%, p = 0.1578). Stage II MSS CC R was more common than L, 56.0% (n = 7571) vs 44.0% (n = 5943), and survival was better in L vs R (5-year OS 73.2% vs 70.8%, p = 0.0029). Stage III MSI-H CC was more common in R than L, 75.6% (n = 2397) vs 24.4% (n = 774) and survival was better in L (5-year OS 62.5% vs 56.5%, p = 0.0026). Stage III MSS CC was more common in R than L, 51.6% (n = 7366) vs 48.4% (n = 6905), and survival was better in L vs R (5-year OS 67.0% vs 54.4%, $p < 0.001$). **Conclusions:** Survival was better in left sided tumors compared to right in stage II MSS, stage III MSS and stage III MSI-H CC. Research Sponsor: None.

4069 Poster Session (Board #61), Fri, 8:00 AM-11:00 AM

Association of postoperative serum carcinoembryonic antigen (CEA) with disease-free survival in patients with stage III colon cancer: ACHIEVE phase III randomized clinical trial. *First Author: Masahito Kotaka, Gastrointestinal Cancer Center, Sano Hospital, Kobe, Japan*

Background: ACHIEVE, as part of the IDEA collaboration, was a multicenter trial randomizing patients with stage 3 resected colon cancer to either 3 versus 6 months of adjuvant FOLFOX/CAPOX. We previously reported that the hazard ratios (HRs) in disease-free survival (DFS) of 3 versus 6 months duration according to risk stage (low-risk [T1-3 and N1] or high-risk [T4 or N2]) and regimen (FOLFOX or CAPOX) as well as in overall population were consistent with those observed in the whole IDEA. This study aimed to clarify the significance of post-operative serum carcinoembryonic antigen (CEA) on DFS in stage 3 colon cancer. **Methods:** Eligibility included post-operative serum CEA value of ≤10 ng/ml at registration in the ACHIEVE trial, which enrolled 1313 patients between 2012 and 2014, out of whom 1291 pts were the modified ITT (mITT) population and used in this study. The cutoff values of CEA analyzed for prognostic analyses were the median value (1.8 ng/ml) in the mITT, the upper limit of normal (ULN) level (5.0 ng/ml), and the half of ULN (2.5 ng/ml). The association of post-operative CEA with DFS were measured by Cox regression analyses. **Results:** Of the 3 cutoff values, the ULN (5.0 ng/ml) was associated with DFS more strongly than the median (1.8 ng/ml) or half of ULN (2.5 ng/ml), with a HR of 1.75 (95%CI, 1.24-2.46) (Table). The 99 patients (7.7%) were identified as the CEA > ULN and 1192 (92.3%) as < ULN. In univariate analysis, regimen (CAPOX or FOLFOX), ECOG PS (0 or 1), T factor (T1-3 or T4), N factor (N1 or N2-3) and CEA (< ULN or > ULN) were significantly associated with DFS. Multivariate Cox regression identified CEA > ULN as an independent poor risk factor (HR = 1.45; 95%CI, 1.03-2.05). Shorter DFS in patients with CEA > ULN than in those with CEA < ULN was consistently observed in each subgroup of baseline factors, including treatment duration, regimen, age, gender, PS, T-stage, N-stage, no of lymph nodes examined, and tumor location; no interaction was observed between CEA and these factors. **Conclusions:** Post-operative serum CEA is also a strong prognostic factor for DFS in stage 3 colon cancer. Clinical trial information: 000008543. Research Sponsor: Japanese Foundation for Multidisciplinary Treatment of Cancer.

cut-off value		EVENT/N	3-year DFS (95% CI)	5-year DFS (95% CI)	HR (95% CI)	p value

4070 Poster Session (Board #62), Fri, 8:00 AM-11:00 AM

Prognostic importance of primary tumor resection and synchronous metastasis on overall survival in metastatic colorectal cancer: Data from the FIRE-3 (AIO KRK-0306) study. *First Author: Jobst C. von Einem, Department of Medicine, Division of Hematology, Oncology, and Tumor Immunology (CCM), Charité Universitaetsmedizin Berlin, Berlin, Germany*

Background: The FIRE-3 study (AIO KRK-0306) was designed as a randomized multicenter trial to compare the efficacy of FOLFIRI plus cetuximab (cet) to FOLFIRI plus bevacizumab (bev) as first-line treatment in KRAS WT mCRC patients. FOLFIRI plus cet as first-line treatment of KRAS WT mCRC patients resulted in comparable overall response rates (ORR) and progression free survival (PFS) when compared to FOLFIRI plus bev. Overall survival (OS) was significantly longer in the FOLFIRI plus cet arm. **Methods:** In the present analysis of the FIRE-3 trial we explored the impact of primary tumor resection on outcome in relation to anti-EGFR vs. anti-VEGF treatment. Furthermore, we investigated the prognostic value of synchronous versus metachronous metastases. **Results:** In patients with synchronous disease no significant difference in OS was detected when comparing resected (n=339) vs. non-resected (n=97) patients (p-value: 0.29, HR: 1.17, 95%-CI: 0.88 – 1.55). In the cetuximab arm, resection (n=167) showed no significant benefit in OS when compared to non-resection (n=52) (p-value: 0.51, HR: 1.15, 95%-CI: 0.77 – 1.71). Treated with bevacizumab, similar results were present, when comparing resection (n=172) vs. non-resection (n=45); (p-value: 0.29, HR: 1.25, 95%-CI: 0.83 – 1.9). A strong trend was seen when comparing OS in treatment arms cet. (n=219) vs. bev. (n=217)) for patients with synchronous disease; (p-value: 0.05, HR: 1,26, 95%-CI: 1.0 - 1.59). 436/592 pts suffered from synchronous, 153/592 from metachronous disease (in 3/592 pts the information was not given). Median OS in pts with synchronous disease was 24.5 months and 29.5 in pts with metachronous disease (p-value: 0.02, HR: 0.76, 95%-CI: 0.6 - 0.96). In pts treated in the cetuximab arm metachronous disease (n=77) was associated with a trend towards longer OS when compared to synchronous disease (n= 219) (p-value: 0.13, HR: 0.76, 95%-CI: 0.54 – 1.1). The same effect was present in the bevacizumab arm (p-value: 0.05, HR: 0.73, 95%-CI 0.53 – 1.0) when comparing pts with synchronous disease (n=217) vs. pts. with metachronous disease (n=76). **Conclusions:** In the FIRE-3 study, metachronous disease was associated with superior OS compared to synchronous disease. This finding was accentuated in the bevacizumab arm. The role of resection of the primary tumor had no impact on survival. Clinical trial information: NCT00433927. Research Sponsor: Merck KGaA, Darmstadt, Germany.

4071 Poster Session (Board #63), Fri, 8:00 AM-11:00 AM

Utility of circulating tumor DNA (ctDNA) versus tumor tissue genotyping for enrollment of patients with metastatic colorectal cancer (mCRC) to matched clinical trials: SCRUM-Japan GI-SCREEN and GOZILA combined analysis. *First Author: Yoshiaki Nakamura, National Cancer Center Hospital East, Kashiwa, Japan*

Background: We recently reported that ctDNA genotyping had advantages compared with tumor tissue testing in terms of enrollment to matched clinical trials across a wide range of GI cancers (Nakamura Y, et al. ASCO-GI 2020). Here, we investigated the utility of ctDNA genotyping in mCRC in a SCRUM-Japan GI-SCREEN and GOZILA combined analysis. **Methods:** In GI-SCREEN, tumor tissue genotyping was performed using a next generation sequencing (NGS)-based assay, Oncomine Comprehensive Assay since Feb 2015. In GOZILA, NGS-based ctDNA genotyping was performed using Guardant360 since Feb 2018. All tests were conducted centrally in a CLIA-certified and CAP-accredited laboratory. Patients with actionable alterations were enrolled into matched company-sponsored or investigator-initiated interventional clinical trials. **Results:** As of Apr 2019, 2,791 mCRC patients (2,754 eligible for analysis) in GI-SCREEN and 470 (464 eligible for analysis) in GOZILA were enrolled. There were no significant differences in baseline patient characteristics between GI-SCREEN and GOZILA. Most of trials affiliated with GI-SCREEN (81%) or GOZILA (78%) targeted the RTK/RAS/RAF pathway. Compared with tumor testing, ctDNA genotyping significantly improved turnaround time (median, 12 vs. 34 days, $P < 0.0001$), sequencing success rate (96.1 vs. 92.3%, $P = 0.002$), and detection rate of actionable alterations (73.3 vs. 62.2%, $P = 0.02$). Among patients with actionable alterations, enrollment to matched clinical trials was achieved in 5.0% in GI-SCREEN and 12.1% in GOZILA ($P < 0.0001$). Median time from enrollment in the respective screening study to enrollment in a matched clinical trial was 6.5 months in GI-SCREEN and 0.9 months in GOZILA, respectively ($P < 0.0001$). Objective response rate and progression-free survival were similar in both groups (tissue vs. ctDNA; ORR: 18.8 vs. 17.1%, $P = 1.00$; median PFS: 2.2 vs. 2.2 months, HR=1.05 [95% CI, 0.71–1.55], $P = 0.79$). **Conclusions:** For patients with mCRC, ctDNA genotyping had advantages over tissue genotyping with shorter turnaround time and higher sequencing success and actionable alteration detection rate, which were associated with improved clinical trial enrollment without compromising the efficacy. 4072 Poster Session (Board #64), Fri, 8:00 AM-11:00 AM

Colorectal cancer under the age of 50 years in U.S. Department of Veterans Affairs: Is there a role of early screening? *First Author: Abdul Moiz Khan, Albany Medical Center, Albany, NY*

Background: While the overall incidence of colorectal cancer (CRC) is decreasing, the rate has increased in population under 50, with higher stages at diagnosis and a greater proportion of African Americans (AA). Hence, there is an ongoing debate about the age of CRC screening. These trends have not been studied in the VA population. **Methods:** ICD-10 codes C18-C20 were used to identify the cases of colon and rectal cancer in National VA Cancer Cube Registry. 43,544 cases of colon cancer, 1,278 below and 42,254 above age 50, and 19,815 cases of rectal cancer, 862 below and 18,948 above age 50 were identified between 2003-17. Younger age group was defined as patients less than 50 years old. IRB approval was obtained. **Results:** Our data comprised > 97% of male patients. In younger group, in the 5 year periods, 2003-07, 2008-12 and 2013-17, colon cancer rate increased from 2.59% to 2.79% to 3.59%, while for rectal cancer it increased from 3.5% to 4.3% to 5.3% ($p < .0001$). Blacks comprise 31.6% cases of colon cancer and 27.15% cases of rectal cancer in under 50 group, compared to 18.5% and 15.9% of cases in above 50 group respectively ($p < .0001$). For under 50 group, 48.6% cases of colon and 42.2% cases of rectal cancer were diagnosed in stage III or IV compared to 35.7% and 34.05% cases in above 50 group respectively ($p < .0001$). For colon cancer, 51.87% of patients in the younger group have a < 5 year survival, worse compared to 45.05% in 50-60 group ($p < .0001$) and similar to 49.3% in 60-70 group ($p = .08$). For rectal cancer, 5 year survival showed no difference between these groups. Stage specific survival shows no difference for either colon or rectal cancer across < 50, 50-60 and 60-70 age groups. **Conclusions:** Rate of CRC is rising in < 50 age group with more advanced stage at diagnosis and higher proportion of African Americans. For colon cancer, < 50 group has a worse 5 year survival as compared to 50-60 age group likely due to increased proportion of patients in stage III or IV, as there is no difference in stage specific survival. For rectal cancer, the 5 year survival or stage specific survival shows no difference in < 50, 50-60 and 60-70 groups. These results add to our understanding of the trends of CRC and should be accounted for in the screening guidelines. Research Sponsor: None.

4073 Poster Session (Board #65), Fri, 8:00 AM-11:00 AM

Translational research of voltage-A1: Efficacy predictors of preoperative chemoradiotherapy and subsequent nivolumab monotherapy in patients with microsatellite-stable locally advanced rectal cancer. *First Author: Koji Inamori, Department of Colorectal Surgery, National Cancer Center Hospital East, Kashiwa, Japan*

Background: In VOLTAGE-A1, after 5 cycles of nivolumab (240 mg q2 weeks) plus radical surgery following chemoradiotherapy (CRT; 50.4 Gy with capecitabine 1,650 mg/m^2), a major pathologic response is observed in 38% (AJCC tumor regression grade 0-1) of 37 patients with microsatellite-stable locally advanced primary rectal cancer. Here, biomarkers for predicting the efficacy of this treatment were investigated. **Methods:** Serial tumor biopsies and blood collections were performed at 4 time points; before CRT, after CRT, after 3 cycles of nivolumab, and before surgery. Tumor-infiltrating lymphocytes (TILs) and DNA/RNA were extracted from tumor samples, and peripheral blood mononuclear cells (PBMCs) were extracted from blood samples. We analyzed the immune status of the patients by flow cytometry using the collected TILs and PBMCs. Whole exome and RNA sequencing analyses were conducted using the extracted DNA and RNA, respectively. The PD-L1 status of tumor samples was also evaluated by *in vitro* diagnostic immunohistochemistry staining. **Results:** Among the 24 patients whose samples were serially collected, 11 (46%) were AJCC grade 0-1 and 13 were 2-3. Before CRT, effector regulatory T (eTreg) cells in TILs were higher in patients with AJCC grade 2-3, and both the CD8$^+$ T cell/eTreg cell ratio in TILs and PD-L1-positive tumor cells (≥1%) were higher in patients with AJCC grade 0-1 ($p = 0.047$, $p = 0.083$, respectively). Ki67 expression by CD8$^+$ T cells in TILs was higher before CRT in patients with AJCC grade 0-1 ($p = 0.037$) and increased after CRT in all patients. Patients with consensus molecular subtype (CMS) 1 and CMS3 achieved AJCC grade 0-1 at rates of 100% (2/2) and 60% (4/6), respectively. In contrast, patients with CMS2 and CMS4 achieved AJCC grade 0-1 at rates of 43% (3/7) and 29% (2/7), respectively. The tumor mutation burden of pre-CRT samples was significantly higher in patients with AJCC grade 0-1 (median 1.45/MB) than in patients with AJCC grade 2-3 (0.84/MB) ($p = 0.016$). **Conclusions:** A higher CD8$^+$ T cell/eTreg cell ratio, PD-L1-positive, Ki67 expression by CD8$^+$ T cells in TILs, CMS1 or 3, and higher tumor mutation burden are good predictors of the efficacy of the sequential combination of CRT and nivolumab. Further results will be reported in the meeting. Clinical trial information: NCT02948348. Research Sponsor: Ono phrmaceutical Co.,Ltd.

4074 Poster Session (Board #66), Fri, 8:00 AM-11:00 AM

Neoadjuvant chemoradiation (CRT) for locally advanced rectal cancer (LARC) with or without oxaliplatin (OX): Individual patient data (IPD) meta-analysis of three randomized controlled trials (RCTs) with subgroup analyses of age cohorts. *First Author: Elisa Fontana, Sarah Cannon Research Institute, London, United Kingdom*

Background: Neoadjuvant CRT with fluoropyrimidine (FP) is standard treatment for LARC, which is increasing in younger patients (pts). RCTs examining the addition of OX are still controversial. A *post hoc* analysis of the CAO/ARO/AIO-04 trial showed significant benefit in pts < 60y. We hypothesised that younger pts with LARC might have improved outcomes with OX-CRT. **Methods:** Systematic review and IPD meta-analysis were performed. Data from 3 RCTs (CAO/ARO/AIO-04, ACCORD-12, PETACC-6) testing the addition of OX to standard FP-based CRT in LARC were available (of 9 RCTs identified). Primary endpoint: disease-free survival (DFS), secondary endpoints: pathologic complete response (pCR), overall survival (OS). Analyses were by intention to treat (ITT), stratified by trial. Age cut-offs were 60y and 50y. Given the focus on young age a multivariate analysis evaluating all possible confounders was not intended in the current work. **Results:** IPD from 2914 pts were included (48.5% of available literature). Median age was 63; 70% were male; 79% had a performance status = 0; 72% were stage ≥III. In ITT (Hazard Ratio [HR] 0.88, 95%CI 0.77-1.01, p = 0.06), DFS was not significantly improved by the addition of OX (Table). In < 60y (n = 1166, 40% total), DFS was significantly improved by OX (HR 0.77, 95%CI 0.62-0.96, p = 0.02). In < 50y (n = 350, 12% total) there was a numerically better DFS, although not significant (HR 0.73, 95%CI 0.49-1.08, p = 0.12). Interaction test between age and DFS was non-significant (60y p = 0.11; 50y p = 0.44). In ITT, OX increased pCR from 13% to 16% (Odds Ratio [OR] 1.28, 95%CI 1.04-1.57, p = 0.024 [stratified by trial]), without significant interaction with age (60y p = 0.11, 50y p = 0.74). No OS benefit was demonstrated (HR 0.97, 95%CI 0.82-1.15, p = 0.75). **Conclusions:** This first IPD meta-analysis of three RCTs evaluating the addition of OX to CRT did not show significant interaction of OX with age. However, we confirm a signal for DFS benefit in pts < 60y and a non-significant increment in DFS in < 50 y although this analysis may be underpowered. Stage-stratified analyses and feasibility/toxicity data in age cohorts will be presented. Research Sponsor: None.

ITT - DFS	HR	0.88	95%CI	0.77-1.01	p-value	0.06

4075 Poster Session (Board #67), Fri, 8:00 AM-11:00 AM

Duration of FOLFOX adjuvant chemotherapy in high-risk stage II and stage III colon cancer with deficient DNA mismatch repair. *First Author: Zehua Wu, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: In the IDEA collaboration, noninferiority was not confirmed for 3 months versus 6 months of FOLFOX adjuvant chemotherapy among patients with high-risk stage II and stage III colon cancer (CC). Patients with deficient DNA mismatch repair (dMMR) have a good prognosis, but for whom, whether limiting the duration of adjuvant therapy will compromise oncologic outcomes remains undefined. We evaluated the impact of 3 months of FOLFOX adjuvant chemotherapy or surgery alone in comparison with 6 months of FOLFOX on disease-free survival (DFS) in dMMR CC patients. **Methods:** This retrospective study included all consecutive patients who underwent curative surgical resection for high-risk stage II or III dMMR CC between May, 2011 and July, 2019. Prognostic factors were analyzed using Cox models, and hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated. **Results:** A total of 242 dMMR CC patients were included (43.4% high-risk stage II, 56.6% stage III). The patients received 6 months of FOLFOX adjuvant chemotherapy (n = 66; median cycles [rang] = 12 [10-12]), 3 months of FOLFOX (n = 87; median cycles [rang] = 6 [4-8]), or surgery alone (n = 89). Three groups were generally well balanced, although more patients with stage III were in the 6-month therapy group (74.2%), compared with the 3-month therapy group (57.5%) and the surgery alone group (42.7%). As compared with 6 months of FOLFOX adjuvant chemotherapy in the overall population, 3 months therapy reduced DFS in multivariable analysis (HR, 2.78; 95CI, 1.18 to 6.47; P = 0.02), similar to surgery alone (HR, 2.30; 95CI, 0.99 to 5.38; P = 0.05). In the subgroup analysis, a therapy duration of 6 months was statistically superior to a duration of 3 months only in the patients with stage III, with a 3-year rate of DFS of 86.2% versus 70.8% (HR, 3.06; 95% CI, 1.14 to 8.19; P = 0.026). **Conclusions:** This study supports the 6-month duration of FOLFOX adjuvant chemotherapy in stage III dMMR CC. Research Sponsor: None.

4076 Poster Session (Board #68), Fri, 8:00 AM-11:00 AM

The mutation of homologous recombination repair genetics is a potential biomarker for immunotherapy in microsatellite stable colon cancer. *First Author: Xueying Wu, Genecast Precision Medicine Technology Institute, Beijing, China*

Background: Patients with microsatellite instability-high (MSI-H) colonic adenocarcinoma (COAD) are always immunotherapy-sensitive for the use immune checkpoint inhibitors, however, the vast majority of COAD patients (85%) are microsatellite stable (MSS). Homologous recombination deficiency (HRD) is demonstrated to be a response predictor to immunotherapies in gynecologic cancers, while limited studies were reported in colon cancer. We focus herein on the mutational pattern of HRR related genes in a large Chinese COAD cohort and further analyze the relationship between HRR-gene mutations and clinical response to immunotherapy in MSS COAD. **Methods:** The genomic profiling of Genecast cohort which is consisted of 406 Chinese patients with COAD were analyzed in a panel of 543 cancer related genes via next generation sequencing (NGS). The correlation between HRR-gene mutations and tumor immunity or clinical outcome using two COAD genomics datasets (TCGA and MSK-COAD) by the bioinformatic approach. **Results:** In Genecast Cohort, seventy of 406 (17.2%) patients were identified genomic alterations in HRR-gene, the most frequently mutated genes were *ATM* (9%), *BRCA2* (4%), *ATR* (3%), *RAD50* (3%) and *BRIP1* (3%). In MSK-COAD cohort (treated with immune checkpoint inhibitors), HRR-mut group (n = 34) had a significantly better OS than HRR-wt group (n = 50) (log-rank test, $P = 0.0087$). From the analysis of TCGA cohort, we found that mutations of HRR-gene could increase immune activity in MSS COAD, including increased cytotoxic cells infiltration ($P = 0.035$), increased exhausted CD8 T cells infiltration ($P = 0.0098$) and higher IFN-g score ($P = 0.03$). In contrary, similar results were not found in MSI-H COAD (all $P > 0.05$). **Conclusions:** Mutations of HRR-gene could significantly increase immune activity in patients with MSS COAD, implying the feasibility of using HRR-mut as a response predictor of immunotherapy in MSS-COAD. Research Sponsor: None.

4077 Poster Session (Board #69), Fri, 8:00 AM-11:00 AM

Tumor mutational load, microsatellite instability and actionable mutations in metastatic colorectal cancer: Results from the TRIBE2 study. *First Author: Carlotta Antoniotti, Department of Translational Research and New Technologies in Medicine and Surgery, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy*

Background: In the TRIBE2 study molecularly unselected and untreated mCRC patients were randomized to receive FOLFOXIRI/bevacizumab (bev) followed by the same agents after disease progression (PD) or FOLFOX/bev followed by FOLFIRI/bev after PD. We performed a comprehensive NGS analysis of samples from randomized patients in order to investigate the prognostic impact of tumor mutational load (TML), its additional value with respect to the assessment of microsatellite instability (MSI), and the overall prevalence of potentially actionable alterations. **Methods:** Tumor DNA was obtained from formalin-fixed, paraffin-embedded blocks from primary tumors of 296 (44%) out of 679 randomized patients and underwent NGS analysis using the Caris MI TumorSeek panel, assessing 592 genes. TML was defined low, intermediate or high if < 7, 7-16 or > 16 mutations/Mb were found. MSI status was determined both by NGS and by IHC. **Results:** TML and MSI were successfully determined by NGS in 224 (76%) cases. NGS and IHC results were concordant in 221 (99%) cases. TML was low, intermediate or high in 56 (25%), 157 (70%) and 11 (5%) cases, respectively. When compared with TML low and intermediate tumors, TML high were more frequently right-sided ($p = 0.013$), mucinous ($p < 0.001$) and MSI-high ($p < 0.001$). TML high tumors were MSI-high or MSS in 8 (73%) and 3 (27%) cases, respectively. Two out of 3 TML high and MSS tumours showed a pathogenic *POLE* mutation (p.S459F and p.P286R). The other TML high, MSS and *POLE* wt tumor was dMMR at IHC (loss of MSH6 expression) and showed a pathogenic *MSH6* mutation (p.F1040fs). As compared with low and intermediate TML, high TML was associated with longer PFS (median PFS: 17.3 vs 10.6; HR: 0.54 [95%CI: 0.35-1.09], $p = 0.098$) and OS (median OS: not reached vs 23.7: HR: 0.45 [95%CI:0-28-1.13], $p = 0.106$). No interaction effect between TML and treatment arm was observed, and no difference between TML low and intermediate tumors was reported in terms of baseline characteristics and prognosis. Actionable alterations (*HER2* mutations [N = 2] and amplifications [N = 4], KRAS G12C [N = 10] and BRAF V600E mutation [N = 39]) were found in 55 (19%) out of 296 cases. No *NTRK/ROS/ALK* or *MET* amplification was found. **Conclusions:** TML high tumors are not limited to MSI-high ones but showed *POLE* or *MSH6* somatic mutation and shower longer PFS and OS. No differences are reported between TML low and intermediate tumors. Molecular alterations predictive of benefit from targeted strategies currently available are detectable only in a small percentage of mCRCs. Research Sponsor: GONO foundation.

Circulating tumor DNA as a promising biomarker of relapse risk for stage II-III colorectal cancer. *First Author: Gong Chen, Department of Colorectal Surgery, Sun Yat-Sen University Cancer Centre, Guangzhou, China*

Background: About 30-50% colorectal cancer patients undergoing a curative resection will experience disease recurrence ultimately. Early detection of recurrence is of great significance for improving the prognosis of colorectal cancer patients. Circulating tumor DNA (ctDNA) has been suggested to be a promising biomarker for postoperative surveillance and prognosis prediction in various cancers including colorectal cancer. However, its performance in predicting early recurrence of colorectal cancer as well as appropriate testing procedures still needs large-scale prospective studies to evaluate. **Methods:** A total of 246 patients with stage II-III colorectal cancer and underwent curative resection from three clinical centers of China were enrolled in this multicenter prospective cohort study. Tissue samples as well as serial plasma samples before surgery, 7 days and 6 months after surgery and 3 months interval afterwards until recurrence were collected, and subjected to deep targeted-panel sequencing containing 425 cancer-related genes. ctDNA baseline genomic alterations and dynamic changes were analyzed. Its performance in predicting early recurrence was evaluated and compared with other clinical routine investigations, including serum biomarkers CEA and CA199, and CT examination. **Results:** The ctDNA positive rates at baseline (before surgery) and 7 days after surgery were 72.9% and 18.1% respectively. Among 199 patients with complete survival data, 18 patients were recurrent during follow up period with a median disease-free survival of 280.5 days (114-461 days). At baseline, high clinical stage ($p = 0.035$), and *PTEN* mutation ($p = 0.009$) were significantly associated with increased recurrent risk; while *APC* mutation ($p = 0.04$) predicted a decreased recurrent risk. Detection of ctDNA 7 days after surgery [HR: 5.9 (1.94-17.97); $p = 0.0004$] or any time point before clinical recurrence [HR: 6.14 (2.3-16.38); $p < 0.0001$] was associated with a significantly higher recurrent risk, and the HR increased accordingly with ctDNA mutation level. In multivariate analyses, ctDNA status was independently associated with relapse after adjusting for known clinicopathological risk factors. CEA status was not significantly ($p > 0.4$) associated with disease-free survival. A risk scoring model comprising of clinical variables and ctDNA detection after surgery was constructed and can predict 18-month recurrence with an AUC of 0.77. **Conclusions:** ctDNA is a promising marker of risk stratification, and early relapse detection in resected stage II/III CRC patients. Clinical trial information: NCT03312374. Research Sponsor: None.

4080 Poster Session (Board #72), Fri, 8:00 AM-11:00 AM

Mutation of DNA damage repair genes confers an immune-privileged tumor microenvironment in colorectal cancer with a prognostic value. *First Author: Dandan Liang, Genecast Precision Medicine Technology Institute, Beijing, China*

Background: Microsatellite instability high (MSI-H)/mismatch-repair-deficient (dMMR) has been proved as a validated biomarker in solid tumors receiving immune checkpoint inhibitors (ICIs). Recently, mutational status of the DNA damage repair (DDR) genes has been linked to anti-tumor immune response in bladder cancer. Therefore, it would be of great interest to unravel the implications of DDR in shaping the immune responsiveness in CRC. **Methods:** The genomic correlates were examined in a publicly available cohort from Memorial Sloan Kettering Cancer Center (MSK ICI cohort). To explore the associations between DDR mutation and immune features, the genomic data of The Cancer Genome Atlas (TCGA) colorectal adenocarcinoma (COADREAD) dataset was analyzed. Further, we determined DDR mutation and MSI status in a Chinese CRC cohort via a 543-gene panel sequencing. **Results:** First, we observed that DDR pathway was commonly mutated (21.79%) in the multi-cancer MSK ICI cohort, with the highest frequency of 36.36% in CRCs. Second, survival analysis revealed that the median overall survival (mOS) in patients with DDR mutations was significantly longer than that in the DDR wild-type subgroup, in both pan-cancer (P = 0.0008; mOS 31 vs 16 months) and CRC patients (P = 0.016; mOS 34 vs 13 months) in the MSK ICI cohort. However, in the TCGA COADREAD dataset, there was no significant difference in OS or progression free survival (PFS) between DDR mutant and DDR wild-type subgroups. These observation indicated a specific prognostic value for DDR mutation in patients with ICI treatment while not conventional treatment. Third, in the TCGA COADREAD dataset, DDR mutations were associated with increased TMB, enrichment of immune cell infiltration and immune checkpoint molecule expression, suggesting an improvement of various steps of the cancer immunity cycles in DDR mutant CRCs. Lastly, we investigated the DDR mutational pattern, and its associations with MSI-H and other genomic features in a Chinese CRC cohort. Notably, MSI-H and DDR mutation account for 5.7% and 13.4% respectively, suggesting that DDR may identify a higher proportion of potential responders than MSI-H. **Conclusions:** Our data suggest that DDR mutation is a potential prognostic biomarker for ICI-treated CRCs. Functional analysis in TCGA dataset revealed that DDR mutation might be an indication of enhanced cancer immunity. The higher incidence of DDR mutation in Chinese CRCs emphasized the future utility of panel-based DDR evaluation in guiding ICI treatment. Research Sponsor: None.

4081 Poster Session (Board #73), Fri, 8:00 AM-11:00 AM

The role of primary tumor (PT) site as prognostic factor after resection of colorectal (CRC) liver metastases (LM): A mono-institutional cohort study. *First Author: Maria Bensi, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli–IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Radical resection of LM is the only chance of cure for liver-only mCRC pts. Besides the evaluation of technical resectability, several factors must be taken into account for the evaluation of recurrence risk. Among them we should consider the Fong Risk Score and its modified version, including RAS/BRAF status (Brudvik's score). Tumor sidedness is an important prognostic factor in CRC. The impact of PT site on the outcome of LM resection is still debated. Hence, we retrospectively analysed mCRC pts, underwent to radical LM resection at our Institution, investigating the impact of PT site on DFS and OS. **Methods:** Liver-only mCRC pts underwent to radical LM resection were included. The association of PT site with DFS and OS was evaluated. The following variables were collected: gender; age ($\geq$ vs $<$ 75 years); ECOG PS; CEA baseline level; PT site; RAS and BRAF status; mucinous histology; grading (G1-2 vs G3); RECIST response during preoperative treatment; resected PT; synchronous vs metachronous; number of LM; bilobar vs unilobar LM; LM diameter $\geq$ 5 cm; R0 vs R1 resection. Univariate and multivariate analyses for DFS and OS were performed. **Results:** A total of 463 liver-only mCRC pts underwent to radical LM resection were included. Seventy (15%) pts had a right-sided (r-s) tumor and 393 (85%) pts a left-sided (l-s) tumor. R-s CRC pts more often had RAS/BRAF mutations in comparison to l-s tumors (76% vs 37%; $p < 0.0001$). Median DFS and OS was 13.1 and 41.6 months, respectively, in r-s CRC vs 16.0 (p = 0.65) and 62.2 months (p = 0.033), respectively, in l-s tumors. At the multivariate analysis no significant association with survival parameters was shown for tumor sidedness. At the multivariate analysis, R0 resection was independently associated both with better DFS and OS; RAS/BRAF wt CRC and resected PT were significantly associated with improved OS. Considering all wt CRC pts (N = 237), 14 (6%) pts had r-s tumor and 223 (94%) l-s tumor. No significant association of tumor sidedness with survival was shown (DFS r = 10.0 vs l = 16.0 months, p = 0.62; OS r = 40.3 vs l = 66.2 months, p = 0.12). **Conclusions:** Our results showed that a significant smaller proportion of r-s CRC underwent to radical LM resection, indirectly confirming its worse prognosis. Among radically resected pts, r-s CRC was associated to a shorter OS (significant) and DFS (not significant) compared to l-s CRC, but it was not confirmed at the multivariate analysis. We can conclude that right PT site should not be considered as a contraindication for radical LM surgery, when feasible. Research Sponsor: None.

4082 Poster Session (Board #74), Fri, 8:00 AM-11:00 AM

Efficacy of third-line anti-EGFR-based treatment (tx) versus (vs) Regorafenib/TAS-102 (R/T) according to primary tumor site in RAS/BRAF wild-type (wt) metastatic colorectal cancer (mCRC) patients (pts). *First Author: Raffaella Vivolo, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli–IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Right- (R) and left-sided (L) mCRCs exhibit different clinical and molecular features. Several retrospective analyses showed that the survival benefit of anti-EGFR-based tx is limited to *RAS/BRAF* wt L-sided mCRC pts, which a larger effect in the first-line setting. Few data are available concerning the anti-EGFR efficacy according to primary tumor site in third line. **Methods:** Pts affected by *RAS/BRAF* wt mCRC treated with third-line anti-EGFR-based tx or R/T were retrospectively collected. The objective of the analysis was to compare tx activity and efficacy according to tumor site. Primary endpoint was PFS; secondary endpoints were OS and RR. PFS and OS analyses were performed using Kaplan-Meier method, and survival curves were compared using the log-rank test. RR was evaluated according to RECIST criteria and it was compared in the two groups using Fisher's exact test. Statistical significance was set at p = 0.05 for a bilateral test. Univariate and multivariate analyses for PFS and OS were performed. **Results:** A total of 76 *RAS/BRAF* wt mCRC pts, treated with third-line anti-EGFR-based tx or R/T, were enrolled. Of those, 19 (25%) pts had R-sided tumor (9 pts received anti-EGFR tx and 10 pts received R/T) and 57 (75%) pts had L-sided tumor (30 pts received anti-EGFR tx and 27 pts received R/T). As shown in the table, a significant PFS and OS benefit in favor of anti-EGFR tx vs R/T was observed in L-sided pts, while no difference both in PFS and OS was observed in R-sided pts. RR was significantly higher in L-sided pts treated with anti-EGFR vs R/T, no difference was shown in R-sided pts. At the multivariate analysis, tx regimen was indipendently associated with PFS in L-sided pts, but not in R-sided pts. **Conclusions:** Our study confirmed the results deriving from the retrospective analysis of the phase III study 20020408. Our results demonstrated a different benefit from third-line anti-EGFR tx according to primary tumor site, confirming the role of L-sided tumor in predicting benefit from third-line anti-EGFR vs R/T, while no difference was observed in R-sided tumors. Research Sponsor: None.

	R-sided	R-sided	L-sided	L-sided
	Anti-EGFR (N = 9)	R/T (N = 10)	Anti-EGFR (N = 30)	R/T (N = 27)
Median PFS (months)	3.5 HR = 1.4 (95%CI 0.53-3.75), p = 0.49	3.8	7.3 HR = 0.47 (95%CI 0.26-0.85), p = 0.0028	3.6
Median OS (months)	9.3 HR = 0.83 (95%CI 0.30-2.26), p = 0.696	9.2	15.2 HR = 0.58 (95%CI 0.31-1.08), p = 0.0428	11.0

Intra-tumoral microbes and overall survival in colorectal cancer patients. *First Author: Pannaga G. Malalur, The Ohio State University/Wexner Medical Center, Columbus, OH*

Background: The presence of certain bacteria among or adjacent to tumor cells may contribute to colorectal cancer (CRC) development. However, the effect of the tumor microbiome on survival in CRC patients undergoing treatment is poorly understood. We hypothesize that intra-tumoral microbes correlate with overall survival (OS) in CRC patients. **Methods:** We obtained RNA-seq data from CRC tumor biopsies from patients treated at The Ohio State University Comprehensive Cancer Center as part of the Oncology Research Information Exchange Network (ORIEN). Reads were aligned to human and exogenous genomes using TopHat2 and Kraken2/Bracken, respectively. **Results:** The analyzed cohort included 99 CRC patients with an age range from 31-83 years, 62% female, and 44% with metastatic CRC. Therapies received prior to sample collection were grouped into chemotherapy with or without radiation (37%), antiVEGF/EGFR therapies (33%), no systemic therapy (23%), immunotherapy (3%); 3% were unknown. Overall, eleven bacteria were significantly associated with shorter OS, including a species in the genus Clostridium and Vibrio. Conversely, five other bacteria including several commensal gut microbes, were associated with longer OS. In patients who received chemotherapy with or without radiation (n = 38), several microbes were significantly associated with shorter OS, including a member of the genus *Streptomyces*. Only three bacteria were significantly associated with longer OS. In the patients who received antiVEGF/EGFR therapies (bevacizumab, cetuximab, panitumumab) (n = 33), several bacterial taxa were associated with shorter OS. In addition, bacteria including a member of the genera Bacillus and Staphylococcus were significantly associated with metastatic CRCs. ($p < 0.05$ for all, Fisher's Exact tests). **Conclusions:** This study suggests that demonstrating the presence or absence of certain microbes in tumor biopsies could have important therapeutic implications for CRC patients. Only bacteria (no fungi, viruses, archaea, etc.) were found to significantly associate with OS across the entire cohort and within treatment subsets. The presence of bacteria was mostly, but not always, associated with worse OS. Antibiotics targeted towards bacterial species associated with negative outcomes could have the potential to improve OS in CRC patients. Research Sponsor: Award Number UL1TR002733.

4084 Poster Session (Board #76), Fri, 8:00 AM-11:00 AM

Consensus molecular subtype (CMS) as a novel integral biomarker in colorectal cancer: A phase II trial of bintrafusp alfa in CMS4 metastatic CRC. *First Author: Amir Mehrvarz Sarshekeh, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Consensus Molecular Subtype 4 (CMS4) colorectal cancer (CRC) features increased TGFβ signaling, which may account for de novo resistance to immunotherapy for patients (pts) with microsatellite stable mCRC. To date, no prior trial has incorporated CMS status as an integral biomarker. Bintrafusp alfa (M7824) is a dual PD-L1 antibody/TGFβ trap with acceptable safety. **Methods:** Primary tumors from pts with metastatic CRC underwent CMS testing in a CLIA setting. In this Simon two-stage phase II trial (Ho: $p < .05$; Ha: $p \geq .25$) for CMS4 mCRC, pts received bintrafusp alfa 1200mg IV every 14 days. RT (8Gy/day x 3 days) to a single metastatic lesion with abscopal intent was administered between doses 2 and 3. The primary objective was to estimate response rate (RR) per iRECIST. Correlative studies including RNA sequencing were performed on pre- and on-treatment biopsies. **Results:** 53 of 137 tested pts (39%) between June 2018-December 2019 had CMS4 mCRC. 13 of 15 treated pts received the agent with RT. All pts were evaluable for toxicity, and 13 for response. Median number of doses was 3 (IQR, 2-4). There was one grade 3 immune-related adverse event (colitis) requiring study discontinuation. There were 2 pts with stable disease and 11 with progressive disease as best response (RR 0%, 95% CI 0-22%). Enrollment was stopped after first stage for futility. Median PFS and OS were 1.6 months and 5.0 months, respectively. In paired samples, treatment with bintrafusp alfa resulted in an increase in the expression of IFNγ signature in nonirradiated metastatic lesions ($p < .001$, $q < .001$). Updated results will be presented. **Conclusions:** This is the first reported clinical trial to utilize CMS status as an integral biomarker for pts with metastatic CRC and capitalizes on treating CRC subpopulations with targeted agents based upon validated RNA-based signatures. Although the efficacy for bintrafusp alfa and RT is low, changes in IFNγ signature provides a potential signal for refining therapeutic strategies based upon TGFβ enrichment in pts with mCRC. Clinical trial information: NCT03436563. Research Sponsor: EMD-Serono.

4085 Poster Session (Board #77), Fri, 8:00 AM-11:00 AM

The effect of aspirin on colorectal cancer incidence in African Americans. *First Author: Oluwadunni Emiloju, Albert Einstein Medical Center, Philadelphia, PA*

Background: From 2011 to 2016, the incidence and mortality rate of colorectal cancer(CRC) were highest among African Americans(AA), compared to other US racial/ethnic groups. Long-term aspirin use is recommended as a strategy to reduce the risk of CRC. Yet, there is scant information on the chemopreventive effect of aspirin among AA. It is imperative to assess whether the reported chemo-preventive effect also occurs in AA. Our central hypothesis is that aspirin use in AA is associated with a lower incidence of CRC, irrespective of race/ethnicity. **Methods:** We conducted a secondary analysis, using data from AA participants in the Atherosclerosis Risk in Communities(ARIC) longitudinal study, who did not have CRC at enrollment, from 1987 to 1998. We extracted demographic, clinical and mortality data to compare the incidence of CRC among participants taking aspirin compared to those who were not taking aspirin, stratified by age, tobacco use, and body mass index. All-cause mortality and CRC mortality will also be assessed, and we will use Cox proportional hazard regression to determine the relationship between aspirin use and CRC incidence, and mortality. **Results:** At baseline in 1987, 15,026 participants enrolled in the ARIC study, 25% of whom were AA, median age 54(range 44-66), including 46.7% who reported using aspirin. We analyzed follow-up data from 10,960 participants in 1996-1998, 20% of whom were AA, and 56.9% of whom were taking aspirin. Non-AA participants were more likely to report using aspirin at baseline and follow-up, compared to AA, 53% vs 30% and 59% vs 50% respectively. After 10years, the total incidence of CRC in AA participants was 1% compared with 1.1% in non-AA($p = 0.7$). There was no difference in CRC incidence by aspirin use among all participants, and when stratified by race(among all participants $p = 0.81$, amongAA $p = 0.68$, among non-AA $p = 0.94$). **Conclusions:** We found no difference in the incidence of CRC among AA compared to Caucasians, by aspirin use. Investigation of consistency and/or dose of aspirin use by race may provide further insights on the relationship between aspirin use and CRC incidence, comparing AA to Caucasians. Predictive and prognostic value of *HER2* gene expression and *HER2* amplification in patients with metastatic colorectal cancer (mCRC) enrolled in CALGB/SWOG 80405 (Alliance). *First Author: Francesca Battaglin, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: The randomized phase III CALGB/SWOG 80405 trial found no difference in overall survival (OS) in first-line mCRC pts treated with either bevacizumab (Bev) or cetuximab (Cet) combined with the same chemotherapy. We investigated the potential prognostic and predictive value of *HER2* amplification and *HER2* gene expression using NGS and Nanostring data. **Methods:** Primary tumor DNA from 559 patients (pts) was profiled for *HER2* amplification by NGS (Foundation One). Tumor tissue from 925 pts was tested for Nanostring gene expression using an 800 gene panel. OS and progression free survival (PFS) were the endpoints as time-to-event variables. Cox proportional hazard models with gene expression fitted with linear spline (one internal knot at median) were used, adjusting for pts baseline characteristics, treatment assignment, and molecular features (microsatellite instability, *BRAF*, all *RAS*). **Results:** Of 505 tumors with both NGS and Nanostring data, 16 harbored *HER2* amplification (copy number variation > 6), limited to microsatellite stable tumors and significantly associated with *HER2* expression ($P < 0.001$) and wild-type *RAS* ($P = 0.036$). *HER2* amplification was neither prognostic nor predictive for OS or PFS. Conversely, *HER2* expression higher than median was associated with longer PFS ($P = 0.018$) but not OS ($P = 0.13$). Among pts with *HER2* not amplified, higher *HER2* expression was associated with better OS (hazard ratio [HR], 0.83; 95%CI, 0.72-0.97; $P = 0.016$) and PFS (HR, 0.85; 95%CI, 0.74-0.98; $P = 0.027$) when the expression was less than median. Additionally, in pts with no *HER2* amplification and *HER2* expression lower than median, treatment with Cet was associated with worse PFS compared to Bev (HR, 1.46; 95%CI, 1.12-1.90; $P = 0.005$). This effect was not observed with expression higher than median regardless of *HER2* amplification status. **Conclusions:** To our knowledge, this is the largest analysis of *HER2* amplification and gene expression in mCRC pts treated with standard therapy. Our results provide novel insight on the predictive and prognostic value of *HER2* gene expression in pts treated with Cet- and Bev-based regimens. Upon validation, these findings could inform pts selection and the design of more effective treatment options for pts with low *HER2* expression. Clinical trial information: NCT00265850. 4088 Poster Session (Board #80), Fri, 8:00 AM-11:00 AM

Novel methylated DNA markers in plasma detect distant recurrence of colorectal cancer. *First Author: Hao Xie, Mayo Clinic, Rochester, MN*

Background: Methylated DNA markers (MDMs) are broadly informative for early detection of colorectal cancer (CRC) but have not been extensively studied for post-treatment surveillance and disease monitoring. We aimed to assess the feasibility of novel CRC-associated MDMs for detection of distant recurrent CRC (rCRC) in plasma. **Methods:** A panel of 13 MDMs previously identified to be discriminant for primary CRC was selected. In a cross-sectional analysis of plasma samples, MDMs were assayed blindly (by target enrichment long-probe quantitative amplified signal assay) from 160 age/sex-balanced patients (60 healthy controls, 60 with resected CRC and no evidence of disease (NED), and 40 rCRC after primary tumor resection). Plasma-derived carcinoembryonic antigen (CEA) was measured on all patients. Random forest modeling was used to derive a prediction algorithm of MDMs (with and without CEA) for the endpoint of rCRC relative to healthy controls. The accuracy of the algorithm was summarized as sensitivity, specificity, and area under the receiver operating characteristic curve (AUC) with 95% confidence intervals (CI) in the test set. **Results:** Median patient age was 55 (interquartile range: 49-64) years. As shown in the Table below, a single MDM with the highest AUC was significantly better than CEA ($p = 0.02$). On cross validation, CEA provided no additional improvement to the performance of the panel of 13 MDMs ($p = 0.2$). The cross-validated panel of MDMs detected rCRC liver metastases with 96% (79-100%) sensitivity, lung metastases with 78% (40-97%) sensitivity, and peritoneal/nodal metastases with 57% (18-90%) sensitivity. Lesions with Response Evaluation Criteria in Solid Tumors sum > 4 cm were detected with 94% (73-100%) sensitivity and ≤ 4 cm with 78% (52-94%) sensitivity. **Conclusions:** Novel MDMs in plasma detect rCRC with promising accuracy. The clinical utility of MDMs for non-invasive post-treatment surveillance and treatment monitoring in CRC warrants further evaluation in longitudinal studies with sufficient follow-up to exclude sub-clinical recurrence in those with NED. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology, Exact Sciences provides the LBgard (Biomatrica) blood tubes and provided the TELQAS assays at no cost.

Modeling	Marker	AUC (95% CI)	rCRC Sensitivity (95% CI)	NED Sensitivity (95% CI)	Healthy controls Specificity (95% CI)	P
No cross-validation	A single MDM	0.93 (0.87-1)	88% (73-96%)	13% (6-25%)	95% (86-99%)	0.02
	CEA (cutoff: 3 ng/ml)	0.79 (0.69-0.9)	65% (48-79%)	12% (5-23%)	87% (75-94%)	
2:1 cross-validation	13 MDM algorithm	0.96 (0.91-1)	85% (70-94%)	22% (12-34%)	95% (86-99%)	0.20
	13 MDM+CEA algorithm	0.96 (0.91-1)	85% (70-94%)	22% (12-34%)	95% (86-99%)	

4089 Poster Session (Board #81), Fri, 8:00 AM-11:00 AM

Consensus molecular subtypes (CMS) as a marker for treatment and disease biology in metastatic colorectal cancer (CRC). *First Author: Michael Lam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Consensus molecular subtypes (CMS) categorize colorectal cancer (CRC) into groups based on gene transcription and are prognostic in early-stage and first-line metastatic settings. Their impact on treatment history is unknown. We hypothesized that the best prognosis CMS2 would have higher utilization of liver-directed therapies and maintenance chemotherapy over the worst prognosis CMS4. **Methods:** Primary surgical resection specimens were annotated for CMS on a translational protocol in a 5FU-refractory metastatic CRC population. Specimens that had neoadjuvant chemotherapy or radiation were excluded. CMS1, CMS3 and indeterminate CMS were also excluded. Liver-directed therapies were defined as any surgery, direct injection of cytotoxics or microspheres, radiation or radiofrequency ablation. Multiple occurrences of liver-directed therapies or maintenance chemotherapy in the same patient were recorded once for statistical tests of association. **Results:** CMS1 (7.4%), CMS3 (8.2%) and indeterminate calls (4.1%) accounted for 20% of all samples tested. There were 43 (44%) CMS2 and 55 (56%) CMS4 patients eligible. Age, stage at diagnosis, mismatch repair and RAS mutational status were similar in both groups. Left-sided tumors were more common in CMS2 (79%) than CMS4 (42%), p = .001. The median overall survival (OS) from stage IV diagnosis was 40 [34 - 51] versus (vs) 28 [21 – 33] months ($p < .0001$) for CMS2 vs CMS4 respectively. Liver-directed therapy was greater in CMS2 (53%) vs CMS4 (31%), p = .024. The number further increased when multiple treatments in a single patient were taken into account. Microsphere injection, radiation and liver surgery combined with RFA were the most skewed towards CMS2 over CMS4. No difference in median OS was seen from first liver-directed therapy in CMS2 vs CMS4 (29 vs 27 months, p = .31). There was a trend towards greater maintenance chemotherapy in CMS2 (47%) vs CMS4 (29%), p = .076. **Conclusions:** Better prognosis with CMS2 is consistent with other studies. Significantly increased liver-directed therapy was observed in CMS2. Selection criteria for liver-directed therapy such as slowly progressing, oligometastatic and hepatic-confined disease may be enriching for CMS2 and gives insight into the natural history of this subtype. Research Sponsor: U.S. National Institutes of Health.

4090 Poster Session (Board #82), Fri, 8:00 AM-11:00 AM

Treatment effects (TEs) of EGFR monoclonal antibodies (mAbs) in metastatic colorectal cancer (mCRC) patients (pts) with KRAS, NRAS, and BRAF mutation (MT) status: Individual patient data (IPD) meta-analysis of randomized trials from the ARCAD database. *First Author: Christos Stelios Karapetis, Flinders Medical Centre, Flinders University, Adelaide, SA, Australia*

Background: EGFR mAbs have become incorporated into clinical practice for the management of mCRC over the last decade. KRAS and NRAS mutations are used as predictive biomarkers and BRAF V600E mutations are associated with an adverse prognosis. The observed TE within biomarker subpopulations has varied between studies. **Methods:** IPD from randomized trials with head-to-head comparison between EGFR mAb versus no EGFR mAb (chemotherapy alone or BSC) in mCRC, across all lines of therapy (first, second and later), were pooled. Biomarker subpopulations are defined in the table. Overall survival (OS) and progression-free survival (PFS) were compared between groups by Cox model, stratified by studies and adjusted by age, gender, and performance status. TEs were estimated by adjusted hazard ratio (HR_{adj}) and 95% confidence interval (CI). Within each biomarker subgroup, EGFR mAb efficacy was explored according to multiple exploratory factors, including line of therapy, type of backbone chemo, gender, sidedness and site of metastasis. Interaction tests were performed. P-values < 0.01 were considered statistically significant to account for multiple comparisons. **Results:** 5729 pts from 8 studies with data available for ≥ 1 biomarker were analysed. PFS benefits (median 9.2 mos in EGFR mAbs, 8.0 mos in no EGFR mAbs) were confirmed in triple-WT pts, but not for OS (refer to table). No OS/PFS benefits were observed for pts with any of the MT tumors. Exploratory analyses showed a potential detrimental TE of EGFR mAbs in KRAS MT mCRC with liver metastasis (OS: HR_{adj} 1.22, p = .003, $p_{interaction}$ .0056; PFS: HR_{adj} 1.24, p = .0009, $p_{interaction}$ .0008). These results were confirmed within the subgroup of pts with all 3 biomarkers available. **Conclusions:** This is the largest IPD analysis to explore the predictive value of RAS/BRAF biomarkers in mCRC. Our findings demonstrate that there is no evidence of efficacy of EGFR mAbs in KRAS, BRAF and/or NRAS MT mCRC. EGFR mAbs might have a detrimental effect in KRAS MT mCRC with liver metastases. Research Sponsor: National Health and Medical Research Council of Australia Project Grant.

		OS		PFS

4092 Poster Session (Board #84), Fri, 8:00 AM-11:00 AM

The development and validation of a novel targeted methylation sequencing technology detecting 0.003 percent tumor signal in early-stage cancer plasma. *First Author: Grace Q. Zhao, Avida Biomed Inc., Fremont, CA*

Background: Methylation analysis in cell-free DNA holds great potential for early cancer detection. In the plasma of early stage cancer patient, the tumor content is estimated to be less than 0.1%, therefore demands a highly sensitive assay. Targeted Methylation Sequencing (TMS) is the most promising approach; however, the current sensitivity and specificity are compromised by low efficiency and low recovery of target enrichment, and further hampered by background noise associated with large panels. The ideal solution would be an in-depth analysis using a focused small cancer-specific methylation biomarker panel, but is not supported by existing technologies. **Methods:** Here we present a new technology designed for TMS analysis in cfDNA: Point-n-Seq, featuring an enrichment of target molecules directly from cfDNA before bisulfite conversion and amplification. Particularly, this technology enables small focused panel that interrogates the methylation status of 1 to ~1000 markers. We designed a CRC panel covering 100 methylation markers in 3 steps: identify ~1000 CRC-specific markers from public databases; eliminate makers with high background signal in baseline cfDNA of healthy population; finalize the list with the most differentiating markers between patient and healthy cfDNA. **Results:** The capture of Point-n-Seq CRC panel is highly efficient resulting in high uniformity (94% > 0.5X) and on-target rate (> 80%). For 20 ng cfDNA input, more than 1000 deduped informative reads were obtained for each marker on average, despite the high GC content (> 80%). The output of informative reads was linear to the cfDNA input ranging from 1 ng to 40 ng. In titration studies, 0.6 pg (0.2X genome equivalent) methylated DNA in 20 ng cfDNA (0.003%) was reliably detected over cfDNA background. Using plasma samples from patients with CRC - early stage (I, n = 7; II, n = 7), late stage (III, n = 11; IV, n = 3), and control individuals (n = 105), the average fractions of methylated signal are 0.0034%, 0.013%, 0.09%, 0.17%, 0.29% for control, stage I, II, III, IV accordingly. With a simple cut-off using methylation fraction, Point-n Seq CRC panel achieved a sensitivity of 86% for stage I, 100% for stage (II-IV) at a specificity of 91%, with AUC = 0.96. **Conclusions:** Point-n-Seq TMS is the first hybridization based NGS technology enables the small focused methylation panel (e.g. 100 markers) sequencing using cfDNA, and it will greatly facilitate the development of practical and cost-effective methylation assays for clinical use. 4093 Poster Session (Board #85), Fri, 8:00 AM-11:00 AM

Can FIT rule out colorectal cancer in symptomatic patients? Diagnostic test accuracy results from 9,822 patients in the NICE FIT study. *First Author: Theo Georgiou Delisle, Croydon University Hospital, London, United Kingdom*

Background: The faecal immunochemical test (FIT) is a non-invasive quantitative test that measures occult blood in faeces (faecal haemoglobin, FHb). FIT is already used worldwide in colorectal cancer (CRC) screening programmes. Bowel symptoms have low specificity for CRC; to diagnose one patient with CRC, a large number of symptomatic patients require investigation. A negative FIT test, when blood is not detected, could be used to rule out CRC in symptomatic patients without invasive investigations such as colonoscopy. We report on the largest diagnostic accuracy study to date of FIT in symptomatic patients. **Methods:** Patients were eligible for recruitment if they experienced bowel symptoms meeting national high-risk criteria and were triaged to investigation with colonoscopy. Patients were excluded from analysis if they did not provide a valid FIT or did not undergo complete colonoscopy. Colonoscopy results were compared to FIT measurements of FHb, and the conduct of the tests was double-blinded. Quality assurance of endoscopy and clinical data was performed by senior clinicians. External statisticians analysed anonymised data. **Results:** 9822 patients from 50 sites across England participated in the study between October 2017 to March 2019. The most common colonoscopy finding was absence of any colorectal disease (31%). The prevalence of CRC at colonoscopy was 3.3%. The sensitivity of FIT at FHb thresholds of 2, 10 and 150 μg/g significantly decreased from 97.0% to 90.9% and 70.8% respectively ($p < 0.01$). FIT positivity rate at these thresholds increased from 7.6%, to 19% and 37.2% respectively ($p < 0.01$). The positive predictive value of FIT for CRC at FHb thresholds of 2, 10 and 150 μg/g was 8.7%, 16.1% and 31.1% respectively and the negative predictive value of FIT at these thresholds was 99.8%, 99.6% and 98.9% respectively. **Conclusions:** The results of this study support the use of FIT at the threshold of detectable blood (2μg/g) as an initial CRC rule-out test to triage patients with high risk CRC symptoms, reducing the number of unnecessary investigations. This is the first study to report that at the lowest threshold of detectable blood, FIT sensitivity is equivalent to the current gold standard investigation of colonoscopy. Clinical trial information: ISRCTN49676259. The study was also supported by the National Institute for Health Research.

4094 Poster Session (Board #86), Fri, 8:00 AM-11:00 AM

APC and TP53 as potential biomarkers for EGFR sensitivity in colorectal cancer. *First Author: Ramya Thota, Intermountain Healthcare, Murray, UT*

Background: The Consensus Molecular Subtypes (CMS) of colorectal cancer (CRC) have prognostic and predictive value in identifying patients that derive benefit from EGFR targeted therapies. The CMS2 cohort was specifically noted to predict response to cetuximab. Besides CMS classification, we recently reported a two-gene mutation signature of APC and TP53 (AP) that predicts potential response to cetuximab. In this study, we hypothesize AP mutations, in addition to CMS cohorts, predict cetuximab sensitivity. **Methods:** A prespecified and validated 203 gene expression signature score measuring cetuximab sensitivity (CTX S-score) was used as a surrogate for response to cetuximab sensitivity. A cohort of 458 patients with colorectal cancer was accrued between October 2006 and September 2011. The population classified into CMS cohorts, and CTX-S scores were determined across each of the cohorts based on AP mutation status. **Results:** Among 458 tumor samples sequenced, AP mutations were identified as significantly associated with higher CTX-S scores. Among the CMS 1-4 cohorts identified, AP mutations were noted in 13 of 77 (17%) patients in CMS1 cohort, 87 of 116 (75%) patients in CMS2 cohort, 15 of 64 (23%) patients in CMS3 cohort, 46 of 112 (41%) patients in CMS4 cohort, indicating that AP mutations are dominant in CMS2 cohort. Further CTX-S score comparisons across CMS cohorts based on AP status show that AP mutated tumors have higher CTX-S scores than non-AP mutated tumors—irrespective of the CMS cohorts ($p<0.05$ unpaired, two-tailed t tests). **Conclusions:** In our study, we noted CMS2 cohort has high predicted sensitivity to cetuximab. Across other CMS cohorts, AP mutations were associated with higher CTX-S scores compared to those with AP wild-type tumors, suggesting both CMS2 and AP mutations contribute to CTX sensitivity. 4095 Poster Session (Board #87), Fri, 8:00 AM-11:00 AM

A population-based study of young-onset colorectal cancer patients: Effect of knowledge gaps among patients and providers on stage at diagnosis and quality of life. *First Author: Ronit Yarden, Colorectal Cancer Alliance, Washington, DC*

Background: Colorectal cancer (CRC) is one of the leading cause of cancer-related death in the US. Despite a decrease in overall incidence and mortality, there has been an alarming increase in CRC diagnosis among young adults (20-49 years old) and causes remain unknown. To explore the unique challenges and unmet needs of the young-adult patients many still establishing their life-long goals, the Colorectal Cancer Alliance launched a comprehensive survey for young-onset CRC patients and survivors via social media to track the self-reported pre-diagnosis awareness, path to diagnosis, and post-diagnosis quality of life experiences of this often overlooked group. **Methods:** A cross-sectional study, conducted in the form of an online survey, was launched via multiple channels of social media. The questionnaire was based on established instruments including PROMIS, EORTC-QOL-30, and EORTC-CR-29 and EORTC-SHC-22. **Results:** The survey was completed by 885 patients and survivors. The median age at diagnosis was 42 +/-7, significantly lower than the recommended screening age. Only 6% of respondents were diagnosed with Lynch syndrome although 29% reported some family history. Most respondents (63%) indicated they were not aware that CRC can affect people younger than 50, which may explain why the majority of patients waited more than 3 months and 23% waited over 12 months after noticing their symptoms to visit their doctor. The majority, 75%, of all patients visited 2+ doctors and 11% of those patients visited 10+ doctors before their doctor suspected colorectal cancer. A significant number of patients felt their doctors were dismissive of their symptoms. 77% of patients were diagnosed with advanced disease and were subjected to aggressive therapies that substantially affected their quality of life including neuropathy, anxiety, clinical depression, sexual morbidity, unemployment, and financial toxicity. Many young patients indicated that their doctors did not inform them about fertility preservation. **Conclusions:** Our survey indicates that medical professionals and young adults need to be aware of the increasing incidence of young-onset CRC, and the importance of timely screening when signs and symptoms are present, regardless of age. Research Sponsor: Colorectal Cancer Alliance.

4096 Poster Session (Board #88), Fri, 8:00 AM-11:00 AM

Adjunctive local therapy in metastatic colorectal cancer in an unselected cohort: Improved patient-survival in comparison to systemic therapies. *First Author: Jan Schroeder, Praxis für Hämatologie und Onkologie, Mülheim, Germany*

Background: Patients with distant metastases in colorectal cancer have a poor prognosis and a low overall survival (OS). In addition to systemic treatments and irradiation, the tumor burden can be reduced by loco-regional therapeutics, including microwave ablation (MWA), radiofrequency therapy (RFA) and trans-arterial chemoembolization (TACE) available. To evaluate the benefit of such local therapies, we compared OS of a single-centre study population to a reference population of patients who underwent no loco-regional treatment within the German Tumor Registry Colorectal Cancer (TKK). **Methods:** The study population consists of a cohort of 51 patients (n = 51) treated loco-regionally in addition to systemic therapy. The patients were recruited in a single cancer centre in Mülheim, Germany during the years 2006 to 2015. A reference population of 788 patients was chosen from a prospective, longitudinal registry of the TKK. Time to event data analysis included the estimation of Kaplan-Meier cumulative survival probabilities and hazard ratios (HR) with corresponding 95% confidence intervals (95% CI) from Cox proportional hazards regression. **Results:** The median OS was 31.3 months (95% CI 26.8 - 41.6) in the study population, as compared to the reference population, where it was 21.9 months (95% CI 20.1 – 24.6). Patients with liver and lung metastases in the study population had an OS of 41.6 months (95% CI 30.5 – 78.2), the corresponding patients from the reference population 21.7 months (95% CI 16.7 – 24.6). Furthermore, patients in the reference group had a 1.79-fold death-rate, as compared to patients treated with additional loco-regional therapy (HR = 2.02; 95% CI: 1.29-3.16). **Conclusions:** Additional treatment with loco-regional therapies of distant metastases in patients with metastatic colorectal cancer appears to be associated with improved OS by nearly 10 months compared to systemic treatments only. Research Sponsor: None.

4097 Poster Session (Board #89), Fri, 8:00 AM-11:00 AM

Phase II trial of adjuvant mFOLFOX6 after metastasectomy for pulmonary metastasis of colorectal cancer: WJOG5810G. *First Author: Nozomu Machida, Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Resection of pulmonary metastasis (PM) is widely accepted to improve the prognosis in selected patients (pts) with metastatic colorectal cancer (CRC). However, the clinical implication of adjuvant chemotherapy after metastasectomy of PM is unknown. We conducted a multi-center phase 2 trial of adjuvant chemotherapy with mFOLFOX6 after metastasectomy of PM-CRC. **Methods:** Main eligibility criteria were first curative metastasectomy of 4 or less PMs and no prior chemotherapy except for adjuvant chemotherapy with fluoropyrimidine monotherapy after curative resection of primary or extrathoracic CRC metastasis. The study treatment was 12 courses of mFOLFOX6 (oxaliplatin 85 mg/m^2, l-leucovorin 200 mg/m^2, 5-fluorouracil 400 mg/m^2 bolus followed by 2400 mg/m^2 continuous infusion, every 2 w). The primary endpoint was overall survival (OS). The secondary endpoints included disease-free survival (DFS), adverse events (AEs), and recurrence sites. The sample size was determined to be 93 expecting 5-year OS rate of 50% with threshold 35% (90% power, alpha error 5%). **Results:** Fifty-two pts from 34 institutions were enrolled between July 2011 and July 2014. Patient enrollment was closed prematurely because of slow accrual. Four patients were ineligible after enrollment and the safety and efficacy cohort comprised 52 and 48 patients, respectively. Patient backgrounds were as follows: gender (male/female) 31/21, median age (range) 63 (42-75) years, ECOG PS (0/1) 48/4, primary site (colon/rectum) 18/34, number of PM (1/2/3/4) 36/9/5/2, synchronous/metachronous PM 11/41, and unilateral/bilateral PM 40/12. With the median follow-up time of 6.0 (1.8-7.7) years, 5-year OS rate was 86% (95% CI: 72-93) and 5-year DFS rate was 59% (95% CI: 43-71). Tumors recurred in 19 patients (13 lung, 3 liver and 7 others). Total 41 pts (79%) completed 12 courses of mFOLFOX6 (reasons for discontinuation: AEs in 3, refusal due to AEs in 8). AEs (> Grade 3) were neutropenia 50%, fatigue 8%, peripheral sensory neuropathy 8%, appetite loss 4%, diarrhea 4%, febrile neutropenia 2% and allergic reaction 2%. There was no treatment related death. **Conclusions:** Adjuvant mFOLFOX6 is feasible and may be effective after metastasectomy for PM-CRC, considering much better OS than we had expected. Clinical trial information: UMIN000005693. Research Sponsor: None.

4098 Poster Session (Board #90), Fri, 8:00 AM-11:00 AM

Is there a benefit of oxaliplatin in neoadjuvant treatment of locally advanced rectal cancer? An updated meta-analysis. *First Author: Gaetan Des Guetz, CH Delafontaine, St Denis, France*

Background: Neoadjuvant fluoropyrimidine (5FU or capecitabine)-based chemoradiotherapy (CRT) has been considered the standard of care for locally advanced rectal cancer (LARC). Whether addition of oxaliplatin (OXP) will further improve clinical outcomes is still unclear. **Methods:** To identify clinical trials combining oxaliplatin in preoperative CRT or perioperative chemotherapy for LARC published until December 2019, we searched PubMed, the Cochrane Library. We also search for relevant ASCO conferences. Primary endpoint was Disease-Free-Survival (DFS). Data were extracted from every study to perform a meta-analysis using Review Manager (version 5.3). **Results:** A total of 7 Randomized Clinical Trials (ACCORD-12, CARO-AIO-04, FOWARC, JIAO, NSABP, PETACC-6 and STAR-01) with 5782 stage II or III rectal cancer patients were analysed, including 2727 patients with OXP + 5FU regimen and 3055 patients with 5FU alone regimen. Compared with 5FU-based regimen group, OXP-based regimen group improved DFS (HR = 0.90, 95% CI: 0.81−0.99, P = 0.03) and increased pathologic Complete Response (OR = 1.21, 95% CI: 1.07−1.37, P = 0.002). Patients treated with OXP-regimen had significantly less metastatic disease (OR = 0.79; 95% CI, 0.67 to 0.94; p = 0.007). Considering Adverse Events (AEs), there was more grade 3-4 diarrhoea with OXP (OR = 2.41, 95% CI: 1.74−3.32, P < 0.00001). However, there were no significant differences grade 3-4 haematologic AEs (OR = 1.16, 95% CI: 0.87−1.57, P = 0.31). **Conclusions:** Combining oxaliplatin with capecitabine or 5FU in preoperative chemoradiotherapy or perioperative chemotherapy seems beneficial significantly and improved DFS. It remains necessary to identify which patients benefit most from the addition of oxaliplatin. Research Sponsor: None.

4099 Poster Session (Board #91), Fri, 8:00 AM-11:00 AM

Clinicopathological and molecular biological characteristics of early-onset stage II/III colorectal adenocarcinoma: An analysis of 25 studies with 47,184 patients (pts) in the adjuvant colon cancer end points (ACCENT) database. *First Author: Zhaohui Jin, Mayo Clinic, Rochester, MN*

Background: Colorectal cancer (CRC) incidence and mortality has decreased since the 1970s but the incidence is increasing in young adults (age 20-49). The incidence of early onset CRC (eoCRC) will keep increasing significantly based on the trends of the SEER CRC registry data. There is limited data suggesting eoCRC may have different behaviors compared to traditional CRC (tCRC, age ≥ 50). **Methods:** Individual pt data of 47184 stage II/III CRC pts from 25 randomized studies in the ACCENT database were pooled. The distributions of demographics, clinicopathological features, biomarker status, and treatment-related data were summarized by age group. Overall survival (OS), disease-free survival (DFS), recurrence-free rate (RFR), and survival after recurrence (SAR) were assessed by Kaplan-Meier curves and Cox models stratified by treatment arms within studies, adjusting for stage, performance status (PS), BMI and grade. **Results:** Using 5% difference between age groups as clinically meaningful cutoff, eoCRC had similar gender, race, ethnicity, PS, risk group, disease sidedness and T stage as tCRC. eoCRC were less likely overweight (30 vs 36%) and more pts had ≥ 12 lymph nodes resected (63 vs 51%). eoCRC had more frequent dMMR status (18 vs 12%), less BRAF mutations (5 vs 13%), and more dMMR/BRAF wild type (WT) status (17 vs 7%). Overall, eoCRC had better OS, DFS, and SAR, with the most significant differences between the < 30 and > = 70 age groups. Similar results were observed within pMMR pts. eoCRC experienced less hematological side effects, diarrhea, and stomatitis, but had more nausea and/or vomiting. **Conclusions:** eoCRC have unique characteristics; although statistically significant, the clinical differences in outcomes between eoCRC and tCRC are potentially due to the difference seen in extremely young and old pts. eoCRC have a different adverse events panel compared to tCRC. Research Sponsor: U.S. National Institutes of Health.

4100 Poster Session (Board #92), Fri, 8:00 AM-11:00 AM

Short-term results of VOLTAGE-A: Nivolumab monotherapy and subsequent radical surgery following preoperative chemoradiotherapy in patients with microsatellite stable and microsatellite instability-high locally advanced rectal cancer. *First Author: Satoshi Yuki, Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan*

Background: Chemoradiotherapy (CRT) followed by radical surgery (S) is standard therapy for patients (pts) with locally advanced rectal cancer (LARC). Sequential use of an anti-PD-1 antibody after radiation demonstrates synergistic effects in *in vivo* models, and an anti-PD-1 antibody is effective in pts with microsatellite instability-high (MSI-H) metastatic colorectal cancer (mCRC). We studied nivolumab (nivo) and radical S following CRT (50.4 Gy with capecitabine 1,650 mg/m^2) in T_{3-4} $N_{any}M_0$ LARC. **Methods:** After the quality-assured CRT, 240 mg q2 weeks x 5 cycles of nivo and radical S were investigated. In cohort A-1, for pts with microsatellite stable (MSS) LARC, the primary endpoint was a centrally confirmed pathological complete response (pCR) rate using AJCC tumor regression grading. The estimated required sample size assuming null and alternative hypotheses pCR = 10% and 30% was 37 pts, with a 1-sided alpha of 5% and power of 90%. In Cohort A-2, 5 pts with MSI-H LARC were included in an exploratory manner. **Results:** From Jan/2017 to Oct/2019, a targeted number of pts was included and assessed. In cohort A-1, 30% (11/37; 90% CI 18-44%) of pCR (AJCC grade (gr) 0) rate and 38% (14/37) of major pathological response (MPR) (AJCC gr 0+1) rate were observed. Clinical CR was observed in one additional pt (3%) refusing S after nivo. In cohort A-2, 60% (3/5) of pCR rate and 60% (3/5) of MPR rate were observed. As of Jan/2020, only 2 pts (1 local and 1 metastatic) in cohort A-1 and none in cohort A-2 recurred. Immune-related severe adverse events were observed in 3 pts (gr 3 myasthenia, gr 3 interstitial nephritis, and gr 2 peripheral motor neuropathy); all fully recovered and received radical S. During the follow-up period, one additional pt with gr 2 colitis was observed. No treatment-related deaths were observed. **Conclusions:** Promising pCR rates of 30% and 60%, with mild toxicities, were shown in MSS and MSI-H LARC pts treated with nivo plus radical S after CRT, suggesting the candidate therapy for the future non-surgical approach. Clinical trial information: NCT02948348. Research Sponsor: ONO Pharmaceutical.

4101 Poster Session (Board #93), Fri, 8:00 AM-11:00 AM

ARISTOTLE: A phase III trial comparing concurrent capecitabine with capecitabine and irinotecan (Ir) chemoradiation as preoperative treatment for MRI-defined locally advanced rectal cancer (LARC). *First Author: David Sebag-Montefiore, University of Leeds, Leeds, United Kingdom*

Background: Phase II studies reported high pathological complete response (pCR) rates and acceptable toxicity using irinotecan and fluoropyrimidine chemoradiation in LARC (ISRCTN:09351447). **Methods:** This phase III, multicentre, open-label trial funded by Cancer Research UK, randomly assigned (1:1) patients with MRI defined LARC threatening or involving resection margins without metastases, to pre-operative radiotherapy (RT) 45Gy/25 fractions combined with either capecitabine 900mg/m^2(CRT) or 650 mg/m2 bd weekdays with Irinotecan iv once-weekly 60mg/m2 weeks 1-4 (IrCRT). The primary endpoint is disease-free survival (DFS). Secondary endpoints include treatment compliance, safety and pCR. **Results:** 75 UK sites randomised 564 eligible patients from Oct/11 to July/18; 284 to CRT and 280 to IrCRT. 370 (66%) male; median age 61 years (range:29-83). Staging in both arms was similar: mrT3 (432/564(77%), mrT4 (89/564(16%); mrCRM involved (275/564(49%); threatened ≤1mm (215/564(38%). Compared with CRT, IrCRT patients were less likely to receive 45Gy RT (207/276(75%) vs 251/283(89%), p < 0.001) or receive ≥90% capecitabine dose in 188/276(68%) vs 253/283(89.4%)p < 0.001). A total of 204/276(74%) received ≥90% irinotecan dose. The grade 3-4 gastrointestinal adverse event rate was 21%(58/276) with IrCRT and 12%(34/283) with CRT (p = 0.004). Patients receiving IrCRT had significantly more diarrhoea 38/276(13.8%) vs 10/283(3.5%)p < 0.001) and neutropenia 27/276(9.8%) vs 3/283 (1.1%) p < 0.001). Two CRT and three IrCRT patients experienced a treatment related death. 237/276(86%) IrCRT and 241/283(85%) CRT patients had surgery. The median time from end of RT to surgery(10.6 weeks), the surgical procedure APE 262/478(55%), AR 189/478(40%), Hartmann's 10/478(2%); and the surgical complications(any event) 38%(181/478) were similar in both arms. The pCR rate is available in > 95% patients and is 20.2%(46/228) for IrCRTvs.17.4%(40/230) for CRT (p = 0.45), A > 84% CRM-ve resection rate is similar in both arms. **Conclusions:** For patients with MRI defined high risk LARC low rates of CRM involvement were observed in both arms reflecting high quality multidisciplinary care. The addition of irinotecan did not significantly improve the pCR rate, was associated with a decrease in the RT and capecitabine compliance and a higher rate of adverse events. Surgical procedure or complications were unaffected. Longer follow-up is required to assess DFS and translational data. Clinical trial information: 09351447. Research Sponsor: Cancer Research UK.

4102 Poster Session (Board #94), Fri, 8:00 AM-11:00 AM

Randomized phase II trial of modified (m) FOLFOX6 induction chemotherapy with or without aflibercept before standard chemoradiotherapy (CRT) and total mesorectal excision (TME) in patients with high-risk rectal adenocarcinoma (HRRC): Final results of the GEMCAD 1402, and by molecular subtypes. *First Author: Carlos Fernandez-Martos, Hospital Quironsalud, Valencia, Spain*

Background: Neoadjuvant chemotherapy (CT) followed by CRT and TME is a treatment option for clinically staged HRRC. The goal of the GEMCAD 1402 trial was to evaluate the benefit of adding an antiangiogenic drug to the neoadjuvant CT. The analysis of primary endpoint showed a better response rate in the experimental arm (Fernandez-Martos et al. Jama Oncol 2019). Here we present 3-year disease-free survival (DFS) and a retrospective analysis of consensus molecular subtypes by Immunohistochemistry (CMSs-IHQ). **Methods:** Patients (p) with middle or distal third, mrT3/T4/N2 rectal adenocarcinoma were randomly assigned (2:1), to mFOLFOX6 with (arm 1, n=115) or without Aflibercept (arm 2, n=65) prior to CRT (capecitabine with 50.4 Gy in 28 fractions) and TME. Tissue microarrays from 90 (58 arm1, 32 arm 2) p were stained for nine markers (CDX2, FRMD6, HTR2B, ZEB1, KER, MSH2, MSH6, PMS2 and MLH1) by IHQ using both semiquantitative and quantitative approaches. Cases were classified as CMS1-IHQ1, CMS-IHQ2/3 or CMS-IHQ 4 (immune, epithelial or mesenchymal subtypes). **Results:** In the intention-to-treat population after a median follow-up time of 38 months, 29 p (25%) in arm 1 had a DFS-related event, as compared with 14 p (21%) in arm 2 (HR 1.2063, 95% confidence interval 0.6374 to 2.2829, P=0.5644. The rate of DFS at three years was 75.2% (95% confidence interval, 66.1% to 82.2%) in arm 1 and 81.5% (95% confidence interval, 69.8% to 89.1%) in arm 2 (P=0.5638 by the exact stratified log-rank test). Overall 0/80/10 p were classified as CMS-IHQ1, CMS-IHQ2/3 or CMS-IHQ4 respectively. The pathological complete response (pCR) rate (ypTON0) was achieved in 27.5% and 0% in epithelial and mesenchymal subtypes respectively. A trend towards worse survival for the mesenchymal subtype was observed. **Conclusions:** Adding aflibercept to induction mFOLFOX6 is not associated with an improvement in DFS. Our findings suggest that CMSs-IHQ subtypes could be predictive for pCR with this treatment strategy. Clinical trial information: NCT02340949. Research Sponsor: SANOFI.

4103 Poster Session (Board #95), Fri, 8:00 AM-11:00 AM

Utilization of adjuvant chemotherapy in "ideal candidates" with stage III colon cancer. *First Author: Mohsin Soleja, UT Southwestern Medical Center, Dallas, TX*

Background: Prior studies have observed under-utilization of adjuvant chemotherapy (ACT) in stage III colon cancer. Our aims were to observe the rate of utilization of ACT in very healthy or "ideal candidates", identify reasons for omission and socioeconomic factors associated with ACT use, and observe patient outcomes. **Methods:** We queried patients from the National Cancer Database (NCDB) with stage III colon cancer, age<65, and Charlson-Deyo score of 0 who underwent resection in the United States between 2004-2015. Patients who received ACT were compared to patients who had surgery only (SO). We used chi-square test for categorical variables, Kaplan-Meier and Cox regression method for survival analyses. **Results:** Out of 243,388 stage III colon cancer patients during the study time, a total of 49,046 patients met the specific criteria of "ideal candidate". Out of these, 88.5% received ACT and 11.5% underwent SO. The primary reason for chemotherapy omission was: no reason given (54.2%), patient/guardian refusal (26.7%), physician recommended against (9.3%), patient died (3%), unknown (6.7%). Patients who received ACT were more likely to be female, non-Hispanic white, have a higher level of education, travel shorter distance for cancer treatment, have private insurance or higher income as compared to counterpart (*all p<.001).* Patients who received ACT had significantly better overall survival (5-year survival rate 74% vs. 54%, *p<.001*). This persisted after multivariable Cox regression analysis [HR:0.48 (CI:0.45-0.50), *p<.001].* **Conclusions:** We observed a high rate of utilization (88.5%) of ACT in patients with stage III colon cancer who were under age 65 and without comorbidities. However, the omission of chemotherapy in this population remains a problem, partially due to patient refusal. Socioeconomic factors associated with lower utilization were primarily related to insurance status (private vs non-private). Patients who received ACT had significantly improved survival as compared to SO group. Research Sponsor: None.

Rate of utilization of adjuvant chemotherapy in "ideal candidates" from 2004-2015.

Characteristics	Adjuvant Chemotherapy	Surgery Only	p value
Total Population	43,382 (88.5%)	5,664 (11.5%)	
Private Insurance	32,426 (90%)	3,280 (9.2%)	*<0.001*
Medicaid/Uninsured	6,868 (83%)	1,371(17%)	*<0.001*
Distance > 50 miles	3,094 (84%)	605 (16%)	<0.001
Income<$40,227	8,230 (86%)	1,336 (14%)	*<0.001*

4104 Poster Session (Board #96), Fri, 8:00 AM-11:00 AM

Pharmacokinetically-guided preoperative FOLFOX chemotherapy for locally advanced colon cancer patients. *First Author: Lucia Ceniceros, Department of Medical Oncology, Gastrointestinal Oncology Unit, Clínica Universidad de Navarra, University of Navarra, Madrid, Spain*

Background: Preliminary results from ongoing randomised trials suggest that neoadjuvant chemotherapy (NAC) may be an alternative approach to conventional adjuvant therapy. We assessed the feasibility and activity of incorporating a pharmacokinetically (PK) guided dose adjustment of 5-FU within preoperative Folfox. **Methods:** Radiologically staged LACC pts, T4 or T3 with extramural depth >5mm beyond the muscularis propia, were planned to receive 4-6 biweekly cycles of Oxalipatin (85mg/m^2), Leucovorin (400 mg/m^2), bolus 5-FU (400 mg/m2) and infusional 5-FU (initial dose of 2400mg/m^2 in 46h and subsequent cycles tailored according to PK monitoring in order to reach a target 5-FU area under the curve (AUC) between 20-30 mg•h•L-1). Dihidrouracil deshidrogenase was determined before the first cycle in order to detect pts with 5-Fu intolerance. Three serum samples were obtained during the 5-Fu infusion in the first two cycles. Pathological tumor regression was graded according to the MSKCC classification and toxicity to the NCI-CTCAE 4.0. **Results:** From June 2012 to August 2017, 45 pts (M/F: 35/10; median age 63) with LACC (T3: 66.7%; T4: 31.1%; T2: 2.2%; N+:66.6%) were evaluated. Median dose of 5-FU was 4500 mg. 48.9% of the pts required a 5-FU dose increase to reach the target AUC. Side effects profile included G3 neutropenia (3 pts), G2 diarrhea (2 pts) and G2 asthenia (9 pts). NAC was discontinued in 3 pts due to small bowell obstruction requiring surgery (no progressive disease during NAC). R0 resection rate was 100% (93.3% laparoscopy-assited). MSKCC score included grades 4, 3+ and 3 in 11.1%, 26.7% and 28.9% of pts, respectively. A complete pathological response was found in 5 pts (11.1%). Median number of harvested nodes was 16 (7-51), 80% ypN0. Those pts with AUC 25-30 had a 3-fold higher likelihood of achieving a MSKCC 3, 3+ and 4 responses. Median time to hospital discharge was 7 days (range 4-22). After a median follow-up of 60 months (44-66), 5-year actuarial PFS is 88.8%. **Conclusions:** Preoperative PK-adjusted FOLFOX in LACC pts is safe and well tolerated, achieving remarkable rates of major pathological responses and R0 resections. 4105 Poster Session (Board #97), Fri, 8:00 AM-11:00 AM

Immunoscore as a parameter predicting time to recurrence and disease-free survival in T4N0 stage II colon cancer patients. *First Author: Jerome Galon, HalioDx, Marseille, France*

Background: Risk assessment is particularly important to decide when to propose an adjuvant treatment for Stage II Colon Cancer (CC) patients. However, the current tumor risk features are imperfect and additional risk factors are needed to guide treatment decisions. The consensus Immunoscore is an alternative and powerful approach that could be used in the T4N0 Stage II colon cancer population. Immunoscore is an *in vitro diagnostic* test that predicts the risk of relapse in patients with CC by measuring the host immune response at the tumor site. **Methods:** From the international Immunoscore consortium study (n = 2681) (Pagès et al. *The Lancet* 2018), a subgroup analysis was performed on T4N0 Stage II colon cancer patients (n = 208). **Results:** In stage II T4N0, Int+Hi Immunoscore represented 65.4% of the population and low-Immunoscore only 34.6%. T4N0 patients with Int+Hi Immunoscore presented a significantly prolonged survival for TTR compared to low Immunoscore patients (5 years recurrence rate Int+Hi: 84.6% (78.3-91.5), Lo: 46.3% (35.1-61); unadjusted HR [Int+Hi *vs* Lo] = 0.21; (95% CI 0.11-0.4); *P*< 0.0001), representing a restricted mean survival time (RMST) difference of 80.9 months (95% CI 51.1-110.6) (*P*< 0.0001). The DFS was significantly different between Int+Hi and Low Immunoscore (5 years recurrence rate Int+Hi: 70.5% (95% CI 62.7-79.1), Lo: 38.5% (95% CI 28.2-52.5); unadjusted HR [Int+Hi *vs* Lo] = 0.31; (95% CI 0.19-0.49); *P*< 0.0001). Using restricted mean survival time (RMST) a significant (*P*< 0.0001) difference of 60.4 months (95% CI 32.6-88.1) was observed between the 2 groups Importantly, Cox multivariate analysis in Stage II T4N0 colon cancer patients, revealed that Immunoscore was the only remaining significant parameter (HR [Int+Hi *vs* Lo] = 0.15; (95% CI 0.05-0.46); *P*= 0.0009). In contrast, all other parameters, gender, sidedness, mucinous, grade, T-stage, VELIPI, MSI were not significant in multivariate analysis. Finally, Immunoscore showed the highest relative contribution to predict relapse (76.2% chi2 relative contribution), stronger than all the other parameters, MSI (16.1%), Grade (5%), sidedness (2%), gender (2%), VELIPI (1%). **Conclusions:** Immunoscore is the most powerful parameter to predict the risk in T4N0 population, and could be a good tool for adjuvant treatment decision in Stage II patients. 4106 Poster Session (Board #98), Fri, 8:00 AM-11:00 AM

Impact of antibiotics (ATB) on the recurrence of resected colorectal cancer (CRC): Results of EVADER-1 a nation-wide pharmacoepidemiologic study. *First Author: Benoit Rousseau, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recent studies suggest that ATB increase the overall risk of CRC incidence through disruption of gut microbiota. Impact of ATB on the risk of CRC recurrence after curative resection remains unknown. **Methods:** Using the French nation-wide *Institut National du Cancer* (INCa – Système National des Données de Santé) database of cancer patients, all newly diagnozed localized CRC patients resected between 01/2012 and 12/2014 were involved. The perioperative ATB intake (6 month before until 1 year after surgery) was classified according to the spectrum, doses and period of use. The primary endpoint was 3-year Disease-Free Survival (3-DFS), stratified on chemotherapy (chemo) administration (yes/no), and assessed using multivariate Cox models. **Results:** Out of 219,884 CRC patients, the present study included 36,640 patients: male 53%, age≥75 years 39%, left colon/rectal 59%, exposure to chemo 44%, at least one ATB intake 74%. At 3-years, 29% of patients had recurred and 18% had died. In multivariate analysis, in patients not receiving chemo, ATB intake as an out-patient was significantly associated with better 3-DFS [HR (one ATB only) = 0.88 (0.82-0.94)]. This effect remained in the same range whatever the number of ATB or cumulative exposure to ATB. In patients receiving chemo, ATB intake as an out-patient had a significant detrimental effect on 3-DFS [HR (one ATB only) = 1.15 (1.08-1.23)], increasing with the number of ATB [HR (≥5 ATB) = 1.54 (1.39-1.71)] and longer exposure [HR (> 30 days) = 1.39 (1.31-1.48)]. Penicillin A, quinolones and ATB combinations were associated with worse 3-DFS. The timing of ATB intake related to chemo revealed that the strongest deleterious effect was observed when ATB were taken during chemo [HR = 1.64 (1.53-1.75)]. No difference in the mean number of chemo cycle was observed comparing patients receiving ATB or not. **Conclusions:** This nation-wide study is the first to suggest that ATB modulate 3-DFS in resected CRC with a differential impact according to chemo exposure. Importantly, ATB intake with chemo is detrimental in a dose- and time-dependent manner suggesting that dysbiosis of gut microbiota during adjuvant chemo might increase risk of recurrence. Total mesorectal excision compared to local excision in locally advanced rectal cancer achieving complete pathological response with neoadjuvant therapy: A National Cancer Database Analysis. *First Author: Ahmed Abdalla, Ascension St John, Grosse Pointe Woods, MI*

Background: Total mesorectal excision (TME) is the standard surgical intervention for patients with locally advanced rectal cancer (LARC) regardless of response to neoadjuvant therapy. In this study, we perform a comprehensive review of the National Cancer Database (NCDP) to compare the clinical and surgical outcomes of TME to local excision (LE) in patients with LARC. **Methods:** NCDP was systematically researched to abstract all patients with stage II and III rectal adenocarcinoma between the years 2004 and 2015. We subsequently excluded all the patients who did not achieve complete pathological response (pT_0) after neoadjuvant therapy. The patients were then divided into two groups; those who underwent TME and those who underwent LE. Data were analyzed using SPSS v. 26.0, SAS v. 9.4. **Results:** A total of 4,705 were included in the study; 4,589 in the TME group and 116 in the LE group. Baseline characteristics were similar between the groups except for age. A total of 81(1.8%) of patients in the TME group and 8(6.9%) of patients in the LE group did not receive radiation (p=0.006) and 19(0.4%) of patients the TME group and 4(3.4%) of patients in the LE group did not receive chemotherapy. There was no difference in median overall survival between TME and LE groups. The median length of hospital stay was remarkably shorter in the LE group compared to the TME group (1 day vs 6 days, p<0.0001). The rate of 30-day and 90-day postoperative mortality were similar between the two groups (p-value=0.334 and 0.06, respectively). In the LE group, 4 (3.4%) of patients were readmitted within 30 days of the resection compared to 374 (8.5%) in the TME group but was not a statistically significant difference (p=0.059). **Conclusions:** In this study, TME and LE had similar overall survival and time to 25% mortality in patients with LARC who achieved complete pathological response after neoadjuvant therapy. Also, LE had a shorter hospital stay compared to the TME group. This study is limited by its retrospective nature, however these interesting observations warrant further investigation in randomized clinical trials. Research Sponsor: None.

Tumor-informed assessment of molecular residual disease and its incorporation into practice for patients with early and advanced-stage colorectal cancer (CRC-MRD Consortia). *First Author: Pashtoon Murtaza Kasi, Mayo Clinic, Jacksonville, FL*

Background: Circulating tumor DNA (ctDNA) testing can be used for the assessment of molecular residual disease (MRD) in patients with early-stage or advanced colorectal cancer (CRC). Prospective evaluation of this methodology in clinical practice has been limited to-date. **Methods:** A personalized and tumor-informed multiplex PCR assay (Signatera 16-plex bespoke mPCR NGS assay) was used for the detection and quantification of ctDNA for MRD assessment. We analyze and present results from an ongoing early adopter program of ctDNA testing across the spectrum of CRC management. **Results:** Here we present a total of 250 patients with colon (n=200), rectal (n=40), and other lower gastrointestinal cancers (n =10; anal, appendiceal, small bowel). MRD positivity rates and ctDNA quantification (mean tumor molecules/mL) are shown in Table. ctDNA detection was significantly associated with stage of disease (p<0.0001 Chi-square: 70.33). Additionally, in patients with radiologically measurable active metastatic disease, ctDNA detection rate was 100%. On the contrary, patients with advanced/metastatic disease who had partial response to treatment or no evidence of disease (NED) showed 28.5% and 19.2% of ctDNA-positivity, respectively. **Conclusions:** This is the first large, real-world study reporting on the results from a clinically validated MRD assay. For the first time we delineate MRD rates and quantify ctDNA concentration in patients with early-stage and advanced CRC. Furthermore, we provide an initial readout that effective ongoing treatment in patients with CRC may be correlated with ctDNA clearance. Ongoing analysis expanded to a cohort of 1200 clinical cases including correlation with genomic and serial testing will be presented. Research Sponsor: Natera, Inc.

MRD rates and quantity of ctDNA detected in patients with early-stage and advanced CRC.

Stages	MRD rates	Quantity of ctDNA (MTM/ml)
Stage I (T1-2N0)	0/6 (0%)	Mean: 41.91.8 Median: 0.63 Range: 0.11-673.01
Stage II (T3N0)	2/28 (7.1%)	
Stage II (T4N0)	2/6 (33%)	
Stage III, low-risk (T1-3N1)	2/18 (11%)	
Stage III, high-risk (T4, N1-2, T Any, N2)	7/19 (37%)	
Stage IV (Oligo-metastatic S/P resection/ablation MRD setting)	14/31 (45.2%)	
Stage IV (Metastatic)*	22/49 (44.9%)	Mean 1858 Median: 2.95 Range: 0.17 – 27,077

* Breakdown of ctDNA-positivity by clinical scenario is described in results

4109 Poster Session (Board #101), Fri, 8:00 AM-11:00 AM

Inpatient mortality, healthcare resource utilization, and complications of elective laparoscopic versus open colectomy in colon cancer patients: A nationwide inpatient sample analysis. *First Author: Ishaan Vohra, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Laparoscopic colectomy (LC) has become an accepted safe and alternative technique to open surgical colectomy (OC) as a treatment option for colon cancer. We compared inpatient mortality, hospital resource utilization and complications in patients who underwent LC vs OC. **Methods:** All patients with known diagnosis of colon cancer who underwent elective colonic resection were identified using Nationwide Inpatient Sample (NIS) 2017. Univariate and multivariate linear and logistic regression was performed to compare the outcomes of patients who underwent LC vs OC. **Results:** In our cohort, 171, 480 adult patients with colon cancer were identified. The number of males and females were equal. The mean age was 67.2 years. They were predominantly Caucasians (67.6%). OC was performed on 3,869 patients. Of 1,345 patients who underwent LC, 385 were converted to OC. As compared to OC, LC was associated with lower postoperative complications including anastomotic leak, stricture, intestinal obstruction(1% vs 10.8%, p<0.01), blood transfusion(2.2 % vs 11.2% p=0.01), malnutrition(0.2% vs 4.4% p=0.02), shock(0.7% vs 1.8%,p=0.04), ICU care(1.9% vs 5.3%), mean length of stay (5.9 days vs 8.7 days, p=0.01), lower hospital charge (88,642$ vs 106,315 $,p<0.01) and lower mortality(0.3% vs 1.9%(p=0.02). There was a trend towards decreased venous thromboembolism (0.3% vs 1.7 %, p=0.9) and post-operative ileus (0.1% vs 0.7% p=0.60) in LC as compared to OC. On multivariate analysis, independent predictors of undergoing LC were younger age, teaching and large bed-sized hospital and lower Charlson comorbidity index. Race, insurance status and income had no significant association with selection of operative approach (Table). **Conclusions:** In our cohort, laparoscopic colectomy was found to have better peri and post-operative clinical outcomes including decreased inpatient mortality and hospital resource utilization. It should be promoted as the curative surgical option for colon cancer whenever clinically indicated. Research Sponsor: None.

Does neoadjuvant FOLFOX chemotherapy improve the oncological prognosis of high-risk stage II and III colon cancers ? Three years' follow-up results of the Prodige 22 phase II randomized multicenter trial. *First Author: Medhi Karoui, La pitié Salpetrière Hospital, Paris, France*

Background: Neoadjuvant chemotherapy in a perioperative setting has proven valuable in locally advanced resectable colon cancer (CC) in terms of toxicity, postoperative morbidity and downstaging, but its effect on oncological outcomes remains uncertain. **Methods:** Prodige 22 was a randomized multicenter phase II trial in patients with resectable high-risk T3, T4 and/or N2 CC on baseline CT-scan. Patients were randomized to receive either 6 months of adjuvant FOLFOX after colectomy (control) or perioperative FOLFOX for 4 cycles before surgery and 8 cycles after (FOLFOX peri-op). In RAS wild-type (wt) patients a third arm testing perioperative FOLFOX-cetuximab was added. Primary endpoint was the Tumor Regression Grade. Secondary endpoints were 3-years overall (OS), disease-free survival (DFS) and time to recurrence (TTR). **Results:** 120 patients were enrolled. At interim analysis, the FOLFOX-cetuximab arm was stopped for futility. The remaining 104 patients (control, n = 52; FOLFOX peri-op n = 52) represented our intention-to-treat population. In the FOLFOX peri-op group, 96% received the schedule 4 cycles prior to surgery and all but one underwent adjuvant FOLFOX for a total of 12 cycles. In the control arm, 38 patients received adjuvant FOLFOX (1 postoperative death and 13 low-risk stage II patients). Median follow-up was 54.3 months [48.5-57.2]. Nineteen deaths and 26 disease recurrences were observed leading to a 3 years-OS of 90.3% in both arms (p = 0.7) and to a 3-years DFS of 76.8% and 69.2% in the peri-op and control arm respectively (p = 0.6). A trend to a better TTR in the peri-op arm was observed with a 3-years TTR of 82% as compared to 72% in the control arm (p = 0.3). No benefit from adding Cetuximab was observed in the 16 RAS-wt treated patients. **Conclusions:** In this pilot randomized study, perioperative FOLFOX chemotherapy has no detrimental effect on long term oncological outcomes and may be an option for some patients with locally advanced CC. A pooled analysis of randomized trials testing peri-operative strategies in this setting is warranted. Clinical trial information: NCT01675999. Research Sponsor: PHRC 2010, Pharmaceutical/Biotech Company.

4111 Poster Session (Board #103), Fri, 8:00 AM-11:00 AM

Early ileostomy closure is safe and feasible during adjuvant chemotherapy after total mesorectal excision surgery for rectal cancer. *First Author: Xiaodong Gu, Department of General Surgery, Huashan Hospital, Fudan University, Shanghai, China*

Background: The aim of this study was to evaluate the comparative clinical and oncological outcomes of temporary ileostomy closure during or after adjuvant chemotherapy in patients with total mesorectal excision (TME) for rectal cancer. **Methods:** This randomized controlled trial investigated 87 patients (51 males, 36 females) with rectal cancer undergoing TME surgery with temporary ileostomy from January 2016 to December 2018. Patients were randomized divided into 2 groups: early group (43 patients, mean age: 60.35) who underwent stoma closure during adjuvant chemotherapy (3 months after primary surgery) and late group (44 patients, mean age 61.80) who underwent stoma closure after adjuvant chemotherapy (6 months after primary surgery). Both clinical and oncological outcomes were analyzed. **Results:** No significant differences were observed in operative time, blood loss, postoperative hospital stay, postoperative complications or hospital costs in ileostomy closure between the 2 groups. Stoma-quality of life (QOL) of patients in early group was significantly better than late group (52.02 ± 5.68 vs 46.91 ± 5.68, $P < 0.05$). No significant difference in overall survival (P = 0.702) or progression-free survival (P = 0.638) was observed between the 2 groups. **Conclusions:** Ileostomy closure during adjuvant chemotherapy was clinically safe, and interruption of chemotherapy due to ileostomy closure did not change oncologic outcomes. Early ileostomy closure can improve QOL in those patients. Clinical trial information: NCT02665026. Research Sponsor: None.

4112 Poster Session (Board #104), Fri, 8:00 AM-11:00 AM

Patient and tumor characteristics as determinants of overall survival (OS) in *BRAF* V600 mutant (mt) metastatic colorectal cancer (mCRC) treated with doublet or triplet targeted therapy. *First Author: Javier Ros Montañá, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: *BRAF* V600 mt mCRC is an aggressive disease with poor OS under standard chemotherapy. Treatment with doublet and triplet targeted combinations, such as *BRAF* inhibitor+ antiEGFR+/- *MEK* inhibitor, has been shown to improve outcomes. Prognostic factors in this targeted treated population remain to be studied. **Methods:** Prospective international cohort of patients who received doublet or triplet anti-BRAF combinations in clinical trials or as compassionate use. Univariate Cox models for OS were constructed and the strongest predictors in stepwise variable selection were used to develop a prognostic score. The final multivariate model with selected predictors was stratified by prior lines. **Results:** In total, 42 patients were enrolled. Median age 60.7 y (33-83), 61% female, 61% right-sided tumors, 26% received 2 or more prior chemotherapy lines. One patient (2.6%) achieved complete response and 36% had partial response with median follow-up of 14.3 months. Median progression-free survival was 5.5 months (CI95% 4.4-10.4) and median OS (mOS) was 10.7 months (CI95% 8.4-22.1). In univariate models, ECOG performance status (1 vs 0), CEA levels (high - > 3.5 ng/mL- vs low - < 3.5 ng/mL), CA 19.9 (high vs. low), LDH (high vs. low), number of metastatic sites and presence of liver metastasis were significant prognostic factors. On the other hand, MSI status and peritoneal or nodal metastasis did not associate with outcome. In multivariable model, strongest determinants of OS were ECOG and baseline CEA levels. If high-risk for both factors (ECOG 1 and CEA high, 46% of the patients), mOS was 5.6 months (CI95% 4.2-NA); if intermediate-risk (either ECOG 1 or CEA high, 33%), mOS was 13.5 months (CI95% 10.6-NA); if low-risk (ECOG 0 and CEA low, 21%), mOS not reached (CI95% 16.5-NA). Differences between intermediate- and high-risk prognostic groups compared to low-risk were significant (HR = 5.9, p = 0.03; and HR = 25.9, p < 0.001, respectively). **Conclusions:** Patients characteristics such as ECOG and surrogates of tumor burden like CEA levels remain important OS determinants in *BRAF* V600 mt mCRC treated with doublet or triplet targeted therapy. In fact, there are not prognostic scores regarding BRAF mt mCRC treated with targeted therapies. Our study suggests that these prognostic factors may be considered as stratification factors in future clinical trials. Research Sponsor: None.

4113 Poster Session (Board #105), Fri, 8:00 AM-11:00 AM

The landscape of *MAP3K1/MAP2K4* alterations in gastrointestinal (GI) malignancies. *First Author: Matthew K Stein, West Cancer Center, U Tennessee, Memphis, TN*

Background: Inactivating alterations in *MAP3K1/MAP2K4* occur in various solid tumors, sensitize cancer models to MEK inhibitors, and have co-mutation partners which may enable therapeutic targeting. **Methods:** We retrospectively reviewed 20290 GI malignancy patients (pts), comprised of 9986 colorectal carcinoma (CRC) and 10304 non-CRC, whose tumors were profiled with Caris Life Sciences from 2015-2019. Profiling included immunohistochemistry (IHC) with programmed death ligand-1 (PD-L1), next-generation sequencing (NGS), tumor mutational burden (TMB) and deficient mismatch repair or microsatellite instability-high status (dMMR/MSI-H). **Results:** *MAP3K1/MAP2K4*-alteration (*MAP3K1/MAP2K4*-MT) was more frequent in CRC than non-CRC pts (2.0% v. 1.2%, $p<0.0001$), with truncating mutations representing the majority of lesions along both genes. While *MAP3K1/MAP2K4*-MT CRC pts were similar in age and gender to wild-type (WT), mutated non-CRC pts were older (median age 69 v. 65 years) and more likely female (51% v. 42%) compared to WT (both $p<0.05$). *MAP3K1/MAP2K4*-MT CRC (25% v. 7%) and non-CRC (30% v. 3%) were more frequently dMMR/MSI-H than WT pts (both $p<0.0001$). *MAP3K1/MAP2K4*-MT CRC cases were affiliated with higher TMB and similar rate of PD-L1 expression compared to WT. A higher rate of *MAP3K1/MAP2K4*-MT CRC pts were right-sided (36% v. 22%, $p<0.0001$) and transverse (8% v. 4%, $p<0.05$) compared to WT, whereas a higher frequency of WT cases were left-sided (20% v. 28%, $p<0.05$) and rectal (15% v 23%, $p<0.05$). Of microsatellite stable (MSS) CRC pts, those with *MAP3K1/MAP2K4*-MT were more likely *PIK3CA* (26% v. 17%) and *APC* (85% v. 78%) and less-likely *TP53* (64% v. 77%) co-mutated versus WT MSS pts (all $p<0.05$); no difference was seen in *BRAF* V600E, *ERBB2/ERBB3* or *KRAS* co-mutation rate in MSS pts. In both all-comers and MSS CRC, *MAP3K1/MAP2K4*-MT pts were more frequently co-mutated than WT with *ARID1A*, *POLE*, *ATM*, *BRCA2* and *PIK3R1* (all ≥7% of *MAP3K1/MAP2K4*-MT pts, $p<0.0001$). A higher frequency of all-comer non-CRC GI malignancy pts with *MAP3K1/MAP2K4*-MT were co-mutated with *PIK3CA* (13% v. 6%), *ERBB2/ERBB3* (8% v. 3%) or *APC* (13% v. 5%) compared to WT (all $p<0.01$). For MSS non-CRC GI cases, *ARID1A* (50% v. 30%) and *SMAD4* (21% v. 12%) were more frequently co-mutated in *MAP3K1/MAP2K4*-MT versus WT pts (all $p<0.05$). **Conclusions:** Truncating *MAP3K1/MAP2K4* alterations occur in nearly 2% of GI malignancy pts and are more commonly associated with dMMR/MSI-H than WT. Potentially targetable co-mutation partners implicated in MAPK and PI3K pathways as well as *POLE*, *BRCA2* and *ATM* warrant further evaluation. Research Sponsor: None.

TPS4114 **Poster Session (Board #106), Fri, 8:00 AM-11:00 AM**

A phase I/II study of PI3Kinase inhibition with copanlisib combined with the anti-PD-1 antibody nivolumab in relapsed/refractory solid tumors with expansions in MSS colorectal cancer. *First Author: Christopher Jakubowski, Johns Hopkins Oncology, Baltimore, MD*

Background: Certain somatic mutations are thought to promote immune evasion and resistance to immunotherapy. PIK3CA was identified in an *in vivo* genomic screen for mechanisms of resistance to anti-PD1 therapy. MC38 cells (murine colon adenocarcinoma) were engineered to express a library of human cancer-associated mutations from TCGA. Resultant tumors *in vivo* were exposed to immune pressure with anti-PD1 therapy. Cells that proliferated were then analyzed for mutations that impart immune resistance. Multiple activating mutations in *PIK3CA* conferred resistance to anti-PD1 therapy. Coadministered PI3K inhibition reversed this resistance. Multiple studies have shown the impact of the phosphatidylinositol 3-kinase (PI3K) pathway on the tumor microenvironment, and 20% of colorectal cancer (CRC) tumors have an activating mutation of PI3K. **Methods:** A multi-center, open-label, phase I/II study with the combination copanlisib and nivolumab, a PD1 inhibitor, in relapsed/refractory solid tumors with expansions in relapsed/refractory microsatellite-stable (MSS) CRC was developed. Copanlisib is an inhibitor of PI3K and exhibits its most potent inhibitory effect on the isoforms PI3Kα and PI3Kδ. The first phase seeks to determine the maximum tolerated dose (MTD) of copanlisib with fixed dose nivolumab of 480 mg given every 4 weeks. Following determination of the MTD the second phase seeks to determine the 6-month objective response rate of the combination in MSS CRC patients and contains two cohorts 1) PIK3CA wildtype, 2) PIK3CA mutated. The study is planned with 21 evaluable subjects per cohort and allows early termination for lack of efficacy. Tumor assessments will be made using RECIST 1.1. Patients will have a pre-treatment biopsy followed by nivolumab on Day 1 of each 4 week cycle and copanlisib on Day 1, 8 and 15. A second biopsy will occur after six weeks. Eligibility criteria includes completed NGS for PI3K status, and patients must have received at least 2 prior lines of standard therapy. Patients can not have received a prior checkpoint inhibitor or PI3K inhibitor. Secondary and exploratory objectives, in addition to survival and safety outcomes, include exploring immune cell subsets in the local tumor microenvironment and in the peripheral circulation, as well as investigating immune activation and suppressive pathways through RNA expression and additional NGS techniques. The clinical study was activated in January 2019 (NCT03711058). Clinical trial information: NCT03711058. Research Sponsor: American Association for Cancer Research (AACR), Stand Up To Cancer (SU2C), Pharmaceutical/Biotech Company.

TPS4115 **Poster Session (Board #107), Fri, 8:00 AM-11:00 AM**

A phase III study of comparing FOLFOX+/-bevacizumab with FOLFOX+/-bevacizumab+ high-dose intravenous vitamin C as first-line therapy in patients with advanced colorectal cancer. *First Author: Feng Wang, Department of Medical Oncology, Sun Yat-sen University Cancer Centre, Guangzhou, China*

Background: Previous studies showed that high dose vitamin C especially when administered intravenously might have anti-cancer effect. A recent preclinical study found that human colorectal cancer cells harboring KRAS or BRAF mutations are selectively killed by high dose vitamin C. Our phase I dose-escalation and expansion study has shown that high dose (up to 1.5g/kg) intravenous vitamin C with FOLFOX or FOLFIRI is well tolerated in patients with colorectal or gastric cancer. This trial is a randomized, multicenter, phase III study of high dose vitamin C infusion combined with FOLFOX +/- bevacizumab versus FOLFOX +/- bevacizumab as first-line therapy in patients with advanced colorectal cancer. **Methods:** This study has enrolled patients with histologically confirmed metastatic adenocarcinoma of colorectum, normal G6PD status and no prior treatment for metastatic disease. 432 patients are randomized 1:1 into one of two groups. Patients in the control group are treated with mFOLFOX6 (oxaliplatin 85 mg/m^2 d1 concurrent with leucovorin 400 mg/m^2, followed by bolus 5FU 400 mg/m^2 d1, followed by infusional 5FU 2400 mg/m^2 over 46 hours) with or without bevacizumab (5mg/kg, d1) every 2 weeks. Patients in the experimental group are treated with vitamin C intravenously (1.5g/kg/day, d1-3) in combination with mFOLFOX6 with or without bevacizumab every 2 weeks. Randomization is stratified by the location of primary site (left-sided or right-sided) and treatment with bevacizumab (with or without). The primary endpoint is progression free survival (assessed by investigator per RECIST v1.1). Secondary endpoints are overall survival, response rate, assessment of treatment-related adverse events, progression free survival and overall survival in RAS or BRAF mutant patients. Genome, microbiome and metabolome are also assessed. Clinical trial information: NCT02969681. Research Sponsor: Sun Yat-Sen University Clinical Research 5010 Program.

TPS4116 **Poster Session (Board #108), Fri, 8:00 AM-11:00 AM**

A phase Ib/II study of the polo-like kinase 1 (PLK1) inhibitor, onvansertib, in combination with FOLFIRI and bevacizumab for second-line treatment of patients with KRAS-mutated metastatic colorectal cancer (mCRC). *First Author: Daniel H. Ahn, Ohio State University Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, Columbus, OH*

Background: Chemotherapy in combination with targeted agents are standard-of-care options for patients for mCRC with response rates >50% in first line. In the second line setting, efficacy of chemotherapy and targeted agents are much lower with response rates of 5% for FOLFIRI (5-fluorouracil, leucovorin, irinotecan) + bevacizumab (anti-VEGF). New treatment options are urgently needed in particular for the 50 % of patients harboring a KRAS mutation. PLK1 is a serine/threonine kinase, master regulator of the mitotic checkpoint and cell division. PLK1 is overexpressed in CRC and its overexpression is associated with poor prognostic. A genome wide RNAi screen identified PLK1 as a synthetic lethal target in KRAS mutant CRC cells, inducing cell cycle arrest and apoptosis upon inhibition. Onvansertib is an oral, highly selective PLK1 inhibitor that demonstrates single agent and synergistic activity with irinotecan in preclinical CRC models. Additionally, KRAS mutated vs wild-type cells showed higher sensitivity to onvansertib. PLK1 inhibition is a potential target in KRAS-mutated mCRC, and the combination of onvansertib + FOLFIRI + bevacizumab may provide a new second-line treatment option. **Methods:** The primary objective of this single-arm Phase 1b/2 study is to assess the safety and preliminary efficacy of onvansertib in combination with FOLFIRI and bevacizumab in the second line setting for KRAS-mutated mCRC patients. For the Phase 1b segment, a standard 3 + 3 dose-escalation design is used to determine the maximum tolerated dose or recommended phase 2 dose (RP2D) of onvansertib. As of January 24, 2020, enrollment in the second dose level is ongoing. Efficacy will be determined by objective response rate (ORR) according to RECIST v1.1 (primary endpoint), progression-free survival and reduction in KRAS allelic burden in liquid biopsies (secondary endpoints). In the phase 2, based on a one-sided one sample log-rank test with 10% Type I error, there will be at least 90% power to detect an improvement in ORR from 5% to 20% with 26 patients. Exploratory endpoints include genomic studies of circulating tumor cells and ctDNA to evaluate altered pathways that correlate with patient clinical response. Clinical trial information: NCT03829410. Research Sponsor: Trovagene.

TPS4117 **Poster Session (Board #109), Fri, 8:00 AM-11:00 AM**

A multicenter phase Ib/II study of DNA-PK inhibitor peposertib (M3814) in combination with capecitabine and radiotherapy in patients with locally advanced rectal cancer. *First Author: Paul Bernard Romesser, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Preoperative chemo-radiotherapy with or without sequential chemotherapy, followed by surgical intervention, is standard of care for patients with locally advanced rectal cancer (LARC). However, 1/3 of these patients still develop distant metastases, indicating the need for more effective therapies. DNA-dependent protein kinase (DNA-PK) regulates a key DNA damage repair pathway for double-strand break repair. Peposertib (M3814), a potent, selective, orally administered DNA-PK inhibitor, has been shown to potentiate the effect of ionizing radiation in a human colon cancer xenograft model and several colon cancer cell lines. Peposertib is being investigated in several different trials across multiple indications. This Phase Ib/II study (NCT03770689) aims to evaluate the safety, tolerability, pharmacokinetics (PK), and efficacy of the neoadjuvant treatment combination of peposertib, capecitabine, and radiotherapy (RT) in patients with LARC. **Methods:** Patients aged ≥18 years with histologically confirmed and resectable Stage II/III rectal adenocarcinoma are eligible. Induction chemotherapy is permitted, but residual disease must first be documented by MRI, digital rectal examination and endoscopy. Patients who received other anticancer therapies or those with prior pelvic RT are excluded. During open-label Phase Ib (open), 18–30 patients (n = 3 per cohort) are due to receive peposertib + capecitabine (orally, 825 mg/m^2 twice daily [BID]) + RT (45–50 Gy), 5 days/week. Peposertib 50 mg once daily (QD) is the starting dose. Additional dose levels will be between 100–800 mg QD. Dose escalation is determined by the safety monitoring committee and guided by a Bayesian 2-parameter logistic regression model. At Phase II (planned), 150 patients will be randomized (1:1) to receive oral capecitabine (825 mg/m^2 BID) + RT (45–50 Gy), with either oral peposertib (recommended phase II dose [RP2D]) or placebo, QD for 5 days/week. Primary objectives are to define a maximum tolerated dose and RP2D (Phase Ib), and to evaluate the efficacy of peposertib + capecitabine + RT in terms of pathological/clinical complete response (Phase II). Secondary objectives include assessment of antitumor activity (Phase Ib), quality of life outcomes (Phase II), and PK of peposertib, and the safety and tolerability of the combination therapy (both phases). One patient has received peposertib 50 mg QD and six patients have received peposertib 100 mg QD. Patients are currently receiving peposertib 150 mg QD. Clinical trial information: NCT03770689. Research Sponsor: Merck KGaA.

TPS4118 Poster Session (Board #110), Fri, 8:00 AM-11:00 AM

NIVACOR: Phase II study of nivolumab in combination with FOLFOXIRI/bevacizumab in first-line chemotherapy for advanced colorectal cancer RASm/BRAFm patients. *First Author: Angela Damato, Medical Oncology Unit. Clinical Cancer Center. AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy*

Background: FOLFOXIRI (fluorouracil, leucovorin, oxaliplatin, and irinotecan) plus bevacizumab has been shown to be one of the therapeutic regimens in first line with the highest activity profile in patients (pts) with metastatic colorectal cancer (mCRC) unselected for biomolecular alterations. Tumors co-opt the PD-1/PD-L1 signaling pathway as one key mechanism to evade immune destruction. Anti-PD-1 monoclonal antibodies are FDA approved only for DNA mismatch repair deficient/microsatellite instability-high (MMRd/MSI-H), which are only about 5% among all mCRC. Nowadays, there are no data demonstrating anti-PD1 activity in stable and proficient (MMRp/MSS) disease. Another critical therapeutic target is the Vascular Endothelial Growth Factor A (VEGF-A), which acts on endothelial cells to stimulate angiogenesis; his inhibition with bevacizumab increase immune cell infiltration, giving a strong rationale for combining VEGF targeted agents with immune checkpoint inhibitors. Based on evidence, we explore the combination of triplet chemotherapy (FOLFOXIRI) with bevacizumab and nivolumab in pts with mCRC all-*RAS/BRAF* mutant regardless of microsatellite status. **Methods:** This is a prospective, open-label, multicentric phase II trial where pts with mCRC RAS/BRAF mutant in first line will receive nivolumab in combination with FOLFOXIRI/Bevacizumab every 2 weeks for 8 cycles followed by maintenance with bevacizumab plus nivolumab every 2 weeks. Bevacizumab will be administered intravenously at dose of 5 mg/kg every 2 weeks and nivolumab intravenously as a flat dose of 240 mg every 2 weeks. The primary endpoint is the overall response rate (ORR) and our hypothesis is that the treatment is able to improve the ORR from 66% to 80%. Secondary endpoints include overall survival, safety, time to progression, duration of response. Collateral translational studies evaluate the tumor mutational burden, and genetic alterations by circulating free DNA (cfDNA) obtained from plasma samples. The trial is open to enrollment, 4 of planned 70 pts have been enrolled. Clinical trial information: EudraCT Number: 2018-002893-38. Clinical trial information: NCT04072198. Research Sponsor: Bristol-Myers Squibb.

TPS4119 Poster Session (Board #111), Fri, 8:00 AM-11:00 AM

Multimodal fluorescence-guided surgery of colorectal peritoneal metastases, a phase I/II clinical trial. *First Author: Jan-Marie de Gooyer, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

Background: Successful treatment of patients with colorectal peritoneal carcinomatosis highly depends on complete surgical tumor resection of all tumor. Oncological outcomes can potentially be improved by intraoperative imaging using a tumor-targeting antibody conjugated to a fluorophore and a radiotracer. This enables preoperative radionuclide imaging, real-time intraoperative fluorescence imaging and gamma detection. In this study we investigate the feasibility, accuracy and safety of CEA-targeted preoperative SPECT/CT and intraoperative fluorescence imaging in patients with colorectal PC. **Methods:** In this phase I/II single arm protein dose escalation study patients with peritoneal metastases of colorectal origin who are scheduled for cytoreductive surgery and HIPEC will receive an intravenous injection of the CEA-targeting tracer ^{111}In-DOTA-labetuzumab-IRDye800CW. The first 15 patients will receive a single dose of 2,10 or 50 mg 6 to 7 days prior to surgery. Four to five days after injection SPECT/CT imaging of the thorax and abdomen is performed to determine intra-abdominal tumor load and detect extra-abdominal metatases. At day 6/7 after injection, standard cytoreductive surgical resection extended with real-time near-infrared fluorescence imaging and radio guidance is performed. After surgery, the peritoneal cavity will be re-examined for residual disease with fluorescence imaging. Resected specimens are analyzed microscopically, immunohistochemically (CEA and H&E) and by gamma counting. Blood samples are drawn for farmacokinetics and safety analysis at 180 minutes, 4 days, 6 days and 3 weeks after tracer injection. In the phase II dose expansion cohort, 14 more patients will receive the optimal dose as determined in the phase I trial. The primary objectives of the trial are to assess the safety, feasibility and accuracy of preoperative SPECT/CT and intraoperative fluorescence imaging after administration of 111In- labetuzumab-IRDye800CW in patients with peritoneal carcinomatosis of colorectal origin who will undergo cytoreductive surgery and HIPEC. The secondary objectives are to assess whether additional malignant lesions can be visualized by fluorescence imaging after cytoreductive surgery, to assess the intensity of fluorescence in malignant and non-malignant tissue, to assess the correlation between localization of the dual-labeled antibody and CEA expression in tumor and healthy tissue and to determine blood concentrations of the dual labelled antibody at several time points in patients. Clinical trial information: NCT03699332. Research Sponsor: Dutch Cancer Foundation.

TPS4120 Poster Session (Board #112), Fri, 8:00 AM-11:00 AM

TRACC: Tracking mutations in cell-free DNA to predict relapse in early colorectal cancer—A randomized study of circulating tumour DNA (ctDNA) guided adjuvant chemotherapy versus standard of care chemotherapy after curative surgery in patients with high risk stage II or stage III colorectal cancer (CRC). *First Author: Gayathri Anandappa, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Adjuvant chemotherapy (ACT) is routinely offered to patients with high risk (HR) stage II or stage III CRC following potentially curative surgery. Over 50% of stage III and $>$ 80% of stage II patients are cured by surgery alone but are being exposed to unnecessary chemotherapy with short- and long-term side effects. Post-operative ctDNA identifies minimal residual disease (MRD) after surgery in CRC. Our national study, TRACC, compares ctDNA guided versus standard of care (SoC) decision making in patients undergoing ACT. **Methods:** This is a UK-wide, multi-centre, prospective, two-arm, randomised trial. Patients with HR risk stage II or stage III CRC who have undergone R0 resection and have detectable ctDNA in their pre-surgical sample are eligible. Patients who undergo neoadjuvant chemoradiotherapy (CRT) for locally advanced rectal cancer with detectable ctDNA pre-CRT are also eligible. Patients are randomised in a 1:1 ratio to receive either SoC ACT or ctDNA guided ACT. In the ctDNA guided arm, patients who are ctDNA negative post-operatively have chemotherapy de-escalated i.e., 3 months(m) of Capecitabine and Oxaliplatin (CAPOX) doublet ACT is reduced to 3 m single agent Capecitabine; 6 m single agent Capecitabine reduced to no chemotherapy. In this group, ctDNA is re-tested at 3 months and if detectable, patients receive 3 months of CAPOX. Primary end-point is 3-year disease free survival (DFS). Secondary end-points include overall survival, neurotoxicity, quality of life and health economics. Based on a standard 3-year DFS of 75% in SoC ACT arm, to demonstrate a non-inferiority margin of 1.25, 810 patients are required per arm (85% power, α = 0.1). Stratification is by tumour staging and site of primary tumour. Target accrual is over 4 years. The study opened to recruitment in January 2020 and is supported by the MRC-NIHR Efficacy and Mechanism Evaluation Grant (NIHR128529). Clinical trial information: NCT04050345. Research Sponsor: National Institute of Health Research-Biomedical Research Centre funding.

TPS4121 Poster Session (Board #113), Fri, 8:00 AM-11:00 AM

Phase II/III study of circulating tumor DNA as a predictive biomarker in adjuvant chemotherapy in patients with stage II colon cancer: NRG-GI005 (COBRA). *First Author: Van K. Morris, NRG Oncology, and UT-MD Anderson Cancer Center, Houston, TX*

Background: There are currently no validated predictive biomarkers for stage II resected colon cancer (CC) after adjuvant chemotherapy. However, circulating tumor DNA (ctDNA) that is shed into the bloodstream represents a highly specific and sensitive approach for identifying microscopic or residual tumor cells. For patients (pts) with CC, the detection of ctDNA is associated with persistent disease after resection and may outperform traditional clinical and pathological features as a prognostic factor to assess risk for recurrence. We hypothesize that for pts whose stage II colon cancer has been resected and who have no traditional high-risk features, a positive ctDNA status may identify those who will benefit from adjuvant chemotherapy. **Methods:** In this prospective phase II/III clinical trial, pts (N=1,408) with resected stage II CC without traditional high-risk features and whom the evaluating oncologist deems suitable for no adjuvant chemotherapy will be randomized 1:1 into 2 arms: standard-of-care/observation (Arm A), or prospective testing for ctDNA (Arm B). Postoperative blood will be analyzed for ctDNA with the GuardantHealth LUNAR panel, covering CC-relevant mutations and CC-specific methylation profiling. Pts in Arm B with ctDNA detected will be treated with 6 months of adjuvant (FOLFOX) chemotherapy. For all pts in Arm A, ctDNA status will be analyzed retrospectively at the time of endpoint analysis. The primary endpoints are clearance of ctDNA with adjuvant chemotherapy (phase II) and recurrence-free survival (RFS) for "ctDNA-detected" pts treated with or without adjuvant chemotherapy (phase III). Secondary endpoints will include time-to-event outcomes (OS, RFS, TTR) by ctDNA marker status and treatment, prevalence of detectable ctDNA in stage II CC, and rates of compliance with assigned intervention. Archived normal and matched tumor and blood samples will be collected for exploratory correlative research. The trial is actively accruing towards the phase II endpoint across all US and Canadian cooperative groups. Support: U10-CA-180868, -180822; UG1CA-189867; GuardantHealth. Clinical trial information: NCT04068103. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS4122 Poster Session (Board #114), Fri, 8:00 AM-11:00 AM

Phase II study of durvalumab plus total neoadjuvant therapy (TNT) in locally advanced rectal cancer: The GEMCAD-1703 DUREC trial. *First Author: Jaume Capdevila, Medical Oncology Department, Vall d'Hebron University Hospital; Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: In clinical stages II and III (cT3-4 and/or N+), preoperative chemoradiotherapy (CRT) or short-course radiation followed by total mesorectal escision (TME) have been the standard of care for the last 15 years. Induction chemotherapy (CT) before CRT (strategy known as TNT) results in fewer toxic effects and improved compliance. TNT may release tumor-neoantigens with platinum-based induction CT, and radiotherapy has the potential ability to induce an immunogenic cell death and counteract an immune-suppressive tumor microenvironment that provides the rationale for combining with immunotherapies. In addition, the presence of tumor infiltrating lymphocytes has been demonstrated in patients with rectal cancer treated with neoadjuvant CRT, reinforcing the rational for immune check-point inhibitors in this setting. We hypothesize that combining TNT with durvalumab (an optimized monoclonal antibody directed against programmed cell death-1 ligand 1) would improve outcome. **Methods:** DUREC is a multicenter, single-arm, open-label, phase Ib/II study for patients with magnetic resonance (mr) image middle or distal third, mrT3c-d/T4/N2 rectal adenocarcinoma. Treatment: Patients will receive 6 cycles of modified FOLFOX6 prior to CRT (capecitabine with 50.4 Gy in 28 fractions) and TME, combined with durvalumab 1500 mg every 4 weeks during induction CT, CRT and waiting period until surgery. To assess the tolerability and toxicity profile we plan to perform a run-in treatment phase including the first 6 patients in the study, holding recruitment until all of them will be operated and 30-days post-surgery period completed. If $\leq$ 2 durvalumab-related dose-limiting toxicities (DLTs) are observed, recruitment will continue. The primary objective is pathological complete response (pCR) rate. Secondary endpoints include toxicity, tumor regression grade, R0 resections, clear circumferential margins, surgical complications, NAR score, disease-free survival and a biomarker program on tumor tissue, blood samples and stool microbiota. Statistical design: 58 evaluable patients (assuming a P0 of 16% and a P1 of 30%, with 0.1 alpha and 0.1 beta); Study started recruitment on December 2019. Clinical trial information: 2018-004835-56. Research Sponsor: AstraZeneca, GEMCAD (Spanish multidisciplinary Group of Digestive Cancers).

TPS4123 Poster Session (Board #115), Fri, 8:00 AM-11:00 AM

A phase II study of induction PD-1 blockade in subjects with locally advanced mismatch repair-deficient rectal adenocarcinoma. *First Author: Andrea Cercek, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The treatment of patients with locally advanced rectal cancer includes total neoadjuvant therapy with chemotherapy, chemoradiation followed by surgery. While most rectal cancers respond to combination induction chemotherapy, patients with mismatch repair deficient (dMMR) or MSI-H tumors have a significantly higher chance of progression with this treatment regimen. dMMR or MSI-H tumors have shown remarkable responses to PD-1 blockade, but the effect of neoadjuvant checkpoint inhibition has not been well studied. In this trial we will determine the pathologic complete response rate (pCR) of neoadjuvant anti-PD-1 blockade followed by standard chemoradiation in dMMR or MSI-H locally advanced rectal cancer. We hypothesize that treatment naïve dMMR or MSI-H rectal cancers will achieve a robust clinical response to PD-1 blockade and that the total neodjuvant therapy with PD-1 blockade followed by chemoradiation will improve pCR rates. **Methods:** Eligible patients $\geq$18 years of age with Stage II (T3-4, N-) or Stage III (any T, N+) histologically confirmed dMMR or MSI-H (by NGS) rectal adenocarcinoma will be enrolled. Patients will receive TSR-042 (500mg IV) every 3 weeks for a maximum of 8 cycles (6 months of treatment). Imaging, internal endoscopic exam and ctDNA blood draw will be performed at 6 weeks and every 3 months during induction anti-PD-1 treatment. Adverse events and surgical complications will be graded according to the NCI CTCAE v5 and the Clavien-Dindo classification, respectively. Following neoadjuvant checkpoint blockade, patients will undergo conventional chemoradiotherapy followed by surgical resection. The primary endpoint is pathologic complete response compared with historical control in pMMR patients. Patients will be followed up every 6 months for assessment of disease-free survival for up to five years. Clinical trial information: NCT04165772. Research Sponsor: Tesaro.

TPS4124 Poster Session (Board #116), Fri, 8:00 AM-11:00 AM

The PEGASUS trial: Post-surgical liquid biopsy-guided treatment of stage III and high-risk stage II colon cancer patients. *First Author: Sara Lonardi, Veneto Institute of Oncology (IOV)-IRCCS, Padua, Italy*

Background: Moving stage III Colon Cancer (CC) into the precision medicine space is a priority in view of the lack of molecular markers driving adjuvant treatment. Retrospective studies have demonstrated the tremendous prognostic impact of circulating tumor DNA (ctDNA) analysis after curative intent surgery, and suggested that lack of conversion of ctDNA from detectable to undetectable after adjuvant chemotherapy reflects treatment failure. With these premises, we have designed the PEGASUS trial (NCT04259944). **Methods:** PEGASUS is a prospective multicentric study designed to prove the feasibility of using liquid biopsy (LB) to guide the post-surgical and post-adjuvant clinical management in 140 microsatellite stable Stage-III and T4N0 Stage-II CC patients. The LUNAR1 test (Guardant Health, Redwood City, CA, USA) will be used for ctDNA determination. For the efficacy analysis, the PEGASUS cohort will be compared with a 3:1 matched cohort of 420 patients from the TOSCA trial (NCT00646607). A LB executed 2-4 weeks post-surgery will guide a "Molecular Adjuvant" treatment: i) ctDNA+ patients will receive CAPOX for 3 months and ii) ctDNA- patients will receive capecitabine (CAPE) for 6 months but will be retested after 1 cycle, and if found ctDNA+ will be switched to CAPOX treatment. At the end of the "Molecular Adjuvant" treatment a further LB will be performed and instruct subsequent treatment. Positive patients (ctDNA+/+ and ctDNA-/+) will receive an upscaled "Molecular Metastatic" systemic treatment for 6 months or until radiological progression or toxicity: i) ctDNA+/+ patients will be treated with FOLFIRI; ii) ctDNA-/+ patients with CAPOX. These patients will be subjected to a LB after 3 months and at the end of treatment: in case of positivity will be switched to FOLFIRI. ctDNA+/- patientswill receive a de-escalated treatment with CAPE for 3 months. 3 LB will be performed within 3 months and in case of positivity the patient will be switched to FOLFIRI. Patients with ctDNA-/- will be subjected to an interventional follow-up comprising 2 further LB and in case of positivity they will be switched to CAPOX treatment. PEGASUS is piggybacked to AlfaOmega (NCT04120935), a Master Observational Protocol that will follow patients from diagnosis to 5 years or recurrence/death (whichever comes first), collecting clinical data, radio-images and biological samples. AlfaOmega provides a clinical and logistic ecosystem for the seamless integration of PEGASUS clinical results with the biological underpinning of colon cancer. Clinical trial information: NCT04259944. Research Sponsor: Italian Association for Cancer Research.

4500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Trastuzumab with trimodality treatment for esophageal adenocarcinoma with HER2 overexpression: NRG Oncology/RTOG 1010. *First Author: Howard Safran, Brown University Oncology Research Group, Providence, RI*

Background: Trastuzumab is a monoclonal antibody against human epidermal growth factor receptor 2 (HER2). The primary objective of RTOG 1010 was to determine if trastuzumab increases disease-free survival (DFS) when combined with trimodality treatment for patients with HER2 overexpressing esophageal adenocarcinoma. **Methods:** This open label, randomized phase III trial included patients with newly diagnosed stage T1N1-2, T2-3N0-2 adenocarcinoma of the esophagus involving the mid, distal, or esophagogastric junction and up to 5cm of the stomach. All patients received chemotherapy (C) of paclitaxel, 50mg/m^2 and carboplatin AUC = 2, weekly for 6 weeks, with radiation (XRT: 3D-CRT or IMRT, 50.4 Gy in 28 fractions) followed by surgery. Patients were randomized 1:1 to receive weekly trastuzumab 4mg/kg week 1 then 2mg/kg/weekly x 5 during CXRT then 6 mg/kg for 1 dose prior to surgery and 6mg/kg every 3 weeks for 13 treatments after surgery. HER2 status was determined by IHC and gene amplification by FISH. With a 2-sided alpha of 0.05, 162 DFS events provide 90% power to detect a signal for an increase in median DFS from 15 to 25 months. DFS and overall survival (OS) were estimated by the Kaplan-Meier method. and arms were compared using the log rank test. The Cox proportional hazards model was used to analyze treatment effect. **Results:** 571 patients were entered for assessment of HER2 expression, 203 HER2+ patients randomized. The median follow-up for alive patients is 5.0 years. The estimated 2, 3, and 4-year DFS (95% CI) for the CXRT +trastuzumab arm were 41.8% (31.8%, 51.7%), 34.3% (24.7%, 43.9%), and 33.1% (23.6%, 42.7%), respectively, and for the CXRT arm were 40.0% (30.0%, 49.9%), 33.4% (23.8%, 43.0%), and 30.1% (20.7%, 39.4%), respectively; log-rank p = 0.85. The median DFS time is 19.6 months (13.5-26.2) for the CXRT +trastuzumab arm compared to 14.2 months (10.5-23.0) for the CXRT arm. The hazard ratio (95% CI) comparing the DFS of CXRT+trastuzumab arm to the CXRT arm was 0.97 (0.69, 1.36). The median OS time was 38.5 months (26.2-70.4) for the CXRT+trastuzumab arm compared to 38.9 months (29.0-64.5) for the CXRT arm, hazard ratio (95% CI): 1.01 (0.69, 1.47). There was no statistically significant increase in treatment-related toxicities with the addition of trastuzumab including no increase in cardiac events. **Conclusions:** The addition of trastuzumab to trimodality treatment did not improve DFS for patients with HER2 overexpressing esophageal adenocarcinoma. Supported by NCI grants U10CA180868, UG1CA189867, U10CA180822 and Genentech. Clinical trial information: NCT01196390. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

4501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Perioperative ramucirumab in combination with FLOT versus FLOT alone for resectable esophagogastric adenocarcinoma (RAMSES/FLOT7): Results of the phase II-portion—A multicenter, randomized phase II/III trial of the German AIO and Italian GOIM. *First Author: Salah-Eddin Al-Batran, University Cancer Center Frankfurt, Institut für Klinisch-Onkologische Forschung and IKF Klinische Krebsforschung GmbH am Krankenhaus Nordwest, Frankfurt, Germany*

Background: Periop. FLOT has become SOC for resectable, esophagogastric adenocarcinoma. However, patient's outcome is still poor. This trial evaluates the addition of the VEGF-R2 inhibitor ramucirumab (RAM) to FLOT for resectable patients (pts). **Methods:** This is a prospective, international, randomized, investigator-initiated phase II/III trial. Pts with resectable, Her2-negative, adenocarcinoma of the stomach and GEJ (≥ cT2 or cN+) were enrolled. Pts were randomized to 4 pre-and post-operative cycles of FLOT (docetaxel 50 mg/m^2; oxaliplatin 85 mg/m^2; leucovorin 200 mg/m^2; 5-FU 2600 mg/m^2, q2w) alone (Arm A) or the same regimen with RAM 8mg/kg q2w, followed by 16 cycles RAM (Arm B, FLOT-RAM). Important endpoints of phase II (exploratory) were major pathological (complete and nearly complete) response, centrally assessed acc. to Becker criteria, R0-resection rate, and safety. GEJ type I tumors and pts requiring transthoracic esophagectomy were excluded for safety reasons during the conduct of the study. **Results:** In total, 180 pts were randomized. Baseline characteristics were similar between arms (male, 73%; median age, 60y; cT3/T4, 83%; cN+, 78%; GEJ, 54%; signet-ring cells, 40%). However, the FLOT-RAM arm included more unfavorable pts with T4 (9% vs. 4%), Siewert type I tumors (18% vs. 13%), impaired ECOG PS of 1 (34% vs. 20%), and concomitant disease (87% vs. 79%). 91% of pts with FLOT and 92% with FLOT-RAM completed the 4 pre- cycles. R0-resection (in the full set) could be achieved in 83% of pts with FLOT and 97% of pts with FLOT-RAM (p = 0.0049). The rate of major path response was similar in both arms and was 30% for FLOT and 27% for FLOT-RAM. Surgical morbidity was observed in 37% of pts with FLOT and 44% of pts with FLOT-RAM. Mortality was 2.5% with FLOT and 5.9% with FLOT-RAM including GEJ type I tumors and dropped to 2.9% in both arms after excluding type I tumors per amendment. There was bit more G≥3 adverse events with FLOT-RAM (78% vs. 89%). **Conclusions:** In this phase II trial, the addition of ramucirumab to perioperative FLOT significantly improved R0-resection rates without an impact on path response, mainly because more patients could proceed to operation. The FLOT-RAM is safe, when type I tumors are excluded. Clinical trial information: NCT02661971. Research Sponsor: Lilly Deutschland GmbH.

4502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Perioperative trastuzumab and pertuzumab in combination with FLOT versus FLOT alone for HER2-positive resectable esophagogastric adenocarcinoma: Final results of the PETRARCA multicenter randomized phase II trial of the AIO. *First Author: Ralf Dieter Hofheinz, University Medical Center Mannheim, Tagestherapiezentrum am ITM, Mannheim, Germany*

Background: Perioperative FLOT is a standard of care for resectable, esophagogastric adenocarcinoma (EGA). This trial evaluates the addition of trastuzumab (tras) and pertuzumab (per) to FLOT for HER2-positive resectable patients (pts). **Methods:** PETRARCA is a prospective, multicenter, randomized, investigator initiated trial planned as a phase II/III investigation. We report the phase II part of this trial. Pts with HER2+ resectable EGA (≥ cT2 or cN+) were enrolled. Pts were randomized 1:1 to 4 pre- and post-operative cycles of FLOT (Docetaxel 50 mg/m^2; Oxaliplatin 85 mg/m^2; Leucovorin 200 mg/m^2; 5-FU 2600 mg/m^2, q2w) (Arm A) or the same regimen with tras 8/6 mg/kg and per 840 mg q3w, followed by 9 cycles tras/per (arm B). Primary endpoint for the phase II part was the rate of pathological complete remission (pCR). Main secondary endpoints were DFS, OS and safety. **Results:** The trial closed prematurely and did not proceed to phase III. In total, 81 pts were randomized (A, 41; B, 40). Baseline characteristics were balanced (overall, male 79%; median age 60; cT3/T4 86%; cN+ 85%; GEJ 75%). 93% in arm A and 90% in arm B completed pre-OP treatment as planned. More pts had at least one dose modification in arm B (A, 44%; B, 70%). The pCR rate was significantly improved with tras/per (A, 12%; B, 35%; p = 0.02). Likewise, the rate of pathological lymph node negativity was higher with tras/per (A, 39%; B, 68%). R0-resection rate (A, 90%; B, 93%) and surgical morbidity (A: 43%; B, 44%) were comparable. Moreover, in-house mortality was equal in both arms (overall 2.5%). Median DFS was 26 months in arm A and not yet reached in arm B (HR 0.58, p = 0.14). After a median follow-up of 22 months median OS was not yet reached. DFS and OS rates [with 95% CI] at 24 months were 54% [38-71%] and 77% [63-90%] in arm A and 70% [55-85%] and 84% [72-96%] in arm B, respectively. In terms of toxicity more ≥ grade 3 adverse events were reported with tras/per (75% vs. 85%), especially diarrhea (5% vs. 41%) and leukopenia (13% vs 23%). **Conclusions:** The addition of tras/per to perioperative FLOT significantly improved pCR and nodal negativity rates in pts with Her2+ resectable esophagogastric adenocarcinoma at the price of higher rates of diarrhea and leukopenia. Clinical trial information: NCT02581462. Research Sponsor: Roche.

4503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Pembrolizumab versus paclitaxel for previously treated patients with PD-L1–positive advanced gastric or gastroesophageal junction cancer (GC): Update from the phase III KEYNOTE-061 trial. *First Author: Charles S. Fuchs, Yale Cancer Center, Smilow Cancer Hospital, New Haven, CT*

Background: KEYNOTE-061 (NCT02370498) is a global phase 3 study of pembrolizumab vs paclitaxel as second-line therapy for GC. At the time of primary analysis (data cutoff: Oct 26, 2017), in patients with PD-L1–positive status (combined positive score [CPS] ≥1), pembrolizumab did not significantly prolong overall survival (OS) vs paclitaxel (9.1 months vs 8.3 months) but did elicit a longer duration of response (DOR) and a favorable safety profile vs paclitaxel. We present results of KEYNOTE-061 in patients with CPS ≥1, ≥5, and ≥10 after 2 additional years of follow-up (cutoff: Oct 7, 2019). **Methods:** Adult patients with GC that progressed after platinum + fluoropyrimidine chemotherapy were randomly assigned 1:1 to pembrolizumab 200 mg Q3W for up to 35 cycles (~2 y) or standard-dose paclitaxel. OS and progression-free survival (PFS) in the CPS ≥1 population were the primary end points. Comparisons were made using stratified log-rank tests. **Results:** At the time of this analysis, 366/395 patients with CPS ≥1 had died (92.6%). Pembrolizumab prolonged OS vs paclitaxel in PD-L1–positive patients (Table). No significant differences appeared between groups in PFS (Table). Objective response rate (ORR) was higher for pembrolizumab in the CPS ≥10 group, and DOR was longer with pembrolizumab using all CPS cutoffs (Table). There were fewer drug-related adverse events (AEs) with pembrolizumab than paclitaxel in the overall population (53% vs 84%). **Conclusions:** This long-term analysis found that second-line pembrolizumab prolonged OS among patients with PD-L1–positive GC and led to fewer drug-related AEs vs paclitaxel. Clinical trial information: NCT02370498. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

SWOG S1505: Results of perioperative chemotherapy (peri-op CTx) with mfolfirinox versus gemcitabine/nab-paclitaxel (Gem/nabP) for resectable pancreatic ductal adenocarcinoma (PDA). *First Author: Davendra Sohal, University of Cincinnati, Cincinnati, OH*

Background: Clinical outcomes after curative treatment of resectable PDA remain suboptimal. To assess the potential of early control of systemic disease with multiagent peri-op CTx, we conducted a prospective trial in the National Clinical Trials Network. **Methods:** S1505 was a randomized phase II trial of peri-op CTx (12 weeks pre-, 12 weeks post-op) with either mFOLFIRINOX (Arm 1) or Gem/nabP (Arm 2). Eligibility required confirmed tissue diagnosis of PDA, ECOG PS 0 or 1, and resectable disease per Intergroup criteria. Primary outcome was 2-year overall survival (OS), using a "pick the winner" design; for 100 eligible patients (pts), accrual up to 150 pts was planned to account for cases deemed ineligible at central radiology review. We previously presented data on eligibility (ASCO 2019 abstr 4137). Here we present the final efficacy and toxicity results for the eligible pts. **Results:** From 2015 to 2018, 147 pts were enrolled; there were 102 eligible pts; 55 in Arm 1; 47 in Arm 2. For Arms 1 and 2 respectively: median age, 66 (44-76) and 64 (46-76) years; males, 36 (65%) and 24 (51%); and ECOG PS 0, 34 (62%) and 31 (66%) pts. Treatment details are shown in Table. For Arm 1 and Arm 2, respectively: Two-year OS was 41.6% and 48.8%; median OS was 22.4 months and 23.6 months. Neither arm's 2-year OS estimate was statistically significantly higher than the *a priori* threshold of 40% (p=0.42 in Arm 1 and p=0.12 in Arm 2). Median disease-free survival (DFS) after resection was 10.9 months in Arm 1 and 14.2 months in Arm 2 (p=0.87). **Conclusions:** We have demonstrated: 1) two-year OS of 41.6% (median 22.4 months) with mFOLFIRINOX and 48.8% (median 23.6 months) with Gem/nabP for all eligible pts starting treatment for resectable PDA; 2) post-resection DFS of 10.9 months and 14.2 months, respectively; 3) adequate safety and high resectability rates with peri-op CTx; 4) little evidence that either regimen improves OS compared with the historical standard. Clinical trial information: NCT02562716. Research Sponsor: U.S. National Institutes of Health.

Outcomes by Treatment Arm for Eligible Patients (N=102).

	Arm 1 (mFOLFIRINOX; N=55)	Arm 2 (Gem/nabP; N=47)
Started pre-op CTx	53 (96%)	45 (96%)
Completed pre-op CTx	46 (84%)	40 (85%)
Surgical resection	40 (73%)	33 (70%)
Complete or major pathologic response*	10 (25%)	14 (42%)
Started post-op CTx	33 (60%)	28 (60%)
Completed all treatment	27 (49%)	19 (40%)
Diarrhea^	15%	7%
Neutropenia^	19%	38%
Peripheral neuropathy^	9%	7%

*Denominator is those who underwent resection (40 and 33 for Arm 1 and 2, resepectively).

4505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

ESPAC-5F: Four-arm, prospective, multicenter, international randomized phase II trial of immediate surgery compared with neoadjuvant gemcitabine plus capecitabine (GEMCAP) or FOLFIRINOX or chemoradiotherapy (CRT) in patients with borderline resectable pancreatic cancer. *First Author: Paula Ghaneh, University of Liverpool, Liverpool, United Kingdom*

Background: Patients with borderline resectable pancreatic cancer have poor survival and low resection rates. Neoadjuvant therapy may improve the outcome for these patients. The aim of this trial was to determine the feasibility and efficacy of a comparison of immediate surgery versus neoadjuvant GEMCAP or FOLFIRINOX or CRT. **Methods:** Eligible patients with NCCN defined borderline resectable (following central review of the baseline CT scan) and biopsy proven pancreatic cancer were randomised (stratified by centre) to receive immediate surgery, or neoadjuvant therapy of either 2 cycles of GEMCAP, or 4 cycles of FOLFIRINOX or 50.4Gy capecitabine-based CRT in 28 daily fractions over 5 $^{1}/_{2}$ weeks. Patients were restaged at 4-6 weeks and underwent surgical exploration if still borderline resectable. Resected patients received adjuvant therapy. Follow up was 12 months. There was quality assurance of surgery and CRT. Primary endpoints were recruitment rate and resection rate (R1/R0). Secondary endpoints included overall survival and toxicity. A target of 90 patients was set to determine feasibility and resection rates. Rates will be presented as point estimates and survival compared across treatment arms using a log-rank test. Analyses will be on an ITT basis. **Results:** Between August 2014 and December 2018, 90 patients were randomised with 88 included in the full analysis set (32 immediate surgery, 20 GEMCAP, 20 FOLFIRINOX, 16 CRT). Median age was 63 years, 44% were men. WHO performance status was 0 and 1 in 45% and 55% respectively. Median CA19-9 was 603 kU/L at baseline. 44 (79%) patients completed neoadjuvant therapy. Recruitment rate was 21 patients per year. Resection rate was 62% for immediate surgery and 55% for neoadjuvant therapy (p=0.668). R0 resection rate on resected patients was 15% and 23% respectively (p=0.721). One year survival rate was 40% [95% CI, 26% – 62%] for immediate surgery and 77% [95%CI, 66% - 89%] for neoadjuvant therapy. Log-rank analysis showed an HR=0.27 [95% CI, 0.13 – 0.55]; $\chi 2$ (1) = 14.91, P<0.001. 9 out of the 51 neoadjuvant patients included in the safety set reported 12 serious adverse events of grade 3 or above. **Conclusions:** There was no difference in resection rate between arms, however neoadjuvant therapy had a significant survival benefit compared with immediate surgery. Clinical trial information: 89500674. Research Sponsor: Cancer Research UK.

4506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Donafenib versus sorafenib as first-line therapy in advanced hepatocellular carcinoma: An open-label, randomized, multicenter phase II/III trial. *First Author: Feng Bi, Department of Medical Oncology, West China Hospital, Sichuan University, Chengdu, China*

Background: Sorafenib is still the standard first-line therapy for advanced hepatocellular carcinoma (HCC). Donafenib, a novel multikinase inhibitor, showed potential benefits in a previous phase Ib study in HCC. **Methods:** In this open-label, randomized phase II/III trial (ZGDH3), patients with unresectable or metastatic HCC, a Child-Pugh liver function score ≤ 7, and no prior systemic therapy were enrolled from 37 sites across China and randomized (1:1) to receive oral donafenib (0.2 g) or sorafenib (0.4 g) twice daily until intolerable toxicity or disease progression. The primary endpoint was overall survival (OS). Efficacy analysis was primarily based on the full analysis set (FAS). **Results:** Between March 2016 and April 2018, 668 patients were randomized (donafenib, 334; sorafenib, 334) and included in the intention-to-treat (ITT) set, of whom 659 were analysed by FAS (328 *vs* 331). Donafenib was associated with a significantly longer median OS than sorafenib in both FAS (12.1 months *vs* 10.3 months, hazard ratio 0.831, 95% confidence interval 0.699–0.988, $p = 0.0363$) and ITT (12.0 months *vs* 10.1 months, 0.839, 0.706–0.996, $p = 0.0446$). There were no significant differences in median progression-free survival (3.7 months *vs* 3.6 months, $p = 0.2824$), objective response rate (4.6% *vs* 2.7%, $p = 0.2448$), and disease control rate (30.8% *vs* 28.7%, $p = 0.5532$). Grade 3 or worse adverse events (AEs) occurred in 191 (57.4%) and 224 (67.5%) patients ($p = 0.0082$), respectively, and AEs of special interest and those leading to treatment interruption occurred in 287 (86.2%) *vs* 309 (93.1%, $p = 0.0049$) and 101 (30.3%) *vs* 141 (42.5%, $p = 0.0013$). A numerically lower number of patients reported serious AEs (55 [16.5%] *vs* 67 [20.2%], $p = 0.2307$) with donafenib. Common AEs with donafenib included hand-foot skin reaction (50.5%), aspartate aminotransferase increased (40.5%), blood bilirubin increased (39.0%), platelet count decreased (37.8%), and diarrhea (36.6%). **Conclusions:** Donafenib significantly improves OS over sorafenib with favourable safety and tolerability. Donafenib is a promising superior first-line therapy for advanced HCC. Funding: Zelgen. Clinical trial information: NCT02645981. Research Sponsor: Zelgen.

4507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Apatinib as second-line therapy in Chinese patients with advanced hepatocellular carcinoma: A randomized, placebo-controlled, double-blind, phase III study. *First Author: Qiu Li, West China Hospital , Sichuan University, Chengdu, China*

Background: Chinese patients (pts) account for more than 50% of hepatocellular carcinoma (HCC) cases in the world and have special features in etiology, biological behavior, treatment strategy and prognosis. The aim of this study was to evaluate the efficacy and safety of apatinib, an inhibitor targeting vascular endothelial growth factor receptor-2, in Chinese pts with pretreated advanced HCC. **Methods:** In this randomized, placebo-controlled, double-blind, phase 3 trial done in 31 sites in China, pts with HCC who had received at least one line of systemic therapy (including sorafenib and oxaliplatin-based chemotherapy, which is another first-line standard-of-care in China) and had Child-Pugh liver function class A or B ≤7 points were enrolled. The pts were randomly assigned (2:1) to receive 750 mg apatinib orally once daily or placebo and stratified by ECOG performance status (0 or 1), previous sorafenib treatment (yes or no), and extrahepatic spread and/or macrovascular invasion (yes or no) in 28-day treatment cycles. The primary endpoint was overall survival (OS). **Results:** Between Apr 01, 2014 and May 03, 2017, 393 pts were randomized and received at least one dose of study treatment (261 in apatinib arm and 132 in placebo arm). The median OS was significantly longer with apatinib than that with placebo (8.7 months [95% CI 7.5-9.8] *vs* 6.8 months [95% CI 5.7-9.1]; hazard ratio 0.785 [95% CI 0.617-0.998]; p=0.0476). Pts in the apatinib arm also had prolonged median progression free survival (PFS) compared with those in the placebo arm (4.5 months [95% CI 3.9-4.7] *vs* 1.9 months [95% CI 1.9-2.0]; hazard ratio 0.471 [95% CI 0.369-0.601]; p<0.0001). The objective response rate was 10.7% (95% CI 7.2-15.1) with apatinib versus 1.5% (95% CI 0.2-5.4) with placebo. Treatment-related adverse events (TRAEs) were reported in 250 (97.3%) pts in the apatinib arm and 92 (70.8%) pts in the placebo arm. The most common TRAEs of grade 3 and 4 were hypertension (71 [27.6%] pts in the apatinib arm *vs* 3 [2.3%] pts in the placebo arm), hand-foot syndrome (46 [17.9%] *vs* 0), decreased platelet count (34 [13.2%] *vs* 1 [0.8%]), and decreased neutrophil count (27 [10.5%] *vs* 0). 24 (9.3%) pts with apatinib and 13 (10.0%) pts with placebo died due to adverse events, and none were deemed treatment-related by investigators. **Conclusions:** Apatinib significantly prolonged OS and PFS in Chinese pts with pretreated advanced HCC, and was well tolerated with a manageable safety profile. Clinical trial information: NCT02329860. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

4508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Efficacy, tolerability, and biologic activity of a novel regimen of tremelimumab (T) in combination with durvalumab (D) for patients (pts) with advanced hepatocellular carcinoma (aHCC). *First Author: Robin Kate Kelley, University of California San Francisco, San Francisco, CA*

Background: The combination of dual immune checkpoint inhibitors (ICI) T (anti–CTLA-4) and D (anti–PD-L1) showed tolerability with a promising objective response rate (ORR) in the initial cohort of this study (NCT02519348). Subsequent evaluation of pts with solid tumors treated with increasing doses of T suggested priming with a higher dose of T may induce a stronger immune response and enhance anti-tumor activity. Thus, the randomized expansion cohorts comprised 4 arms evaluating T and D as monotherapies and 2 T+D regimens, including a novel T+D regimen featuring a single, priming dose of T. **Methods:** ICI-naïve pts with aHCC who progressed on, were intolerant to, or refused sorafenib were randomized to one of two T+D combinations: T300+D (T 300 mg + D 1500 mg 1 dose followed by D Q4 weekly [Q4W]) or T75+D (T 75 mg Q4W + D 1500 mg Q4W [4 doses] followed by D Q4W); or single agent D (1500 mg Q4W) or T (750 mg Q4W). Safety was the primary endpoint. ORR by blinded, independent central review using RECIST v1.1, duration of response (DoR), circulating lymphocytes, and overall survival (OS) were assessed. **Results:** At data cut-off (09/02/2019), 332 pts were enrolled. Median follow-ups were 11.7 months (mo) for T300+D, 14.6 (T75+D), 8.9 (D), and 15.8 (T). Treatment-related adverse event (trAE) incidences are shown (Table); no deaths were attributed to trAEs for T300+D or T. The T300+D arm had the highest confirmed ORR (DoR not reached [NR]) and longest OS (Table). A unique proliferative T cell profile was identified for pts in the T300+D arm, suggesting additive biologic activity for the combination, and showed pts with an OR exhibited high cytotoxic (CD8) counts. **Conclusions:** The encouraging clinical activity and tolerable safety profile suggest T300+D provides the best benefit-risk profile as opposed to T75+D or monotherapies. The unique pharmacodynamic activity of the T300+D regimen further supports its use in aHCC. T300+D and D are being evaluated in the ongoing phase III HIMALAYA study (NCT03298451) in first-line HCC vs sorafenib. Funding: AstraZeneca. Clinical trial information: NCT02519348. Research Sponsor: AstraZeneca.

Intrathoracic versus cervical anastomosis after minimally invasive esophagectomy for esophageal cancer: A randomized controlled trial. *First Author: Moniek Verstegen, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

Background: Robust evidence is lacking whether Ivor Lewis minimally invasive esophagectomy (MIE) or McKeown MIE should be preferred for patients with mid to distal esophageal or gastro-esophageal junction Siewert I-II (GEJ) cancer. **Methods:** In this multicenter randomized controlled trial, patients with esophageal (below the level of the carina) or GEJ cancer planned for curative resection were recruited. Eligible patients were randomly assigned (1:1) to either Ivor Lewis MIE or McKeown MIE. The primary endpoint was anastomotic leakage (AL) requiring endoscopic, radiologic or surgical intervention. Secondary outcome parameters were overall AL rate, postoperative complications, length of stay and mortality. **Results:** A total of 262 patients were randomly assigned to Ivor Lewis MIE (n = 130) or McKeown MIE (n = 132). Seventeen patients were excluded from the trial due to not meeting inclusion criteria (n = 2), physical unfitness for surgery (n = 3), patients' choice (n = 3), interval metastases (n = 5) or peroperative metastases (n = 4). AL necessitating reintervention occurred in 15 (12.3%) of 122 patients after Ivor Lewis MIE and in 39 (31.7%) of 123 patients after McKeown MIE (relative risk 0.39, 95% CI 0.22-0.65; risk difference 19.4%, 95% CI 7.9%-31.8%). Overall AL rate was 12.3% after Ivor Lewis MIE and 34.1% after McKeown MIE. Severe complications (Clavien-Dindo $\geq$ 3b) were observed in 10.7% after Ivor Lewis MIE and in 22.0% after McKeown MIE. Pleural effusion requiring drainage occurred in 9.8% of patients after Ivor Lewis MIE and 21.1% of patients after McKeown MIE. RLN palsy rate was 0% after Ivor Lewis MIE and 7.3% after McKeown MIE. Median length of hospital stay was 10 days (IQR 8 – 15 days) after Ivor Lewis MIE and 12 days (IQR 9 – 18 days) after McKeown MIE. ICU length of stay and mortality rates were comparable between groups. **Conclusions:** These findings provide evidence for a lower rate of AL requiring reintervention after Ivor Lewis MIE compared to McKeown MIE for patients with mid to distal esophageal or GEJ cancer. Clinical trial information: NTR4333. Research Sponsor: ZonMw.

Laparoscopic sentinel node navigation surgery versus laparoscopic standard gastrectomy with lymph node dissection in early gastric cancer: Final three-year survival results of multicenter randomized controlled phase III trial (SENORITA trial). *First Author: Keun Won Ryu, National Cancer Center, Goyang, South Korea*

Background: The benefits and hazards of laparoscopic sentinel node navigation surgery (LSNNS), compared with laparoscopic standard gastrectomy (LSG) with lymph node dissection in early gastric cancer (EGC), are unknown. The SENORITA trial investigated the clinical impact of LSNNS in EGC in terms of short-term surgical outcomes, long-term survival and quality of life. **Methods:** This study is a prospective, multicenter, randomized controlled, non-inferiority trial. Patients with preoperatively diagnosed gastric adenocarcinoma with T1N0 of 3 cm or less in diameter, regardless of histology, except absolute indication for endoscopic resection were eligible. Patients were randomized to LSG or LSNNS using dual tracers. The primary endpoint is 3-year disease-free survival (3yDFS). Planned sample size per arm is 290 patients with the non-inferiority margin of 2.737 in hazard ratio (HR) assuming that LSG achieve 97% 3yDFS, 5% of type 1 error and 80% of power. Three-year recurrence-free survival (3yRFS), overall survival (3yOS) and disease specific death rate (3yDSDR) were evaluated as secondary endpoints. **Results:** From March 2013 to December 2016, 580 patients were randomized (LSG arm 292 vs. LSNNS arm 288). After 53 patients dropped out before surgery, operation was performed in 527 patients (269 vs. 258), representing the full analysis set. LSG was performed in 266 according to the protocol excluding 3 open conversion. After exclusion of 13 without LSNNS due to various reasons, LSNNS was performed in 245 patients according to the protocol. After median follow up of 47.5 months, 3yDFS were 95.5% and 91.8% (HR 1.901, CI 0.911 – 3.967), respectively. The 3yRFS was 98.9% and 95.2% (p=0.019), and 3yOS was 99.2% and 97.6% (p=0.166), and 3yDSDR was 99.5% and 99.1% (p=0.591), respectively. **Conclusion:** LSNNS in EGC did not show non-inferiority compared with LSG in terms of 3yDFS. However, 3yOS and 3yDSDR of LSNNS were comparable to LSG by the rescue surgery of recurrence. LSNNS might be an alternative surgical option instead of LSG in selected EGC patients. Clinical trial information: NCT01804998. Research Sponsor: Grant 2010150-1 from National Cancer Center, Korea.

Sintilimab in patients with advanced esophageal squamous cell carcinoma refractory to previous chemotherapy: A randomized, open-label phase II trial (ORIENT-2). *First Author: Jianming Xu, Department of Gastrointestinal Oncology, The Fifth Medical Center of the PLA General Hospital, Beijing, China*

Background: Patients (pts) with advanced esophageal squamous cell carcinoma (ESCC) refractory to first-line chemotherapy have limited treatment options. The study aims to evaluate the efficacy and safety of sintilimab, a PD-1 inhibitor, versus chemotherapy in these pts, and explore predictive value of PD-L1 and neutrophil-to-lymphocyte ratio (NLR) on efficacy of sintilimab. **Methods:** The open-label, multi-center phase 2 trial (NCT03116152) enrolled advanced ESCC pts refractory to first-line chemotherapy, and randomly assigned (1:1) them to receive sintilimab (200mg, Q3W) or chemotherapy (paclitaxel, 175mg/m^2, Q3W; or irinotecan, 180mg/m^2, Q2W), intravenously. The primary endpoint was overall survival (OS). Explorative endpoint were effects of PD-L1 and NLR on efficacy of sintilimab. **Results:** From May 16, 2017 to Aug 30, 2018, 190 pts were randomly assigned to sintilimab or chemotherapy (n = 95 per group). With the median follow-up of 7.2 months for sintilimab group and 6.2 months for chemotherapy group, the median OS in sintilimab was significantly higher than chemotherapy (7.2m vs. 6.2m, hazard ratio [HR] 0.70, P = 0.034). The objective response rate (ORR) was greater in sintilimab than chemotherapy with 12.6% vs. 6.3%, and the median duration of response was longer (8.3m vs. 6.2m). Incidences of treatment-related adverse events (TRAEs) of any grade (54.3% vs. 90.8%) and of grade 3-5 (20.2% vs. 39.1%) were both numerically less in sintilimab than in chemotherapy. The ORR in sintilimab versus chemotherapy in pts with tumor PD-L1 tumor proportion score (TPS) $\geq$1% and with TPS $\geq$10% were 20.2% vs. 0%, and 35.7% vs. 0%, respectively. In sintilimab group, pts with low NLR ($<$ 3) had a significant longer median OS (HR 0.54, P = 0.019) than with high NLR. **Conclusions:** Sintilimab was superior to chemotherapy with a significantly prolonged survival benefit and a favorable safety profile in pts with advanced ESCC refractory to first-line chemotherapy. High tumor PD-L1 expression (TPS $\geq$1% or $\geq$10%) might indicate more response benefit to sintilimab for these pts, and low NLR might be a positive predictive factor for sintilimab. Clinical trial information: NCT03116152. Research Sponsor: Innovent Biologics, Inc.

The association of molecular biomarkers with efficacy of pembrolizumab versus paclitaxel in patients with gastric cancer (GC) from KEYNOTE-061. *First Author: Charles S. Fuchs, Yale Cancer Center, Smilow Cancer Hospital, New Haven, CT*

Background: KEYNOTE-061 (NCT02370498) was a randomized, open-label, phase 3 study of pembrolizumab vs paclitaxel in patients with advanced gastric or gastroesophageal junction adenocarcinoma with tumor progression after first-line therapy (N =592). We explored the association of tissue tumor mutational burden (tTMB) status and clinical outcomes in patients with GC enrolled in KEYNOTE-061, including the relationship with PD-L1 combined positive score (CPS) and microsatellite instability-high (MSI-H) status. **Methods:** In patients from KEYNOTE-061 with evaluable tumor and matched normal whole exome sequencing (WES) data (N = 420; pembrolizumab, 218; paclitaxel, 202), the association of tTMB (continuous $\log_{10}$ scale) with confirmed ORR and PFS by blinded central radiology review per RECIST v1.1, and OS was evaluated within each treatment arm using logistic regression (ORR) and Cox proportional hazards regression (PFS; OS). The clinical utility of tTMB was assessed using the prespecified cutoff of 175 mut/exome. Clinical data cutoff: October 26, 2017. **Results:** tTMB was significantly associated (α=0.05) with ORR, PFS, and OS in patients treated with pembrolizumab (one-sided P<0.001) but not paclitaxel (two-sided P>0.600). The area under the receiver operating characteristics curve for tTMB and response (pembrolizumab vs paclitaxel) was 0.68 (95% CI, 0.56-0.81) vs 0.51 (95% CI, 0.39-0.63). Patient outcomes by tTMB cutoff are reported in Table. There was low correlation between tTMB and PD-L1 CPS in both treatment arms (r<0.18). tTMB remained significantly associated with all clinical end points with pembrolizumab after adjusting for PD-L1 CPS and with PFS and OS after excluding MSI-H patients. **Conclusions:** This exploratory analysis from KEYNOTE-061 is the first to demonstrate a strong association between tTMB and response to pembrolizumab in patients with GC. Data further suggest tTMB is a significant and independent predictor beyond PD-L1 status. Clinical trial information: NCT02370498. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Trastuzumab deruxtecan (T-DXd; DS-8201) in patients with HER2-positive advanced gastric or gastroesophageal junction (GEJ) adenocarcinoma: A randomized, phase II, multicenter, open-label study (DESTINY-Gastric01). *First Author: Kohei Shitara, National Cancer Center Hospital East, Chiba, Japan*

Background: T-DXd is an antibody-drug conjugate composed of an anti-HER2 antibody, cleavable tetrapeptide-based linker, and topoisomerase I inhibitor. In a phase 1 trial of T-DXd (5.4 or 6.4 mg/kg), the objective response rate (ORR) was 43.2% (19/44) and median progression-free survival (mPFS) was 5.6 mo in patients with advanced HER2+ gastric cancer (GC). DESTINY-Gastric01 (DS8201-A-J202; NCT03329690) is an open-label, multicenter, randomized, phase 2 study of T-DXd in HER2-expressing advanced GC or GEJ adenocarcinoma; results are from the primary analyses for ORR and interim overall survival (OS) in HER2+ patients. **Methods:** Patients with centrally confirmed HER2+ (IHC 3+ or IHC 2+/ISH+ on archival tissue) GC that progressed on ≥ 2 prior lines were randomized 2:1 (T-DXd 6.4 mg/kg q3w or physician's choice [PC] irinotecan or paclitaxel). All patients received prior HER2 therapy. Stratification factors were region, ECOG PS (0;1), and HER2 status. The primary endpoint was unconfirmed ORR by independent central review. Secondary endpoints were OS (alpha controlled), PFS, disease control rate (DCR), duration of response (DOR), and safety. **Results:** 187 patients received T-DXd (n = 125) or PC (n = 62 [55 irinotecan; 7 paclitaxel]); 79.7% Japan, 20.3% Korea. Patients had a median of 2 prior lines of therapy, and 44.4% had ≥ 3. At data cutoff (8 Nov 2019), 22.4% of T-DXd and 4.8% of PC patients remained on treatment. ORR was 51.3% (61/119; 11 CR and 50 PR) with T-DXd vs 14.3% (8/56; all PR) with PC (P < .0001); confirmed ORR, 42.9% vs 12.5% (P < .0001); DCR, 85.7% vs 62.5% (P = .0005); mDOR, 11.3 vs 3.9 mo; mPFS, 5.6 vs 3.5 mo (HR, 0.47 [95% CI, 0.31-0.71]; P = .0003). OS was significantly prolonged with T-DXd (mOS, 12.5 vs 8.4 mo; HR, 0.59 [95% CI, 0.39-0.88]; P = .0097; prespecified O'Brien Fleming boundary, P = .0202); 12-month OS, 52.1% vs 28.9%. Grade ≥ 3 AEs occurred in 85.6% of patients with T-DXd vs 56.5% with PC; the most common were neutrophil count decreased (51.2%; 24.2%), anemia (37.6%; 22.6%), and white blood cell count decreased (20.8%; 11.3%). 12 patients (9.6%) had T-DXd–related interstitial lung disease (ILD; 2 grade 3, 1 grade 4, no grade 5) vs 0 with PC. 1 drug-related death (pneumonia [non-ILD] in the T-DXd arm) occurred. **Conclusions:** T-DXd demonstrated statistically significant and clinically meaningful improvements in ORR and OS compared with standard chemotherapy (paclitaxel or irinotecan) in patients with HER2+ advanced gastric or GEJ adenocarcinoma. Clinical trial information: NCT03329690. Research Sponsor: Daiichi Sankyo Co., Ltd.

FOLFIRI plus ramucirumab versus paclitaxel plus ramucirumab as second-line therapy for patients with advanced or metastatic gastroesophageal adenocarcinoma with or without prior docetaxel: Results from the phase II RAMIRIS Study of the AIO. *First Author: Sylvie Lorenzen, Klinikum rechts der Isar, Technische Universität München, III, Medizinische Klinik und Poliklinik, Munich, Germany*

Background: Ramucirumab (Ram) as monotherapy or plus paclitaxel is a proven second-line option for advanced gastroesophageal adenocarcinoma (GEA). More and more patients (pts) are pretreated with docetaxel in the perioperative or first-line setting. These pts may benefit more from another, non-cross resistant chemotherapy backbone regimen. This trial evaluates the addition of Ram to FOLFIRI as second line treatment. **Methods:** This is a multicenter, randomized, investigator initiated, phase II trial. Pts with GEA who have progressed after treatment with a fluoropyrimidine/platinum-containing regimen were randomized 2:1 to either FOLFIRI plus Ram every two weeks (Arm A) or paclitaxel (days 1, 8, 15 of a 28-day cycle) plus Ram every two weeks (Arm B). Major endpoints were overall survival (OS), objective response rate (ORR), disease control rate (DCR), progression free survival (PFS) and toxicity. **Results:** 111 pts (median age 61 years, 65% of pts had prior docetaxel therapy) were enrolled and 110 analyzed within intention to treat population (ITT, Arm A, 72; Arm B, 38). In the ITT, there was no significant difference in median OS (A, 6.8 vs. B, 7.6 months, HR 0.94, p = 0.77) and median PFS (A, 4.6 vs. B, 3.6 months, HR 0.72, p = 0.12). For pts with prior docetaxel use (71/110), median PFS was A, 4.3 vs. B, 2.0 months, HR 0.49, p = 0.008 and median OS was A, 7.5 vs. B, 6.4 months, HR 0.71, p = 0.25. In 101 pts with tumor assessment and included in the response analysis, ORR and DCR was 23% and 65% in Arm A and 11% and 60% in Arm B, respectively. 67 pts assessable for response were pre-treated with docetaxel. In these pts, ORR was 24% in Arm A and 9% in Arm B. Disease control rate (DCR) was 67% and 41% for Arm A and B respectively. Both therapies were similarly tolerable, final safety results will be shown. **Conclusions:** The RAMIRIS trial demonstrated feasibility of the combination of FOLFIRI and Ram. With a response rate of 24% and a median PFS of 4.3 months, docetaxel pre-treated pts seemed to derive pronounced benefit from FOLFIRI-Ram, providing a rationale for a phase III trial, which is currently ongoing. Clinical trial information: NCT03081143. Research Sponsor: Lilly.

Phase III APACT trial of adjuvant *nab*-paclitaxel plus gemcitabine (*nab*-P + Gem) versus gemcitabine (Gem) alone for patients with resected pancreatic cancer (PC): Outcomes by geographic region. *First Author: Michele Reni, IRCCS Ospedale, San Raffaele Scientific Institute, Milan, Italy*

Background: The APACT trial was one of the largest and most geographically diverse trials of adjuvant chemotherapy for resected PC, allowing for comparison of outcomes by geographic region. In this analysis, we report updated overall survival (OS) results for the intent-to-treat (ITT) population and examine outcomes by geographic region. **Methods:** Treatment-naive patients with histologically confirmed PC, macroscopic complete resection, Eastern Cooperative Oncology Group performance status 0 or 1, and carbohydrate antigen 19-9 < 100 U/mL were eligible. Stratification factors were resection status (R0/R1) and lymph node status (positive/negative). Treatment was initiated ≤ 12 weeks postsurgery. Patients received *nab*-P 125 mg/m^2 + Gem 1000 mg/m^2 or Gem 1000 mg/m^2 on days 1, 8, and 15 of six 28-day cycles. The primary endpoint was disease-free survival by independent review. Secondary endpoints were OS and safety. **Results:** The updated OS analysis (data cutoff date, January 2020) revealed a median OS of 41.8 months with *nab*-P + Gem compared with 37.7 months with Gem alone (hazard ratio [HR] 0.81; 95% CI, 0.68 - 0.97; nominal P = 0.047; Table). In each geographic region, the median OS with *nab*-P + Gem was numerically longer than with Gem alone. **Conclusions:** The updated OS analysis of the ITT population supports the previously reported trend favoring *nab*-P + Gem. The geographic regional analyses reveal numerically longer OS with *nab*-P + Gem vs Gem alone and variable outcomes by region; however, the differences do not support the trend observed in the ITT population, potentially due to limited sample sizes. Registration: EudraCT (2013-003398-91). Clinical trial information: NCT01964430. Research Sponsor: Bristol-Myers Squibb.

ESPAC-4: A multicenter, international, open-label randomized controlled phase III trial of adjuvant combination chemotherapy of gemcitabine (GEM) and capecitabine (CAP) versus monotherapy gemcitabine in patients with resected pancreatic ductal adenocarcinoma: Five year follow-up. *First Author: John P. Neoptolemos, University of Heidelberg, Heidelberg, Germany*

Background: The ESPAC-4 trial demonstrated that adjuvant GEM/CAP for pancreatic cancer significantly improved survival compared to GEM monotherapy. The aim of this study is to evaluate the long-term outcomes in the ESPAC-4 trial. **Methods:** Patients with pancreatic ductal adenocarcinoma were randomized within 12 weeks of surgery (stratified for R0/R1 resection margin status and country) to have either six 4-week cycles of IV GEM alone or GEM with oral CAP. The primary endpoint was five-year survival; secondary endpoints were toxicity and relapse free survival. 722 patients (480 expected events), 361 in each arm, were needed to detect a 10% difference in 2-year survival rates with 90% power (log-rank test with 5% two-sided alpha). **Results:** Between Nov 10 2008 and Sep 11 2014, 732 patients were randomized with 730 included in the full analysis set (366 GEM, 364 GEM/CAP). Median age was 65 years, 57% were men. WHO performance status was 0, 1 or 2 in 42% 55% and 3% respectively. Postoperative median CA19-9 was 19 kU/L. Median maximum tumor size was 30 mm, 61% were R1 resections, 80% were node positive and 40% were poorly differentiated. The data freeze was on 24 February 2020; median follow up was 60 months with 531 overall deaths, 280 in GEM, and 251 in GEM/CAP. Median (95% CI) survival (months) for patients treated with GEM/CAP was 27.7 23.3 – 31.2) and 26.0 (22.7 – 28.4) for GEM. Five-year (95% CI) survival rates were 20 (16 – 25) % for GEM and 28 (23 – 33) % for GEM/CAP. Stratified log-rank analysis revealed an HR=0.84 [95% CI, 0.70 – 0.99]; χ^2 (1) = 3.87, P=0.049. 70 out of 366 GEM patients in the safety set reported 101 grade 3/4 serious adverse events, while 65 out of 359 GEM/CAP patients reported 97 grade 3/4 serious adverse events (P=0.724). **Conclusions:** Adjuvant GEM/CAP for pancreatic cancer had a statistically significant improvement in survival compared to GEM monotherapy. Clinical trial information: 96397434. Research Sponsor: Cancer Research UK.

A prospective randomized controlled trial of selective transarterial chemoembolization using drug-eluting beads loaded with epirubicin versus selective conventional transarterial chemoembolization using epirubicin-lipiodol for hepatocellular carcinoma: The JIVROSG-1302 PRESIDENT study. *First Author: Masafumi Ikeda, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Transarterial chemoembolization (TACE) with selective catheterization into the segmental or subsegmental hepatic arteries supplying HCC is often performed to achieve the complete local control of HCC in the patients with a limited number of small sized nodules. To clarify which of TACE with drug-eluting beads loaded with epirubicin (DEB-TACE) or conventional TACE with epirubicin-lipiodol (cTACE) can achieve the complete response (CR) more frequently, we performed a randomized controlled trial of DEB-TACE vs. cTACE. **Methods:** Between March 2016 and May 2019, unresectable HCC patients with Child-Pugh class A or B who were scheduled to receive selective TACE were randomly assigned 1:1 to the DEB-TACE group and the cTACE group. The primary endpoint was the CR rate at 3 months, and the secondary endpoints were the CR rate at 1 month and rate of adverse events (AEs). The response and AEs were assessed according to the modified RECIST by an independent review committee and the National Cancer Institute Common Terminology Criteria for Adverse Events, version 4.0., respectively. **Results:** A total of 200 patients (DEB-TACE, 99 patients; cTACE 101 patients) were enrolled from 22 Japanese institutions. The patient characteristics were well-balanced between the two groups. The median number of tumors was one in both groups and the median tumor size was 20.0 mm in the DEB-TACE group and 20.5 mm in the cTACE group. The table shows the CR rates and frequencies of AEs. The CR rates of cTACE at 3 and 1 months were significantly higher than those of DEB-TACE. The frequency of AEs (all grades), including pyrexia, malaise, increased serum total bilirubin (T-Bil) and increased serum alanine transaminase (ALT), was significantly higher in the cTACE group than in the DEB-TACE group. **Conclusions:** Selective cTACE appeared to have greater efficacy for local tumor control as compared to selective DEB-TACE, however, the frequencies of post-embolization syndromes were higher in the cTACE group than in the DEB-TACE group. Clinical trial information: UMIN000021250. Research Sponsor: National Cancer Center Research and Development Fund (26-A-27).

	DEB-TACE N = 99	cTACE N = 101	*p*-value
CR rate at 3 months	27.6%	75.2%	< 0.0001
CR rate at 1 month	35.7%	84.2%	< 0.0001

A phase Ib study of lenvatinib (LEN) plus pembrolizumab (PEMBRO) in unresectable hepatocellular carcinoma (uHCC). *First Author: Andrew X. Zhu, Massachusetts General Hospital Cancer Center and Jiahui International Cancer Center, Boston, MA*

Background: LEN is a multikinase inhibitor of VEGFR 1–3, FGFR 1–4, PDGFRα, RET, and KIT, approved for first line (1L) treatment of uHCC. PEMBRO, an anti-PD-1 monoclonal antibody, was granted accelerated approval for the treatment of patients (pts) with HCC after sorafenib therapy. We assessed the safety and efficacy of LEN + PEMBRO in uHCC. **Methods:** In this phase 1b trial (NCT03006926), pts received LEN 12 mg/day (bodyweight [BW] ≥60 kg) or 8 mg/day (BW <60 kg) orally + PEMBRO 200 mg IV on Day 1 of a 21-day cycle. Primary endpoints were safety and tolerability for Part 1 and objective response rate (ORR) and duration of response (DOR) by mRECIST and RECIST v1.1 per independent imaging review (IIR) in the 1L setting for Part 2. **Results:** 104 pts (part 1, n=6; part 2, n=98) were enrolled. No DLTs were reported in Part 1; 100 pts were included in the 1L analysis of LEN + PEMBRO–4 pts (part 1) excluded due to prior sorafenib. At data cutoff (October 31, 2019) and median follow-up of 10.6 months, 37 pts continued treatment (LEN only, n=3; both drugs, n=34); median duration of treatment was 7.9 months (LEN, 7.6 months; PEMBRO, 7.4 months). Median OS was 22.0 months (95% CI 20.4–not estimable [NE]), median PFS was 8.6 months (95% CI 7.1–9.7), and ORR was 36% (95% CI 26.6–46.2) (RECIST v1.1 per IIR). Additional efficacy outcomes are shown in the table. Treatment-emergent adverse events (TEAEs) occurred in 99% of pts (grade ≥3, 85%; grade ≥4, 23%). The most common grade ≥3 TEAE was hypertension (18% of pts). Treatment-related AEs (TRAEs) occurred in 95% of pts (grade ≥3, 67%; grade ≥4, 4%). The most common grade ≥3 TRAE was hypertension (17% of pts). 36% of pts had serious TRAEs and 3 pts died from a TRAE (acute respiratory failure/acute respiratory distress syndrome, n=1; intestinal perforation, n=1; abnormal hepatic function, n=1). **Conclusions:** LEN + PEMBRO has promising antitumor activity with a tolerable safety profile. An ongoing phase 3 trial (NCT03713593) is assessing LEN + PEMBRO vs LEN alone as 1L therapy for uHCC. Clinical trial information: NCT03006926. Research Sponsor: This study was sponsored by Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co. Inc., Kenilworth, NJ, USA.

Phase II study assessing tolerability, efficacy, and biomarkers for durvalumab (D) ± tremelimumab (T) and gemcitabine/cisplatin (GemCis) in chemonaïve advanced biliary tract cancer (aBTC). *First Author: Do-Youn Oh, Seoul National University Hospital, Seoul, South Korea*

Background: In aBTC, GemCis is the standard of care as 1st-line treatment. Immunotherapies have shown early promising efficacy in some BTC patients (pts). We assessed D (anti-PD-L1) ± T (anti-CTLA-4) and GemCis in 1L BTC pts, including an extensive biomarker analysis (NCT03046862). **Methods:** Pts were first enrolled in the biomarker cohort (BMC) to receive 1 cycle of Gem 1000 mg/m^2 + Cis 25 mg/m^2 on D1 & D8, followed by GemCis + D 1120 mg and T 75 mg, Q3W until disease progression (PD). Subsequent pts were allocated to GemCis + D (3 combo cohort [3C]) or GemCis + D+T (4 combo cohort [4C]) until PD. In all cohorts, tumor biopsies were obtained pretreatment, after 1 cycle, and at PD. Blood samples for ctDNA were obtained every cycle. **Results:** 121 pts were enrolled. Median follow-up durations were 28.5 months (m; 95% CI, 26.5-30.5), 11.3 m (95% CI, 9.1-13.5), and 11.9m (95% CI, 8.4-15.4) in the BMC, 3C, and 4C arms, respectively. Efficacy data are shown (Table). The most common adverse events (AEs, any grade) were neutropenia (54.5%), nausea (59.5%), and pruritus (55.44%). The most common grade 3/4 AEs were neutropenia (50.4%), anemia (35.5%), and thrombocytopenia (16.5%). In the BMC cohort, frequent mutations were found in DNA damage repair, cell cycle regulation, and genome instability genes (eg, *ATM*, *BRCA2*, *POLE*, *MSH2*, *CDKN2A*). Distinct somatic variants were detected in responders vs non-responders. Baseline tissue TMB did not correlate with PFS or OS. Reductions in ctDNA variant allele frequency (VAF) were more prominent among responders during early D+T cycles. ctDNA VAF on C3, D1 was significantly correlated with ORR (P< 0.015). Pretreatment PD-L1 expression was not associated with efficacy, but PD-L1 expression after 1st GemCis cycle trended with improved PFS. **Conclusions:** These are the first clinical data of D±T plus chemotherapy in chemo-naïve aBTC pts. The addition of immunotherapy to chemotherapy was tolerable and showed very promising efficacy. Biomarker analyses show early signs of markers associated with response. The combination of GemCis + D is being investigated in the Phase 3 TOPAZ-1 trial (NCT03875235). Clinical trial information: NCT03046862. Research Sponsor: AstraZeneca.

Neoadjuvant chemotherapy plus surgery for high-risk advanced gastric cancer: Long-term results of KDOG1001 trial. *First Author: Kei Hosoda, Department of Upper Gastrointestinal Surgery, Kitasato University School of Medicine, Sagamihara, Japan*

Background: In the phase 2, open-label, KDOG1001 (UMIN000003642) study, neoadjuvant chemotherapy (NAC) with docetaxel, cisplatin, and S-1 (DCS), followed by gastrectomy with D2 lymph node dissection for high-risk advanced gastric cancer showed feasibility of DCS therapy with an enough R0 resection rate of 90%. Here we present long-term results after a minimum follow-up of 3 years. **Methods:** Patients with bulky node metastasis (bulky N), linitis plastica (type 4), or large ulcero-invasive-type tumors (type 3) received up to four 28-day cycles of DCS neoadjuvant chemotherapy (docetaxel at 40 mg/m^2, cisplatin at 60 mg/m^2 on day 1, and S-1 at 40 mg/m^2 twice daily for 2 weeks) followed by gastrectomy with D2 lymphadenectomy. This analysis presents the final preplanned assessment of outcomes after 3 years. Primary endpoint was R0 resection rate. Secondary endpoints included overall survival (OS), progression free survival (PFS), completion rate of the protocol treatment, and pathological response rate (pRR) of DCS NAC. **Results:** Of 40 patients enrolled from May 2010 through January 2017, 7 (17.5%) had bulky N, 18 (45.0%) had type 4, and 16 (40%) had large type 3 with 1 (2.5%) having both large type 3 and bulky N2. All included patients underwent preoperative DCS chemotherapy followed by surgery with D2 lymphadenectomy with 32 (80%) completed postoperative S-1 therapy for 1 year. After a median follow-up for surviving patients of 67 mo (range, 36 mo to 110 mo) at the last follow-up in January 2020, 3-year OS was 78% [95% confidence interval (CI) 62–88%], while 3-year PFS was 63% (95% CI 47–76%). Completion rate of the protocol treatment was 62.5% (25/40) with pRR of 57.5% (23/40). In bulky N2, 3-y OS was 86% and 3-y PFS was 71% with pRR of 100%. In type 4, 3-y OS was 67% and 3-y PFS was 50% with pRR of 44%. In large type 3, 3-y OS was 88% and 3-y PFS was 75% with pRR of 56%. Patients with type 4 had significantly worse OS and PFS than those with the other types [HR 7.20 (95% CI 2.23–32.21) and HR 3.00 (95% CI 1.21–8.19)]. **Conclusions:** Preoperative chemotherapy with up to four cycles of DCS followed by gastrectomy plus adjuvant S-1 therapy is a promising treatment strategy for patients with bulky node metastasis, type 4 and large type 3 gastric cancers. For type 4 cancer, further improvement of treatment strategy is needed. Clinical trial information: 000003642. Research Sponsor: None.

4522 Poster Session (Board #130), Fri, 8:00 AM-11:00 AM

A phase II study of rh-endostatin combined with paclitaxel and nedaplatin in treating patients with recurrent or metastatic esophageal squamous cell carcinoma (ESCC). *First Author: Zhiqiang Wang, Department of Medical Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, China*

Background: For patients (pts) with metastatic ESCC, the prognosis is poor. Rh-endostatin (endostar), a potent inhibitor of angiogenesis, has shown clinical activity when combined with chemoradiotherapy in treating locally advanced ESCC. This single-arm phase 2 study was designed to assess the efficacy and safety of endostar combined with paclitaxel and nedaplatin in treating pts with recurrent or metastatic ESCC. **Methods:** Eligible pts had recurrent or metastatic ESCC and Karnofsky score ≥70. Endostar (30 mg/day, continuous infusion, day 1-14) plus paclitaxel (150 mg/m^2, day 4) and nedaplatin (80 mg/m^2, day 4) were administered every 3 weeks for 6 cycles followed by maintenance therapy with endostar. Primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS) and adverse events (AEs). **Results:** From January 2015 to August 2019, 53 pts were enrolled. 44 (83%) pts were male. The median age was 59 years. 43 (81%) pts had pathology of poor or moderate differentiated ESCC. The middle and lower thirds of the esophagus (81%) were the most common primary tumor sites. 11 (21%) patients had undergone esophagectomy. At the time of treatment, 49 (93%) pts were diagnosed with clinical stage IVB. The most common metastatic sites were lymph node (91%), lung (32%) and liver (26%). 50 pts were assessable for response. No complete response was observed. 21 pts achieved a best response of partial response and 14 pts had stable disease. ORR was 42% and DCR was 70%. The median PFS and OS was 5.1 months (95% CI 3.7-6.6 months) and 13.2 months (95% CI 8.0-18.4 months) respectively. The most common AEs observed during this study were anemia (49.1%), neutropenia (34%), fatigue (28.3%) and anorexia (26.4%). The most common Grade 3/4 AE observed was neutropenia (17%). **Conclusions:** The combination of endostar plus paclitaxel and nedaplatin is a well tolerated treatment modality with promising activity in previously untreated recurrent or metastatic ESCC. Its efficacy and safety could be further studied in randomized trials. Clinical trial information: NCT02350517. Research Sponsor: Simcere.

4523 Poster Session (Board #131), Fri, 8:00 AM-11:00 AM

Pembrolizumab (pembro) versus standard of care chemotherapy (chemo) in patients with advanced gastric or gastroesophageal junction adenocarcinoma: Asian subgroup analysis of KEYNOTE-062. *First Author: Hironaga Satake, Kobe City Medical Center General Hospital, Kobe City, Japan*

Background: First-line treatment with pembro or pembro + chemo vs chemo alone was evaluated in patients with PD-L1 combined positive score (CPS) ≥1, HER2-negative advanced gastric cancer in the randomized, active-controlled, phase 3 KEYNOTE-062 study (NCT02494583). We present results from the Asian subpopulation receiving pembro monotherapy or chemo. **Methods:** Eligible patients were randomly assigned 1:1:1 to pembro 200 mg, pembro + chemo (cisplatin + 5-FU or capecitabine), or placebo + chemo every 3 weeks for ≤35 cycles (~2 years). Randomization was stratified by region, disease status, and fluoropyrimidine treatment. Primary end points for this analysis were overall survival (OS) in patients with CPS ≥1 and patients with CPS ≥10; progression-free survival (PFS) and objective response rate (ORR) were exploratory end points. Data cutoff was March 26, 2019. **Results:** Globally, 256 patients received pembro monotherapy and 250 received chemo. Pembro was noninferior to chemo for OS in CPS ≥1 per prespecified margins (median OS, 10.6 vs 11.1 months, respectively; HR [99.2% CI], 0.91 [0.69-1.18]). In the Asian population 62 patients received pembro and 61 received chemo; 26 and 22 had CPS ≥10 (Table). Compared with the global population, Asian patients had a higher proportion of ECOG performance status 0, more diagnoses of stomach cancer, and a greater proportion with 0-2 metastatic sites. Median OS was longer with pembro than chemo using both CPS cutoffs (HR [95% CI]: CPS ≥1, 0.54 [0.35-0.82]; CPS ≥10, 0.43 [0.21-0.89]); 12- and 24-month OS rates were higher for pembro using both CPS cutoffs (12-month OS: CPS ≥1, 69% vs 54%; CPS ≥10, 81% vs 68%; 24-month OS: CPS ≥1, 45% vs 23%; CPS ≥10, 54% vs 27%). The HR (95% CI) for PFS was 1.11 (0.76-1.64) for CPS ≥1 and 0.71 (0.36-1.39) for CPS ≥10. **Conclusions:** In Asian patients with advanced gastric cancer, OS favored pembro in patients with CPS ≥1 and CPS ≥10. Clinical trial information: NCT02494583. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4524 Poster Session (Board #132), Fri, 8:00 AM-11:00 AM

HX008, an anti-PD1 antibody, plus irinotecan as second-line treatment for advanced gastric adenocarcinoma: A phase II clinical trial. *First Author: Yan Song, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Patients with advanced gastric or gastro-oesophageal junction cancer that progresses on chemotherapy have poor outcomes. We investigated HX008, an Anti-PD1 Antibody, with irinotecan in patients with advanced gastric or gastro-oesophageal junction cancer that progressed on first-line chemotherapy with a platinum and/or fluoropyrimidine. **Methods:** This study is a multicenter, open, phase II clinical study of recombinant humanized anti-pd-1 monoclonal antibody HX008 injection plus Irinotecan that was conducted at 11 hospitals in China. Eligible patients are adults with histologically confirmed advanced gastric or gastro-oesophageal junction cancer. Subjects participating in this study are required to submit a archived tumor tissue specimen or newly obtained biopsy of tumor lesions at the site of no previous radiotherapy and peripheral blood (2mL) for detection of PD-L1 and MSI/MMR expression. The samples will be tested for expression of PD-L1 and MMR by immunohistochemistry (IHC) in the central laboratory, and MSI levels will be determined by polymerase chain reaction (PCR) and gel electrophoresis. Subjects received PD-1 monoclonal antibody HX008 at 200mg (d1, intravenous drip, once every 3 weeks) plus irinotecan at 160mg/m2 (d1, intravenous drip, 60 ~ 120min, once every 2 weeks). Response was assessed every 6 weeks in accordance with Response Evaluation Criteria in Solid Tumors version 1.1. Primary endpoints was objective remission rate (ORR). **Results:** Between October 2018 and September 2019, a total of 58 patients with advanced gastric or gastro-oesophageal junction cancer were enrolled in this study. Median (range) age was 61 (27-71) years, and most patients were male (72.4%). Among 53 patients who were evaluated, 15 (28.3%) experienced objective response and 22 (41.5%) experienced stable disease (SD). The median progression free survival (PFS) was 5.4 months, the one-year survival rate was 71.3%. The most common treatment-related adverse events of grade 3 or 4 included neutropenia(31.0%), anemia(15.5%), loss of appetite (6.9%), vomiting(5.2%), nausea(3.4%), diarrhea (1.7%) and fatigue (1.7%). There were no treatment-related deaths. **Conclusions:** HX008 injection plus Irinotecan demonstrated promising activity and manageable safety in patients with advanced gastric or gastro-oesophageal junction cancer that progressed on first-line chemotherapy with a platinum and fluoropyrimidine. Clinical trial information: NCT03704246. Research Sponsor: None.

4525 Poster Session (Board #133), Fri, 8:00 AM-11:00 AM

A phase Ib study of nivolumab plus trastuzumab with S-1/capecitabine plus oxaliplatin for HER2-positive advanced gastric cancer (Ni-HIGH study): Safety evaluation. *First Author: Daisuke Takahari, Department of Gastroenterology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Addition of an anti-PD-1 antibody to trastuzumab (Tmab) reportedly enhances ADCC activity of Tmab, leading to an additive antitumor effect. We investigated the safety and tolerability of nivolumab (Nivo) plus Tmab combined with S-1 or capecitabine (Cape) and oxaliplatin (Ox) for pts with HER2-positive (+) advanced gastric cancer (AGC). Here, we report the safety evaluation results. **Methods:** This open-label, phase 1b study was conducted at four centers in Japan. The study consisted of safety (n = 12) and expansion (n = 24–30) parts. Chemotherapy-naïve pts aged ≥ 20 years with histopathologically confirmed HER2+ AGC and measurable lesions were eligible. In the safety evaluation, pts were assigned to cohort 1 or 2 in sequence. Pts received Nivo (360 mg, day 1), Tmab (course 1: 8 mg/kg; course 2–: 6 mg/kg, day 1), Ox (130 mg/m^2, day 1) and either S-1 (40 mg/m^2 bid, days 1–14; cohort 1) or Cape (1000 mg/m^2 bid, days 1–14; cohort 2) every 3 weeks until disease progression or unacceptable toxicity. The primary purpose of the safety evaluation was to determine the toxicity and tolerability of this combination therapy. An independent data and safety monitoring committee assessed the tolerability of the study treatments before starting the second treatment course. A preliminary evaluation of tumor response on the cut-off date (December 16, 2019) was also performed. **Results:** From November 2018 to August 2019, 12 pts with HER2+ AGC were enrolled in the safety part (six pts each in cohorts 1 and 2). During the 1st course, all 12 pts experienced at least one adverse event (AE). The most common AEs were peripheral sensory neuropathy (PSN) (n = 4) and leukocytopenia (n = 3) in cohort 1 and PSN (n = 5) and anorexia (n = 4) in cohort 2. AEs of grade ≥ 3 were observed in only one pt in cohort 1 (grade 3 neutropenia). No pt suspended or discontinued study treatments due to AEs. One pt in cohort 1 reduced dose of S-1 due to grade 2 erythema and continued the subsequent courses with the dose. After a median follow-up of 6.1 (range, 3.1–13.3) months, one pt from cohort 1 achieved a complete response, eight pts (four in each cohort) achieved a partial response, and three pts (one in cohort 1 and two in cohort 2) showed stable disease. No progressive disease was observed. **Conclusions:** Both Nivo plus Tmab and either S-1 or Cape plus Ox are tolerable in pts with HER2+ AGC. Both cohorts 1 and 2 have progressed to the expansion part of the study. Clinical trial information: 000034222. Research Sponsor: ONO pharmaceutical co.

4526 Poster Session (Board #134), Fri, 8:00 AM-11:00 AM

Assessment of FcgRIIIA single nucleotide polymorphisms (SNPs) on the efficacy of IgG1 monoclonal antibodies (mAbs) in PANGEA study patients (pts) with advanced gastroesophageal adenocarcinoma (aGEA). *First Author: Anthony Serritella, University of Chicago Medical Center, Chicago, IL*

Background: Targeted therapies (Ttx) have had limited efficacy in aGEA. The phase IIa PANGEA trial assessed the outcomes of pts treated with IgG1 mAbs targeting receptor tyrosine kinases (RTKs) or PD-1 based on predefined molecular groups. The fragment C (Fc) portion of mAbs binds to IgG receptors (FcgR) of immunologic effector cells such as natural killer (NK) cells, leading to antibody-dependent cell-mediated cytotoxicity (ADCC). The FcgR subclass, FcgRIIIA, has genetic variants with different Fc binding affinities. A single nucleotide polymorphism (SNP) in FcgRIIIA substitutes phenylalanine (F) with valine (V) at amino acid position 158, enhancing FcgR's affinity for the IgG1 Fc domain. Pts with V/V or V/F FcgRIIIA allotypes have enhanced NK cell binding affinity compared to the homozygous F/F allotype. We evaluated the association of FcgRIIIA SNPs on Ttx outcomes amongst PANGEA pts and another cohort of aGEA pts treated with IgG1 mAbs. **Methods:** Whole-blood samples were identified from aGEA pts (N = 104), including 70/80 available PANGEA pts, who were treated with an IgG1 mAb (trastuzumab 24, anti-EGFR 21, anti-PD1 30, ramucirumab 48) in at least 1 Ttx line. After lymphocyte DNA extraction, FcgRIIIA genotyping was performed. The Cox proportional hazard model and log-rank tests, adjusted for pt age, were used to assess for an association of genotype with overall survival (OS). **Results:** Of 104 genotyped pts, the F/F, F/V & V/V genotypes were observed at a frequency of 32%, 51% and 17% respectively. There was no significant difference in median OS (mOS) between the F/F, F/V or V/V or comparing F/F vs V/F+V/V overall, nor in the PANGEA-only cohort. A trend of increased mOS was seen in 20 non-PANGEA pts harboring F/V or V/V compared to 14 F/F pts (mOS 43.4 vs 23.1 months, HR 0.41 [0.15-1.14] p = 0.09). However, 3-year OS rates trended higher in V/F+V/V pts (22%, 16/71) compared to F/F pts (7%, 2/33) (p = 0.09). At 3 years, 50% of V/V+V/F non-PANGEA pts were alive versus 13% of F/F pts (p = 0.04), while 13% of V/V+V/F PANGEA pts were alive versus 0% of F/F pts (p = 0.32). **Conclusions:** Amongst pts receiving IgG1 mAbs, the high affinity V FcgRIIIA SNP enriched for a subgroup of 'extreme responders' alive 3 years from diagnosis. Multivariate analyses accounting for baseline characteristics in a larger number of pts are ongoing to further elucidate the role of FcgRIIIA SNPs as predictive biomarkers. These findings may have implications on IgG1 mAb ADCC optimization. 4527 Poster Session (Board #135), Fri, 8:00 AM-11:00 AM

Tumor response and growth rate of nivolumab treatment in advanced gastric cancer: Real-world data from a large observational/translational study, JACCRO GC-08 (deliver trial). *First Author: Ryohei Kawabata, Department of Surgery, Osaka Prefectual General Medical Center, Osaka, Japan*

Background: Nivolumab (Nivo) demonstrated survival benefit in previously treated gastric cancer (GC) patients (pts), with a response rate (RR) of 11% and a disease control rate (DCR) of 40% (Kang YK, et al. *Lancet* 2017). There are few real-world data of Nivo and its predictive markers are needed in GC. It has been demonstrated that some tumors grow rapidly after Nivo treatment, but the proportion is uncertain. **Methods:** DELIVER trial was a prospective, multicenter, observational/translational study which assessed pts with advanced GC treated with Nivo alone and ECOG Performance Status (PS) 0-2 (UMIN000030850). The aims were to evaluate the efficacy and safety of Nivo in real world, and to discover novel host-related immune-biomarkers (gut microbiome, genetic polymorphism, gene expression, and metabolome) using fecal and blood samples which were collected before and after Nivo treatment. The RR, DCR, progression-free survival, overall survival, and tumor growth rate (TGR) were estimated as the efficacy. The response was evaluated by first imaging based on RECIST version 1.1. The TGR was calculated as a percentage increase in tumor volume during 1 month (Champiat et al. *Clin Cancer Res* 2017). **Results:** A total of 501 pts was enrolled in this study from Mar 2018 to Aug 2019, and 487 pts were evaluable for analysis (median age 70-y, 71% male, ECOG PS0/1/2 42%/44%/14%, tub/por/sig 45%/41%/5%, 21% HER2-pos, 42% pts with ascites). The DCR was 39.2% (95%CI 34.9-43.7) in evaluable pts. In 282 pts with measurable lesions, the RR was 6.7% (95%CI 4.1-10.3) and DCR was 36.5%. Sub-analysis by patient background indicated that DCR was 41% for PS0, 42% for PS1, and 24% for PS2. In addition, the DCR was lower in pts with ascites compared to those without ascites (28.6% vs. 47.0%, p= 0.005). The TGR decreased after introduction of Nivo in 124 (56.6%) of 219 evaluable pts for TGR; however, 20.5% pts were identified as experiencing hyper-progressive disease (HPD) which was defined as a ≥2-fold increase of the TGR before and after Nivo. When defining HPD as a ≥2-fold increase of tumor growth kinetics ratio and 50% increase of tumor burden, 9.6% pts experienced it. **Conclusions:** The real-word data of the large observational trial showed a comparable DCR to that of clinical trial in advanced GC treated with Nivo. This trial revealed the tumor behavior and some pts who experienced rapid tumor growth after Nivo treatment in clinical practice; biomarkers for HPD and the definition should be established. Clinical trial information: UMIN000030850. Research Sponsor: Ono Pharmaceutical and Bristol-Myers Squibb.

4528 Poster Session (Board #136), Fri, 8:00 AM-11:00 AM

Evaluation of spatiotemporal heterogeneity of PDL1 expression in gastroesophageal adenocarcinoma (GEA) at baseline diagnosis and after chemotherapy. *First Author: Katherine I. Zhou, University of Chicago, Chicago, IL*

Background: PDL1 expression is a predictive marker for response to anti-PD1/PDL1 agents (IO) for GEA. As a prognostic biomarker, data are conflicting. Molecular heterogeneity of various biomarkers for GEA has been established. To characterize heterogeneity of PDL1 expression and its clinical relevance, we compared PDL1 expression in primary (1^O) and metastatic (met) tumors of newly diagnosed stage IV advanced GEA (aGEA), and before and after chemotherapy treatment (tx) for stage II–IV GEA. We assessed the prognostic relevance of PDL1 expression in aGEA. **Methods:** We retrospectively reviewed a cohort of 130 patients (pts) diagnosed with GEA in 2013–2019, with a total of 328 tumor samples with PDL1 expression data. PDL1 was defined as positive if combined positive score (CPS) was ≥1 using the 22C3 pharmDx assay. Analysis was performed by McNemar's test for paired PDL1 and univariate Cox proportional-hazards model for overall survival (OS). **Results:** Of 328 tumors, 45% were PDL1+ and 55% PDL1-. CPS ranged 0–100 (median 1, IQR 0–5), and CPS was ≥10 for 19% of tumors. Concordance between PDL1 status of paired baseline 1^O and baseline met tumors was 63% (32/51) (Table). Of 31 PDL1+ baseline 1^O tumors, 52% (16/31) had PDL1- paired baseline met tumors, while of 20 PDL1- baseline 1^O tumors, only 15% (3/20) had PDL1+ paired baseline met tumors. Only 35% (18/51) of met tumors were PDL1+, compared to 61% (31/51) PDL1+ 1^O tumors ($p<$ 0.003). Post-tx tumors exhibited 62% (46/74) concordance of PDL1 status compared to pre-tx 1^O tumors. Of 43 PDL1+ baseline tumors, 35% (15/43) were PDL1- post-tx; of 31 PDL1- baseline tumors, 42% (13/31) were PDL1+ post-tx (p= 0.71). In pts with aGEA at diagnosis, OS did not significantly differ depending on baseline 1^O tumor PDL1 status (median OS of 17.9 [95% CI 14.6–26.5] months for PDL1- and 16.7 [12.0–26.3] months for PDL1+; p= 0.6), nor depending on baseline met PDL1 status. **Conclusions:** PDL1 expression demonstrated notable baseline discordance between 1^O and met tumors, particularly directional from PDL1+ 1^O tumor to PDL1- met. Discordance before and after chemotherapy was also observed, but with similar proportions of PDL1+ pre-tx and post-tx tumors. These findings may have predictive IO therapeutic implications if confirmed in larger independent analyses. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

	Baseline met PDL1-	Baseline met PDL1+	Post-tx PDL1-	Post-tx PDL1+
Baseline 1^O PDL1-	17	3	18	13
Baseline 1^O PDL1+	16	15	15	28

4529 Poster Session (Board #137), Fri, 8:00 AM-11:00 AM

Phase II study of intraperitoneal paclitaxel combined with S-1 plus cisplatin for gastric cancer with peritoneal metastasis: SP + IP PTX trial. *First Author: Daisuke Kobayashi, Department of Gastroenterological Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: Intraperitoneal (IP) chemotherapy is a promising treatment option for gastric cancer with peritoneal metastasis. Although a phase III study failed to show a statistically significant superiority of IP paclitaxel (PTX) combined with S-1 and intravenous PTX over S-1/cisplatin (SP), the standard of care as a first-line treatment in Japan, the sensitivity analysis suggested clinical efficacy of the IP PTX. Thus, attempts to combine IP PTX with other systemic therapies with higher efficacy have been warranted. After a dose-finding study, we sought to explore efficacy of a new regimen that combined IP PTX with SP. **Methods:** Gastric cancer patients with peritoneal metastasis confirmed by diagnostic imaging, laparoscopy or laparotomy were enrolled in the phase II multi-institutional prospective trial. In addition to the established SP regimen (S-1 administered orally at a dose of 80 mg/m^2 bid for 21 days followed by a 14-day rest and cisplatin administered intravenously at a dose of 60 mg/m^2 on day 8), IP PTX was administered on days 1, 8 and 22 at a dose of 20 mg/m^2. The primary endpoint is overall survival (OS) rate at one year after treatment initiation. Secondary endpoints are progression free survival (PFS), response rate and toxicity. **Results:** Fifty-three patients were enrolled and fully evaluated for OS and toxicity. The median number of courses was 7 (range 1-20). The 1-year OS rate was 74% (95% CI, 60-83%). The median survival time was 19.4 months (95% CI, 16.7 months-). The 1-year PFS rate was 57% (95% CI, 42-69%). The overall response rate was 20% (95% CI, 1-72%) in 5 patients with target lesions. Cancer cells ceased to be detected by peritoneal cytology in 23 (64%) of 36 patients. Fourteen (26%) patients underwent gastrectomy after response to chemotherapy. The incidences of grade 3/4 hematological and non-hematological toxicities were 43% and 47%, respectively. The frequent grade 3/4 toxicities included neutropenia (23%), anemia (29%), diarrhea (13%) and anorexia (17%). Intraperitoneal catheter and implanted port-related complications were observed in 4 patients. There was 1 treatment-related death. **Conclusions:** IP PTX combined with SP is well tolerated and active in gastric cancer patients with peritoneal metastasis. Clinical trial information: UMIN000023000. Research Sponsor: Japan Society of Clinical Oncology.

4530 Poster Session (Board #138), Fri, 8:00 AM-11:00 AM

Gastric inflammatory prognostic index (GIPI) to predict efficacy of PD-1/PD-L1 immune checkpoint inhibitors in metastatic gastroesophageal junction (GOJ)/gastric cancer (GC) patients. *First Author: Cristina Morelli, Tor Vergata University Hospital, Rome, Italy*

Background: ICIs demonstrated improved overall survival (OS) in heavily pretreated mGOJ/GC pts. Pts selection exclusively based on PD-L1 tissue expression appears to be suboptimal, despite data from subgroup analyses of KEYNOTE trials. Strong rationale suggests a potential predictive role of inflammatory biomarkers in ICIs treated mGOJ/GC pts. **Methods:** Ten systemic inflammatory markers [platelets, monocytes, neutrophil/lymphocyte ratio (NLR), platelets-lymphocyte ratio, lymphocytes, sum of mononuclear cells, albumin, lactate dehydrogenase, c-reactive protein (CRP) and serum globulin] were retrospectively analyzed at baseline in 57 mGOJ/GC pts with unknown PD-L1 status treated in second-line with ICIs, and correlated with OS. Least Absolute Shrinkage and Selection Operator (LASSO) method was used to select variables (preliminarily subject to optimal coding using HR smoothed curves for OS) with the highest prognostic value. Selected variables were then analyzed in a multivariate Cox Regression Model and used to build a GIPI nomogram. **Results:** NLR and CRP taken as continuous variables and albumin categorized as $<$ vs $>$ 30 g/dL were found as the most meaningful independent predictors of OS and used to build the GIPI nomogram. Nomogram-based lowest (l), mid-low, mid-high and highest (h) risk quartiles were associated with median(m)OS of 14.9, 7.1, 5.6 and 2.1 months (mos), respectively [HR of l vs h 4.94, p 0.0002]. By optimally dichotomizing CRP and NLR, pts with one or more of the following risk factors: NLR $>$6, CRP $>$15 mg/L, albumin $<$30 g/dL (n: 29) had a mOS of 3.9 mos vs 14.2 mos of pts with no risk factor (n: 28) (HR 2.48, p 0.001). **Conclusions:** GIPI, combining NLR, CRP and Albumin, is the first inflammatory index with a significant prognostic value in mOGJ/GC pts receiving second-line ICIs. Its implementation in correlation with PD-L1 expression in the present cohort is ongoing. GIPI merits validation in independent cohorts and prospective clinical trials. Research Sponsor: None.

4531 Poster Session (Board #139), Fri, 8:00 AM-11:00 AM

X versus XELOX versus PF in definitive concurrent chemoradiotherapy (DCRT) for local advanced squamous esophageal cancer (ESCC): Update from a multicenter, open-label, randomized III trial, CRTCOESC trial. *First Author: Ruinuo Jia, Henan Key Laboratory of Cancer Epigenetics, Cancer Hospital, The First Affiliated Hospital, College of Clinical Medicine, Medical College of Henan University of Science and Technology, Luoyang, China*

Background: PF (5-fluorouracil plus cisplatin) is the standard regimen for local advanced ESCC with DCRT. CRTCOESC aims to evaluate the effect and safety of X (capecitabine) regimen versus XELOX (capecitabine plus oxaliplatin) and PF in Chinese local advanced ESCC with DCRT by randomized, open-label, multicenter designed. **Methods:** Patients with ESCC (T2-4N0-2M0) were randomized to 3 groups as X (capecitabine 625mg/m^2, bid d1-5, 6 weeks), XELOX (oxaliplatin : 65mg/m^2 , d1 , 8 , 22, 29; capecitabine: 625mg/m^2, bid d1-5; 6 weeks), or PF (cisplatin: 75mg/m^2 d1 , 29, 5-Fu : 750mg/m^2 CIV24h d1-4 , d29-32), Intensity Modulated Radiation Therapy (IMRT) was delivered by 50Gy/2Gy currently. In addition, quadratic randomize were done within all groups to decide whether 2 cycles chemotherapy adding or not after DCRT. 2-year OS and Grade 3-5 AEs were the primary endpoints, 2-year PFS and short-term efficacy (STE) as rates of CR and ORR (CR+PR+SD) (confirmed by gastroscopy biopsy at 16 weeks) were the secondary endpoints. **Results:** 244 pts successfully were accrued from 13 centers during 2014.10-2020.1. 209 pts were finished DCRT and 193 were evaluated STE at 16 weeks. 192 and 147 pts were followed up for 1- and 2- years respectively. There were no differences between 3 groups on patients' baseline characters including age, gender, ECGO score, clinical stage, pathology grade and smoking. In X, XELOX and PF groups, the 2-year OS were 63.8% (30/46), 61.5% (32/52) and 62.5% (30/49) (P = 0.973), the median OS were 39.7 (6.567), 40 (5.195) and 34 (5.736) (months, P = 0.703); the incidences of AEs (grade 3-5) were 26.5% (18/68), 33.8% (25/74) and 49.3% (33/67) (P = 0.0193); the 2-year PFS were 54.3% (25/46), 53.8% (28/52) and 51% (25/49) (P = 0.939), the median PFS were 29.06 (6.124), 17.4 (8.745) and 24.833 (6.777) (months, P = 0.811); the CR rate were 43.8% (28/64), 41.4% (29/70), and 42.4% (25/59) (P = 0.964), and the ORR were 85.6%, 88.6%, and 96.6% (P = 0.119), respectively. There were no differences on OS, PFS and rates of CR and ORR between 3 groups but the incidence of AEs in X group was the lowest significantly. Subgroup analysis results shown adding 2 cycles chemotherapy after CRT had both OS and PFS advantages but lacked statistically significance. **Conclusions:** Compared with PF, DCRT with X or XELOX shown lower incidence of AEs and similar OS, PFS and STE. X regimen carried out the lowest AEs incidence. Adding 2 cycles chemotherapy after DCRT seemly had advantages on OS and PFS. Clinical trial information: NCT02025036. Research Sponsor: National Natural Science Foundation of China.

4532 Poster Session (Board #140), Fri, 8:00 AM-11:00 AM

Final results of a phase II trial of first-line FOLFIRINOX for advanced gastroesophageal cancers. *First Author: Ramon Jin, Washington University School of Medicine, St. Louis, MO*

Background: Standard first-line regimens for patients with metastatic gastroesophageal adenocarcinomas have moderate clinical benefit with objective response rates (ORR) of approximately 40-50%. FOLFIRINOX has been shown to be an effective and well-tolerated first line therapy in other GI cancers. In this open-label, single-arm phase II study of patients with advanced gastroesophageal adenocarcinomas, we sought to evaluate the safety and clinical activity of FOLFIRINOX. **Methods:** The primary endpoint was ORR, and secondary endpoints included safety profile, progression free survival (PFS), overall survival (OS), time to progression (TTP), clinical benefit rate (CBR), and duration of response. Estimated sample size included 41 patients with HER2 negative disease with 90% power to detect an ORR$\geq$60% with alpha of 0.10. No enrollment goal was planned for HER2 positive patients, but they were allowed participation to receive study treatment in combination with trastuzumab. Treatment consisted of 400mg/m2 5-FU bolus, 400 mg/m2 leucovorin, 2400 mg/m2 5-FU infusion over 46 hours, 180 mg/m2 irinotecan, and 85 mg/m2 oxaliplatin. Trastuzumab was administered intravenously as a 6 mg/kg loading dose then given 4 mg/kg every 14 days for HER2 positive patients. This trial is registered with ClinicalTrials.gov, NCT01928290. **Results:** From November 2013 to May 2019, 67 patients were enrolled, of which 26 (39%) had HER2 positive disease. Median follow-up was 16.1 months. ORR was 61% (25/41) for HER2 negative and 85% (22/26) for HER2 positive groups. Overall, one patient (2%) had a complete response, 36 patients (69%) had partial responses, and 13 patients (19%) had stable disease for $>$6 months; therefore, CBR was 96%. Median PFS was 11.9 months, median OS was 17.4 months. 41 patients (83.7%) had dose modification or treatment delay with the most common toxicities being neutropenia, diarrhea, peripheral sensory neuropathy, and nausea with no unexpected toxicities. **Conclusions:** FOLFIRINOX is a highly effective three-drug regimen for first-line treatment of advanced gastroesophageal cancer with expected, tolerable toxicities. Clinical trial information: NCT01928290. Research Sponsor: Washington University School of Medicine Internal Funding.

4533 Poster Session (Board #141), Fri, 8:00 AM-11:00 AM

Disease-free survival as a surrogate for overall survival in neoadjuvant trials of gastroesophageal adenocarcinoma: Pooled analysis of individual patient data from randomized controlled trials. *First Author: Ulrich Ronellenfitsch, University Hospital Halle (Saale), Department of Visceral, Vascular and Endocrine Surgery, Halle (Saale), Germany*

Background: Disease-free survival (DFS) is an appealing surrogate endpoint for overall survival (OS) in trials on neoadjuvant or adjuvant cancer therapy, because it is available faster and with less follow-up effort. The aim of this study was to assess if DFS can be a valid surrogate endpoint for OS when comparing neoadjuvant treatment followed by surgery to surgery alone for gastroesophageal adenocarcinoma. **Methods:** Individual patient data (IPD) from eight randomized controlled trials (n = 1,126 patients) which compared neoadjuvant therapy followed by surgery with surgery alone for gastroesophageal adenocarcinoma were used for the analysis. Correlation between OS-time and DFS-time was calculated. Kaplan-Meier survival curves and corresponding hazard ratios (HRs) for treatment effects were separately determined for each trial. Subsequently, HRs were pooled in a meta-analysis using a random-effects model. An error-in-variables linear regression model was used to compare observed and predicted values. The minimum treatment effect on DFS necessary to predict a non-zero treatment effect on OS was estimated by calculating the surrogate threshold effect. **Results:** OS-time correlated strongly with DFS-time. HRs for OS and DFS were highly similar for all single trials. The meta-analysis yielded almost identical overall HRs for treatment effects on OS and DFS. The determination coefficient for the association between HRs for OS and DFS was 0.912 (95% confidence interval 0.75-1.0), indicating a strong trial-level surrogacy between OS and DFS. The surrogate threshold effect was calculated at 0.79, indicating that a future trial yielding a hazard ratio for the treatment effect on DFS < 0.79 could be expected with a 95% probability to yield a hazard ratio for the treatment effect on OS < 1. **Conclusions:** DFS and OS strongly correlate both after neoadjuvant therapy followed by surgery and after surgery alone for gastroesophageal adenocarcinoma. Likewise, the treatment effects on the two endpoints are very similar. Consequently, DFS can be regarded an appropriate surrogate endpoint for OS in trials on neoadjuvant therapy for gastroesophageal adenocarcinoma. Research Sponsor: None.

4534 Poster Session (Board #142), Fri, 8:00 AM-11:00 AM

First-in-human phase I study of BVAC-B cell therapy in HER2-positive advanced gastric cancer. *First Author: Jii Bum Lee, Yonsei Cancer Center, Seoul City, South Korea*

Background: BVAC-B is an autologous B cell- and monocyte-based immunotherapeutic vaccine transfected with recombinant HER2/neu gene and loaded with alpha-galactosyl ceramide, a natural killer T cell ligand. It may have activity against HER2/neu positive cancer. Preclinical data in mouse models have shown promising anti-tumor activity by eliciting broad spectrum of immune responses against HER2/neu positive tumor cells. We report here the results of phase 1 study of BVAC-B in HER2 positive advanced gastric cancer. **Methods:** Metastatic gastric cancer with IHC $> 1+$ of HER2/neu were eligible for enrollment. Two weeks before treatment, subjects were admitted to hospital for collection of PBMC and plasma by lymphapheresis. The PBMC were sent to Cellid for vaccine manufacturing which took a day. BVAC-B was given intravenously at 0, 4, 8, and 12 weeks. Subjects received low (2.5X 10^7 cells/dose), medium (5.0X 10^7 cells/dose) or high dose (1.0X 10^8 cells/dose). Endpoints included safety, tolerability and MTD for phase 2 trial. Exploratory outcomes included immune responses after BVAC-B administration. **Results:** As of January 29, 2020, 8 subjects were treated with BVAC-B at doses of 2.5X 10^7 cells/dose (n=1), 5.0X 10^7 cells/dose (n=1) and 1.0X 10^8 cells/dose (n=6). Median line of therapy at which BVAC-B was administered was 4 (range, 2-9). Mean duration treatment was 1.8 (range 1-4) cycles. The most common treatment related adverse events were fever (n=4, 50%). One subject enrolled in medium dose experienced cytokine release syndrome (G2) with high fever (39.3℃) and hypotension 8 hours after first administration, but was manageable with hydration and supportive management. Other adverse events included increase of AST and ALT (G1, n=1 and G2, n=2), and hypotension (G1, n=1). There were no adverse events which led to treatment discontinuation. Immunologic response analysis showed that BVAC-B induced activation of natural killer T cells, natural killer cells, HER2/neu specific T cells, and release of HER2/neu specific antibody upon vaccinations in few patients who were evaluated. **Conclusions:** BVAC B is feasible and has acceptable toxicity profile. We considered all dose evaluated in this study available for phase 2 study, given that the maximum tolerated dose is expected to exceed the maximum dose administered in this study. For clinically relevant effect, further studies are warranted, including earlier line of exposure to BVAC-B as well as combination treatments. Clinical trial information: NCT03425773. Research Sponsor: Ministry of Trade, Industry & Energy (MOTIE), Korea Institute for Advancement of Technology (KIAT) through the Research and Business Development Program (No. N056300021).

4535 Poster Session (Board #143), Fri, 8:00 AM-11:00 AM

Personalized neoantigen/cancer testis antigen nanovaccine (PVAC) mobilize specific therapeutic immunity for high-risk resected gastric cancer. *First Author: Qin Liu, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: 35% of stage IIIB/C Gastric cancer patients will recurrent after D2 gastrectomy within one year. Mutation-derived epitopes (neoantigens) has been demonstrated to induce tumor cell specific immune responses controlling the tumor growth. Nanovaccine can increase antigen presentation efficiency and elicit potent antitumor T cell responses with robust therapeutic efficacy. We hypothesized that vaccination with neoantigens/cancer testis (CT) antigens could expand pre-existing and induce antigen-specific T-cells populations, favouring of tumor control enhancement. Here, we report the first-in-human application of this concept in gastric cancer. **Methods:** Patient-specific mutation-containing neoantigens were selected on the basis of tumour-specific mutations whole-exome sequencing (WES) and RNA sequencing. Cancer testis antigens were obtained according to immunohistochemical staining and HLA-binding affinity prediction. PVAC is an amphiphiles nanovaccine loaded with multiple personalized neoantigens/cancer testis antigens designed to induce antigen specific T cells and associated antitumor responses. PVAC will be administrated to stage IIIB/IIIC gastric carcinoma after six cycles of adjuvant chemotherapy (S-1/Oxaliplatin or S-1/docetaxel). Each patient received PVAC by subcutaneous injection on Days 1, 4, 8, 15, 22, 43, 64, 85, 169, administrated with the adjuvant montanide ISA 51 VG. Safety, immunogenicity and clinical efficacy will be evaluated. **Results:** 25 stage IIIB or IIIC gastric cancer patients were enrolled in this study. Mean age was 54.3 years old (range: 34-70), and ECOG performance scores were 0 or 1. Repeated dosing has been well tolerated with mild local discomfort and no DLTs. Three patients were observed grade 2 local skin reactions in the injection sites. No SAEs related to PVAC have been observed. Among median follow up time of 12.6 months (range: 8.5-25.0 months), only two patients had local recurrence at 24.0 months and 10.5 months after surgery, respectivelt. The rest 23 patients remain disease free on study. Neoantigen specific T cell responses have been detected by IFN-γ Elispot from PBMCs. **Conclusions:** PVAC is a multiple neoantigen/CT antigens nanovaccine that personalizes tumor specific antigens and the individual patient's capacity to respond. Addition of PVAC may prolong progression-free survival (PFS) after the standard of care chemotherapy. Clinical trial information: ChiCTR1800017319. Research Sponsor: the National Natural Science Foundation of China.

4536 Poster Session (Board #144), Fri, 8:00 AM-11:00 AM

Camrelizumab combined with FOLFOX as neoadjuvant therapy for resectable locally advanced gastric and gastroesophageal junction adenocarcinoma. *First Author: Ying Liu, Department of Medical Oncology, Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China*

Background: Neoadjuvant chemotherapy has been demonstrated to improve the pathological complete response(pCR) and 5-year survival rate of patients with locally advanced gastric and gastroesophageal junction adenocarcinoma (GC/GEJC). Immunotherapy has become a new promising treatment for advanced GC/GEJC. Therefore, we intended to evaluate the safety and efficacy of Camrelizumab (anti-PD-1 antibody) combined with FOLFOX as the neoadjuvant therapy for patients with locally advanced GC/GEJC. **Methods:** Eligiblepatients were locally advanced GC/GEJC with clinical stage≥T2 and/or positive lymphoglandula confirmed by endoscopic ultrasonography (EUS) and imaging. They received 4 cycles neoadjuvant therapy which including Camrelizumab(200mg ivgtt D1), FOLFOX(Oxaliplatin 85mg/m^2 ivgtt D1, 5-Fu 400mg/m^2 iv D1, LV 200mg/m^2 ivgtt D1, 5-Fu 2.4mg/m^2 CIV 46 hours) every 14 days. Imaging evaluation was performed in 2-4 weeks after neoadjuvant therapy. Patients without progression disease (PD) received D2 radical gastrectomy. The primary endpoint was pCR, the secondary endpoints were R0 resection rate and safety. **Results:** From July 24 2019 to January 31 2020, 16 patients were eligible. The median age was 57 years (29-72 years). A total of 11(69%) males and 5(31%) females, ECOG PS 0 (n=9, 56%) , ECOG PS 1 (n=7, 44%). All the patients completed 4 cycles treatment and none of them was confirmed PD by image. One of the patients refused gastrectomy and withdraw from the study. The other 15 patients underwent operation. Unfortunately, intraperitoneal metastases were confirmed in 2 patients during operation. 13 patients received D2 radical gastrectomy and all of them experienced R0 resection. Among the 13 evaluable patients, 1 patient (8%) was observed pCR, 3 patients (23%) experienced TRG1, 10 patients (77%) achieved stage reduction. Notably, 8 patients (62%) had lymphonodus pCR. The grade 3-4 treatment-related AEs were neutropenia (n=3, 19%), leukopenia (n=2, 13%) and anorexia (n=1, 6%). No serious AEs resulted in termination of treatment. Either severe immune-related AEs or treatment-related death was not observed. **Conclusions:** Camrelizumab combined with FOLFOX as neoadjuvant regimen in patients with locally advanced GC/GEJC showed promising pCR with good tolerance. Clinical trial information: NCT03939962. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

4537 Poster Session (Board #145), Fri, 8:00 AM-11:00 AM

The association of tissue tumor mutational burden (tTMB) using the Foundation Medicine genomic platform with efficacy of pembrolizumab versus paclitaxel in patients (pts) with gastric cancer (GC) from KEYNOTE-061. *First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan*

Background: KEYNOTE-061 (NCT02370498) was a randomized, open-label, phase 3 study of pembrolizumab vs paclitaxel in pts with advanced gastric or gastroesophageal junction (GEJ) adenocarcinoma with tumor progression after first-line therapy (N = 592). In this analysis, we evaluated tTMB using FoundationOne CDx (F1CDx; Foundation Medicine) in pts with gastric or GEJ cancer in KEYNOTE-061. **Methods:** In pts with evaluable F1CDx tTMB data (n = 204), we analyzed the association of tTMB with confirmed objective response rate (ORR), progression-free survival (PFS), and overall survival (OS) within each treatment arm using one-sided (pembrolizumab) and two-sided (paclitaxel) Wald test nominal *P* for logistic regression (ORR) and Cox proportional hazards regression (PFS; OS) adjusted for ECOG performance status; significance was prespecified at 0.05. The clinical utility of tTMB was assessed using the prespecified cutoff of 10 mut/Mb for F1CDx. Clinical data cutoff: Oct 26, 2017. **Results:** tTMB was positively associated with ORR ($P < 0.001$; AUROC, 0.68), PFS ($P < 0.001$), and OS ($P = 0.003$) with pembrolizumab but not paclitaxel (ORR, $P = 0.047$; AUROC, 0.30; PFS, $P = 0.605$; OS, $P = 0.084$). Pt outcomes by tTMB cutoff are reported in the Table; prevalence of TMB ≥10 mut/Mb was 17%. In pts with microsatellite stable disease-only, HRs (95% CI) by treatment arm for OS by F1CDx cutoff were 0.40 (0.14-1.17) for tTMB ≥10 mut/Mb (n = 21) vs 0.97 (0.70-1.34) for tTMB <10 mut/Mb (n = 168). **Conclusions:** In this exploratory analysis from KEYNOTE-061, tTMB as determined by F1CDx demonstrated a positive association with clinical outcomes with pembrolizumab, but not paclitaxel, in pts with GC; these findings are consistent with those reported with whole exome sequencing. Pembrolizumab demonstrated an OS benefit vs paclitaxel in the subgroup with tTMB ≥10 mut/Mb, which remained when pts with microsatellite instability-high disease were excluded. Clinical trial information: NCT02370498. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4538 Poster Session (Board #146), Fri, 8:00 AM-11:00 AM

PILGRIM: Phase III clinical trial in evaluating the role of hyperthermic intraperitoneal chemotherapy for locally advanced gastric cancer patients after radical gastrectomy with D2 lymphadenectomy(HIPEC-01). *First Author: Shu-zhong Cui, Affiliated Cancer Hospital & Institute of Guangzhou Medical University, Guangzhou, China*

Background: Gastric cancer remains the 3rd leading cancer related death worldwide due to early disease recurrence. We hypothesize that hyperthermic intraperitoneal chemotherapy (HIPEC) may effectively prevent local regional recurrence for locally advanced gastric cancer patients who received curative intent surgery. **Methods:** Pathology proven gastric cancer patients with clinical T3/T4NxM0 disease are eligible for the study and will be randomized to either control group, who will receive standard radical gastrectomy and D2 lymph node dissection or HIPEC group, who will receive the same surgery and HIPEC with paclitaxel x 2 within the first week after surgery. All patients will receive either XELOX or SOX adjuvant chemotherapy. The primary end point is overall survival. **Results:** 648 patients from 16 high volume gastric medical centers were enrolled between May, 2015 and March, 2019. 331 and 317 patients were randomized to control and HIPEC groups respectively. The median follow-up time is 12.1 months. The common grade 3/4 toxicities (> 5%) in control and HIPEC groups are anemia 6% vs. 4.1%, intraabdominal infection 5.4% vs. 3.8%, pneumonia 9.7% vs. 9.8%, fever 10.6% vs. 11.4% and hypoalbunemia 15.1% vs. 16.7% respectively. All three perioperative death (within 30 days after surgery) occurred in control group. One patient died from duodenum stump leak which led to multiple organ failure. One patient died from anastomotic led to intraabdominal infection and shock. The 3rd death was suicide caused by severe depression. At the time of this report, the number of event has not reached for final efficacy analysis. **Conclusions:** It is safe to administer HIPEC to patients received radical gastrectomy with D2 lymph node dissection within one week of surgery. The primary analysis will be expected in one year. Clinical trial information: NCT02356276. 4539 Poster Session (Board #147), Fri, 8:00 AM-11:00 AM

Translational analysis of esophageal adenocarcinoma (EAC) patients treated with oxaliplatin and capecitabine (Xelox) +/- the dual ErbB inhibitor AZD8931 in the DEBIOC study. *First Author: Anita Lavery, The Patrick G Johnston Centre for Cancer Research, Queen's University Belfast, Belfast, United Kingdom*

Background: The Dual Erb B Inhibition in Oesophago-gastric Cancer (DEBIOC) trial reported an acceptable safety profile for neoadjuvant Xelox +/- AZD8931 but limited efficacy. We utilized EAC patient samples from DEBIOC to evaluate the impact of neoadjuvant Xelox +/-AZD8931 on biological pathways using a unique software driven solution. **Methods:** 24 pre-treatment FFPE EAC biopsies and 17 matched surgical resection specimens were transcriptionally profiled using the Almac Diagnostics Xcel Array. Gene expression data was analyzed using the Almac clara^T total mRNA report V3.0.0, reporting on 92 gene expression signatures and 7337 single genes associated with 10 key biologies. Paired Wilcoxon tests (5% significance level) were used to evaluate changes in clara^T scores pre- and post-treatment. EGFR and Her2 expression were assessed by IHC and FISH. **Results:** 15 patients received Xelox+AZD8931 and 9 Xelox alone. Hierarchical clustering of biopsies identified 4 major clusters: Inflammation active, Genomic Instability active, EGFR & MAPK active, and EMT & Angiogenesis active. Comparison of signature scores pre- and post- neoadjuvant treatment demonstrated a significant reduction in scores relating to DNA damage repair (DDR) deficiency (Almac DNA Damage assay, $p < 0.0001$; BRCAness Profile, $p = 0.0025$; HRD Gene Signature, $p < 0.0001$; BRCA1ness Signature, $p = 0.0004$) and a significant increase in angiogenesis signatures (Almac Angiogenesis Assay, $p = 0.0002$; Angio Predictive G model, $p = 0.0228$; Angiogenesis Signature A, $p = 0.0034$) and EMT signatures (EMT Signature, $p = 0.0031$, EMT Enrichment Score, $p = 0.0013$, PanCan EMT Signature B, $p = 0.0001$). Comparing pre- and post-treatment signature scores in patients treated with Xelox +/-AZD8931 revealed a significant reduction in EGFR Sensitivity Signature ($p = 0.0088$), ERBB2-specific Gene Expression Signature ($p = 0.0127$) and Hallmark PI3K-AKT-MTOR Signaling ($p = 0.0195$) in those treated with Xelox + AZD8931 in keeping with the mechanism of action of AZD8931. Downregulation of AKT signaling was confirmed in AZD8931 treated and resistant cell lines. **Conclusions:** We report the use of a novel software tool to apply 92 gene expression signatures to EAC biopsy and resection specimens from the DEBIOC trial to provide insight into mechanisms of action. Neoadjuvant treatment was associated with a reduction in DDR deficiency and an increase in angiogenesis and EMT signatures whilst a reduction in EGFR, Her2 and AKT pathways was noted with AZD8931 treatment. 4540 Poster Session (Board #148), Fri, 8:00 AM-11:00 AM

Phase Ib/II open-label, randomized evaluation of 2L atezolizumab (atezo) + PEGPH20 versus control in MORPHEUS-pancreatic ductal adenocarcinoma (M-PDAC) and MORPHEUS-gastric cancer (M-GC). *First Author: Andrew H. Ko, University of California San Francisco, San Francisco, CA*

Background: The MORPHEUS platform consists of multiple, global, open-label, randomized Phase Ib/II trials designed to identify early efficacy signals and safety of treatment (tx) combinations across cancers. Within MORPHEUS, atezo (anti–PD-L1) was tested with PEGylated recombinant human hyaluronidase (PEGPH20), an anti–stromal and extracellular matrix modulator, in patients (pts) with metastatic (m) PDAC or advanced/mGC. **Methods:** In 2 separate randomized trials, eligible pts with 2L mPDAC or mGC received atezo (1200 mg IV q3w) + PEGPH20 (3 μg/kg IV on D1, 8, 15). Control tx for M-PDAC (NCT03193190) was mFOLFOX6 or gemcitabine + *nab*-paclitaxel. In M-GC (NCT03281369), control tx was ramucirumab + paclitaxel. Primary endpoints were ORR (investigator-assessed RECIST 1.1) and safety. **Results:** Pts were followed up for ≥ 18 wk in M-PDAC (data cutoff: Aug 5, 2019) and ≥ 24 wk in M-GC (data cutoff, Jul 11, 2019). In M-PDAC, 66 pts received atezo + PEGPH20 and 42 received control in both preliminary and expansion phases. Confirmed ORRs were 6.1% (95% CI: 1.7, 14.8) and 2.4% (95% CI: 0.06, 12.6), respectively. Duration of response ranged from 5.3 to 11.3 mo in tx arm and was 3.9 mo in control. Median PFS was 1.5 mo (95% CI: 1.4, 2.6) and 2.3 mo (95% CI: 1.6, 4.0), respectively. Median OS was 7.1 mo (95% CI: 4.6, 9.5) and 6.8 mo (95% CI: 5.6, 8.3). Updated survival data will be presented. Respectively, 62.2% and 59.5% of pts had Gr 3-4 AEs; Gr 5 AEs were seen in 4.5% and 2.4% of pts; serious AEs (SAEs) occurred in 45.5% and 45.2% of pts; 16.7% and 4.8% of pts had tx-related AEs leading to tx withdrawal. The most common tx-related AEs were myalgia (65.2%) and peripheral edema (28.8%) in the combination arm. In M-GC, 13 pts received atezo + PEGPH20 and 12 received control. Confirmed ORRs were 0% (95% CI: 0, 24.7) and 16.7% (95% CI: 2.1, 48.4), respectively. Gr 3-4 AEs were seen in 30.8% and 75.0% of pts, respectively. No Gr 5 AEs occurred in either arm. SAEs occurred in 7.7% and 50.0% of pts, respectively. Only 1 pt in the control arm had a tx-related AE leading to tx withdrawal. While tumor hyaluronan (HA) appears to be associated with poor prognosis in the M-PDAC control, there was no clear association between HA levels and response to atezo + PEGPH20. PK data will also be presented. **Conclusions:** Limited efficacy was seen with the chemotherapy-free combination of atezo + PEGPH20 in PDAC. No efficacy was seen in GC. The safety of atezo + PEGPH20 was consistent with each agent's known safety profile; no new safety signals were identified. Clinical trial information: NCT03193190. Research Sponsor: F. Hoffmann La-Roche Ltd.

4541 Poster Session (Board #149), Fri, 8:00 AM-11:00 AM

Enhanced efficacy of anti-VEGFR2/taxane therapy after progression on immune checkpoint inhibition (ICI) in patients (pts) with metastatic gastroesophageal adenocarcinoma (mGEA). *First Author: Lionel Aurelien Kankeu Fonkoua, Mayo Clinic, Rochester, MN*

Background: Anti-VEGFR2 therapy (ramucirumab/paclitaxel [RAM/TAX]) and ICI are approved as 2nd- and 3rd-line therapy (Tx), respectively, for pts with mGEA. We unexpectedly saw durable responses in 2 pts on RAM/TAX after progression on an ICI trial (KN-059; PMID 29674442). We performed a pilot to examine the clinical activity of ICI followed by RAM/TAX. Then we retrospectively compared the outcomes of pts who received this serial Tx to pts who received RAM/TAX without prior ICI. **Methods:** All pts with mGEA at Mayo Clinic who received RAM/TAX (2014-19) were included (N = 87). Outcomes were best objective response rate (ORR: complete [CR] or partial response) per RECIST1.1, progression-free survival (PFS), duration of response (DOR), and overall survival (OS). Chi square and multivariate (MV) logistic and Cox regression were used. **Results:** 15 consecutive pts with measurable mGEA received ICI immediately followed by RAM/TAX after irRECIST progression. Most pts (95%) did not respond to ICI. Yet on RAM/TAX, 100% (15/15) had tumor reduction (range -8% to -100%) with an ORR of 73% (11/15), including 3 CRs. In these pts (who received ICI followed by RAMTAX), PFS on RAMTAX was longer than on last chemotherapy before ICI (12.3 vs 3.0 m, $P < .001$). Outcomes on RAM/TAX in these pts were significantly better than in pts who received RAM/TAX alone (see Table). Associations were strengthened after adjusting for total lines of Tx, line of Tx of RAM/TAX, age, and ECOG PS. Exploratory analysis of paired tumor biopsies collected pre-ICI and on RAM/TAX in a small subset revealed that the frequency of intratumoral immunosuppressive $FOXP3^+$ Tregs decreased on RAM/TAX, whereas the frequency of antitumor $CD8^+$ T cells was preserved. **Conclusions:** RAM/TAX immediately preceded by ICI was associated with significantly higher OS, ORR, and DOR than RAM/TAX alone, suggesting ICI may enhance efficacy of subsequent anti-VEGFR/taxane therapy. This novel sequence of therapy will be tested prospectively in a new randomized phase 2 trial (NCT04069273). Research Sponsor: None.

	RAM/TAX ...		
	With preceding ICI *n = 19* [a]	Without preceding ICI *n = 68*	p
ORR	58%	18%	< .001
DOR	10.5 m	4.3 m	.021
OS	15.0 m	7.6 m	.003

Impact of frontline doublet versus triplet therapy on clinical outcomes: Exploratory analysis from the RAINBOW study. *First Author: Samuel J Klempner, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: Treatment (tx) of advanced gastric cancer (GC/GEJ) is highly heterogeneous, with substantial variability in tx patterns. Frontline tx choice may affect outcomes of subsequent tx, thereby influencing choice/efficacy of second-line (2L) tx. In RAINBOW, 2L ramucirumab(R) plus paclitaxel(P) significantly improved overall survival (OS) of patients (pts) with GC/GEJ. Here we explore efficacy, safety and quality of life (QoL) based on prior tx. **Methods:** Pts were grouped into doublet (DB) or triplet (TP) regimens based on prior cytotoxic tx received. OS and PFS were estimated using Kaplan-Meier method and tx effects on OS and PFS were evaluated by Cox PH model; safety and QoL were assessed descriptively for DB vs TP. **Results:** Use of DB and TP was similar between arms, with 23% in R+P and 26% in placebo (PB)+P arm receiving TP. Baseline characteristics were generally balanced between tx arms within DB and TP subgroups, with majority of TP administered in western regions (91%). Pts ≥65 years of age was 40% for DB and 28% for TP. DB pts (n = 498; 75%) received S1+cis (n = 97, 15%) and cape+ox (n = 71; 11%) as most common prior tx, while TP pts (n = 163; 25%) received epi+cape+ox (n = 74, 11%) and epi+cis+5FU (n = 53, 8%). Similar to ITT population, R+P improved OS and PFS in both DB and TP subgroups (Table). Patterns of overall and Grade ≥3 TEAEs between arms were similar regardless of prior tx. Higher rates of serious TEAEs were reported in TP pts (57%, 49%) than DB pts (44%, 40%) in R+P and PBO+P arms, respectively. Similar trend was observed for TEAEs leading to discontinuation for TP (40%, 30%) vs DB (29%, 22%) in respective tx arms. Baseline QoL scores were similar between tx arms within subgroups, but mean scores were > 5 points worse (range 0-100) for prior TP for role functioning, fatigue, pain, and appetite loss. Changes in mean scores were generally similar between arms and within subgroups. **Conclusions:** This exploratory analysis of RAINBOW suggests that although safety-related outcomes were less favorable in pts with prior TP, regardless of tx arm, similar improvements in efficacy were noted for R+P irrespective of prior DB or TP. Clinical trial information: NCT01170663. Research Sponsor: Eli Lilly and Company.

Impact of body measurements (BM) on overall survival (OS) and quality of life (QoL) in real-world patients (pts) with metastatic esophageal cancer. *First Author: Joelle Soriano, Princess Margaret Cancer Center, Toronto, ON, Canada*

Background: Body fat and muscle influence prognosis in many cancer types. However, this association is unclear for real-world MEC pts, who are often in worse performance status than their previous baseline. In addition, the relationship of BM at presentation and QoL is unknown. We used real-world MEC pts to assess the importance of BM in OS and QoL. **Methods:** BM were done at baseline computed tomography in MEC pts, treated from 2006-2014 at the Princess Margaret Cancer Centre. Two radiologists (correlation 0.9-1.0) assessed L3 level using SliceOMatic to determine Skeletal Muscle Index (SMI - muscle area at L3 normalized by height), Visceral Adiposity Tissue (VAT), and Subcutaneous Adiposity Tissue (SAT). We used previously published cut-offs for sarcopenia based on sex and BMI, and the highest tertile as the cut-off for adiposity. We used prospectively collected QoL surveys including EuroQol 5D-5L (EQ5D) and the Functional Assessment of Cancer Therapy – Esophageal (FACT-E). **Results:** Of 200 pts, 164 (82%) were male, 180 (92%) were non-Asian; mean age was 62 y; ECOG: 0-1 = 142 (71%), 2 = 58 (29%); 69% had adenocarcinoma; 5% were underweight, 44% normal weight, 30% overweight, and 21% obese. 40 (20%) pts completed QoL measures. We found that 104 (52%) were sarcopenic at baseline, 66 (33%) had high VAT, and 67 (34%) had high SAT. A multivariable Cox model showed that sarcopenia and VAT were independent prognostic variables for three-year OS: sarcopenia increased the risk of death by 50% (adjusted hazard ratio, aHR 1.50, p 0.02), whereas every 100-cm^2 increase in VAT improved OS by 24% (aHR 0.76, p 0.03). Finally, sarcopenic pts had significantly worse physical well-being (p 0.01) on FACT-E after adjusting for sex and age. Numerically, the EQ5D also showed lower scores in sarcopenic pts but this was not statistically significant (p 0.18). **Conclusions:** In MEC pts, sarcopenia and low visceral adiposity result in worse OS; sarcopenia is also significantly associated with poor QoL. Future work will need to focus on potential rehabilitation strategies such as nutritional support and exercise training to offset the poor prognosis associated with sarcopenia and reduced adiposity. Research Sponsor: None.

Final analysis of single-arm confirmatory study of definitive chemoradiotherapy including salvage treatment in patients with clinical stage II/III esophageal carcinoma: JCOG0909. *First Author: Yoshinori Ito, Department of Radiation Oncology, Showa University School of Medicine, Tokyo, Japan*

Background: Definitive chemoradiotherapy (dCRT) consisting of 5-fluorouracil (5-FU) and cisplatin (CDDP) with 60 Gy radiotherapy (RT) for clinical (c) Stage II/III esophageal carcinoma (EC) is a standard treatment for patients (pts) refusing surgery (S) in Japan based on the previous trial (JCOG9906). However, poor survival, high incidence of late toxicities, and severe complications of salvage S are problems. We conducted a single-arm confirmatory study of CRT modifications including salvage treatment (ST) to reduce CRT toxicities and facilitate ST to improve survival. We reported the 3-year survival at 2018 ASCO Annual Meeting. We report the final data after 5-year follow-up. **Methods:** EC pts with cStage II/III (UICC 6th, non-T4), PS 0-1, and age 20-75 years were eligible. Chemotherapy (CT) was CDDP (75 mg/m^2 on days 1, 29) and 5-FU (1000 mg/m^2/d on days 1-4, 29-32). RT was administered to a total dose of 50.4 Gy with elective nodal irradiation of 41.4 Gy. Good responders after dCRT received additional 1-2 cycles of CT. For residual or recurrent disease, salvage endoscopic resection (ER) or S was performed based on the prespecified criteria. Planned sample size was 95, with one-sided alpha of 5% and power of 80%, expected and threshold 3-year overall survival (OS) as 55% and 42%. Key secondary endpoint was ST related toxicity. Final analysis was planned after 5-year follow-up for all pts. **Results:** From 4/2010 to 8/2014, 96 pts were enrolled, two were ineligible and 94 were included in efficacy analysis (cStage IIA/IIB/III, 22/38/34). Complete response was achieved in 55 pts (59%). Salvage ER and S were performed in 5 (5%) and 27 pts (29%). R0 resection of salvage S was achieved in 23 (85%). With a median follow-up of 5.95 years, 3- and 5-year OS was 74.2% (90% CI 65.9-80.8%) and 64.5% (95% CI 53.9-73.3%). 5-year progression-free survival and esophagectomy-free survival were 48.3% (95% CI 37.9-58.0%) and 54.9% (95% CI 44.3-64.4%). 5-year OS after salvage S was 31.0% and hazard ratio of R1-2 to R0 was 5.635 (95% CI: 1.818-17.467). No complications occurred after salvage ER. Five pts (19%) showed ≥ grade 3 operative complications and 1 treatment related death due to bronchus-pulmonary artery fistula occurred after salvage S. Only 9 pts (9.6%) showed grade 3 late toxicities. And no late operative complications more than grade 3 were observed. **Conclusions:** This combined modality treatment of dCRT with ST showed acceptable toxicities, favorable 5-year survival, and promising esophageal preservation. Clinical trial information: jRCTs031180110. Research Sponsor: National Cancer Center Research and Development Funds.

4546 Poster Session (Board #154), Fri, 8:00 AM-11:00 AM

Evaluation of spatiotemporal heterogeneity of tumor mutational burden (TMB) in gastroesophageal adenocarcinoma (GEA) at baseline diagnosis and after chemotherapy. *First Author: Katherine I. Zhou, University of Chicago, Chicago, IL*

Background: Tumor mutational burden (TMB) may be a predictive marker for response to anti-PD1/PDL1 agents (IO). Molecular heterogeneity of various biomarkers for GEA has been established. To characterize heterogeneity of TMB and its clinical relevance, we compared TMB in primary (1^O) & metastatic (met) tumors at baseline newly diagnosed stage IV advanced GEA (aGEA), and before & after chemotherapy treatment (tx) for stage II–IV GEA. We assessed the prognostic relevance of TMB in aGEA. **Methods:** We retrospectively reviewed a cohort of 127 patients (pts) diagnosed with GEA in 2012–2019, for a total of 280 tumor samples with TMB data. TMB level was defined as low (≤5/Mb), intermediate (int) (> 5/Mb, ≤15/Mb), or high (hi) (≥15/Mb), determined by Foundation One. Analysis was performed by Fisher's exact test for PDL1/TMB, McNemar's test for paired TMB, and univariate Cox proportional-hazards model for overall survival (OS). **Results:** Of 280 tumors, 50% (140/280) had low TMB, 45% (125/280) int TMB, & 5% (15/280) hi TMB. TMB ranged 0–58.6/Mb (median 5.3/Mb). Of tumors with hi TMB, 53% (8/15) were MSI-Hi, while of MSI-Hi tumors, 100% (8/8) were TMB hi. TMB level did not correlate with PDL1 status (p= 0.83). Concordance between TMB levels of paired baseline 1^O and baseline met tumors was 66% (29/44) (Table). TMB level was lower in the met than in the 1^O in 23% (10/44) of cases, and higher in the met in 11% (5/44). Of 4 TMB hi baseline 1^O tumors, 2 were not TMB hi in the met; of 40 TMB low/int baseline 1^O tumors, 0 were TMB hi in the met (p= 0.16). Post-tx tumors exhibited 71% (42/59) concordance of TMB levels compared to pre-tx 1^O tumors. Of 2 TMB hi baseline tumors, 1 was not TMB hi in the post-tx tumor; of 57 TMB low/int baseline tumors, 0 were TMB hi in the post-tx tumor (p= 0.32). In pts with aGEA at diagnosis, OS did not significantly differ depending on baseline 1^O tumor TMB level (median OS of 21.4 [95% CI 15.4–27.9] months for TMB low, 14.6 [10.9–23.5] months for TMB int, and 9.6 [3.9–NA] for TMB hi; p= 0.3), nor depending on baseline met TMB level. **Conclusions:** Notable baseline spatial discordance of TMB was observed, particularly TMB hi 1^O to low/int met. Discordance was also observed before & after tx, without significant increase towards TMB hi temporally. Spatiotemporal heterogeneity may impact the role of TMB as a predictive biomarker & warrants further study. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

	Baseline met TMB low	Baseline met TMB int	Baseline met TMB hi	Post-tx TMB low	Post-tx TMB int	Post-tx TMB hi
Baseline 1^O TMB low	16	5	0	21	7	0
Baseline 1^O TMB int	8	11	0	9	20	0
Baseline 1^O TMB hi	1	1	2	0	1	1

4547 Poster Session (Board #155), Fri, 8:00 AM-11:00 AM

Morphologic and molecular analysis of early-onset gastroesophageal adenocarcinomas. *First Author: Namrata Setia, University of Chicago, Chicago, IL*

Background: The incidence of early-onset gastroesophageal adenocarcinomas (EO-GEA) is increasing, and these tumors now constitute > 30% of all gastroesophageal cancers. Besides hereditary gastric cancer syndromes, which form ~3% of EO-GEA, the morphologic and molecular spectrum of these tumors is not well-studied. **Methods:** Next-generation sequencing (NGS) data obtained from routine clinical care from patients with EO-GEA, defined as age ≤50 years, from 3 tertiary care centers was evaluated and compared with tumor profiles of 2,081 patients with GEA from cBioPortal for Cancer Genomics. Available histologic slides were reviewed, and the tumors were classified into Lauren and WHO subtypes. Tumor-detected pathogenic variants of potential germline origin were identified from the NGS data. **Results:** The study cohort was formed by 79 patients with gastroesophageal (42%) and gastric (58%) adenocarcinoma. The most commonly mutated genes included *TP53* (28.5%), *CDH1* (10%), *ARID1A* (5%), *KRAS* (3.9%) and *PIK3CA* (3.9%). EO-GEA were less likely to harbor *TP53* (28.5% vs. 57.5%, p 0.003) and *ARID1A* (5% vs. 20.6%, p 0.002) mutations when compared with cBioPortal data. Based on the Lauren scheme, the tumors were classified into intestinal (40%), diffuse (24%), mixed (12%), and indeterminate (15%) subtypes. Driver mutations in *CDH1*,*TP53*, *FBXW7*, *BAP1* genes were seen in diffuse/mixed subtype, and *TP53*, *ARID1A*, *KRAS*, *PIK3CA*, *APC*, *ATM*, *NBN*, *MUTYH* genes in intestinal subtype. The indeterminate subtype showed *TP53* mutations and additional alterations, including *SMARCB1*/*SMARCA4* loss leading to rhabdoid/undifferentiated morphology. *ERBB2* amplification was more likely to be present in intestinal and indeterminate subtypes (p = 0.003).*CD274* amplification/PD-L1 expression was more likely to be present in indeterminate subtype (p < 0.0001). Potential germline variants included mutations in gastric cancer susceptibility genes such as *CDH1* (2.5%) and *APC* (1%), and other cancer susceptibility genes such as *ATM* (4%), *NBN* (1%), *MUTYH* (1%) and *POLD1* (1%). **Conclusions:** The molecular profile of EO-GEA is distinct from traditional gastric cancers. Histologic subtypes of EO-GEA correlate with distinct genomic alterations. Our findings also support multigene germline panel testing in parallel for patients with EO-GEA. Research Sponsor: None.

4548 Poster Session (Board #156), Fri, 8:00 AM-11:00 AM

Perioperative FLOT in elderly patients with resectable gastric cancer: Subgroup analysis from the observational RealFLOT study. *First Author: Elisa Giommoni, Medical Oncology, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy*

Background: The treatment strategy for patients with resectable gastric cancer changed in the last few years with perioperative treatments. FLOT regimen (fluorouracil, oxaliplatin, docetaxel) turned out to be feasible and effective, offering significant improvement in survival outcomes. However, the safety profile of triplet therapies for elderly patients deserves a special attention and, consequently, the best treatment strategy for these patients is still debated. **Methods:** Focusing on the elderly patient population (age ≥65 years), real-world data from patients with resectable gastric or gastro-oesophageal junction (GEJ) adenocarcinoma (T≥2 and/or N+) enrolled in the observational RealFLOT study were collected. **Results:** A total of 206 patients with resectable gastric or GEJ adenocarcinoma received perioperative FLOT at 15 Italian centers in routine clinical practice, between September 2016 and September 2019. The median age was 63 years (range 36-77) and 43% of patients enrolled (n = 89) were ≥65 years. Among elderly patients, 46 (52%) received FLOT for at least 4 full-dose cycles in the preoperative phase, 82 (92%) underwent surgery, and 56 (62%) started the postoperative phase. The primary end point of the study, pathological complete response (pCR) rate, was similar among patients aged ≥65 and < 65 (6.7% vs 7.7%, respectively). The distribution of pathological stages did not differ according to age (p = 0.473), and disease-free survival (DFS) is unrelated to the age of patients (log-rank 0.57; p = 0.89). The incidence of grade (G) 3-4 adverse events (AEs) was similar in the two age groups (Table) and the 30-day mortality rates after surgery did not differ according to age. **Conclusions:** FLOT regimen demonstrated to be feasible and safe in elderly patients since no differences were observed in terms of pCR, DFS and safety profile according to age. Research Sponsor: None.

Preoperative and postoperative G3-4 AEs registered.

Preoperative	**Patients ≥65 (n = 89)**	**Patients < 65 (n = 117)**
- Hematological	17%	22%
- Gastrointestinal	10%	4%
Postoperative	**Patients ≥65 (n = 56)**	**Patients < 65 (n = 86)**
- Hematological	14%	19%
- Gastrointestinal	9%	10%

4549 Poster Session (Board #157), Fri, 8:00 AM-11:00 AM

Interim safety analysis of the DANTE trial: Perioperative atezolizumab in combination with FLOT versus FLOT alone in patients with resectable esophagogastric adenocarcinoma—A randomized, open-label phase II trial of the German Gastric Group at the AIO and SAKK. *First Author: Nils Homann, Klinikum Wolfsburg, Med. Klinik II, Wolfsburg, Germany*

Background: The DANTE study evaluates atezolizumab in the perioperative treatment of locally advanced, potentially resectable gastric or GEJ adenocarcinoma in combination with perioperative FLOT. Here, we report the protocol-defined interim safety analysis. **Methods:** DANTE is a multinational, prospective, multicenter, randomized, investigator-initiated, open label phase II trial. Patients (pts) with locally advanced, potentially resectable adenocarcinoma of the stomach and GEJ (≥cT2 and/or N-positive) without distant metastases are enrolled. Pts are randomized 1:1 to 4 preoperative 2-week cycles of FLOT followed by surgery and 4 additional cycles of FLOT plus atezolizumab at 840 mg every 2 weeks, followed by a total of 8 additional cycles of atezolizumab at 1200 mg every 3 weeks as monotherapy (arm A) or FLOT alone (arm B). Primary endpoint is time to disease progression or relapse after surgery (PFS/DFS). **Results:** Recruitment started in Sep 2018; by Feb 2020, a total of 175 pts have been randomized. This analysis is based on the first 40 pts (20 pts in each arm). The pts had a median age of 62 y and 75% of pts had an ECOG PS of 0 in both arms. The cohort was well balanced in terms of tumor location and clinical stage. 5% of the 40 patients (overall 7.4% of 175 pts enrolled) showed microsatellite instability. 90% of pts enrolled completed all pre-operative cycles in each arm. Total number of adverse events with relation to study treatment was 154 in arm A and 148 in arm B. Total number of serious adverse events (SAE; related or not) was 16 in Arm A and 14 in arm B. 20% of pts in each arm had an SAE due to perioperative morbidity. No surgical mortality was observed. 18 and 19 pts proceeded to operation in arms A and B, respectively. Premature treatment discontinuation occurred in 2 pts in each arm: disease progression (1) and deterioration of general health condition (1) in arm A; and pts' wish (1) and death (1) in arm B. Median hospitalization time was 15 days in arm A and 16 days in arm B. **Conclusions:** Perioperative atezolizumab plus FLOT is feasible and safe. The study continues recruitment. Clinical trial information: NCT03421288. Research Sponsor: Roche.

4550 Poster Session (Board #158), Fri, 8:00 AM-11:00 AM

A population-based study on gender differences in tumor and treatment characteristics and survival of curable gastroesophageal cancer. *First Author: Marianne C. Kalff, Department of Surgery, Amsterdam UMC, Amsterdam, Netherlands*

Background: Although curative treatment options for gastroesophageal cancer are identical for men and women, outcomes may vary. This study examined differences in tumor and treatment characteristics and survival between men and women with potentially curable gastroesophageal cancer. **Methods:** Nationwide data was acquired from the Netherlands Cancer Registry. Patients with a potentially curable gastroesophageal carcinoma (cT1-T4a or cTx, any cN, cM0 or cMx) diagnosed between 2006 and 2017 were selected. Patient stratification was performed for tumor location and histology. The primary endpoint, relative survival, was compared between men and women with esophageal adenocarcinoma (EAC), esophageal squamous cell carcinoma (ESCC) and gastric adenocarcinoma (GAC), adjusted for the normal life expectancy for men and women separately. **Results:** In total, 13,391 patients with an EAC (79.1% men), 5,103 patients with an ESCC (54.7% men), and 8,149 patients with a GAC (60.1% men) were included. Women with gastroesophageal cancer were older than men. Lower cT-stages were observed in women with EAC and ESCC (both $p < 0.001$) and lower cN-stages were observed in women in all groups, although clinical T- and N-stage were more frequently graded as cTx and cNx in women. In women, EAC tumors were less frequently located in the distal esophagus (70.4% vs. 58.6%, $p < 0.001$), ESCC tumors had a more proximal tumor location ($p < 0.001$), and GAC tumors were more frequently located at the antrum (32.3% vs. 37.2%, $p < 0.001$). For EAC and GAC, but not for ESCC, men were more frequently allocated to a potentially curative treatment; endoscopic resection, surgical resection or definitive chemoradiotherapy (EAC: 74.6% vs. 60.1%, $p < 0.001$; GAC: 69.0% vs. 65.4%, p 0.001; ESCC: p 0.117). An inferior 5-year relative survival was observed in women with EAC (34.3% vs. 30.1%, $p < 0.001$) and GAC (36.1% vs. 33.2%, p 0.016). In women with ESCC a superior 5-year relative survival was observed (24.4% vs 28.5%, p 0.001). **Conclusions:** Remarkable differences in 5-year relative survival were observed between men and women with gastroesophageal cancer, in addition to important differences in tumor stage, tumor location and treatment. Strikingly, men with esophageal and gastric adenocarcinoma were more frequently allocated to a potentially curative treatment compared to women. These findings illustrate the need for further exploration and consideration of gender differences in gastroesophageal cancer treatment. Research Sponsor: None.

4551 Poster Session (Board #159), Fri, 8:00 AM-11:00 AM

Diagnostic accuracy of CT-staging of advanced gastric cancer following neoadjuvant chemotherapy. *First Author: Jong Keon Jang, Asan Medical Center, Seoul, South Korea*

Background: Neoadjuvant or perioperative chemotherapy has been accepted as a standard treatment globally in patients (pts) with locally advanced gastric cancer (LAGC). In PRODIGY phase III study (n = 530), we have demonstrated that neoadjuvant chemotherapy with DOS regimen (docetaxel, oxaliplatin, S-1) led to significant tumor downstaging and improved PFS in Korean LAGC pts (Kang, et al. ESMO 2019). Although CT has been performed to re-stage the tumor after neoadjuvant chemotherapy, there has been a relative paucity of diagnostic accuracy data. This study is to evaluate the diagnostic performance of restaging of LAGC after neoadjuvant chemotherapy using CT in PRODIGY study population. **Methods:** Of 266 pts, who had been diagnosed LAGC of T2-4 or N+ stage as assessed with CT and randomized to neoadjuvant chemotherapy arm (CSC) in PRODIGY study, 214 pts underwent gastrectomy were included in this analysis. The post-chemotherapy T- and N- stage was determined based on CT scan taken just prior to surgery and compared with the pathologic stage (AJCC 7th edition). Two experienced radiologists independently evaluated depth of primary tumor and reached consensus if any discrepancy between two readers. Diameter of short axis of the largest regional lymph node was measured to predict metastatic lymph node. Result of histopathologic T- and N-staging using surgical specimen was used as reference standard. **Results:** The study cohort consisted of pathologic T0 (n = 22), T1(n = 39), T2(n = 31), T3(n = 79), and T4(n = 43). The overall diagnostic accuracy of CT was 45%. For each T-stage, accuracy of T0,T1,T2,T3, and T4 was 0%, 26%, 29%, 55% and 79%, respectively. Rate of over- and under- staging was 47% and 8%, respectively. Accuracy for prediction of downstaging to early gastric cancer (T0-T1) was 83%. Interobserver agreement of T-staging was moderate (k = 0.41). There were 98 patients of N+ and 116 patients of N- at histopathology. Area under the curve of receiver operating characteristics to differentiate lymph node metastasis was 0.63. Sensitivity and specificity of size criteria of the largest lymph node (cut off value: $>$ 6mm, $>$ 7mm, and $>$ 8mm) to predict pathologic N+ were 90% and 17%, 78% and 34%, and 68% and 51%, respectively. **Conclusions:** Re-staging using CT after neoadjuvant chemotherapy showed suboptimal accuracy and over-staged residual tumor. However, it predicted downstaging of gastric cancer with high accuracy. Research Sponsor: None.

4553 Poster Session (Board #161), Fri, 8:00 AM-11:00 AM

Prediction of esophageal fistula from esophageal cancer CT images using multi-view multi-scale attentional convolutional neural network (MM-Atten-CNN). *First Author: Yiyue Xu, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China*

Background: We aimed to propose a risk model based on MM-Atten-CNN for predicting esophageal fistula in patients with esophageal cancer (EC) from computerized tomography (CT) -based radiomics. **Methods:** EC patients who didn't received esophageal surgery between July 2014 and August 2019 were collected. Of these, 186 patients (cases) who developed esophageal fistula were enrolled and compared with 372 controls (1:2 matched with the diagnosis time of EC, sex, marriage, and race). All 558 patients were divided into training set (n = 390) and validation set (n = 168) randomly. The MM-Atten-CNN risk model was trained over 2D slices from nine views of planes, where there were three patches of contextual CT, segmented tumor and neighbouring information in each view. In the training set (130 cases and 260 controls), data augmentation was performed including pixel shifting [-10, -5, +5, +10] and rotation [-10, +10]. In total, there were (130+260) *16*2 = 12480 subjects used for training. Finally, the risk model was validated in the validation set (56 cases and 112 controls) and measured by accuracy (acc), sensitivity (sen), and specificity (spe). **Results:** The developed risk model achieved (acc, sen, spe) of (0.839, 0.807, 0.926), which were more predictive for the occurrence of esophageal fistula when compared to CNN models using single coronal view (acc 0.763, sen 0.581, spe 0.837), multi-view 2D contextual CT slices (acc 0.779, sen 0.656, spe 0.896), and 3D CNN using contextual CT volumes (acc 0.781, sen 0.689, spe 0.852). **Conclusions:** MM-Atten-CNN CT-based model improved the performance of esophageal fistula risk prediction, which has the potential to assist individualized stratification and treatment planning in EC patients. 4554 Poster Session (Board #162), Fri, 8:00 AM-11:00 AM

PET-directed chemoradiation (CRT) with induction FOLFOX compared to induction carboplatin/paclitaxel (CP) in patients with locally advanced esophageal adenocarcinoma (EA). *First Author: Rebecca Carr, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Induction chemotherapy with PET-directed CRT and surgery is the standard treatment for locally advanced EA at our institution. Following results of the CALGB 80803 trial, FOLFOX has recently replaced CP as the preferred induction regimen. **Methods:** We retrospectively evaluated patients with locally advanced EA treated with induction CP vs FOLFOX, followed by trimodality therapy between January 2010 and June 2019. Patients treated with CP with RT followed by surgery without induction chemo were also included. We compared pathological complete response (pCR) and near pCR (ypN0 with ≥90% response) rates in the induction FOLFOX group to the induction CP and no-induction groups. Univariable and multivariable analyses were used to adjust for confounding factors. Disease-free survival (DFS) was estimated by the Kaplan-Meier method and compared between groups using max-combo weighted log rank test. **Results:** 445 patients were included. Patients in the induction FOLFOX group had significantly higher pCR and near pCR rates vs induction CP patients. Notably, pCR rate was 38% among FOLFOX PET responders vs 19% in non-responders. In multivariable analysis, compared to induction CP, induction FOLFOX administration was an independent predictor of near pCR (OR: 2.22, 95%CI: 1.20-4.20, p = 0.012). Compared to 24% pCR rate among no-induction patients, induction FOLFOX pCR rate was slightly higher at 32%. DFS by 2-years was higher in induction FOLFOX compared to no-induction-treated patients (62% vs. 42%, p = 0.05). Postoperative complication rates were similar among the three groups. **Conclusions:** PET-directed CRT with FOLFOX instead of CP improves pCR and near pCR rates. Improved DFS was observed in the FOLFOX vs no-induction patients. Longer follow-up is needed to confirm any survival benefits. Research Sponsor: None.

Treatment Group	Induction FOLFOX	Induction CP	p-value (Induction FOLFOX vs Induction CP)	No-induction	p-value (Induction FOLFOX vs no-induction)
Total Number	71	237		137	
Number of PET Responders	50	140		N/A	
pCR: n (%)	23 (32.4%)	38 (16.0%)	0.004	33 (24%)	0.2
pCR in PET Responders	19/50 (38%)	29/140 (21%)	0.022		
pCR in PET Non-Responders	4/21 (19%)	9/97 (9.3%)	0.2		
Near pCR: n (%)	40 (56.3%)	81 (34.2%)	0.001	60 (44%)	0.11
Near pCR in PET Responders	29/50 (58%)	56/140 (40%)	0.032		
Near pCR in PET Non-Responders	11/21 (52%)	25/97 (26%)	0.034		
Median Follow-Up among survivors in Months (range)	12.3 (5.3-78.6)	41.1 (0.7-108.5)		18.7 (0.7-82.7)	
2-year DFS (95% CI)	62% (48-78%)	51% (45-58%)	0.23	42% (34-53%)	0.05

4556 Poster Session (Board #164), Fri, 8:00 AM-11:00 AM

Intestinal and tumor microbiome analysis combined with metabolomics of the anti-PD-L1 phase II PERFECT trial for resectable esophageal adenocarcinoma. *First Author: Nicolien C. de Clercq, Amsterdam UMC, University of Amsterdam, Department of Internal and Vascular Medicine, Amsterdam, Netherlands*

Background: Both human and rodent studies provide evidence for a role of the microbiome in patients who respond to checkpoint inhibition (CI). So far, no study has unraveled the physiological link between intestinal and tumor microbiome composition in relation to response to CI. The PERFECT trial was a single-arm phase II feasibility study investigating the addition of atezolizumab (PD-L1 inhibitor) to neoadjuvant chemoradiotherapy (nCRT) for resectable esophageal adenocarcinoma (NCT03087864). An exploratory objective of this trial was to evaluate intestinal and tumor microbiome composition including plasma metabolomics as potential biomarkers for immunological and pathological response. **Methods:** Using 16S rRNA gene sequencing, we analyzed fecal, duodenal and tumor samples at baseline (V0), 3 weeks after start of atezolizumab (V1), and 1 week before surgery (V2). We compared microbiome composition and metabolomics from patients with pathological complete response (pCR; ypT0N0) to patients with a pathological incomplete response. Differences in alpha diversity metrics were tested using mixed linear models. Beta-diversity associations were assessed using permutational MANOVA (adonis) and multilevel PCA (mixOmics). Biomarkers were identified using a machine learning model (XGboost) feature selection. Plasma metabolomics (Metabolon) were determined with liquid chromatography mass spectrometry (LC-MS). **Results:** Microbiome profiles were significantly altered after start of treatment in all sample types. None of the sample types showed a relation between alpha or beta diversity and pCR. On taxonomical level, we found that the tumor and duodenal baseline samples were weak predictors for response (AUC 0.60 and 0.62, respectively), but better compared to fecal microbiome composition (AUC = 0.49). We identified the top 20 microbes that predicted pCR best in tumor and fecal samples and found significant correlations with metabolites involved in bile acid metabolism. **Conclusions:** Both tumor and duodenal baseline biopsies were better predictors of pathological response compared to fecal microbiome. Microbes predictive of pCR showed significant correlations with metabolites involved in bile acid metabolism, which is known to indirectly influence immunosurveillance in cancer. Data on immune response in relation to the microbiome and metabolomics are expected Spring 2020. Clinical trial information: NCT03087864. Research Sponsor: Roche.

4557 Poster Session (Board #165), Fri, 8:00 AM-11:00 AM

Prognostic significance of nutritional markers in metastatic gastric and esophageal adenocarcinoma. *First Author: Lucy Xiaolu Ma, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Malnutrition and sarcopenia (defined as low skeletal muscle mass) are recognized as poor prognostic factors in many cancers. Studies to date in gastroesophageal cancer have largely focused on patients (pts) undergoing curative intent surgery. This study aims to evaluate the prognostic utility of nutritional markers and sarcopenia in pts with de novo metastatic gastric and esophageal adenocarcinoma (GEA). **Methods:** Pts with de novo metastatic GEA seen at the Princess Margaret Cancer Centre from 2010-2016 with available pre-treatment abdominal computed tomography imaging were identified from an institutional database. Nutritional index (NRI) was calculated using weight and albumin, with moderate/severe malnutrition defined as NRI < 97.5. Skeletal muscle index (SMI) normalized by height was calculated at the L3 level using Slice-O-Matic software. Sarcopenia was defined as SMI $< 34.4 cm^2/m^2$ in women and $< 45.4 cm^2/m^2$ in men based on previously established consensus. **Results:** Of 175 consecutive pts, median age was 61, 69% were male, 79% had ECOG performance status 0-1, and 71% received chemotherapy. Median BMI was 24.2 (range 15.7-39.8), 70% of pts had $> 5\%$ weight loss in the preceding 3 months, and 29% had moderate/severe malnutrition. 68 pts (39%) were sarcopenic, of whom 46% were malnourished. Median overall survival (OS) was 9.3 months (95% CI 7.3-11.4) for all pts. OS was significantly worse in malnourished pts (5.5 vs 10.9 months, $p = 0.000475$) and displayed a non-significant trend in sarcopenic pts (7.8 vs 10.6 months, $p = 0.186$). On univariable Cox proportional hazards (PH) analysis, ECOG ($p < 0.001$), number of metastatic sites ($p = 0.029$) and NRI ($p < 0.001$) were significant prognostic factors, while BMI ($p = 0.57$) and sarcopenia ($p = 0.19$) were not. On multivariable Cox PH analysis, ECOG ($p < 0.001$) and NRI ($p = 0.025$) remained significant as poor prognostic factors for OS. **Conclusions:** This study demonstrates in a large cohort of de novo metastatic GEA pts that ECOG and NRI were significantly associated with poor OS. NRI was superior to BMI alone. Early identification of malnourished pts using NRI may allow for supportive interventions to optimize nutritional status. Further study is needed to determine whether these factors can be modified to improve prognosis in these pts. Research Sponsor: None.

4558 Poster Session (Board #166), Fri, 8:00 AM-11:00 AM

Molecular correlates of PD-L1 expression in patients (pts) with gastroesophageal (GE) cancers. *First Author: Jingyuan Wang, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: The increased PD-L1 expression evaluated by combined positive score (CPS) is associated with improved efficacy of immunotherapy in GE cancers. The impact of tumor molecular alterations on PD-L1 expression is still not well-studied. We aimed to characterize specific molecular features of tumors with different CPS levels in GE cancers. **Methods:** 2,707 GE tumors [1,662 gastric/GE junction adenocarcinoma (GA), 856 esophageal adenocarcinoma (EA), 75 esophageal squamous (ES) and 114 GE unspecified] collected between 2000.8 and 2019.7 were analyzed using NextGen DNA sequencing (NGS), immunohistochemistry (IHC) and fragment analysis (FA) (Caris Life Sciences, Phoenix, AZ). Tumor mutation burden (TMB) was calculated based on somatic nonsynonymous missense mutations. dMMR/MSI status was evaluated by a combination of IHC, FA and NGS. PD-L1 expression measured by IHC (22c3) was evaluated by CPS scores. Molecular alterations were compared in three groups (CPS $\geq$ 10, H; CPS = 1~9, M; CPS = 0, L) using Fisher-Exact or Chi-square and adjusted for multiple comparison by Benjamini-Hochberg. Significance was determined by adjusted (adj) $p < .05$. **Results:** Overall, CPS-H, M, and L were seen in 18% (n = 494), 28% (n = 765) and 53% (n = 1,448) of GE tumors respectively. CPS-H was the most prevalent in ES (43%) followed by GA (19%) and lowest in EA (14%). Overall, TMB was similar between CPS-L and M, but was significantly increased in H (average TMB = 8.4 vs. 8.6 vs. 11 mt/MB, adj $p < .0001$); the effect was seen in EA and GA, but not in ES. An overall significant association between MSI/dMMR status and PD-L1 expression levels was seen (2%, 3.2% and 12% in CPS-L, M and H, adj $p < .05$) in GE tumors; the significance was seen in GA, but not in EA or ES. Amplifications of *PD-L1* (H: 1.5%, M: 0.1% and L: 0) and *PD-L2* (H: 1.1%, M: 0.1%, L: 0) were the highest in CPS-H, while *ASPSCR1* (H: 0, M: 0, L: 1%) and *TNFRSF14* (H: 0, M: 0.4, L: 2%) were the lowest (adj $p < .01$). Genes involved in epigenetic modification (top 5: *ARID1A*, *ASXL1*, *BCL9*, *BCOR*, *CREBBP*), MAPK (*KRAS*, *MAP2K1*) and mismatch repair (*MLH1*, *MSH6*) had the highest mutation rates in CPS-H, compared to M and L ($p < .0001$). In contrast, *CDH1* had higher mutation rates in CPS-L (12%), compared to M and H (5% and 5%) ($p < .0001$). **Conclusions:** This is the largest study to investigate the distinct molecular landscape of pts with different PD-L1 expression levels in GE cancers. Our data may provide novel insights for pt selection (e.g. pts with gene mutations involved in epigenetic modification) and the development of rational combination immunotherapy (e.g. drugs targeting MAPK pathway). Pembrolizumab with trastuzumab and chemotherapy (PTC) in HER2-positive metastatic esophagogastric cancer (mEG): Plasma and tumor-based biomarker analysis. *First Author: Steven Brad Maron, Memorial Sloan Kettering, New York, NY*

Background: Pembrolizumab can be safely combined with trastuzumab and chemotherapy and has promising activity with median OS 27 months and 91% objective response rate in HER2-positive mEG cancer irrespective of PD-L1 status (NCT02954536; Janjigian ESMO 2019). Tumor biopsies and blood samples were collected in this phase II trial to identify molecular and immune predictors of response and resistance to PTC. **Methods:** Pre-treatment and post-progression biopsies were analyzed using WES and IHC (HER2, PD-L1). Peripheral blood was collected pre-treatment, every 9 weeks on-treatment and at progression for plasma ctDNA (Guardant 360, Guardant Health, Redwood, CA). Tumor-matched DNA alterations were identified by correlating ctDNA and solid tumor WES results. Landmark PFS analysis was used to compare ctDNA clearance status at 9 weeks post-treatment. **Results:** Baseline ctDNA was analysed from 31 of 37 patients of whom 84% (26/31) had tumor-matched ctDNA detected at baseline. Patients who cleared ctDNA at 9 weeks (n = 17/23) achieved a longer median PFS than those who did not - mPFS 12.3 months (95% CI 7.44-NA vs 3.9 months (95% CI 2.01-NA) (log-rank $p = 0.02$). On serial blood monitoring of 16 patients with eventual radiographic progression, ctDNA re-appearance preceded CT detection in 8 (50%) patients. WES was completed in 31 patients with pre-treatment, and 12 patients post-progression, including matched samples from 10 patients. Loss of HER2 over-expression/amplification was noted in 44% (7/16) of post-progression samples by IHC/FISH (2 IHC 0/1, 5 FISH-). In paired post-progression samples on WES, we observed loss of *ERBB2* in 2 patients, and new amplifications of *CCND1/3, FGF3/4/19, CDK6/12, KRAS, MYC*, and *MET*, as well as mutations in *KRAS, PIK3CD and PIK3RA*. Plasma analysis at progression demonstrated copy number increases and/or new amplifications in *MET*, *CKD6*, *PIK3CA*, *KRAS*, *FGFR2*, *EGFR* and *CCDN1* as well as *KRAS*, *RB1*, *PTEN*, *NF1, NOTCH1*, *BRAF*, and *FGFR1* mutations. **Conclusions:** The majority of patients with previously untreated HER2 positive mEG have detectable plasma ctDNA at baseline. The re-appearance of ctDNA during therapy may serve as an early predictor of progression and help identify genetic drivers of acquired resistance. Loss of *ERBB2* over-expression/amplification and activating MAPK alterations occur at PTC progression. Evaluation of tumor immune environment by multiplex IHC and additional ctDNA analysis is underway. 4560 Poster Session (Board #168), Fri, 8:00 AM-11:00 AM

A phase II study of efficacy and safety of RC48-ADC in patients with locally advanced or metastatic HER2-overexpressing gastric or gastroesophageal junction cancers. *First Author: Zhi Peng, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China*

Background: RC48-ADC is an antibody-drug conjugate (ADC) drug comprised of a novel humanized anti-HER2 IgG1, a linker, and a microtubule inhibitor, MMAE. The MoA included inhibition of HER2 signal pathway and cytotoxicity of MMAE. RC48-ADC has demonstrated promising anti-tumor activity in preclinical and early clinical studies. The current study is designed to evaluate the efficacy and safety of RC48-ADC in heavily treated patients with HER2-overexpressing (IHC 2+ or 3+) gastric or gastro-esophageal junction cancers. **Methods:** This is an open-label, multicenter, single-arm, phase II study. Eligibility criteria include: histologically confirmed gastric or gastro-esophageal junction cancers, HER2-overexpression (IHC 2+ or 3+), ECOG PS 0-1, post-to ≥2 prior systemic treatment. The patients received RC48-ADC, 2.5 mg/kg, q2w until disease progression, unacceptable toxicity, withdrawal, or study termination. The primary endpoint was ORR. PFS, OS, and safety were also evaluated. **Results:** Patient enrollment started in July 2017, and completed in November 2019. By the data cut-off date on 17-Dec-2019, 127 patients were enrolled. The median age was 58 years. At baseline, 59 patients (46.5%) had received ≥ 3 lines prior treatment. For the overall 127 patients, the investigator-assessed confirmed ORR was 18.1% (95% CI: 11.8%, 25.9%). Sub-group ORR was 19.4% and 16.9% for the patients post to 2 lines and ≥ 3 lines, respectively. For the 111 patients who were monitored for ≥ 2 cycles of efficacy assessments (i.e. 12 weeks), the ORR was 20.7% (95% CI: 13.6%, 29.5%). For the 127 patients, the mPFS was 3.8 months (95% CI: 2.7, 4.0, 89 events [70.1%]) and the mOS was 7.6 months (95% CI: 6.6, 9.2, 52 events [40.9%]). The most commonly reported treatment-related AEs were leukopenia (52.0%), alopecia (51.2%), neutropenia (48.0%), and fatigue (42.5%). **Conclusions:** RC48-ADC demonstrated a clinically meaningful response and survival benefit in the heavily treated patients with HER2-overexpressing gastric or gastro-esophageal junction cancers. The safety profile was in line with the previously reported data of RC48-ADC. RC48-ADC showed positive benefit/risk ratio for the target population. Clinical trial information: NCT03556345. Research Sponsor: RemGen, Ltd.

4561 Poster Session (Board #169), Fri, 8:00 AM-11:00 AM

Personalized antibodies for gastroesophageal adenocarcinoma (PANGEA): Secondary and final primary efficacy analyses. *First Author: Daniel V.T. Catenacci, University of Chicago Medical Center and Biological Sciences, Chicago, IL*

Background: Targeted therapies (tx) have had limited benefit in advanced (aGEA) due to baseline spatial (primary vs metastatic tumor PT/MT) & temporal molecular heterogeneity (BMH/TMH). We previously reported PANGEA methods & results: 35% BMH rate & 1^{O} OS results achieving 1yr OS of 66% & mOS of 16.4 months (m) using the personalized tx strategy (Catenacci *et al.* GI ASCO 2020 Abstr356). Here we will report the TMH rates at progressive disease points (PD1 & PD2), ORR/PFS/DCR in each of 3 tx lines, time to strategy failure (TTF), & updated OS/safety. **Methods:** PANGEA enrolled newly diagnosed aGEA pts who then received up to 3 cytotoxic (cx) tx lines (L). Baseline tissue biomarker profiling (BP) was mandated on PT/MT & PD1/PD2, & ctDNA analysis throughout. After initiating 1L cx & upon learning MT BP results, antibody (AN) was added by a predefined prioritized tx algorithm incorporating tissue & blood BP (Table). At PD1, pts went to 2L cx + initial AN. Upon results of PD1 BP, pts changed AN only if BP evolved per tx algorithm. The same was done at PD2. The 1^{O} endpoint was 1yr OS; enrolling 68 pts provided 80% power to detect a 63% 1yr OS compared to historical 50% 1yr OS (HR 0.67), using a 1-sided test (0.10 alpha). **Results:** 80 pts were enrolled, & 68 tx'd per protocol. At data cut-off 2/1/20, 15 pts were still on trial with only 2 of these pts on tx <12m (8 pts in 1L, 5 in 2L, 2 in 3L). All 68 pts had at least 1 dose of 1L tx, 87% 2L tx, & 36% 3L tx. AN assigned by the tx algorithm at 1L, OS, TTF, & $ORR_1/PFS_1/DCR_1$ of 1L tx are shown in Table; 2L & 3L ORR/DCR outcomes will be shown. The 3yr & 4yr OS rates were 12% & 8%. TMH leading to molecular subgroup change by tx algorithm was 51% after 1L & 36% after 2L; details & results by subgroup will be provided. Any grade >3 non-heme tox thru all 3 tx lines was seen in 25% of pts. **Conclusions:** PANGEA showed superior 1^{O} & 2^{O} endpoint efficacy, even when excluding HER2- pts, compared to historical outcomes. Clinical trial information: NCT02213289. Research Sponsor: U.S. National Institutes of Health, Other Foundation, U.S. National Institutes of Health.

Health-related quality-of-life assessment in accordance with reconstruction procedures for distal gastrectomy for stage I gastric cancer using data from JCOG0912. *First Author: Keiichi Fujiya, Division of Gastric Surgery, Shizuoka Cancer Center, Shizuoka, Japan*

Background: There are three major reconstruction methods after gastrectomy for distal gastric cancer; Billroth-I (B-I), Roux-en-Y (RY) and pylorus-preserving gastrectomy (PPG). These procedures can affect postoperative health-related quality-of-life (HRQoL), but the method is often selected due to physician's preference or each institutional policy without solid evidence. We aimed to explore differences in HRQoL after each reconstruction procedure selected in JCOG0912, a phase III noninferiority trial comparing open and laparoscopic distal gastrectomies for stage I gastric cancer. **Methods:** Among 33 institutions participated in JCOG0912, 4 major cancer centers were selected for HRQoL assessment. HRQoL was assessed using the EORTC QLQ-C30 and STO22 before (baseline) and at 1, 3, 12, and 36 months after surgery as preplanned exploratory analysis. **Results:** Excluding 2 patients who didn't answer the questionnaire, 590 patients were analyzed in this study. For reconstruction, B-I was performed for 222 patients (37.7%), RY for 178 (30.2%) and PPG for 189 (32.1%). Proportion of the opted reconstruction procedures was not different in open and laparoscopic gastrectomies. Global health status (GHS) scores of QLQ-C30 were not different among 3 groups at any time point. In comparison of B-I and RY, B-I was better than RY in constipation, while RY was better than B-I in diarrhea and reflux symptoms. In comparison of B-I and PPG, B-I was better than PPG in constipation and reflux symptoms, while PPG was better than B-I in diarrhea. When comparing RY and PPG, RY was better than PPG in constipation and reflux symptoms, while PPG was better than RY in taste (table). **Conclusions:** GHS scores were similar regardless of the reconstruction procedure, however postoperative symptoms including reflux, constipation, and diarrhea were various according to reconstruction methods. Research Sponsor: Japan National Cancer Center, Ministry of Health, Labour and Welfare of Japan, Japan Agency for Medical Research and Development.

Cabozantinib (cabo) combined with durvalumab (durva) in gastroesophageal (GE) cancer and other gastrointestinal (GI) malignancies: Preliminary phase Ib CAMILLA study results. *First Author: Anwaar Saeed, University of Kansas Medical Center, Kansas City, KS*

Background: Cabo targets multiple tyrosine kinases, including VEGFR, MET, and AXL, and has been reported to show immunomodulatory properties that may counteract tumor-induced immunosuppression, providing a rationale for combining it with PD-L1 inhibitors like durva. We conducted a phase Ib GI basket trial to evaluate the safety & efficacy of this regimen in advanced GE adenocarcinoma (GEA), colorectal cancer (CRC), & hepatocellular carcinoma (HCC). **Methods:** Patients received cabo and durva in 3+3 dose escalation then expansion to determine the dose limiting toxicity (DLT), Recommended Phase 2 Dose (RP2D), ORR, PFS & OS. Cabo was dosed at 20mg QD, 40mg QD, and 60mg QD in the first, second, and third cohorts respectively. Durva was dosed at 1500mg IV Q4W in all cohorts. DLT window was 28 days. Scans were obtained every 8 wks. Treatment beyond progression was allowed. **Results:** 23 Pts (16 M, 7 F), median age 60 yrs (range 33-79) were currently enrolled. 12 in the dose escalation cohort with cabo 20mg (6 pts), or 40mg (3 pts), or 60mg (3 pts). 11 pts enrolled in the dose expansion cohort with cabo 60mg. 8 pts had GEA, 13 pts had CRC, and 2 pts had HCC. Median number of prior chemotherapies was 3 (range 1-3). 3 pts were not evaluable for DLT due to missing ≥30% of DLT window doses, not related to DLT. No DLTs were observed. Drug-related Grade (G) 1&2 AEs included fatigue (83%), abnormal LFTs (39%), anorexia (26%), diarrhea (26%), nausea (13%), & hand foot syndrome (13%). One pt each developed drug related G3 hypertension, hyperthyroidism, thrombocytopenia, & thromboembolic event, all occurring outside the DLT window. 19 pts were evaluable for response: 4 PR (2 GEA & 2 CRC), 12 SD, 3 PD; ORR 21%; clinical benefit rate 84%; median time to PD 16 wks (range 8-40+). **Conclusions:** RP2D was determined to be Cabo 60mg QD and Durva 1500mg Q4W. Enrollment to phase I dose expansion is ongoing. RP2D may be adjusted based on additional experience & long-term tolerability. Early efficacy data was encouraging. This is an investigator-initiated trial funded by Exelixis & Astrazeneca. Clinical trial information: NCT03539822. Research Sponsor: AstraZeneca and Exelixis.

4564 Poster Session (Board #172), Fri, 8:00 AM-11:00 AM

Final results of a phase III randomized trial of comparison of three paclitaxel-based regimens concurrent with radiotherapy for patients with local advanced esophageal squamous cell carcinoma. *First Author: Dashan Ai, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Paclitaxel (PTX) is effective in concurrent chemoradiation (CCR) against esophageal squamous cell carcinoma (ESCC). Which regimen, among cisplatin (DDP) (TP), carboplatin (CBP) (TC) or 5-Fu (TF) in combination with PTX concurrent with radiotherapy, provides best prognosis with minimum adverse events (AEs) is still unknown. **Methods:** The study compared two pairs of regimens: TF vs. TP and TF vs. TC concurrent with radiotherapy. Patients with histologically confirmed ESCC (clinical stage II, III or IVa) 20 were randomized into the three groups. Patients in TP group were treated with 2 cycles of CCR followed by 2 cycles of consolidation chemotherapy with TP (DDP 25 mg/m2/d, d1-3, PTX 175 mg/m2, d1, q28d). Patients in TF group were treated with 6 cycles of TF (5-Fu 300 mg/m2, civ 96h, PTX 50 mg/m2, d1, qw) in CCR followed by 2 cycles of TF (5-FU 1800 mg/m2, civ 72h, PTX 175 mg/m2, d1, q28d) in consolidation chemotherapy. Patients in TC group were treated with 6 cycles of TC (CBP AUC = 2, d1, PTX 50 mg/m2, d1, qw) in CCR followed by 2 cycles of TC (CBP AUC = 5, d1, PTX 175 mg/m2 d1, q28d) in consolidation chemotherapy. The radiotherapy dose in all groups was 61.2 Gy delivered in 34 fractions. The primary endpoint was overall survival (OS) and the secondary endpoints were progression-free survival (PFS) and adverse events. **Results:** Between July 2015 and January 2018, 321 ESCC patients in 11 centers were enrolled. Median follow-up of patients who survived was 36.3 months (IQR 27.9–45.2). The 3-yr OS was 58.2% in TF group and 59.5% in both TP and TC group. (TF vs. TP, HR 0.935, 95% CI 0.627-1.417; TF vs. TC, HR 0.881, 95% CI 0.578-1.342; $P = 0.839$). No significant differences were found in 3-yr PFS between TF, TP and TC groups [48.3% vs. 45.5%(TP) or 48.3% (TC). $P = 0.820$]. TP group had a significant higher incidence of acute Grade 3/4 neutropenia [60.7% vs. 16.8%(TF) or 32.7%(TC)], thrombocytopenia [13.1% vs. 2.8%(TF) or 4.7%(TC)], anemia [5.6% vs. 1.9%(TF) or 3.7% (TC)], fatigue [10.3% vs. 1.9%(TF) or 0.9%(TC)] and vomiting [5.6% vs. 0%(TF) or 0.9%(TC))]than other two groups ($P< 0.05$). TF group had a significant higher incidence of Grade 3/4/5 esophagitis [11.2% vs. 0.9%(TP) or 4.7%(TC))]and pneumonitis [4.6% vs. 0%(TP) or 1.9% (TC)]than other two groups ($P< 0.05$). **Conclusions:** No statistical differences were found in OS and PFS among TF, TP and TC groups. TC might be an option used in CCR in ESCC patients with mild of side effects compared with other two groups, although it did not significantly prolong OS. Clinical trial information: NCT02459457. Research Sponsor: 2015 Prospective Clinical Research Fund of Fudan University Shanghai Cancer Center.

4565 Poster Session (Board #173), Fri, 8:00 AM-11:00 AM

Second primary malignancies in patients with clinical T1bN0 esophageal squamous cell carcinoma after definitive therapies: Supplementary analysis of the JCOG trial, JCOG0502. *First Author: Seiichiro Mitani, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: Esophageal squamous cell carcinoma (ESCC) is associated with synchronous or metachronous cancer at other primary sites. Previous studies have suggested that patients (pts) with ESCC are still at a high risk of second primary malignancies after definitive therapies. In particular, early-stage ESCCs result in good prognosis, which is associated with a higher risk of second primary malignancies. **Methods:** The JCOG0502 was a phase III trial, which included a randomized and a non-randomized part and compared esophagectomy with definitive chemoradiotherapy in clinical T1bN0 ESCC. We additionally reviewed data of all pts enrolled in the JCOG0502 for second primary malignancies. Lugol-voiding lesions (LVLs) were assessed in the noncancerous esophageal mucosa before the treatments. **Results:** Among 379 enrolled pts, 213 pts received esophagectomy and the remaining received chemoradiotherapy. Patient characteristics of overall cohort were as follows: male, 85%; median age, 63 (range, 41–75) years; upper- /middle- /lower thoracic esophagus, 11/63/27%; alcohol consumption history, 79%; smoking history, 66%; prevalence of no LVLs/several LVLs/many LVLs/unknown, 45/36/8/11%. With a median follow-up of 7.1 years, a total of 118 second malignancies were observed in 99 pts (26%). Cumulative incidences of second malignancies after 3, 5, 10 years were 9, 15, 36%, respectively. Most common primary tumor sites were head and neck (35%), followed by stomach (20%) and lung (14%). In multivariable analyses, several LVLs [hazard ratio (HR): 2.24, 95% confidential interval (CI): 1.32–3.81, vs. no LVLs] and many LVLs (HR: 2.88, 95% CI: 1.27–6.52, vs. no LVLs) were significantly associated with the development of second malignancies. Regarding the three most common types of cancers, 62 out of the 77 cancers (81%) were diagnosed in clinical stage 0–I. Seventeen pts died due to second primary malignancies. There were 4 and 3 deaths from head and neck and lung cancer, respectively. Whereas, mortality caused by stomach cancer was not observed. **Conclusions:** In the JCOG0502, the incidence of second malignancies was high, indicating that careful follow-up is required for ESCC pts even after treatment completion. The presence of LVLs in esophagus was identified as an independent predictive factor for second primary malignancies, which may be useful for surveillance strategies. Clinical trial information: UMIN000000551. Research Sponsor: Japanese Ministry of Health, Labour and Welfare.

4566 Poster Session (Board #174), Fri, 8:00 AM-11:00 AM

Prognostic role of mismatch repair deficiency (MMR-D) in patients receiving first-line fluoropyrimidine and platinum (FP) doublet chemotherapy for metastatic and locally advanced unresectable gastric cancers (GCs). *First Author: Eo Jin Kim, Asan Medical Center, Seoul, South Korea*

Background: Although chemotherapy has been suggested to have the potential to cause a detrimental effect on treatment outcomes of localized GC with MMR-D, it remains unclear whether chemotherapy for metastatic/recurrent/unresectable GC with MMR-D would also adversely affect the survival outcomes. Anti PD-1 antibody (Ab) showed remarkable efficacy in patients with MMR-D and is being actively investigated in combination with cytotoxic chemotherapy. Hence, we aim to evaluate the impact of MMR status on treatment outcomes of advanced GC. **Methods:** We reviewed our database to identify all patients with HER2 negative, metastatic, recurrent, and locally advanced unresectable GC who received FP doublet chemotherapy from January 2015 to August 2018. For those who had an available tumor tissue, MMR protein expression was assessed by immunohistochemistry (IHC) and correlated with clinical characteristics and treatment outcomes. **Results:** Out of 895 patients identified from the database, 543 underwent IHC testing for MMR. The median age was 58 years (range, 24 – 86) with male comprising 64.0%. Most patients had initially metastatic disease (n = 382, 70.3%) followed by recurrent (n = 127, 23.3%) and locally advanced unresectable disease (n = 34, 6.3%). MMR-D was found in 4.4% (n = 24) and associated with age ≥ 65 years (50% vs. 29.9%; P = 0.04) and signet ring cell histology (0% vs. 17.7%, P = 0.01). According to our prognostic model (Koo DH et al, 2011), only 4.2% of patients with MMR-D were classified as Poor-risk group (vs. 16.8% of patients with MMR-P, $p= 0.10$). In the Good-risk group, patients with MMR-D (n = 10) had significantly shorter median progression-free survival (PFS, 6.0 vs. 9.0 months, P = 0.05) and overall survival (OS, 10.1 vs 20.9 months, P = 0.047) compared to those with MMR-P (n = 188), while there was no significant difference in survival outcomes depending on MMR status in the Moderate and Poor-risk groups. In multivariate analysis for OS, MMR status was a significant prognostic factor for OS in Good-risk group GC patients. **Conclusions:** GC patients with MMR-D had poorer median PFS and OS than those with MMR-P on standard cytotoxic chemotherapy in the Good-risk group. Thus, for Good-risk GC patients with MMR-D, anti PD-1 Ab alone might be considered rather than combining cytotoxic chemotherapy. Further investigation with next-generation sequencing is in process to determine underlying molecular mechanisms and will be presented in ASCO 2020. Research Sponsor: None.

4567 Poster Session (Board #175), Fri, 8:00 AM-11:00 AM

HER2 heterogeneity in adenocarcinoma of the distal esophagus and stomach. *First Author: Rogier Butter, Amsterdam UMC - University of Amsterdam, Amsterdam, Netherlands*

Background: Patients with HER2 positive adenocarcinoma of the esophagus or stomach are eligible for HER2 targeted therapy, which can improve survival in selected patients. Previous research shows that HER2 gene amplification and HER2 overexpression is frequently heterogeneous within these tumors. Biopsies taken from heterogeneous tumors for predictive testing may therefore result in false-negative outcomes. The objective of this study was to assess HER2 amplification and expression in biopsies and paired resection specimens with adenocarcinoma of the esophagus or stomach, from patients who did not receive neoadjuvant systemic therapy. **Methods:** Paired biopsies and resection specimens of patients with adenocarcinomas of the esophagus or stomach were retrospectively selected. Immunostaining was performed on all samples using antibody 4B5 (Ventana Medical Systems) and *Silver-In-Situ-Hybridization* was performed in selected cases. Scoring for HER2 was performed according to the method described by Hofmann et al. (2008). **Results:** We included 378 cases for analysis. In both biopsies and resection specimens 14% of the cases were HER2 positive. Intratumor heterogeneity in HER2 positive tumors was present in 45% (n= 24/53) in biopsies and 75% (n= 39/52) in resection specimens. In HER2 positive resection specimens, 65% (n= 34/52) of paired biopsies were also positive. In the 18 remaining discordant tumors (resection HER2 positive, biopsy negative), intratumor heterogeneity was present in 16/18 cases. For HER2 negative resection specimens all paired biopsies were also HER2 negative. SISH was performed in 110 tumors. Agreement of HER2 gene amplification between biopsy and resection specimens was observed in 86% (n = 95/110). Five HER2 negative biopsies were positive in the resection specimen. **Conclusions:** The results of this study indicate that predictive HER2 assessment in adenocarcinoma of the esophagus or stomach can lead to false negative results based on biopsies. As a result, patients with HER2 positive tumors can unintentionally be denied neoadjuvant HER2 targeted therapy. The set of patients investigated in this present study is unique because of the absence of any systemic and/or radiation therapy between the biopsy and the resection of the tumor. Hopefully these results can help in developing methods for improved patient selection for HER2 targeted therapy. Research Sponsor: F. Hoffmann-La Roche AG.

4568 Poster Session (Board #176), Fri, 8:00 AM-11:00 AM

PD-L1 positive esophagogastric (EG) cancer is associated with distinct bacteria. *First Author: Steven Brad Maron, Memorial Sloan Kettering, New York, NY*

Background: Pembrolizumab is approved for chemotherapy-refractory PD-L1 CPS >1 mEG cancer. In clinical trials, pts with MSI-H, EBV+ and PD-L1 CPS >10 EG cancers derive the greatest benefit with immune checkpoint blockade (ICB). Pre-clinical data suggest that the gut microbiome modulates response to ICB; however, the EG cancer microbiome has not been characterized in EG cancer with respect to PD-L1 and MSI-H status. Therefore, we evaluated the EG tumor microbiome in the context of PD-L1 expression in order to define biologically unique EG tumor phenotypes for future therapeutic development. **Methods:** Clinical and pathologic characteristics, including age, stage at diagnosis, tumor PD-L1 CPS, HER2 IHC, EBV ISH, genomic analysis, treatment history and survival status were reviewed. CPS was stratified *a priori* using cutoffs of >1/>10/>20 due to biologic differences. MSK-IMPACT, a capture-based next-generation sequencing platform that detects mutations, copy-number alterations, and select fusions was used to detect non-human bacterial reads identified in the NCBI NT database. Bacterial species found in >2 pts were analyzed and stratified by highest PD-L1 CPS score for each individual patient (Vanderbilt, AMP 2018) and Bonferroni correction was used for odds ratio (OR) confidence intervals where each unique species was considered an independent hypothesis. **Results:** Molecular data from 311 pts was clinically annotated. PD-L1 results (Table) correlated with bacterial species identified on tumor sequencing. PD-L1 CPS >1 was associated with *Selenomonas sputigena* (OR: 8.2, 95% CI:1.2-53.6), and PD-L1 CPS >20 was associated with presence of *Bifidobacterium dentium* (OR: 7.4, 95% CI:1.1-48.5) and *Prevotella denticola* (OR: 4.2, 95% CI: 1.1-16.6) after multiple comparison correction for the 166 bacterial species identified in the cohort. No differences were seen between PD-L1 < 10 vs >10. Four patients were also found to have EBV+ tumors using this approach, including the 1/54 patients identified by EBER ISH. **Conclusions:** PD-L1 > 20 EG cancer represents a biologically unique subset, enriched for *Bifidobacterium dentium* and *Prevotella denticola*. Correlation between PD-L1 expression, microbial and immune environment, and survival on ICB is underway. Research Sponsor: U.S. National Institutes of Health, Conquer Cancer Foundation of the American Society of Clinical Oncology.

PD-L1	All Pts (%) n = 313	MSI-H (%) n = 16	EBV+ (%) n = 4
CPS < 1	152 (49)	2 (12.5)	0
CPS 1-9	92 (29)	2 (12.5)	1 (25)
CPS 10-19	28 (9)	4 (25)	1 (25)
CPS >20	41 (13)	8 (50)	2 (50)

4569 Poster Session (Board #177), Fri, 8:00 AM-11:00 AM

Radiotherapy after esophageal cancer stenting (ROCS): A pragmatic randomized controlled trial evaluating the role of palliative radiotherapy in maintaining swallow. *First Author: Anthony Thomas Byrne, Velindre Cancer Centre, Cardiff, United Kingdom*

Background: Most patients with oesophageal cancer (OC) present with incurable disease; 80% of new cases, and deaths, occur in low and middle income nations. Median survival for advanced disease is 3-5 months, a majority requiring intervention for dysphagia. Insertion of self expanding metal stents is the commonest way of palliating, but dysphagia may recur within three months owing to tumour progression. Evidence reviews have called for trials of combination treatment for OC dysphagia. The ROCS study (funding - UK NIHR programme) examined effectiveness of palliative radiotherapy, following stent, in maintaining swallow. It also examined impact on quality of life, bleeding events, and survival. **Methods:** A multicentre RCT with follow up monthly for a year. Patients referred for stent insertion as primary management of dysphagia related to incurable OC were recruited in secondary care, with all planned follow up at home. Patients were randomised 1:1 to stent insertion alone or stent insertion plus palliative radiotherapy at a dose of 20Gy in five fractions or 30Gy in ten fractions. Primary outcome was difference in proportions of participants with recurrent dysphagia at 12 weeks, defined as deterioration of 11 points or more in the dysphagia scale of the EORTC QLQ-OG25 questionnaire. Secondary outcomes included quality of life, bleeding risk, survival. **Results:** 220 patients were randomised Dec 2013-Aug 2018 at 23 UK sites. Addition of radiotherapy did not reduce the proportion of primary events at 12 weeks: 49% in control arm vs 45% in the intervention, adjusted OR 0.82 (95%CI 0.40-1.68; p = 0.587) and it was less cost effective. Sensitivity analyses did not alter the results. Dysphagia deterioration-free survival was similar in both arms: adjusted HR 0.92 (95%CI 0.68-1.26; p = 0.618). Median survival was 19.7 weeks in control arm and 18.9 weeks in the intervention. Those in the radiotherapy arm had significantly fewer bleeding events (18.6% compared to 10.3%), giving a number needed to treat of 12. **Conclusions:** Palliative external beam radiotherapy is widely accessible to patients with advanced cancer. ROCS is the largest trial assessing its role in combination with stenting for OC dysphagia, and is the first to prospectively assess impact on bleeding risk. It demonstrates no reduction in risk of dysphagia recurrence at 12 weeks, nor impact on survival. Reductions in bleeding events should be considered in the context of patient described trade offs of fatigue and burdens of attending hospital. Clinical trial information: NCT01915693. Research Sponsor: UK National Institute for Health Research Health Technology Assessment (HTA) Programme.

Identification of SLX4 as the most frequently mutated gene in homologous recombination deficiency in Asian gastric cancer. *First Author: Shi Zhang, Department of Gastrointestinal Surgery, Second Affiliated Hospital, Guangzhou Medical University, Guangzhou, China*

Background: Gastric cancer is the third most common malignancy worldwide. Homologous recombination (HR) is a type of genetic recombination, and homologous recombination deficiency (HRD) is highly involved in multiple types of cancers and can predict response to anticancer therapies. However, homologous recombination deficiency is not well characterized in patients with Asian gastric cancer. **Methods:** 196 Asian patients with gastric cancer were analyzed in this study. A list of 102 genes related to HRD was compiled based on previous literature. Haplox 605-gene panel was used to capture the sequencing library. Mutations related to HRD were analyzed following next-generation sequencing. In addition, tumor mutational burden (TMB) was calculated by dividing the total number of mutations by the size of the coding region. The correlation analysis between HRD and TMB was also conducted. **Results:** In total, 43 (21.94%) of 196 Asian patients with gastric cancer harbored at least one HRD gene. The top 10 mutant HRD genes included *SLX4* (3.57%), *ATR* (2.04%), *RECQL* (1.53%), *NBN* (1.53%), *ERCC4* (1.53%), *BAP1* (1.53%), *ATM* (1.53%), *RAD54L* (1.02%), *BRCA1* (1.02%) and *PARP1* (1.02%). In addition, the occurrence of HRD mutations was significantly correlated with a higher TMB. The median TMB of HRD group (8.28 muts/Mb) was significantly higher than that of the Non-HRD group (3.07 muts/Mb) ($p < 0.01$). The overall upper quantile value (4.80 muts/Mb) was used to screen patients with high TMB (TMB-H). The TMB-H in HRD group was significantly higher than the Non-HRD group (44.19% VS 17.92%, $p < 0.01$). **Conclusions:** Our study described that *SLX4* was the most frequently mutated HR-related gene in Asian gastric cancer. Moreover, the positive correlation with homologous recombination deficiency (HRD) and tumor mutational burden (TMB) was observed in these patients. Research Sponsor: None.

4571 Poster Session (Board #179), Fri, 8:00 AM-11:00 AM

A novel gene signature for predicting response to chemoradiotherapy in locally advanced esophageal adenocarcinoma. *First Author: Divya Sahu, Department of Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of City of Hope, Monrovia, CA*

Background: While neoadjuvant chemoradiotherapy (CRT) has emerged as an important treatment modality in patients with locally advanced esophageal adenocarcinoma (EAC), ~60%-70% of patients do not respond to such treatments; but are exposed to their toxicity nonetheless. This highlights the clinical need for the development of biomarkers that can robustly predict response to CRT and spare others from the toxicity and expense associated with these treatments. Herein, we systematically and comprehensively identified a biomarker signature that predicts response to neoadjuvant therapy in EAC patients. **Methods:** A cohort of 31 EAC patients treated with chemotherapy or chemoradiotherapy was assembled, with a majority of patients receiving carboplatin, paclitaxel and concurrent radiotherapy. Specifically, we performed a capture based targeted sequencing in *paired* biopsy specimens obtained at baseline and 3-6 weeks post-treatment. In addition, we also analyzed the predictive potential of a panel of immune-related genes (TIM3, LAG3, IDO1 and CXCL9) in these matched pre- and post-treatment tissues. **Results:** In our cohort, based upon pathologic response to neoadjuvant CRT, 8 EAC patients were categorized as non-responders, while 23 were deemed as responders to CRT. Among responders, the most frequently mutated genes were MKI67, SYNE1, PCLO, RECQL4, MSH3, NOTCH2, ILR7, CIITA, LRRK2 and EML4, and the overall tumor mutation burden (TMB) was significantly reduced for these genes in post-treatment samples (*P*=5.73E-03). Similarly, in non-responders NLRP1, MAP3K1, ASMTL, and ALK harbored frequent mutations, and the TMB was significantly reduced for these genes in post-treatment samples (*P*=5.57E-03). We compared responders and non-responders from the pre-treatment samples and identified differentially mutated genes including EPHA5, ZNF217, RELN, PALB2 and MYO18A. Similarly, responders had all four immune-related genes significantly up-regulated in post-treatment samples than pre-treatment samples. We constructed a risk-stratification model that comprised of mutational score from 5 differentially mutated genes, together with 4 immune-related genes, which achieved an AUC of 0.96 in predicting response to CRT in EAC patients (*P*=1.03E-04). **Conclusions:** Using a systematic biomarker discovery approach, we have developed a novel biomarker signature that robustly predicts response to CRT in EAC patients and has a significant potential for personalized management of locally advanced EAC patients. 4572 Poster Session (Board #180), Fri, 8:00 AM-11:00 AM

Durvalumab following multimodality therapy for locally advanced esophageal and GEJ adenocarcinoma: Updated survival and early translational results from Big Ten Cancer Research Consortium Study. *First Author: Hirva Mamdani, Barbara Ann Karmanos Cancer Institute, Detroit, MI*

Background: Concurrent chemoradiation(CRT) followed by esophagectomy is a standard of care for locally advanced esophageal(LA-EAC) and GEJ adenocarcinoma. Approximately 50% of patients(pts) experience disease relapse within the 1st yr after treatment(tx) completion. Immune checkpoint inhibitors have activity in metastatic PD-L1 positive EAC. Preclinical studies have shown radiation +/- chemotherapy upregulates PD-1/PD-L1 pathway. **Methods:** We conducted a phase II trial evaluating safety and efficacy of PD-L1 inhibitor durvalumab(durva) in pts with LA-EAC and GEJ adenocarcinoma who had residual disease in surgical specimen after neoadjuvant CRT and R0 resection. Pts received durva 1500mg IV every 4 weeks for up to 1yr. **Results:** Initially 24 pts were enrolled, study was expanded to enroll additional 13 pts. Median age: 61yrs (range, 43-73). 31 received carbo/paclitaxel and 6 received cis/5-FU concurrently with RT. 24(64.9%) pts had positive lymph nodes(LN) at the time of surgery following CRT: N3(n = 3,8.1%), N2(n = 10, 27%), N1(n = 11,29.7%).17 pts relapsed: 11 on tx, 6 had late relapses. 3/5 late relapses were locoregional and were re-treated with chemo-RT. Remaining relapses were systemic with lung and LN being the most common sites. 2 of 3 pts who developed grade 3 irAEs are alive and disease free at 17 and 23 mo. RFS/OS:1 yr- 79.2%/95.5%, 2yr-55.5%/67.4%. 20/37 pts have HER-2 status available: 5/6 HER2 positive pts had disease relapse, 1 is undergoing tx. Molecular profiling is available on 8 relapsed pts: all were microsatellite stable with low TMB and PD-L1 $<$ 10% CPS. Mutations in DNA repair genes (*ARID1A, ATM, ATR, CHEK2*), and *PIK3CA* E542K were more prevalent among late relapsing pts. Circulating tumor cells (CTCs) analysis is available for 10/37 pts. 4/5 pts where CTCs increased from C1 to C4 had disease relapse. Molecular profiling of the remaining pts and correlation of PD-L1 expression, TMB, specific genes mutations, CTCs, and Immunoscore with outcomes with durva is being evaluated will be presented at the meeting. **Conclusions:** Adjuvant durva following trimodality therapy for LA-EAC and GEJ adenocarcinoma improved 1-yr RFS to 79.2% compared to historical rate of 50%.2-yr RFS and OS data are encouraging in this high risk pt population. HER-2 positivity may be associated with lack of benefit from durva. Mutations in DNA repair genes are prevalent in pts with delayed relapse. Rise in CTCs during durva tx may be an early marker of disease relapse. Clinical trial information: NCT02639065. Research Sponsor: AstraZeneca/MedImmune.

4574 Poster Session (Board #182), Fri, 8:00 AM-11:00 AM

Hepatic arterial infusion of oxaliplatin plus raltitrexed in patients with unresectable hepatocellular carcinoma (HAIROX): A phase II, single-arm, prospective study. *First Author: Shiguang Chen, Fujian Cancer Hospital, Fuzhou, China*

Background: Chemoembolisation and oral sorafenib are the recommended treatment for unresectable hepatocellular carcinoma (HCC); however, some patients respond poorly to these. Hepatic arterial infusion (HAI) chemotherapy may have potential benefit in these patients. We aimed to investigate the efficacy and safety of HAI of oxaliplatin plus raltitrexed in patients with unresectable HCC. **Methods:** In this phase II, single-arm clinical trial, we enrolled patients aged 18–70 years with unresectable HCC at the Fujian Cancer Hospital (China). We performed HAI with oxaliplatin (100 mg/m^2 for 4 hours) and raltitrexed (3 mg/m^2 for 1 hour). Treatment was repeated every 3 weeks and was discontinued either because of disease progression, unacceptable toxicity levels, or refusal of further treatment. We used Simon's two-stage design. The primary endpoint was the objective response rate according to the Response Evaluation Criteria in Solid Tumors version 1.1. **Results:** Fifty-one patients were screened between January 5, 2018 and August 7, 2019. Of these, 39 patients (34 men and 5 women; median age, 53 years) were enrolled and included in the intention-to-treat population. Objective response was achieved in 18 (51.4%) of 35 patients in the per-protocol population and in 18 (46.2%) of 39 patients in the intention-to-treat population. Treatment-related grade 4 adverse events or deaths were not reported, and the observed grade 3 adverse events were elevated aspartate aminotransferase levels (5[12.8%]), elevated alanine aminotransferase levels (1 [2.6%]), leukopenia (1 [2.6%]), thrombocytopenia (1 [2.6%]), and abdominal infection (1 [2.6%]). **Conclusions:** HAI of oxaliplatin plus raltitrexed showed promising efficacy and acceptable toxicity levels in patients unresectable HCC, and further evaluation is warranted. Clinical trial information: ChiCTR-OOC-17014182. Research Sponsor: None.

Treatment responses of HAI of oxaliplatin plus raltitrexed in unresectable HCC.

	Intention-to-treat population (n=39)	Per-protocol population (n=35)
Complete response	1(2.6%)	1(2.9%)
Partial response	17(43.6%)	17(48.6%)
Stable disease	13(33.3%)	13(37.1)
Overall response	18(46.2%)	18(51.4%)
Disease control	31(79.5%)	31(88.6%)

4575 Poster Session (Board #183), Fri, 8:00 AM-11:00 AM

Peripheral blood immune correlates associated with TGF-β inhibition (galunisertib) and stereotactic body radiotherapy (SBRT) in patients with advanced hepatocellular carcinoma (HCC). *First Author: Max Miller Wattenberg, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: TGF-β is a pleiotropic cytokine with immunosuppressive activity. In mouse models, blockade of TGF-β signaling enhances the activity of radiation and invokes T cell dependent anti-tumor immunity. We previously reported preliminary safety and efficacy results from a pilot study combining galunisertib (LY2157299), an oral TGF-β inhibitor, with SBRT for the treatment of patients with advanced HCC. Here, we investigate immunological mechanisms and potential biomarkers associated with therapeutic activity. **Methods:** Patients with advanced HCC who had progressed on or refused sorafenib were treated with galunisertib (150 mg PO BID) on days 1-14 of each 28-day cycle. SBRT (18 Gy) was delivered in a single dose between days 15-28 of cycle 1. Blood was collected at baseline, following two weeks of galunisertib and following SBRT for high-dimensional analysis using a 37-marker CyTOF panel. Patients were dichotomized based on best response as either progressor (PD) or non-progressor (PR+SD). The frequency of immune subsets was compared between groups. **Results:** Fifteen patients were enrolled and treated. One patient was not evaluable. The most common adverse event was grade 1 or 2 fatigue in 53% of patients. The only possibly-related grade 3 event was achalasia in one patient which coincided with disease progression. Two patients achieved a PR and six patients had SD (DCR 57%) with a median progression-free survival of 3.7 months and a median overall survival of 9.0 months. For most patients, regardless of outcome, galunisertib treatment was associated with a decrease in activated Ki67+ Treg cells. However, pre-treatment immune composition within the blood of progressors and non-progressors was distinct. At baseline, progressors had an increased frequency of naive-like CD8+ T cells, whereas non-progressors had an increased frequency of non-classical monocytes. After combination therapy, only non-progressors showed a significant increase in CD8+PD1+TIGIT+ T cells. **Conclusions:** Galunisertib combined with SBRT was well-tolerated with modest efficacy. Immune profiling of the blood revealed distinct pre- and post-treatment signatures that differentiated patients with progression versus non-progression. These findings show that the combination of anti-TGF-β therapy with radiation can mediate disease control and identify potential correlates of efficacy. Clinical trial information: NCT02906397. Research Sponsor: Lilly Oncology, Conquer Cancer Foundation of the American Society of Clinical Oncology, U.S. National Institutes of Health.

4576 Poster Session (Board #184), Fri, 8:00 AM-11:00 AM

IDH1 mutation detection in plasma circulating tumor DNA (ctDNA) and association with clinical response in patients with advanced intrahepatic cholangiocarcinoma (IHC) from the phase III ClarIDHy study. *First Author: Elia Aguado, Agios Pharmaceuticals, Inc., Cambridge, MA*

Background: Mutations in isocitrate dehydrogenase 1 (*IDH1*) are detected in ~13% of IHCs. Ivosidenib (IVO) is a first-in-class, oral inhibitor of the mutant IDH1 (mIDH1) protein. In ClarIDHy, a global, phase 3, double-blind study in previously treated patients with advanced m*IDH1* IHC (N = 186), IVO demonstrated an improvement in progression-free survival (PFS) vs placebo (hazard ratio 0.37, p $<$ 0.001) (Abou-Alfa et al., Ann Oncol 2019; NCT02989857). Feasibility of m*IDH1* detection in plasma ctDNA from patients with IHC was demonstrated and was highly concordant with mutation status in tumor tissue (Aguado-Fraile et al., Cancer Res 2019). This analysis was extended to the larger patient cohort from ClarIDHy, and longitudinal m*IDH1* detection from ctDNA was assessed and correlated with clinical response. **Methods:** Baseline plasma and tumor tissue samples were obtained before randomization; longitudinal plasma samples were collected on day 1 of each treatment cycle. m*IDH1* status in tissue was prospectively and centrally confirmed using Oncomine Focus Assay. A BEAMing digital PCR test was used for quantification of m*IDH1* in plasma. *IDH1* mutation clearance (*IDH1*-MC) was achieved when plasma m*IDH1* variant allele frequency was below the assay's sensitivity (0.02% for R132C/L/S/G; 0.04% for R132H). **Results:** m*IDH1* detection in plasma ctDNA and tissue was concordant in 92% (193/210) of samples screened. As of 31 Jan 2019, median PFS was 2.7 months for IVO vs 1.4 months for placebo. Longitudinal analysis with biomarker data available as of Jan 2020 demonstrated *IDH1*-MC in plasma from 10 IVO-treated patients with PFS $\geq$2.7 months (n = 36) vs 0 patients with PFS $<$ 2.7 months (n = 40). No *IDH1*-MC was observed in patients treated with placebo, irrespective of response (n = 49). **Conclusions:** These results reinforce the feasibility of *IDH1*-R132 detection in plasma from patients with IHC, with a 92% concordance with detection in tumor tissue, supporting m*IDH1* detection in liquid biopsy as a viable patient selection strategy where tissue exhaustion can limit conventional methods. Plasma *IDH1*-MC was also observed in a subset of IVO-treated patients who achieved disease control. Clinical trial information: NCT02989857. Research Sponsor: Agios Pharmaceuticals, Inc.

4577 Poster Session (Board #185), Fri, 8:00 AM-11:00 AM

Algorithm for blood-based panel of methylated DNA and protein markers to detect early-stage hepatocellular carcinoma with high specificity. *First Author: Naga P. Chalasani, Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, IN*

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related deaths worldwide. Though biannual ultrasound surveillance with or without alpha-fetoprotein (AFP) testing is recommended for at-risk patients, its sensitivity for early-stage HCC detection is suboptimal. We therefore evaluated performance of a biomarker panel incorporating methylated DNA markers (MDMs) and proteins for early HCC detection in at-risk patients with chronic liver disease. **Methods:** In an international, multicenter, case-control study, blood specimens were collected from patients with HCC per AASLD criteria and controls matched for age and liver disease etiology. All patients had underlying cirrhosis or chronic HBV infection. Whole blood was collected in cell-free DNA stabilizing and serum-separation tubes and shipped to a central laboratory for processing. The levels of 5 MDMs, AFP, and AFP-L3 were assessed along with age and sex. We used 537 samples in a 5-fold validation for developing a LASSO regression algorithm to classify samples as HCC positive or negative. Model robustness was tested by perturbing the data *in silico* and analyzing results with the predictive algorithm. Algorithm performance was compared to AFP alone and the GALAD score (Gender, Age, AFP-L3, AFP, and DCP). **Results:** The study included 136 HCC cases (81 early-stage—BCLC stage 0/A) and 401 controls. With specificity set at 89%, we developed a model using sex, AFP, and 3 MDMs (HOXA1, TSPYL5, B3GALT6) with higher sensitivity (70%) for early-stage HCC compared to GALAD (54%) or AFP (31% at 20 ng/mL or 52% at ≥7.7 ng/mL) (Table). The AUC for the HCC marker panel was 0.91 (95% CI 0.89 – 0.94) compared to GALAD (0.88; 95% CI 0.85 – 0.91) or AFP (0.84; 95% CI 0.81 – 0.87). The panel performed similarly in viral (AUC = 0.94) and non-viral (AUC = 0.89) etiologies. **Conclusions:** The robust algorithm based on novel blood-based biomarkers presented here provides higher sensitivity for early-stage HCC compared to other available blood-based biomarkers and, therefore, could significantly impact HCC clinical management and patient outcomes. Further clinical studies to validate the algorithm are ongoing. Clinical trial information: NCT03628651. Research Sponsor: Exact Sciences.

Performance of HCC marker panel.

	Sensitivity % (95% CI)		Specificity % (95% CI)	All-Stage AUC (95% CI)
	Early-Stage	All-Stage		
Current HCC marker panel	70 (60 – 80)	81 (74 – 87)	89 (86 – 92)	0.91 (0.89 – 0.94)
GALAD	54 (43 – 65)	68 (59 – 75)	89 (86 – 92)	0.88 (0.85 – 0.91)
AFP (≥7.7 ng/mL)	52 (41 – 63)	64 (56 – 72)	89 (86 – 92)	0.84 (0.81 – 0.87)

4578 Poster Session (Board #186), Fri, 8:00 AM-11:00 AM

Associating liver partition and portal vein ligation for staged hepatectomy versus portal vein embolization in staged hepatectomy for hepatocellular carcinoma: A randomized comparative study. *First Author: Gang Huang, Eastern Hepatobiliary Surgery Hospital, National Innovation Alliance for Hepatitis and Liver Cancer, Shanghai, China*

Background: Both Portal Vein Embolization (PVE) and Associating Liver Partition and Portal vein ligation for Staged hepatectomy (ALPPS) have been used in patients with unresectable hepatocellular carcinoma (HCC) due to insufficient volumes in future liver remnant (FLR). But it remains unclear for which thetapy has better long-term overall survival. **Methods:** This study was a single-center, prospective randomized comparative study. Patients were randomly assigned in a 1:1 ratio to the 2 groups. The primary endpoints was three-year overall survival rates. **Results:** Between November 2014 to June 2016, 76 patients with unresectable HCC due to inadequate volume of FLR were randomly assigned to ALPPS groups (n = 38) and PVE groups (n = 38). Thirty-seven patients (97.4%) in the ALPPS Group compared with 25 patients (65.8%) in the PVE Group were able to undergo staged hepatectomy (risk ratio 1.48, 95% CI 1.17-1.87, $p < 0.001$). The three-year overall survival (OS) rate of the ALPPS group (65.8%) (95% CI 50.7-80.9) was significantly better than the PVE Group (42.1%) (95% CI 26.4-57.8), (HR 0.50, 95% CI 0.26-0.98, two-sided p = 0.036). Major postoperative complications rates after the stage-2 hepatectomy were 54.1% in the ALPPS group and 20.0% in the PVE group ((risk ratio 2.70, 95% CI 1.17-6.25, p = 0.007). **Conclusions:** ALPPS resulted in significantly better long-term overall survival outcomes, at the expenses of a significantly higher perioperative morbidity rate compared with PVE in patients who had initially unresectable HCC. Clinical trial information: ChiCTR-IOC-14005646. Research Sponsor: Science Fund for Creative Research Groups, NSFC, China, (81521091).

4579 Poster Session (Board #187), Fri, 8:00 AM-11:00 AM

Primary tumor (p-bx) versus metastatic tumor (m-bx) tissue versus liquid biopsy (lb) in intrahepatic cholangiocarcinoma (IHCC): A comparative comprehensive genomic profiling (CGP) study. *First Author: Jeffrey S. Ross, Foundation Medicine, Cambridge, MA*

Background: Genomic alterations (GA) characteristic of IHCC are well known. We queried whether GA from Pbx would differ from Mbx and Lbx in IHCC. **Methods:** Hybrid-capture based CGP was performed on 1,268 tissue samples of advanced stage IHCC using Pbx in 1,048 cases and Mbx from 220 cases and 364 Lbx cases (solid tissue: 318-327 genes, Lbx: 72 genes). Tumor mutational burden (TMB) was determined on 0.8-1.1 Mbp of sequenced DNA. PD-L1 expression in tumor cells (Dako 22C3) was measured by IHC. **Results:** Mbx sites included: lymph nodes (63), soft tissues (47), peritoneum (34), lung/pleura (27), omentum (15), bone (10), abdomen (7), GYN tract (5), liver (4), brain (2), Upper GI (2), colon (2), bladder (1), and adrenal (1). The GA/sample and biomarkers of immuno-oncology (IO) drug response were similarThe *KRAS* mutation frequency including G12C alterations was doubled in Mbx compared to Pbx and Lbx ($p < 0.001$). Frequencies of untargetable GA were similar overall. *IDH1* ($p < 0.001$) and *FGFR2* GA known to be enriched in IHCC were less frequent in Mbx than Pbx. Both *IDH1* and *FGFR2* were identified in Lbx. GA in *STK11* ($p < 0.001$) and *SMAD4* (p = 0.0016) were more frequently identified in Mbx. **Conclusions:** GA found in Pbx vs Mbx and Lbx in IHCC are significantly different; the Mbx cohort features greater *KRAS* and lower *IDH1* and *FGFR2* GA. Lbx detected more IDH1 GA than Mbx. This suggests that the Mbx group may contain non-IHCC cases whose metastatic lesions were actually derived from other primary sites and incorrectly assigned the diagnosis of IHCC. Adjuvant lenvatinib in combination with TACE for hepatocellular carcinoma patients with high risk of postoperative relapse (LANCE): Interim results from a muticenter prospective cohort study. *First Author: Jin-hong Chen, Department of General Surgery, Huashan Hospital, Cancer Metastasis Institute, Fudan University, Shanghai, China*

Background: Surgical resection was the main treatment for hepatocellular carcinoma (HCC) in China. Multiple clinical studies had demonstrated that the overall survival (OS) of the surgical resection group was significantly better than the transcatheter arterial chemoembolization (TACE) or radiotherapy group even for HCC patients with BCLC stage B or C. There was no standard adjuvant therapy for HCC patients to decrease the post-operative tumor relapse. For HCC patients with high recurrence risk, TACE significantly reduced tumor recurrence, prolonged the disease free survival (DFS) and OS, and was recommended as the adjuvant therapy. However, its effect is not very satisfactory. The purpose of this study was to assess the efficacy and safety of lenvatinib in combination with TACE versus TACE alone as adjuvant therapy in HCC patients with high recurrence risk after resection. **Methods:** This is a muti-center prospective cohort study. The criteria of HCC patients with high postoperative recurrence risk included: accompanied with gross vascular or bile duct invasion (tumor thrombi in portal vein, hepatic vein or bile duct); or tumor rupture or invasion of adjacent organs; or grade 2 of microvascular invasion (MVI) (M2) along with the tumor number more than 3 or the maximum diameter of tumor larger than 8cm or tumor showed invasive growth with unclear boundaries and imcomplete capsules. The patients were divided into two groups, the lenvatinb (8mg qd for weights < 60kg and 12mg qd for weights≥60kg) in combination with TACE (Len+TACE) group and the TACE group. **Results:** A total of 90 patients were enrolled into the study, while 45 patients in the Len+TACE group and 45 in TACE group. The media age was 52 years (range from 23 to 73 years). Most patients were males (82.2%) and 66 patients had HBV background (73.3%). There were no significant differences between the two groups in the baseline clinicopathological characteristics including gender, age, HBV background, liver cirrhosis, liver function, tumor characteristic and AFP level. The media DFS was 12.0 months (95% CI 8.0-NA) in the Len+ TACE group, which was longer than that of TACE group (8.0 months, 95% CI 6.0-12.0, P = 0.0359; HR 0.5, 95% CI 0.3-1.0). The most common grade 3 or 4 adverse events were hypertension (11.1%) and diarrhea (7.7%) in the Len+TACE group. **Conclusions:** Lenvatinib in combination with TACE was effective and safe as adjuvant therapy, which can prolong the DFS of HCC patients with high recurrence risk after resection. Clinical trial information: NCT03838796. Research Sponsor: China National Key Projects for Infectious Disease (No.2017ZX10203207).

4581 Poster Session (Board #189), Fri, 8:00 AM-11:00 AM

A multicenter nonrandomized controlled trial to evaluate the efficacy of surgery versus radiofrequency ablation for small hepatocellular carcinoma (SURF cohort trial). *First Author: Ryosuke Tateishi, Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*

Background: In parallel with a multicenter randomized controlled trial that reported an equal recurrence-free survival (RFS) of early-stage hepatocellular carcinoma (HCC) patients who underwent either surgery (SUR) or radiofrequency ablation (RFA), we also enrolled HCC patients who fulfilled the enrollment criteria but did not give consent to participate in the RCT. **Methods:** All patients gave informed consent to participate in this study. Inclusion criteria were as follows: primary HCC with less than or equal to 3 tumors, each measuring 3 cm or smaller; without vascular invasion or extrahepatic metastasis; Child-Pugh score of 7 or less; and ages between 20 and 79 years. The feasibility for both treatments was confirmed by a joint chart review by surgeons and hepatologists. The primary endpoint was RFS and overall survival. A pre-specified interim analysis was performed to compare RFS. **Results:** Between April 2009 and August 2015, 740 patients (371 in SUR, 369 in RFA) were enrolled from 49 participating hospitals in Japan. The SUR group had significantly fewer patients with chronic hepatitis C (56.6% vs. 69.4%), higher median value of platelet count (145 vs. 120 $\times$ 10^9/L), and more patients with $>$ 2 cm tumors (49.9% vs. 27.9%); most patients had a single tumor (91.1% vs. 88.3%). During the median follow-up period of 5 years, tumor recurrence was observed in 192 of SUR and 218 of RFA with 3-year RFS being 66.0% and 61.7%, respectively (P = 0.091). In subgroup analysis, RFS was significantly better in SUR in patients with $\leq$ 2 cm tumors (62.9% vs. 51.7% in 3 years; hazard ratio [HR] 0.72, 95% confidence interval [CI] 0.56-0.93; P = 0.014), whereas the difference was not significant in those with $>$ 2 cm tumors (52.7% vs. 46.4%; HR 0.85, 95% CI 0.63-1.18; P = 0.34). The adjusted HR for RFS using inversed probability of treatment weighting was 0.89 (95% CI, 0.72-1.10; P = 0.287). **Conclusions:** The imbalance in patient characteristics reflected a real-world practice. Factors related to background liver disease rather than tumor characteristics might have a larger impact on the recurrence in early HCC. Clinical trial information: C000001796. Research Sponsor: Health Labour Sciences Research Grant from The Ministry of Health Labour and Welfare of Japan.

4582 Poster Session (Board #190), Fri, 8:00 AM-11:00 AM

A multicenter randomized phase II study of nivolumab in combination with gemcitabine/cisplatin or ipilimumab as first-line therapy for patients with advanced unresectable biliary tract cancer (BilT-01). *First Author: Vaibhav Sahai, University of Michigan, Ann Arbor, MI*

Background: Patients (pts) with advanced biliary tract cancers (BTC) have poor prognosis with a median overall survival (OS) less than 12 months (mos). This randomized phase 2, multi-institutional, study was designed to investigate the role of combinational immunotherapy, using nivolumab (nivo) with gemcitabine (gem)/cisplatin (cis), or nivo with ipilimumab (ipi) in pts with untreated advanced BTC. **Methods:** Key eligibility criteria include histologically confirmed unresectable or metastatic BTC without prior systemic therapy, measurable disease per RECISTv1.1, ECOG PS 0-1, and absence of autoimmune disease or chronic steroid use. Arm A included gem 1000 mg/m^2 and cis 25 mg/m^2 d1, 8 Q3w + nivo 360 mg d1 Q3w for 6 mos followed by nivo 240 mg Q2w monotherapy for a total duration of 2 yrs; Arm B included nivo 240 mg Q2w and ipi 1 mg/kg Q6w for 2 yrs, in absence of disease progression. Primary endpoint is progression-free survival (PFS) rate at 6 mos with an alternative hypothesis of 80% (null hypothesis of 59%, one-sided alpha 0.05, power 80%) for each non-comparative arm. Secondary endpoints include overall response rate (ORR) per immune related (ir) RECIST, median PFS and OS and safety. Exploratory objectives include biomarker analysis using include sequential whole exome/transcriptome and immune cell subsets in tissue and blood. **Results:** 71 eligible pts (49% male, 83% Caucasian) with 35 in Arm and 36 in Arm B with a median age of 62 (range 20-80) yrs, and majority with metastatic disease (90%) were enrolled across 6 US sites. PFS rate at 6 mos was 70% in Arm A and 18.6% in Arm B. The median PFS was 8.8 mos (95% CI, 6.1 to 11.3) in Arm A and 4.1 mos (95% CI, 2.4-5.2) in Arm B. Ten patients on Arm A and 2 on Arm B remain on active treatment; additional 7 are in follow-up for OS. ORR, safety data and median OS evaluation are underway and will be presented at the meeting. Exploratory analyses are pending. **Conclusions:** The observed PFS rates at 6 mos in either arm are insufficient to reject the null hypothesis of 59% PFS at 6 months. While Arm B is inferior, Arm A appears to be as effective as standard of care although OS estimates are pending maturity. Clinical trial information: NCT03101566. Research Sponsor: Bristol-Myer's Squibb, University of Michigan Rogel Cancer Center.

4583 Poster Session (Board #191), Fri, 8:00 AM-11:00 AM

Adjuvant concurrent chemoradiotherapy in extrahepatic cholangiocarcinoma. *First Author: Walid Labib Shaib, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Resected cholangiocarcinomas are rare and have high relapse rates. Adjuvant chemotherapy is the standard of care (BiLCAP Trial). Adjuvant radiation therapy benefit is not well defined. This study aims to evaluate survival outcomes of the effect of adjuvant chemoradiotherapy compared to chemotherapy in extrahepatic cholangiocarcinoma (EHC) using the National Cancer Database (NCDB). **Methods:** Patients with resected EHC between 2004 and 2013 were identified from the NCDB using ICD-O-3 histology and topography codes: 8140, 8160, 8161, 8162 and C24.0. Patients with neoadjuvant therapy were excluded from this analysis. Univariate and multivariable analyses were conducted, and Kaplan-Meier Curves were used to compare overall survival (OS) based on treatment received. **Results:** A total of 236 EHC patients were identified. Males comprised 60.6% and 88.1% were Caucasian. Median age was 64 (range, 31-84) years. The majority were distal (72.0%, N = 157) followed by perihilar (20.6%, N = 45), hilar (6.4%, N = 14) and cystic (0.9%, N = 2). Distribution across stages I-III was 28.8% (N = 68), 56.8% (N = 134), and 14.4% (N = 34), consecutively. Adjuvant chemotherapy was given in 37.7% (N = 89) and adjuvant chemoradiotherapy in 62.3% (N = 147). The median dose of radiation was 50.4 Gy. Adjuvant chemoradiotherapy was mostly given in regional node positive disease (p = 0.016) and negative surgical margin (p = 0.002) compared to regional node negative disease and positive surgical margin, respectively. The use of adjuvant chemoradiotherapy was associated with improved OS compared to chemotherapy alone in univariate (HR 0.64; 95% CI 0.44-0.93; p = 0.019) and multivariable analysis (HR 0.65; 95% CI 0.44-0.96; p = 0.030). Median survival and 1 year-OS for patients that received chemoradiotherapy was 33.8 months (95% CI 28, NA) and 87.7% (80.9%, 92.1%) compared to chemotherapy alone which was 23.8 months (95% CI 18.9, 35.4) and 75.5% (64.9%, 83.3%). **Conclusions:** Adjuvant chemoradiotherapy was associated with improved survival in patients with resected EHC compared to chemotherapy alone. This conclusion warrants further prospective studies to confirm these results. Research Sponsor: None.

4584 Poster Session (Board #192), Fri, 8:00 AM-11:00 AM

Different organ-specific response to nivolumab to determine the survival outcome of patients with advanced hepatocellular carcinoma (aHCC). *First Author: Han Sang Kim, Yonsei Cancer Center, Seoul, South Korea*

Background: Previously, two phase III clinical trials of immune checkpoint inhibitors (ICI) failed to meet their primary endpoints, leading to doubts regarding the clinical activity of ICI monotherapy in patients with aHCC. Here, we comprehensively examined clinicopathological factors and estimated their association with survival outcomes in aHCC patients treated with nivolumab. **Methods:** A total of 261 eligible patients from 5 high-volume centers who were treated with nivolumab between June 9, 2012 and March 14, 2018 and had measurable diseases were reviewed. We reviewed more than 80 clinicopathological factors and categorized them into 6 areas: 1) demographics (n = 16); 2) baseline laboratory values (n = 19); 3) tumor burden (n = 12); 4) previous treatment (n = 12); 5) treatment response (n = 5); 6) toxicity profiles (n = 18). Their association with survival outcomes were evaluated, and organ-specific response evaluation, adapted from RECIST 1.1, was conducted. **Results:** Of the 261 patients, 218 (84%) had extrahepatic spread. The median follow-up time was 4.5 months. The median progression-free survival (PFS) and overall survival (OS) were 2.3 months (95% CI, 1.8-2.8) and 6.3 months (95% CI, 5.0-8.2). Objective response rate was 15%. Subgroup analyses revealed that compensated liver function (Child-Pugh score A5/6), surrogate markers for low tumor burden (low AFP, low PIVKA, and low LDH level), inflammatory markers (low C-reactive protein [CRP], low erythrocyte sedimentation rate [ESR], low neutrophil-to-lymphocyte ratio [NLR], high lymphocyte-to-monocyte ratio [LMR]), and low intrahepatic tumor burden were significantly associated with longer OS. A total of 456 individual lesions (liver, n = 249; lung, n = 124; lymph node, n = 35; others such as boner soft tissues, n = 48) were examined. Organ-specific response rates (hepatic tumor, 9%; lung, 25%; lymph node, 37%; others metastasis, 15%) were different, of which intrahepatic tumor was the least responsive organ to ICI treatment in aHCC. **Conclusions:** Underlying liver function, the tumor extent and burden, and the degree of plasma lymphocytes are crucial for determining tumor response to ICI in aHCC. Antitumor immune response to ICI differs in an organ-specific manner. The hepatic tumors of HCC may be less responsive to nivolumab than extrahepatic lesions. Research Sponsor: None.

4585 Poster Session (Board #193), Fri, 8:00 AM-11:00 AM

Clinical value of atezolizumab + bevacizumab for first-line unresectable hepatocellular carcinoma (HCC): A network meta-analysis. *First Author: Arndt Vogel, Hannover Medical School, Hannover, Germany*

Background: The IMbrave150 pivotal study in unresectable HCC showed superiority of atezolizumab + bevacizumab (atezo + bev) vs sorafenib for OS and PFS. Based on these data supporting first-line atezo + bev for HCC, we conducted a network meta-analysis (NMA) to compare the efficacy of atezo + bev with other systemic and local therapies approved for HCC. **Methods:** A systematic literature review identified randomized controlled trials in adults with locally advanced or metastatic HCC and no prior systemic therapy for HCC. Studies of therapies now approved for any line of HCC treatment with data reported for first-line treatment since sorafenib approval in 2007 were eligible. Screening of 8783 records yielded 55 trials for inclusion; 9 studies were eligible for the evidence network. Reported hazard ratios (HRs) for OS and PFS were extracted from published studies. The IMbrave150, REFLECT and CheckMate-459 study populations were considered sufficiently similar to compare. A generalized linear model with random effects was used to estimate indirect treatment effects. Informative priors for the heterogeneity of treatment effects across trials were adopted given the limited number of trials to inform each pairwise comparison. HRs with 95% credible intervals (CrIs) and Bayesian posterior probability of atezo + bev being superior to other treatments were calculated for each treatment comparison. The base case NMA compared the relative efficacy of atezo + bev vs sorafenib observed in the IMbrave150 study with the relative effect of other therapies. Sensitivity analyses were performed to compare subgroup results as appropriate based on disease etiology, extrahepatic spread and geography. **Results:** NMA results suggested improved OS with atezo + bev vs lenvatinib (HR, 0.63; 95% CrI: 0.32, 1.25; probability of atezo + bev being superior to lenvatinib: 93.7%) or nivolumab (HR, 0.68; 95% CrI: 0.35, 1.38; probability of atezo + bev being superior to nivolumab: 90.3%) and improved PFS with atezo + bev vs lenvatinib (HR, 0.91; 95% CrI: 0.23, 3.65; probability of atezo + bev being superior to lenvatinib: 61.5%) or nivolumab (HR, 0.63; 95% CrI: 0.16, 2.59; probability of atezo + bev being superior to nivolumab: 85.5%). **Conclusions:** This NMA suggested greater OS and PFS benefits with first-line atezo + bev treatment vs other therapies approved for treatment of unresectable HCC. 4586 Poster Session (Board #194), Fri, 8:00 AM-11:00 AM

A randomized phase II feasibility study of individualized stereotactic body radiation therapy (SBRT) versus transarterial chemoembolization (TACE) with DEBDOX beads as a bridge to transplant in hepatocellular carcinoma (HCC). *First Author: Francis W. Nugent, Beth Isreal/Lahey Health, Burlington, MA*

Background: For HCC pts undergoing LT, loco-regional treatment as a "bridge" is standard. The best bridging modality is unclear. SBRT is safe and effective when used in pts with advanced HCC. We prospectively compared SBRT to TACE as a bridge for HCC pts undergoing LT. **Methods:** From 9/2014-10/2019, 60 pts within Milan Criteria with CTP Class A/B8 cirrhosis were consented. 54 pts were randomized to TACE vs. SBRT. TACE pts (n =30) were scheduled to receive 2 treatments one month apart utilizing DEBDOX beads. TACE pts were hospitalized after each TACE. Pts receiving SBRT (n =24) received a median total dose of 45Gy delivered over 5 fractions using fiducials. Mean liver dose, Veff, and NTCP determined prescription dose. Pts were assessed by using mRECIST criteria at 2 months and every 3 months thereafter until LT or death. Toxicity and QOL were assessed before treatment, during treatment, two weeks post-treatment, and then every three months using the PIQ-6 Pain Impact Questionnaire and the SF-36v2 Health Survey. The 1° endpoint was time to recurrent or residual dz. Secondary endpoints were toxicity, pathologic response, radiologic response, number of subsequent treatments, cost, and QOL. 50 pts are evaluable for review. **Results:** See table. **Conclusions:** For early stage HCC patients with CTP Class A/B liver cirrhosis, SBRT appears as effective as TACE at controlling HCC prior to LT, may engender less toxicity, and eliminates the need for hospitalization. A larger multi-center trial is ongoing. Clinical trial information: NCT02182687. Research Sponsor: Wise Grant, Pharmaceutical/Biotech Company.

Effect of pembrolizumab (pembro) on hepatitis B viral (HBV) load and aminotransferase (ALT) levels in patients (pts) with advanced hepatocellular carcinoma (aHCC) in KEYNOTE-224 and KEYNOTE-240. *First Author: Stephen Lam Chan, The Chinese University of Hong Kong, Hong Kong, China*

Background: The effect of PD-1 inhibition on HBV infection is unclear, and pts with HBV are often excluded from trials. This analysis evaluated HBV viral load and liver function (ALT levels) in pts with HBV infection in 2 trials of pembro: KEYNOTE-224 and KEYNOTE-240. **Methods:** Eligible pts with aHCC post first-line sorafenib and controlled HBV received pembro 200 mg IV Q3W until progression. Pts with active HBV (HBsAg positive and/or HBV DNA detectable) and inactive HBV (anti-HBc positive, HBsAg negative, and HBV DNA not detectable) at baseline (BL) were included. **Results:** Of 104 pts in KEYNOTE-224 and 413 pts in KEYNOTE-240, 8 (7.7%) and 101 (24.5%) had active HBV and 13 (12.5%) and 102 (24.7%) had inactive HBV, respectively. All pts with HBV received nucleos(t)ide analogs. In KEYNOTE-240, 2 (2.8%) pts with active HBV in the pembro arm and 1 (3.4%) in placebo (pbo) had a > 1 log increase (incr) of HBV DNA and 1000 IU/mL over BL; none in the pembro arm were associated with ALT elevation. No pts with inactive HBV in KEYNOTE-240 and no pts in KEYNOTE-224 had a > 1 log incr and 1000 IU/mL over BL. No pts in KEYNOTE-224 and 28 (38.9%) with active HBV and 1 (1.4%) with inactive HBV in the pembro arm, and 8 (27.6%) with active HBV and 0 with inactive HBV in the pbo arm in KEYNOTE-240 had a > 1 log decrease (decr) in HBV DNA. **Conclusions:** Few pts with aHCC and HBV had viral load incr with pembro. In KEYNOTE-240 no clinically meaningful differences between pembro and pbo were observed. ALT elevation was not associated with viral load incr with pembro. These data suggest that pembro is unlikely to significantly affect underlying HBV infection in pts with aHCC receiving HBV antiviral therapy. Clinical trial information: KEYNOTE-224, NCT02702414; KEYNOTE-240, NCT02702401. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

2) BL ALT ≥2×ULN and post-BL ALT > 3×BL level
3) ALT > 500 U/L regardless of BL level

4588 Poster Session (Board #196), Fri, 8:00 AM-11:00 AM

Combination immunotherapy with ipilimumab and nivolumab in patients with advanced biliary tract cancers. *First Author: Oliver Klein, Medical Oncology Unit, Austin Health, Heidelberg, Australia*

Background: Patients (pts) with advanced biliary tract cancers (BTC) have a poor prognosis with first and second line chemotherapy resulting in modest survival benefits. Immunotherapy using single agent anti-PD-1 therapy has also shown low activity with an objective response rate (ORR) of less than 10%. Combined CTLA-4/PD-1 blockade using ipilimumab (ipi) and nivolumab (nivo) has demonstrated superior efficacy compared to single agent anti-PD-1 therapy in pts with advanced melanoma and renal cell carcinoma. To date, no trials in BTC pts with ipi/nivo therapy have been reported. **Methods:** 39 pts with metastatic BTCs were enrolled into the CA 209-538 clinical trial for rare cancers. Patients received nivo 3mg/kg and ipi 1mg/kg q 3 weekly for 4 doses, followed by nivo 3mg/kg q 2 weekly. Treatment continued for up to 96 weeks, or until disease progression or the development of unacceptable toxicity. Response (RECIST 1.1) was assessed every 12 weeks. The primary endpoint was clinical benefit rate (CBR = CR +PR + SD). Exploratory endpoints include correlation of efficacy with biomarkers including PD-L1 expression and tumour mutation burden. **Results:** 39 pts with BTC were enrolled and 33 pts (85%) had received at least one prior line of systemic treatment (0-2 lines). The ORR was 24% and the CBR 45% with the median duration of response not been reached (range 2-26+months). Responses were observed in 3/14 intrahepatic, 1/10 extrahepatic, 0/2 unspecified cholangiocarcinoma and 5/13 gallbladder ca pts. None of the responding pts had a microsatellite instable tumour. 2 pts with durable partial responses were subsequently rendered surgically free of disease. Median OS and PFS were 6.1 and 3.1 months respectively. 22 (56%) pts experienced an immune –related adverse event (irAE) with grade3/4 irAEs being observed in 8 (20%) pts. **Conclusions:** Combination immunotherapy with ipi/nivo demonstrates significant clinical activity in a subset of patients with advanced microsatellite stable BTC. The response rate compares favourably to clinical trials investigating single agent anti-PD-1 therapy. Clinical trial information: NCT02923934. Research Sponsor: Australian Federal Department of Health.

4589 Poster Session (Board #197), Fri, 8:00 AM-11:00 AM

Genomics and translational precision oncology for 803 patients with biliary tract cancer. *First Author: Jianzhen Lin, Peking Union Medical College Hospital and Chinese Academy of Medical Sciences, Beijing, China*

Background: Both incidence and mortality of biliary tract cancer (BTC) are increasing, and BTCs are characterized by poor prognosis and limited antitumoral treatments. There is no well-received regimen as the non-first-line treatment in patients with advanced BTCs, leading to the urgency of umbrella-setting personalized therapies according to genomic alterations. **Methods:** We performed genomic sequencing in a total of 803 BTCs, including 160 patients with whole-exome sequencing and 643 patients with hybrid capture–based comprehensive genomic profiling. Our molecular tumor board developed precise targeted therapies for patients with actionable targets. **Results:** Overall, the median tumor mutation burden was 3.0 (IQR: 0.8-6.1) Mut/Mb, with 10.5% patients of hypermutated BTCs. The most frequently mutated genes included *TP53* (51%), *KRAS* (23%), *ARID1A* (16%) and *SMAD4* (11%). The most common genes with significantly amplified oncogenes were *CCND1* (6.97%), *MET* (6.72%) and *MDM2* (6.6%), while the frequently deleted tumor-suppressor genes are *CDKN2A* (5.73%) and *CDKN2B* (5.35%). The mutational map of BTCs highlighted pathways of receptor-tyrosine kinase (RTK)/RAS and *p53* signaling were frequently altered. Somatic truncating mutations of mismatch repair genes were identified in 6.1% (49/803) of patients, and germline pathogenic mutations in DNA damage response genes occurred in 8% (64/803) of BTCs. In addition, we demonstrate the amplified chromosomal focal at 7q31.2 was an oncogenic factor and it independently predicts both disease-free survival and overall survival of BTC patients. When molecular screening was linked to targeted therapies, 25.4% (204/803) of patients could match biomarker-assigned drug treatment (BADT). The frequent actionable biomarkers included amplifications of *ERBB2* and *MET*, *FGFR2/3* fusions and *IDH1* mutations. For 46 patients with refractory BTCs received BADT, the objective response rate was 26.1%, with a median progression-free survival (mPFS) of 5.0 (95%CI: 3.5-6.5) months, and 56.8% patients achieved a $\geq$1.3 ratio of PFS2/PFS1. 4 of 6 (67%) patients with high microsatellite instability (MSI-H) BTCs had a responsive status after immunotherapy of PD1 inhibitor, confirming that MSI-H status was a robust biomarker of anti-PD1 treatments. **Conclusions:** Our study established the largest cohort in Chinese BTC patients to investigate the tumor mutational profiling and its translational clinical applications. Clinical trial information: NCT02715089. Research Sponsor: International Science and Technology Cooperation Projects.

4590 Poster Session (Board #198), Fri, 8:00 AM-11:00 AM

A phase II open-label, single-center, nonrandomized trial of Y90-radioembolization in combination with nivolumab in Asian patients with advanced hepatocellular carcinoma: CA 209-678. *First Author: Wai Meng David Tai, National Cancer Center Singapore, Singapore, Singapore*

Background: Nivolumab (N) and Y90-radioembolization (RE) are both therapeutic options in advanced hepatocellular carcinoma (aHCC). Increasing evidence suggests that radiotherapy synergizes with immune checkpoint inhibitors to augment anti-tumour effects. **Methods:** Eligible Child-Pugh A aHCC patients (pts) were treated with Y90-RE followed by N 240mg, 21 days after Y90-RE and every 2 weeks thereafter. Pre- and on-treatment tumor biopsies together with circulating biomarkers were obtained. Primary end-point was overall response rate (ORR) (per RECIST v 1.1). Overall response was defined as the composite overall response observed for the lesions within Y90-RE field and outside Y90-RE field. Key secondary end points included disease control rate (DCR), progression free survival (PFS), overall survival (OS), and safety. 36 evaluable pts were needed to assess whether the addition of N improved the ORR of Y90-RE from 21% to 41% as determined by Simon two-stage optimal design with 80% power and one sided significance level of 0.05. **Results:** Forty pts were enrolled of which 36 were evaluable. At baseline: 63.9% were HepB in aetiology; 63.9% BCLC stage C; 47.2% had AFP $>$ 400ng/mL; number of liver lesions – median 5 (range 1- 20); size of largest liver lesion – median 80mm (range 14-177mm); 27.8% had prior TACE; and 13.9% had prior systemic therapy. ORR was 31% (95% CI 16.4 - 48.1%). Eight out of 11 responders had not progressed at study cut-off. DCR was 58.3%. 81% of target lesions within Y90-RE field regressed. With a median follow up of 16.4 months, median PFS and OS were 4.6 months (95% CI 2.3m - 8.4m) and 15.1 months (95% CI 7.8m - NE) respectively. Six- and 12-month PFS rates were 44.2% (95% CI 27.3% - 59.9%) and 26.1% (95% CI 11.2% - 43.8%) respectively. Overall, N+ Y90-RE was well tolerated and safe; only 11% had grade 3/4 treatment related adverse events (AEs). Responders demonstrated significant alterations of LIF, MIG and Eotaxin3 levels in the pre-treatment cytokine analyses. **Conclusions:** Combination N+Y90-RE resulted in an encouraging ORR of 31% (95% CI 16.4 - 48.1%) in aHCC. 81% of target lesions within Y90-RE field regressed suggesting synergy in combining Y90-RE with nivolumab. This combination is safe and tolerable with low G3/4 treatment related AEs of 11%. Further biomarker analyses will be presented at the meeting. Clinical trial information: NCT03033446. Research Sponsor: National Medical Research Council Singapore, BMS, SIRTEX.

4591 Poster Session (Board #199), Fri, 8:00 AM-11:00 AM

A retrospective analysis of post second-line chemotherapy treatment outcomes for patients with advanced or metastatic cholangiocarcinoma and FGFR2 fusions. *First Author: Milind M. Javle, MD Anderson Cancer Center, Houston, TX*

Background: Cholangiocarcinoma (CCA) is the most common biliary tract malignancy with an estimated incidence of 8,000–10,000 patients/year in the US. Chemotherapy is the most common second-line treatment with reported outcomes in patients with CCA. Response rates of $<$ 10% and median progression-free survival (PFS) times of ~3–4 months have been reported with second-line chemotherapy regimens, including FOLFOX in the ABC-06 trial. Fibroblast growth factor receptor 2 (*FGFR2*) fusions occur in 13–17% of CCA and multiple targeted agents are in development for patients with *FGFR2* fusions. To date, the outcome of patients with CCA and *FGFR2* fusions receiving standard second-line chemotherapy is unknown. **Methods:** Patients with advanced CCA and *FGFR2* fusions after prior treatment with gemcitabine-based chemotherapy were enrolled in a single-arm phase 2 study (NCT02150967) and received the FGFR1–3 selective TKI infigratinib (previously BGJ398) 125 mg orally qd on d1–21, cycles repeated q28 days until unacceptable toxicity, disease progression, investigator discretion, or withdrawal of consent. A retrospective analysis of a subset of patients who received infigratinib as third- or later-line treatment was performed. Investigator-assessed PFS and best overall response (BOR, per RECIST 1.1) following second-line chemotherapy (pre-infigratinib) and third-line or later-line infigratinib were calculated. **Results:** Of the 71 patients (44 women; median age 53 years) with *FGFR2* fusions enrolled at the time of analysis (datacut 8 August 2018), 37 (52%) were included in this retrospective analysis. Median PFS with standard second-line chemotherapy was 4.63 months (95% CI 2.69–7.16) compared with 6.77 months (95% CI 3.94–7.79) for third- and later-line infigratinib. BOR for second-line chemotherapy was 5.4% (95% CI 0.7–18.2) compared with 21.6% for third- and later-line infigratinib (95% CI 9.8–38.2). **Conclusions:** Outcomes from second-line chemotherapy in patients with CCA and *FGFR2* fusions were similar to those reported in the literature for all patients with CCA regardless of genomic status and remain dismal. Infigratinib administered as third- and later-line treatment resulted in a meaningful PFS and ORR benefit in patients with CCA and *FGFR2* fusions. Clinical trial information: NCT02150967. Research Sponsor: QED Therapeutics.

4592 Poster Session (Board #200), Fri, 8:00 AM-11:00 AM

Clinical activity and safety of penpulimab (Anti-PD-1) with anlotinib as first-line therapy for advanced hepatocellular carcinoma (HCC). *First Author: Shun Chang Jiao, Department of Oncology, The First Medical Center of Chinese PLA General Hospital, Beijing, China*

Background: Advanced HCC is a deadly disease with few systemic therapeutic options. VEGF blockade potentiates the effect of PD-1 inhibition by opposing the immunosuppressive effects of VEGF-A (increased DC maturation, enhanced T-cell infiltration, reduced MDSCs and Tregs in tumors). A sBLA has been submitted for an anti-PD-L1 + anti-VEGF combination as 1L treatment for advanced HCC. Penpulimab is a novel humanized anti-PD-1 IgG1 antibody with complete removal of Fc receptor mediated effect, and featuring slow antigen binding off-rate and high receptor occupancy. Anlotinib is a multi-targeted tyrosine kinase inhibitor selective for VEGF receptors 1/2/3, FGF receptors 1-4, PDGF receptors α and β, and c-kit. **Methods:** In this open-label, multicenter phase Ib/II study, treatment-naive pts with advanced HCC received penpulimab 200mg Q3W in combination with anlotinib 8mg QD (2 weeks on 1 week off) until loss of clinical benefit or unacceptable toxicity. The primary objectives were to assess antitumor activity by ORR (RECIST v1.1). The secondary objectives were to assess antitumor activity by DCR, DoR, TTP, and to assess the safety and tolerability of the combination. **Results:** As of Jan 14, 2020, 31 pts (median age 56 years [23-74], male 81%, ECOG 0/1 [64%/36%], BCLC B/C [23%/77%], HBV/HCV [61%/7%]) received combined therapy (a median of 6 [1-15] doses). Treatment-related adverse events (TRAEs) occurred in 93.5% of pts (G3 in 9.7% [3/31], no G4, and leading to treatment discontinuation in 6.5% [2/31]). Most frequent TRAEs were increased AST (35.5%), increased ALT (29%), asthenia (22.6%), decreased platelet count (19.4%), increased blood bilirubin (19.4%), increased bilirubin conjugated (19.4%), and rash (16.1%). Of 25 evaluable pts (with the opportunity to be followed-up for $\geq$2 scans, 12 weeks), confirmed ORR was 24% (6/25) and DCR was 84% (21/25). Five responders remained in response with DoR ranging 1.4+ to 6.9+ months. Median TTP was not reached and 6m-TTP rate was 63% (95% CI: 38%, 81%). **Conclusions:** Penpulimab in combination with anlotinib had a manageable safety profile and encouraging antitumor activities in patients with advanced HCC. No unexpected AEs were identified beyond the established safety profile for each agent. Evaluation of penpulimab + anlotinib (10 mg QD) in a phase 3 study for 1L HCC is currently underway. Clinical trial information: NCT04172571. Research Sponsor: Akeso Biopharma, Inc., Zhongshan, China.

4593 Poster Session (Board #201), Fri, 8:00 AM-11:00 AM

Perioperative circulating tumor DNA analysis to predict patient prognosis in liver cancer. *First Author: Ledu Zhou, Department of General Surgery, Xiangya Hospital, Central South University, Changsha 410008, China., Changsha, China*

Background: Resection is a major method for early-stage liver cancer patients. Unfortunately, there still a few patients with post-operation recurrences. Circulating tumor DNA (ctDNA) had been reported as a biomarker in reflecting tumor load and treatment efficacy in some cancer species. Here, we report an application of ctDNA in the perioperative period of liver cancer using targeted sequencing with a 1021-gene panel. **Methods:** 97 patients diagnosed with liver cancer were enrolled in this study. Postoperative peripheral blood samples were collected within 7 days after surgery and analyzed using hybridization capture based NGS ERSeq method from all patients. Whether a mutant gene was detected in the peripheral blood was defined as ctDNA(+) and ctDNA(-), respectively. **Results:** Multivariate Cox analysis showed that the post-operation ctDNA was an independent poor prognostic predictor (AFP, RR: 1.0002, 95% CI: 1.0001-1.0002; ctDNA, RR: 3.738, CI: 1.872-7.691). 21 patients were ctDNA(+), and all of them had recurrenced (21/21, 100%), while 76 patients were ctDNA(-), and only 12 (12/76, 15.8%) patients had recurrenced. The median disease-free survival time was 5.0 months in ctDNA(+) group and the ctDNA(-) group had not reach the median time (Log-rank test, $P < 0.0001$). ctDNA combined with AFP would effectively predict the prognosis of patients after surgery. AFP(H) (> = 400 ng/mL) and ctDNA(+) patients have the worst prognosis and all of the patients had relapsed, while AFP(L) (< 400 ng/mL) and ctDNA(-) patients had the best prognosis, with less than 20% of patients had relapsed (Log-rank test, $P < 0.0001$). The median disease-free survival time was 2.0, 6.0 and 7.0 months in ctDNA(+)-AFP(H) (n = 8), ctDNA(-)-AFP(H) (n = 30) and ctDNA(+)-AFP(L) (n = 13) groups, respectively, while ctDNA(-)-AFP(L) group (n = 46) had not reach the median time statistically (Log-rank test, $P = 0.0364$). **Conclusions:** In summary, Perioperative ctDNA detection has great potential value clinically, and it also suggests that patients with positive ctDNA after surgery should receive some adjuvant treatments as soon as possible to improve the survival time. Research Sponsor: National Nature Science Foundation of China.

4594 Poster Session (Board #202), Fri, 8:00 AM-11:00 AM

Predictive value of changes in plasma vascular endothelial growth factor at eight weeks after lenvatinib administration in patients with unresectable hepatocellular carcinoma. *First Author: Kaoru Tsuchiya, Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital, Tokyo, Japan*

Background: Lenvatinib (LEN) has been used in patients with unresectable hepatocellular carcinoma (u-HCC) and there is no established predictive biomarker. Previously it was reported that a plasma vascular endothelial growth factor (VEGF) concentration decrease at 8 weeks after starting sorafenib might predict favorable overall survival (OS) in patients with u-HCC (Tsuchiya, et al. Cancer, 2013). We aimed to investigate the value of changes in plasma VEGF at 8 weeks after LEN administration in patients with u-HCC. **Methods:** Forty-six patients with u-HCC who received LEN between April 2018 and August 2019 at our institution were enrolled. Plasma concentrations of VEGF and serum α-fetoprotein (AFP) levels were measured at baseline, 4 and 8 weeks after administration of LEN. A VEGF decrease was defined as > 5% decrease during 8 weeks after the beginning of LEN therapy. AFP response was defined as > 20% decrease during 8 weeks according to the previous reports. **Results:** Median overall survival (OS) was not reached and progression-free survival (PFS) was 5.9 months. Median observation period and treatment duration were 10.1 and 6.3 months. The objective response rate and disease control rate by mRECIST criteria were 43.5% and 82.6%. Median PFS in patients who had a VEGF decrease at week 8 (n = 29) was significantly longer than those who did not have a VEGF decrease (n = 17; 7.1 months vs 5.0 months; p = 0.014). AFP response was not associated with PFS. There were no significant differences in baseline VEGF, AFP, ALBI score, and extrahepatic metastasis between the patients with and without a VEGF decrease. A VEGF decrease was significantly associated with radiological objective response (p = 0.001) and 18 of 20 patients who achieved CR (n = 3) or PR (n = 17) had a VEGF response in LEN therapy. **Conclusions:** A decrease of plasma VEGF level at 8 weeks in patients with u-HCC on LEN was significantly associated with PFS. Changes in plasma VEGF could become a new biomarker for molecular targeted therapies including VEGF inhibitors in patients with unresectable HCC. Research Sponsor: Japan Agency for Medical Research and Development.

4595 Poster Session (Board #203), Fri, 8:00 AM-11:00 AM

Comparison of response using mRECIST versus RECIST 1.1 Criteria in advanced hepatocellular carcinoma: A retrospective analysis of multicenter clinical trials. *First Author: Jayant Narang, Parexel Informatics Inc, Rochester, NY*

Background: mRECIST 2010 criteria for Hepatocellular Carcinoma (HCC) response assessment were focused on a concept of measuring viable tumor tissue showing enhancement in arterial phase of contrast enhanced CT/MRI, whereas RECIST 1.1 focuses mainly on the morphological measurements quantifying the tumor size irrespective of viability of the tumor and associated response to therapy. RECIST 1.1 does not address measures of antitumor activity other than tumor shrinkage, underestimating responses in HCC. **Methods:** We retrospectively analyzed multiple, phase III, multi-center clinical trials using both mRECIST and RECIST 1.1 criteria, read separately. The intent was to compare the overall responses at post-baseline assessments read independently by the two criteria. A total of 1682 subjects with 6159 post-baseline imaging timepoints were included in the analysis. The Overall response rate (ORR) as measured by sum of complete response (CR) and partial response(PR) and the Complete response rate (CRR) were evaluated. In addition, we also assessed the number of not evaluable (NE) time points by each criteria separately. We tested the following hypotheses 1. mRECIST may have better ORR and CRR compared to RECIST 1.1. 2. RECIST 1.1 may have more timepoints with Stable disease (SD) compared to mRECIST. 3. mRECIST may have more Not evaluable (NE) timepoints due to stringent imaging specifications. **Results:** The results are tabulated in the table below: **Conclusions:** The results above suggest that mRECIST shows more than double the CRR than RECIST 1.1, and the ORR is 62% higher using mRECIST than RECIST 1.1. Stable disease as expected was more commonly observed in RECIST 1.1 analysis. A NE response was 60% more common in mRECIST criteria evaluation. Our analysis confirms that reduction in viable tumor/enhancing area using contrast-enhanced radiologic imaging is the more optimal method to assess treatment response in HCC, and using RECIST 1.1 tumor measurement of a longest diameter as the sole measure of response, may not be adequate in response assessment for HCC. Our analysis validates and supports more widespread adoption of mRECIST in HCC tumor response assessment. Our results also indicate the need for uniform image acquisition and rigorous image quality control for a valid response in mRECIST criteria. Research Sponsor: None.

mRECIST versus RECIST 1.1 Overall Response.

	mRECIST	RECIST 1.1
CR	111	46
PR	1497	966
SD/NN (Stable Disease/Non-CR Non-PD)	1994	2661
PD (Progressive Disease)	2509	2457
NE	48	29
ORR	26.10%	16.41%
CRR	1.8%	0.7%

4596 Poster Session (Board #204), Fri, 8:00 AM-11:00 AM

Complete responses (CR) in patients receiving atezolizumab (atezo) + bevacizumab (bev) versus sorafenib (sor) in IMbrave150: A phase III clinical trial for unresectable hepatocellular carcinoma (HCC). *First Author: Richard S. Finn, Jonsson Comprehensive Cancer Center, Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: In the Phase III IMbrave150 trial, statistically significant and clinically meaningful improvements in OS and PFS were seen with atezo + bev vs sor in pts with unresectable HCC who had not received prior systemic therapy (Cheng, ESMO Asia, 2019). Historically, CR rates have been low in HCC clinical trials. Here we report the baseline characteristics for IMbrave150 pts with a CR. **Methods:** IMbrave150 enrolled systemic treatment-naive pts with unresectable HCC. Pts were randomized 2:1 to receive either atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w or sor 400 mg BID until unacceptable toxicity or loss of clinical benefit per investigator. Co-primary endpoints were OS and PFS by independent review facility (IRF)–assessed RECIST 1.1. The key secondary endpoints IRF ORR per RECIST 1.1 and IRF ORR per HCC mRECIST were also part of the study statistical testing hierarchy. **Results:** The ITT population included 336 pts randomized to atezo + bev and 165 pts randomized to sor. With a median follow-up of 8.6 mo (data cutoff, Aug 29, 2019), OS HR was 0.58 (95% CI: 0.42, 0.79; $P = 0.0006$) and PFS HR was 0.59 (95% CI: 0.47, 0.76; $P < 0.0001$) with atezo + bev vs sor. ORR was 27% vs 12% ($P < 0.0001$) per IRF RECIST 1.1 and 33% vs 13% ($P < 0.0001$) per IRF HCC mRECIST with atezo + bev vs sor, respectively. For responders (per IRF RECIST 1.1), median time to response was 2.8 mo (range, 1.2-11.3) with atezo + bev and 3.3 mo (range, 1.2-7.2) with sor. CR per IRF-assessed RECIST 1.1 was achieved by 18 pts in the atezo + bev arm and 0 pts in the sor arm. The baseline characteristics for atezo + bev CR pts are shown in the table. Additional characteristics will be shown. **Conclusions:** IMbrave150 demonstrated statistically significant and clinically meaningful improvement in both OS and PFS with atezo + bev vs sor in pts with unresectable HCC who have not received prior systemic therapy. Pts achieved CRs regardless of poor prognostic factors or etiology. Atezo + bev may be a practice-changing treatment for pts with unresectable HCC. Clinical trial information: NCT03434379. Research Sponsor: F. Hoffmann-La Roche, Ltd.

4597 Poster Session (Board #205), Fri, 8:00 AM-11:00 AM

Results from TreeTopp: A randomized phase II study of the efficacy and safety of varlitinib plus capecitabine versus placebo in second-line (2L) advanced or metastatic biliary tract cancer (BTC). *First Author: Milind M. Javle, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with advanced or metastatic BTC who progress on first-line (1L) gemcitabine-based doublet chemotherapy have few 2L treatment options. Varlitinib is a reversible small molecule pan human epidermal growth factor receptor (HER) inhibitor with low nanomolar potency against HER1 (EGFR), HER2 and HER4 with promising early results in advanced BTC. **Methods:** TreeTopp (NCT03093870) was a global, multicenter, double blind phase 2 study in which patients with advanced BTC who progressed after 1L therapy that included ≥6 doses of gemcitabine, with radiographically measurable disease based on RECIST v1.1, ECOG PS 0 or 1 and albumin ≥3 g/dL were randomized (1:1) to varlitinib (300 mg BID) plus capecitabine (1000 mg/m^2 BID 14 days on/ 7 off)(V+C) or placebo plus capecitabine (P+C). The dual primary endpoints were Objective Response Rate (ORR) and Progression Free Survival (PFS) defined as the time from randomization to radiological progression assessed by Independent Central Review. Secondary end points included Overall Survival (OS). **Results:** Overall, 127 patients were randomized (V+C, n = 64; P+C, n = 63) from May−Dec 2018 and demographics/baseline characteristics were generally well balanced, although the V+C arm had a lower proportion of females vs. P+C (31% vs. 48%). The odds ratio for ORR was numerically higher with V+C vs. P+C was 2.278 (9.4% vs. 4.8%, p = 0.42), the HR for PFS for V+C vs. P+C was 0.90 (median PFS, 2.8 vs. 2.8 months; p = 0.63), and the HR for OS for P+C vs. V+C was 1.11 (median OS, 7.8 vs. 7.5 months; p = 0.66). Although not powered to evaluate sub-group interactions, in sub-group analysis, V+C showed PFS benefit versus P+C in two sub-groups; gallbladder cancer (GBC, HR = 0.55, 95% CI: 0.25, 1.22; median PFS, 2.9 vs. 1.6 months) and females (HR = 0.59, 95% CI: 0.28, 1.23; median PFS, 4.1 vs. 2.8 months). There was no PFS benefit for V+C vs. P+C among males and non-GBC. Toxicities were generally balanced between arms apart from a slightly higher incidence of hyperbilirubinemia, diarrhea and fatigue in the V+C vs. P+C arm. Grade 3/4 toxicities were reported in 66% and 59% of patients in the V+C and P+C arms, respectively. **Conclusions:** V+C is well tolerated but did not improve ORR, PFS or OS vs. P+C in 2L advanced BTC. Exploratory analyses suggested that patients with GBC and female patients achieved comparatively higher median PFS with V+C vs. P+C. Clinical trial information: NCT03093870. Research Sponsor: ASLAN Pharmaceuticals.

4598 Poster Session (Board #206), Fri, 8:00 AM-11:00 AM

Comprehensive gene expression analysis of IDH1/2 mutant biliary cancers (BC). *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Isocitrate dehydrogenases (IDH) mutations (mut) identify a distinct subtype of BC that has yet to be fully characterized. We recently showed that *IDH1/2* mutant (mIDH) BC harbor specific gene alterations involving chromatin remodeling and DNA repair, and a differential immune markers profile compared to other mIDH GI tumors. Here we aim to further dissect the molecular profile of mIDH BC through a comprehensive gene expression profiling analysis. **Methods:** 524 BC samples (303 intrahepatic cholangiocarcinoma, IHCC, 67 extrahepatic cholangiocarcinoma, EHCC, 141 gallbladder, 13 unspecified) collected between February to December of 2019 were included. Samples were analyzed using NextGen DNA sequencing (NextSeq, 592 gene panel), whole transcriptome RNA sequencing (NovaSeq) and immunohistochemistry (Caris Life Sciences, Phoenix, AZ). EBseq was used to identify differentially expressed genes in mIDH vs wild type (WT) tumors with control for FDR ($Q < 0.2$). Pathway and functional enrichment analysis was performed using g:Profiler and Enrichr. **Results:** mIDH frequency in our cohort was 11.4% (60/524), with higher prevalence of *IDH1* mut (8.8%). IHCC showed the highest mut prevalence: *IDH1* 13.5%, *IDH2* 4.6%. mIDH was more common in females ($P = 0.0036$). A total of 774 genes were significantly differentially expressed between mIDH and WT: 582 underexpressed (Fold change, FC: 0.025~0.699); 192 overexpressed (FC: 1.43~3.3). Pathway enrichment showed a significant decrease of gene expression in cytokine-cytokine receptor interaction ($Q = 0.002$) and inflammatory response genes ($Q = 0.005$) in mIDH. Interferon-γ- and PD1 signaling-related genes expression was significantly lower in mIDH vs WT ($Q = 0.02$) including *IFNG* (FC 0.32), *NKG7* (FC 0.36), *CD8B* (FC 0.37), *BATF* (FC 0.40), *PD1* (FC 0.53), *SLAMF6* (FC 0.55) and *PD-L2* (FC 0.60). Wnt and cadherin signaling were also enriched for altered expression in several genes in mIDH BC (Q = 3.86e-7 and < 0.00001, respectively). **Conclusions:** To our knowledge, this is the largest and most extensive gene expression profiling study focused on mIDH BC. Our data show for the first time a distinct gene expression profile characterizing mIDH tumors which display significant downregulation of inflammatory response pathways and immune-related genes. These findings contribute to further the understanding of mIDH BC and may inform the future development of rational combination therapies. 4599 Poster Session (Board #207), Fri, 8:00 AM-11:00 AM

Final results of a randomized, open label, perioperative phase II study evaluating nivolumab alone or nivolumab plus ipilimumab in patients with resectable HCC. *First Author: Ahmed Omar Kaseb, GI Medical Oncology Department, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In resectable hepatocellular carcinoma (HCC) surgical resection is associated with high recurrence rates. However, there is no approved neo-adjuvant or adjuvant therapies yet. Neoadjuvant immunotherapy effect has never been reported in this setting in HCC. **Methods:** This is a randomized phase II trial of nivolumab (Arm A) or nivolumab + ipilimumab (Arm B) as peri-operative treatment for patients (pts) with HCC who are eligible for surgical resection. Pts in Arm A are given nivolumab 240 mg iv, every 2 weeks (wks) for a total of 3 doses followed by surgery on week 6. Pts in Arm B are treated with nivolumab per same schedule as arm A plus concurrent ipilimumab 1 mg/kg on day 1. Adjuvant part of study starts 4 weeks after surgery, with Nivolumab at 480 mg iv every 4 weeks for 2 years in arm A. Pts in Arm B are treated with nivolumab per same schedule as arm A plus concurrent ipilimumab 1 mg/kg every 6 weeks times 4 doses after resection. The primary objective was the safety/tolerability of nivolumab +/- ipilimumab. Secondary objectives include overall response rate, pathologic complete response (pCR) rate and time to progression. Exploratory objectives include evaluating the pre- and post-treatment immunological changes in tumor tissues and peripheral blood. **Results:** 30 patients were enrolled, 2 patients withdrew consent, one patient was not eligible at time of therapy, and 27 randomized (13 to Arm A and 14 to Arm B). 21 patients proceeded with resection as planned and surgery was aborted for 6 patients; 1 for frozen abdomen due to old surgery, 2 for small residual volume, and 3 for progressive disease. Pts age ranged between 32-83 yo, 75 % were males, 7 pts had HCV, 7 had HBV and 7 had no hepatitis. Pathologic complete response (pCR) was observed in 5/21 pts (24% pCR rate) – 2 in Arm A and 3 Arm B, and 3/21 pts (16%) – 1 in Arm A, 2 in Arm B, achieved major pathologic response (necrosis effect of 50-99%). 5 patients in Arm B and 1 in Arm A experienced grade 3 or higher toxicity prior to surgery. No grade 4 or higher toxicity were observed and surgery was not delayed or cancelled due to oxicity. **Conclusions:** Our study reached its primary endpoint of safety. Importantly, we report a 40% pathologic response rate = pCR rate of 24%, and major necrosis rate of 16% for resectable HCC after preoperative immunotherapy in a randomized phase II pilot trial. After future validation, these promising results may contribute to a paradigm shift in the perioperative treatment of resectable HCC. Clinical trial information: NCT03222076. Research Sponsor: M.D. Anderson Cancer Center.

4600 Poster Session (Board #208), Fri, 8:00 AM-11:00 AM

Genome-wide plasma cell-free DNA methylation profiling to identify high-performing biomarkers for early detection of hepatocellular carcinoma. *First Author: Xin-Rong Yang, Zhongshan Hospital Liver Cancer Institute, Shanghai, China*

Background: Hepatocellular carcinoma (HCC) represents the second most common cause of cancer deaths worldwide. □-fetoprotein (AFP) is the most common serological test used for screening and diagnosis of HCC. However, it is widely recognized that AFP has lower sensitivity with sub-optimal specificity. Tumor-originated circulating cell-free DNA (cfDNA) provides new opportunity for non-invasive detection of liver cancer. **Methods:** HCC-specific differentially methylated regions (DMRs) were identified by whole genome bisulfite sequencing (WGBS) in 44 pairs of HCC tissues and adjacent tissues. We then performed methylome profiling on cfDNA from HCC patients and healthy individuals by targeted bisulfite sequencing covering genome-wide CpG islands, shelves, and shores. We employed machine learning approaches to build diagnostic models based on cfDNA regional methylation level to classify the plasma of HCC (n = 140) from that of healthy individuals (n = 84). Further analyses were performed in the validation cohort, including 155 HCC patients, and a control group with 96 healthy individuals, 21 chronic hepatitis B infection (CHB)/liver cirrhosis (LC) patients and 34 patients with benign hepatic lesions (BHL). Area under the receiver operating characteristic curve (AUC-ROC) was used to evaluate diagnostic performance. **Results:** A random forest classifier achieved an AUC of 0.97 (sensitivity: 92.9%; specificity: 89.4%) with 10-fold cross-validation using a panel of 39 DMR markers. The AUC of the diagnostic panel was 0.93 (sensitivity: 81.3%; specificity: 90.7%) in validation cohort, and it performed equally well in detecting BCLC stage 0+A (AUC = 0.90; sensitivity: 74.7%) and AFP negative (AUC = 0.92; sensitivity: 79.4%) HCC, as well as differentiating HCC from CHB/LC and BHL. Based on these results, we have further developed a small targeted bisulfite sequencing panel covering 127 CpG sites for non-invasive diagnosis of HCC. The panel had similar performance in training and validation cohorts, an AUC of 0.96 (sensitivity: 90.7%, specificity: 88.2%) in the training set, and 0.91 (sensitivity: 80.0%, specificity: 88.7%) in the validation set. **Conclusions:** Our diagnostic panel with 39 DMR markers showed high sensitivity and specificity in HCC diagnosis as well as surveillance in high-risk populations for developing HCC. More importantly, simple diagnostic model show similar diagnostic performance for early HCC diagnosis, which was easily to transfer to clinical application in the future. 4601 Poster Session (Board #209), Fri, 8:00 AM-11:00 AM

Phase Ib dose escalation and cohort expansion study of the novel myeloid differentiating agent MTL-CEBPA in combination with sorafenib in patients with advanced hepatocellular carcinoma (HCC). *First Author: Debashis Sarker, Guy's Hospital, King's College London, London, United Kingdom*

Background: MTL-CEBPA is the first small activating RNA to enter clinical trials and upregulates C/EBPα, a master regulator of myeloid cell differentiation. We previously reported a favourable safety profile of MTL-CEBPA as a single agent in HCC (Sarker D et al, ASCO 2018). After discontinuation of MTL-CEBPA, 3 out of 5 patients (pts) treated with sorafenib off study had a complete response (CR) of 7-18 months duration; 2 pts of which demonstrated resolution of lung metastases for > 1 year. Here we provide new data on pts prospectively treated with MTL-CEBPA + sorafenib. **Methods:** Primary objective was to assess safety and tolerability of MTL-CEBPA 90-130mg/m^2 QW or BIW in combination with sorafenib 400mg BD administered to HCC patients either concomitantly or sequentially, in cohorts either tyrosine kinase inhibitor (TKI) naive or resistant. Secondary objectives included preliminary assessment of activity by response rate (RECIST v1.1) and immune landscape analysis. **Results:** As at the cut off date of 1 Feb 2020, 12 pts have been treated with MTL-CEBPA co-administered with sorafenib and 14 pts with MTL-CEBPA followed by sorafenib (23M/3F, median age 65.5years, range 44-83, ECOG PS 0/1: 18/8). The most common treatment-related AEs (all grades/grade 3-4) in these groups include facial flushing (4/0), raised AST (4/2) raised ALT (2/1), fatigue (5/0), raised ALP (2/0), and anaemia (2/2), diarrhoea (3/0), rash (2/0) and anorexia (1/0). Of 14 evaluable pts in the TKI naive cohorts, 2 pts had CR, 3 pts had partial response and 7 had stable disease. 9/10 pts in the TKI resistant cohorts evaluable for efficacy had stable disease. Flow cytometry demonstrated statistically significant decreases in frequency of immature CD66$^+$CD10$^-$ neutrophils and myeloid derived suppressor cells. IHC demonstrated significant reduction in M2 macrophages in tumour biopsies. **Conclusions:** MTL-CEBPA + sorafenib is well tolerated with an acceptable safety profile. This study has confirmed signals of objective response to the combination treatment in TKI naïve HCC patients with viral aetiology, warranting expanded development in these patients. Updated efficacy and safety data will be presented. Clinical trial information: NCT02716012. Research Sponsor: MiNA Therapeutics.

4602 Poster Session (Board #210), Fri, 8:00 AM-11:00 AM

Immediate post-thermal ablation biopsy of colorectal liver metastases to predict oncologic outcomes. *First Author: Nikiforos Vasiniotis Kamarinos, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Thermal ablation (TA) is used as a local cure for selected colorectal liver metastases (CLM) with minimal risk. A critical limitation of TA has been early local tumor progression (LTP). The goal of this study is to establish the role of ablation zone (AZ) biopsy in predicting LTP. **Methods:** This institutional review board-approved prospective study included patients with CLM of 5cm or less in maximum diameter, with confined liver disease or stable, limited extrahepatic disease. Both radiofrequency(RF) and microwave(MW) ablation modalities were used. A biopsy of the center and margin of the AZ was performed immediately after ablation. The applicators were also examined for the presence of viable tumor cells. All samples containing morphologically identified tumor cells were further interrogated with immunohistochemistry to determine the proliferative and viability potential of the detected tumor cells. Ablation margin size was evaluated on the first CT scan performed 4–8 weeks after ablation and was confirmed by 3D assessment with Ablation Confirmation Software (Neuwave™). Variables were evaluated as predictors of time to LTP with the competing-risks model (uni- and multivariate analyses). **Results:** Between November 2009 and February 2019, 102 patients with 182 CLMs were enrolled. Mean tumor size was 2.0 cm (range, 0.6–4.8 cm). MW was used in 95/182 (52%) tumors and RF in 87/182 (48%). Median follow-up was 19 months. Technical effectiveness was evident in 178/182 (97%) ablated tumors on the first contrast material–enhanced CT at 4–8-weeks post-ablation. The cumulative incidence of LTP at 12 months was 19% (95% confidence interval [CI]: 14, 27). Samples from 64 (35%) of the 178 technically successful cases contained viable tumor. At univariate analysis, tumor size, minimal margin size, and biopsy results were significant in predicting LTP. In a multivariate model, margin size of less than 5 mm ($P < .001$; hazard ratio [HR], 4.3), and positive biopsy results ($P = .02$; HR, 1.8) remained significant. LTP within 12 months after TA was noted in 3% (95% CI: 1, 6) of tumor-negative biopsy CLMs with margins of at least 5 mm. **Conclusions:** Biopsy and pathologic examination of the AZ predicts LTP regardless of TA modality used. This can optimize ablation as a potential local cure for patients with limited CLM. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

4603 Poster Session (Board #211), Fri, 8:00 AM-11:00 AM

A randomized phase II study of oxaliplatin/5-FU (mFOLFOX) versus irinotecan/5-FU (mFOLFIRI) chemotherapy in locally advanced or metastatic biliary tract cancer refractory to first-line gemcitabine/cisplatin chemotherapy. *First Author: Jin Won Kim, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seognnam, South Korea*

Background: In locally advanced or metastatic biliary tract cancer (BTC), second-line chemotherapy is challenging after progression from first-line gemcitabine/cisplatin, although mFOLFOX has been proven to be superior to active symptom control in ABC-06 trial. Irinotecan is an active drug in other gastrointestinal cancers. This study evaluated whether mFOLFIRI was superior to mFOLFOX in second-line treatment of BTC. **Methods:** Patients diagnosed with BTC with disease progression after prior gemcitabine/cisplatin were randomized (1:1) to either mFOLFOX (oxaliplatin 100mg/m2 over 2 hours, leucovorin 100mg/m2 over 2 hours, 5-fluorouracil 2400mg/m2 over 46 hours, every 2 weeks) or mFOLFIRI (irinotecan 150mg/m2 over 2 hours, leucovorin 100mg/m2 over 2 hours, 5-fluorouracil 2400mg/m2 over 46 hours). Randomization was stratified by tumor location (intrahepatic vs extrahepatic vs gallbladder vs ampulla of vater) and ECOG performance status (0, 1 vs 2). Primary end-point was overall survival (OS) rate at 6 months. **Results:** In total, 120 patients were enrolled and 114 patients were treated (mFOLFOX:57, mFOLFIRI:57). Median age was 63 years old. Most patients had ECOG 0/1 (89.5%). Tumor location was intrahepatic in 47 patients (41.2%), extrahepatic in 27 (23.7%), gallbladder in 35 (30.7%) and ampulla of vater in 5 (4.4%). At the median follow-up duration of 10.7 months (95% CI, 8.2-13.2), 6-month OS rate was 58.1% in mFOLFOX and 46.0% in mFOLFIRI. Of 102 evaluable patients (mFOLFOX:51, mFOFIRI:51), objective response rate and disease control rate were 5.9% (95% CI, 0-12.4) and 64.7% (95% CI, 51.6-77.8) in mFOLFOX and 3.9% (95% CI, 0-9.2) and 58.8% (95% CI, 45.3-72.3) in mFOLFIRI. Median progression-free survival was 2.8 months (95% CI, 2.3-3.3) in mFOLFOX and 2.1 months (95% CI, 1.3-2.9) in mFOLFIRI ($p = 0.682$). Median OS was 6.6 months (95% CI, 5.6-7.6) in mFOLFOX and 5.9 months (95% CI, 4.3-7.5) in mFOLFIRI ($p = 0.887$). The most common grade 3/4 adverse events were neutropenia (26.3%) and AST/ALT elevation (15.8%) in mFOLFOX and neutropenia (24.6%) and anemia (17.5%) in mFOLFIRI. Peripheral neuropathy (36.8%) and thrombocytopenia (35.1%) in mFOLFOX and vomiting (19.3%) and cholangitis (10.5%) in mFOLFIRI occurred more frequently. No chemotherapy-related deaths were reported. **Conclusions:** In second-line treatment of BTC, mFOLFIRI was tolerable But, mFOLFIRI was not superior to mFOLFOX. Adverse events were different between two groups. Clinical trial information: NCT03464968. Research Sponsor: CJ health care, Jeil pharmaceutical company.

4604 Poster Session (Board #212), Fri, 8:00 AM-11:00 AM

Safety of ^{177}Lu-DOTATATE in patients with advanced neuroendocrine tumors: Data from a U.S. expanded access program. *First Author: Martin S. Auerbach, Department of Molecular and Medical Pharmacology, University of California, Los Angeles, CA*

Background: The NETTER-1 clinical trial showed that peptide receptor radionuclide therapy (PRRT) with ^{177}Lu-DOTATATE increased progression-free survival in patients with somatostatin-receptor-positive advanced midgut neuroendocrine tumors (NETs) compared with high-dose octreotide long-acting repeatable, and was associated with few serious adverse events (AEs). To assess the safety profile of ^{177}Lu-DOTATATE in a real-world population, we analyzed safety data from a US expanded access program (NCT02705313). **Methods:** Patients had inoperable, histologically proven, somatostatin-receptor-positive, locally advanced or metastatic midgut NETs (Ki-67 index ≤ 20%) that progressed after somatostatin analog therapy. Exclusion criteria were: surgery, radiotherapy or chemotherapy in the last 12 weeks; treatment with an interferon, mTOR inhibitor, or other systemic therapy in the last 4 weeks; or ongoing octreotide therapy that could not be interrupted for PRRT. Patients with impaired renal function (serum creatinine > 1.7 mg/dL or creatinine clearance < 50 mL/min) or serious coexisting conditions were excluded. The analysis included patients who received ≥ 1 cycle of ^{177}Lu-DOTATATE between July 5, 2016 and December 21, 2018. Data were collected from the first cycle to the latest data collection point (up to October 7, 2019). **Results:** 299 patients received a mean ^{177}Lu-DOTATATE cumulative dose of 552 mCi (20.4 GBq) (standard deviation [SD]: 220 mCi [8.1 GBq]) over a mean of 2.8 cycles (SD: 1.1). Mean age was 60.8 years (SD: 11.7); 38.5% of patients were men. Over a mean follow-up of 131 days (SD: 87), 48.8% of patients reported treatment-related AEs (TRAEs), with a maximum severity of grade 1, 2 and 3 for 26.8% (n = 80), 18.1% (n = 54) and 4.0% (n = 12) of patients, respectively; there were no grade 4–5 TRAEs. The most common TRAEs of any grade (≥ 5.0% of patients) were nausea (31.1%), vomiting (13.7%), fatigue (9.4%) and thrombocytopenia (6.0%). The most prevalent grade 3 TRAEs were lymphocyte count decrease (1.0%) and thrombocytopenia (0.7%). Serious TRAEs occurred in 1.0% of patients (carcinoid crisis, dehydration, syncope and vomiting). AEs led to dose modification in 1.7% of patients, dose delay in 6.4% (most commonly due to nausea [2.0%] or thrombocytopenia [2.0%]) and discontinuation in 1.3% (due to thrombocytopenia [1.0%] and extravasation [0.3%]). **Conclusions:** In a real-world population of US patients with advanced midgut NETs, ^{177}Lu-DOTATATE treatment was well tolerated with few TRAEs, consistent with the safety profile in the NETTER-1 trial. Clinical trial information: NCT02705313. Research Sponsor: Advanced Accelerator Applications, a Novartis company.

4605 Poster Session (Board #213), Fri, 8:00 AM-11:00 AM

Risk of cancer-specific death for patients diagnosed with neuroendocrine tumors: A population-based analysis. *First Author: Julie Hallet, Odette Cancer Centre, Toronto, ON, Canada*

Background: While patients with neuroendocrine tumours (NETs) are known to experience prolonged overall survival, the contribution of cancer-specific and non-cancer deaths is undefined. We examined cancer-specific and non-cancer death after NET diagnosis. **Methods:** We conducted a population-based retrospective cohort study of adult patients with NETs from 2001-2015 by linking administrative healthcare datasets. Using competing-risks methods, we estimated the cumulative incidence of cancer-specific and non-cancer death and stratified by primary NET site and metastatic status. Sub-distribution hazard models examined prognostic factors. **Results:** Among 8,607 included patients, median follow-up was 42 months (interquartile range: 17-82). The risk of cancer-specific was higher than that of non-cancer death, with 27.3% (95%CI: 26.3-28.4%) and 5.6% (95%CI: 5.1-6.1%) at 5 years. Cancer-specific deaths largely exceeded non-cancer deaths in synchronous and metachronous metastatic NETs. Patterns varied by primary tumour site, with highest risks of cancer-specific death in broncho-pulmonary and pancreatic NETs. For non-metastatic gastric, small intestine, colonic, and rectal NETs, the risk of non-cancer death exceeded that of cancer-specific deaths. Advancing age, higher material deprivation, and metastases were independently associated with higher hazards, and female sex and high comorbidity burden with lower hazards of cancer-specific death. **Conclusions:** Among all NETs, the risk of dying from cancer is higher than that of dying from other causes. Heterogeneity exists by primary NET site. Some patients with non-metastatic NETs are more likely to die from non-cancer than from cancer causes. This information is important for counselling, decision-making, and design of future trials. Cancer-specific mortality should be included in outcomes when assessing treatment strategies. Research Sponsor: CIHR.

4606 Poster Session (Board #214), Fri, 8:00 AM-11:00 AM

Outcome analyses in patients with metastatic gastroenteropancreatic neuroendocrine tumors receiving peptide receptor radionuclide therapy with ^{177}Lu-DOTATATE – Impact of treatment order and combination on mortality. *First Author: Alexander Rheinhard Siebenhuener, Klinik für Medizinische Onkologie und Hämatologie, UniversitätsSpital Zürich, Zürich, Switzerland*

Background: Neuroendocrine tumors of the gastroenteropancreatic tract present heterogeneous with several systemic treatment options in the advanced setting. PRRT with ^{177}Lu-DOTATATE targeting the SSTR-2 receptor of these tumors showed effective responses in the NETTER-1 trial in the short as well as long term follow-up of patients. The aim of our study was to determine the HRQoL and outcome of GEP-NET patients. **Methods:** 41 GEP-NET patients who received ^{177}Lu-DOTATATE (mean: 3 cycles) between 2012 and 2017 at University Hospital Zurich (USZ) were included in this retrospective analysis. HRQoL parameters (fatigue, insomnia, loss of appetite, abdominal pain, nausea, emesis, diarrhea, weight loss) were assessed before and after treatment. At least 3 weeks after the last PRRT cycle, data on blood parameters, HRQoL, and overall survival data were extracted from patient records. To determine factors influencing the success of PRRT therapy and survival, we recorded pre- and post-PRRT treatments (e.g. selective internal radiation therapy/SIRT, somatostatin analogue therapy/SSA, TKI or chemotherapy) and the time-point of PRRT in the therapeutic sequence was analyzed. **Results:** Baseline rates of HRQoL and ECOG performance status were assessed (baseline mean: ECOG 0). PRRT was well tolerated, with most patients reporting no significant deterioration in HRQoL after treatment. Blood parameters (hemoglobin, leucocyte and platelet counts, creatinine) and glomerular filtration rate were not significantly affected by PRRT therapy. The number of previous treatments did not influence survival after PRRT; neither did the length of the time period between first diagnosis and PRRT. Patients with a SIRT treatment prior to PRRT had an elevated mortality odds ratio of 4.083. If SIRT was applied to patients with a pancreatic tumor, the mortality odds ratio was 1.33 compared to patients without a pancreatic tumor. Post-PRRT SSA increased the odds for survival, with a mortality odds ratio of 2.33 for patients without SSA after PRRT. **Conclusions:** Patients with advanced GEP-NETs may benefit from PRRT with ^{177}Lu-DOTATATE, as this treatment appears to be well tolerated and does not significantly impair the HRQoL or symptom load. SIRT before PRRT seems to lower the chances of response and reduces survival instead using this sequence vice versa. This trend was also seen if SSA was not used after PRRT. But these trends have to be proven in prospective trials. Research Sponsor: None.

4607 Poster Session (Board #215), Fri, 8:00 AM-11:00 AM

Multicenter analysis of treatment outcomes for well differentiated grade 3 neuroendocrine tumors (NET G3). *First Author: Leonidas Apostolidis, Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany*

Background: Well differentiated grade 3 neuroendocrine tumors (NET G3) have been distinguished from poorly differentiated neuroendocrine carcinomas (NEC) in the most current WHO classifications from 2017 and 2019. Retrospective data suggest that commonly applied first-line chemotherapy protocols with cisplatin or carboplatin in combination with etoposide (PE) are less effective in NET G3 than NEC. Therefore, current treatment guidelines suggest alternative first-line treatment protocols like temozolomide-based (TEM), streptozotocin-based (STZ) and FOLFOX which have only been studied in second-line so far. The aim of this multicenter analysis was to evaluate treatment outcomes for NET G3 with a focus on the efficacy of different first-line regimens. **Methods:** We performed retrospective analysis of all patients with NET G3 in the NEN databases of 3 German cancer centers. All histopathological findings were reviewed by the investigators in order to comply with the most current WHO classification. **Results:** A total of 131 patients could be identified. Median Ki67 was 30 %, primary tumors were located in the pancreas in 71 % of cases, 20 patients had a history of prior NET G1/G2 diagnosis. Median overall survival (OS) was 138.1 months with a median follow-up of 20.4 months. 125 patients received palliative first-line therapy: PE n = 34, FOLFOX n = 36, TEM (mostly temozolomide+capecitabine) n = 21, STZ n = 19, other (including targeted agents, somatostatin analogues, PRRT and multimodal combination approaches) n = 15. Overall response (ORR) and disease control rate was 35.3 % and 67.6 % for PE, 52.8 % and 80.6 % for FOLFOX, 28.6 % and 66.7 % for TEM, 47.4 % and 68.4 % for STZ, 20.0 % and 73.3 % for other respectively. Median progression-free survival for PE was 5.2 months. Compared to PE, PFS in the other treatment groups was 6.0 months for FOLFOX (p = 0.164), 12.0 months for TEM (p = 0.059), 5.7 months for STZ (p = 0.519), 14.1 months for other (p = 0.003). All non-PE patients combined showed a significantly prolonged PFS vs. PE (9.0 vs. 5.2 months; p = 0.011). 89 patients received second-line systemic therapy with a median PFS of 5.3 months. **Conclusions:** In this first multicenter analysis of different treatment strategies for NET G3, patients receiving upfront treatment with non-PE regimens had a significantly prolonged PFS. Of the single defined protocols, FOLFOX showed the highest ORR, and TEM the longest PFS. Further prospective evaluation of the optimal therapeutic strategy for this newly defined tumor entity is needed. Research Sponsor: None.

4608 Poster Session (Board #216), Fri, 8:00 AM-11:00 AM

Australasian Gastrointestinal Trials Group (AGITG) CONTROL NET Study: Phase II study evaluating the activity of ^{177}Lu-Octreotate peptide receptor radionuclide therapy (LuTate PRRT) and capecitabine, temozolomide CAPTEM)—First results for pancreas and updated midgut neuroendocrine tumors (pNETS, mNETS). *First Author: Nick Pavlakis, Northern Cancer Institute, St Leonards, Sydney, Australia*

Background: CAPTEM is an accepted regimen for patients (pts) with advanced pNETs. Single agent ^{177}Lu-Octreotate PRRT is now a standard of care for progressive WHO Grade (G) 1/2 mNETs. High activity was seen with LuTate/CAPTEM in a single arm Phase I/II trial. This study was undertaken to determine the relative activity of adding CAPTEM to LuTate PRRT in pts with mNETs and pNETs. **Methods:** Non-comparative randomised open label parallel group phase II trial with 2:1 randomisation to PRRT/CAPTEM (experimental arm) vs. PRRT (mNETs control) and CAPTEM (pNETS control). PRRT/CAPTEM: 7.8GBq LuTate day(D) 10, 8 weekly (wkly) x 4, with b.i.d. oral CAP 750mg/m^2 D1-14 & TEM 75mg/m^{2}D10-14, 8 wkly x 4; PRRT: 8 wkly x 4; CAPTEM 8 wkly x 4. Primary endpoint: Progression free survival (PFS). mNETS- at 15 months (mo) assuming 15mo PFS 66.4% in control arm, aiming for PFS ³ 80%; pNETS- at 12mo assuming 12mo PFS 60% in control arm, aiming for PFS ³ 75%. Secondary endpoints: Objective tumour response rate (complete or partial) (OTRR), clinical benefit rate (OTRR, stable disease) (CBR), toxicity, quality of life. **Results:** 75 pts enrolled (Dec 2015 – Nov 2018): mNETs 33 PRRT/CAPTEM and 14 PRRT; pNETS 19 PRRT/CAPTEM and 9 CAPTEM. mNETS: Median follow-up 35mo; 15mo PFS was 90% (95% CI: 73-97%) v 92% (95% CI: 57-99%); OTRR 31% vs 15%; and CBR 97% vs 92% for PRRT/CAPTEM v PRRT respectively. Treatment related adverse events (AEs): 24/32 PRRT/CAPTEM pts had at least one G3 event (75%) vs 5/13 (38%, PRRT); and 4/32 pts at least one G4 event (13%) v 1/13 (8%) respectively, mostly haematologic (haem). Only one patient failed to complete therapy (PRRT/CAPTEM). pNETS: Median follow-up 34mo; 12mo PFS was 76% (95% CI: 48-90%) v 67% (95% CI: 28-88%); OTRR 68% vs 33%; and CBR 100% vs 100% for PRRT/CAPTEM v CAPTEM respectively. Treatment related AEs: 5/18 PRRT/CAPTEM pts had at least one G3 event (28%) vs 3/9 (33%) CAPTEM; 3/18 pts at least one G4 event (17%) v 1/9 (11%) respectively. **Conclusions:** CAPTEM/PRRT is active, meeting its target landmark PFS for CAPTEM/PRRT (12mo pNETs; 15mo mNETs) with numerically greater OTRR in both pNETs and mNETs, but with more haem toxicity in mNETs. As activity was high in both control arms longer follow up is required to determine if the relative activity of PRRT/CAPTEM is sufficient to warrant Phase III evaluation. Clinical trial information: ACTRN12615000909527. Research Sponsor: Unicorn Foundation, Tour de Cure Australia.

4609 Poster Session (Board #217), Fri, 8:00 AM-11:00 AM

Pretherapeutic ^{68}Ga-DOTATATE PET SUV predictors of survival of radionuclide therapy for metastatic neuroendocrine tumors. *First Author: Rahul Ladwa, Princess Alexandra Hospital & University of Queensland, Brisbane, Australia*

Background: Peptide receptor radionuclide therapy (PRRT) is an effective treatment option in patients with advanced neuroendocrine tumours (NETs). Patients are pre-selected based on ^{68}Gallium-DOTA-(0-Tyr3)-octreotate Positron Emission Tomography (^{68}Ga-DOTATATE PET) uptake. The level of uptake in tumour on the baseline ^{68}Ga-DOTATATE PET scan has been explored as a predictor of response in NETs with inconclusive evidence. The aim of this study is to determine the correlation between ^{68}Ga-DOTATATE PET SUV parameters to survival outcomes. **Methods:** We retrospectively analysed 142 lesions (up to five lesions per patient) in 73 patients with NET undergoing PRRT with ^{177}Lutetium octreotate (8.0-8.3GBq) and pretherapeutic ^{68}Ga-DOTATATE PET/CT in a single institution. Standardised uptake values (SUVs) max and mean were correlated with progression-free survival (PFS) and overall survival (OS). **Results:** A total of 73 patients were included in the analysis. The median age was 63 (28-89) years. NET origin was gastroenteric (49%), pancreatic [pNET] (38%), bronchial (10%) and other (3%). Ki-67 proliferation index ($<$ 3%: 36%, 3-20%: 36%, $>$ 20%-$<$ 50%: 8%, unknown: 21%) was seen. Pretherapeutic SUV max but not SUV mean was higher in pNETs (P = 0.04). No difference was seen with Ki-67 index. The median PFS was 32 (95%CI: 26-38) months. Median PFS was reduced with increasing ECOG performance status [PS] (P= 0.029), increasing tumour grade (P = 0.003), increasing Ki-67 proliferation index (P = 0.013), reduced SUV max (P= 0.003), reduced SUV mean (P= 0.001). Multivariate analysis confirmed SUV mean (HR =-1.71 [95%CI: -2.66- -0.80]; P$<$0.01) and Ki-67 index (HR = 1.11 [1.06-1.17]; P $<$ 0.01) as maintaining significance when incorporating ECOG PS (HR = 1.96 [0.68-5.47]; P = 0.22). The mean OS was 40 [37-44] months. A higher SUV max (SUV max $<$ 30: 34 [30-40] months vs SUV max $>$ 30: 48 [44-51]; P$<$0.01) and higher SUV mean (SUV mean $<$ 20: 33 [28-39] months vs SUV mean $>$ 20: 47 [43-51]; P$<$0.01) were associated with improved mean OS. Mean OS was not affected by ECOG performance status (P = 0.896), primary site of origin (P = 0.567) and Ki-67 index (P = 0.110). **Conclusions:** ^{68}Ga-DOTATATE PET SUV measures correlated with an improved PFS on multivariate analysis as well as improved OS in this select group of patients suitable for PRRT. Those patients with lower SUV mean may benefit from escalation of therapy such as increasing administered therapeutic activity. Research Sponsor: None.

4610 Poster Session (Board #218), Fri, 8:00 AM-11:00 AM

Efficacy and safety of surufatinib in United States (US) patients (pts) with neuroendocrine tumors (NETs). *First Author: Arvind Dasari, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Surufatinib (S) is a targeted inhibitor of tyrosine kinases VEGFR1, 2, & 3, FGFR1, and CSF-1R. Safety and efficacy of S has previously been studied in China in early phase development, and in 2 randomized phase 3 placebo controlled trials (NCT02588170 & NCT02589821). These trials enrolled pts with NETs of extrapancreatic (epNET) and pancreatic (panNET) origin, respectively. Both trials are completed, stopping at their pre-planned interim analysis after meeting the primary endpoint of improved PFS. S demonstrated significant efficacy in pts with advanced epNETs, achieving a median Progression Free Survival [mPFS] of 9.2 v 3.8 months when compared to placebo. The mPFS achieved in pts with advanced panNETs is currently pending future disclosure at an upcoming scientific conference. **Methods:** A dose escalation (ESC)/expansion (EXP) study was conducted to evaluate and confirm the effects of S in US pts. Dose ESC was completed and the maximum tolerated dose and recommend phase 2 dose was determined to be 300mg QD; the same as previous trials. The primary objective of EXP was to evaluate anticancer activity in pts with select indications including panNETs and epNETs. **Results:** As of 21-Jan-20, 32 pts with heavily pre-treated progressive NETs (median prior lines of treatment [Tx]: 3; range 1-8) were enrolled. The 32 pts included 16 pts with panNET and 16 with epNET. All previously received everolimus and/or sunitinib. The median duration of Tx at the time of the data cut-off was 19 wks for all pts; 30.9 wks for panNET and 11 for epNET. 19 pts remain on active Tx (13 epNET and 6 panNET pts), 9 pts discontinued due to progression of disease, 2 withdrew consent and 2 discontinued due to adverse event (AE) (grade 3 tricuspid valve insufficiency, and grade 3 GI bleed). An objective response rate of 9.4% was observed. 3 panNET pts achieved a confirmed partial response (PR) and 1 had an unconfirmed PR per RECIST 1.1; no epNET pts achieved a PR. The safety profile of S remains consistent with previously completed trials. 27 pts (84.4%) had reported at least one adverse event (AE), and 16 pts (50%) reported $\geq$ grade 3 AE's. The most common AE's reported were: hypertension, fatigue, diarrhea, proteinuria and nausea. Pharmacokinetics (PK) analyses has shown similar exposure in panNET and epNET pts as was observed in ESC, and pts from the collective pool of pts. **Conclusions:** S has demonstrated promising antitumor activity in US pts with progressive NETs with a manageable safety profile. Additionally, PK and dose exposure data is consistent with trial results from large randomized phase 3 trials. Clinical trial information: NCT02549937. Research Sponsor: Hutchison MediPharma International Inc.

4611 Poster Session (Board #219), Fri, 8:00 AM-11:00 AM

Correlation of DLL3 expression in gastroenteropancreatic neuroendocrine neoplasms with loss of RB1 and prognostic significance. *First Author: Chiara Liverani, Osteoncology and Rare Tumors Center, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy*

Background: Neuroendocrine neoplasms (NENs) are a rare subgroup of tumors with challenging management due to their unpredictable and heterogeneous behaviour. The identification of clinically useful biomarkers is a top priority need in this disease. The negative notch regulator DLL3 has gained increasing attention in small cell lung carcinoma, large cell neuroendocrine carcinoma and neuroendocrine prostate cancer, confirming the tumor suppressor function of Notch-1 signaling in neuroendocrine cells. **Methods:** A retrospective immunohistochemical analysis of DLL3, PD-L1 and RB1 was performed on FFPE samples from 43 patients with gastroenteropancreatic (GEP)-NENs and correlated with clinical characteristics. **Results:** DLL3 was expressed in high-grade (G3) GEP-NENs. The presence of DLL3 was significantly associated with poorly differentiated NEC (77.8% positive tumors), while none of the patients with well-differentiated NET expressed this marker. Expression of DLL3 was correlated with loss of RB1 and negative ^{68}Ga-PET/CT scan. The 85.7% of DLL3- positive tumors showed loss of RB1 expression, while only 1 out of 35 DLL3- negative tumors had RB1 loss. DLL3 was expressed in 75% of patients with negative ^{68}Ga-PET/CT, while only in 25% of patients with positive ^{68}Ga-PET/CT scan. The presence of DLL3 was negatively associated with PFS and OS. Median PFS was 41.9 months in DLL3-negative patients versus 7.9 months in DLL3-positive patients; median OS was 72.9 months in DLL3-negative patients versus 11.7 months in DLL3-positive patients. No correlation was found with DLL3 and PD-L1 expression. The presence of PD-L1 was not associated with any clinical characteristics. **Conclusions:** DLL3 is expressed in high grade GEP-NENs and is associated with loss of RB1, negative ^{68}Ga-PET/CT scan and unfavourable clinical outcome. The presence of DLL3 discriminates poorly differentiated NEC from well-differentiated NET. DLL3 could represent the ideal prognostic factor to stratify patients with GEP-NENs and a candidate therapeutic target in NEC patients. Research Sponsor: None.

4612 Poster Session (Board #220), Fri, 8:00 AM-11:00 AM

Inefficacy of chromogranin a assays as neuroendocrine tumor diagnostic tools compared to the NETest. *First Author: Anna Malczewska, Medical University of Silesia, Katowice, Poland*

Background: Chromogranin A (CgA) remains a commonly used diagnostic and monitoring tool for neuroendocrine tumor disease despite NCCN guidelines identifying it as a category 3 (major concerns about utility) biomarker. Several commercial assays have been developed to measure this protein (or its fragments) and are available both at CLIA-certified laboratories (USA) as well as in NET Centres of Excellence (CoEs - Europe). CgA is typically reimbursed by insurance companies and appears in several guidelines (e.g., ENETS). We sought to directly evaluate the accuracy of detecting NET disease using two different CgA assays, one in the USA (NEOLISA, EuroDiagnostica, IBL-America, CLIA-certified laboratory) and one in an ENETS CoE (CgA ELISA, Demeditec Diagnostics, Germany). We compared the results to the NETest, a circulating mRNA assay, recently validated as an *IVD* for NETs. **Methods:** Patients: NETs (n=258) including lung: n=43; duodenum n=9; gastric: n=44; pancreas: n=67; small bowel: n=40; appendix: n=10; rectum: n=45. No image-evidence of disease (n=122) (IND) and image-positive disease (IPD) (n=136). CgA assays (plasma): NEOLISA, ULN $>$108ng/ml, DD: ULN$>$99ng/ml. Data mean$\pm$SEM. NETest (whole blood): qRT-PCR - multianalyte algorithmic analyses, CLIA-laboratory. All samples de-identified and assessed blinded. Statistics: Mann-Whitney U-test, Pearson correlation & McNemar-test. **Results:** In the entire group (n=258), NEOLISA assay CgA levels were significantly ($p$$<$0.0001) higher (216$\pm$91ng/ml) vs. the DD-assay (76$\pm$8ng/ml). The assays exhibited a high concordance in output (Pearson r=0.81, $p$$<$0.0001), but there were 10.9% (n=31) discordant results. This reflected the NEOLISA assay detecting more CgA-positive samples. IPD group: CgA-positives were detected in 48/136 (35%, NEOLISA) vs. 28 (21%, DD-assay). McNemar's Chi^2=15.04, $p$$<$0.001 OR: 11.0, indicating the NEOLISA was significantly better than the DD-assay. The NETest, in contrast, was positive in 135/136 (99%; OR: 87-106, $p$$<$0.0001). IND group: CgA-positives were detected in 12/122 (10%, NEOLISA) vs. 9 (7%, DD-assay; p=NS). The majority (75%) of positives were associated with gastric NETs. The NETest was positive in 7 (6%); 4 were gastric NETs and 3 exhibited elevated CgA. **Conclusions:** Two standard CgA assays used for NET management (one accepted by Medicare in the USA, the second used at a CoE in Europe) only detect NET disease in 21-35% of cases. In contrast, a circulating mRNA fingerprint, the NETest, is ~99% accurate for detecting NET disease. Research Sponsor: None.

4613 Poster Session (Board #221), Fri, 8:00 AM-11:00 AM

Health-related quality-of-life results from SANET-ep: A phase III study of surufatinib versus placebo for advanced extrapancreatic neuroendocrine tumors. *First Author: Chunmei Bai, Peking Union Medical College Hospital, Beijing, China*

Background: In the phase 3 study (SANET-ep, NCT02588170), surufatinib significantly prolonged progression free survival compared with placebo in patients with progressive, well-differentiated advanced extrapancreatic neuroendocrine tumors (epNETs) (ESMO 2019 Abs. LBA76). Here, we report the results of health-related quality-of-life (HRQoL) from this study. **Methods:** Eligible patients were randomized in a 2:1 ratio to receive surufatinib or placebo, 300 mg, orally, once daily, until disease progression or intolerable adverse events. Patient-reported outcome questionnaires, including the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 and the QLQ-G.I.NET-21, were collected at baseline, Day 15 of the first cycle (28 Days/cycle), and Day 1 of every cycle thereafter and at discontinuation. Time until definitive deterioration (TUDD) was defined as time from randomization to deterioration of 10 points in domain score compared with baseline score (without subsequent observations of deterioration of less than 10 point or any improvement as compared to baseline score), or death due to any cause. TUDD and mean change from baseline based on a longitudinal repeated measures analysis of each domain were analyzed retrospectively. Significance testing was at two-sided 0.05 without adjustment for multiplicity. **Results:** Of 198 pts randomized (surufatinib n = 129; placebo n = 69), 197 (99.5%) patients completed HRQoL questionnaires at baseline. The questionnaire compliance rate was > 90% for most on-treatment assessments. The TUDD was significantly longer in the surufatinib arm versus the placebo arm in the dyspnea domain (hazard ratio [HR] 0.52, p = 0.0103) and social function scale (HR 0.58, p = 0.0222), while the TUDD of diarrhea was significantly shorter in the surufatinib arm compared to placebo (HR 2.68, p = 0.0074). There was no significant difference of TUDD in the remaining domains of QLQ-C30 and G.I.NET-21. There was also no significant difference of the mean change of scores from baseline by repeated measures in the domains between the two arms except diarrhea (increase of 14.0 points [95% CI 9.6, 18.4] in the surufatinib arm versus 2.1 points [95% CI -4.1, 8.4] in the placebo arm, p = 0.0007). **Conclusions:** Treatment with surufatinib resulted in superior efficacy, acceptable toxicity, while generally maintaining HRQoL, which support surufatinib as a treatment option in this patient population that was previously treated with available therapies for epNETs. Clinical trial information: NCT02588170. Research Sponsor: Hutchison MediPharma Limited.

4614 Poster Session (Board #222), Fri, 8:00 AM-11:00 AM

Toxicity analysis of capecitabine/temozolomide in NETs. *First Author: Taymeyah E. Al-Toubah, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: The capecitabine/temozolomide regimen has significant activity in advanced NETs. Concerns exist regarding risk of opportunistic infections and long-term myelotoxicity. Analysis of large patient cohorts is needed for evaluation of rare toxicities and for assessment of risk factors. **Methods:** Retrospective study of all patients with advanced neuroendocrine neoplasms seen at the Moffitt Cancer Center between 1/2008 and 6/2019 who received treatment with CAPTEM. Patients who initiated treatment at outside institutions were included if they were prescribed treatment at appropriate doses and if complete records were available. **Results:** 462 patients met eligibility criteria for evaluation: 210 (45%) females and 252 (55%) males with a median age of 59. Median starting doses of CAP and TEM were 658mg/m^2 and 180mg/m^2 respectively. Median duration on treatment was 8 months. 25% of patients required a dose reduction and 16% discontinued due to toxicity of any grade. Incidence of grade 4 thrombocytopenia was 7%: 10% in females and 5% in males (p = 0.02). 4 cases were complicated by bleeding (0.8%). Incidence of grade 4 neutropenia was 3%: 5% in females and 1% in males (p = 0.004). Incidence of grade 4 lymphopenia was 2%. Only one case (0.2%) of suspected PCP was observed in a patient taking corticosteroids. There were 5 cases of herpes zoster and no other opportunistic infections. 3 patients developed myelodysplastic or myeloproliferative disease, all of whom had also received prior PRRT with Lutetium-Dotatate. There were no acute treatment related deaths, although one patient died 2 months after a thrombocytopenic bleed. **Conclusions:** Severe myelotoxicity is rare, but risks of grade 4 thrombocytopenia and neutropenia are significantly increased in females compared to males. Gender-based dosing should be considered. While alkylating agents are often associated with MDS, there were no cases except among patients who also had received PRRT, a known risk factor. PCP is not a significant risk with this regimen in patients not concurrently on corticosteroids. Research Sponsor: None.

4615 Poster Session (Board #223), Fri, 8:00 AM-11:00 AM

Phase II clinical trial of nab-paclitaxel plus gemcitabine in elderly patients with previously untreated locally advanced or metastatic pancreatic adenocarcinoma: BIBABRAX study. *First Author: Jaime Feliu Batlle, Medical Oncology Department, La Paz University Hospital, Madrid, Spain*

Background: FOLFIRINOX and nab-paclitaxel plus gemcitabine (nab-P+G) are the standard of care in the first-line treatment of mPC patients (pt) with good performance status. However, no standards of care exist for elderly (> 70 years) pt as they are usually excluded in clinical trials. This study aimed to evaluate whether the clinical benefit of nab-P+G could be extended to elderly pt with mPC. **Methods:** This was an open-label, single-arm, multicenter, phase II trial, to assess the efficacy and safety of Nab-P+G in elderly pt (≥ 70 years) with ECOG PS 0–1 and untreated unresectable locally advanced or metastatic PC. Pt received four-week cycles of intravenous (i.v.) nab-paclitaxel 125 mg/m2, followed by i.v. gemcitabine 1,000 mg/m2, on days 1, 8 and 15, until disease progression. Efficacy was evaluated according RECIST v 1.1 criteria and safety according NCI-CTCAE v 4.0 criteria. **Results:** Eighty pt were enrolled in the study. Median age was 74.6 years (range 70-87.9), 57.5% were men, 71% had ECOG PS 1 and 86% metastatic disease. 16.3% of patients had a history of prior tumor surgical resection, 12.5% received chemotherapy and 3.8% radiotherapy. Primary tumor was located in head (32.5%), tail (25.0%) and body (22.5%). Nab-P and G was reduced in 49% and 41% of pt respectively. 15 pt definitely interrupt study treatment due to toxicity: neurotoxicity (7), asthenia (5), neutropenia (1), leukocytosis (1) and hepatotoxicity (1). Time until definite deterioration (reduction ≥10 points as compared to baseline in EORTC-QLQ C30) was 1.6 months and deterioration-free rate at 3 months was 54.3%. Overall response rate was 13.8%, clinical benefit rate 67.5%, median PFS 7.2 months and median OS 9.2 months. The most common treatment-related adverse events were asthenia (60.0%), diarrhea (40.0%), neutropenia (33.8%), hair loss (28.8%), thrombocytopenia (26.3%), and nausea (23.8%). Only asthenia and neutropenia presented a relatively high incidence of grade 3 and 4 toxicities (21.3%). At least 1 SAE was reported in 55% of pt. **Conclusions:** BIBABRAX study confirms the clinical benefit of nab-P+G in an elderly population with mPC, in terms of survival, clinical response and tolerance, therefore it could be considered a treatment option for elderly patients. However, it was unable to demonstrate the preplanned benefit on the quality of life. Further research is needed on treatment strategies that could reduce deterioration of the quality of life in these pt. Clinical trial information: NCT02391662. Research Sponsor: Celgene.

4617 Poster Session (Board #225), Fri, 8:00 AM-11:00 AM

Circulating tumor DNA is prognostic and potentially predictive of eryaspase efficacy in patients with advanced pancreatic adenocarcinoma. *First Author: Jean-Baptiste Bachet, Pitié-Salpêtrière Hospital, Paris, France*

Background: Eryaspase is composed of L-asparaginase encapsulated in erythrocytes. It has demonstrated significant efficacy in combination with chemotherapy in a randomized phase 2 trial in second-line in patients with advanced pancreatic adenocarcinoma. We assessed, in this study, the prognostic and predictive value of circulating tumor DNA (ctDNA) in plasma samples of patients included in the eryaspase phase 2 trial. **Methods:** Samples prospectively collected pre-treatment at each 28-day cycle were centrally analyzed by next-generation sequencing (BPER method). Prognostic values of baseline ctDNA and ctDNA early changes between day 0 and 28 were assessed in both arms combined on objective response rate (ORR), progression free survival (PFS) and overall survival (OS). We conducted interaction test between ctDNA positivity and treatment arm, and the predictive value of ctDNA for eryaspase efficacy was investigated. **Results:** Patients with at least one available plasma sample have been included (n = 122/141). The presence of ctDNA at baseline was identified in 68% (77/113) of patients and was an independent negative prognostic factor for OS (4.6 vs 8.8 months; p = 0.0025) and PFS (1.6 vs 3.3 months; p = 0.00043). Early change in ctDNA levels was assessed by separating patients into three categories (one without detectable ctDNA, and two according to radio median value between day 0 and day 28) that were significantly correlated with ORR, PFS and OS. A significant interaction was observed between the presence of ctDNA and eryaspase efficacy. In patients with ctDNA detectable at baseline, eryaspase was associated with better PFS (HR = 0.53; 95% CI: 0.3-0.94) and OS (HR = 0.52; 95% CI: 0.29-0.91). **Conclusions:** We confirm from a prospective randomized trial that 1/ the presence of ctDNA at baseline is a major prognostic factor, 2/ the early change of ctDNA correlates with treatment outcome and 3/ the ctDNA could be a predictive biomarker of eryaspase efficacy. Clinical trial information: NCT02195180. Research Sponsor: Erytech.

4618 Poster Session (Board #226), Fri, 8:00 AM-11:00 AM

Concordance between independent and investigator assessment of disease-free survival (DFS) in the APACT trial. *First Author: Michele Reni, IRCCS Ospedale, San Raffaele Scientific Institute, Milan, Italy*

Background: APACT was a phase III trial of adjuvant *nab*-paclitaxel + gemcitabine (*nab*-P + Gem) vs Gem alone in patients with resected pancreatic cancer (PC) and the first adjuvant PC trial to use independently assessed DFS as the primary endpoint (DFS by investigator review was a prespecified sensitivity analysis). We examined concordance between independent and investigator DFS review. **Methods:** For the independent assessment, reviewers determined recurrence by computed tomography or magnetic resonance imaging but were blinded to treatment and clinical data. Investigator-assessed DFS was based on all available data. Concordance was summarized by κ statistics. Patients who did not have recurrence or were alive were censored at the last tumor assessment date with disease-free status or the randomization date if the last tumor assessment with disease-free status was missing. Patients who received new anticancer therapy or cancer-related surgery prior to recurrence or death were censored at the date of last tumor assessment with disease-free status prior to the start of new anticancer therapy or cancer-related surgery or the randomization date if the last tumor assessment date with disease-free status prior to the start of subsequent new anticancer therapy or cancer-related surgery was missing. All censoring rules were the same for analysis of DFS by independent and investigator review. **Results:** Median DFS by independent review was 19.4 (*nab*-P + Gem) vs 18.8 (Gem) months (hazard ratio [HR] 0.88; 95% CI, 0.73 - 1.06; $P = 0.18$); median investigator-assessed DFS was 16.6 (*nab*-P + Gem) vs 13.7 (Gem) months (HR 0.82; 95% CI, 0.69 - 0.97; nominal $P = 0.017$). Moderate concordance was found between independent- and investigator-assessed DFS (Table); similar results were observed in the *nab*-P + Gem (concordance, 78%; κ coefficient, 0.56) and Gem alone (concordance, 76%; κ coefficient, 0.53) arms. **Conclusions:** The results reflect the complexities of defining the recurrence timepoint accurately and suggest that radiological review in the absence of clinical context is suboptimal for recurrence detection in resected PC. These findings may inform future clinical trial design. Registration: EudraCT (2013-003398-91); ClinicalTrials.gov (NCT01964430). Clinical trial information: NCT01964430. Research Sponsor: Bristol-Myers Squibb.

Concordance of DFS (Total; N = 814).

PANasta Trial: Cattell Warren versus Blumgart techniques of pancreatico-jejunostomy following pancreato-duodenectomy—A double-blinded multi-centered trial, trial results. *First Author: Christopher Halloran, University of Liverpool, Liverpool, United Kingdom*

Background: Pancreatic anastomosis failure following pancreatic head excision, for suspected pancreatic cancer, leads to longer recovery and failure to start or complete adjuvant chemotherapy. The aim of this study is to evaluate whether a Blumgart anastomosis (BA) reduces the post operative pancreatic fistula (POPF) rate compared to a more traditional Cattell-Warren anastomosis (CWA). **Methods:** Patients with suspected pancreatic cancer, undergoing elective pancreato-duodenectomy were randomized intra-operatively to either a BA or a CWA. Anastomoses were constructed according to prior agreed techniques and an operative manual describing key surgical steps. Quality control of these key steps and adherence to the arm of randomization was ensured by operative photographs. Surgical drain amylase was measured post-operatively to establish the primary end point of POPF. These were graded A (biochemical) or B and C (clinically relevant, CR-POPF). Secondary endpoints included: Entry in adjuvant therapy, hospital stay, mortality and survival. Overall survival was estimated using the method of Kaplan Meier and defined as the time from randomisation until death by any cause with alive patients censored at the end of study date. **Results:** Between May 5 2015 and August 7 2017, 238 patients were randomized, 2 patients withdrew, leaving 236 patients for analysis (112 BA, 124 CWA). Median age was 70 years, 63% were men. Median time from diagnosis to randomization (surgery) was 33 days for both arms. In the BA arm there were 28 POPF's (15-A, 10-B and 3-C) and 32 in the CWA arm (18-A, 12-B and 2-C), p = 0.887. In total 27 patients (11.4%) developed a CR-POPF, BA 13 (5.5%), CWA 14 (5.9%), p = 0.857. 75% of eligible patients entered chemotherapy, with a median (IQR) time to the start treatment of 2.55 (2.27, 3.15) months for the BA group and 2.87 (2.56, 3.75) for the CWA group. Median hospital stay (IQR) in days was 13 (10-24) for BA and 14.5 (10-22) for CWA, p = 0.232. The overall surgical related mortally at 90 days was 1.7%. 44 study deaths were observed, 35 were due to disease progression (BA 19, CWA 16). A hazard ratio (95% CI) of 0.72 (0.4, 1.311) shows better, but not statistically significant survival for the CWA group. **Conclusions:** This is the largest surgical trial ever conducted comparing these techniques and there was no significant difference in the POPF rate between the BA and CWA anastomoses. In a UK population the clinically relevant POPF rate is 11% and 75% of eligible patients enter chemotherapy. Clinical trial information: ISRCTN52263879. Research Sponsor: Cancer Research UK.

4620 Poster Session (Board #228), Fri, 8:00 AM-11:00 AM

Landscape of DNA-damage-repair/homologous recombination deficiency (DDR/HRD) in hepatopancreaticobiliary (HPB) cancers. *First Author: Wungki Park, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: Biallelic HR-gene mutations (HRm) confer HRD and sensitivity to DDR-targeted therapies including platinum and PARPi in pancreatic cancer (PDAC). The landscape of DDR/HRD phenotypes in HPB cancers and their clinical implication is yet to be evaluated, the subject of this effort. **Methods:** Hybrid capture-based comprehensive genomic profiling was performed in a CLIA-certified, CAP-accredited lab (Foundation Medicine, Inc.) on up to 395 genes, including the HR-genes (*BRCA1/2, PALB2, RAD50/51B/C/D, MRE11, ATRX, ATR, ATM, BAP1, BRIP1, CHEK2, NBN,* and *FANCA*). Putative DDR/HRD phenotype was assessed using percent genome under LOH (gLOH) (PMID: 28916367). Variant zygosity was assessed as previously described (PMID: 29415044). From an independent PDAC subgroup among HPB cancers, we evaluated their outcomes on first-line platinum. **Results:** From a total of 11,174 tumors, pathogenic DDR/HRm were identified in 18% (1980/11174) of HPB cancers, 15% (863/5941) of PDAC, 25% (744/2998) of cholangiocarcinoma, 15% (141/958) of hepatocellular carcinoma, and 17% (152/873) of gallbladder carcinoma. We observed a majority (63%) of DDR/HRm with LOH. Rigorous filtering for tumor purity and copy number quality metrics yielded 34% (4051/11774) cases evaluable. The median gLOH of any biallelic DDR/HRm was 12.9% compared to 8.8% in no DDR/HRm (p=5.7E-33). Strength of the association varied by gene, with the strongest association in *BRCA1* (22.3, p=1.5E-10), *BRCA2* (20.1, p=1.7E-35), *RAD51C* (16.7, p=7.8E-4), *PALB2* (16.4, p=1.4E-5), *BRIP1* (14.3, p=0.02), *RAD51B* (13.7, p=0.02), and *ATM* (13.6, p=7.7E-12) (Table). Most other DDR/HR-genes and monoallelic DDR/HRm had weak gLOH. PDAC accounted for 60% of this HPB dataset. In an independent dataset of PDAC at MSK (n=262), biallelic DDR/HRm patients (n=29, 11%) had mostly germline mutations and had significantly improved median PFS on first-line platinum vs. non-platinum (13.3 [95%CI: 9.57-NR] vs 3.8 [95%CI: 2.79-NR] months, $p<0.0001$). **Conclusions:** Biallelic DDR/HRm is a distinct population of HPB cancers beyond PDAC and may confer better phenotype in DDR-targeted treatment. Further independent validation is underway. Research Sponsor: U.S. National Institutes of Health, Parker Institute for Cancer Immunotherapy MSKCC Pilot Award.

Olaparib sensitivity observed in metastatic pancreatic cancer (mPaC) with a wide spectrum of germline *BRCA1* and *BRCA2* mutations (gBRCAm). *First Author: Talia Golan, The Oncology Institute Sheba Medical Center, Tel-Hashomer, Israel*

Background: The POLO study (NCT02184195) showed that mPaC patients (pts) with a deleterious or suspected deleterious gBRCAm, and whose disease had not progressed during ≥16 weeks of first-line platinum-based chemotherapy, had significantly longer progression-free survival (PFS, primary endpoint) with maintenance olaparib vs placebo: median 7.4 vs 3.8 months, hazard ratio (HR) 0.53; $P=0.004$. PFS benefit was observed in pts with g*BRCA1*m (HR 0.40) and g*BRCA2*m (HR 0.63). The POLO study represents the largest BRCAm prevalence study in pancreatic cancer. We report additional exploratory analysis to further characterize patient gBRCAm profiles, including the relationship with efficacy. **Methods:** Pts were enrolled based on either a previously identified gBRCAm status from a local test result and subsequently confirmed by central testing, or a prospectively identified gBRCAm. Pts received maintenance olaparib 300 mg twice daily (tablet) or placebo. PFS was assessed by blinded independent central review (modified RECIST v1.1). **Results:** Of 3194 prospectively screened pts, a valid BRCA test result was obtained for 3175 (99%) from 12 countries; gBRCAm prevalence was 6.2% in pts not previously known to harbor a gBRCAm (196/3175; 1.6% g*BRCA1*m, 4.5% g*BRCA2*m). In countries (n=8) with >100 pts prospectively tested, highest gBRCAm prevalence was 9.2% (USA) and lowest 4.0% (Spain). Prevalence by race (>100 pts); 6.4% Caucasian, 4.6% Asian. In total, 154 pts with a gBRCAm satisfied all eligibility criteria and were randomized (106 prospectively tested and 48 by local test [44/48 subsequently confirmed by Myriad testing]). 37/154 (24%) randomized pts carried a common Ashkenazi Jewish founder mutation, the majority being from Israel (21 pts). From a total of 151 variants, frameshift mutations were most frequent (g*BRCA1*m 69.6%, g*BRCA2*m 71.4%) followed by nonsense mutations (g*BRCA1*m 6.5%, g*BRCA2*m 17.1%). The efficacy (PFS) of olaparib vs placebo in the different subgroups are shown in the table. **Conclusions:** In pts with mPaC enrolled in POLO, g*BRCA2*m were more prevalent than g*BRCA1*m and mutation type was predominantly frameshift. PFS benefit was consistent across a heterogenous spectrum of gBRCAm and with the previously reported full analysis set. Clinical trial information: NCT02184195. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4622 Poster Session (Board #230), Fri, 8:00 AM-11:00 AM

A phase I trial targeting advanced or metastatic pancreatic cancer using a combination of standard chemotherapy and adoptively transferred nonengineered, multiantigen specific T cells in the first-line setting (TACTOPS). *First Author: Brandon George Smaglo, Baylor College of Medicine, Houston, TX*

Background: Immunotherapy is emerging as a potent therapy for a range of hematologic malignancies and solid tumors. To target pancreatic carcinoma we have developed an autologous, non-engineered T cell therapy using T cell lines that simultaneously target the tumor-associated antigens (TAAs) PRAME, SSX2, MAGEA4, NY-ESO-1 and Survivin. These multiTAA-specific T-cell lines could be consistently prepared by culturing PBMCs in the presence of a Th1-polarizing/pro-proliferative cytokine cocktail, and adding autologous pepmix-loaded DCs as APCs. **Methods:** Patients with locally advanced or metastatic pancreatic adenocarcinoma who achieved cancer control with three months of standard chemotherapy were eligible to receive up to 6 infusions of multiTAA T-cells (fixed dose - $1x10^7$ cells/m^2). While also continuing the same chemotherapy, T-cells were given at monthly intervals from month four, onwards. The primary study endpoints were safety and feasibility of completing all 6 planned infusions, with secondary and tertiary endpoints including anti-tumor effects, patient survival, in vivo expansion and T cell persistence of the infused cells as well as recruitment of the endogenous immune system. **Results:** Between June 2018 and December 2019, we treated 13 patients with multiTAA T-cells. For 12/13 patients, we generated sufficient cells for all 6 planned doses; 2 doses were available for the remaining patient. Of the 13 patients, 8 maintained cancer control for a longer than expected duration, compared to historical controls. With administration of T-cells, 3 of these 8 patients had partial responses and 1 patient had a radiographic complete response (per RECIST). These responses were seen in patients with metastatic cancer. Notably, no patient had infusion-related systemic- or neuro-toxicity. Thus, infusion of autologous multiTAA-targeted T cells directed to PRAME, SSX2, MAGEA4, NY-ESO-1 and Survivin has been safe and provided durable clinical benefit to patients with pancreatic adenocarcinoma. **Conclusions:** Autologous, TAA cytotoxic T-cells can reliably be generated and safely administered to patients in conjunction with standard of care chemotherapy. In some patients, addition of T-cells may extend duration of first line therapy cancer control and induce additional tumor responses, and activation of the endogenous immune system has been documented in all patients. Exploration in a higher phase study is warranted. Clinical trial information: NCT03192462. Research Sponsor: V-Foundation and PanCan.

4623 Poster Session (Board #231), Fri, 8:00 AM-11:00 AM

Survival outcomes of patients with resectable pancreatic cancer treated with upfront surgery versus neoadjuvant chemotherapy: A retrospective tertiary care center experience. *First Author: Fang Liu, University Hospital, Cleveland, OH*

Background: The role of neoadjuvant chemotherapy (NAC) for resectable pancreatic cancer (RPC) remains controversial. We sought to compare the outcomes of NAC with upfront surgery (UFS). **Methods:** The study retrospectively enrolled patients with RPC who had UFS or received neoadjuvant FOLFIRINOX (FFX) or gemcitabine plus albumin-bound paclitaxel (GA). Between-group differences were assessed with T-test for continuous variables, and Chi-square / Fisher's exact test for categorical variables. The overall survival (OS) and recurrence-free survival (RFS) were determined by the Kaplan-Meier method with Wilcoxon test for the difference between groups. The effects of NAC vs. UFS on OS and RFS were further estimated using Cox regression controlling the effects of age and CA 19-9. **Results:** Between 2011 and 2019, 131 patients with RPC underwent UFS followed by adjuvant chemotherapy (gemcitabine, n = 65; gemcitabine/capecitabine, n = 18; FFX, n = 9). Up to 32 patients (24.4%) could not receive adjuvant chemotherapy due to surgical complications or poor recovery. Total 50 patients with RPC received NAC (FFX, n = 32; GA, n = 18). Median of 5.5 cycles of FFX or 3 cycles of GA were given prior to surgery. Resection rate was 72% (FFX 62.5%; GA 88.9%). The rest (28%) were no longer surgical candidates due to disease progression rather than toxicities from NAC. On surgical pathological review, complete resection (R0) was achieved in 83.3% of resected cases after NAC (FFX 90%; GA 75%) and 79.4% with UFS. The tumor size distribution was: pT1 11.1%, pT2 41.7%, pT3 44.4% with NAC; pT1 5.4%, pT2 18.3%, pT3 76.3% with UFS. The nodal status distribution was: pN0 27.8%, pN1 55.5%, pN2 16.7% with NAC; pN0 23.7%, pN1 71.0%, pN2 5.3% with UFS. Median pre-treatment CA 19-9 was 321.95 unit/mL in the NAC group and 79.99 unit/mL in the UFS group ($p = 0.009$). Median age was 70.5 in the NAC group and 72 in the UFS group ($p = 0.374$). There was no significant difference in the performance status between the two groups. In Kaplan-Meier analysis, there was a significant difference of OS between UFS and NAC with median OS of 648 days under UFS versus 884 days under NAC ($p = 0.029$); the median of RFS was 390 days under UFS versus 392 days under NAC ($p = 0.953$). The hazard ratio (NAC vs UFS) adjusted for CA19-9 and age was 0.7 ($p = 0.176$) for OS and 0.98 ($p = 0.918$) for RFS. **Conclusions:** We observed a signal of tumor downstaging, higher R0 rate, and improved OS with NAC compared with UFS. Further prospective trials are needed to validate these results. Research Sponsor: None.

4624 Poster Session (Board #232), Fri, 8:00 AM-11:00 AM

Liposomal irinotecan plus fluorouracil/leucovorin versus FOLFIRINOX as the second-line chemotherapy for patients with metastatic pancreatic cancer: Multicenter study of the Korean Cancer Study Group (KCSG). *First Author: Hongjae Chon, CHA Hospital, Seongnam, South Korea*

Background: There is no clear consensus on the second-line treatment for patients with metastatic pancreatic cancer (mPC). The aim of this study was to compare the efficacy and tolerability between liposomal irinotecan (nal-IRI) plus fluorouralcil/leucovorin (FL) and FOLFIRINOX (oxaliplatin/irinotecan/leucovorin/fluorouracil) in patients who failed to first-line gemcitabine-based therapy. **Methods:** In this retrospective study, 378 mPC patients who received nal-IRI/FL (n = 104) or FOLFIRINOX (n = 274) as the second-line treatment across 11 institutions from January 2015 to August 2019 were analyzed. The primary end point was progression free survival (PFS), and secondary end points were overall survival (OS), overall response rate, and tolerability. **Results:** There were no significant differences between the two groups in terms of baseline characteristics, except first-line regimen (previous gemcitabine/nab-paclitaxel, nal-IRI/FL, 85.6% vs. FOLFIRINOX, 51.5%; previous gemcitabine monotherapy, 5.8% vs. 24.5%). The median follow-up time was 6.0 months. The median PFS (nal-IRI/FL, 3.7 months vs. FOLFIRINOX, 5.0 months) and OS (nal-IRI/FL, 7.7 months vs. FOLFRINOX, 9.7 months) were comparable between two groups ($P = 0.40$ and 0.13, respectively). The overall response rate was not significantly different between two groups (nal-IRI/FL, 14% vs. FOLFRINOX, 16%; $P = 0.644$). In multivariate analysis, poor ECOG status, presence of liver metastasis, high NLR, and high CA19-9 were independent prognostic factors for PFS and OS, but chemotherapy regimen (nal-IRI/FL vs. FOLFRINOX) was not. In a subgroup analysis of patients with liver metastasis, FOLFIRINOX exerted significant PFS (median: 2.1 months vs. 4.1 months for nal-IRI/FL vs. FOLFIRINOX, respectively; $P = 0.02$) and OS (median: 6.7 months vs. 8.4 months for nal-IRI/FL vs. FOLFIRINOX, respectively; $P = 0.04$) benefit compared with nal-IRI/FL. Grade 3 neutropenia or higher were more frequently observed in FOLFIRINOX (47.2%) than nal-IRI/FL (35%) ($P = 0.033$). Grade 3 peripheral neuropathy was also common in FOLFIRIONX (5.9%) group compared with nal-IRI/FL (1.0%) ($P = 0.049$). **Conclusions:** In second-line setting for mPC after progression on gemcitabine-based therapy, both nal-IRI/FL and FOLFIRINOX regimen showed comparable efficacy and acceptable safety outcomes. FOLFIRINOX regimen might be preferentially considered in patients with liver metastasis. Research Sponsor: None.

4625 Poster Session (Board #233), Fri, 8:00 AM-11:00 AM

Real-life results from the prospective QoliXane trial of the platform for outcome, quality of life, and translational research on pancreatic cancer (PARAGON) registry. *First Author: Salah-Eddin Al-Batran, University Cancer Center Frankfurt, Institut für Klinisch-Onkologische Forschung and IKF Klinische Krebsforschung GmbH am Krankenhaus Nordwest, Frankfurt, Germany*

Background: Gemcitabine and nab-paclitaxel (NPG) is standard first-line therapy for metastatic pancreatic cancer (mPC), but the pivotal study did not include quality of life (QoL) analyses. **Methods:** The QOLIXANE-PARAGON study started as a prospective, non-interventional, multicenter study conducted in Germany and transitioned into a permanent registry for pancreatic cancer patients (pts) considering all types of treatments. This report focuses on the pts enrolled into the QOLIXANE portion of the study. Pts were recruited from 95 German centers. QoL was prospectively measured via EORTC-C30 questionnaires (prior to and every month thereafter): therapy and efficacy parameters were prospectively collected. QoL and efficacy endpoints were analyzed in the intention-to-treat population (ITT). The primary endpoint was the rate of pts without deterioration of QoL/Global Health Score (QoL/GHS) at 3 months. **Results:** 600 pts were enrolled. Mean GHS/QoL score at baseline was low and was 46.2 (SD 22.8). Median progression-free survival was 5.85 months (95% CI, 5.23 to 6.25). Median overall survival (OS) was 8.91 months (95% CI, 7.89 to 10.19). The KM-analysis showed that 61% and 41% of pts had maintained QoL/GHS after 3 and 6 months, respectively. Median time to deterioration of QoL/GHS was 4.68 months (95% CI, 4.04 to 5.59). Mean QoL/GHS improved from 46.1 (SD 22.7) at baseline to 52.8 (SD 21.3) after 6 months. In the QoL response analysis, 34.6%, 37.4% and 28% of evaluable pts had improved, stable and worse QoL/GHS after 3 months, respectively. In the Cox regression analysis, GHS/QoL scores strongly predicted survival with a HR of 0.86 ($p < 0.0001$). **Conclusions:** QoliXane the largest study on QoL of mPC. It shows that time to deterioration of QoL is short but that a relevant group of mPC in first line have improved or maintained QoL after 3 and 6 months and that QoL is a predictor of pts outcome. Clinical trial information: NCT02691052. Research Sponsor: Celgene.

4626 Poster Session (Board #234), Fri, 8:00 AM-11:00 AM

POLO: Quality-adjusted (QA) progression-free survival (PFS) and patient (pt)-centered outcomes with maintenance olaparib in pts with metastatic pancreatic cancer (mPaC). *First Author: Hyun Kyoo Yoo, AstraZeneca, Cambridge, United Kingdom*

Background: In the Phase III POLO trial (NCT02184195), maintenance olaparib significantly prolonged PFS vs placebo in pts with a germline *BRCA1* and/or *BRCA2* mutation (gBRCAm) and mPaC (median 7.4 vs. 3.8 months). The aim of maintenance treatment is to extend PFS and survival without compromising health-related quality of life due to adverse events. The duration of time spent without symptoms or toxicities (TWiST) and the QA-PFS were assessed in a post hoc analysis of the POLO trial. **Methods:** Patients were randomized 3:2 to receive maintenance olaparib (tablets; 300 mg bid) or placebo. Restricted mean (RM)-PFS was calculated by estimating the area under the Kaplan–Meier PFS curve between randomization and 29.8 months after randomization (maximum follow-up for the placebo arm in POLO). Patient-centered outcomes were assessed by QA-PFS (derived from the product of the EQ-5D-5L single-index utility score from randomization to disease progression and RM-PFS) and TWiST (RM-PFS minus time with toxicity after randomization). **Results:** RM-PFS was significantly longer with olaparib, with a between-treatment difference of 4.8 months (P=0.009; Table). Over this period, no significant or meaningful differences in mean EQ-5D-5L index were observed between treatment groups. The corresponding mean QA-PFS was significantly longer with olaparib vs placebo. TWiST analysis demonstrated a benefit with olaparib over placebo (Table): between-arm difference, 3.8 months (P=0.039) for the primary analysis (criteria 1: grade ≥2 nausea, vomiting or fatigue). Sensitivity analysis (criteria 1 plus abdominal pain, diarrhea, decreased appetite or constipation) also revealed a trend toward benefit with olaparib (difference: 3.4 months, P=0.062). **Conclusions:** Consistent with the primary PFS analysis of the POLO trial, RM-PFS and QA-PFS were significantly longer with maintenance olaparib than with placebo. As demonstrated by the findings of the TWiST analyses, the PFS benefit observed with olaparib in pts with a gBRCAm and mPaC persists even when symptoms of toxicity are considered. Clinical trial information: NCT02184195. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, US.

Endpoints (months)	Placebo N=62	Olaparib N=92	Difference (P)
RM-PFS	7.01	11.78	4.77 (0.009)
Mean EQ-5D-5L*	0.81	0.78	−0.03 (0.28)
Mean QA-PFS	5.65	9.18	3.53 (0.016)
Mean TWiST (primary analysis)	6.89	10.69	3.81 (0.039)
Mean TWiST (sensitivity analysis)	6.80	10.18	3.39 (0.062)

*Higher scores indicate better health status.

4628 Poster Session (Board #236), Fri, 8:00 AM-11:00 AM

Safety and efficacy of biweekly gemcitabine in combination with capecitabine (GemCap) in elderly and frail patients (pts) with resected pancreatic cancer (PC). *First Author: Nausheen Hakim, Northwell Health Cancer Institute, Lake Success, NY*

Background: ESPAC-4 study showed that GemCap conferred a survival benefit over gemcitabine monotherapy in resected PC patients. ESPAC-4 included patients with median age of 65 years (37-81) and ECOG performance status (PS) of 0 (43%), 1 (54%) and 2 (2%) who received a median cumulative dose of gemcitabine of 15,000 mg/m2, capecitabine. Here we present our experience with an adopted biweekly regimen of GemCap in patients who were ≥ 75 years and those who were deemed not suitable for ESPAC-4 regimen. **Methods:** Patients ≥ 75 years with resected PC, ECOG PS of 0-2 and no prior treatments were included. Patients were treated with a modified regimen of gemcitabine (1000-2000 mg/m2) every 2 weeks and capecitabine (800-1000 mg/m2) day 1-7 every 2 weeks. Patients were evaluated for progression-free survival (PFS), overall survival (OS) and sites of recurrence. Toxicities were graded according to NCI CTCAE v5.0. **Results:** Thirty-five (22M, 13F) patients, ≥ 75 (median age 79) treated with biweekly Gem-Cap adjuvant treatment. 7 (28%) patients had ECOG PS of 1 and 28 (72%) had ECOG PS of 2. There were 5, 7 and 16 patients with stage I, II and III disease. Nine patients (25%) had R1 and 26 (75%) had R0 resection. The median PFS and OS were 8.0 months and 22.0 months. Nine (25%) had local recurrence, 21 (60%) had metastatic disease and 3 (8.6%) had NED. Two patients were lost to follow-up. The most frequent toxicities were grades 1-2 anemia (20%), thrombocytopenia (8%) and hand-foot syndrome (HFS) (10%). Grade ≥3 included diarrhea (4%) and HFS (1%) with no treatment-related discontinuations. Treatment compliance was 100%. Delays were necessary in 7% of cases and dose reduction was required in 4% of cases. There was no treatment related death. **Conclusions:** This schedule of biweekly GemCap regimen suggests an acceptable option in for elderly, frail patients with PC and warrants further exploration in patients not suitable for FOLFIRINOX, full dose GemCap or a clinical trial. This regimen required fewer dose reduction, omission or delays and allowed to administer pegylated-filgrastim. Previous studies have also shown decreased toxicity and equal efficacy of 7/7 schedule of capecitabine. Moreover, fewer visits to oncology and related expense do favor towards benefit. Additionally, this tolerable regimen is ideal to be combined with immunotherapy in clinical trials for this patient population. Research Sponsor: None.

4629 Poster Session (Board #237), Fri, 8:00 AM-11:00 AM

Enrichment of alterations in targetable molecular pathways in KRAS wild-type (WT) pancreatic cancer (PC). *First Author: Philip Agop Philip, Karmanos Cancer Institute, Detroit, MI*

Background: Genomic profiling has identified KRAS mutations in 88-90% of PC. KRAS WT tumors represent a molecularly heterogeneous group that may harbor targetable alterations (TA). We studied KRAS WT PC using NextGen sequencing (NGS) and whole transcriptome sequencing (WTS) to characterize the molecular landscape of this unique group and to assess the prevalence of TA. **Methods:** A total of 1164 PC tumors were tested at Caris Life Sciences by NGS (592 genes), WTS (NovaSeq), IHC and fragment analysis. Comparison of KRAS WT vs. mutant (MT) was done by Fisher-Exact or Chi2 and was corrected for multiple tests. **Results:** The KRAS WT cohort included 144 tumors (12.4%). No differences were seen in gender (female: 46% in both WT & MT) and age (median: 66 & 67) compared to KRAS MT. In KRAS WT tumors, targetable fusions tested by WTS and pathogenic mutations by NGS were seen in 22% (32 of 144) and 52% (75 of 144) respectively; potentially targetable amplifications (amp) were seen in 5 additional tumors. No TA were seen in 22% of WT tumors. Key alterations are in Table. Alterations inducing MAPK activation, including BRAF, RAF1, NF1 and GNAS changes were seen in 38 (26%) tumors. Frequent alterations were seen in FGFR genes (11 tumors), MET (4, including 1 exon 14 skip), and ERBB receptor and ligands (10). Fusions in ALK, ROS1, RET and NOTCH1 were seen (8), largely exclusive of other drivers. Wnt, PI3K, chromatin remodeling (CR) and DDR changes were common and sometimes seen concurrent with other alterations. Compared to KRAS MT, no difference of PD-L1 or TMB-H was seen. BRAF, APC, PBRM1, CTNNB1 mutations, MDM2 amp, gene fusions and MSI-H/dMMR were all more frequent in KRAS WT tumors (corrected $p < 0.05$). **Conclusions:** KRAS WT PC is enriched with TA (e.g., BRAF, ALK, ROS1, NRG1, MSI-H). The use of WTS in combination with NGS identifies activated molecular pathways in the majority of KRAS WT tumors. Based on our findings, comprehensive profiling of PC at the DNA and RNA level is recommended to provide patients with therapeutic opportunities beyond standard treatments. Research Sponsor: None.

4630 Poster Session (Board #238), Fri, 8:00 AM-11:00 AM

Outcomes and Immunogenicity of pancreatic cancer stratified by the HRDetect score. *First Author: Grainne M. O'Kane, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The HRDetect score uses whole genome sequencing (WGS) to incorporate patterns of substitution base signatures and structural variation to identify tumours deficient in homologous recombination repair (HRD). HRD-tumours, with a higher mutational burden, may be more immunogenic. **Methods:** We applied HRDetect to 182 resected pancreatic cancers (PDA) and 233 advanced PDA enrolled on the COMPASS trial; both cohorts underwent WGS after tumour enrichment. Patients were classified as high(^{hi}) or low(^{lo}) according to the published score threshold of 0.7; clinical characteristics and survival outcomes were determined. Immunogenicity of the cohorts was explored by analyzing cytolytic activity (CYT) as measured by RNA expression of perforin and granzyme A. **Results:** 14% of resected (25/182) and 14% of advanced cases (32/233) were considered HRDetect^{hi} . The median age at PDA diagnosis was younger in HRDetect^{hi} vs HRDetect^{lo} (61 vs 66 years, p = 0.005), with no difference in sex between groups. Of the 57 cases identified, 37 (65%) were considered true HRD-PDA with inactivation of *BRCA1, BRCA2, PALB2, RAD51C* and *XRCC2*. The remaining 20 cases, were considered false positives for HRD; of these 7 had evidence of a tandem duplicator phenotype with duplications ranging from 10Kbp to 1Mbp in size and 13 had no defining genomic characteristics of the HRD-subtype. In resected PDA, the HRDetect score after adjusting for stage, was not prognostic. In contrast in a multivariable analysis of advanced cases, both HRDetect (HR 0.51, 95% CI 0.30-0.87, p = 0.01) and the Moffitt RNA classifier were highly prognostic (HR 1.99, 95% CI 1.32-3.00, p = 0.0001) with improved survival in HRDetect^{hi} and classical PDA. Of patients receiving platinum in advanced disease (n = 128) HRDetect^{hi} PDA had longer survival compared to the HRDetect^{lo} (15.6 vs. 9.9 months, p = 0.02) although the interaction term between chemotherapy regimen (gemcitabine vs. platinum) and HRDetect score was not significant in this cohort. HRDetect^{hi} tumours had increased cytolytic activity than HRDetect^{lo} PDA; furthermore, within the cohort of HRDetect^{hi} PDA, higher CYT scores were evident in primary lesions compared to metastatic sites sequenced. **Conclusions:** A high HRDetect score is prognostic in advanced PDA where patients treated with platinum have longest survival. HRDetect^{hi} tumours have increased cytolytic activity with differences observed between primary and metastatic lesions. Research Sponsor: Ontario Institute of Cancer Research, Pancreas Cancer Canada.

4631 Poster Session (Board #239), Fri, 8:00 AM-11:00 AM

Paclitaxel protein bound (A) plus gemcitabine (G) plus cisplatin (C), and paricalcitol (P)neoadjuvant therapy for localized pancreatic ductal adenocarcinoma (PDAC). *First Author: Erkut Hasan Borazanci, HonorHealth, Scottsdale, AZ*

Background: Localized PDAC management has recently evolved. Due to concerns over micro metastases at diagnosis the use of neoadjuvant chemotherapy for PDAC has become more common. Typical therapies involve the use of multiagent systemic chemotherapies with or without radiation therapy. In retrospective studies, Cancer Antigen 19-9 (CA 19-9) normalization in borderline resectable (BR) and locally advanced (LA) PDAC has been associated with greater OS. The addition of cisplatin (C) to gemcitabine (G) and paclitaxel protein bound (A), has shown promising clinical data in a previously reported study in advanced PDAC [JAMA Oncol. 2020;6(1):125-132]. We conducted a prospective, phase 2 clinical trial of patients with resectable (R), BR, and LA PDAC utilizing a regimen combining A + G + C + paricalcitol (P) with the primary endpoint of CA 19-9 normalization (NCT03138720). **Methods:** Eligibility criteria include patients with histologically confirmed R, BR, or LA PDAC, elevated CA 19-9, and a KPS $\geq$ 70% with normal end organ function. Doses are A 125 mg/m2, G 1000 mg/m2, C 25 mg/ m2, P at a fixed dose of 25 μg on days 1, 8 of a 21-day cycle (all treatment IV). Primary objective is to evaluate CA 19-9 normalization with the neoadjuvant chemotherapy. Secondary objectives are to assess R0 rate, pathologic complete response (pCR), safety and tolerability, radiologic response rate, and 2 year overall survival (OS) from date of study entry. Exploratory objectives include evaluating imaging biomarkers and vascular involvement by tumor in relation to therapy. **Results:** To date 24 of the planned 24 patients have been enrolled. 13 male, 11 female; age range 49 to 84 yo. Patient classifications is 8 R; 7 BR; 9 LAPC. Median baseline CA 19-9 156 (range 45-3674). Most common drug related grade (gr) 3-4 adverse events (AEs) are: thrombocytopenia gr 3 29%, gr 4 25%, anemia gr 3 45.8%, gr 4 4.2%, and hypophosphatemia gr 3 8.3%. CA 19-9 normalization occurred in 50% (12/24) who have completed at least 1 cycle of treatment. To date, 14 individuals went to surgery, with 13/14 achieving R0, (1 pCR). Overall response rate in measurable patients is 38% (1 CR, 8 PR). Median OS and 2-year survival data are not yet matured. **Conclusions:** In patients with non-metastatic PDAC, the use of A+G+C+P resulted in a CA 19-9 normalization rate in 50% of individuals. The study is ongoing and OS data is maturing. Clinical trial information: NCT03138720. Research Sponsor: HonorHealth Foundatio, Marley Foundation, Stand Up to Cancer, Seena Magowitz Foundation.

4632 Poster Session (Board #240), Fri, 8:00 AM-11:00 AM

Interim data: Phase I/IIa study of EGFR-targeted EDV nanocells carrying cytotoxic drug PNU-159682 (E-EDV-D682) with immunomodulatory adjuvant EDVs carrying α-galactosyl ceramide (EDV-GC) in patients with recurrent, metastatic pancreatic cancer. *First Author: Joanne Lundy, Peninsula and Southeast Oncology, Frankston, VIC, Australia*

Background: Targeted EDV nanocells loaded with doxorubicin and microRNA16a have shown excellent safety profiles in Phase I trials in recurrent glioma and mesothelioma. This planned safety analysis of an ongoing first-in-human, open label Phase I/IIa study in patients with treatment-refractory metastatic pancreatic cancer, assesses safety, biologic and clinical activity of EGFR-targeted EDV nanocells carrying cytotoxic drug PNU-159682, designed to overcome drug resistance, combined with EDV nanocells carrying immunomodulatory adjuvant α-galactosyl ceramide, designed to stimulate anti-tumour immune response. **Methods:** 9 patients with advanced pancreatic cancer enrolled in the dose escalation phase to evaluate safety of the EDV combination. Doses gradually escalated from 2×10^9 EDVs/dose to a maximum of 7×10^9 EDVs/dose in Week 7, with subsequent dosing at the maximum dose achieved in Cycle 1. iRECIST criteria was used to assess tumour response after each cycle, and blood was collected each cycle for cytokine and PBMC analysis. **Results:** Combination EDVs were well tolerated with no DLTs, and no drug related SAEs. A minority of patients experienced G1 infusion reactions, which responded promptly to supportive treatment. PR or SD was achieved at 8 weeks in 8/9 patients (CBR 89%), with responses confirmed at 4 months in 4/5 evaluable patients (80%), with 2 durable responses seen beyond 6 months. Exploratory analyses have revealed elevation of IFN-α and IFN-γ in almost all evaluable patients (6/8). In addition, we observed elevated CD8+ T cells (2/8), iNKT, dendritic and NK cells (3/8), and a reduction in exhausted CD8+ T cells (3/8), suggesting activation of both innate and adaptive immune responses. **Conclusions:** EDVs carrying the cytotoxic drug and immune adjuvant are safe and well tolerated. Early signals point to durable responses, possibly related to the development of an innate and adaptive immune response along with cytotoxic effects on drug resistant tumour cells. The Phase IIa study plans to enrol an additional 35 patients to further evaluate safety and anti-tumour efficacy. Clinical trial information: ACTRN12619000385145. Research Sponsor: EnGeneIC Pty Ltd.

4633 Poster Session (Board #241), Fri, 8:00 AM-11:00 AM

Single-nucleus RNA-seq of frozen archival primary pancreatic ductal adenocarcinoma uncovers multi-compartment intratumoral heterogeneity associated with neoadjuvant treatment. *First Author: William L. Hwang, Harvard Radiation Oncology Program, Boston, MA*

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a treatment-refractory disease and existing molecular subtypes do not inform clinical decisions. Previously identified bulk transcriptomic subtypes of PDAC were often unintentionally driven by "contaminating" stroma. RNA extraction from pancreatic tissue is difficult and prior single-cell RNA-seq efforts have been limited by suboptimal dissociation/RNA quality and poor performance in the setting of neoadjuvant treatment. We developed a robust single-nucleus RNA-seq (sNuc-seq) technique compatible with frozen archival PDAC specimens. **Methods:** Single nuclei suspensions were extracted from frozen primary PDAC specimens (n = 27) derived from patients with (borderline)-resectable PDAC who underwent surgical resection with or without neoadjuvant chemoradiotherapy (CRT). Approximately 170,000 nuclei were processed with the 10x Genomics Single Cell 3' v3 pipeline and gene expression libraries were sequenced (Illumina HiSeq X). **Results:** Distinct nuclei clusters with gene expression profiles/inferred copy number variation analysis consistent with neoplastic, acinar, ductal, fibroblast, endothelial, endocrine, lymphocyte, and myeloid populations were identified with proportions similar to corresponding multiplexed ion beam imaging. Non-negative matrix factorization revealed intra-tumoral heterogeneity shared across patients. Neoplastic cells featured eight distinct transcriptional topics characterized by developmental (epithelial, mesenchymal, endoderm progenitor, neural progenitor) and environmental (anabolic, catabolic, cycling, hypoxic) programs. CAFs exhibited four different transcriptional topics (activated/desmoplastic, myofibroblast, neurogenic, osteochondral). Differential gene expression and gene set enrichment analyses demonstrated that CRT was associated with an enrichment in myogenic programs in CAFs, activation pathways in immune cells, and type I/II interferons in malignant cells. CRT was also associated with a depletion in developmental programs within malignant cells. **Conclusions:** We uncovered significant intratumoral heterogeneity and treatment-associated differences in the malignant, fibroblast, and immune compartments of PDAC using sNuc-seq. Deconvolution of clinically-annotated bulk RNA-seq cohorts and characterization of intercellular interactions with receptor-ligand analysis and spatial transcriptomics are ongoing. Research Sponsor: Lustgarten Foundation, Conquer Cancer Foundation of the American Society of Clinical Oncology, U.S. National Institutes of Health.

4634 Poster Session (Board #242), Fri, 8:00 AM-11:00 AM

A phase I study of nanoliposomal irinotecan and 5-fluorouracil/folinic acid in combination with interleukin-1-alpha antagonist for advanced pancreatic cancer patients with cachexia (OnFX). *First Author: Andrew Eugene Hendifar, Samuel Oschin Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Interleukin-1-alpha (IL-1α) promotes tumor inflammation by shaping the tumor microenvironment, including tumor infiltrating myeloid cell recruitment, angiogenesis, and skewing and suppression of anti-tumor immunity. IL-1a inhibition in cancer subjects increased lean body mass and decreased fatigue, pain, and appetite loss. We report results of a single site phase 1 trial for an IL-1α antagonist (bermekimab) in combination with nanoliposomal irinotecan (Nal-Iri) and 5-fluorouracil (5FU)/folinic acid (FA) in patients with advanced pancreatic adenocarcinoma and cachexia who have failed gemcitabine-based chemotherapy. **Methods:** A Bayesian adaptive design based on escalation with overdose control was used. Data are presented as frequency (percentage, %) for categorical variables and mean ($\pm$ standard deviation) for continuous variables. Lean body mass (LBM) and fat mass were assessed at cycle 1 and 3, and T-test was used to assess changes. **Results:** Of 21 pts enrolled, 18 were evaluable. Median age was 68. Bermekimab in combination with nanoliposomal irinotecan (70 mg/m2) and 5-fluorouracil (2400mg/m2) was well tolerated at the highest dose level (12mg/kg). 10 pts experienced grade 3/4 toxicities including sepsis, anemia, hypokalemia, neutropenia, or leukopenia. There were no instances of grade 3/4 diarrhea. Ten pts (56%) had weight stability (< 0.1 kg/BMI). Efficacy results include PR (n = 4, 22%), SD (n = 13, 72%), and PD (n = 1, 6%). PFS 7.7 m (95% CI: 4.34-12.73) and OS 10.5 m (95% CI: 5.79-17.70) were reported. LBM and fat mass change was -1.6 kg ($\pm$ 2.0; p-value = 0.003) and -1.4 kg ($\pm$ 1.7; p-value = 0.004). CRP was 20.4 ($\pm$ 35.6) at cycle 1 and decreased significantly (p-value = 0.005). Serum VEGF decreased from C1 to C3 (p-value = 0.007). QLQ-PAN26 domains improved, particularly hepatic function (p = 0.04). FAACT scores improved for functional well-being (p = 0.02). Average daily step counts increased by 589 steps/day (p = 0.29) and resting heart rate decreased by 2.5 beats per minute (p = 0.005), as assessed by actigraphy. **Conclusions:** Bermekimab, nano-liposomal irinotecan and 5-fluorouracil in refractory pancreatic cancer patients with cachexia was well-tolerated with promising efficacy and improvements in patient performance. Clinical trial information: NCT03207724. Research Sponsor: Ipsen.

4635 Poster Session (Board #243), Fri, 8:00 AM-11:00 AM

A single-arm, open-label, phase I study of CPI-613 (Devimistat) in combination with gemcitabine and nab-paclitaxel for patients with locally advanced or metastatic pancreatic adenocarcinoma. *First Author: Angela Tatiana Alistar, Atlantic Health System, Morristown, NJ*

Background: Glycolic and mitochondrial metabolism are aberrant in pancreatic cancer and translate into chemoresistance. Inhibition of glutamine metabolism can potentially synergize with therapies that increase intracellular reactive oxygen species, such as nab-paclitaxel. CPI- 613 is a novel antimitochondrial agent developed by Rafael Pharmaceuticals that showed promising clinical activity in combination with modified FOLFIRINOX in patients with stage IV pancreatic cancer. Preclinical data suggested possible synergy of CPI-613 with nab-paclitaxel. **Methods:** Single arm, open-label, phase I study of CPI-613 with gemcitabine and nab-paclitaxel in patients with locally advanced or metastatic pancreatic cancer to determine MTD, safety, and preliminary efficacy of CPI-613 in combination with chemotherapy. Key eligibility criteria included: histologically documented and measurable locally-advanced or metastatic, PDAC. ECOG performance status 0-2; and first line systemic treatment. CPI-613 was infused intravenously with a starting dose of 500 mg/m^2 followed by modified dose nab-paclitaxel (100mg/m2) and gemcitabine (800 mg/m2) on Days 1, 8, and 15 of a 28-day cycle. The the primary endpoint, the MTD of CPI-613 was determined by a two-stage, dose-escalation schema, with 6-month treatment duration for patients exhibiting treatment response. Secondary endpoints were treatment-related adverse events, complete response (CR) and partial response (PR). **Results:** From February 2018 to 2020, 26 patients were screened, (23 metastatic and 3 locally advanced), 22 patients enrolled and 18 patients underwent a restaging scan. As of the time of submission 3 patients are still on active treatment. Patient demographics were: median age of 65, ECOG was 0-1, The MTD of CPI- 613 was determined to be 1500 mg/m^2. The dose limiting toxicities were not achieved. Overall the treatment was well tolerated with toxicities mainly related to chemotherapy; most common grade 3 and 4 toxicities were hematologic toxicity and neuropathy. 1 patient achieved CR, 9 PR, 8 stable disease and 1 progressive disease for an objective response rate of 50% with a CR rate of 5.5%. **Conclusions:** The results demonstrate that CPI 613 can be safely administered with gemcitabine and nab-paclitaxel at doses up to 1,500 m/g2. Efficacy data suggest synergy with chemotherapy. Further clinical studies of CPI-613 efficacy in pancreatic cancer are in progress. Clinical trial information: NCT03435289. Research Sponsor: Rafael Pharmaceuticals, 1 Duncan Drive, Cranbury, NJ, Atlantic Health System.

4636 Poster Session (Board #244), Fri, 8:00 AM-11:00 AM

Pharmacokinetically-guided 5-FU dose optimization within the preoperative FOLFOXIRI regimen in resectable pancreatic cancer patients. *First Author: Anna Vilalta, Department of Medical Oncology, Clinica Universidad de Navarra, University of Navarra, Pamplona, Spain*

Background: Neoadjuvant therapy is an increasingly used approach in patients with resectable pancreatic cancer (PC). A positive link between chemotherapy dose intensity and patients' outcome has been suggested in PC. The aim of this study was to rule out whether 5-FU pharmacokinetic (PK) parameters correlate with outcome in resectable PC patients treated with preoperative FOLFOXIRI. **Methods:** Patients with resectable and borderline resectable PC treated with Oxaliplatin (85mg/m^2), Leucovorin (400mg/m^2), Irinotecan (150 mg/m^2) and 5-FU (initial dose of 3200 mg/m^2 in 46h infusion and subsequent doses based on PK-guided dose adjustements targeting an AUC of 25-30 mcg*h/ml) were included. 5-FU PK analysis was performed taking two plasma samples during 5-FU infusion in at least two cycles. Drug concentrations were analysed by High-Perfomanced Liquid Chromatography. After induction polychemotherapy (IPCT), patients with no progressive disease received chemoradiation (CRT) (50.4 Gy with concurrent Capecitabine and Oxaliplatin) followed by surgical resection 4 to 6 weeks after the completion of CRT. Subsequent follow-up until disease progression was remained. An exploratory analysis with Log-Rank test was performed to assess progression free survival (PFS) based on 5-FU AUC values. **Results:** From November 2012 to October 2018, 29 patients were retrospectively assessed: median age 63 (46-75); M/F rate 20/9; R0 resection rate of 90% in the intention-to-treat analysis. The pathological response according to CAP classification was 0, 1, 2 and 3 in 14, 58, 19.5 and 8.5%, respectively; and median number of resected lymph nodes was 11 (2-22), with lymph node infiltration (ypN1) in 14% of patients. Grade 3-4 IPCT related toxicities and grade 3 CRT related toxicities were reported in 40 and 30% of patients, respectively. Median PFS was 723 days (24 months) and median 5-FU AUC 28.5 mcg*h/ml (23-53). Median PFS for patients with 5-FU AUC $\geq$27 mcg*h/ml was 29 months versus 15 months in patients with 5-FU AUC $<$ 27 mcg*h/ml (adjusted hazard ratio for disease progression 0.223; 95% CI = 0.059-0.848; p = 0.028; in a model controlled by age, sex and irinotecan dose intensity). **Conclusions:** 5-FU pharmacokinetic parameters achieving a target of AUC $\geq$ 27 mcg*h/ml seem to correlate with longer PFS in this subset of patients. Research Sponsor: None.

4637 Poster Session (Board #245), Fri, 8:00 AM-11:00 AM

Olaparib (O) in patients (pts) with pancreatic cancer with BRCA1/2 inactivating mutations: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Eugene R Ahn, Cancer Treatment Centers of America, Zion, IL*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of pancreatic cancer pts with germline or somatic BRCA1/2 inactivating mutations treated with O are reported. **Methods:** Eligible pts had advanced pancreatic cancer, no standard treatment (tx) options available, measurable disease, ECOG Performance Status (PS) 0-2, and adequate organ function. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts received O tablets or capsules dosed at 300 mg (n=27) or 400 mg (n=3), respectively, orally twice daily until disease progression. Simon 2-stage design tested the null disease control (DC) (objective response (OR) or stable disease at 16+ weeks (wks) (SD16+) according to RECIST) rate of 15% vs. 35% (power = 0.85; α = 0.10). If $\geq$2 of 10 pts in stage 1 have DC, 18 more pts are enrolled. If $\geq$7 of 28 pts have DC, the tx is worthy of further study. Secondary endpoints are progression-free survival (PFS), overall survival (OS), and safety. **Results:** Thirty pts with *BRCA1/2* inactivating mutations were enrolled from Nov 2016 to Aug 2019; 20 were previously treated with platinum based therapy. Two were not evaluable and excluded from efficacy analyses. Demographics and outcomes are summarized in Table. One partial response (PR) and 7 SD16+ were observed for DC and OR rates of 31% (90% CI: 18% - 40%) and 4% (95% CI: 0% - 18%), respectively. Seven pts had at least one grade 3 AE or SAE at least possibly related to O including anemia, diarrhea, fever, elevated liver enzymes, enterocolitis, increased bilirubin, and oral mucositis. **Conclusions:** Monotherapy O showed anti-tumor activity in heavily pre-treated pts with pancreatic cancer with germline (5/12 pts with OR or SD16+) or somatic (3/16 pts with OR or SD16+) *BRCA1/2* inactivating mutations extending findings of recent studies of O in pts with advanced pancreatic cancer. Clinical trial information: NCT02693535. Research Sponsor: AstraZeneca, Pharmaceutical/Biotech Company.

A phase II trial of preoperative FOLFIRINOX followed by gemcitabine-based chemoradiotherapy in patients with borderline resectable pancreatic ductal adenocarcinoma (BR PDAC). *First Author: Michael Wysota, Montefiore Medical Center, Bronx, NY*

Background: Preoperative (preop) therapy is widely accepted as the standard of care for patients (pt) with BR PDAC with limited evidence for a specific regimen. This study aimed to assess the efficacy of FOLFIRINOX (FOL) chemotherapy followed by gemcitabine-based chemo-radiotherapy (RT) as preop therapy in pt with BR-PDAC. **Methods:** This single arm Simon two stage phase II trial in pt with BR PDAC was conducted in two phases. The first phase included 4 cycles of FOL, and the second included weekly gemcitabine (1000 mg/m2) for 6 cycles with concomitant intensity-modulated RT (50.4 Gy in 28 fractions)(Gem/RT).The primary aim was to compare R0 resection rate (H_0: $\leq$40% vs $H_a \geq$60%) using one-sample one-sided Z test. Secondary outcomes, including overall survival (OS) and progression-free survival (PFS) were assessed using Kaplan-Meier method. **Results:** Of 22 enrolled pt, 18 (81.8%) completed preoperative treatment. Median age at diagnosis was 63.4 years and 12 (54.5%) were female. There were 10 (45.5%) Hispanics, 4 (18.2%) non-Hispanic black, and 8 (36.4%) non-Hispanic white. Tumor location was predominantly head/neck (21, 95.5%), 15 (68.1%) had T2/3, and 9 (40.9%) had N2 (clinical) disease. Fourteen (64.6%) pt, had venous involvement, 5 (22.7%) had arterial, and 3 (13.6%), both. In the first phase, 20 (90.9%) completed 4 cycles of FOL, 6 (27.3%) required dose-reduction and dose was delayed in 12 (54.5%). Stable disease (SD) was achieved in 10 (52.6%), partial response (PR) in 8 (42.1%) and disease progression (PD) in 1 (5.3%) pt. Of 21 pt that entered the second phase, 18 (85.7%) completed 6 cycles of Gem/RT, 5 (26.3%) required dose-reduction and dose was delayed in 6 (31.6%). SD was achieved in 10 (55.6%), PR in 3 (16.7%) and PD in 5 (27.8%). All pt experienced at least one grade 1 adverse event (AE) and 12 (54.5%) at least one grade 3/4 AE, of which neutropenia was the most common-11 (50%). Of the 15 (68.1%) pt who underwent surgical resection, 12 (80%) achieved R0 margins and 5 (33.3%) required vascular reconstruction. The R0 rate among pt that received $>$1 cycle of FOLFIRINOX was 54.5%. Adjuvant chemotherapy was offered to 6/15 pt (40%). The PFS and OS will be reported. **Conclusions:** An R0 resection rate of 54.5% with this limited sample size is significant at the 10% level. Neoadjuvant FOLFIRINOX followed by concomitant Gem/RT was well-tolerated. The study will be amended to include adjuvant FOL in line with the PRODIGE intergroup adjuvant study results. Clinical trial information: NCT01897454. Research Sponsor: None.

4639 Poster Session (Board #247), Fri, 8:00 AM-11:00 AM

FOLFIRINOX de-escalation in advanced pancreatic cancer (aPC): A multicenter real-life study. *First Author: Hortense Chevalier, University of Lille, Lille, France*

Background: FOLFIRINOX (5FU, irinotecan, and oxaliplatin) is a reference first line (L1) of chemotherapy (CT) in fit patients (Pts) with advanced pancreatic cancer (aPC). Limiting toxicities (in particular, neuropathy) are frequent and maintaining quality of life without a lack of efficacy is a crucial need. Modalities and efficacy of maintenance strategy in aPC remain scarcely studied. Our study describes the French practices of a FOLFIRINOX de-escalation and maintenance in a real-life multicentric cohort. **Methods:** We performed a retrospective multicentric study in 5 French centers. Pts receiving FOLFIRINOX L1 for aPC were recruited between January 2011 and December 2018. FOLFIRINOX de-escalation was defined as stopping oxaliplatin and/or irinotecan in patients without tumor progression, after at least 4 cycles of FOLFIRINOX. Maintenance schedules were oral capecitabine or intravenous (IV) 5FU, FOLFOX or FOLFIRI. Primary endpoint was overall survival (OS). Secondary endpoints were first progression-free survival (PFS1) and, in case of reintroduction of FOLFIRINOX, second progression free survival (PFS2). OS and PFS were estimated using the Kaplan-Meier method and compared using the log-rank test. **Results:** Among the 321 patients included, 147 (46%) received a maintenance therapy. Median age was 60.0 (53–66), 35 (24%) had locally advanced PC and 91 (62%) had metastatic PC. The median total number of cycles was 14.0 (11.0–19.0), including 4.5 (2.0–9.0) of maintenance CT. Median OS was 16.1 months (95%CI = 13.7-20.3). Median PFS1 was 8.8 months (95%CI = 8.3-9.7). The preferred maintenance regimen was fluoropyrimidine (FP) in 66 (45%), vs FOLFIRI in 52 (35%) and FOLFOX in 25 (17%). Eighty-two percent of Pts received a second-line chemotherapy. Among 118 Pts who received a maintenance CT with FOLFIRI or FP, there was no difference in PFS1 (median: 9.0 vs 9.3, respectively, p = 0.31) or OS (median: 16.6 versus 18.7, p = 0.60) between the 2 maintenance regimens. After progression under maintenance CT with FOLFIRI or FP, reintroduction of FOLFIRINOX was performed in 16.1% of Pts, with a median PFS2 of 3.4 months (95%CI = 2.5-23.2). As previously reported in the PANOPTIMOX trial, the rates of G3-4 toxicity were significantly higher during FP maintenance CT than with FOLFIRI (41% vs 9%, p = 0.03), especially neuropathy (41% vs 9%). **Conclusions:** FOLFIRINOX de-escalation in aPC is largely used in France. Fluoropyrimidine maintenance chemotherapy appears to be as effective as FOLFIRI. Research Sponsor: None.

4640 Poster Session (Board #248), Fri, 8:00 AM-11:00 AM

A phase Ib study of sEphB4-HSA combined with first-line chemotherapy in patients (pts) with advanced pancreatic (PC) and biliary cancers (BC). *First Author: Diana L. Hanna, Hoag Cancer Center, Newport Beach, CA*

Background: EphB4, a receptor kinase expressed in most epithelial tumors, binds EphrinB2 to affect cancer cell growth, apoptosis and angiogenesis. EphB4 overexpression is associated with advanced stage and shorter survival in multiple cancers. sEphB4-HSA, the albumin-bound extracellular fragment of EphB4, is a first-in-class inhibitor which blocks EphB4-EphrinB2 bidirectional signaling and results in downstream suppression of KRAS, PI3K, and promotes recruitment of CD3 and CD8 T cells into the tumor. The RP2D of sEphB4-HSA is 10 mg/Kg IV q week. Here, we report on sEphB4-HSA in combination with standard first-line chemotherapy. **Methods:** Pts with advanced PC or BC and no prior therapy for metastatic disease were eligible and enrolled into separate cohorts. Pts with PC received gemcitabine 1,000 mg/m2 + nab-paclitaxel 125 mg/m2 on Days 1, 8, 15 of a 28-day cycle. Pts with BC received gemcitabine 1,000 mg/m2 + cisplatin 25 mg/m2 on Days 1, 8 of a 21-day cycle. sEphB4-HSA 10 mg/kg IV was given weekly starting in Cycle 2. Response was assessed every 2 cycles. Primary endpoint was safety and tolerability; secondary endpoints were objective response rate (ORR) by RECIST 1.1, PFS, OS. Expression of EphrinB2 and EphB4 in tumor was examined by IHC and classified as 1+ (weak staining); 2+ (moderate staining); 3+ (strong, uniform staining). **Results:** A total of 44 pts with advanced PC (n = 21) and BC (n = 23; 70% gallbladder cancer) were enrolled. Median age 66 yrs; ECOG 1 (70%), 52% male. Median number of cycles received were 5 (PC) and 7 (BC). Median PFS was 5.6 mo in PC and 5.8 mo in BC (95% CI: 3.1-8.1 [PC]; 2.7-7.0 [BC]). Median OS was 7.9 mo in PC and 9.1 mo in BC (95% CI: 6.5-15.0 [PC]; 5.4-15.0 [BC]). In response evaluable pts (20 PC, 22 BC), ORR was 40% in PC (95% CI: 21%, 63%) and 23% in BC (95% CI: 9%, 45%). Stable disease was noted in 48% of PC and 61% of BC pts. The most common grade 3 or 4 treatment-related AEs in ≥10% of pts in both cohorts combined were hypertension (n = 16; 36%), neutropenia (n = 15; 34%), anemia (n = 14; 32%), thrombocytopenia (n = 7, 16%), fatigue (n = 7, 16%). In the PC cohort, there was an association between EphB4 expression and objective response (p = 0.009). **Conclusions:** sEphB4-HSA has a manageable safety profile in combination with chemotherapy in pts with PC and BC. Clinical activity is manifested by a high disease control rate in both cohorts and a promising RR in PC. Additional biomarker analyses will be presented. Future studies combining chemoimmunotherapy with sEphB4-HSA in pancreatic cancer are planned. Clinical trial information: NCT02495896. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

4641 Poster Session (Board #249), Fri, 8:00 AM-11:00 AM

Comprehensive analysis of KRAS variants in patients (pts) with pancreatic cancer (PDAC): Clinical/molecular correlations and real-world outcomes across standard therapies. *First Author: Andrew Eugene Hendifar, Samuel Oschin Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Approximately 90% of PDAC tumors are driven by activating KRAS mutations. The biological and clinical impact of common KRAS variants (e.g. G12D, G12V, G12R) and less common variants (e.g. G12C, Q61H, Q61R) remains largely unknown despite the emergence of variant-specific treatment strategies. **Methods:** We retrospectively analyzed real-world outcomes from 1475 PDAC pts who underwent molecular profiling via the Know Your Tumor program. Overall survival (OS) and progression-free survival (PFS) were analyzed by choice of 1st line standard therapies. Outcomes in pts with specific KRAS mutations were compared against the KRAS G12D cohort using Cox regression. Based on our prior data, tumor profiles with actionable molecular findings (DDR mutations or other drivers) were evaluated separately. **Results:** The prognostic/predictive value of specific KRAS variants revealed differences in real-world outcomes (Table). OS was greater in pts with KRAS G12V and G12R variants, as was PFS on 5FU-Based Therapy (e.g. FOLFIRINOX) but not for Gemcitabine/nab-Paclitaxel. Opposing trends were noted for KRAS Q61. Pts with KRAS wild type tumors as well as both actionable subgroups also had an improved OS. **Conclusions:** In this large national dataset, we demonstrate that KRAS mutation status and specific variants appear to be prognostic as well as predictive in pancreatic cancer. Research Sponsor: Pancreatic Cancer Action Network (patient advocacy organization), Perthera (private healthcare company).

Real-world outcomes by KRAS mutation in PDAC.

Cobimetinib plus gemcitabine is an active combination in KRAS G12R-mutated in previously chemotherapy-treated and failed pancreatic patients. *First Author: Bach Ardalan, University of Miami, Miami, FL*

Background: he KRAS proto-oncogene is involved in the RAS/MAPK pathway. Various G12X mutations have been examined with the most common mutations being G12D (40%), G12V (30%), and G12R (15-20%) in pancreatic cancer patients. Throughout the course of studying the G12X mutations, we have observed that not all KRAS mutations are equal. Preclinical data shows G12R is impaired in pI3Kα signaling, as compared to KRAS G12V/D. This mechanism is important in PDAC as it allows tumor growth to be sustained. In preclinical studies, PDX derived tumors were transplanted in mice and were treated with a MEK inhibitor plus chemotherapy, which demonstrated a greater tumor regression than either agent alone. Therefore, we have decided to treat patients with Gemcitabine alongside a 2nd generation MEK inhibitor (Cobimetinib). **Methods:** In our single arm study, 13 KRAS mutated pancreatic patients (KRAS G12D, G12V, and G12R) received the combination of Cobimetinib 20mg BID weekly for three weeks alongside Gemcitabine at 1000mg/m^2 weekly, followed by one week of rest. The above constitutes one cycle. **Results:** Patients were divided into two groups; *Group 1* consists of seven patients that were KRAS G12D/G12V mutated, and *Group 2* included six KRAS G12R mutated patients. In Group 1, seven patients on treatment progressed and died within two months on the study. In Group 2, one achieved PR and others stable disease. Median progression-free survival was 6.0 months (95% CI 3-9.3 months) and median OS has not been reached. All patients are alive at 8 months. Common adverse reactions include rash, fatigue, nausea, and vomiting. Cancer antigen 19-9 decreased in ≥ 50 of all patients in the latter group. We would like to report our positive study to the society. Moreover, we intend to confirm the study in a larger patient cohort. **Conclusions:** Pancreatic cancer patients that demonstrate KRAS G12R mutations are treatable with a new active combination chemotherapy. Research Sponsor: None.

4643 Poster Session (Board #251), Fri, 8:00 AM-11:00 AM

A pilot study to determine the feasibility of a customized low glycemic load diet in patients with stage I-III colorectal cancer. *First Author: Michelle Elizabeth Treasure, Cleveland Clinic Foundation, Cleveland, OH*

Background: Observational evidence associates energy balance factors, particularly diet, with survival in patients with colorectal cancer (CRC). Consumption of a diet with high glycemic indices has been associated with inferior cancer-specific outcomes, but there is limited prospective evidence that alterations in dietary habits improve cancer outcomes. This was a pilot study to determine the feasibility and acceptability of following a low glycemic load (GL) diet in patients with stage I-III CRC and to assess the nutritional resources necessary to follow the diet. **Methods:** 18 patients with stage I-III CRC, who completed definitive cancer therapy and consumed an avg daily GL $>$ 150 participated in a 12 week, tailored, in-person dietary intervention with a target GL of $\leq$102. Compliance was assessed using 24 hour telephone recalls. Acceptability of the diet was assessed using a food acceptability questionnaire, and exploratory correlative laboratories were assessed monthly. **Results:** 67% of patients were compliant with a low GL diet $\geq$ 75% of the time, over a 12 week time period. Majority of participants experienced a decrease in BMI and waist circumference, 28% experienced meaningful weight loss defined as $\geq$ 5%. The nutritionist spent an avg of 6.97 hours (SD 2.18) in-person and 1.58 hours (SD 0.68) by phone with each participant. In the overall group, significant decreases were seen in total cholesterol (7.2% decrease; t = -2.33, p = 0.03), VLDL (26.8% decrease; t = -2.33, p = 0.03) and triglycerides (26.6% decrease; t = -2.29; p = 0.04). All participants were satisfied with the diet; 43% were extremely satisfied. 75% of participants liked the foods they were able to eat "very much" or "extremely". All participants felt the in-person meetings were helpful. 77% did not feel an online video could replace the in-person meetings. 62% of participants did not feel a virtual meeting (e.g skype, etc.) could replace the in- person meeting while 38% felt it could. **Conclusions:** Patients with stage I-III CRC are able to follow a low GL diet with an in-person dietary intervention. Significant decreases in laboratory measures confirm the efficacy of the diet in altering metabolic indices. All participants who completed the study were satisfied with the diet, the majority of whom enjoyed the foods and planned to continue to follow the diet after study completion. The majority felt in-person contact with the nutritionist was essential to their success. This study was an essential step in designing a larger scale trial to evaluate the impact of low GL diet on cancer outcomes. Clinical trial information: NCT02129218. 4644 Poster Session (Board #252), Fri, 8:00 AM-11:00 AM

Ramucirumab in patients with advanced HCC and elevated alpha-fetoprotein (AFP): Outcomes by treatment-emergent ascites. *First Author: Andrew X. Zhu, Harvard Medical School, Massachusetts General Hospital, Boston, MA*

Background: REACH and REACH-2 investigated ramucirumab (RAM) vs placebo (PL) in patients (pts) with advanced HCC following sorafenib, with REACH-2 enrolling only pts with baseline AFP $\geq$400 ng/mL. Ascites is common in HCC and associated with poorer outcomes. An exploratory analysis of outcomes by treatment-emergent (TE)-ascites was done. **Methods:** Pts with HCC, Child-Pugh A, ECOG PS $\leq$1, prior sorafenib, and no clinically meaningful ascites were randomized (REACH 1:1; REACH-2 2:1) to RAM 8 mg/kg or PL Q2W. A pooled meta-analysis of independent pt data (stratified by study) from REACH-2 and REACH (AFP $\geq$400 mg/mL) was done. OS and PFS were evaluated by Kaplan-Meier estimator and Cox models. Prognosis of TE-ascites in OS was evaluated by multivariate Cox models (adjusted for baseline ECOG PS, AFP, macrovascular invasion (MVI), and treatment [trt]). **Results:** Baseline characteristics were generally balanced between TE-ascites and non-ascites pts; however, more pts with ascites had MVI at baseline. Any-grade ascites was reported at a higher rate in RAM than PL (66 [21%] vs 33 [15%] pts, respectively), with most being low grade. Rate of Gr $\geq$3 ascites was similar between arms (15 [5%] vs 9 [4%] pts). Median time to onset (43 vs 47 days) and median duration of ascites (13 vs 18 days) were similar in RAM vs PL, with furosemide (22%) and spironolactone (19%) as most common trt and paracentesis (18%) as most common procedure for ascites in both arms. Ascites trended as a prognostic factor for OS after adjustment (with vs without; HR=1.3, 95% CI: 0.99, 1.62). Ascites was more commonly linked with hypoalbuminemia (odds ratio 4.9, 95% CI: 2.5, 9.3), but was not associated with proteinuria or hypertension. TEAEs occurred more frequently in pts with ascites in both arms. The most frequent Gr $\geq$3 TEAE in pts with ascites was hypertension. One RAM pt discontinued trt due to ascites. RAM trt was beneficial irrespective of presence of ascites (Table), and pts with ascites received more post-discontinuation therapy on RAM than PL (18% vs 6%). **Conclusions:** Acknowledging limitations of sample size, RAM provided a survival benefit in pts who did or did not experience TE-ascites. RAM was well tolerated and no new safety findings were observed. Clinical trial information: NCT01400347; NCT02435433. Research Sponsor: Eli Lilly and Company.

Efficacy.

4645 Poster Session (Board #253), Fri, 8:00 AM-11:00 AM

Adjuvant chemoradiotherapy impact on the overall survival of completely resected ampullary and periampullary carcinoma: An updated meta-analysis. *First Author: Philip A. Haddad, Feist-Weiller Cancer Center at LSUHSC-Shreveport, Overton Brooks VAMC, Shreveport, LA*

Background: Ampullary and Periampullary carcinomas (APAC) are uncommon gastrointestinal cancers that are often amenable to surgical resection. The benefit of postoperative adjuvant chemoradiotherapy (ACRT) in patients with completely resected localized AC has been controversial. A meta-analysis which was conducted in 2017 found no associated survival benefit for adjuvant therapies in APAC. However, this meta-analysis was methodologically flawed and combined studies that used adjuvant chemotherapy alone with those that used ACRT. The purpose of this meta-analysis is to evaluate the impact of ACRT on the overall survival (OS) of patients with completely resected APAC incorporating more recent studies. **Methods:** A review of the medical literature was conducted using online databases. Inclusion criteria consisted of resected Ampullary and Periampullary carcinoma, English language, publications from 1999 to the present, comparative studies reporting OS with hazard ratios (HR) or Kaplan-Meier curves of patients that underwent ACRT versus those that did not, and studies that reported the aggregate OS data of adjuvant therapies where the preponderance of the cohort received ACRT. Adjuvant chemotherapy studies and those that reported aggregate OS for a cohort with preponderance of adjuvant chemotherapy were excluded. A meta-analysis was conducted using an inverse variance method with a random-effects model. **Results:** Sixteen retrospective series with a total of 1122 patients were included and analyzed. The majority of APAC patients that received ACRT tended to have high risk features. Four of these studies analyzed their OS data for the high risk APAC patients in addition to the cohort as a whole. Intra-arterial chemotherapy and concomitant radiotherapy was used in one study. ACRT was found to be significantly associated with better OS in patients with completely resected APAC (HR 0.76, 95%CI: 0.65-0.88, p $<$ 0.001). **Conclusions:** This is the first meta-analysis to show that adjuvant chemoradiotherapy is associated with a survival benefit in patients with completely resected high risk Ampullary and Periampullary carcinoma. In the absence of randomized clinical trials, this meta-analysis represents the most compelling data supporting the use of ACRT in this patient population. Research Sponsor: None.

TPS4646 Poster Session (Board #254), Fri, 8:00 AM-11:00 AM

Randomized phase III trial to evaluate omentum preserving gastrectomy for patients with resectable advanced gastric cancer: JCOG1711 (ROAD-GC). *First Author: Takanobu Yamada, Kanagawa Cancer Center, Yokohama, Japan*

Background: Standard surgery for resectable advanced gastric cancer is D2 (standardized extended lymph node dissection) gastrectomy with omentectomy. The reason why omentectomy has been performed is as follows; (1) principal surgery for gastrointestinal cancers is en-block resection of mesothelium including regional lymph nodes. Omentum is a part of the mesothelium of the stomach. (2) Cancer cells implanted into the peritoneal cavity aggregated in the milky-spot of the omentum and formed peritoneal dissemination in an animal model. (3) By special staining, micrometastasis detected in the omentum. There is some arguments for this theory. (1) no prospective study showed survival benefit of omentectomy as compared with omentum preservation. (2) anatomically, milky-spot is found not only in the omentum but also in other mesothelium or Douglas pouch. (3) JCOG1001 phase III study showed no survival benefit of bursectomy against non-bursectomy although bursa is a part of mesothelium of the stomach. (4) Anti-immunity is accelerated by antigen presentation by macrophage in the milky-spot of the omentum. Preservation of the omentum may have several benefits; (1) decrease in blood loss and operation time, (2) preservation of physical function by omentum such as reaction to peritonitis and prevention of adhesion, and (3) overcoming difficulties in laparoscopic omentectomy and avoidance of organ injury during surgery. **Methods:** The study is multicenter randomized phase III trial designed to confirm non-inferiority of omentum preservation to omentectomy for resectable advanced gastric cancer. Patients aged 20-79 years, histologically proven gastric adenocarcinoma, clinical subserosal/serosal invasion, and expected R0 (curative) resection are randomly assigned (1:1) during surgery to either omentum preservation or omentectomy. Total or distal gastrectomy with D2 dissection is performed in both arms. Laparoscopic gastrectomy is not allowed. Intraoperative photographs of the dissected field are centrally reviewed for all patients for quality control. The primary endpoint is relapse-free survival (RFS) and the secondary endpoints are overall survival, blood loss, operation time, and adverse events. Sample size was set at 1050 considering expected 3-year RFS of 77% in both arms with non-inferiority margin of 5%, one-sided alpha of 5%, and power of 80%. Planned accrual and follow up period are 6.5 years and 3 years respectively. The trial was activated in March 2019, and 177 patients are enrolled as of January 2020. Clinical trial information: UMIN000036253. Research Sponsor: None.

TPS4647 Poster Session (Board #255), Fri, 8:00 AM-11:00 AM

POF (paclitaxel/oxaliplatin/5-FU/leucovorin) versus SOX/CAPOX/FOLFOX as a postoperative adjuvant chemotherapy for curatively resected stage III gastric cancer: Study protocol for a randomized controlled trial, FNF-014 trial. *First Author: Liyu Su, Gastrointestinal Medical Oncology, Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou, China*

Background: Postoperative chemotherapy (S-1, CAPOX, or Docetaxel/S-1) is a standard treatment for stage II/III gastric cancer in Asia. With regard to single agent or doublet, the need for improvement has consistently been pointed out because of the relatively poor outcome for patients with stage III gastric cancer. Triplet (FLOT) has shown significant survival benefits in perioperative setting. POF, our regiment similar to FLOT, demonstrated priority to doublet (FOLFOX) in advanced setting (2019 ASCO-GI). We conducted a randomized, multicenter, phase III study to compare triplet to doublet regimens for patients with stage III gastric cancer. **Methods:** This is currently enrolling patients (n = 544) with pathologic stage III gastric cancer after D2 lymph node dissection. Patients are randomized 1:1 and stratified by tumor stage (IIIA, IIIB, or IIIC, AJCC 8th) into POF or SOX/CAPOX/FOLFOX (chosen by the clinicians). SOX: oxaliplatin 130 mg/m2 on day 1, oral S-1 80mg/m2 divided by two on days 1 to 14 every 21 days for 8 cycles. CAPOX: oxaliplatin 130 mg/m2 on day 1, oral capecitabine 1000 mg/m2 twice daily on days 1 to 14 every 21 days for 8 cycles. FOLFOX: oxaliplatin 85 mg/m2, levo-leucovorin 200 mg/m2, and 5-FU 400 mg/m2 bolus on day 1, then 5-FU 2400 mg/m2 continuous infusion over 46 hours, every 14 days for 12 cycles. Three doublets were chosen by the clinicians. POF: paclitaxel 135 mg/m2, followed by FOLFOX omitted 5-FU bolus, every 14 days for 12 cycles. Eligibility criteria: patients aged 18-70 years, primary histologically proven gastric adenocarcinoma (including adenocarcinoma of the gastro-esophageal junction) of stage III with no evidence of metastatic disease, R0 resection with D2 lymph node dissection, good performance status (ECOG PS $\leq$1). Subjects must be able to take orally, and without other concomitant medical conditions that required treatment, initially treated with curative surgery followed by chemotherapy within 42 days. Life expectancy estimated more than 6 months. Adequate organ function. All patients provided written informed consent prior to treatment. Key exclusion criteria: patients with other primary malignancies, gastrointestinal bleeding. The primary end point is 3-year disease-free survival. Secondary end points are 3-year overall survival, 5-year overall survival, 5-year disease-free survival, and adverse events. Clinical trial information: NCT03788226. Research Sponsor: None.

TPS4648 Poster Session (Board #256), Fri, 8:00 AM-11:00 AM

Phase III study of first-line zolbetuximab + CAPOX versus placebo + CAPOX in Claudin 18.2$^+$/HER2$^-$ advanced or metastatic gastric or gastroesophageal junction adenocarcinoma: GLOW. *First Author: Manish A. Shah, Weill Cornell Medical College, New York, NY*

Background: Gastric cancer is the fourth leading cause of cancer death worldwide. Capecitabine + oxaliplatin (CAPOX) is a standard first-line treatment for advanced gastric cancer. Claudin (CLDN)18.2 has emerged as a promising targetable biomarker. In healthy tissue, CLDN18.2, a tight junction protein, is confined to gastric mucosa (ie, cells in the pit and base regions of gastric glands). Upon malignant transformation, structural loss in gastric or gastroesophageal junction (G/GEJ) adenocarcinoma cells may allow antibodies more access to previously unavailable CLDN18.2. Zolbetuximab is a chimeric IgG1 monoclonal antibody that specifically binds to CLDN18.2 and mediates cell death through antibody-dependent cellular cytotoxicity and complement-dependent cytotoxicity. Results of a phase 2 study (NCT01630083) showed prolonged survival of patients with CLDN18.2-positive (CLDN18.2$^+$) advanced G/GEJ adenocarcinoma treated with zolbetuximab + epirubicin, oxaliplatin, and capecitabine (EOX) vs EOX alone. **Methods:** This phase 3, double-blind, placebo-controlled study (NCT03653507) will enroll ~500 adult patients from global sites. Patients are required to have CLDN18.2$^+$/HER2$^-$ locally advanced unresectable or metastatic G or GEJ adenocarcinoma that is radiographically evaluable per RECIST v1.1. Patients are not permitted to have received prior treatment with chemotherapy for advanced or metastatic G or GEJ adenocarcinoma. Patients will be randomly assigned 1:1 to receive either zolbetuximab plus CAPOX or placebo plus CAPOX. Randomization will be stratified by region (Asia vs non-Asia), number of metastatic sites (0 to 2 vs $\geq$3), and prior gastrectomy (yes vs no). Zolbetuximab will be administered at a loading dose of 800 mg/m^2 IV on Cycle 1 Day 1 followed by 600 mg/m^2 IV every 3 weeks. Central testing of tumor tissue will determine CLDN18.2 and HER2 status (if unknown); patients will be considered CLDN18.2$^+$ if $\geq$75% of tumor cells demonstrate moderate-to-strong membranous immunohistochemical staining. The primary objective is to compare progression-free survival between treatment arms. Secondary endpoints are overall survival; objective response rate; duration of response; and the safety/tolerability, pharmacokinetics, and immunogenicity of zolbetuximab. As of January 31, 2020, 127 sites were active and open to enrollment. Clinical trial information: NCT03653507. Research Sponsor: Astellas Pharma, Inc.

TPS4649 Poster Session (Board #257), Fri, 8:00 AM-11:00 AM

Trial in progress: A phase I study of AMG 199, a half-life extended bispecific T-cell engager (HLE BiTE) immune therapy, targeting MUC17 in patients with gastric and gastroesophageal junction (G/GEJ) cancer. *First Author: Joseph Chao, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Prognosis for advanced G/GEJ cancer is poor and new treatment modalities are urgently needed. MUC17 is a transmembrane protein overexpressed and differentially localized on the cell membrane of G/GEJ cancer cells; expression and localization in normal cells is much more limited. AMG 199 is an HLE BiTE immune therapy designed to engage CD3-positive T cells to MUC17-positive G/GEJ cancer cells, mediate redirected tumor cell lysis, and induce T cell activation and proliferation. A clinical trial is being conducted for this novel and targeted immune therapy agent in patients with MUC17-positive G/GEJ cancer. **Methods:** This is a first-in-human phase 1, open-label, dose escalating study (NCT04117958) evaluating AMG 199 in patients with MUC17-positive G/GEJ cancer. Key eligibility criteria include metastatic or locally advanced unresectable MUC17-positive (as determined by IHC using a central laboratory assay) gastric adenocarcinoma or gastroesophageal junction adenocarcinoma ineligible for curative surgery and relapsed or treatment-refractory following $\geq$2 lines including a platinum, a fluoropyrimidine, taxane or irinotecan, and an approved vascular endothelial growth factor receptor antibody or tyrosine kinase inhibitor. Patients eligible for human epidermal growth factor receptor 2 (HER2) directed therapy should have received an approved HER2 targeting antibody. Primary endpoints include: dose-limiting toxicities, treatment-emergent or -related adverse events, vital signs, electrocardiogram (ECG), and laboratory changes. Secondary endpoints include: pharmacokinetics of AMG 199, objective response, duration of response, time to progression, 6-month and 1-year progression-free survival, and 1-year and 2-year overall survival. The dose exploration (n = 30) will estimate the maximum tolerated dose and/or recommended phase 2 dose; this will be followed by a dose expansion (n = 40) and evaluation of the benefit/risk profile of AMG 199. The study began enrolling patients in January 2020 and is ongoing. This is the first clinical trial to investigate MUC17 as a potential anti-tumor target. For more information, please contact Amgen Medical Information: medinfo@amgen.com. Clinical trial information: NCT04117958. Research Sponsor: Amgen.

TPS4650 Poster Session (Board #258), Fri, 8:00 AM-11:00 AM

A randomized phase II/III study of paclitaxel/cisplatin versus cisplatin/5-fluorouracil in neoadjuvant chemoradiotherapy (CRT) followed by surgery for patients with locally advanced esophageal squamous cell carcinoma (ESCC). *First Author: Ta-Chen Huang, National Taiwan University Hospital, Taipei, Taiwan*

Background: Meta-analyses have shown the survival benefit of cisplatin/5-fluorouracil (PF) neoadjuvant CRT over surgery alone for patients with locally advanced ESCC. The CROSS study has demonstrated the statistically significant survival benefit of paclitaxel/carboplatin neoadjuvant CRT for patients with locally advanced esophageal cancer, especially ESCC. A network meta-analysis based on published phase III trials suggested that paclitaxel/platinum might be superior to PF as neoadjuvant CRT in patients with ESCC (Huang et al: Jpn J Clin Oncol. 2015;45:1023–8). However, a direct comparison of two CRT regimens in a prospective randomized clinical trial has not been performed in ESCC. We designed this clinical trial to test the hypothesis that paclitaxel-platinum is superior to PF as neoadjuvant CRT in patients with locally advanced ESCC. **Methods:** This single center open-label phase 2/3 study randomizes patients with histologically confirmed ESCC, T3/4aN0M0 or T1-3N1-3M0 (AJCC 7th edition), in 1:1 ratio, to receive TP (paclitaxel, 50 mg/m2/week; cisplatin 30 mg/m2/week; for 5 weeks) or PF (cisplatin 75 mg/m2, d1; 5-FU 1,000 mg/m2, d1-4; on week 1 and week 5)-neoadjuvant CRT (180 cGy/d, 5 days/week, for 5 weeks). Esophagectomy will be performed 6 to 10 weeks after completing CRT. All patients must be eligible to esophagectomy, with tumor length $\leq$8cm and tumor radial $\leq$5cm, with adequate organ functions, and have ECOG performance status of 0-2. In the phase 2 stage, 128 patients will be enrolled, assuming the pathologic complete response (pCR) rate of TP and PF as 45% and 25%, respectively, with a power of 80% and one-sided 10% significance level. If the primary endpoint of pCR is met, additional 120 patients will be enrolled for the phase III stage with overall survival as the primary endpoint, assuming the hazard ratio of TP versus PF as 0.65 with a power of 80% and a 5% significance level. The trial started patient enrollment in May, 2017. As of Jan of 2020, 52 of planned 128 patients for phase II part have been enrolled. Clinical trial information: NCT03623737. Research Sponsor: Grant for investigator initiated clinical trials.

TPS4651 **Poster Session (Board #259), Fri, 8:00 AM-11:00 AM**

A phase II/III study of perioperative nivolumab and ipilimumab in patients (pts) with locoregional esophageal (E) and gastroesophageal junction (GEJ) adenocarcinoma: A trial of the ECOG-ACRIN Cancer Research Group (EA2174). *First Author: Jennifer Rachel Eads, University of Pennsylvania, Philadelphia, PA*

Background: E/GEJ adenocarcinoma has a high mortality rate despite curative intent treatment. A pathologic complete response (pCR) is associated with better overall survival (OS) but occurs in less than 30% of pts. Immunotherapy is effective in the metastatic setting. Here we aim to evaluate the contribution of immunotherapy in the neoadjuvant and adjuvant settings in pts with locoregional E/GEJ cancer. **Methods:** This is a multi-center, randomized phase II/III trial. Surgical candidates with locoregional E/GEJ adenocarcinoma receive carboplatin AUC 2 IV and paclitaxel 50 mg/m2 IV, both weekly x 5 during concurrent radiation (50.4 Gy) either with or without nivolumab 240 mg IV during weeks 1 and 3, followed by surgery. Pts with no post-operative disease receive nivolumab 240 mg IV every 2 weeks for 12 cycles either with or without ipilimumab 1 mg/kg IV every 6 weeks for 4 cycles. Eligibility criteria include pts with T1-N1-3M0 or T2-3N0-2M0 disease whom are candidates for surgery, no prior chemotherapy or radiation for this disease, no prior immunotherapy, no significant autoimmune disease. Pts must be disease free for adjuvant treatment. Primary neoadjuvant endpoint is pCR rate; primary adjuvant endpoint is disease free survival (DFS). Secondary endpoints include toxicity, DFS and OS. Pre- and mid-treatment diffusion weighted imaging MRI will be conducted during the neoadjuvant portion of the study. A neoadjuvant safety run in of 30 pts is underway. Overall, 278 pts will be needed to detect an absolute improvement of 15% in pCR rate in pts receiving and not receiving neoadjuvant nivolumab and 236 pts will be needed to detect a HR of 0.65 in favor of adjuvant ipilimumab/nivolumab over nivolumab (90% power, one sided alpha of 0.10). Accrual is expected over 34 months at a rate of 8 patients per month. If favorable at interim analysis. Clinical trial information: NCT03604991. Research Sponsor: U.S. National Institutes of Health.

TPS4652 **Poster Session (Board #260), Fri, 8:00 AM-11:00 AM**

A phase II study of selective HDAC6 inhibition with KA2507 for second-line treatment of advanced biliary tract cancer (ABC-11). *First Author: John A. Bridgewater, University College London Cancer Institute, London, United Kingdom*

Background: The ABC-02 trial provided Level A evidence supporting the use of cisplatin plus gemcitabine as first-line chemotherapy for advanced biliary tract cancer (ABC) [Valle, 2010]. In second line therapy oxaliplatin and 5FU and ivosedinib for IDH1 mutated cancers are options [Lamarca, 2019; Abou-Alfa, 2019] however there remains significant unmet need for patients without actionable alterations. Histone deacetylase 6 (HDAC6) is overexpressed in cholangiocarcinoma, reducing primary cilia. This is mediated through increased resorption in normal human cholangiocytes via tubulin deacetylation in the ciliary axoneme. Inhibition of HDAC6 elicits both cell intrinsic and extrinsic anti-cancer activity. HDAC6 inhibition reversed oncogenic loss of ciliation and demonstrated preclinical efficacy in a syngeneic rat orthotopic biliary cancer model [Gradilone, 2013]. KA2507 is a potent and selective small molecule inhibitor of HDAC6. Phase I dose escalation study identified an oral dose of 800mg bid for further development, being well tolerated and showing evidence of selective target engagement. **Methods:** ABC-11 is a Phase II multi-centre, open-label study of KA2507 in 40 evaluable patients with advanced biliary tract cancer previously treated with standard of care chemotherapy. The study follows a single-arm single-stage design using A'Hern's methodology. Eligible patients receive continuous 28-day cycles of fixed daily oral dose of KA2507 until death, disease progression or other pre-defined reason for study drug discontinuation. Tumour assessment is made at baseline and at 8-weekly intervals using RECIST 1.1 criteria until disease progression; primary endpoint is PFS at 4 months. Independent Data Monitoring Committee will review 4 month PFS and other data after first six patients, after a total of 17 patients (futility analysis, corresponding to cut-off of the Simon's minimax 2-stage design; 33% was set as the target 4-month PFS rate expected with KA2507) and at least annually thereafter. Subject to availability of adequate tissue, mandatory pre-treatment and on-study tumour biopsy samples will undergo multiparameter flow cytometry of immune cell subsets, immunofluorescence analysis of immune cell subsets (activation status and topology) and T cell repertoire studies. The study received regulatory and ethical approval to proceed in January 2020 and enrolment is in progress. Clinical trial information: NCT04186156. Research Sponsor: Karus Therapeutics Ltd.

TPS4653 **Poster Session (Board #261), Fri, 8:00 AM-11:00 AM**

Neoadjuvant chemotherapy with gemcitabine plus cisplatin followed by radical liver resection versus immediate radical liver resection alone with or without adjuvant chemotherapy in incidentally detected gallbladder carcinoma after simple cholecystectomy or in front of radical resection of BTC (ICC/ECC): A phase III study utilizing the German Registry of Incidental Gallbladder Carcinoma Platform (GR)—The AIO/CALGP/ACO-GAIN-Trial. *First Author: Thorsten Oliver Goetze, Institute of Clinical Cancer Research, Krankenhaus Nordwest, UCT University Cancer Center, Frankfurt am Main, Germany and Institute of Clinical Cancer Research (IKF) GmbH at Krankenhaus Nordwest, Frankfurt, Germany*

Background: Currently, complete surgical resection represents the only potentially curative treatment option for Biliary Tract Cancer (BTC) including Gallbladder Cancer (GBC). Even after curative resection, 5-year OS is only 20–40%. GBC is relatively rare, but still the fifth most common neoplasm of the digestive tract and even the most frequent cancer of the biliary system. Gallbladder carcinoma is suspected preoperatively in only 30% of all pts, while the majority of cases are discovered incidentally by the pathologist after cholecystectomy for a benign indication. For improving curative rates in BTC and GBC, early systemic therapy combined with radical resection seems to be a promising approach. The earliest moment to apply chemotherapy would be in front of radical surgery. Encouraging results of neoadjuvant/perioperative concepts in other malignancies provide an additional rationale to use this treatment in the early phase of GBC management and even in intrahepatic and extrahepatic cholangiocarcinoma. Especially because data regarding pure adjuvant chemotherapy in BTC`s are conflicting. **Methods:** This is a multicenter, randomized, controlled, open-label phase III study including pts with incidentally discovered GBCs after simple cholecystectomy in front of radical liver resection and pts with resectable/borderline resectable cholangiocarcinomas (ICC/ECC) scheduled to receive perioperative chemotherapy (Gemcitabine + Cisplatin 3 cycles pre- and post-surgery) or surgery alone followed by a therapy of investigator's choice. Primary endpoint is OS; secondary endpoints are PFS, R0-resection rate, toxicity, perioperative morbidity, mortality and QoL. A total of N=333 patients with GBC or BTC will be included. Recruitment has just started; first patient in was on December 6, 2020. EudraCT number: 2017-004444-38. Clinical trial information: NCT03673072. Research Sponsor: Deutsche Forschungsgesellschaft (DFG).

TPS4654 **Poster Session (Board #262), Fri, 8:00 AM-11:00 AM**

Multicenter phase II study of trastuzumab deruxtecan (DS-8201) for HER2-positive unresectable or recurrent biliary tract cancer: HERB trial. *First Author: Akihiro Ohba, National Cancer Center Hospital, Tokyo, Japan*

Background: Biliary tract cancer (BTC) is one of the most lethal cancers with limited treatment options. Early clinical trials showed a hint of activity of HER2 blockade for HER2 positive BTC, the prevalence of which was reported to be from 5% to 20%. Trastuzumab deruxtecan (DS-8201) is an antibody-drug conjugate composed of an anti-HER2 antibody, cleavable terapeptide-based linker, and a topoisomerase I inhibitor, which showed durable response in HER2 positive breast cancer as well as in a wide spectrum of cancer subtypes in a phase I study. In addition, preclinical research demonstrated the effectiveness of trastuzumab deruxtecan for HER2 positive BTC patient derived xenograft model. This phase II study is being conducted to evaluate the efficacy and safety of trastuzumab deruxtecan for HER2 positive BTC. **Methods:** The main inclusion criteria are unresectable or recurrent BTC, histologically diagnosed as adenocarcinoma or adenosquamous carcinoma, confirmed HER2-expressing status by central pathological examination, refractory or intolerant to treatment including gemcitabine, and adequate organ function. Patients are registered and receive 5.4 mg/kg trastuzumab deruxtecan every 3 weeks until disease progression or unacceptable toxicities. Primary endpoint is the overall response rate (ORR) in HER2 positive (defined as IHC3+, or IHC2+/ISH+; ISH+ defined as *HER2/CEP17* $\geq$2.0) patients by central imaging review. The ORR in all HER2-expressing patients (including HER2 low expressing defined as IHC/ISH status of 0/+, 1+/-, 1+/+, or 2+/-), progression-free survival, overall survival, and incidence of adverse events are assessed as secondary endpoints. Thirty-two patients will be enrolled, including 24 with HER2 positive BTC as primary cohort and 8 with HER2 low expressing BTC. The study has 80% power for primary endpoint in HER2 positive BTC patients, with one-sided alpha error of 5%; threshold ORR of 15% and expected ORR of 40%. Pharmacokinetics and circulating tumor DNA analyses serially are performed. The study was initiated in May 2019 with enrollment ongoing. A total of 15 patients were enrolled as of January 2020. Funding: Japan Agency for Medical Research and Development, and Daiichi Sankyo. Clinical trial information: JMA-IIA00423. Research Sponsor: Japan Agency for Medical Research, Pharmaceutical/Biotech Company.

TPS4655 **Poster Session (Board #263), Fri, 8:00 AM-11:00 AM**

Perioperative MVT-5873, a fully human monoclonal antibody against a CA 19-9 epitope, for operable CA 19-9 producing pancreatic cancers, cholangiocarcinomas, and metastatic colorectal cancers. *First Author: Shreya Gupta, National Cancer Institute, Bethesda, MD*

Background: Operable hepatopancreatobiliary (HPB) cancers continue to pose significant challenges. Radical resections are rarely curative, and chemotherapy is able to reduce tumor recurrence for only a fraction of patients. Despite the obvious advantages of extirpation of the identifiable tumor(s), the inflammatory milieu that accompanies surgery and the obligate time off cytotoxic agents allows for activation of remote quiescent disseminated tumor cells, leading to metastatic recurrence. We are conducting a study to determine the safety and efficacy of immediate peri-operative MVT-5873, a cytotoxic monoclonal antibody targeting Carbohydrate Antigen 19-9 (CA 19-9), in patients undergoing resections pancreatic cancer, cholangiocarcinoma or metastatic colorectal cancer to the liver. MVT-5873 is a human IgG1 antibody isolated from a patient following immunization with a sLe^a-KLH vaccine. MVT-5873 has demonstrated cell surface binding in sLe^a positive human tumor lines and has been shown to be potent in complement-dependent cytotoxicity assays and antibody-dependent cell mediated cytotoxicity assays. In patients with CA 19-9-producing cancers, MVT-5873 treatment has been shown to decrease serum CA 19-9 levels and prevent tumor progression. This trial may open the door for investigation of additional and/or synergistic agents in the immediate peri-operative period and usher in a new paradigm in the management of surgically treated cancers. **Methods:** This is a prospective, Phase II trial designed to determine the efficacy (increase in 1-yr DFS) and safety of peri-operative MVT-5873 for subjects with operable pancreatic, liver and bile duct cancers with elevated CA 19-9 levels. Patients may receive any standard neoadjuvant regimen prior to enrollment at the NIH Clinical Center in Bethesda, Maryland. Eligible patients will receive a pre-operative dose of MVT-5873 three days prior to the planned operation to remove all demonstrable disease. Following the operation, patients will receive a total of four doses of MVT-5873; the first two doses on postoperative days four and ten. The third dose will be administered on the normally scheduled postoperative clinic visit, followed by a final dose one month after discharge from the hospital and prior to the start of adjuvant treatment. Clinical trial information: NCT03801915. Research Sponsor: U.S. National Institutes of Health.

TPS4656 **Poster Session (Board #264), Fri, 8:00 AM-11:00 AM**

Phase II study of nivolumab (anti-PD1), tadalafil, and oral vancomycin in patients with refractory primary hepatocellular carcinoma or liver dominant metastatic cancer from colorectal or pancreatic cancers. *First Author: M. Cecilia Monge B., National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Treatment options for advanced hepatocellular carcinoma (HCC) and liver dominant metastatic disease from colorectal or pancreatic cancers are limited with poor overall survival. Tadalafil has shown to increase anti-tumor immunity by decreasing myeloid derived suppressor cells (MDSC) and impair tumor growth in preclinical HCC models. Oral vancomycin affects bile acid metabolizing gut commensal bacteria leading to increased CXCL16 expression in the liver resulting in NKT mediated liver-selective anti-tumor effects. This study combines immune checkpoint inhibition (ICI) treatment with nivolumab in combination with tadalafil and oral vancomycin. We aim to evaluate the synergy of the antitumor effect induced by the change in gut microbiome with oral vancomycin and the immunomodulatory effect of PDE5 inhibition combined with ICI with nivolumab in advanced liver cancer or liver metastasis. Correlative Studies: Paired liver tumor biopsies are analyzed for genomic analysis (WES, RNA-seq), immune cell infiltration, proteomics and metabolomic studies (bile acids) and chemokine expression. Stool samples are analyzed for microbiota. Blood samples are analyzed for immune monitoring, cytokine profiles and pharmacokinetics of study drugs. Serum bile acid levels are determined in blood in the 2 hour period after test meal ingestion. **Methods:** This is a single-arm study of nivolumab, oral vancomycin and tadalafil. Treatment is delivered in 4-week cycles (C) and continues until off treatment. Imaging is done every 8 weeks. Biopsies are done at baseline and during week 3 of C2. Nivolumab is administered on day (D)1 of each C at a dose of 480 mg IV. Tadalafil is administered orally (PO); 10 mg daily starting on D1 of C1 and continues daily until off study. Vancomycin administration starts on D1 of C1 at 125 mg PO every 6 hours for a total daily dose of 500 mg. Patients will be on vancomycin 3 weeks on, 1 week off per regimen. The study is currently enrolling without DLT. Clinical trial information: NCT03785210. Research Sponsor: U.S. National Institutes of Health.

TPS4657 **Poster Session (Board #265), Fri, 8:00 AM-11:00 AM**

An exploratory study of fruquintinib as second-line treatment for patients with advanced or metastatic biliary tract cancer. *First Author: Qiu Li, West China Hospital , Sichuan University, Chengdu, China*

Background: Biliary tract cancer (BTC) is a relatively uncommon but highly fatal malignancy and most patients with BTC are diagnosed at advanced stages. Currently, no standard second-line treatment has been established following recurrence from the first-line treatment. VEGF is highly expressed in more than 50% of BTC, which indicates anti-angiogenesis might be a potentially effective method to improve the outcome in BTC. Fruquintinib is a novel small molecule tyrosine kinase inhibitor targeting VEGFR1, VEGFR2, and VEGFR3 and is currently being evaluated in clinical trials for multiple cancers including lung cancer, gastric cancer and colorectal cancer, and showed strong anti-tumor activity. However, the effect and safety of fruquintinib has not been investigated in the setting of second-line treatment for BTC. **Methods:** The study is a multicenter, single-arm, phase 2 trial of fruquintinib (5 mg, po, for 3 weeks, followed by 1 week off, 4 weeks for a cycle) for patients with advanced or metastatic BTC who have failed to first-line chemotherapy. The primary endpoint is progression-free survival (PFS) with the null hypotheses of 8 weeks, and the median PFS$\geq$15 weeks as evidence of the study drug activity (α=0.05, 80% power, one-sided). The number of patients required to complete the study is 27. Allowing for 20% expulsion rate, the study needs 33 patients. The secondary endpoints include objective response rate (ORR), disease control rate (DCR), overall survival (OS), safety and quality of life (QoL). Meanwhile, the study also set an exploratory objective to evaluate the mutation status of related genes in plasma (cfDNA) and tumor tissue and explore the interplay between mutation patterns with efficacy. Major eligibility requirements: Age $\geq$18 years; Histologically or cytologically confirmed diagnosis of advanced or metastatic biliary tract adenocarcinoma; First-line chemotherapy failed (tumor progression or intolerable adverse events); No less than 3 months of expected survival; ECOG PS$\leq$1; At least one measurable lesion according to RECIST 1.1 criteria; Adequate organ function. Eligible patients with advanced or metastatic BTC refractory to first-line chemotherapy will be enrolled at 7 medical centers in China. The study is open and actively enrolling at time of submission. Clinical trial information: NCT04156958. Research Sponsor: None.

TPS4658 **Poster Session (Board #266), Fri, 8:00 AM-11:00 AM**

An exploratory study of sorafenib plus toripalimab for unresectable hepatocellular carcinoma with portal vein tumor thrombus. *First Author: Yu Yang, Department of Medical Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China*

Background: Portal vein tumor thrombosis (PVTT) is common among advanced hepatocellular carcinoma (HCC) , resulting in poor prognosis. As the standard first-line treatment, the efficacy of Sorafenib is not satisfactory in HCC with PVTT. Although immune checkpoint inhibitors have made a breakthrough in treatment of advanced HCC, objective response rate (ORR) of anti-PD-1 monoclonal antibody monotherapy is only 17-20%. Recently, PD-1/PD-L1 inhibitors combined with anti-angiogenesis therapy have shown good efficacy in the clinical studies. However, the data on immunotherapy for HCC with PVTT are still limited. Toripalimab is the first Chinese-produced anti-PD-1 monoclonal antibody marketed. We designed the study to evaluate the efficacy and safety of Sorafenib plus Toripalimab as the first-line treatment for unresectable HCC with PVTT. **Methods:** The study is a multicenter, single-arm, phase Ib/II trial. The primary objectives are 6-month progression-free survival (PFS) rate and safety. Secondary objectives include ORR, disease control rate, PFS, overall survival. The escalation stage includes two dose cohorts: Sorafenib 400 mg po qd or 400 mg bid combined with Toripalimab 240 mg iv d1 q3w. 6-12 patients are estimated to evaluate the dose-limiting toxicity within the first 42 days of administration. In the expansion stage, patients are treated with the recommended dose based on the escalation stage, until progressive disease or intolerable toxicity. Assuming Sorafenib plus Toripalimab can improve the 6-month PFS rate to 40% (Sorafenib:20%, β = 0.2 , α = 0.05) and dropout is 10%, this stage need 39 patients. A total of 45-51 patients are enrolled. Major eligibility requirements include: unresectable HCC with diagnoses confirmed histologically or cytologically, or confirmed clinically in accordance with Chinese guideline for HCC diagnosis and treatment (v2017); radiographic evidence of PVTT; age $\geq$18 and $<$ 75 years; at least one measurable lesion according to RECIST 1.1; a predicted life expectancy $\geq$ 3 months; ECOG PS$\leq$1, Child-Pugh class A or B ($\leq$7); no any prior systemic anti-cancer treatment; adequate organ function. Patients with hepatitis B treated with antiviral therapy (viral load $<$ 100 IU/mL) or patients with chronic hepatitis C can be included. The study is open and actively enrolling at time of submission. Clinical trial information: NCT04069949. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd.

TPS4659 Poster Session (Board #267), Fri, 8:00 AM-11:00 AM

Phase II study of pembrolizumab plus olaparib in the treatment of patients with advanced cholangiocarcinoma. *First Author: Aiwu Ruth He, Georgetown University Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Lack of an effective second-line treatment of patients (pts) with advanced cholangiocarcinoma (CC) necessitates the development of new therapies. Preclinical studies suggest CC susceptibility to PARP inhibition (PARPi): *ERCC1* is underexpressed in 74% of CCs, and olaparib is selective for *ERCC1* deficiency, profoundly inhibiting DNA repair. Additionally, PARPi exploits *IDH* mutation-related DNA damage repair deficiency, which is found in about 25% of CCs. Unfortunately, PARPi also upregulates PD-1-PD-L1 receptor-ligand binding, which attenuates anticancer immunity and counteracts the efficacy of PARPi. However, this can be prevented by PD-1 inhibition—blockade of PD-1-PD-L1 acts to re-sensitize cancer cells to T-cell killing. Hence, we hypothesize that the combination of olaparib and pembrolizumab will produce a durable anti-tumor response against CC by synergistically inducing DNA damage and increasing immune response. **Methods:** Thirty-six pts with advanced CC, who either failed to respond to or progressed on first-line therapy, will be enrolled to receive olaparib (300 mg PO bid) daily plus pembrolizumab (200 mg IV Q3 weeks) for 12 months, unless unacceptable toxicities or cancer progression occur, in which cases therapy will cease. MRI or CT tumor assessment will occur just before therapy, every 6 weeks for the first 6 months of therapy, and then every 9 weeks for the next 6 months of therapy (total, 12 months). Three tumor biopsies will be collected: at baseline; at week 4; and at time of progression. In each biopsy, ERCC1, PD-1, and PD-L1 expression, *IDH1/2* mutation status, and immune cell (CD3 and CD8) response will be assessed. The total study duration will be 20-36 months. The primary endpoint will be overall response rate; the secondary endpoints will be PFS, OS, duration of response, and safety and tolerability. It is hypothesized that in pts with advanced CC, second-line therapy with olaparib plus pembrolizumab will improve the response rate from 17.5% to 35%, as well as increase PFS and OS compared to cytotoxic chemotherapy. Study enrollment began in Q1 2020. NCI number pending at time of abstract submission. Clinical trial information: pending at time of submission. Research Sponsor: Merck.

TPS4660 Poster Session (Board #268), Fri, 8:00 AM-11:00 AM

Etctn 10388: A phase I trial of triapine and lutetium Lu 177 dotatate in well-differentiated somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs). *First Author: Aman Chauhan, University of Kentucky, Division of Medical Oncology, Lexington, KY*

Background: Radiolabeled somatostatin analogues provide a means of delivering targeted radiation with a high therapeutic index to NETs that express somatostatin receptors (SSTRs). Radiolabeled somatostatin analogue Lutetium Lu 177 Dotatate (Lutathera) is a beta-emitting radionuclide, recently FDA approved for use in SSTR positive gastroenteropancreatic neuroendocrine tumors (GEPNETS) in the US based on the NETTER-1 Phase III trial. Despite favorable PFS and safety profile, the drug has limited cytoreductive capability with a 17% ORR. We hypothesize that addition of an effective radiation sensitizer could help improve antitumor activity of Lutathera. Ribonucleotide reductase (RNR) is the only enzyme responsible for conversion of ribonucleoside diphosphate to deoxyribonucleotide diphosphate (dNDP), the key building blocks for DNA synthesis. Radiation is a potent inducer of DNA double-strand breaks (DSBs), and RNR is the rate-limiting enzyme in the repair of DNA in this setting. Triapine is an inhibitor of RNR. This study will test the hypothesis that radiation sensitizer triapine can be safely combined with peptide receptor radionuclide therapy and ultimately may improve antitumor activity of Lutetium Lu 177 Dotatate. **Methods:** This study is an investigator initiated, NCI sponsored, multicenter phase 1 trial of triapine and Lutetium Lu 177 Dotatate in well-differentiated somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumor (GEP-NETs) after the failure of at least one line of prior systemic cancer treatment. A total of 29 patients will be enrolled in the dose escalation with help of Bayesian optimal interval design (BOIN) and dose expansion cohorts. The study will be open through the NCI ETCTN (National Cancer Institute Experimental Therapeutics Clinical Trials Network) program. Patients will be treated with 177 lutetium dotatate in combination with triapine. Triapine will be administered orally (100 mg once a day starting dose) from D1-14 with each dose of PRRT [200 mCi]. Primary endpoint is to evaluate recommended phase II dose (RP2D). Secondary endpoints are to evaluate safety, pharmacokinetics, and clinical activity (ORR and PFS). We are also evaluating NETEST, a novel blood based test that evaluates levels of 51 neuroendocrine tumor gene transcripts. In addition, the study will correlate clinical outcome with baseline somatostatin receptor density, somatic tumor mutations and germline mutations. Clinical trial information: 04234568. Research Sponsor: NCI CTEP.

TPS4661 Poster Session (Board #269), Fri, 8:00 AM-11:00 AM

NAPOLI-3: An open-label, randomized, phase III study of first-line liposomal irinotecan + 5-fluorouracil/leucovorin + oxaliplatin versus nab-paclitaxel + gemcitabine in patients with metastatic pancreatic ductal adenocarcinoma. *First Author: Zev A. Wainberg, University of California, Los Angeles, Medical Center, Los Angeles, CA*

Background: Liposomal irinotecan administered with 5-fluorouracil/leucovorin (5-FU/LV) is approved in the USA for metastatic pancreatic ductal adenocarcinoma (mPDAC) following progression with gemcitabine-based therapy. A phase 1/2 study in previously untreated locally advanced/metastatic PDAC showed promising anti-tumor activity with liposomal irinotecan 50 mg/m^2 free base + 5-FU 2400 mg/m^2 + LV 400 mg/m^2 + oxaliplatin (OX) 60 mg/m^2 on days 1 and 15 of a 28-day cycle (Wainberg *et al. Ann Oncol* 2019;30 Suppl 4: SO-005). Herein, we present the design of the phase 3 NAPOLI-3 study investigating the efficacy and safety of this regimen as first-line therapy in patients with mPDAC. **Methods:** NAPOLI-3 (NCT04083235) is a phase 3, open-label, randomized, global study in adults with histologically/cytologically confirmed pancreatic adenocarcinoma not previously treated in the metastatic setting. Patients are required to have one or more metastatic tumors measurable with computed tomography/magnetic resonance imaging and an Eastern Cooperative Oncology Group performance status score of 0–1. Site activation began in Dec 2019 and enrollment is ongoing. Random allocation (1:1) of 750 patients is planned to liposomal irinotecan + 5-FU/LV + OX (regimen as per phase 1/2 study) or nab-paclitaxel 125 mg/m^2 + gemcitabine 1000 mg/m^2 on days 1, 8 and 15 in a 28-day cycle. The primary endpoint is overall survival (OS). Secondary endpoints (progression-free survival [PFS] and overall response rate assessed with Response Evaluation Criteria in Solid Tumors v1.1 criteria) will be compared only if the primary endpoint shows superiority for liposomal irinotecan + 5-FU/ LV + OX over nab-paclitaxel + gemcitabine. Safety assessments include adverse-event monitoring. Patients will continue treatment until disease progression, unacceptable toxicity or study withdrawal, and will then be followed for survival every 2 months until death or study end (when all patients have died, withdrawn consent or are lost to follow-up). Clinical trial information: NCT04083235. Research Sponsor: Ipsen.

TPS4662 Poster Session (Board #270), Fri, 8:00 AM-11:00 AM

A phase II trial of PD-1 inhibition with INCMGA00012 in patients with previously treated unresectable or metastatic adenosquamous pancreatic cancer. *First Author: Christopher Jakubowski, Johns Hopkins Oncology, Baltimore, MD*

Background: Adenosquamous pancreatic cancer (ASQ) constitutes 1-5% of all pancreatic cancers and compared to pancreatic adenocarcinoma (PDAC) has a worse survival. ASQ has glandular and squamous histologic components and given its rarity and aggressiveness, in practice there is no current standard regimens for ASQ. Unfortunately, checkpoint blockade has had an overall disappointing impact on survival in PDAC. In an effort to identify a patient subgroup most likely to respond to immunotherapy, the immune tumor microenviroment (TME) in ASQ was evaluated. Tissue microarrays from archived ASQ samples were first created. Then immunocytochemistry (IHC) staining for immune cells and immune checkpoint proteins was performed. PD-L1 expression and the combined presence of PD-L1+, IDO+, LAG3+, and VISTA+ was seen. All ASQ cases had some degree of tumor infiltrating lymphocytes (TIL, including CD8+ T-cells). Furthermore, PD-L1 and other checkpoint positivity correlated with increased TIL. These findings suggest the presence of adaptive immune resistance. This is in contrast to standard PDAC, in which the expression of immune checkpoints is rarely accompanied by increased effector T-cells. **Methods:** We are conducting a multiple-center, single arm, phase II clinical trial to evaluate PD-1 inhibition with INCMGA00012 in locally advanced unresectable and metastatic ASQ patients. INCMGA00012 is a humanized monoclonal antibody antagonistic to PD-1. The primary objective is to determine the disease control rate at 4 months using RECIST 1.1. The study is planned with 21 evaluable subjects and allows early termination for lack of efficacy. Patients have a pre-treatment biopsy followed by INCMGA00012 500 mg on Day 1 of each cycle (every 4 weeks). A second biopsy will occur eight weeks later. Eligibility criteria includes histologically- or cytologically-proven adenosquamous carcinoma of the pancreas by central pathologic review and patients must have received (or been intolerant to or ineligible for) at least 1 prior line of cytotoxic chemotherapy and received no more than 2 prior systemic treatments. Patients with known MSI-H/dMMR status are excluded. Exploratory objectives include examining changes in the TME checkpoint expression and immune cell infiltrate in the biopsies via IHC and RNA expression studies. The clinical study was activated in February 2020. Clinical trial information: NCT04116073. Research Sponsor: None.

TPS4663 **Poster Session (Board #271), Fri, 8:00 AM-11:00 AM**

Phase I study of proton therapy in adjuvant pancreatic cancer (PROTON-PANC). *First Author: Benjamin Adam Weinberg, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: Pancreatic adenocarcinoma (PAC) has a poor prognosis, with a 5-year survival rate of 10%. The current standard of care for patients with resectable disease is surgical resection followed by 6 months of adjuvant modified FOLFIRINOX (FFX, leucovorin, fluorouracil, irinotecan, and oxaliplatin). As survival outcomes and distant recurrence improve with the use of FFX, locoregional recurrence remains a cause of morbidity and mortality. We seek to integrate adjuvant short-course proton radiation therapy (PRT) to the surgical bed in between cycles of FFX. While there is limited literature on the combination of short course PRT and FFX, there are analogous experiences using 5 fraction SBRT or IMRT following FFX in routine clinical practice. The ongoing Alliance 021501 trial of preoperative chemotherapy vs. chemotherapy plus radiation (IMRT using 5 Gy X 5 or SBRT 6.6 X 5) in borderline resectable pancreatic cancer mandates that radiation starts 5 days or more following the last dose of FFX. Additionally, at the Lombardi Comprehensive Cancer Center, we routinely combine 5 fraction SBRT after a 10-14 day interval from FFX. **Methods:** This is a phase I, single-arm, open-label study. Eligible pts are $\geq$ 18 years old, have histologically confirmed, resected PAC of the pancreatic head (R0 or R1) on adjuvant FFX, an ECOG performance status of 0-1, and adequate normal bone marrow and hepato-renal function. Exclusion criteria are prior radiation to the upper abdomen (neoadjuvant chemotherapy is allowed). This study will use a 3+3 dose-escalation design to determine the safety and feasibility of combining 5 fractions of adjuvant PRT with FFX using different intervals between cycle 6 of FFX and PRT: dose level 1 uses a 12 day interval, and dose level 2 uses a 5 day interval. The primary endpoint is to determine the RP2D between the 2 proposed schedules. Using a 3+3 dose-escalation schema, 2-12 patients will be required to determine the RP2D. Enrollment began in Q4 2019. Clinical trial information: NCT03885284. Research Sponsor: The Ruesch Center for the Cure of Gastrointestinal Cancers.

TPS4664 **Poster Session (Board #272), Fri, 8:00 AM-11:00 AM**

A randomized phase II study of second-line treatment with liposomal irinotecan, and S-1 versus liposomal irinotecan and 5-fluorouracil in gemcitabine-refractory metastatic pancreatic cancer patients. *First Author: Esther Pijnappel, Amsterdam UMC Location AMC, Amsterdam, Netherlands*

Background: Pancreatic ductal adenocarcinoma (PDAC) is the deadliest form of cancer with a 5-year survival of less than 5% for patients with metastatic disease. Despite improvements over the past years, with the introduction of FOLFIRINOX and gemcitabine plus nab-paclitaxel, the majority has disease progression within 6 months after start of first line treatment. The NAPOLI trial was the first phase III study showing that patients with metastatic pancreatic cancer that progressed after treatment with gemcitabine-based chemotherapy benefitted from second line treatment. Patients received liposomal irinotecan (nal-IRI) either as a single agent or in combination with 5-fluorouracil/leucovorin (5-FU/LV), or 5-FU/LV alone. Patients treated with both nal-IRI and 5-FU/LV experienced a median overall survival (mOS) of 6.1 months versus 4.2 months for the 5-FU/LV group. Recently, two Japanese studies (GEST and JASPAC 01) reported on the use of S-1 in patients with PDAC. In patients with locally advanced or metastatic PDAC, S-1 was non-inferior compared to gemcitabine in terms of mOS (8.8 months for gemcitabine versus 9.7 months for S-1). In the adjuvant setting, S-1 showed superior mOS compared to gemcitabine, 46.5 and 25.5 months respectively, HR for mortality of S-1 compared with gemcitabine was 0.57 (95% CI 0.44–0.72). In view of these results, the objective of this NAPAN study is to compare the progression free survival (PFS) of nal-IRI plus S-1, with nal-IRI plus 5-FU/LV in a Western study population for second line treatment of PDAC. **Methods:** This is a multi-center, open label, randomized phase II trial. Patients $\geq$ 18 years of age with histologically or cytologically confirmed PDAC, previously treated with gemcitabine (-based) therapy, or progression within 6 months of adjuvant gemcitabine-based treatment are eligible. After a safety run-in of the nal-IRI plus S-1 regimen, patients will be randomized between nal-IRI plus S-1 and nal-IRI plus 5-FU/LV. Primary endpoint of the run-in phase is to determine dose limiting toxicity (DLT) and maximum tolerated dose (MTD) of nal-IRI when co-administered with fixed dose S-1. The primary endpoint of the phase II part is to determine the efficacy of the treatment arms in terms of PFS. Secondary endpoints include OS, response rate according to RECIST 1.1, adverse events according to CTC version 5.0 and Quality of life. Until now 2 of the planned 120 patients have been enrolled. Clinical trial information: NCT03986294. Research Sponsor: Servier and Nordic Pharma.

TPS4665 **Poster Session (Board #273), Fri, 8:00 AM-11:00 AM**

PD-1 antibody combined with paclitaxel (albumin bound) and gemcitabine as first-line therapy in patients with metastatic pancreatic cancer. *First Author: Jiujie Cui, Department of Medical Oncology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China, Shanghai, China*

Background: Pancreatic cancer is a malignant tumor with limited therapeutic strategies and poor prognosis. About 60% of the patients have metastasis disease at time of diagnosis and lose the opportunity for surgery. Thus, therapy based on drugs becomes a vital part in pancreatic cancer. In 2013, MPACT showed that albumin-bound paclitaxel combined with gemcitabine in the treatment of metastatic pancreatic cancer could increase the mOS from 6.6 months to 8.7 months (HR = 0.72, 95% CI: 0.62-0.83; P $<$ 0.001). Nowadays, the immunosuppressive checkpoint inhibitors acting on PD-1/PD-L1 pathway have shown a significant efficacy in enhancing tumor immune surveillance and anti-tumor immune response. In 2018, two studies reported in ASCO showed the preliminary efficacy of albumin paclitaxel, gemcitabine and PD-1 inhibitor in the treatment of advanced pancreatic cancer. Among patients who have not received treatment before, the disease control rate was even up to 100%. Therefore, this study will further explore the domestic PD-1 antibody combined with albumin-bound paclitaxel and gemcitabine as the first-line treatment of advanced pancreatic cancer among Chinese pancreatic cancer patients. **Methods:** This is a prospective, single-armed, exploratory, investigator initiated trial to explore the efficacy and safety of PD-1 antibody combined with albumin-bound paclitaxel and gemcitabine as first-line treatment of metastatic pancreatic cancer. This study is, to our knowledge, the first one to test the efficacy and safety of PD-1 antibody on metastatic pancreatic cancer patients among Chinese population. Survival index is median survival estimated by Kaplan-Meier and draw the survival curve. The response rate was compared by χ 2 test / Fisher test. All primary and secondary outcomes will be analyzed on the full analysis set. PD-1 antibody, 200mg, D1 administration; paclitaxel (albumin binding type), 125mg/m2, D1, 8 days administration; gemcitabine, 1000mg/m2, D1, 8 days administration, every 21 days as a cycle and PD-1 antibody (200mg, D1, every 21 days) single drug maintenance treatment is given after the completion of 6 cycle chemotherapy. Major eligibility criteria is that each participant must have metastatic pancreatic cancer confirmed by histology or cytology and has never received systemic anti-tumor therapy before. So far, 11 of planned 20 patients have been enrolled. Clinical trial information: NCT04181645. Research Sponsor: HENGRUI MEDICINE.

TPS4666 **Poster Session (Board #274), Fri, 8:00 AM-11:00 AM**

TRYbeCA-1: A randomized, phase III study of eryaspase in combination with chemotherapy versus chemotherapy alone as second-line treatment in patients with pancreatic adenocarcinoma (NCT03665441). *First Author: Pascal Hammel, Hôpital Beaujon (AP-HP), Clichy, and University Paris VII, Paris, France*

Background: Second-line treatment options for advanced pancreatic adenocarcinoma are currently limited. Eryaspase, asparaginase (ASNase) encapsulated in red blood cells (RBCs) is an investigational product under development. Following infusion, asparagine and glutamine are actively transported into RBCs where they are hydrolyzed by the encapsulated ASNase. We have recently reported the outcome of a randomized Phase 2b study inpatients with advanced pancreatic cancer whose disease progressed following first-line treatment(NCT02195180). Eryaspase in combination with gemcitabine monotherapy or FOLFOX combination therapy improved overall survival (OS) and progression free survival (PFS). The safety profile of eryaspase was acceptable. The results of this Phase 2b study provided a rationale for initiating this confirmatory Phase 3 pivotal trial (TRYbeCA-1). **Methods:** TRYbeCA-1 is a randomized, open-label Phase 3 trial (N = ~500) of eryaspase combined with chemotherapy in patients with adenocarcinoma of the pancreas who have failed only one prior line of systemic anti-cancer therapy for advanced pancreatic cancer and have measurable disease. Patients are randomized in a 1:1 ratio to receive gemcitabine/Abraxane or irinotecan-based therapy (FOLFIRI [FOLinic acid-Fluorouracil-IRInotecan regimen] or irinotecan liposome injection/5-fluorouracil/leucovorin) with or without eryaspase, administered as IV infusion on Day 1 and Day 15 of each 4-week cycle. Key eligibility criteria include performance status 0 or 1; stage III-IV disease; documented evidence of disease progression; available tumor tissue; and adequate organ function. The primary endpoint is OS. Key secondary endpoints include PFS and objective response rate, safety, quality of life, pharmacokinetics and pharmacodynamics, and biomarker research. A hazard ratio in OS of 0.725 is being targeted which represents a conservative estimate based on the Phase 2b data and is viewed as being highly clinically relevant. An IDMC is established to review safety at regular intervals andto review efficacy data at the planned interim and final analyses. IDMC last reviewed the trial in October 2019 and suggested the trial continue as planned. Clinical trial information: NCT03665441. Research Sponsor: Erytech.

TPS4667 **Poster Session (Board #275), Fri, 8:00 AM-11:00 AM**

Phase II, open-label, randomized study of first-line zolbetuximab plus gemcitabine and nab-paclitaxel (GN) in Claudin 18.2–positive metastatic pancreatic cancer (mPC). *First Author: Wungki Park, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: Combinations of folinic acid, fluorouracil (5-FU), irinotecan, and oxaliplatin (FOLFIRINOX) along with GN are standard first-line treatment options for mPC. Despite treatment advances, mPC has a poor prognosis with a 5-year survival rate of $< 5\%$, emphasizing an urgent need for new targeted therapeutics. Claudin 18.2 (CLDN18.2) is a tight junction protein restricted to normal gastric mucosa cells; however, in the context of malignant transformation, CLDN18.2 is frequently expressed in carcinomas derived from organs that do not normally express it, such as pancreatic adenocarcinoma (50-70% express CLDN18.2). Zolbetuximab is a chimeric IgG1 monoclonal antibody that specifically binds to CLDN18.2, designed to mediate cancer cell death through antibody-dependent cellular cytotoxicity and complement-dependent cytotoxicity. **Methods:** This phase 2 study (NCT03816163) with a safety lead-in phase will assess safety and antitumor activity of zolbetuximab plus GN in patients (pts) with histologically confirmed mPC with high CLDN18.2 expression ($\geq$75% of tumor cells demonstrate moderate-to-strong IHC staining). The safety lead-in will assess safety/tolerability of zolbetuximab (n = 3 at 1,000 mg/m^2 on Cycle 1 Day 1 then 600 mg/m^2 Q2W then expand/de-escalate using a 3+3 design) plus GN and confirm the recommended phase 2 dose (RP2D). Dose-limiting toxicities (DLTs), defined as a specified toxicity that occurs during the DLT assessment period and is related to zolbetuximab, will be assessed after Cycle 1 (28 days). After determining the RP2D, approximately 129 pts will be randomly assigned 2:1 to receive either zolbetuximab RP2D Q2W on Days 1 and 15 plus GN on Days 1, 8, and 15 of each cycle (*Arm 1*), or GN alone on Days 1, 8, and 15 of each cycle (*Arm 2*). Randomization will be stratified by ECOG performance status (0 or 1) and liver metastasis (yes or no). Imaging (CT/MRI) will be performed at baseline and every 8 weeks until investigator-assessed disease progression (per RECIST v1.1 criteria) or the start of other systemic anticancer treatment, whichever comes earlier. Primary objectives are to confirm RP2D (safety lead-in), to assess antitumor activity measured by overall survival (randomization phase), and to establish the safety/tolerability profile of zolbetuximab plus GN across the study. Key secondary endpoints in the randomization phase are progression-free survival and objective response rate. As of January 2020, this study is recruiting pts at 74 centers. Clinical trial information: NCT03816163. Research Sponsor: Astellas Pharma, Inc.

TPS4668 **Poster Session (Board #276), Fri, 8:00 AM-11:00 AM**

HGCSG 1803: Single-arm phase II study evaluating efficacy of oxaliplatin, irinotecan and S-1 combination therapy (OX-IRIS) in metastatic pancreatic cancer as first-line treatment. *First Author: Shintaro Nakano, Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan*

Background: Combination chemotherapy with oxaliplatin, irinotecan, fluorouracil and leucovorin (FOLFIRINOX) showed improved survival compared to gemcitabine monotherapy for patients with metastatic pancreatic cancer and has become the one of the standard regimens. Despite of its clinical benefit, FOLFIRNIOX needs continuous infusion of 5-FU for 46 hours, which impairs quality of life. In other gastrointestinal cancer, infuser pomp free regimens, in which oral 5-FU drug replace the continuous infusion of 5-FU, have developed as alternative regimen. Therefore, we planned to develop new combination chemotherapy with oxaliplatin, irinotecan and S-1 (OX-IRIS) for advanced pancreatic cancer. We previously conducted the phase I study for assessing the safety and determining the recommended dose of OX-IRIS regimen. **Methods:** To evaluate efficacy and safety of OX-IRIS, HGCSG1803 study staeted as a multicenter, non-randomized, single arm, prospective, phase II study in December 2019. The patients with untreated metastatic or relapsed pancreatic cancer are eligible for this study. OX-IRIS is administered as follows; a 30-min intravenous infusion (IV) of antiemetic, a 2-h IV of oxaliplatin at 85 mg/m^2, a 1.5-h IV of irinotecan at 150 mg/m^2 on day 1 and day 15 of each 4-week cycle, and S-1 (40 mg/m^2) was taken orally twice daily, from after dinner on day 1 to after breakfast on day 15, followed by a 14-day rest, and to be repeated every 2 weeks until disease progression, unacceptable toxicity, or patient refusal. The primary endpoint is response rate, and the secondary endpoints are overall survival, progression-free survival, safety, and dose intensity for each drug. A total of 40 cases are planned for registration from 18 institutions in Japan within 2.5 years. Clinical trial information: jRCTs011190008. Research Sponsor: None.

TPS4669 **Poster Session (Board #277), Fri, 8:00 AM-11:00 AM**

EndoTAG-1 plus gemcitabine versus gemcitabine alone in patients with measurable locally advanced and/or metastatic adenocarcinoma of the pancreas failed on FOLFIRINOX treatment (NCT03126435). *First Author: Li-Tzong Chen, National Health Research Institutes, Tainan, Taiwan*

Background: Pancreatic cancer (PC) is the 3rd deadliest cancer in the United State surpassing breast cancer in 2016, with the overall survival rate of - 9% for those newly diagnosed individuals. The notorious disease is set to become the 2nd leading cause of death from cancer by 2020 in US (National Cancer Institute, NIH). FOLFIRINOX regimen is one of the standard 1st-line treatments for PC patients with good performance status; however, there is currently no standard of care in 2nd-line therapy after FOLFIRINOX failure. EndoTAG-1 is a novel formulation of cationic liposomes embedded with Paclitaxel, which specifically displays antivascular and antiangiogenic activities. By binding and internalizing at tumor endothelial cells after intravenous administration, the cytostatic activity of paclitaxel will be targeted to the activated tumor endothelial cells. **Methods:** Eligible patients with measurable locally advanced and/or metastatic adenocarcinoma of the pancreas failed on FILFIRINOX treatment will be screened and randomized (1:1) into one of the two arms in the study (n=218). The primary endpoint of the study is overall survival (OS), with secondary endpoints include progression-free survival (PFS), objective response rate (ORR), duration of response (DOR) and quality of life (QoL). Arm A: EndoTAG-1 plus Gemcitabine: Patients will receive intravenous injection with EndoTAG-1 (22 mg/m^2) twice weekly plus gemcitabine (1,000 mg/m^2) once weekly for consecutively 3 weeks followed by 1 week rest. The treatment will be repeated every 4 weeks, with 8 weeks per cycle. The treatment will be kept until any one of the following occurs: progressive disease or unacceptable toxicity or withdrawal of consent. Arm B: Gemcitabine: Patients will receive gemcitabine (1,000 mg/m^2) once weekly for consecutive 3 weeks followed by 1 week rest. The treatment will be repeated every 4 weeks, with 8 weeks per cycle. The treatment will be kept until any one of the following occurs: progressive disease or unacceptable toxicity or withdrawal of consent. The phase III trial began enrollment since November 2018. The trial will continue as planned from the last review in January 2020. Clinical trial information: NCT03126435. Research Sponsor: SynCore Biotechnology Co., Ltd., Other Government Agency

TPS4670 **Poster Session (Board #278), Fri, 8:00 AM-11:00 AM**

Adaptive dose optimization trial of stereotactic body radiation therapy (SBRT) with or without GC4419 (avasopasem manganese) in pancreatic cancer. *First Author: Elizabeth Charlotte Moser, Galera Therapeutics, Malvern, PA*

Background: Local progression causes up to 30% of deaths from pancreatic cancer (PC) and is also a significant source of morbidity. Stereotactic body radiotherapy (SBRT) offers the potential for improved therapeutic index over standard fractionation, but current regimens of 5 fractions of 5-7 Gy/fraction are constrained by nearby organ tolerance and offer only palliation without improving survival. Safe dose escalation may be necessary to improve SBRT efficacy. Avasopasem, a superoxide dismutase mimetic, selectively converts superoxide (O2$\bullet$ -) to hydrogen peroxide (H_2O_2) and oxygen. O2$\bullet$ -initiates normal tissue damage due to RT. Avasopasem is in a Phase 3 trial (NCT03689712) to reduce RT-induced oral mucositis in head and neck cancer, based on positive results in a randomized Phase 2 trial for that indication (Anderson, JCO 2019). Avasopasem improved the survival of mice receiving 8.5 Gy x 5 to the upper abdomen. Cancer cells are less tolerant to elevated H_2O_2, and more tolerant to elevated O2$\bullet$ -, than normal cells, and avasopasem demonstrated mechanism-dependent synergy with high dose-fraction RT in a human tumor xenograft with inducible expression of catalase (Sishc, AACR 2018). Thus, adding avasopasem to SBRT may increase both the efficacy and the safety of the latter. **Methods:** 48 patients with locally advanced PC, who have completed medically-indicated induction chemotherapy, are randomized 1:1 to placebo or avasopasem, 90 mg IV, prior to each of 5 consecutive daily (M-F) SBRT fractions. A phase I/II Late Onset Efficacy/ Toxicity tradeoff (LO-ET) based adaptive design adaptive model drives assignment of SBRT dose escalation in each arm based on a dual endpoint (Gr 3-4 GI toxicity or death; local stable disease or better) by 90 days post SBRT. The planned dose levels are 10, 11 and 12Gy x 5 fractions (BED10 = 100,112.5 and 132Gy, respectively) as an integrated boost to the gross tumor volume (GTV). Primary endpoint: Maximum tolerated dose of SBRT with avasopasem or placebo. Secondary endpoints progression-free survival, response rate, and acute (90 day) and late (12 month) radiation toxicity with avasopasem vs placebo. Exploratory correlative studies include ctDNA, tumor exome/transcriptome sequencing, and immune profiling. Clinical trial information: NCT03340974. Research Sponsor: Galera Therapeutics.

TPS4671 **Poster Session (Board #279), Fri, 8:00 AM-11:00 AM**

Phase I study of SEA-CD40, gemcitabine, nab-paclitaxel, and pembrolizumab in patients with metastatic pancreatic ductal adenocarcinoma (PDAC). *First Author: Andrew L. Coveler, Seattle Cancer Care Alliance/University of Washington, Seattle, WA*

Background: SEA-CD40 is an investigational non-fucosylated, humanized IgG1 monoclonal antibody directed against CD40, a co-stimulatory receptor expressed on antigen-presenting cells (APCs). Activation of CD40 on APCs upregulates cytokine production and co-stimulatory receptors, enhancing tumor antigen presentation to T cells. Preclinical data indicate that treatment of PDAC with chemotherapy in conjunction with a CD40 agonist could enhance antigen presentation and initiate an antitumor immune response (Byrne KT and Vonderheide RH, Cell Rep 2016;15, 2719–32). An ongoing Phase 1 study (SGNS40-001) is evaluating SEA-CD40 as monotherapy and in combination with pembrolizumab in patients with advanced solid or hematologic malignancies. A new cohort is enrolling to evaluate the combination of SEA-CD40, gemcitabine, nab-paclitaxel, and pembrolizumab in PDAC. **Methods:** The cohort consists of patients with metastatic PDAC who have had no prior therapy for metastatic disease. Patients must be ≥18 years old, with (neo)adjuvant therapy completed >4 months prior to enrollment, ECOG status ≤1, adequate renal, hepatic, and hematologic function, and measurable disease per RECIST v 1.1 criteria. A standard regimen of gemcitabine and nab-paclitaxel on Days 1, 8, and 15 of each 28-day cycle is administered with SEA-CD40 IV on Day 3. Pembrolizumab is administered every 42 days starting on Day 8. The primary objective is antitumor activity; secondary objectives are safety and tolerability and SEA-CD40 and pembrolizumab pharmacokinetics. Efficacy endpoints are confirmed RECIST ORR per investigator (primary), disease control rate (response or stable disease ≥16 weeks), duration of response, PFS, and OS. Disease is assessed every 8 weeks using RECIST and immune-based RECIST (iRECIST). Treatment continues until occurrence of unacceptable toxicity, progressive disease per iRECIST, consent withdrawal, or study closure. Assessment of dose-limiting toxicity will occur initially in groups of 6 patients to identify the recommended phase 2 dose of SEA-CD40 for the cohort. Enrollment to this cohort began in November 2019. Clinical trial information: NCT02376699. Research Sponsor: Seattle Genetics, Inc.

TPS4672 **Poster Session (Board #280), Fri, 8:00 AM-11:00 AM**

A phase II study of siG12D-LODER in combination with chemotherapy in patients with locally advanced pancreatic cancer (PROTACT). *First Author: Anna M. Varghese, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: KRAS alterations are the most frequent driver alterations identified in pancreas cancer; however, KRAS has remained an elusive therapeutic target. siG12D-LODER is a novel, miniature bio-degradable polymeric matrix encompassing a novel small interfering RNA targeting KRAS G12D and all additional G12X mutations (G12C, G12V...). The siG12D-LODER is inserted directly into the pancreas tumor via endoscopic intervention. A Phase 1/2a dose escalation and expansion study of patients receiving a one-time dose of siG12D-LODER with ongoing chemotherapy demonstrated that the combination was well-tolerated and safe and exhibited promising potential efficacy with 10/12 patients achieving disease control and median overall survival 15.1 months (Golan, Oncotarget 2015). **Methods:** This phase 2 study was initially designed as a randomized, two arm, open label study of gemcitabine and nab-paclitaxel with or without siG12D-LODER for patients with locally advanced pancreas cancer with planned 40 patients in each arm and primary endpoint of progression-free survival. Eighteen patients were enrolled in the chemotherapy alone arm and 18 in the chemotherapy and siG12D-LODER arm. After an interim analysis, the study design has been amended and is now a single arm study in which patients (N=39) with both borderline resectable and locally advanced pancreas cancer will receive investigator's choice of chemotherapy (the combination of gemcitabine/nab-paclitaxel or modified FOLFIRINOX) and all patients will receive up to three doses of the siG12D-LODER administered once every 12 weeks. Primary endpoint is overall response rate after final siG12D-LODER insertion. Secondary endpoints include duration of response, progression-free survival, overall survival, time to response, percentage of patients proceeding to surgical resection, and percentage of patients receiving radiation therapy. Exploratory analyses include evaluation of KRAS mutation status and monitoring of circulating free DNA and circulating tumor cells. The amended protocol is now open for accrual and four patients having been enrolled to date. Trial accrual is anticipated to be completed by December 2020. Clinical trial information: NCT01676259. Research Sponsor: Silenseed.

TPS4673 **Poster Session (Board #281), Fri, 8:00 AM-11:00 AM**

Improving FOLFIRINOX safety in pancreatic cancer patients through multidimensional remote monitoring and proactive care using a domomedecine mobile platform. *First Author: Mohamed Bouchahda, Clinique du Mousseau, Ramsay Générale de Santé, Evry, France*

Background: Pancreatic cancer is a poor prognosis and fast-growing cancer, whose five-year survival is 6% in Europe and the US. FOLFIRINOX has been established as the reference medical treatment for this disease worldwide, yet it also causes leuko-neutropenia, thrombocytopenia, diarrhea, anorexia, asthenia, weight loss, and peripheral sensory neuropathy. Its indication is usually limited to patients having a WHO performance status of 0 or 1. This treatment is often interrupted once Grade 3-4 clinical or hematological toxicities occur, resulting in poor patient performance status and quality of life. Presently, no prospective study monitor and evaluate the qualitative and quantitative effects of FOLFIRINOX on the daily life of pancreatic cancer patients in real-time. Such monitoring would provide early warning signals for the identification of any improvement or deterioration of the patient condition. Whenever necessary, proactive interventions would be triggered to avoid emergency hospitalization for severe adverse events and to enhance treatment compliance. **Methods:** Our study involves the use of the mobile e-Health platform PiCADo (JMIR 2018) to track and analyse circadian rhythms, symptoms, and body weight in real time in 45 advanced pancreatic cancer patients at 4 centres. The patients are continuously telemonitored for rest-activity, temperature and 3D-orientation via a BLE sensor during the six weeks following the first FOLFIRINOX course. Patients weigh themselves daily on a BLE scale and self-rate their symptoms using a touchscreen on GPRS tablet. Alerts are generated according to preset yet modifiable thresholds of automatically computed critical parameters. From these data, we will evaluate the rate of emergency hospital admissions and the admission-free survival, the rates of severe adverse events, patients' symptoms dynamics, and their relations with the disruption of the patients' circadian rhythm. Patient satisfaction and research experience will also be assessed, since engagement is at the core of the success of the approach. The results will guide a future randomized trial comparing standard pancreatic cancer patient care with a personalized FOLFIRINOX approach, including chronotherapy delivery. Support: Ramsay-Sante, Altran. Research Sponsor: Ramsay Générale de Santé.

5000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

IMvigor010: Primary analysis from a phase III randomized study of adjuvant atezolizumab (atezo) versus observation (obs) in high-risk muscle-invasive urothelial carcinoma (MIUC). *First Author: Maha H. A. Hussain, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

Background: Radical surgery ± cisplatin-based neoadjuvant chemo (NAC) is the mainstay treatment (tx) for MIUC, with no conclusive level 1 evidence for adjuvant chemo (AC). Here we present the primary analysis from IMvigor010, a global, open-label, multicenter, randomized trial of adjuvant atezo (anti–PD-L1; approved in metastatic UC [mUC] settings) in pts with MIUC at high risk of recurrence following primary resection. **Methods:** Pts with MIUC (bladder, upper tract [UT]), ECOG PS 0-2 and resected tissue for PD-L1 testing on immune cells (IC; VENTANA SP142 assay) were enrolled ≤ 14 wks after radical cystectomy/nephroureterectomy with lymph node (LN) dissection. Pathologic stage: 1) ypT2-4a or ypN+ if pts had NAC or 2) pT3-4a or pN+ if pts did not have NAC. No postsurgical radiation or AC was allowed; if no NAC was given, pts must have been ineligible for or declined cisplatin-based AC. Pts were randomized 1:1 to atezo 1200 mg IV q3w or obs for 16 cycles or 1 y (stratification factors: no. of LNs resected, pathologic nodal status, pathologic tumor stage, PD-L1 status, prior NAC). Disease-free survival (DFS) was the primary endpoint (EP). Final DFS, first interim overall survival (OS; secondary EP) and safety are reported. **Results:** The ITT population included 809 pts (median follow-up, 21.9 mo). In the atezo and obs arms, respectively, 48% and 47% had NAC; 7% and 6% had UTUC as primary disease; 48% each had LN+ disease. DFS and OS are in Table. Baseline prognostic/clinical factors did not influence DFS tx benefit; stratified HR was 0.81 (95% CI: 0.63, 1.05) in IC0/1 pts (PD-L1 < 5%; n = 417) and 1.01 (0.75, 1.35) in IC2/3 pts (PD-L1 ≥ 5%; n = 392). 16% of atezo-treated pts had a tx-related G3-4 AE. Skin and gastrointestinal toxicities most commonly led to tx discontinuation. **Conclusions:** IMvigor010, the first phase 3 adjuvant study of a checkpoint inhibitor in MIUC, did not meet its primary EP of DFS. More tx discontinuation due to AEs was seen vs mUC studies. Safety was generally consistent with previous studies. Clinical trial information: NCT02450331. Research Sponsor: F. Hoffmann-La Roche Ltd.

5001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Pembrolizumab plus axitinib versus sunitinib as first-line therapy for advanced renal cell carcinoma (RCC): Updated analysis of KEYNOTE-426. *First Author: Elizabeth R. Plimack, Fox Chase Cancer Center, Philadelphia, PA*

Background: The randomized, open-label, phase 3 KEYNOTE-426 study (NCT02853331) demonstrated that pembrolizumab (pembro) + axitinib (axi) significantly improved OS, PFS, and ORR vs sunitinib as first-line therapy for advanced RCC (aRCC) at the first pre-planned interim analysis (minimum study follow-up of 7 mo). Updated analyses are presented here. **Methods:** Treatment-naive patients (pts) with clear cell aRCC, KPS ≥70%, and measurable disease (RECIST v1.1) were randomly assigned 1:1 to receive pembro 200 mg IV Q3W for up to 35 doses + axi 5 mg orally BID or sunitinib 50 mg orally QD on a 4-wk on/2-wk off schedule until progression, toxicity, or withdrawal. Randomization was stratified by IMDC risk (favorable vs intermediate vs poor) and geographic region (North America vs Western Europe vs rest of world). Primary end points were OS and PFS. Secondary end points were ORR, DOR, and safety. All *P* values are nominal. A post-hoc exploratory analysis was done to evaluate association of depth of response (maximum reduction from baseline in sum of diameters of target lesions) and OS using landmark analysis up to 6 mo after randomization. **Results:** 861 pts were randomly assigned (pembro + axi, n = 432; sunitinib, n = 429). Median (range) duration of follow-up for all pts was 27.0 mo (0.1-38.4). Pembro + axi improved OS (HR, 0.68 [95% CI, 0.55-0.85]; $P < 0.001$; 24-mo OS rate, 74% vs 66%) vs sunitinib. Median (95% CI) OS was not reached with pembro + axi and was 35.7 mo (33.3-NR) with sunitinib. Pembro + axi improved PFS (HR, 0.71 [95% CI, 0.60-0.84]; $P < 0.001$; 24-mo PFS rate, 38% vs 27%) vs sunitinib. For pembro +axi vs sunitinib respectively, median (95% CI) PFS was 15.4 (12.7-18.9) vs 11.1 mo (9.1-12.5); ORR was 60% vs 40% ($P < 0.0001$); CR rate was 9% vs 3%; and median DOR was 23.5 mo (range 1.4+ to 34.5+) vs 15.9 mo (range 2.3-31.8+). In general, the pembro + axi benefit was observed in all subgroups tested, including IMDC risk and PD-L1 expression subgroups. Post-hoc landmark analysis at 6-mo showed that pts on pembro + axi with ≥80% target lesion reduction had OS similar to that of pts with CR per RECIST v1.1 based on Kaplan-Meier curves and HR [95% CI] estimates (0.20 [0.05-0.84] vs. 0.10 [0.01-0.76], respectively) vs pts with 0-30% target lesion reduction. No new safety signals were observed. **Conclusions:** Pembro + axi continued to demonstrate superior and durable antitumor activity vs sunitinib in pts with first-line aRCC with a 27-mo median follow up; no new safety signals were observed. Clinical trial information: NCT02853331. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

SAVOIR: A phase III study of savolitinib versus sunitinib in pts with MET-driven papillary renal cell carcinoma (PRCC). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: PRCC is the most common type of non-clear cell RCC, accounting for 10–15% of renal malignancies. As a subset of PRCC cases are MET-driven, MET inhibition may be an appropriate targeted treatment approach. In a single-arm Phase II study, savolitinib (AZD6094, HMPL-504, volitinib), a highly selective MET-tyrosine kinase inhibitor, demonstrated antitumor activity in pts with MET-driven PRCC (Choueiri et al. JCO 2017). The Phase III SAVOIR study (NCT03091192) further assessed savolitinib vs standard of care sunitinib in pts with MET-driven PRCC. **Methods:** In this open-label (sponsor blinded), randomized study, pts with centrally confirmed MET-driven (*MET* and/or *HGF* amplification, chromosome 7 gain and/or *MET* kinase domain mutations), metastatic PRCC were randomized to savolitinib 600 mg once daily (QD), or sunitinib 50 mg QD 4 weeks on / 2 weeks off. Primary objective was progression-free survival (PFS; RECIST 1.1 by blinded independent central review). Secondary objectives included overall survival (OS), objective response rate (ORR), and safety and tolerability. **Results:** After external data on predicted PFS with sunitinib in pts with MET-driven disease became available, study enrollment was closed. At data cutoff (Aug 2019), only 60 of the planned 180 pts were randomized (savolitinib n = 33; sunitinib n = 27). Most had chromosome 7 gain (savolitinib 91%; sunitinib 96%) and no prior therapy (savolitinib 85%; sunitinib 93%). PFS, OS, and ORR were numerically improved with savolitinib vs sunitinib (Table). CTCAE grade ≥3 adverse events (AEs) were reported in 42% and 81% of pts; dose modifications were related to AEs in 30% and 74% of pts with savolitinib and sunitinib respectively. After discontinuation, 36% of all savolitinib and 19% of all sunitinib pts received subsequent anticancer therapy. **Conclusions:** Although pt numbers and follow-up were limited, savolitinib demonstrated encouraging efficacy and an improved safety profile vs sunitinib, with fewer grade ≥3 AEs and fewer dose modifications required. Sunitinib performance was poorer than expected based on external retrospective data. Further investigation of savolitinib as a treatment option for MET-driven PRCC is warranted. Clinical trial information: NCT03091192. Research Sponsor: AstraZeneca.

5003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II study of the oral HIF-2α inhibitor MK-6482 for Von Hippel-Lindau disease–associated renal cell carcinoma. *First Author: Eric Jonasch, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients (pts) with Von Hippel-Lindau disease (VHL) are at risk for several cancers, including clear cell renal cell carcinoma (ccRCC). Inactivation of *VHL* results in constitutive activation of the HIF-2α transcription factor, which drives tumor growth. MK-6482, a potent, selective, small molecule HIF-2α inhibitor, has shown favorable safety and antitumor activity in a phase 1/2 study. We present initial results of the open-label phase 2 study of MK-6482 for treatment of VHL-associated ccRCC (NCT03401788). **Methods:** Adult pts with a pathogenic germline *VHL* variation, measurable localized/nonmetastatic ccRCC, no prior systemic anticancer therapy, and ECOG PS of 0/1 received MK-6482 120 mg orally once daily until progression, intolerable toxicity, or investigator/pt decision to withdraw. Primary end point was ORR of VHL-associated ccRCC tumors per RECIST v1.1 by independent radiology review. Secondary end points were DOR, time to response (TTR), PFS, and safety and tolerability. **Results:** As of December 6, 2019, 61 pts were enrolled; median (range) age was 41 years (19-66) and most pts were male (52.5%) and had ECOG PS of 0 (82.0%). The most common lesions outside the kidney (non-RCC tumors) were CNS hemangioblastomas (80.3%) and pancreatic lesions (50.8%). Median (range) duration of treatment was 9.9 mo (1.9-18.2) and 95.1% of pts remain on therapy. Three pts discontinued (AE, n = 1; death [fentanyl toxicity], n = 1; pt decision, n = 1). There were 17 confirmed responses (ORR, 27.9% [95% CI, 17.1-40.8%]) and 8 (13.1%) unconfirmed (documented at 1 timepoint and to be confirmed at subsequent timepoint) responses; all responses were PRs. Of 61 pts, 53 (86.9%) had decrease in size of target lesions. In 17 pts with confirmed response, median (range) DOR was not reached (2.1-9.0 mo) and median (range) TTR was 5.5 mo (2.7-14.0). Responses were also observed in CNS, retinal, and pancreatic lesions. Median PFS was not reached; 12-mo PFS rate was 98.3%. Treatment-related AEs (TRAEs) occurred in 96.7% of pts, mostly grade 1 (44.3%) or grade 2 (42.6%) and primarily (≥20%) anemia (83.6%; considered an on-target-toxicity), fatigue (49.2%), and dizziness (21.3%). Grade 3 TRAEs occurred in 9.8% of pts, primarily fatigue (4.9%) and anemia (3.3%). There were no grade 4 or 5 TRAEs. One pt discontinued because of a TRAE (dizziness). **Conclusions:** MK-6482 showed promising efficacy and tolerability in pts with VHL-associated ccRCC and responses in other VHL-related lesions. These data support further investigation of MK-6482 in VHL disease. Clinical trial information: NCT03401788. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results from a phase II study of bevacizumab and erlotinib in subjects with advanced hereditary leiomyomatosis and renal cell cancer (HLRCC) or sporadic papillary renal cell cancer. *First Author: Ramaprasad Srinivasan, Urologic Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: HLRCC is a familial cancer syndrome associated with a type 2 papillary RCC (pRCC) variant. HLRCC is caused by germline mutations in the gene for the Krebs cycle enzyme fumarate hydratase (FH). FH inactivation results in VHL-independent upregulation of hypoxia inducible factor, a reliance on aerobic glycolysis, and activation of the NRF2 pathway, features also shared by some sporadic pRCC tumors. We hypothesized that the metabolic alterations underlying these tumors would be susceptible to targeted therapy with a combination of bevacizumab and erlotinib. **Methods:** Patients with advanced pRCC were eligible to enroll on this phase II study. To enrich for patients with FH deficiency, those with 1) HLRCC and 2) sporadic pRCC were enrolled into parallel, independent cohorts. All patients received bevacizumab 10 mg/kg IV every 2 weeks and erlotinib 150 mg orally daily. Patients who had received no more than two agents targeting the VEGFR pathway were included. Patients remained on treatment until unacceptable toxicity or progression. The primary endpoint was overall response rate (ORR); secondary endpoints were progression free survival (PFS) and duration of response. **Results:** A total of 83 patients with pRCC, including 42 in the HLRCC cohort and 41 in the sporadic cohort were enrolled on study. The majority of patients were IMDC intermediate risk (53/83, 64%) and 27 (33%) had at least one prior treatment. The ORR was 51% (42/83; 95% CI, 40 – 61) in all patients, 64% (27/42; 95% CI, 49 – 77) in the HLRCC cohort, and 37% (15/41; 95% CI, 24 – 52) in the sporadic cohort. The median PFS was 14.2 months (95% CI, 11.4 – 18.6) in all patients, 21.1 months (95% CI, 15.6 – 26.6) in the HLRCC cohort, and 8.7 months (95% CI, 6.4 – 12.6) in the sporadic cohort. The majority of treatment related adverse events (TRAEs) were grade 1 or 2 with the most common being acneiform rash (92%), diarrhea (77%), proteinuria (71%), and dry skin (61%). Grade ≥3 TRAEs occurred in 47% of patients, including hypertension (34%) and proteinuria (13%), with one patient (1.2%) with a grade 5 GI hemorrhage possibly related to bevacizumab. **Conclusions:** The combination of bevacizumab and erlotinib is well tolerated and is associated with encouraging activity in advanced pRCC, particularly in patients with FH deficient tumors. This is the first and largest prospective study in HLRCC and provides the basis for considering bevacizumab and erlotinib as a preferred option in a patient population that has no widely accepted standard. Clinical trial information: NCT01130519. Research Sponsor: U.S. National Institutes of Health, U.S. National Institutes of Health, This research was supported [in part] by the Intramural Research Program of the National Cancer Institute. Funded by the NCI Contract No. [HHSN261200800001E, 75N910D00024, Task Order No. (75N91019F00129)]. Genentech-Roche provided study drug but not funding.

5005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Optimized management of nivolumab (Nivo) and ipilimumab (Ipi) in advanced renal cell carcinoma (RCC): A response-based phase II study (OMNIVORE). *First Author: Rana R. McKay, Dana-Farber Cancer Institute, Boston, MA*

Background: Nivo + Ipi is an established first-line treatment (tx) for advanced RCC. We hypothesized that the addition of CTLA-4 blockade may not be required for all patients (pts). Furthermore, the optimal duration of Nivo maintenance in responding pts is unknown. In this phase II response-adaptive trial, we investigate the sequential addition of 2 doses of Ipi to induce response in Nivo non-responders (NR) and duration of Nivo in responding pts (NCT03203473). **Methods:** We enrolled pts with advanced RCC with no prior checkpoint inhibitor exposure. All pts received Nivo alone with subsequent arm allocation based on RECISTv1.1 response within 6 months (mos) of tx. Pts with a confirmed partial response (PR) or complete response (CR) within 6 months (mos) discontinued Nivo and were observed (Arm A). Arm A pts reinitiated Nivo if they developed progressive disease (PD); Ipi was added to Nivo if PD persisted or recurred. Pts with stable disease (SD) or PD after no more than 6 mos of Nivo alone received 2 doses of Ipi (Arm B). The primary endpoints were the proportion with PR/CR at 1-year (yr) after Nivo discontinuation (Arm A) and proportion of Nivo NR who convert to PR/CR after adding Ipi (Arm B). **Results:** 83 pts initiated tx of whom 99% had ECOG 0-1, 96% clear cell RCC, 51% tx-naïve, and 69% IMDC intermediate/poor risk. Median follow-up was 17.0 mos. 15 pts were not allocated to an arm [7 withdrew for PD, 7 withdrew for toxicity, 1 still on tx with unconfirmed PR (uPR)]. At 6 mos, induction Nivo resulted in a confirmed PR in 11% of pts (n=9/83): 12% (n=5/42) tx-naïve, 10% (4/41) prior tx, 8% (n=1/13) favorable risk, 11% (n=8/70) intermediate/poor risk (Table). 11 pts (13%: 9 PR, 1 uPR, 1 SD) were allocated to Arm A, of whom 5 (45%, 90% CI 20-73%) remained off Nivo at ≥ 1 yr. Of 57 pts (69%) allocated to Arm B, 2 pts converted to a PR (4%, 90% CI 1-11%), both of whom had prior tx and PD as best response to Nivo alone. Grade 3-4 treatment related adverse events (TrAE) occurred in 7% (n=6/83) on induction Nivo and in 23% (n=13/57) on Arm B (Nivo + Ipi). **Conclusions:** We cannot currently recommend a strategy of Nivo followed by response-based addition of Ipi due to the absence of CR and low PR/CR conversion rate (4%). Though a subset of pts treated with Nivo alone can maintain durable responses off tx at 1-yr, early Nivo discontinuation in the absence of toxicity cannot currently be recommended. Investigation into biomarkers to guide tx is ongoing. Clinical trial information: NCT03203473. Research Sponsor: BMS.

	Induction Nivo (n=83)	Ipi Added in NR Arm B (n=57)
PR	9 (11%)	2 (4%)
uPR	3 (4%)	0
SD	36 (43%)	24 (42%)
PD	35 (42%)	23 (40%)
Unevaluable		8 (14%)

5006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II study of nivolumab and salvage nivolumab + ipilimumab in treatment-naïve patients (pts) with advanced renal cell carcinoma (RCC) (HCRN GU16-260). *First Author: Michael B. Atkins, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Nivolumab (nivo) is FDA approved for pts with VEGFR TKI-resistant RCC and the nivo + ipilimumab (nivo/ipi) combination is FDA approved for treatment naïve pts with IMDC intermediate and poor risk RCC. Little information is available on the efficacy and toxicity of nivo monotherapy in treatment naïve RCC or the efficacy of nivo/ipi salvage therapy in pts with tumors resistant to initial nivo monotherapy. **Methods:** Eligible pts with treatment naïve RCC received nivo 240mg IV q2 wk x 6 doses followed by 360mg IV q3 wk x 4 doses followed by 480 mg q4 wk until progressive disease (PD), toxicity, or completion of 96 wks of treatment (Part A). Pts with PD prior to or stable disease (SD) at 48 wks (pSD) were potentially eligible to receive salvage nivo (3mg/kg) /ipi (1 mg/kg) q3 wk x 4 doses followed by q4 wk nivo maintenance for up to 48 wks (Part B). All pts were required to submit tissue from a metastatic lesion obtained within 12 months (mo) prior to study entry and prior to Part B. Pathology specimens will be analyzed by immunohistochemistry, quantitative immunofluorescence, WES and RNAseq with results linked to clinical outcome. **Results:** 123 pts with clear cell(cc) RCC were enrolled between 5/2017 and 12/2019 at 12 participating HCRN sites. Median age 65 (range 32-86 years); 72% male. IMDC favorable 30 (25%), intermediate 79 (65%) and poor risk 12 (10%). 22 (18%) had a component of sarcomatoid histology (SARC). 117 pts are currently evaluable for response. RECIST defined ORR was: 34 (29.3%)[CR 5 (4.3%), PR 29 (24.8%)], SD 47 (40.2%), PD 36 (30.7%). ORR by irRECIST was 35%. ORR by IMDC was: favorable 12/29 (41.4%), intermediate/poor 22/87 (25.3%) and for SARC 6/22 (27.3%). Median DOR is 13.8 (10.9, NA) mo. Median PFS is 7.4 (5.5, 10.9) mo. 110 pts remain alive. 60 pts (54 PD, 6 pSD) to date were potentially eligible for salvage nivo/ipi (Part B), but 28 did not enroll due to symptomatic PD (17), grade 3-4 toxicity on nivo (8), other (3). 27 of 32 Part B pts are currently evaluable for efficacy and 30 for toxicity. Best response to nivo/ipi was PR (11%), SD (30%), PD (59%). ORR by irRECIST was 19%. Grade 3-5 Treatment-related AEs (TrAE) were seen in 35/123 (28)% on nivo with 1 death due to respiratory failure. Grade 3-4 TrAE were seen in 10/30 (33%) on nivo/ipi with 0 deaths. Correlative studies are pending. **Conclusions:** Nivo monotherapy is active in treatment naïve ccRCC across all IMDC groups. Toxicity is consistent with prior nivo studies. Salvage treatment with nivo/ipi after nivo monotherapy was feasible in 53% of pts with PD/pSD, with 11% responding. Clinical trial information: NCT03117309. Research Sponsor: Bristol Meyers Squibb.

5007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

FRACTION-RCC: Innovative, high-throughput assessment of nivolumab + ipilimumab for treatment-refractory advanced renal cell carcinoma (aRCC). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: The immuno-oncology (I-O) combination nivolumab + ipilimumab (NIVO+IPI) is approved for first-line (1L) and NIVO is approved for second-line treatment post TKI therapy in aRCC. The open-label, randomized, phase 2 Fast Real-Time Assessment of Combination Therapies in Immuno-Oncology (FRACTION-RCC; NCT02996110) platform study has an adaptive design allowing rapid evaluation of I-O therapies, including NIVO+IPI or other investigational combinations. This FRACTION analysis reports preliminary outcomes with NIVO+IPI in aRCC pts after progression on checkpoint inhibitor therapy. **Methods:** All pts, except 1, had previously received and progressed on checkpoint inhibitor treatment. Pts received NIVO+IPI (NIVO 3 mg/kg + IPI 1 mg/kg Q3W ×4, then after 6 weeks, NIVO 480 mg Q4W), up to 2 years or until progression, toxicity, or protocol-specified discontinuation. Primary endpoints were confirmed objective response rate (ORR; per investigator using RECIST v1.1), duration of response (DOR), and progression-free survival probability at week 24. Safety outcomes were reported. **Results:** 46 pts were randomized to NIVO+IPI. Pts had 0 (n = 1), 1 (n = 10), 2 (n = 12), 3 (n = 10), or ≥4 (n = 13) prior lines of therapy. All pretreated pts had prior anti-PD-(L)1-, none had prior anti-CTLA-4- therapy, and 37 had prior TKI-based therapy; 45 pts progressed on anti-PD-(L)1 as the most recent therapy. Most pts had clear cell aRCC (n = 44). After a median study follow-up of 8.9 months, ORR was 15.2%; no pts achieved complete response and 7 achieved partial response. DOR ranged from 2–19+ months (n = 7); 5 pts had ongoing response. Six of 7 responders had received ≥2 prior lines of therapy. Any-grade treatment-related adverse events (AEs) were reported in 36 pts (78.3%; fatigue, rash [both 19.6%], and diarrhea [17.4%] were most common). Grade 3–4 treatment-related AEs were reported in 13 pts (28.3%; diarrhea [8.7%], ↑amylase and ↑lipase [both 6.5%] were most common). Treatment-related immune-mediated AEs of any grade were reported in 22 pts (47.8%; rash [19.6%], diarrhea [17.4%], and ↑alanine aminotransferase [8.7%]). No treatment-related deaths were reported. Updated and expanded results with an additional 3 months of follow-up will be presented. **Conclusions:** These results suggest that NIVO+IPI may provide durable partial response in some pts with prior progression on checkpoint inhibitors, including some heavily pretreated pts. The safety profile of NIVO+IPI in FRACTION pts was similar to historic data in aRCC with this combination. Clinical trial information: NCT02996110. Research Sponsor: Bristol-Myers Squibb.

5008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II trial of lenvatinib (LEN) plus pembrolizumab (PEMBRO) for disease progression after PD-1/PD-L1 immune checkpoint inhibitor (ICI) in metastatic clear cell renal cell carcinoma (mccRCC). *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: LEN, a multikinase VEGFR inhibitor, plus everolimus is approved for advanced RCC after prior VEGF-targeted therapy. PEMBRO, an anti-PD-1 antibody, plus axitinib is approved as first-line therapy of advanced RCC. We report phase 2 results of the RCC cohort of a phase 1b/2 trial (Study 111/KEYNOTE-146) of LEN + PEMBRO in patients (pts) who progressed after ICI therapy. **Methods:** We performed a multicenter, open-label study of pts with mccRCC, who previously had disease progression by RECIST (confirmed ≥ 4 weeks later) during or following ICI therapy. Pts had measurable disease by immune-related RECIST, and ≥ 1 prior therapy. Pts received LEN 20 mg orally once daily plus PEMBRO 200 mg IV every 3 weeks until disease progression or toxicity. Tumor assessments were performed every 6 weeks (until week 24), then every 9 weeks. The primary endpoint was objective response rate (ORR) at Week 24 by irRECIST. **Results:** 104 pts were enrolled. At data cutoff (January 12, 2020), 71 (69%) pts were still on study treatment. Most pts had ≥2 prior anticancer regimens (58%). 91 of 104 pts were evaluable for response at Week 12 (13 pts NE at Week 12); 46 of 91 pts achieved a confirmed partial response for an ORR of 51% (Table). Median progression-free survival (PFS) was 11.7 months and median duration of response (DOR) was 9.9 months. The most common treatment-related adverse events (TRAEs) were fatigue (49%), diarrhea (44%), proteinuria (37%), hypertension (31%), nausea (31%), dysphonia (29%), stomatitis (29%), and arthralgia (27%). There was 1 grade 5 TRAE (upper gastrointestinal hemorrhage). 43% of pts required dose reduction and 12% of pts discontinued treatment due to TRAEs. Response and safety data will be updated to include all pts evaluable at an April 9, 2020 cut-off. **Conclusions:** LEN + PEMBRO demonstrated promising antitumor activity in pts with mccRCC with disease progression following ICI therapy. No new safety signals were detected. Efficacy outcomes by investigator review per irRECIST. Clinical trial information: NCT02501096. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co. Inc., Kenilworth, NJ, USA.

Biomarker analyses from the phase III CheckMate 214 trial of nivolumab plus ipilimumab (N+I) or sunitinib (S) in advanced renal cell carcinoma (aRCC). *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In CheckMate 214 (NCT02231749), N+I demonstrated superior clinical outcomes vs S in patients (pts) with aRCC. Here, we report exploratory biomarker analyses of pretreatment tumor samples relative to outcomes. **Methods:** Formalin-fixed, paraffin-embedded aRCC samples were characterized by immunohistochemistry (tumor programmed death ligand 1 [PD-L1], n = 992; PD-L1 combined positive score [CPS], n = 980), whole exome sequencing (WES; tumor mutational burden, indel burden, HLA class I zygosity, and *PBRM1* mutation status; n = 481), and RNAseq (n = 213). Gene signature scores were calculated as the median value of Z-scored expression for transcripts. Association with outcome was tested using Fisher s exact test and Cox proportional hazards model. With ≥ 42 mo follow-up, prolonged progression-free survival (PFS) with N+I (< or ≥ 18 mo; n = 82 vs 27, respectively) was analyzed by *limma* and gene set enrichment analysis of Hallmark gene sets (MSigDB). **Results:** PD-L1 CPS did not have improved predictive power over tumor PD-L1. The WES-derived biomarkers were not associated with outcomes in pts treated with N+I or S. For the RNAseq cohort, objective response rates (ORR) for pts with ≥ median scores, and hazard ratios (HR) relative to < median are shown (Table). A higher angiogenesis (Angio) gene signature score was associated with higher ORR and PFS for S; lower Angio score was associated with higher ORR in N+I. Immune signature scores were not predictive for ORR in N+I. Prolonged PFS with N+I (≥ 18 mo, n = 27) was associated with higher expression of Hallmark inflammatory response and Hallmark epithelial mesenchymal transition (EMT) gene sets (both adjusted $P = 0.002$). **Conclusions:** The Angio gene signature was associated with ORR for S (high score) and N+I (low score). Prolonged PFS in 27 pts receiving N+I was linked with inflammation (consistent with findings from PD-1 blockade monotherapy), but associated with EMT-related transcripts (in contrast with findings in other tumor types). Further validation of these exploratory analyses will be required. Clinical trial information: NCT02231749. Research Sponsor: Bristol-Myers Squibb.

Immunogenomic characterization of advanced clear cell renal cell carcinoma treated with PD-1 blockade. *First Author: David A. Braun, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune checkpoint inhibitors targeting the PD-1 pathway have transformed the management of many advanced malignancies, including clear cell renal cell carcinoma (ccRCC), but the drivers and resistors of PD-1 response remain incompletely elucidated. Further, the common paradigm in solid tumor immunology that pre-existing CD8+ T cell infiltration, in combination with high numbers of nonsynonymous mutations (which, in the context of diverse HLA class I alleles, may be presented as neoantigens) drives response to PD-1 blockade, has not been thoroughly explored in ccRCC. **Methods:** We analyzed 592 tumors collected from advanced ccRCC patients enrolled in prospective clinical trials (CheckMate 009, CheckMate 010, CheckMate 025) of treatment with PD-1 blockade (n = 362) or mTOR inhibition (as control arm; n = 230) by whole-exome (n = 454) and RNA-sequencing (n = 311), integrated with CD8 immunofluorescence analysis (n = 219), to uncover the immunogenomic determinants of therapeutic response and survival. Wilcoxon rank-sum test was used to compare somatic alteration burden between clinical benefit (CB) v.s no CB (NCB); Fisher's exact test was used to compare mutations and copy number alteration by infiltration state; and hazard ratio (HR) was calculated from Cox PH model for progression-free (PFS) and overall survival (OS) endpoints. All tests were at a significance level of $p < 0.05$. **Results:** Conventional genomic markers (tumor mutation burden, p = 0.81; neoantigen load, p = 0.47 for CB vs. NCB) and degree of CD8+ T cell infiltration (p = 0.88 for PFS; p = 0.65 for OS) were not associated with clinical response or altered survival with PD-1 blockade. These advanced ccRCC tumors were highly CD8+ T cell infiltrated, with only 22% having an immune desert phenotype and 5% with an immune excluded phenotype. Our analysis revealed that CD8+ T cell infiltrated tumors are depleted of clinically favorable PBRM1 mutations (p = 0.013) and enriched for unfavorable chromosomal losses of 9p21.3 ($p < 0.001$) when compared to non-infiltrated tumors. When found within infiltrated tumors, del(9p21.3) was associated with worse CB rate (36% (9/25) for del(9p21.3) vs. 88% (7/8) for wildtype at that locus, p = 0.017) and worse survival (HR = 2.38, p = 0.01 for PFS; HR = 2.44, p = 0.01 for OS) with PD-1 blockade. **Conclusions:** These data demonstrate how the potential interplay of immunophenotypes with somatic mutations and chromosomal alterations impacts therapeutic efficacy in advanced ccRCC. Research Sponsor: Department of Defense (CDMRP), U.S. National Institutes of Health, Bristol Myers-Squibb.

5011 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Tumor, immune, and stromal characteristics associated with clinical outcomes with atezolizumab (atezo) + platinum-based chemotherapy (PBC) or atezo monotherapy (mono) versus PBC in metastatic urothelial cancer (mUC) from the phase III IMvigor130 study. *First Author: Matt D. Galsky, Mount Sinai Hospital, New York, NY*

Background: Tumor mutational burden (TMB), PD-L1 expression, T-effector gene expression (GE) and a fibroblast TGF-β–response signature (F-TBRS) are associated with clinical outcomes with atezo mono in mUC (Mariathasan, *Nature*, 2018). Here we explore the potential predictive role of these biomarkers and APOBEC mutagenesis in IMvigor130. **Methods:** Pts receiving first-line (1L) mUC treatment (tx) were randomized 1:1:1 to atezo + PBC, atezo mono, or placebo + PBC. Coprimary efficacy endpoints were PFS and OS. Planned exploratory biomarker analyses included PD-L1 expression, TMB (FoundationOne), and T-effector GE (RNA-seq). **Results:** The 851 biomarker-evaluable pts (BEP) were representative of the 1200 ITT pts. Biomarker results are shown in Table. PD-L1 IC2/3 was associated with significantly longer OS for atezo mono vs placebo + PBC and a combination of PD-L1 IC2/3, and high TMB (> 10 muts/Mb) identified a pt subset (≈ 14% of BEP) with particularly favorable outcomes with atezo mono vs placebo + PBC; similar results for PD-L1 and TMB were not seen with atezo + PBC vs placebo + PBC. APOBEC mutagenesis was associated with improved OS with atezo-containing regimens whereas high F-TBRS was associated with inferior OS with atezo mono. **Conclusions:** These results reinforce the potential predictive nature of biomarkers associated with response/resistance to atezo and highlight potentially distinct biology driving benefit with atezo and atezo + PBC. These findings suggest a possible biomarker-directed approach to 1L mUC tx that warrants mechanistic interrogation and prospective validation. Clinical trial information: NCT02807636. Research Sponsor: F. Hoffmann-La Roche.

DUTRENEO Trial: A randomized phase II trial of DUrvalumab and TREmelimumab versus chemotherapy as a NEOadjuvant approach to muscle-invasive urothelial bladder cancer (MIBC) patients (pts) prospectively selected by an interferon (INF)-gamma immune signature. *First Author: Enrique Grande, MD Anderson Cancer Center Madrid, Madrid, Spain*

Background: Cisplatin-based neoadjuvant chemotherapy (CT) followed by radical cystectomy (RC) is a standard treatment for MIBC. PD-1/L1 inhibitors as single agent induce pathological complete responses (pCR) in this setting. Predictors of response are still ill defined. DUTRENEO trial aimed to prospectively explore the activity of anti-PDL1 + anti-CTLA4 vs CT in pts selected according to a tumor pro-inflammatory IFN-gamma signature (tumor immune score, TIS). **Methods:** Cisplatin-eligible pts with urothelial MIBC (cT2-T4a, N≤1, M0) candidates to RC were classified as "hot" or "cold" according to a tumor TIS determined by Nanostring technology. Patients with "hot" tumors were randomized to DU 1500 mg + TRE 75 mg every 4 weeks x 3 cycles or standard cisplatin-based CT (GEMCIS or MVACdd). Pts in the "cold" arm received standard CT. Primary endpoint was to achieve ≥8 pCR in the DU+TRE arm. PDL1 expression was assessed using immunohistochemistry. **Results:** 61 pts were recruited in 10 sites between oct-2018 and dec-2019. Pts randomized in the "hot" arms received standard CT (n = 22) or DU+TRE (n = 23) and had a pCR rate of 8/22 pts (36.4%) vs 8/23 pts (34.8%), respectively [OR = 0.923 (0.26 – 3.24)]. In the "cold" arm, 16 pts received CT obtaining a pCR rate of 68.8% (11/16 pts). There were more PDL1 low tumors in the "cold" TIS arm (10/12, 83.3%). pCR rate by PDL1 status is shown in the table. One pt in the DU+TRE arm refused RC. Full treatment was delivered to 81.3% of CT "cold" vs 59.1% of CT "hot" vs 73.9% in the DU+TRE arm pts. Grade 3-4 toxicities were more frequent in the CT arms. **Conclusions:** The combination of DU+TRE is safe and active in MIBC patients in the neoadjuvant setting. Nevertheless prospective stratification by a pro-inflammatory IFN-gamma signature failed to select patients more likely to benefit from IO vs CT in this context. Further studies are required to guide treatment selection. Clinical trial information: NCT03472274. Research Sponsor: AstraZeneca.

	COLD: CT (N = 16)	HOT: CT (N = 22)	HOT: DU+TRE (N = 23)
Pathologic complete response	11 (68.8%)	8 (36.4%)	8 (34.8%)
Progressive disease	0 (0.0%)	2 (9.1%)	1 (4.3%)
pCRs in PDL1 high (%)	50.0%	60.0%	57.1%
pCRs in PDL1 low (%)	90.0	60.0%	14.3%

Cabozantinib in combination with atezolizumab in urothelial carcinoma previously treated with platinum-containing chemotherapy: Results from cohort 2 of the COSMIC-021 study. *First Author: Sumanta K. Pal, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Cabozantinib (C), an inhibitor of MET, AXL, and VEGFR, has been shown to promote an immune-permissive environment and has shown promising clinical activity in combination with immune checkpoint inhibitors (ICIs) in solid tumors including renal cell carcinoma and urothelial carcinoma (UC). ICI monotherapy is approved for patients (pts) with locally advanced or metastatic UC with disease progression after platinum-containing chemotherapy. COSMIC-021, a multi-center phase 1b study, is evaluating the combination of C with atezolizumab (A) in various solid tumors (NCT03170960). We report results from Cohort 2 in UC pts with prior platinum-containing chemotherapy. **Methods:** Eligible pts had ECOG PS 0-1 and had progressed on or after a platinum-containing chemotherapy (including pts with disease recurrences < 12 months after the end of perioperative chemotherapy). Pts received C 40 mg PO QD and A 1200 mg IV Q3W. CT/MRI scans were performed Q6W for first year and Q12W thereafter. The primary endpoint is objective response rate (ORR) per RECIST v1.1 by investigator. Other endpoints include safety, duration of response (DOR), PFS, and OS. **Results:** As of Dec 20, 2019, 30 pts with advanced UC were enrolled with a median follow-up of 16.5 mo (range 12, 21). Median age was 66 yrs (range 44, 84), 73% were male, and 60% had ECOG PS 1. Primary tumor sites were bladder (80%), renal pelvis (10%), and ureter (10%); the most frequent metastatic sites included lung (40%) and liver (27%). Fourteen pts (47%) had received ≥2 prior systemic anticancer therapies. The most common treatment-related AEs (TRAEs) of any grade were asthenia (37%), diarrhea (27%), decreased appetite (23%), increased transaminases (23%), and mucosal inflammation (20%). Grade 3/4 TRAEs occurred in 57% of pts, with no grade 5 TRAEs. Confirmed ORR per RECIST v1.1 was 27% (8 of 30 pts), including 2 pts with CR. DCR (CR+PR+SD) was 64%. Median DOR was not reached, with the longest DOR ongoing at 14.3+ mos. Median PFS was 5.4 mo (range 0.0+, 17.3+). **Conclusions:** C in combination with A demonstrated encouraging clinical activity in pts with advanced UC with an acceptable safety profile. Additional cohorts of pts with advanced UC are being explored in the study. Clinical trial information: NCT03170960. Research Sponsor: Exelixis Inc.

5014 Poster Discussion Session; Displayed in Poster Session (Board #83), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Safety and preliminary efficacy of rogaratinib in combination with atezolizumab in a phase Ib/II study (FORT-2) of first-line treatment in cisplatin-ineligible patients (pts) with locally advanced or metastatic urothelial cancer (UC) and *FGFR* mRNA overexpression. *First Author: Jonathan E. Rosenberg, Memorial Sloan Kettering Cancer, New York, NY*

Background: Programmed cell-death ligand 1 (PD-L1) overexpression is a mechanism for immune escape in UC. Rogaratinib, an oral pan-FGFR1-4 inhibitor, showed promising efficacy in a Phase I study in pts with solid tumors, including UC, with *FGFR1-3* mRNA overexpression (Schuler et al. Lancet Oncol 2019). This Phase Ib/II study is evaluating rogaratinib in combination with atezolizumab, a PD-L1 inhibitor, in pts with *FGFR*-positive, locally advanced or metastatic UC (NCT03473756). We report results from the Phase Ib study. **Methods:** Cisplatin-ineligible pts with untreated metastatic UC were eligible if high *FGFR1* or *3* mRNA was detected by RNA *in situ* hybridization of archival tissue (RNAscope). Pts were treated at a starting dose of rogaratinib 800 mg p.o. BID and atezolizumab 1200 mg i.v. on day 1 (21-day cycle). Primary objectives were safety, tolerability, and determination of the recommended Phase II dose. **Results:** 27 pts were treated (rogaratinib 800 mg + atezolizumab, n = 11; rogaratinib 600 mg + atezolizumab, n = 16); 85% were male, median age was 72 years (range 47-83), 37% had an ECOG PS of 1, and 96% had negative/low *PD-L1* expression. Most common treatment-emergent adverse events (TEAEs) were diarrhea (63%), hyperphosphatemia (44%), and urinary tract infection (37%). Dose interruption/reduction due to AEs occurred in 67%/37% of pts; TEAEs lead to discontinuation in 45.5% (800 mg) and 12.5% (600 mg). Most common grade 3/4 TEAEs were increased lipase without pancreatitis (11%), rash, and increased alanine aminotransferase (7% each). Rogaratinib-related unique TEAEs were hyperphosphatemia (44%) and retinal pigment epithelium detachment (4%). The maximum tolerated dose (MTD) was rogaratinib 600 mg BID based on lower overall frequency of AEs. Of 23 evaluable pts (600 mg, n = 13; 800 mg, n = 10), overall 9 (39%) pts had an objective response (RECIST v1.1); 3 (13%) pts had a complete response (600 mg: 2/13 pts), 6 (26%) pts had a partial response (600 mg: 5/13 pts), and 6 (26%) pts had stable disease (600 mg: 4/13 pts). **Conclusions:** Rogaratinib with atezolizumab showed promising efficacy and safety in cisplatin-ineligible pts with tumor *FGFR1 or 3* mRNA-positive UC, with nearly all pts demonstrating low or negative *PD-L1* expression. Pts are being enrolled at the MTD of rogaratinib 600 mg BID plus atezolizumab. Clinical trial information: NCT03473756. Research Sponsor: Bayer AG. Writing support provided by Complete HealthVizion.

ERDAFITINIB in locally advanced or metastatic urothelial carcinoma (mUC): Long-term outcomes in BLC2001. *First Author: Arlene O. Siefker-Radtke, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Erdafitinib (JNJ-42756493; ERDA) is the only pan-FGFR kinase inhibitor with US FDA approval for treatment of adults with mUC with susceptible FGFR3/2 alterations (alt) and who progressed on ≥ 1 line of prior platinum-based chemotherapy (chemo). Approval was based on data from the primary analysis of the pivotal BLC2001 trial[1]. Here we report long-term efficacy and safety data from the 8 mg/d continuous dose regimen in BLC2001. **Methods:** BLC2001 (NCT02365597) is a global, open-label, phase 2 trial of pts with measurable mUC with prespecified FGFR alt, ECOG 0-2, and progression during/following ≥ 1 line of prior chemo or ≤ 12 mos of (neo)adjuvant chemo, or were cisplatin ineligible, chemo naïve. The optimal schedule of ERDA determined in the initial part of the study was 8 mg/d continuous ERDA in 28-d cycles with uptitration to 9 mg/d (ERD 8 mg UpT) if a protocol-defined target serum phosphate level was not reached and if no significant treatment-related adverse events (TRAEs) occurred. Primary end point was the confirmed objective response rate (ORR=% complete response + % partial response). Key secondary end points were progression-free survival (PFS), duration of response (DOR) and overall survival (OS). **Results:** Median follow-up for 101 patients treated with ERDA 8 mg UpT was ~24 months. Confirmed ORR was 40%. Median DOR was 5.98 mos; 31% of responders had DOR ≥ 1 yr. Median PFS was 5.52 mos, median OS was 11.3 mos. 12-mos and 24-mos survival rates were 49% and 31%, respectively. Median treatment duration was 5.4 mos. The ERDA safety profile was consistent with the primary analysis. No new TRAEs were seen with longer follow-up. Central serous retinopathy (CSR) events occurred in 27% (27/101) of patients; 85% (23/27) were Grade 1 or 2; dosage was reduced in 13 pts, interrupted for 8, and discontinued for 3. On the data cut-off date, 63% (17/27) had resolved; 60% (6/10) of ongoing CSR events were Grade 1. There were no treatment-related deaths. **Conclusions:** With a median follow-up of 2 yrs, ERDA in mUC + FGFR alt showed a manageable safety profile and consistent efficacy, with median OS of 11.3 mos. 31% had a DOR ≥12 mos and 31% were alive at 24 mos. ERDA monotherapy vs. immune checkpoint inhibitor (PD-1) or chemo is being further analyzed in a randomized control study (THOR; NCT03390504).Reference: Loriot Y, et al. *N Engl J Med.* 2019;381: 338-48. Final results of PEANUT: Pembrolizumab and nanoparticle albumin-bound paclitaxel (nab-paclitaxel) as salvage therapy for metastatic urothelial carcinoma (UC). *First Author: Patrizia Giannatempo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Pembrolizumab (pembro) is a new standard of care in chemotherapy (CT) pre-treated patients (pts) with metastatic UC. Nab-paclitaxel demonstrated preliminary activity in advanced UC. In the PEANUT study (NCT03464734) we investigated their combination in advanced UC after CT failure. **Methods:** In an open-label, single-arm, phase 2 trial, pts received 200 mg pembro, intravenously (IV), on D1 and 125 mg/m^2 IV nab-paclitaxel on D1 and D8, every 3 weeks, until disease progression (PD) or unacceptable toxicity. Inclusion criteria were: predominant UC histology, failure of ≤2 platinum-based CT for metastatic disease. Response was evaluated by RECIST v.1.1 criteria every 2 cycles. Biomarkers included PD-L1 combined positive score (CPS) and comprehensive genomic profiling on tumor and blood samples (FoundationONE and FoundationACT assay). The primary endpoint was the progression-free survival (PFS). The target was to detect an improvement in the median PFS from ≤3.0 months (H0) to ≥5.0 months (H1). **Results:** Between 01 and 12/2019, PEANUT study enrolled 65 pts: 24% were female, median age was 69 yrs (IQR: 61-73); 25% had failed > 1 prior systemic therapies; 35% had ECOG-performance status 1; 33% had liver metastases. The median TMB was 6.9 mut/Mb. After median follow-up (FUP) of 5.5 months, 34 pts have relapsed (52.3%). The median PFS was 5 months (95%CI: 3-not reached). The 3-month PFS was 60.7% (95%CI: 49.8-74.1). The confirmed objective response-rate (ORR) was 47.7% (95% CI: 35.2-60.4): 22 partial responses and 9 complete responses (13.8%). The median duration of response was not reached, and 4 pts (6.1%) are long-term responders (> 12 months). Grade 3 treatment-related adverse events (TRAE) were seen in 20 pts (30.7%). Most common any-grade TRAE included alopecia (76%), neutropenia (33.3%) and asthenia (33%). Neither TMB nor CPS were significantly associated with PFS on univariable analyses. In matched tumor/blood samples, objective responses were seen in 8/10 pts with *PI3KCA* mutations (80%); 6/10 pts with *RB1* alterations (60%); 5/12 pts with DNA damage repair gene alterations (41.7%). **Conclusions:** Pembro-nab-paclitaxel, the first salvage CT-immunotherapy combination in UC, demonstrated a good tolerability, promising PFS and a clinically meaningful ORR in II-III line setting of advanced UC. As more mature data on biomarker selection emerges, this combination warrants additional studies in either second-line or earlier disease settings. Clinical trial information: NCT03464734. Phase II study of nivolumab and ipilimumab for advanced rare genitourinary cancers. *First Author: Bradley Alexander McGregor, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients with rare genitourinary malignancies (Bladder cancer of variant histologies (BCVH), adrenal tumors, chemotherapy refractory germ cell tumors (CRGCT), penile carcinoma and prostate cancer of variant histology (PCVH)) have poor outcomes. Nivolumab and ipilimumab has demonstrated safety and efficacy in genitourinary malignancies. In this multicenter, single arm, multi-cohort phase II trial we evaluated the efficacy of nivolumab and ipilimumab in pts with advanced rare genitourinary cancers (NCT 03333616). Herein, we report the results of the fully accrued BCVH, adrenal and other cohorts. **Methods:** Eligible pts had a metastatic rare genitourinary malignancy, ECOG performance status of 0-2 and no prior immune checkpoint inhibitor exposure; aside from CRGCT pts could be treatment naïve. Eligible pts received nivolumab 3 mg/kg and ipilimumab 1 mg/kg intravenously every 3 weeks for 4 doses with continued nivolumab 480 mg IV every 4 weeks. The primary endpoint was overall response rate (ORR) by RECIST 1.1. **Results:** 56 pts were enrolled at 6 institutions between 4/2018 and 7/2019 in 3 cohorts: BCVH (N = 19), adrenal tumors (n = 18) and other tumors (n = 19). Median follow-up was 9.9 (range < 1~21) months. 28(50%) pts received all 4 doses of nivolumab and ipilimumab. 25 pts received nivolumab maintenance at a median of 4 (range 1-18) cycles. ORR in entire cohort was 16% (n = 9: 2 CR 7 PR, Table); 67% of responders (6/9) maintained response greater than 9 months. Median PFS was 2.8 (2.7-5.2) months. 22 pts (39%) developed treatment-related ≥ grade 3 toxicity; 23% required high dose steroids (≥40 mg prednisone or equivalent) and 15 (27%) pts discontinued treatment due to an AE. Grade 5 toxicity occurred in 3 pts; 1 death was treatment related. **Conclusions:** Nivolumab and ipilimumab resulted in objective responses in a subset of pts with rare GU malignancies, especially in BCVH. Biomarkers are being evaluated and an additional cohort exploring the activity in genitourinary tumors with neuroendocrine differentiation is ongoing. This combination warrants further investigation in these pts with substantial unmet needs. Clinical trial information: NCT 03333616. Research Sponsor: BMS.

Phase II neoadjuvant (N-) gemcitabine (G) and pembrolizumab (P) for locally advanced urothelial cancer (laUC): Interim results from the cisplatin (C)-ineligible cohort of GU14-188. *First Author: Hristos Z. Kaimakliotis, Indiana University Simon Cancer Center, Indianapolis, IN*

Background: Patients (pts) with laUC who are C-ineligible have inferior survival compared to counterparts who receive C based N-therapy and have a pathologic response at radical cystectomy (RC). Cohort 2 (C2) of the GU14-188 trial is designed to assess the tolerability and efficacy of N- G and P in laUC pts who are C-ineligible. **Methods:** Eligible pts for C2 were surgical candidates and C-ineligible with cT2-4aN0M0 bladder UC or mixed histology. Enrollment followed a Simon 2-stage design for H_0 of interval futility which was rejected at stage 1, and fully enrolled. Pts were treated with N- G (1000mg/m^2) on days 1, 8, and 15 of a 28 day cycle (cy) for a total of 3 cy, and overlapped with P 200mg every 3wks starting on cy 1 day 8 x 5 doses. Minimum criteria for evaluation of safety: 1 dose of P, and for efficacy: 2 doses P and RC. The primary endpoint of pathologic muscle invasive response rate (PaIR, ≤pT1N0) was assessed at RC and designed for 86% power, 4% significance to detect PaIR difference from 18 to 40%. Molecular subtyping is planned. **Results:** 37 pts were enrolled to C2 with a median (mdn) age of 72, 70% male, 55% > cT2. C-ineligibility was due to renal function (49%), hearing (30%), neuropathy (12%). Mdn per-pt doses given (intended) for P:5(5) and G:9(9). The PaIR was 51.6% (95%CI 0.35, 0.68), P0 (ypT0N0) rate of 45.2%, and neither correlated with baseline PD-L1 score. Downstage to PaIR occurred in 57% of pts with cT2, and 47% of > cT2. Mdn time to RC from last dose was 5.6wks. Six were not included in the primary analysis: 3 (8.1%) did not have RC due to progression (RFS censored), 2 did not receive required protocol therapy, and 1 withdrew consent. At mdn follow up of 10.8mo (4-24), the estimated 12mo RFS, OS, and DSS is 74.9%, 93.8%, and 100%, respectively. Treatment related AE included grade (gr) 3/4 neutropenia (24%), anemia (13%), and platelets (5%). There were no gr 4 non-heme AE, and of 14 (36%) pts with gr 3, 12 did not preclude RC. Of these, there were 4 gr 3 investigator assessed immune related adverse events (IAirAE) of pneumonitis (5%), colitis (3%), and AST elevation (3%). Though IAirAE improved, protocol therapy was discontinued in 3 pts: 2 did not have RC due to progression. **Conclusion:** N- G with P in C-ineligible pts with laUC is feasible with manageable toxicity, and has a pathologic downstage rate comparable to standard of care in the C-eligible population. G and P warrants further study with component contribution as a C- free N- option in laUC. Clinical trial information: NCT02365766. Research Sponsor: Merck & Co.

Biomarker analysis and updated clinical follow-up of preoperative ipilimumab (ipi) plus nivolumab (nivo) in stage III urothelial cancer (NABUCCO). *First Author: Nick Van Dijk, The Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Encouraging pathological complete response (pCR) rates were observed in trials testing neoadjuvant pembrolizumab or atezolizumab in urothelial cancer (UC). In cT3-4N0 tumors, pCR to atezolizumab was only 17% and restricted to tumors showing characteristics of preexisting T cell immunity. In NABUCCO, we aimed to increase response to pre-operative checkpoint blockade, particularly in high risk patients (pts), by combining ipi plus nivo in stage III UC. We previously reported pCR in 46% and downstaging to no remaining invasive disease in 58% (ESMO2019). Here, we present biomarker analyses and updated clinical follow-up (FU) data. **Methods:** Twenty four stage III (cT3-4aN0 or cT2-4aN1-3) UC pts who were unfit to receive cisplatin-based chemotherapy or refused, were treated with ipi 3 mg/kg (day 1), ipi 3 mg/kg + nivo 1 mg/kg (day 22), and nivo 3 mg/kg (day 43), followed by resection. The primary endpoint was feasibility (resection < 12 weeks). Efficacy (pCR), safety and biomarker analysis were secondary endpoints. Whole-exome sequencing (WES) was done on baseline tumor samples and local lymph node (LN) metastases showing no response. RNA-seq and multiplex immunofluorescence (mIF) for immune cell markers were done pre- and post-therapy. **Results:** After a median FU of 15.6 months, 2 pts relapsed (both non-pCR); 1 of these 2 pts died of metastatic disease. Tumors showing complete response (CR, for biomarker analysis defined as pCR, CIS or pTa) had a significantly higher tumor mutational burden than non-CR tumors. CR to ipi+nivo was independent of baseline CD8 T-cell presence. There was no difference between CR and non-CR tumors in baseline immune gene signatures, such as interferon gamma and T-effector signatures. Surprisingly, exploratory gene expression analysis revealed that non-CR was associated with a baseline B cell immune signature, particularly immunoglobulins and genes involved in B cell receptor signaling. CD20 positive cells (by mIF) and presence of tertiary lymphoid structures (TLS) at baseline were also associated with non-CR. Upon treatment with ipi+nivo, early and mature TLS increased significantly in responding tumors. A subset of pts showed CR in the bladder, but non-CR in a local LN tumor focus. WES revealed that these LN metastases were genetically different from the primary tumor bulk. **Conclusions:** At 15.6 months follow-up, recurrence after pre-operative ipi+nivo was low. Pathological complete response was not restricted to tumors exhibiting preexisting T cell immunity. Clinical trial information: NCT03387761. Research Sponsor: BMS.

A phase Ib trial of neoadjuvant/adjuvant durvalumab +/- tremelimumab in locally advanced renal cell carcinoma (RCC). *First Author: Moshe Chaim Ornstein, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Effective neoadjuvant and adjuvant therapies are lacking in locally advanced RCC. Given robust activity of checkpoint inhibitors in mRCC, a phase Ib trial of perioperative Durvalumab (D) +/- Tremelimumab (T) in locally advanced RCC was conducted (NCT02762006). **Methods:** Pts with radiographic evidence of high risk localized RCC (clinical stage T2b-4 and/or N1, M0 disease), adequate performance status, and adequate laboratory values were eligible. Primary objective was safety and feasibility of neoadjuvant/adjuvant D +/- T. **Results:** Twenty-nine pts were enrolled. Cohorts, regimens, and immune-related adverse events (irAE) are detailed in the table. In total, 79% male, median age 61 (range, 42-84), 8%/88%/4% clinical T2/T3/T4, 27% positive clinical lymph nodes (LN+), and median time from neoadjuvant dose to surgery was 7 days. On surgical pathology: 5%/14%/77%/5% pathologic T1/T2/T3/T4, and 13% LN+. Median time from treatment to first grade (Gr) >3 irAE or any Gr irAE requiring corticosteroids was 99 days (range, 32-207). There were no treatment-related delays to nephrectomy or surgical complications. Although not meeting the protocol-defined MTD, given higher than expected irAEs, the study was suspended. **Conclusions:** Perioperative durvalumab in locally advanced RCC appears safe. The addition of tremelimumab is associated with higher rates of toxicity. Updated toxicity will be presented. Clinical trial information: NCT02762006. Research Sponsor: AstraZeneca.

Phase II trial of atezolizumab in BCG-unresponsive non-muscle invasive bladder cancer: SWOG S1605 (NCT #02844816). *First Author: Peter C. Black, Vancouver Prostate Centre, University of British Columbia, Vancouver, BC, Canada*

Background: Radical cystectomy (RC) is the standard of care for patients with BCG-unresponsive high risk non-muscle invasive bladder cancer (NMIBC), but many patients are unfit for surgery or elect bladder preservation. Based on the reported efficacy of atezolizumab in metastatic urothelial carcinoma and the known expression of PD-L1 in NMIBC after BCG therapy, this trial was designed to evaluate the activity of atezolizumab in BCG-unresponsive high risk NMIBC. **Methods:** This single arm phase II registration trial testing systemic atezolizumab (1200 mg IV) every 3 weeks for one year aimed to enroll 135 (70 CIS and 65 non-CIS) eligible patients with histologically proven BCG-unresponsive high risk NMIBC who were unfit for or declined RC. Here we report on the subset with CIS (with or without concomitant Ta/T1) among patients who received at least one protocol treatment. The primary endpoint was pathological complete response (CR) rate at 6 months as defined by mandatory biopsy with a null hypothesis of 30% and alternative of 50% with a 1-sided alpha = 0.05 and 96% power. The 3 month CR rate, defined by cytology, cystoscopy and for-cause biopsy, is reported here as a secondary endpoint, in addition to safety. **Results:** Seventy-five eligible CIS patients were enrolled. Two received no treatment and are not evaluable. Of 73, median patient age was 73.4 years and median number of prior BCG doses was 12. Concomitant Ta/T1 tumor was found in 30 (41.1%) patients, including T1 disease in 16 (21.9%). A CR was observed in 30 (41.1%; 95% CI 29.7%, 53.2%) patients at 3 months and 19 (26.0%; 95% CI 16.5%, 37.6%) at 6 months. Any possibly or probably treatment-related adverse event (AE) was observed in 61 (83.6%) patients. The most frequent AEs were fatigue 36 (49.3%), pruritis 8 (11.0%), hypothyroidism 8 (11.0%), and nausea 8 (11.0%). Grade 3-5 AEs occurred in 9 (12.3%) patients and there was one treatment-related death (myasthenia gravis with respiratory failure and sepsis). **Conclusion:** The observed response to atezolizumab at 3 and 6 months in patients with BCG-unresponsive CIS was similar to that reported in recent similar trials and meets the benchmark for initial CR defined by the FDA guidance. This trial provided no new safety concerns. The duration of response will determine if this is a suitable treatment option for patients with BCG-unresponsive high risk CIS. Clinical trial information: 02844816. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Evaluation of predictive biomarkers for nivolumab in patients (pts) with metastatic clear cell renal cell carcinoma (mccRCC) from the CheckMate-025 (CM-025) trial. *First Author: Miriam Fícial, Brigham and Women's Hospital, Boston, MA*

Background: We previously showed that levels of CD8+ tumor infiltrating cells (TIC) expressing PD-1 but not TIM-3 and LAG-3 ($CD8^+$ $PD1^+TIM3^-LAG3^-$) were associated with response to nivolumab (nivo) in pretreated mccRCC pts (Pignon et al, 2019). Here, we sought to validate these findings in a randomized Phase III trial of nivo versus everolimus (evero) (CM-025) and explore the association of the biomarker with transcriptomic profiles. **Methods:** Tumor tissues from the CM-025 trial were analyzed (nivo arm: n = 116, evero arm: n = 107). Density/percentage of $CD8^+$ $PD1^+TIM3^-LAG3^-$ TIC was evaluated by immunofluorescence (IF) and PD-L1 expression on tumor cells (TC) was evaluated by IHC. Linear association with outcomes was assessed using binary logistic (ORR, clinical benefit (CB) defined as CR/PR and PFS≥12 months) and Cox PH (PFS, OS) regression models (1-sided p-values shown). Bulk RNA-seq was performed in a subset of samples (n = 71) and data analyzed using ssGSEA and Gene Signature Scores (GSS). **Results:** In the nivo arm, density of $CD8^+$ $PD1^+TIM3^-LAG3^-$ TIC (IF biomarker) was associated with ORR (OR = 1.43, p = 0.03) and CB (OR = 1.54, p = 0.02) while a trend was observed with PFS (HR = 0.87, p = 0.06). At an optimized cutoff, nivo treated pts with high IF biomarker (24/116, 20.7%) had higher ORR (45.8% vs 19.6%, p = 0.01) and CB (33.3% vs 14.1%, p = 0.03) and longer median PFS (9.6 vs 3.7 months, p = 0.03) than pts with low IF biomarker. A significant interaction between the IF biomarker and treatment was seen for both PFS and OS (2-sided p = 0.02 and 2-sided p = 0.08, respectively; significance determined as $p < 0.15$). By bulk RNA-seq, several inflammatory pathways (FDR $q < 0.1$) and inflammatory GSS (FDR $q < 0.05$) were enriched in the high IF biomarker group. When combined with the IF biomarker, TC PD-L1 expression (≥1%) further separated clinical outcomes (ORR, CB and PFS) in the nivo arm. In the evero arm, the IF biomarker was neither prognostic nor predictive of any clinical outcome. **Conclusions:** High levels of $CD8^+$ $PD1^+TIM3^-LAG3^-$ TIC predicted response to nivo (but not to control evero) in mccRCC pts and were associated with activation of inflammatory response. Combination with TC PD-L1 further improved its predictive value, confirming our previous findings (Pignon et al, 2019). Further validation in the setting of first-line anti-PD-1 therapy is ongoing. Research Sponsor: Department of Defense (CDMRP), Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

Association of gene expression with clinical outcomes in patients with renal cell carcinoma treated with pembrolizumab in KEYNOTE-427. *First Author: David F. McDermott, Dana-Farber Cancer Center, Harvard Medical School, Boston, MA*

Background: We assessed the association of baseline RNA-sequencing–based gene expression signatures and DNA alterations with response or resistance to pembrolizumab in patients with advanced renal cell carcinoma in cohorts A (clear cell; n = 110) and B (non-clear cell; n = 165) of the phase 2 KEYNOTE-427 study (NCT02853344). **Methods:** Using RNA-sequencing, we analyzed the association of gene expression signatures (18-gene T-cell–inflamed gene expression profile [GEP]; 10 non–T-cell–inflamed GEP canonical signatures [angiogenesis, gMDSC, glycolysis, hypoxia, mMDSC, MYC, proliferation, RAS, stromal/EMT/TGFβ, WNT]) quantifying tumor microenvironment elements (TME) with objective response rate (ORR) and progression-free survival (PFS). Canonical signatures were derived from 2 databases (TCGA, Moffit) using an algorithm that included genes based on their correlation to reference signatures in the literature. Signature definitions were finalized before linking to the clinical data, and significance was prespecified at 0.10 given the potential for limited power. Canonical signatures were analyzed through regression testing of response for association with consensus signatures after adjusting for T-cell–inflamed GEP and International Metastatic RCC Database Consortium scores in the model. *P* values were adjusted for multiplicity. Using whole exome sequencing, we also summarized the association of renal cell carcinoma driver gene mutations with ORR. Clinical data cutoff: Jan 30, 2019. **Results:** Patient characteristics for this analysis were comparable to the overall population. In cohort A, T-cell–inflamed GEP (n = 78) was statistically significantly associated with a better ORR ($P = 0.021$; AUROC = 0.65) but not PFS ($P = 0.116$). No other TME canonical signatures showed a correlation with ORR or PFS. ORR was estimated for mutations (Table). **Conclusions:** RNA-sequencing–based, T-cell–inflamed GEP was associated with ORR in patients with clear cell renal cell carcinoma receiving first-line pembrolizumab. Precision was limited by sample size for estimating ORR by specific gene mutation status. Evaluation of tissue-based biomarkers in larger studies are planned. Biomarker analyses from patients in cohort B will also be presented. Clinical trial information: NCT02853344. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5025 Poster Session (Board #94), Fri, 8:00 AM-11:00 AM

CD68+ tumor-associated myeloid cells as the target of adenosine-induced gene products and predictor of response to adenosine blockade with ciforadenant (cifo) in renal cell cancer (RCC). *First Author: Martin H Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Adenosine in the tumor microenvironment (TME) is immunosuppressive and may play a role in resistance to immunotherapy. We described an adenosine induced gene expression signature (AS, Fong, Cancer Disc 2020) that correlates with response to therapy with cifo, an adenosine A2A receptor antagonist, as monotherapy or in combination with atezolizumab in refractory RCC. These genes express chemokines that signal through CCR2 and CXCR2 to recruit myeloid cells including immunosuppressive tumor associated-M2 macrophages, which are thought to mediate resistance to anti-PD(L)1 treatment. We now identify tumor infiltrating $CD68^+$ myeloid cells as the effector cell for adenosine mediated immunosuppression. **Methods:** 82 RCC pts have been treated in an ongoing Phase 1/1b trial evaluating cifo (100mg po bid) monotherapy or combination with atezolizumab (840mg IV q 2 weeks). Tumor biopsies, obtained at screening and on therapy, are available for analysis in 32 pts to date. RNA expression was measured in tumors using Nanostring. Immunohistochemistry (IHC) for CD68 was performed on biopsies with CD68+ tumors defined as $>$ 4% tumor area containing CD68+ cells. **Results:** Pt characteristics are median age 63; median prior therapies 3, with 72% failing prior anti-PD(L)1. Gene expression of M2 markers consisting of CD68 ($p = 0.0008$) and CD163 ($p = 0.03$) was higher in baseline samples from AS+ compared to AS- pts. By IHC, 10 pts had CD68+ cells infiltrating the tumor; 9 of 10 AS+. Tumor regression was observed in 6 of 10 CD68+ pts (N = 3 monotherapy and 3 combination) including 4 partial responses (PR, RECIST). No PRs and 2 minor responses were seen in 22 pts who were CD68- ($p < 0.005$). Median time to progression was not reached for CD68+ vs 2 mo for CD68-. Paired biopsies showed a significant reduction in infiltrating CD68+ cells ($p = 0.03$) with treatment including 2 of 2 evaluable PRs. **Conclusions:** Adenosine immunosuppression is mediated by M2 macrophages, which can be reversed by cifo. Enumerating tumor infiltrating CD68+ cells may be a valuable biomarker for identifying pts that will respond to adenosine blockade. Clinical trial information: NCT02655822. Research Sponsor: Corvus Pharmaceuticals.

Clinical outcomes and economic burden for bladder cancer patients: An analysis from a Swedish cancer registry. *First Author: Joaquim Bellmunt, Beth Israel Deaconess Medical Center, Boston, MA*

Background: To investigate the clinical and economic disease burden for patients (pts) with non-muscle invasive bladder cancer (NMIBC), muscle invasive bladder cancer (MIBC), and metastatic urothelial carcinoma (mUC) using a Swedish bladder cancer registry. **Methods:** Pts diagnosed with bladder cancer in the Stockholm Gotland region between 2005-2013 were included and followed until May 31, 2015 or until death. MIBC was classified if a T, N, M at diagnosis was T2, T3, T4, N1, N2, N3, or M1, otherwise pts were classified as NMIBC. All diagnostic and therapeutic interventions were captured and differentiated. Inpatient and outpatient healthcare resource utilization (days) and associated costs (US $) were also analyzed. **Results:** 3587 bladder cancer pts were identified (NMIBC-2728; MIBC-859) with a median observation time of 49.7 (Q1-Q3: 27.8-78.7) versus 17.2 (Q1-Q3: 6.5-39.3) months. 5-year survival for patients with NMIBC at diagnosis was 71.3% (95% CI; 69.5-73.3) and 26.4% (95%CI; 23.4-29.8) for MIBC. By year 1, survival for MIBC-T2, T3, and T4 was 66%, 41.7%, and 28.4%, respectively. Progression from NMIBC to MIBC was estimated in 19.4% (528/2728) of pts. In year 1, 84% (2,275/2,728) of TURBT procedures were performed on NMIBC pts. Over the next 2-10 years of follow-up, 11,035 repeat TURBT procedures were undertaken in this cohort. In the 859 MIBC pts, 607 TURBT procedures and 333 radical cystectomies occurred in year 1. In the same cohort, 28.3% (243/859), 15.5% (78/505), and 8.6% (29/338) received systemic chemotherapy in years 1, 2, and 3, respectively. Total health resource utilization (HRU) cost for the NMIBC and MIBC cohorts is provided in Table. Median HRU cost per person-year was estimated at $30,470 for MIBC versus $9,228 for NMIBC in year 1. For MIBC-T2, T3, and T4, median cost per person-year was $30,154, $33,917, and $38,959 in year 1, respectively. **Conclusions:** This retrospective analysis accomplished its primary purpose to provide a real-world understanding for the clinical and economic impact of bladder cancer over a 10-year period when treatment interventions were relatively consistent. Total HRU Costs for Patients with NMIBC and MIBC per Follow-up Year (Years 1 to 5). Research Sponsor: Janssen.

Diagnosis	Follow-up year	No. of Patients	Person-Years	Total HRU Costs (US $)
NMIBC	1	2,728	2,632	34,811,317
	2	2,531	2,393	14,867,314
	3	2,200	1,972	10,188,457
	4	1,765	1,574	7,323,923
	5	1,399	1,252	5,152,229
MIBC	1	859	666	21,083,790
	2	505	418	4,598,487
	3	338	280	2,082,339
	4	237	203	1,227,474
	5	178	156	693,829

5027 Poster Session (Board #96), Fri, 8:00 AM-11:00 AM

Early results of TROPHY-U-01 Cohort 2: Sacituzumab govitecan (SG) in platinum-ineligible patients (pts) with metastatic urothelial cancer (mUC) who progressed after prior checkpoint inhibitor (CPI) therapy. *First Author: Daniel Peter Petrylak, Yale University School of Medicine, New Haven, CT*

Background: SG is an antibody-drug conjugate consisting of a humanized monoclonal anti–Trop-2 antibody coupled to the cytotoxic agent, SN-38, via a unique hydrolyzable linker. The epithelial cell surface antigen, Trop-2, demonstrates greater expression between UC vs normal tissue, and is a promising target. In a phase 1/2 basket study (IMMU-132-01), SG showed an overall response rate (ORR) of 31% and manageable toxicity in 45 pts with mUC who had a median of 2 (range 1–6) prior therapy lines (Tagawa 2019 ASCO GU). Recent interim results for cohort 1 of the TROPHY-U-01 study in 35 pts with mUC who progressed on platinum and CPI therapy demonstrated an ORR of 29% in pts with a median of 3 prior treatment lines (range 2–6) (Tagawa 2019 ESMO). The most common grade $\geq$3 treatment-related AE (TRAE) was neutropenia. **Methods:** TROPHY-U-01 (NCT03547973) is a global, open-label, phase 2 trial evaluating the antitumor activity of SG (10 mg/kg, days 1 and 8 of 21-day cycles) in pts with advanced UC with measurable disease and ECOG PS 0 or 1. Cohort 2 includes platinum-ineligible pts who progressed after CPI therapy in the first-line metastatic setting. The primary objective is ORR evaluated with RECISTv1.1 by central review. Secondary objectives include progression-free survival, overall survival, and duration of response. **Results:** 18 pts with baseline tumor assessment (50% male; median age 79 y [range 57–87], 67% visceral metastases; 28% liver metastases) received a median of 2 (range 1–5) prior therapies. At a median follow-up of 6 months, ORR was 28% (5/18) with 4 confirmed PRs, and 1 PR pending confirmation. The majority of pts (61% [11/18]) had target lesion reduction. The safety profile was consistent with prior reports. Key grade $\geq$3 TRAEs were neutropenia (39%), fatigue (33%), diarrhea (28%), leukopenia (22%), anemia (17%), and febrile neutropenia (11%). No events of interstitial lung disease, ocular toxicities, or grade $>$ 2 neuropathy were reported. There were no treatment-related deaths. **Conclusions:** In cisplatin-ineligible pts, the ORR for currently approved first-line CPI treatments is ~23–29% (Balar 2017 *Lancet;* Vuky 2018 ASCO). These preliminary data with SG show a manageable safety profile with an encouraging ORR of 28% and support the development of SG in platinum-ineligible pts with mUC who have progressed after CPI therapy. Clinical trial information: NCT03547973. Research Sponsor: Immunomedics, Inc.

5028 Poster Session (Board #97), Fri, 8:00 AM-11:00 AM

Association of molecular subtypes with pathologic response in a phase II study of co-expression extrapolation (COXEN) with neoadjuvant chemotherapy (NAC) for localized, muscle-invasive bladder cancer (SWOG S1314; NCT02177695). *First Author: Seth P. Lerner, Baylor College of Medicine, Houston, TX*

Background: Cisplatin-based NAC is recommended for patients with MIBC prior to radical cystectomy (RC) but the majority will not have a pathologic response. To identify responders the COXEN gene expression model with chemotherapy-specific scores (for DD-MVAC and GC) was developed and in a prospective rPII clinical trial (SWOG S1314) the GC score was associated with path downstaging in the pooled arms. We investigated RNA based molecular subtypes as additional predictive biomarkers for response to NAC in patients treated in S1314. **Methods:** Eligibility required cT2-T4a N0 M0, predominant urothelial, $>$ 5 mm tumor, cisplatin eligible, and plan for RC and PLND. 237 patients were randomized between 4 cycles of ddMVAC and GC. Based on Affymetrix transcriptomic data used to assign COXEN scores, we determined subtypes using 3 classifiers: TCGA (k=5), Consensus (k=6), and MD Anderson (MDA; k=3). Primary objective was to assess subtype association with pathologic response to NAC in the pooled arms and to determine any association with COXEN. TCGA and Consensus classifiers were collapsed into 3 groups for ROC analyses. We tested whether each classifier contributed additional predictive power when added to a model based on pre-defined stratification factors (PS 0 vs. 1; T2 vs. T3, T4a). **Results:** 161 patients had adequate tissue and gene expression results, received at least 3 of 4 cycles of NAC and had pT-N response based on RC. Covariates were 78% PS=0, 89% T2, 84% male, median age 65, 51% randomized to ddMVAC, 49% GC with 33% pT0 and 52% downstaging. Although the TCGA 3 group classifier (Basal-Squamous (BS)/Neuronal, Luminal, Luminal infiltrated) and GC Coxen score yielded the largest AUCs (0.607, 0.610) for pT0 response, neither reached statistical significance ($p=0.20$, $p=0.22$). For downstaging ($<$pT2), the 3 category Consensus classifier (BS/NE-like, Luminal, Stroma-rich) significantly increased the AUC from 0.568 (strat factors alone) to 0.620 ($p=0.044$). The MDA classifier AUC was 0.640 and the GC Coxen score AUC was 0.626, but neither were significant ($p=0.076$, $p=0.14$. The MVAC Coxen score did not improve the AUC beyond the stratification factors. **Conclusions:** The Consensus classifier, which is based in part on the TCGA and MDA classifiers, modestly improved prediction for pathologic downstaging when added to clinical stage and PS. With additional followup, we will assess the association of COXEN scores and subtypes with overall survival. Clinical trial information: NCT02177695. Research Sponsor: U.S. National Institutes of Health.

5029 Poster Session (Board #98), Fri, 8:00 AM-11:00 AM

Outcomes and the impact of genomic characteristics on patients with metastatic urothelial carcinoma enrolled in early phase trials. *First Author: Omar Alhalabi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: With the recent approvals of checkpoint inhibitors (CPIs), a fibroblast growth factor receptor (FGFR) inhibitor, and an antibody-drug conjugate, patients with platinum-refractory metastatic urothelial carcinoma (mUC) have several treatment options available. However, many patients with platinum-refractory mUC need novel therapies after progressing on current therapies. We assessed the role of early phase trials in treatment of mUC and the impact of genomic alterations on their outcomes. **Methods:** We retrospectively analyzed medical records of patients with mUC who received an investigational therapy at the phase 1 clinic and had CLIA-certified clinical next generation sequencing. Clinical parameters and mutations were abstracted. Progression-free survival (PFS) and overall survival (OS) were calculated using Kaplan-Meier methods. Hazard ratios (HR) were calculated using the Cox proportional hazard model. **Results:** Among the 57 pts enrolled in 41 unique phase 1 trials between 2015 and 2019, 16% (9/57) had variant histology: neuroendocrine carcinoma (n = 3) and urachal carcinoma (n = 6). Median age was 64. Majority were males (72%). 97% received prior platinum therapy and 60% had received prior CPI therapy. Across the pure urothelial carcinoma cohort (n = 48), median PFS was 4.2 months (m), median OS was 9.8 m, and the overall response rate (ORR) was 19%. *TP53, FGFR, TERT, and ARID1A* alterations (alt) were detected in 54%, 41%, 21% and 17% of UC patients, respectively. Patients harboring a *TP53* alt, compared to no alt, had a shorter median PFS of 3.2m vs 9.6 m (HR = 2.738 [1.247 - 6.011], p = 0.0121). On the contrary, median PFS was longer in *FGFR* alt, compared to no alt, 6.3m vs 3.2m (HR = 0.4662 [0.224 - 0.971], p = 0.0415). Of note, 64% of FGFR alt patients were treated under an early phase FGFR targeting trial. Median OS was numerically longer in *FGFR* alt and shorter in *TP53* alt but did not reach statistical significance (table). **Conclusions:** Patients with mUC may derive clinical benefit from enrollment in phase I clinical trials. Patients with TP53 alterations had numerically worse outcomes. Patients with mUC should be considered for an FGFR targeting therapy in the setting of an FGFR alteration. Research Sponsor: None.

	UC	*TP53* alteration vs. no alteration	*FGFR* alteration vs. no alteration
PFS	4.2 m	3.2 m vs 9.6 m	6.3 m vs 3.2 m
HR for PFS (95% Confidence Interval)	--	2.74 (1.25 - 6.01) p = 0.01	0.4662 (0.224 - 0.971) p = 0.0415
OS	9.8 m	5.9 m vs 16.5 m	16.5 m vs 5.3 m
HR for OS (95% Confidence Interval)	--	1.52 (0.73 - 3.15) p = 0.26	0.55 (0.26 - 1.17) p = 0.12

5030 Poster Session (Board #99), Fri, 8:00 AM-11:00 AM

Pathological response rates and quality of life outcomes of neoadjuvant cabazitaxel and cisplatin chemotherapy for muscle-invasive transitional cell carcinoma of the urinary bladder. *First Author: Amarnath Challapalli, University Hospital Bristol NHS Foundation Trust, Bristol, United Kingdom*

Background: Neoadjuvant cisplatin-based combination chemotherapy (NAC) improves survival in muscle invasive bladder cancer (MIBC). However, response rates and survival remain suboptimal. We sought to evaluate the efficacy, safety and tolerability of cisplatin cabazitaxel combination in this patient group. **Methods:** A phase 2 single arm trial (Simon 2 stage), to recruit at least 26 evaluable patients was designed with 80% power to detect the primary endpoint, objective response rate (ORR) of $>$ 35%. ORR was defined as pathological complete response (pCR) plus partial response (pathological downstaging), measured by pathologic staging (T2 or greater at diagnosis, to T1 or less at radical cystectomy). Treatment was with Cisplatin 70mg/m2 and Cabazitaxel 15mg/m2 on day 1 of a 21 day cycle, for 4 cycles prior to surgery. Toxicity was recorded using CTCAE v.4.03. Quality of Life (QoL) data were collected at baseline, prior to each cycle of chemotherapy and at 3-5 weeks after 4th cycle of chemotherapy using EQ-5D and EORTC QLQ-C30, BLM30 questionnaires. **Results:** Objective response was seen in 15 out of 26 evaluable patients, 57.7% and over a third of patients achieved pCR (9/26; 34.6%). 78% (21/27) of patients completed all cycles of treatment, with only 6.7% of the reported adverse events (AEs) being graded 3 or 4. There were 6 treatment related SAEs reported but no SUSARs. In patients who achieved objective response the median progression free (PFS) and overall survival (OS) were not reached (median follow up: 41.5m). In contrast, median PFS (7.2m) and OS (16.9m) were significantly worse (p = 0.001) in patients who did not respond. Response rates for EORTC QLQ-C30, BLM 30 and EQ5D questionnaires was 70.4, 70.4 & 63% respectively, at end of treatment. There was no significant difference in EORTC QLQ C30 summary, global health scores and EQ5D score with treatment. There was a significant decline in mean QLQ C30 domain scores after 1st cycle compared to baseline, but no further deterioration with subsequent cycles of chemotherapy. **Conclusions:** Cabazitaxel with cisplatin as NAC of MIBC can be considered a safe, well-tolerated and effective regimen with higher pCR rate of 34.6%. This compares favorably to that with Cisplatin/Gemcitabine (23-26%). Minimal changes in Global Health & EQ5D observed during NAC further demonstrates the excellent tolerability of this regimen and to our knowledge are the first data regarding QoL in NAC in MIBC. These results warrant further evaluation in a larger phase 3 study. Clinical trial information: 2011 004090 82. Research Sponsor: Sanofi.

5031 Poster Session (Board #100), Fri, 8:00 AM-11:00 AM

Assessing the potential cost-effectiveness of the addition of atezolizumab to first-line platinum chemotherapy in advanced urothelial cancer: Implications for value-based pricing. *First Author: Ali Raza Khaki, University of Washington, Seattle, WA*

Background: Data from interim analysis of IMvigor130 trial showed that 1st line treatment of advanced urothelial cancer (aUC) with atezolizumab (Atezo) + platinum-based chemotherapy (PBC) significantly improved progression-free survival (PFS), but not overall survival (OS), vs PBC. Switch maintenance anti-PD(L)1 after completion of PBC as 1st line therapy is an alternate strategy, recently reported to significantly prolong OS. We aimed to compare cost-effectiveness of combined treatment (Atezo+PBC) vs PBC based on IMvigor130. **Methods:** We used a partitioned-survival model to evaluate the potential cost-effectiveness of treatment with A) Atezo+PBC (gemcitabine with cisplatin or carboplatin) or B) PBC alone with checkpoint inhibitor pembrolizumab at progression (standard-of-care). PFS and OS curves were extracted from IMvigor 130 and parametric models were fit to approximate outcomes with Atezo+PBC with the hazard ratio (HR) from the trial used to project outcomes for PBC alone. We used a health-care payer perspective with a two-year time horizon. Model outputs — costs, life-years, quality-adjusted life years (QALYs) — were used to calculate an incremental cost-effectiveness ratio (ICER). A scenario analysis evaluated the "value-based price" needed for Atezo+PBC to be cost-effective; a one-way sensitivity analysis was also performed. **Results:** Results of the cost-effectiveness analysis are summarized in the table. The mean projected incremental cost of Atezo+PBC compared to PBC was $59,604 for a mean incremental gain of 0.09 life-years and 0.07 QALYs. This resulted in an ICER of $629,755/life-year and $895,800/QALY, respectively. A 33% reduction would be needed in the price of atezolizumab to make Atezo+PBC cost-effective at an ICER of $150,000/QALY. Results were sensitive to cost of pembrolizumab at progression, the cost of Atezo+PBC, and the OS HR between Atezo+PBC and PBC. **Conclusions:** Combined chemoimmunotherapy with atezolizumab and PBC would likely not be cost-effective for the first-line treatment of aUC. However, with a price rebate of 33%, it would approach being cost-effective at a widely used cost-effectiveness threshold. Research Sponsor: U.S. National Institutes of Health.

	PBC	Atezo + PBC	Incremental Results
Costs per person	$92,135	$151,738	$59,604
Life-Years per person	1.27	1.37	0.09
QALYs per person	1.01	1.07	0.07
ICER	QALYs	Life-Years $895,800	$629,755

5032 Poster Session (Board #101), Fri, 8:00 AM-11:00 AM

Comparative effectiveness of second-line (2L) single-agent atezolizumab (A), nivolumab (N), and pembrolizumab (P) in patients (Pts) with locally advanced or metastatic urothelial cancer (aUC) who progressed on platinum-based systemic chemotherapy (plat-chemo): Results from a real-world dataset. *First Author: Umang Swami, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Five PD-1/L1 inhibitors (PDi) are approved for 2L therapy (Rx) for aUC after progression on plat-chemo, but none compared with each other in randomized trials. Here, we assessed comparative effectiveness of 2L PDi in real-world setting. **Methods:** Pt level data of Pts with aUC were extracted from Flatiron Health EHR-derived de-identified database. Inclusion criteria: 1L Rx with plat-chemo; receipt of single agent PDi in 2L; initiation of 2L PDi 6 mos before data-cut off. Exclusion criteria: $>$90 days from diagnosis to date of next visit to ensure active engagement of Pts with data providing site; initiation of 2L after 7/31/2016 to ensure uptake of PDi for aUC. OS was compared from the date of initiation of 2L Rx. Comparative effectiveness was examined by Cox proportional hazards model, stratified by treatment propensity score. Each Pts' propensity of receiving each 2L PDi was modeled via a random forest based on Pt and disease characteristics potentially driving Rx selection for a PDi (gender, smoking status, race/ethnicity, relapsed vs de novo disease, time between 1L & 2L Rx, cis vs carboplatin in 1L; year of Rx with PDi & following characteristics before 2L Rx: ECOG, Hb, age, ICD codes for liver or CNS mets, albumin & PD-L1 status when available). **Results:** 703 Pts with aUC who initiated 2L Rx between 8/1/2016 to 10/31/2019 were eligible. 2L Rx were A (n=322), N (n=127) & P (n=254). Durvalumab & avelumab were excluded due to low utilization in this dataset. Median follow up from 2L initiation was 4.8 mos. Median OS (mos; 95% CI) with A (6.4 mos; 5-8.7), N (8 mos; 6.3-11.3) and P (8.5 mos; 6.1-11.6) were similar (propensity stratified log rank p=0.19; simple log-rank p=0.34). Over time proportion of Pts receiving 2L A decreased, P increased & N increased then decreased ($p<0.001$). Propensity stratified comparative effectiveness estimates are below. **Conclusions:** In this real-world cohort of Pts with aUC, OS with 2L Rx with A, N, & P were similar on both univariate and propensity stratified analyses. These results agree with prior trial level meta-analysis (PMID 31200951). Strength of this analysis includes large Pt level data from a real world cohort. Limitations include retrospective nature of this study. Research Sponsor: None.

Propensity stratified pairwise comparative effectiveness estimates.

2L	Hazard ratio	95% CI	p value
N vs A	0.82	0.63-1.08	0.16
P vs A	0.82	0.64-1.05	0.11
P vs N	1.00	0.74-1.34	0.99

Early response marker during pembrolizumab treatment in metastatic urothelial cancer: Temporal shift in peripheral CD4 T cells expressing chemokine receptors. *First Author: Maud Rijnders, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, Netherlands*

Background: Approval of PD1 blockade greatly improved treatment possibilities for patients with platinum-resistant metastatic urothelial cancer (mUC), however the current response rate for pembrolizumab is less than 25%. Since PD-L1 expression does not have predictive value in this setting, the aim of this study was to identify new markers to improve patient selection. **Methods:** Between Sept 2017 and Jan 2020, 84 mUC patients received pembrolizumab in a prospective biomarker discovery study (NCT03263039). Peripheral blood samples (n = 22) taken prior to and at 6 and 12 weeks after start of treatment were analyzed for frequencies of CD4 and CD8 T cells expressing co-inhibitory, co-stimulatory and chemokine receptors using multiplex flow cytometry. Plasma chemokine levels were determined using ELISA (n = 38), and fresh tumor biopsies obtained prior to and during treatment (n = 26) were analyzed for densities and phenotypes of T cells using multiplex immunofluorescence staining. T cell receptor clonality was analyzed in peripheral blood (n = 10) and tumor biopsies (n = 6) using RNA sequencing. Patients were classified as responder (complete or partial response) or non-responder (progressive disease) according to RECIST v1.1 after 12 weeks of treatment. **Results:** Longitudinal sampling revealed that upon treatment the frequency of CXCR3+ CD4 T cells decreased in responders, whereas the frequency of CXCR3+ CCR1+ CD4 T cells drastically increased in non-responders. Before treatment, the frequency of CD4 T cells co-expressing CXCR3 and CCR1 was already decreased in responders. Notably, in responders, the treatment-related decrease in frequency of CD4 T cells expressing chemokine receptors was accompanied by a decrease in the frequency of CD4 T cells expressing the co-inhibitory receptor PD1, whereas an increase in the frequency of CD4 T cells expressing the co-stimulatory receptor 4-1BB was observed. These findings will be complemented with chemokine levels in plasma, contexture of T cells in tumor biopsies, and T cell receptor clonality analysis. **Conclusions:** mUC patients responding to pembrolizumab treatment demonstrated an on-treatment decrease in frequency of CD4 T cells expressing chemokine receptors that is accompanied by a changed frequency of co-signaling receptor expressing CD4 T cells. These data show that dynamic immune phenotyping can distinguish effective from less effective immune activation by pembrolizumab, and may provide early markers for benefit from PD1 blockade in mUC patients. Research Sponsor: Merck Sharp & Dohme.

5034 Poster Session (Board #103), Fri, 8:00 AM-11:00 AM

First-line pembrolizumab (pembro) monotherapy in advanced non-clear cell renal cell carcinoma (nccRCC): Updated follow-up for KEYNOTE-427 cohort B. *First Author: Jae-Lyun Lee, Asan Medical Center and University of Ulsan College of Medicine, Seoul, South Korea*

Background: KEYNOTE-427 (NCT02853344), a single-arm, open-label, phase 2 study, showed antitumor activity with first-line pembro monotherapy in nccRCC (cohort B). Studies of RCC and immune-oncology have shown that depth of tumor response may correlate with long-term benefit. We present the association between depth of response and OS plus updated efficacy and safety data in cohort B. **Methods:** Pts with histologically confirmed nccRCC, who did not receive prior systemic therapy, and who have measurable disease (RECIST v1.1) received pembro 200 mg IV Q3W for 2 y or until progressive disease, unacceptable toxicity, or withdrawal. End points were ORR (primary), DOR, and PFS (RECIST v1.1); OS; and safety. Association between depth of response, defined as maximum reduction from baseline in sum of target lesions, and OS was evaluated using a Cox proportional hazards model with target lesion reduction group as time-varying covariate. **Results:** Of 165 pts, 72% had papillary histology, 13% had chromophobe histology, and 16% were unclassified. Median time from enrollment to data cutoff was 18.7 mo (range, 9.9-26.0). ORR was 26.1% (95% CI, 19.5-33.5; 10 CRs, 33 PRs). Median (range) DOR was 15.3 mo (2.8-21.0+); 57.3% had DOR ≥12 mo. At 18-mo, PFS rate was 18.9% and OS rate was 67.0%. Most pts (58.8%) had some reduction in target lesions. Pts with a > 30% reduction in target lesions had an increased probability of survival (Table). ORR (95% CI) was similar for papillary (28.0% [20.1-37.0]) and unclassified (30.8% [14.3-51.8]) histology but lower for chromophobe (9.5% [1.2-30.4]). OS rates at 18 mo were 70.8%, 66.7%, and 50.0 in the papillary, chromophobe, and unclassified groups, respectively. Treatment-related AEs (TRAEs) occurred in 67.9% of all pts, primarily pruritus (19%), hypothyroidism (14%), and fatigue (14%). Grade 3-5 TRAEs occurred in 14% of pts; 2 pts died of TRAEs (pneumonia and cardiac arrest). **Conclusions:** First-line pembro monotherapy continued to show antitumor activity in nccRCC with no new safety concerns. In general, for pts who had greater reductions in target lesions, the trend was toward improved OS; pts with reduction of tumor burden ≥80% had comparable long term outcomes to those who achieved a RECIST 1.1 defined CR. Clinical trial information: NCT02853344. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Atezolizumab (atezo) therapy for locally advanced/metastatic urinary tract carcinoma (mUTC) in patients (pts) with poor performance status (PS): Analysis of the prospective global SAUL study. *First Author: Daniel Castellano, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Pts with PS > 1 have a poor prognosis and are often excluded from clinical trials. The single-arm SAUL study (NCT02928406) evaluated atezo in a 'real-world' population. Overall, safety and efficacy were consistent with prior trials. However, ECOG PS 2 pts had worse overall survival (OS) but fewer adverse events (AEs) than ECOG PS 0/1 pts [Sternberg, 2019], likely reflecting shorter treatment duration and warranting exploration. **Methods:** Pts with mUTC received atezo 1200 mg q3w until loss of clinical benefit or unacceptable toxicity. The primary endpoint was safety. Post hoc analyses compared baseline factors, AEs and efficacy in pts with ECOG PS 2 vs 0/1. In this analysis, AE incidences were restricted to the first 45 days of atezo to adjust for differing treatment exposure. **Results:** None of the baseline factors explored was significantly associated with worse OS or disease control rate (DCR) in ECOG PS 2 pts. However, pts with visceral metastases and ECOG PS 2 had particularly poor outcomes. Safety appeared similar between subgroups. **Conclusions:** ECOG PS 2 pts have a dismal prognosis. The higher proportion with poor prognostic factors despite similar age in ECOG PS 2 vs 0/1 pts may suggest that poor PS was related to disease rather than comorbidities. Risk/benefit should be considered especially carefully when treating pts with ECOG PS 2 due to high-burden/visceral disease. Clinical trial information: NCT02928406. Research Sponsor: F Hoffmann-La Roche Ltd, Basel, Switzerland.

5036 Poster Session (Board #105), Fri, 8:00 AM-11:00 AM

Impact of renal impairment on clinical outcomes in patients (pts) with locally advanced or metastatic (LA/M) urinary tract carcinoma (UTC) treated with atezolizumab (atezo): Analysis of the international SAUL study. *First Author: Margitta Retz, Rechts der Isar Medical Center, Technical University of Munich, Munich, Germany*

Background: Atezo, which targets PD-L1, is an approved therapy for LA/M urothelial carcinoma based on the IMvigor210 and IMvigor211 trials. The single-arm SAUL study (NCT02928406) showed consistent activity and safety in a broader population, including understudied scenarios, eg pts with renal impairment or other IMvigor211 exclusion criteria. **Methods:** Pts with LA/M UTC received atezo 1200 mg q3w until disease progression or unacceptable toxicity. The primary endpoint was safety; secondary endpoints included overall response rate (ORR) and overall survival (OS). Post hoc analyses explored outcomes in pts classified as: chemotherapy (CT) ineligible (calculated creatine clearance [CrCl] 15– < 30 mL/min); cisplatin ineligible and carboplatin eligible (CrCl 30– < 60 mL/min); or cisplatin eligible (CrCl ≥60 mL/min). **Results:** Of 1004 enrolled pts, 46 (5%) were classified as CT ineligible and 420 (42%) as cisplatin ineligible. Results are summarized below. **Conclusions:** These post hoc analyses suggest pts typically considered cisplatin or CT ineligible are candidates for atezo. Pts with renal impairment achieved similar ORR and DCR to pts with CrCl ≥60 mL/min, without increased toxicity. Imbalances in pt characteristics may explain numerical differences in OS. Clinical trial information: NCT02928406. Research Sponsor: F Hoffmann-La Roche Ltd, Basel, Switzerland.

5037 Poster Session (Board #106), Fri, 8:00 AM-11:00 AM

Phase I expansion study of cabozantinib plus nivolumab (CaboNivo) in metastatic urothelial carcinoma (mUC) patients (pts) with progressive disease following immune checkpoint inhibitor (ICI) therapy. *First Author: Daniel da Motta Girardi, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Previous treatment with ICI is more common in clinical practice since recent FDA-approval of 5 ICIs in second-line and 2 in first-line for mUC. There is lack of data regarding the use of ICI after progression on a prior ICI. Cabozantinib has been shown to have immunomodulatory properties and may have synergistic effect with ICI. **Methods:** This is a phase I expansion cohort of mUC pts, who received prior ICI, treated with Cabozantinib 40mg daily and Nivolumab 3mg/kg every 2 weeks until disease progression/unacceptable toxicity. The primary objective was to determine the efficacy and tolerability of CaboNivo. **Results:** Twenty-nine mUC pts were treated. Median follow-up was 14.1 months (mo). The majority of pts were male (75.8%); 27 were White (93.1%), and 2 were Asian (6.9%). Primary tumor was bladder in 21 pts (72.4%) and upper tract in 8 (27.6%). Twenty-two pts (75.9%) had visceral metastasis (mets), 4 (13.8%) had lymph node only mets and 13 (44.8%) had liver mets. The median number of prior lines of treatment for mUC was 2 (range 0-8) with 17 pts (58.6%) receiving 2 prior lines of treatment. The majority of pts (86.2%) received prior chemotherapy for mUC and all pts received prior ICI. The median number of cycles of prior ICI was 7 (range 1-20) and median time between previous ICI and CaboNivo was 2.5 mo (range 1-18). The best response to previous ICI was partial response (PR) in 1 pt (3.4%), stable disease (SD) in 13 (44.9%), progressive disease (PD) in 14 (48.3%) and one (3.4%) was not evaluable (NE). The overall response rate for CaboNivo was 13.8% with 4 pts achieving PR (13.8%), 15 SD (51.7%), 7 PD (24.2%) and 3 NE (10.3%). Responses were seen in the liver, lung, and lymph nodes. Among 4 pts with PR, 2 were primary refractory to previous ICI and 2 had SD. At cutoff date the median duration of response was not reached and 3 PR were still ongoing: 1 had just began and the other 2 were ongoing at 12.3 and 26.4 mo. Among 15 pts with SD, 4 had SD for more than 6 mo and 2 were still ongoing at 8.1 and 25.1 mo. Median progression-free survival was 3.6 mo (95% CI: 2.1 – 5.3 mo) and median overall survival was 10 mo (95% CI: 5.8 – 16.7 mo). Grade 1/ 2 treatment related adverse events (AEs) occurred in 28 pts (97%) and >Grade 3 (G>3) AEs occurred in 14 pts (48%). The most common G>3 AEs were fatigue (14%), hypophosphatemia (14%), lymphocyte count decrease (14%), hypertension (7%) and hyponatremia (7%). **Conclusions:** CaboNivo is clinically active and safe in heavily pretreated pts with progressive mUC following ICI. Clinical trial information: NCT02496208. Research Sponsor: U.S. National Institutes of Health.

5038 Poster Session (Board #107), Fri, 8:00 AM-11:00 AM

Infigratinib and treatment response in advanced/unresectable or metastatic urothelial carcinoma in first-line and later-line treatment settings. *First Author: Yung Lyou, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Infigratinib (BGJ398) is a potent and selective FGFR1–3 tyrosine kinase inhibitor (TKI), previously reported to be effective and well tolerated in patients with locally advanced/unresectable or metastatic urothelial carcinoma (mUC) bearing *FGFR3* alterations [Pal et al. Cancer Discovery 2018]. However, this previous study did not examine differences in infigratinib activity based on number of prior lines of treatment (LOT). TKIs studied in other indications (e.g. VEGFRis in renal cell carcinoma) have shown consistent activity in both the first and later LOT. Given the effect seen with other TKIs, we sought to determine if infigratinib showed consistent treatment responses in patients with mUC according to LOT. **Methods:** Eligible patients had mUC and prior platinum-based chemotherapy unless contraindicated and activating *FGFR3* mutations/ fusions. Infigratinib was dosed at 125 mg orally daily (3 weeks on/1 week off). The primary endpoint of objective response rate (ORR: partial response [PR] and complete response [CR]) was assessed, as well as disease control rate (DCR: CR + PR + stable disease [SD]). After classification of LOT for each patient, subgroup analysis of response by LOT was performed. **Results:** 67 patients were enrolled; 81% received ≥1 prior LOT for mUC. 13 patients (19.4%) received infigratinib as 1st LOT for mUC due to ineligibility to receive platinum-based chemotherapy. ORR for the 67 patients was 25% (95% CI 15.5–37.5) and DCR was 64% (95% CI 51.5–75.5). The ORR with 1st-line infigratinib was 31% (95% CI 9.1–61.4) compared with 24% (95% CI 13.5–37.6) for 2nd and later (salvage) LOT. DCR was 46% (95% CI 19.2–74.9) for 1st-line and 69% (95% CI 54.4–80.5) for ≥2 LOT. 13 of the 59 patients with urothelial bladder carcinoma (UBC) received 1st-line treatment with an ORR of 31% (95% CI 9.1–61.4) and 46 patients in ≥2 LOT had an ORR of 20% (95% CI 9.4–33.9). All 8 patients with upper tract urothelial carcinoma (UTUC) received salvage therapy, with an ORR of 50% and a DCR of 100%. An analysis of other outcome measures (e.g. PFS, OS) will be presented. **Conclusions:** These results indicate that infigratinib has activity in patients with mUC regardless of LOT. Additionally, patients with UTUC showed a trend for better ORR and DCR. Taken together, these results support the ongoing adjuvant PROOF 302 study comparing infigratinib with placebo in patients with resected disease, assessing infigratinib in an even earlier setting in a UTUC-enriched population (NCT04197986). Clinical trial information: NCT01004224. Research Sponsor: QED Therapeutics.

5039 Poster Session (Board #108), Fri, 8:00 AM-11:00 AM

Ipilimumab challenge/re-challenge in metastatic urothelial carcinoma (mUC) and other genitourinary (GU) tumors treated with cabozantinib+nivolumab (CaboNivo) or cabozantinib+nivolumab+ipilimumab (CaboNivoIpi). *First Author: Scot Anthony Niglio, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: We investigated challenging/re-challenging pts with ipilimumab (ipi) after progression on CaboNivo or CaboNivoIpi. **Methods:** In a phase I expansion study, patients with mUC post-platinum chemotherapy and other GU tumors patients who progressed on Cabo 40 mg daily plus nivolumab, 3 mg/kg every 21 days (CaboNivo) alone or with ipi, 1 mg/kg every 21 days for 4 cycles (CaboNivoIpi)-and achieved a PR or SD≥6 mo, were challenged/re-challenged with ipi, 1 mg/kg every 21 days for up to 4 cycles. Restaging scans were done every 6 wks for the first 12 wks, then every 8 wks and evaluated by RECIST 1.1. **Results:** In total, 24 patients were evaluated: 18 pts (8 UC (5 bladder and 3 upper tract), 4 clear cell renal cell carcinoma (RCC), 3 urachal adenocarcinoma (adeno), 2 bladder adeno, and 1 sarcomatoid clear cell RCC) who progressed on CaboNivo were challenged with ipi. In the challenge group, median (m) follow-up was 21.2 months. One pt achieved a PR in the LNs, but was found to have brain metastases before the next restaging, 13 had SD and 4 had PD. Median duration of PR or SD was 3.6 months (95% CI: 1.4 – 7.8 months). The mOS from start of ipi challenge was 13.9 months (95% CI: 5.8 months- not estimable); mPFS was 4.6 months (95% CI: 1.9 – 8.7 months). Grade 1/2 treatment related adverse events (AEs) occurred in all 18 pts (100%) and ≥Grade 3 (G≥3) AEs occurred in 11 pts (61%). The most common G≥3 AEs were hypophosphatemia (22%), hypertension (6%), adrenal insufficiency (6%), increased AST (6%), and ALT (6%). Six patients (3 bladder UC, 1 penile squamous cell (SCC) carcinoma, 1 urethral SCC, and 1 clear cell RCC with sarcomatoid features) who progressed on CaboNivoIpi were re-challenged with Ipi. On re-challenge, mfollow-up was 20.9 months. There were no PRs, 3 SDs and 3 PDs. mOS from start of re-challenge was 4.0 months (95% CI: 2.2 – 23.3 months) and mPFS was 1.9 months (95% CI: 1.1 – 2.6 months). Grade 1/2 treatment related AEs occurred in all 6 pts (100%) and ≥Grade 3 (G≥3) AEs occurred in 2pts (33%). G≥3 AEs included 1 hypertension (17%) and 1 hyperphosphatemia (17%). **Conclusions:** Ipi challenge/ re-challenge showed low response rates in pts previously treated with CaboNivo or CaboNivoIpi. However, pts treated with CaboNivo who were challenged with ipi had a better OS than patients who had progressed on CaboNivoIpi and were re-challenged with ipi. Larger trials are warranted testing the ipi challenge in pts progressing on CaboNivo. Clinical trial information: NCT02496208. Research Sponsor: U.S. National Institutes of Health.

5040 Poster Session (Board #109), Fri, 8:00 AM-11:00 AM

Recombinant humanized anti-PD-1 monoclonal antibody toripalimab in patients with metastatic urothelial carcinoma: Results of an open-label phase II clinical study Polaris-03. *First Author: Xinan Sheng, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Patients with advanced metastatic urothelial carcinoma (UC) who experience disease progression after standard therapy have limited treatment options. Phase I study of toripalimab in subjects with heavily pretreated metastatic UC had demonstrated an acceptable safety profile and promising clinical activity. Here we report the safety and efficacy result of toripalimab in a phase II clinical study (POLARIS-03) in Chinese patients with metastatic urothelial carcinoma. (Clinical trial ID: NCT03113266). **Methods:** Metastatic UC Patients receive toripalimab 3 mg/kg Q2W until disease progression, unacceptable toxicity or voluntary withdrawal. Clinical response is assessed every 8 weeks. Tumor PD-L1 expression and other biomarkers will be evaluated for correlation with clinical response. **Results:** From May 2017 to September 2019, 204 patients were screened and the study enrollment was completed with 151 patients enrolled from 15 participating centers. The median age was 62 years and 66% were male. 87% patients had visceral metastasis. By the cut-off date of Jan 6, 2020, 92.1% (139/151) patients experienced treatment related adverse event (TRAE) and grade 3 and above TRAE occurred in 35.8% (54/151) patients. Most common TRAE included anemia, triglycerides increased, proteinuria, fatigue, and hyperglycemia. Treatment discontinuation due to a TRAE occurred in 6 (4.0%) patients, while dose delay due to a TRAE occurred in 23 (15.2%) patients. Three patients with major protocol deviations were excluded from efficacy analysis. Among 148 patients assessed by IRC per RECISTv1.1, 2 CR, 36 PR, and 30 SD were observed for an ORR of 25.7% and a DCR of 45.9%. The median DOR was 15.7 months. The median PFS was 1.9 months, and the median OS was estimated 20.8 months. PD-L1 expression results were obtained from 141 patients. PD-L1+ patients (n=46) had significant better ORR than PD-L1- patients (n=95), 41.3% versus 16.8% ($p<0.01$). **Conclusions:** Toripalimab has demonstrated encouraging clinical activity in chemo-refractory UC patients with a manageable safety profile. Patients will be continuously monitored for safety and overall survival. Clinical trial information: NCT03113266. Research Sponsor: Shanghai Junshi Bioscience Co., LTD, Shanghai, China.

5041 Poster Session (Board #110), Fri, 8:00 AM-11:00 AM

Pembrolizumab (pembro) for the treatment of patients with Bacillus Calmette-Guérin (BCG) unresponsive, high-risk (HR) non–muscle-invasive bladder cancer (NMIBC): Over two years follow-up of KEYNOTE-057. *First Author: Arjun Vasant Balar, Perlmutter Cancer Center, NYU Langone Health, New York, NY*

Background: Pembro was recently approved for the treatment of HR NMIBC based on results from the phase 2 KEYNOTE-057 (NCT02625961) study. Herein we present safety, efficacy, and posttreatment outcomes with > 2 y follow-up from KEYNOTE-057 cohort A. **Methods:** Patients with histologically confirmed HR BCG-unresponsive carcinoma in situ (CIS) with or without papillary tumors who received adequate BCG therapy and were ineligible for or opted out of radical cystectomy (RC) received pembro 200 mg Q3W for up to 2 y or until disease recurrence, progression, or unacceptable toxicity. The primary end point was complete response rate (CRR). Key secondary end points were duration of response (DOR) and safety. **Results:** Overall, 102 patients were initially enrolled, and 96 were included in the efficacy analysis. Median time from enrollment to data cut off was 28.4 months (range, 18.2-40.5). CRR was 40.6% (95% CI, 30.7-51.1), and median DOR was 16.2 months (range, 0+ to 30.4+). Among 39 patients with CR, 18 (46.2%) had a DOR ≥12 months. No patient's disease progressed to muscle-invasive or metastatic bladder cancer while on study treatment. Median PFS and OS were not reached. At 12 months, PFS was 82.7% and OS was 97.9%. A total of 36 patients (37.5%) underwent RC after discontinuation from study treatment, which included 9 of 22 patients (40.9%) who had recurrence after initial CR and 27 of 57 (47.4%) nonresponders. Of the 36 who underwent RC, 33 (91.6%) had no pathological upstaging to MIBC and 3 (8.3%) had at least pT2 disease at time of RC. For subsequent treatments other than RC, 27 of 96 (28.1%) patients received additional intravesical therapy (eg, BCG, gemcitabine, or mitomycin), 21 of 96 (21.9%) underwent local procedures (eg, TURBT), and 3 of 96 (3.1%) received systemic therapy (eg, pembro). In 102 patients treated with pembro, treatment-related AEs (TRAEs) occurred in 67 (65.7%) patients; most frequently reported TRAEs were fatigue, pruritus, and diarrhea (10.8% each). Grade 3/4 TRAEs occurred in 13 patients (12.7%), and 21 patients (20.6%) experienced immune-mediated AEs. There were no grade 5 TRAEs. **Conclusions:** After > 2 y of follow-up, durable and clinically meaningful activity of pembro was observed in patients who had HR BCG-unresponsive CIS with or without papillary tumors and who were ineligible for or opted out of RC. Pembro did not seem to limit the opportunity for subsequent therapies, including RC. The safety profile was consistent with what is reported in the literature. Clinical trial information: NCT02625961. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5042 Poster Session (Board #111), Fri, 8:00 AM-11:00 AM

Thromboembolism (TE) in patients (pts) with bladder cancer treated with checkpoint inhibitors (CPIs). *First Author: Iris Yeong- Fung Sheng, Cleveland Clinic, Cleveland, OH*

Background: Most pts with bladder cancer will be treated with immunotherapy. There is concern for increased TE risk with CPIs in this already high risk population. We present the first analysis of the incidence and outcomes of venous (VTE) and arterial (ATE) thromboembolism in pts with bladder cancer treated with CPIs. **Methods:** Consecutive pts with bladder cancer treated with CPIs at the Cleveland Clinic from 1/2015 to 12/2019 were identified and TE events noted. Overall survival (OS) was estimated using Kaplan-Meier method and the impact of VTE on OS was evaluated using Cox proportional hazards regression. **Results:** Of 274 pts, 72% were men (median age 73.3 years, 89% white), 82% had pure UC, 92% had lower tract disease, and 67% had a Bajorin score ≥1 (median KPS 90, 61% visceral metastases), 59% had prior systemic therapy (median 1, range 0-4) and 36% had prior TE (14% ATE, 19% VTE, 0.4% both). At CPI initiation, 24% were on antiplatelet therapy, and 15% on therapeutic anticoagulation. CPI (median doses 5, range 8.5-59) included: 40% atezolizumab, 3% nivolumab, 57% pembrolizumab. VTE occurred in 14% (n = 37), including 8% DVT, 4% PE, 2% both. DVT locations were 56% lower limb, 26% upper limb, 15% visceral vein, 4% visceral+upper limb. 2% (n = 5) had ATE (1% CVA, 0.4% visceral, 0.4% left subclavian). 92% of VTE and all ATE occurred within 6 months of CPI initiation. The incidence of TE was 10.9% (95%CI 6.6%—15.1%) at 6 months and 19.8% (95%CI 13.3%-26.4%) at 12 months. 82% of VTE (mean 6 days) and all ATE (mean 5 days) resulted in hospitalization. Multivariate analysis showed TE (HR 2.296, 95%CI 1.451-3.632, p = 0.0004), Bajorin score 1 (HR 1.490, 95%CI 1.036-2.142, p = 0.0315), and Bajorin score 2 (HR 3.50, 95%CI 2.14-5.74, p < 0.0001) were independently associated with worse OS. **Conclusions:** CPIs in bladder cancer pts are associated with a high TE risk, especially within six months of initiation. TE is associated with worsened survival. Further investigation into the risk factors for CPI-associated TE is needed to identify if benefits exist from thromboprophylaxis. Research Sponsor: None.

5043 Poster Session (Board #112), Fri, 8:00 AM-11:00 AM

Dissecting outcomes of patients (pts) with <ypT2N0 disease after neoadjuvant chemotherapy (NAC) for muscle invasive bladder cancer (MIBC): Results from a large, international, multicenter collaboration. *First Author: Praful Ravi, Dana-Farber Cancer Institute, Boston, MA*

Background: Pathologic complete response (pCR) after NAC for MIBC is strongly correlated with long-term overall survival. However, there are sparse data on the risk of recurrence based on depth of pathologic response (pT0, pTa, pTis, pT1), and the differential impact of clinicopathologic factors and NAC regimen on recurrence. **Methods:** Baseline data on all pts with cT2-4N0-1 MIBC receiving NAC and who achieved < ypT2N0 disease at radical cystectomy (RC) from 9 international centers were obtained. The key outcome was time to recurrence (TTR) – defined as the time to any recurrence in the urinary tract or regional/distant metastasis, with death (in the absence of recurrence) considered a competing risk. Cox regression analysis was used to analyze the impact of clinical factors on recurrence. **Results:** A total of 506 pts were available. Median age was 66 years (range 33-86) and 78% (n = 396) were male; median follow-up after RC was 2.6 years. The majority of patients had pure urothelial histology (n = 371, 73%), and baseline stage was cT2N0 (n = 368, 73%), cT3-4N0 (n = 95, 19%) and TanyN1 (n = 43, 9%). NAC regimens were gemcitabine-cisplatin (GC, n = 296, 59%), dose-dense methotrexate-vinblastine-doxorubicin-cisplatin (ddMVAC, n = 141, 28%), split-dose GC (n = 29, 6%), MVAC (n = 29, 6%) and non-cisplatin based regimens (n = 11, 2%). At RC, 304 patients (60%) had ypT0N0 disease, 32 (6%) had ypTaN0, 107 (21%) had ypTisN0 and 63 (13%) had ypT1N0. Overall, 43 patients (8%) recurred with a median TTR of 56 weeks (range 7-251); 5-year freedom from recurrence was 87% (95% CI 83-91). The majority (n = 38) recurred outside the urinary tract. On multivariable analysis, ypTa (HR = 3.36 [1.24-9.11]) and ypT1 (HR = 2.88 [1.33-6.22], p = 0.013) disease at RC were predictors of shorter TTR, while female sex was associated with longer TTR (HR = 0.52 [0.27-0.98], p = 0.043). The type of NAC was not predictive of TTR (GC vs. other, HR = 1.49 [0.75-2.97], p = 0.26). **Conclusions:** To our knowledge, this is the largest study to quantify the risk of recurrence in pts achieving pathologic response after NAC and RC for MIBC. 8% of patients undergoing NAC and achieving < ypT2N0 at RC recurred. Residual ypTa and ypT1 disease conferred a significantly higher risk of recurrence, while ypTis did not; female sex was associated with a lower risk of recurrence. Importantly, the type of cisplatin-based NAC regimen used was not an independent predictor of recurrence. Research Sponsor: None.

5044 Poster Session (Board #113), Fri, 8:00 AM-11:00 AM

Study EV-103: Durability results of enfortumab vedotin plus pembrolizumab for locally advanced or metastatic urothelial carcinoma. *First Author: Jonathan E. Rosenberg, Memorial Sloan Kettering Cancer, New York, NY*

Background: Platinum chemotherapy is the standard for patients (pts) with metastatic urothelial carcinoma (mUC) in the first line (1L) setting. PD-1/PD-L1 inhibitors, such as pembrolizumab (P), have shown promising durability in this setting for PD-L1 high patients. Enfortumab vedotin (EV) is an antibody-drug conjugate that delivers the microtubule-disrupting agent MMAE to cells expressing Nectin-4, which is highly expressed in UC. EV recently received FDA accelerated approval based on tumor response rates for adults with locally advanced or mUC who have previously received a PD-1/PD-L1 inhibitor and a platinum-containing chemotherapy. EV is investigational in the 1L setting. Initial EV + P data were previously presented (Hoimes ESMO 2019); this provides durability data and an update on safety/ORR. **Methods:** This multicohort study (NCT03288545) evaluated the safety/activity of EV + P. We report a cohort of 1L cisplatin-ineligible patients treated with EV 1.25 mg/kg + P. In each 3-week cycle, EV was administered on Days 1 and 8 and P on Day 1. The primary endpoint was safety/tolerability; secondary objectives included determination of recommended EV dose, ORR, DCR, DOR/PFS per RECIST v1.1, and OS. **Results:** As of 8 Oct 2019, 45 1L or previously untreated mUC pts (median age 69 yr [51–90]) received a median of 9 (range 1-22) cycles of EV + P. The most common treatment-emergent adverse events (AE) were fatigue (58%, 11% ≥G3), alopecia (53%), and peripheral sensory neuropathy (53%, 4% ≥G3). One pt died due to an AE reported as related (multiple organ failure). With a median follow-up of 11.5 mo, confirmed investigator-assessed ORR was 73.3% (95% CI, 58.1, 85.4) including 15.6% CRs; DCR was 93.3%. The ORR in pts with liver metastasis was 53.3% (8/15). The ORR in pts with available PD-L1 status was 78.6% in PD-L1 high (11/14) and 63.2% in PD-L1 low (12/19). Of the 33 responders, 18 (55%) have ongoing responses including 11 responses beyond 10 months. The median DOR was not reached (range 1.2 to 12.9+ mo); the 12-month DOR rate was 53.7% (95% CI, 27.4, 74.1). The median PFS was 12.3 mo (95% CI, 7.98, -); the 12-month PFS rate was 50.1% (95% CI, 33.0, 65.0). The median OS was not reached (range 0.66 to 19.2+ mo); the 12-month OS rate was 81.6% (95% CI, 62.0, 91.8). **Conclusions:** In 1L cisplatin-ineligible pts with mUC, EV + P, a potential platinum free option, demonstrates promising activity and durability, with a manageable safety profile. Further evaluation of EV + P in mUC and muscle-invasive UC is ongoing. Clinical trial information: NCT03288545. Research Sponsor: Seattle Genetics, Inc, Pharmaceutical/Biotech Company.

5045 Poster Session (Board #114), Fri, 8:00 AM-11:00 AM

Impact of timing of antibiotic use on clinical outcomes in patients with urothelial cancer treated with immune checkpoint inhibitors (ICIs). *First Author: Chana Weinstock, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Although recent evidence has suggested that patients who receive antibiotics (ABX) during the course of ICI treatment might decrease overall survival (OS) (1), our previous analysis did not support a difference in OS in urothelial cancer patients who did and did not use ABX during the course of ICI treatment without regard to timing (2). This updated analysis aims to addresses the question of timing; specifically, use of ABX in the 30-day window pre- or post- initiation of ICI treatment. **Methods:** We pooled data from 7 trials that led to drug approval and which included 1747 patients with advanced urothelial cancer treated with an ICI. Five trials enrolled patients who received prior platinum and 2 enrolled cisplatin-ineligible patients. Concomitant medication datasets were searched for systemic ABX use. The association between ABX use and survival was evaluated using Kaplan-Meier estimates and Cox proportional hazards regression models stratified by study. **Results:** Overall, 56% of patients were exposed to antibiotics (ABX+) and 43% were not exposed (ABX-). In an exploratory analysis, median OS was similar between arms: 9.7 vs. 9.3 months in ABX+ vs. ABX- patients, respectively (HR 0.96). However, OS results differed in the 27% of patients who were exposed to antibiotics in the 30-day window pre- or post- initiation of ICI treatment, for whom median OS was 4.7 months vs. 11.5 months in the ABX+ vs. ABX- patients, respectively (HR 1.8). This remained true after controlling for baseline risk prognostic factors (Bajorin and Bellmunt scores). Similar trends were observed for progression-free survival (PFS). **Conclusions:** Patients treated with ABX while on therapy with an ICI for urothelial cancer had similar OS outcomes to those not treated with ABX. However, in an exploratory analysis looking at ABX use in the 30-day window pre- or post-initiation of ICI treatment, OS appeared decreased in ABX+ vs ABX- patients. Our exploratory analyses appear to show an association of OS/PFS with timing of antibiotics. References: 1) Routy B, Science (2017) 2) Weinstock C, ASCO 2019, abstract. Research Sponsor: None.

Detection of urothelial carcinoma using plasma cell-free methylated DNA. *First Author: Pier Vitale Nuzzo, Department of Medical Oncology, Dana-Farber Cancer Institute, Brookline, MA*

Background: Methylation profiling of circulating cell-free DNA (cfDNA) is a promising approach for non-invasive tumor detection due to the presence of tissue-specific epigenetic signatures that are detectable in cfDNA. Cell-free methylated DNA immunoprecipitation and high-throughput sequencing (cfMedDIP-seq) is a sensitive, low-input, cost-effective, bisulfite-free approach to profiling cfDNA methylomes, capable of detecting and classifying various tumor types. We tested the feasibility of cfMeDIP-seq to detect urothelial carcinoma (UC) in plasma samples. **Methods:** We performed cfMeDIP-seq on plasma samples from 43 patients (pts): 18 metastatic UC (UC) pts, 12 pre-cystectomy non-metastatic UC pts, and 13 cancer-free controls. Six (50%) of pre-cystectomy cases were non-muscle invasive UC. cfDNA was immunoprecipitated and enriched using an antibody targeting 5-methylcytosine and PCR-amplified to create a sequence-ready library. The top differentially methylated regions (DMRs) between UC and control samples were used to train a regularized binomial generalized linear model using 80% of the samples as a training set. The 20% of withheld test samples were then assigned a probability of being UC or control. This process was repeated 100 times. **Results:** The average amount (standard deviation) of cfDNA isolated from 1 ml of UC plasma samples was 29.2 (27.4) ng/μL and 8.02 (3.58) ng/μL in cancer-free controls. We identified 9,826 DMRs in plasma samples at an adjusted p-value of < 0.01, which partitioned UC and control samples. Iterative training and classification of held out samples using the top 300 DMRs resulted in a mean AUROC of 0.987. **Conclusions:** cfMeDIP-seq is an interesting new approach for non-invasive detection of UC. cfMeDIP-seq demonstrates high sensitivity to detect UC across all stages of UC, including non-muscle invasive disease. 5047 Poster Session (Board #116), Fri, 8:00 AM-11:00 AM

Phase Ib/II neoadjuvant (N-) pembrolizumab (P) and chemotherapy for locally advanced urothelial cancer (laUC): Final results from the cisplatin (C)- eligible cohort of HCRN GU14-188. *First Author: Christopher J. Hoimes, Duke Cancer Institute, Durham, NC*

Background: Patients (pts) with laUC who are C-eligible for N- therapy may benefit from combination chemo-immunotherapy. Cohort 1 (C1) of the GU14-188 trial is a phase 1b/2 trial designed to assess the tolerability and efficacy of N- gemcitabine (G), C, and P in pts with laUC. The current standard of care is ddMVAC with a pathologic non-muscle invasive rate (PaIR, ≤pT1N0) of ~44%. **Methods:** Eligible pts for C1 were surgical candidates and C-eligible with cT2-4aN0M0 bladder UC. Enrollment followed a Simon 2-stage design for H_0 of interval futility which was rejected at stage 1, and fully enrolled. Phase 1b (no DLT) /2 treatments were the same: P 200mg q3wks on day 8 x5 doses; with C (70mg/m2) day 1, and G (1000mg/m2) days 1 and 8 of a 21 day cycle (cy), for 4 cy; followed by radical cystectomy (RC). Minimum criteria for evaluation of safety: 1 dose of P, and for efficacy: 2 doses P and RC. The primary endpoint of PaIR was assessed at RC and designed for 86% power with 4% significance to detect a difference from 23 to 48%. Secondary endpoints include relapse free survival and overall survival. **Results:** 43 pts were enrolled to C1 with a median (mdn) age 64, 63% male, 51% > cT2. Mdn per-pt doses given (attempted) for: P:5(5), C:4(4), G:8(8). The PaIR was 61.1% (95%CI 0.45, 0.75), P0 (ypT0N0) rate of 44.4%, and did not correlate with baseline PD-L1 score. Downstage to PaIR occurred in 53% of cT2, and 74% of cT3/4. Mdn time to RC from last dose was 5.3wks. Seven were not included in the primary analysis: 4 (9.3%) without RC, 1 progressed, 1 lost to f/u during C1, 1 did not receive required protocol therapy. There was 1 death on post-RC day 9 due to mesenteric ischemia. Of 4 pts who did not have RC, 3 refused and 1 due to gr4 thrombocytopenic purpura; 4pts are alive and without recurrence at mdn f/u of 32mo. One pt with presumed gr3 MI during cy 4 had a negative inpt cardiac workup and completed therapy and RC without further AE. One gr4 hyponatremia and ten gr3 events did not preclude RC (2-each thromboembolism, elevated creatinine, hyponatremia;1-each: dehydration, emesis, neutropenic fever, infection). Gr 3/4 cytopenias occurred in 57% of pts. At mdn f/u of 34.2mo (3.9-47.4), the estimated 36mo RFS, OS, and DSS is 63%, 82%, and 87%, respectively. **Conclusion:** Neoadjuvant GC with P in laUC has manageable toxicity and has improved pathologic outcomes compared to historic controls. Durable long-term survival in those with- and without -RC is noteworthy in this advanced cohort. KEYNOTE 866, NCT03924856, is a Phase III study of GC with perioperative P. Clinical trial information: NCT02365766. Research Sponsor: Merck & Co.

Outcomes of patients (pts) with metastatic urothelial carcinoma (mUC) following discontinuation of enfortumab-vedotin (EV): Emergence of a new unmet need. *First Author: Catherine Curran, Dana Farber Cancer Institute, Boston, MA*

Background: Enfortumab vedotin (EV) is an antibody drug conjugate recently approved to treat mUC following prior platinum and PD1/L1 inhibitors. The outcomes and patterns of therapy of pts following discontinuation of EV has yet to be studied. We investigated outcomes of pts who completed EV treatment for mUC at multiple institutions in order to identify benchmarks for evaluation of new agents following EV. **Methods:** Clinical data were obtained from mUC patients who had completed EV treatment from collaborating academic institutions. Descriptive stats were performed to describe the overall dataset and compare patient characteristics and outcomes of those who went on to receive further treatment post-EV and those who did not. **Results:** Data were available for 63 patients from 6 collaborating institutions: DFCI, University of Michigan, University of Washington, Moffitt Cancer Center, INT Milan and University of Miami. 17 (27%) were female and 46(73%) were male. The median age was 68 (range 43-83. The primary site of malignancy included bladder, upper tract, and other in 43 (68%), 19 (30%), and 1pt (.02%), respectively. The histologies included pure UC and mixed predominant UC in 49 (78%), and 14 pts (22%), respectively. 32 pts (51%) received further therapy after EV and 31pts (49%) did not. Longer duration of prior EV therapy was associated with receipt of post-EV therapy (p=0.0437). Treatments received post-EV were: trial therapy (n=14), PD1/L1 inhibitor (n=7), pemetrexed (n=4), taxane (n=3), carboplatin (n=2) and unknown in 2 pts. Objective response was observed in 3 of 32 pts (9.4%) who received therapy post-EV. The median duration of time from end of EV to death was 24 weeks. The median overall survival (OS) of those who received post-EV therapy and did not receive post-EV therapy was 37.5 weeks and 12 weeks, respectively. **Conclusions:** Outcomes of mUC following discontinuation of EV are dismal with only 51% receiving subsequent therapy. This study identifies an unmet need setting and establishes benchmarks for the interpretation of activity of new agents evaluated following EV. Research Sponsor: None.

Analysis of chemotherapy-related modulation of the immune microenvironment in muscle invasive bladder cancer. *First Author: Elshad Hasanov, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Novel immune checkpoint inhibitors provide significant clinical benefits for patients with metastatic bladder cancer. It is known that chemotherapy administered to muscle invasive patients prior to radical cystectomy (neoadjuvant chemotherapy) improves survival. However, it is unknown whether immune checkpoint inhibitor therapy in combination with chemotherapy can provide further clinical benefits as neoadjuvant therapy. Here, we test the hypothesis that treatment of bladder cancer with certain chemotherapy agents can modulate bladder tumor immune microenvironment (TIME) for optimal combination with immune checkpoint therapy. **Methods:** Time course and dose response experiments were performed using eight human bladder cancer cell lines (UMUC3, RT4, 253J, RT112, J82, HT1376, T24, and HT1197) and two murine bladder cancer cell lines (MB49, MBT2). Conventional chemotherapy agents and combinations (MVAC, GemCis, PemVin) were used to treat bladder cancer cell lines. Flow cytometry analysis was used to measure immune cell subsets and PD-L1 expression. For *in vivo* studies, the subcutaneous MB49 murine bladder cancer model was used to evaluate responses to chemotherapy and anti-PD-L1 combinations. Pre- and post-treatment bladder tumors from patients who received neoadjuvant MVAC and GemCis are selected to evaluate changes in TIME. **Results:** Our data demonstrate that chemotherapy agents varies in their ability to up-regulate PD-L1 expression on bladder cancer cell lines. Vinblastine, gemcitabine, and pemetrexed treatment each resulted in significant upregulation of PD-L1 expression. Combination regimens with GemCis or PemVin demonstrated induction of PD-L1 across different cell lines. In *in-vivo* studies, GemCis + anti-PD-L1 had a synergistic activity in causing tumor regression. We also found that sequential versus concurrent treatment with chemotherapy and anti-PD-L1 had a similar outcome. Tissue analyses show that combination chemotherapies increased CD4 Th cell infiltration while decreasing Treg cells in TIME. Consistent with the in vitro data, PD-L1 expression was also up-regulated with combination treatment. The evaluation of TIME modulation in human bladder tumors treated with neoadjuvant MVAC or GemCis is ongoing. **Conclusions:** Our data suggest that chemotherapy could favorably modulate TIME and thus, may be combined with immune checkpoint inhibitor to improve anti-tumor responses in the neoadjuvant setting for patients with muscle invasive bladder cancer. 5050 Poster Session (Board #119), Fri, 8:00 AM-11:00 AM

Clinicogenomic predictors of extreme responses to anti-PD1/PDL1 checkpoint inhibitors (CPI) in metastatic urothelial cancer (mUC). *First Author: Min Yuen Teo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Only a subset of mUC patients (pts) derives benefit from CPI. We sought to evaluate potential clinical and genomic predictors, with additional focus on extreme outcomes. **Methods:** CPI-treated mUC with tumor sequencing with MSK-IMPACT (up to 468 genes) were identified. Pre-CPI clinical variables (including hemoglobin [hgb], lymphocyte [lymph], neutrophil [neut] and eosinophil [eos] counts) were extracted. Endpoint was time on treatment (ToT). Poor responders were defined as ToT $\leq$9 weeks and overall survival $\leq$3 months; exceptional responders had ToT $>$20 months. A multivariate Cox model for ToT was performed with clinical variables chosen by stepwise selection minimizing Akaike information criterion. Genomic analyses were adjusted for multiple testing. **Results:** 166/171 identified mUC were evaluable. Median age was 68 years, 78% were male. 72% had bladder primary, while 17%, 35% and 28% had liver, lung and bone metastases (mets). 67% had prior platinum chemo. 24 pts (14%) were poor and exceptional responders, respectively. In univariate analysis, liver mets were associated with shorter ToT while DNA damage repair (DDR) gene alterations, higher body mass index (BMI), eos, hgb and tumor mutation burden (TMB) were associated with longer ToT. No specific genomic alterations achieved q$<$.05. In multivariate model, prior chemo (HR 1.6, p=.01), liver mets (HR 2.4, p$<$.01) and high neut were associated with shorter ToT while urethral primary (HR 0.1, p$<$.01), higher TMB (HR 0.9, p$<$.01) and higher eos (HR 0.1, p$<$.01) were independently associated with ToT. Univariate logistic regression to identify poor and exceptional responders are tabulated. Multivariate results will be reported. **Conclusions:** In addition to validation of various known mUC prognosticators, we observed potential non-linear influence of clinical and genomic factors on extreme outcomes. Research Sponsor: None.

Maintenance oral etoposide (VP-16) after high-dose chemotherapy (HDCT) for patients with relapsed metastatic germ-cell tumors (mGCT). *First Author: Bilal Anouti, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: HDCT and peripheral-blood stem-cell transplant (PBSCT) can cure up to 60% of patients with relapsed mGCT. Maintenance daily oral VP-16 after salvage therapy has been shown effective in inducing remissions (J Clin Oncol 1995;13:1167-9). We evaluate the role of maintenance VP-16 post HDCT+PBSCT compared to observation. **Methods:** The prospectively maintained Indiana University testicular cancer database was interrogated. Patients with relapsed non-seminoma who completed HDCT+PBSCT and achieved serologic remission and hematologic recovery were evaluated. Outcomes of patients who received maintenance VP16 (N = 141) were compared to patients who were observed (N = 252). In this retrospective study, Kaplan-Meier method was used to analyze progression free survival (PFS) and overall survival (OS). Univariable and multivariable cox regression models were used to determine variables associated with PFS. **Results:** 2-year PFS in the maintenance VP-16 versus observation group was 55% vs. 44% (p = 0.008). 2-year OS was 61% vs. 52% (p = 0.01). A multivariable analysis was performed including the factors: primary tumor site (testis vs. mediastinum), IGCCCG risk, platinum refractory, HDCT line of therapy (2^{nd} vs. $\geq 3^{rd}$), tumor marker amplitude at HDCT initiation, and receipt of maintenance VP-16 post HDCT vs. observation. Maintenance VP-16 was confirmed as an independent predictor of improved PFS with HR 0.48 [95% CI, 0.35-0.66] (p $<$ 0.001). **Conclusions:** Maintenance oral VP-16 post HDCT+PBSCT improved PFS and OS. In a multivariable model including known adverse prognostic factors, maintenance VP-16 was an independent predictor of improved PFS. Research Sponsor: Internal funds from Indiana University.

5052 Poster Session (Board #121), Fri, 8:00 AM-11:00 AM

Multicenter analysis of serum tumor markers, treatment patterns, and relapse in patients with testicular cancer in clinical stage IS. *First Author: Maximilian Peter Johannes Karl Brandt, University Clinic for Urology and Pediatric Urology, Mainz, Germany*

Background: Testicular germ cell tumors (TGCT) in clinical stage I (CSI) are tumors confined to the testis without evidence of metastasis. Around 50% of all TGCT patients present with elevated serum tumor markers (TM) such as alpha-feto protein (AFP), beta-humanochoriongonadotropin (ß-HCG) and lactate-dehydrogenase (LDH). After ablatio testis, TMs usually return to normal according to half-life kinetics, however, in clinical stage IS (CSIS) TMs remain elevated or increase after surgery. Follow-up data on CSIS is scarce and our study aims to assess clinical characteristics and oncologic outcomes in a large TGCT cohort. **Methods:** In this multicenter study we collected data from 5 tertiary referring hospitals in Germany, included patients with CSIS and evaluated TM levels, treatment and the primary outcome relapse-free survival. False CSIS was defined as documented CSIS but TMs that returned to normal after respective half-life kinetics. Differences between predefined groups (chemotherapy, TM, true/false CSIS) was analyzed with fisher's exact and chi-square test. **Results:** Overall, 2616 patient data files were analyzed. Forty-three patients (1.6%) were documented as CSIS of which 27 (63%) were true and 16 (37%) false CSIS. Six (14%) had seminomas and 37 (86%) non-seminomas. In the true CSIS group AFP, ß-HCG, AFP plus ß-HCG and LDH were elevated in 13, 6, 3 and 2 cases. Four true CSIS patients received surveillance, 21 had 3x or 2x courses of BEP (bleomycin, etoposide and cisplatin) and 2 carboplatin. Within the false CSIS group, 2 patients were treated with surveillance, 10 received 3x BEP, one 3x PEI (cisplatin, etoposide and ifosfamid) and 3 had carboplatin. Chi-Square test revealed no difference between true or false CSIS classification in respect to application of chemotherapy (any chemotherapy, p = 0.83). Relapse-free survival after 5 and 10 years was 88.9% and 77.8%, respectively. Three patients in the true CSIS group relapsed (2 seminomas had carboplatin, 1 non-seminoma had surveillance). All relapses were treated with 3 courses of BEP with no documented death in the CSIS population. **Conclusions:** Overall, less than 2% of all TGCT were documented CSIS of which 37% were falsely classified. We report a high proportion of relapse-free survival in CSIS treated with surveillance or BEP with a high heterogeneity in treatment patterns. Correct classification of CSIS remains of critical importance to avoid toxicity for patients that could be safely treated with surveillance. Research Sponsor: None.

5053 Poster Session (Board #122), Fri, 8:00 AM-11:00 AM

Outcome of men with HIV-associated germ cell cancer: Results from an international collaborative study. *First Author: Marcus Hentrich, Red Cross Hospital, University of Munich, Munich, Germany*

Background: Previous studies showed that men with HIV-associated germ cell cancer (HIV-GCC) have a similar cancer-free outcome compared with their HIV-negative counterparts. However, the overall survival (OS) was inferior and little data is available on treatment and outcome of HIV-GCC in the era of combined antiretroviral therapy (cART). **Methods:** Men living with HIV aged ≥ 18 years (yrs) with a diagnosis of histologically proven GCC made from 01/1996 to 07/2018 were included. Primary outcomes were OS and progression-free survival (PFS). Secondary outcomes included characteristics of GCC and HIV-infection, treatment and causes of death. **Results:** Data of 89 men from 23 institutions and 6 countries with a total of 92 HIV-GCC (2 synchronous and 1 metachronous bilateral GCC) were analysed, among them 64 (70%) seminomas and 28 (30%) nonseminomas. 10/89 (11%) cases were primary extragonadal GCC. Median age was 36 yrs (range, 22-52) and median time from HIV to GCC diagnosis was 5 yrs (range, 0-29). Median CD4 count at GCC diagnosis was 420 cells/μl (range, 3-1503) and 83% of pts were on cART. Stage I disease was found in 44/80 (55%) gonadal GCC (metachronous bilateral case included). Of 46 cases with stage II/III/extragonadal GCC 78%, 17% and 4% were assigned to the IGCCCG good, intermediate and poor prognosis group, respectively. Of the 44 stage I cases, 22 (50%) were followed by active surveillance, and 11 (25%) received adjuvant chemotherapy (CT) or radiotherapy. Relapses occurred in 14 pts (6 from stage I, 8 in pts primary disseminated GCC) and CT was applied to 13/14 pts, of which 3 received high-dose CT. Overall, 12/89 (13%) pts have died. Causes of death were refractory GCC (n = 5), an AIDS-defining illness (n = 3) and other (n = 4). After a median follow-up of 6.5 yrs (range, 0.3-20.9), the 5- and 10-year PFS rate was 81% and 73%, and the 5- and 10-year OS rate was 91% and 85%, respectively. There were no significant differences between the good and intermediate prognosis group or between pts with CD4 counts < 200/μl or ≥ 200/μl. **Conclusions:** The 5- and 10-year PFS and OS rates of men with HIV-GCC are similar to those reported for HIV-negative GCC. Pts with HIV-GCC should remain on cART and be managed in an identical fashion to HIV-negative pts. Research Sponsor: None.

5055 Poster Session (Board #124), Fri, 8:00 AM-11:00 AM

Prognostic role of early interim [18F] fluoro-deoxy-glucose positron emission tomography in patients with advanced seminoma undergoing standard treatment. *First Author: Daniele Raggi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In patients (pts) with advanced seminoma, efforts are underway to tailor a risk-adapted treatment strategy to the individual pt. Our main objective was to prospectively determine the prognostic value of [18F]fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT2) after two cycles of bleomycin, etoposide and cisplatin (BEP) or EP chemotherapy under standardized treatment and PET evaluation criteria. **Methods:** Pts with advanced-stage seminoma were treated with BEP or EP according to guidelines. PET/CT examinations were performed at baseline, after two cycles in all pts and after chemotherapy at physician's choice. PET/CT response was qualitatively evaluated by two independent nuclear medicine physicians. Contrast-enhanced CT scans were also performed according to the guidelines (at baseline, after treatment, during follow-up). The primary endpoint was the relapse-free survival (RFS). **Results:** From 01/2009 to 01/2017, 75 consecutive pts were enrolled, of whom 70 were evaluable. The clinical stage was IIA-B and IIC-III in 40% and 60% of the pts, respectively. Eight pts (11.4%) received consolidation radiotherapy. By local assessment, 46 PET/CT2 scans (65.7%) were reported as negative, and 46% of these pts presented with stage IIC-III. The median follow-up was 79 months. Five-year RFS of PET/CT2-positive pts was 75% (95%CI: 60-95%) compared with 97.8% (95%CI: 93.7-100%) of PET/CT2-negative pts (p = .002). This significant improvement in RFS was maintained when analyzing only pts with clinical stage IIC-III (p = 0.04) and by excluding those who received consolidation RT (p = 0.02). An increasing linear association was found between the maximum diameter of retroperitoneal lymph nodes and the rate of PET/CT2+. In univariable Cox regression analyses, PET/CT2+ (HR: 12.9, 95%CI: 1.5-106.9, p = 0.02) and elevated HCG levels (HR: 6.3, 95%CI: 1.2-32.3, p = 0.03) were significantly associated with RFS, whereas IGCCCG risk group was not (p = 0.1). PET/CT2 result was also associated with the tumor shrinkage post-BEP (p = 0.009), whereas complete response at CT did not predict the RFS (p = 0.3). **Conclusions:** No residual FDG-uptake after 2 cycles of conventional chemotherapy is prognostic in advanced seminoma, may outperform the utility of standard prognostic risk groups and may be more accurate to predict the RFS compared to standard response criteria. Benchmark RFS estimates for the design of the next clinical trials of chemotherapy de-escalation are offered. Research Sponsor: Fondazione IRCCS Istituto Nazionale dei Tumori.

5056 Poster Session (Board #125), Fri, 8:00 AM-11:00 AM

Persistence of platinum in semen of cisplatin-treated survivors of advanced testicular cancer. *First Author: Eoghan Ruadh Malone, Princess Margaret Hospital, Toronto, ON, Canada*

Background: Cisplatin is highly curative treatment for testicular cancer. Most survivors develop azoospermia immediately after cisplatin with recovery expected in 50% at 2 years and 80% at 5 years. Platinum is a heavy metal that can be detected at low levels in serum many years after treatment, however, it is not known whether platinum also persists in semen and if platinum persistence in semen is associated with impaired fertility. **Methods:** Testicular cancer survivors previously treated with cisplatin were enrolled, relapsed disease treated with salvage chemotherapy was excluded. Semen samples were collected to assess semen quality. Repeat semen collections were performed if azoo- or oligospermia was noted. Serum and semen Platinum levels were determined using HPLC-tandem mass spectrometry. DNA Fragmentation Index (DFI) was measured. **Results:** From 11/2017 to 12/2019, 38 pts (median age 32 years; range: 19-52; median BSA 2.03; range: 1.81-2.61) were enrolled, 31 were treated with 3 cycles of Bleomycin, Etoposide, Cisplatin. Median cumulative cisplatin dose was 300 mg/m^2 (range: 274-404). Median serum platinum concentration was 0.1 ng/mL (range: 0-22.6) at a median of 11 months (range 0.5-36) post treatment completion. Median semen platinum concentration was 0.5 ng/mL (range: 0.2-28.7) at a median of 14 months (range: 1.3-40) post treatment completion. Semen platinum levels were higher in semen than in blood drawn at the same time (p = 0.03). Semen platinum levels were associated with time from last cisplatin dosing (r = -0.34; p = 0.09) but not cumulative cisplatin dose (r = -0.10, p = 0.63). Sperm concentration was correlated with time from last cisplatin dosing (r = 0.58, p < 0.001) but not with semen platinum level (r = -0.15, p = 0.46). DFI was associated with time from last cisplatin dosing (r = 0.55, p = 0.08) but not with semen platinum level (r = -0.32, p = 0.33). In 4 pts with serial semen samples available, semen platinum level decreased with time, sperm concentration and motility increased. **Conclusions:** Platinum can be detected in semen in long-term testicular cancer survivors at higher levels than matched blood samples. Our preliminary findings may have important implications for reproductive health of survivors of advanced testicular cancer, further studies are needed to assess the relationship between platinum persistence in semen and recovery of fertility post chemotherapy. Research Sponsor: Department of Medical Oncology and Hematology Grant (Internal Princess Margaret Hospital).

Model to predict brain metastasis (BM) in patients with metastatic germ-cell tumors (mGCT). *First Author: Ryan Ashkar, Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN*

Background: BM is an independent adverse prognostic factor that can lead to treatment complications and failure in pts with mGCT. We aimed to establish an effective and practical model for prediction of BM in mGCT. **Methods:** 2,256 consecutive pts with mGCT treated at Indiana University between January 1990 and September 2017 were identified. Pts were divided into 2 categories: BM present (N = 144) and BM absent (N = 2112). Kaplan-Meier methods were used to analyze progression free survival (PFS) and overall survival (OS). Logistic regression was used to determine a predictive model for whether BM was present. The data was separated 50/50 into training and validation datasets with equal numbers of events in each. **Results:** Baseline characteristics for 2 groups are listed in Table. 2-yr PFS and OS for pts with vs without BM: 17% vs 66% (p < 0.001) and 62% vs 91% (p < 0.001) respectively. Among the 144 pts with BM, 64 (44%) had radiation only (whole-brain radiotherapy or gamma knife), 21 (15%) had BM-surgery only, 14 (10%) had both radiation and BM-surgery. 45 pts (31%) did not receive local therapy for BM. A stepwise selection was used to determine the best model with p < 0.15 as the entry and staying criteria. The model with the largest ROC AUC was used moving forward. The model was tested in the validation dataset. A model was generated including age at diagnosis≥40 (1 point), presence of pulmonary metastases (3 points), bone metastasis (1 point), pre-chemotherapy hCG≥5000 (1 point), and choriocarcinoma predominant histology (1 point). Patients with 0 points had a 0.4% probability of BM, 1 point: 1%, 2 points: 2.6%, 3 points: 7%, 4 points: 16%, 5 points: 32%, 6 points: 56%, and 7 points: 77%. Details regarding analysis in training and validation datasets will be presented. **Conclusions:** The prediction model developed in this study demonstrated discrimination capability of predicting BM occurrence and can be used by clinicians to identify high-risk pts. Research Sponsor: None.

Variable	BM present N = 144	BM absent N = 2112
Median age at diagnosis (range)	29 (16-49)	30 (13-75)
Primary site		
-Testis	125 (87%)	1966 (93%)
-Retroperitoneum	8 (6%)	81 (4%)

Olaparib as salvage treatment for advanced germ cell tumors after chemotherapy failure: Results of the open-label, single-arm, IGG-02 phase II trial. *First Author: Ugo De Giorgi, Department of Medical Oncology, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy*

Background: Therapeutic options for patients with advanced germ cell tumors (GCTs) after multiple relapses or resistant disease are limited. Olaparib is an inhibitor of poly ADP ribose polymerase (PARP), an enzyme involved in DNA repair. We aimed to evaluate olaparib activity in patients with refractory GCT. **Methods:** In this proof-of principle open-label, single-arm, phase II trial of olaparib 300 mg twice daily in patients with relapsed/refractory metastatic germ cell cancer IGG-02 study (NCT02533765), patient eligibility included failure after high-dose chemotherapy or after at least 2 different cisplatin-based regimens. Measurements of serum tumor markers and computed tomography were carried out at baseline and every 6 weeks of olaparib treatment. The study primary endpoint was the overall response rate, the study planned to recruit initially 18 patients and not continue further recruitment until one or more responses were observed. **Results:** Between September 2015 and February 2019, 18 patients, median age 39 years (range, 22-61) were enrolled. The number of prior chemotherapy regimens was: 2 for 3 patients (16.7%), 3 for 5 patients (27.8%), >3 for 10 patients (55.6%). Sixteen cases (89.9%) received prior high-dose chemotherapy with support of hematopoietic progenitor cells. Grade 3-4 adverse events were observed in 5 patients (27.7%). There were no partial responses, 5 cases (27.8%) with stable disease (SD) lasting 3, 4, 4, 7 and 7+ months and 13 (72.2%) progressive disease. The 12-week progression-free survival probability was 27.8% [95% confidence interval (CI): 10.1%-48.9%]. The 12-month overall survival probability was 27.8% (95% CI: 10.1%-48.9%). A germline DNA repair profile panel showed only a BRCA1 mutated case associated with a SD lasted 4 months. **Conclusions:** Olaparib as a single agent has marginal activity in heavily pretreated GCT patients, however, an anecdotic 4-month SD in the only BRCA mutated patient has been reported. Plans for future studies with olaparib are suggested in combination or following salvage chemotherapy in less pretreated and more selected GCT patients. The Study has been conducted with AstraZeneca contribution. Clinical trial information: NCT02533765. Research Sponsor: Astrazeneca.

5059 Poster Session (Board #128), Fri, 8:00 AM-11:00 AM

SBRT versus nephrectomy in the treatment of renal cell carcinoma. *First Author: Mausam Patel, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Stereotactic body radiotherapy (SBRT) is being increasingly used for renal cell carcinoma (RCC) treatment in non-surgical candidates. However, no studies have compared survival between nephrectomy and SBRT. The National Cancer Database (NCDB) database was used to assess overall survival in patients undergoing SBRT vs nephrectomy. **Methods:** All cases of T1-T4, N0, M0 RCC diagnosed between 2004 and 2016 were extracted from the NCDB. Only patients undergoing either nephrectomy or SBRT, but not both, were included in the final analysis. Primary outcome was overall survival, defined as time in months from diagnosis to death due to any cause. Descriptive statistics were calculated for all variables. Univariate survival analysis was performed using the Kaplan Meier method and log rank test. Multivariate Cox proportional hazards regression models were performed to determine the predictive performance of covariates with respect to overall survival, reported as hazard ratio [HR] with 95% CIs. Nephrectomy patients were propensity score matched to SBRT patients for sub-cohort survival analysis. Comparisons were considered statistically significant at $P < 0.05$. **Results:** There were 243,754 patients meeting inclusion criteria with 243,488 undergoing nephrectomy and 266 undergoing SBRT. Five year OS rates were 53% and 80% for SBRT and nephrectomy, respectively ($P < 0.001$). On multivariate Cox regression, SBRT was associated with an increased risk of death as compared to nephrectomy (HR, 2.05; 95% CI, 1.72 – 2.44; $P < 0.001$). Sex, race, insurance coverage, comorbidity index, tumor grade, lymphovascular invasion status, T-stage, tumor size, and academic status of treatment facility were also independent predictors of survival. After propensity score matching of 266 SBRT patients to 266 nephrectomy patients, there were no significant differences in baseline characteristics between the groups. However, SBRT continued to demonstrate worse survival and an increased risk of death as compared to nephrectomy (HR, 1.85; 95% CI, 1.41 – 2.44; $P < 0.001$). **Conclusions:** Among node-negative, non-metastatic RCC patients, SBRT is associated with inferior survival outcomes as compared to nephrectomy, even after correcting for underlying differences in demographics, tumor characteristics, socioeconomic status, and comorbidities. These results indicate that nephrectomy should remain the standard of care for RCC patients, with SBRT reserved for non-surgical candidates. Research Sponsor: None.

5060 Poster Session (Board #129), Fri, 8:00 AM-11:00 AM

INMUNOSUN-SOGUG trial: A prospective phase II study to assess the efficacy and safety of sunitinib as second-line (2L) treatment in patients (pts) with metastatic renal cell cancer (RCC) who received immunotherapy-based combination upfront. *First Author: Enrique Grande, MD Anderson Cancer Center Madrid, Madrid, Spain*

Background: Immunotherapy (IO)-based combinations have replaced tyrosine kinase inhibitors (TKI) as standard upfront treatment of metastatic RCC pts. Selection of 2L treatment after progression to novel combinations in 1st-line (1L) is mostly based on retrospective series or subgroups analysis of randomized trials. We aim to evaluate the activity and safety of sunitinib in advanced RCC after progression on an IO-based 1L approach. **Methods:** This is a prospective, non-randomized, open-label and multicenter phase II study. Pts with ECOG 0-2 and locally advanced or metastatic RCC after treatment in 1L with a prior PD-1 and/or PD-L1 and/or CTLA-4 inhibitor were included. Sunitinib was administered at 50 mg/day on a 4/2 schedule until disease progression. Primary endpoint was overall response rate (ORR) by RECIST v 1.1 criteria. **Results:** Twenty pts were enrolled in the study. Median age was 66 yo, 70% had intermediate prognosis by Heng's scale, and 88% ECOG 1. 45% of pts received atezolizumab, 30% pembrolizumab, 20% nivolumab and 15% ipilimumab-based regimens as 1L. ORR to 1L treatment was 45%. Median time from end of 1L to sunitinib onset date was 1.1 months (0.3-22.1). Two (10%) pts had partial response with sunitinib and 11 (55%) stable disease for a total disease control rate of 65%. With a median follow-up of 8.8 months, median PFS was 6.8 months (0.0-13.9) and median OS 13.6 months (10.5-16.6). Median duration of treatment was 4 months (0.9-16-2). Most common treatment-related adverse events, all grades, were asthenia (55%), dysgeusia (35%), diarrhea (30%), hypertension (30%), mucosal inflammation (25%), palmar-plantar erythrodysesthesia (25%), anemia (20%), neutropenia (20%) and nausea (15%); grade 3 were asthenia (15%), hypertension (10%) and neutropenia (10%). **Conclusions:** To our knowledge, the INMUNOSUN trial is the first study to evaluate prospectively the activity of a single agent TKI in a pure 2L setting of metastatic RCC pts treated with an IO-based approach upfront. ORR and PFS with sunitinib seem lower than expected when used as a 1L. Consistency in toxicity profile was observed. Clinical trial information: NCT03066427. Research Sponsor: Pfizer.

5061 Poster Session (Board #130), Fri, 8:00 AM-11:00 AM

Association of neutrophil to lymphocyte ratio (NLR) with efficacy from JAVELIN Renal 101. *First Author: Mehmet Asim Bilen, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: The phase 3 JAVELIN Renal 101 trial (NCT02684006) in treatment-naive patients with advanced renal cell carcinoma (aRCC) demonstrated significantly improved progression-free survival (PFS; hazard ratio [HR], 0.69; 95% CI, 0.56, 0.84; $P < 0.001$) and higher objective response rate (ORR; 51.4% vs 25.7%) with avelumab + axitinib vs sunitinib (Motzer RJ, et al. N Engl J Med. 2019;380:1103-15). NLR has emerged as a potential prognostic biomarker in aRCC; elevated NLR is associated with poorer prognosis. Here, we describe the association of NLR with the efficacy of avelumab + axitinib from JAVELIN Renal 101. **Methods:** We examined baseline NLR and its association with efficacy outcomes. PFS, best overall response (per blinded independent central review using RECIST 1.1), and overall survival (OS) data from the avelumab + axitinib arm from the first interim analysis of JAVELIN Renal 101 were analyzed (data cutoff, June 20, 2018). Multivariate Cox regression analyses of PFS and OS were also conducted. **Results:** In the avelumab + axitinib arm, patients with < median NLR (N = 217) had longer observed PFS (stratified HR, 0.85; 95% CI, 0.634, 1.153) and longer observed OS (stratified HR, 0.51; 95% CI, 0.300, 0.871) than patients with ≥ median NLR (N = 217). The ORR was 57.1% in patients with < median NLR vs 47.5% in patients with ≥ median NLR, with complete response in 5.5% vs 1.4%. Multivariate analysis showed that low NLR was associated with longer PFS and OS by treating baseline NLR as either a continuous variable or a binary variable (dichotomized by median). **Conclusions:** Low NLR was associated with better observed treatment outcomes in patients with aRCC who received avelumab + axitinib. Clinical trial information: NCT02684006. Research Sponsor: This study was funded by Pfizer, as part of an alliance between Pfizer and Merck KGaA, Darmstadt, Germany.

5062 Poster Session (Board #131), Fri, 8:00 AM-11:00 AM

TIVO-3: Final OS analysis of a phase III, randomized, controlled, multicenter, open-label study to compare tivozanib to sorafenib in subjects with metastatic renal cell carcinoma (RCC). *First Author: Sumanta K. Pal, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Tivozanib (T) is a potent and highly selective VEGFR inhibitor. TIVO-3 is a phase 3 study designed to compare the efficacy and safety of T with those of sorafenib (S) as 3rd and 4th line therapy in patients with metastatic RCC. **Methods:** Subjects with RCC who failed 2 or 3 prior systemic regimens, one of which included a VEGFR TKI other than S or T, were stratified by IMDC risk category and type of prior therapy (two TKIs; TKI plus checkpoint inhibitor (CPI); TKI plus other) then randomized in a 1:1 ratio to T or S. **Results:** The 2 arms were well balanced for demographics and prior cancer history. 60% of subjects had 2 prior lines of therapy and 40% had 3 prior lines. 26% had prior treatment with a CPI. Patients treated with T demonstrated PFS superiority compared to S, 5.6 (95% CI 7.3 - 5.3) v. 3.9 mos (95% CI 5.6 – 3.7; HR 0.73; p=0.02). ORR was 18% for T compared to 8% for S (p=0.02). 44% of T treated subjects experienced a grade 3 treatment-related adverse event compared to 55% for S. The predefined, interim analysis for OS performed two years after enrollment was closed had a HR of 0.99 based on 227 events. The final analysis will be presented based on an estimate of 263 events. **Conclusions:** T is superior to S as measured by PFS; 2-year PFS, and ORR in this heavily-treated/relapsed or refractory RCC population and is better tolerated than S. Final OS data will be updated prior to presentation. Clinical trial information: 02627963. Research Sponsor: AVEO Oncology.

5063 Poster Session (Board #132), Fri, 8:00 AM-11:00 AM

Application of IMDC criteria across first-line (1L) and second-line (2L) therapies in metastatic renal-cell carcinoma (mRCC): New and updated benchmarks of clinical outcomes. *First Author: Shaan Dudani, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: In patients with mRCC, the International mRCC Database Consortium (IMDC) criteria have been validated as a prognostic tool in patients treated with targeted therapy in the 1-4L settings and with 2L Nivolumab (Nivo). However, it is unknown whether the IMDC criteria can be used to risk stratify in recently approved 1L IO combination therapies, including Ipilimumab + Nivolumab (IOIO) and Axitinib + Pembrolizumab/Avelumab (IOVE). We sought to assess the ability of the IMDC criteria to risk stratify with the use of novel 1L IO combinations and provide updated benchmarks for older 1L and 2L treatments. **Methods:** Patients with mRCC starting systemic therapy between 2010-2019 were identified through the IMDC. IMDC risk score was calculated at the time of starting the line of therapy of interest. The primary endpoint was overall survival (OS) from time of initiating the treatment of interest. **Results:** From a total of 6596 unique patients, 5043 treated in the 1L setting and 2498 treated in the 2L setting were included in the analysis. Across the entire cohort, median age was 61, 73% were male, 16% had sarcomatoid features, 79% underwent nephrectomy and 88% had clear-cell histology. IMDC risk groups for 1L and 2L treatment were 17%, 57%, 27% and 10%, 60%, 30% for favourable-, intermediate- and poor-risk disease, respectively. IMDC criteria appropriately risk stratified into 3 prognostic groups in 1L IOIO and 1L IOVE combinations, in addition to older treatments: 1L VEGF TT, 2L VEGF TT, 2L Nivo and 2L Everolimus. Results are displayed in Table. Due to the novelty of 1L IO combinations, median follow up time was shorter and thus landmark OS values are presented. **Conclusions:** IMDC criteria may be used to risk stratify in recently approved 1L IO combination therapies in addition to older 1L and 2L treatments. These data provide contemporary benchmarks for OS that may be used for patient counseling and trial design. Research Sponsor: None.

	Favourable-Risk	Intermediate-Risk	Poor-Risk	P-value (log-rank)
		Median OS (months) by IMDC Risk Group		
1L VEGF TT* (N=4662)	47.8	27.2	8.3	<0.01
2L VEGF TT† (N=1230)	41.0	21.4	7.0	<0.01
2L Nivo (N=586)	NR	28.2	6.7	<0.01
2L Everolimus (N=682)	21.4	14.7	4.8	<0.01
		Landmark OS by IMDC Risk Group		
1L IOIO (N=291)				
1-year OS	96%	83%	56%	<0.01
2-year OS	76%	65%	44%	
1L IOVE (N=90)				0.01
1-year OS	96%	86%	51%	0.01
2-year OS	84%	69%	34%

Immunomodulation by HDAC inhibition: Results from a phase I study with entinostat in combination with atezolizumab and bevacizumab in metastatic renal cell carcinoma patients. *First Author: Roberto Pili, Indiana University, Indianapolis, IN*

Background: Immunosuppressive regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs) limit the efficacy of immunotherapies. We have previously reported that the HDAC inhibitor entinostat has synergistic antitumor effect in combination with immunotherapies in preclinical models by inhibiting Tregs and MDSCs function. The combination of atezolizumab (PD-L1 inhibitor) and bevacizumab (VEGF inhibitor) is active in renal cell carcinoma (RCC). Thus, we have conducted a Phase I study with entinostat, atezolizumab and bevacizumab in patients (pts) with metastatic RCC. **Methods:** The primary objective was to evaluate safety and tolerability. The phase I portion included 3 dose levels of entinostat (1 mg, 3 mg or 5 mg, PO weekly) and fixed, standard doses of atezolizumab (1200 mg IV every 21 days) and bevacizumab (15 mg/Kg IV every 21 days). Pts with any histological type and prior therapies were included. **Results:** Dose levels were completed with up to 1 DLT/dose level. 5 mg was the Phase II recommended dose for entinostat. DLTs included hypertension, encephalopathy, hyponatremia and pruritus. The most common resolved grade 3/4 toxicities were hypophosphatemia (33%), hypertension (17%), and pneumonitis (11%). We have enrolled 18 pts (17 evaluable for ORR by RECIST). 5 pts continue on treatment. 3 pts discontinued treatment because of adverse events, 9 pts for disease progression, and one pt for physician decision. Good risk and intermediate risk pts were 61% and 39%, respectively. Overall ORR was 47.1% (95% CI 23.0-72.2) and median PFS was 7.6 months (95% CI 1.6-16.3). In pts with no prior therapies (12) the ORR was 58.3% (95% CI 27.7-84.8) and median PFS was 13.4 months (95% CI 1.5-28.9). One additional PR was observed by ir-RC but was not confirmed within the data cut-off date of 11/11/19. In pts with prior immune checkpoint inhibitors (ICIs) (5) ORR was 20% (95% CI 0.5-71.6) and median PFS was 7.6 months (95% CI 1.3-NR). Preliminary data show a statistically significant lower % of circulating monocytic MDSC ($HLADR^{-}1CD11b^{+}CD33^{high}CD14^{+}CD15^{-}$) and exhausted T cells ($CD45^{+}CD3^{+}CD8^{+}TIM3^{+}$) following treatment in pts (4) with objective responses as compared to pts (4) with progressive disease. **Conclusions:** The results from this phase I suggest that the combination of entinostat, atezolizumab and bevacizumab is relatively well tolerated and is active in renal cell carcinoma patients, in both ICIs naïve and resistant disease. A phase II portion of this study is currently accruing patients. Clinical trial information: NCT03024437. Research Sponsor: None.

5065 Poster Session (Board #134), Fri, 8:00 AM-11:00 AM

A phase II multicenter study of stereotactic radiotherapy (SRT) for oligoprogression in metastatic renal cell cancer (mRCC) patients receiving tyrosine kinase inhibitor (TKI) therapy. *First Author: Patrick Cheung, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada*

Background: SRT is increasingly considered to delay the need to change systemic therapy in metastatic cancer patients who develop oligoprogression. This prospective phase II study evaluated the use of SRT in the setting of mRCC patients who developed oligoprogression while on 1st or 2nd line TKI therapy. **Methods:** IMDC favourable or intermediate risk mRCC patients (pts) who had previous stability or response on ≥ 3 months of TKI therapy were eligible if they developed radiographic progression of ≤ 5 metastases. The oligoprogressive tumours were treated with SRT while other metastases which were stable or responding to TKI therapy were left alone. TKI therapy was temporarily stopped during SRT, and the same TKI drug then resumed. Endpoints included local control of the irradiated lesions, progression free survival (PFS), overall survival (OS), and cumulative incidence of changing systemic therapy after study entry. **Results:** 37 pts (median age 63, IMDC favourable 12, intermediate 25) with 57 oligoprogressive tumours were enrolled. 35 pts were on sunitinib and 2 on pazopanib. Median duration of TKI therapy prior to study entry was 18.6 months. 4 pts had IL-2 therapy prior to a 2nd line TKI. 21 pts had a solitary oligoprogressive tumour, while 17 pts had 2-3 oligoprogressive tumours treated with SRT. Median biological effective dose (BED_{10}) was 72 Gy, corresponding to an SRT dose of 40 Gy in 5 fractions. Irradiated tumour sites were the following: 21 lung/pleural, 15 bone, 7 lymph node, 4 adrenal, 4 liver, 3 brain, 2 spleen, and 1 pancreas. At a median followup of 11.6 (1.8-53.5) months the median PFS from study entry was 9.6 months (95%CI 7.4-20.5) with the vast majority of progression occurring outside of the irradiated areas. The 2-year local control of the irradiated tumours was 96%. The 2-year OS from study entry was 77%. The cumulative incidence of changing systemic therapy was 47% at 1 year and 75% at 2 years, with a median time to a change in systemic therapy of 12.6 months. There were no grade 3-5 SRT related toxicities. **Conclusions:** To our knowledge, this is the first prospective evaluation of the use of SRT for oligoprogressive metastatic cancer. Local control of irradiated oligoprogressive mRCC tumours was high. After delivering SRT, mRCC patients did not need a change in their systemic therapy for a median of 1 year, effectively increasing the PFS of their TKI therapy. This novel approach should be studied in patients with oligoprogression on immunotherapy. Clinical trial information: NCT02019576. Research Sponsor: Pfizer Canada.

5066 Poster Session (Board #135), Fri, 8:00 AM-11:00 AM

Clinically advanced renal cell carcinoma (RCC) and renal sarcoma (RSC) in young patients: A comprehensive genomic profiling (CGP) study. *First Author: Gennady Bratslavsky, Urologic Oncology Branch, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: We queried whether the landscape of genomic alterations (GA) would differ in patients with metastatic RCC under 40 years of age (under40) and patients 40 years of age or older (over40). **Methods:** FFPE tissues from 2,128 clinically advanced RCC and 25 RSC underwent hybrid-capture based CGP to evaluate all classes of GA. Samples were classified at time of sequencing as the following RCC subtypes: clear cell (ccRCC), papillary (papRCC), chromophobe (chrRCC), medullary (medRCC), collecting duct (cdRC), sarcomatoid (sarcRCC) and NOS (nosRCC). Tumor mutational burden (TMB) was determined on up to 1.1 Mbp of sequenced DNA. Tumor cell PD-L1 expression was determined by IHC (Dako 22C3). **Results:** The male preponderance increased in the over40 patients. The GA/tumor increased in the over40 cohorts except for medRCC. Similarly, TMB was consistently higher in over40 groups. MSI high status was virtually absent. PD-L1 expression, available only in small subsets, was generally absent although 44% high positive staining in sarcRCC was noteworthy. Differences in GA in under40 vs over40 RCC were seen and included increased *PBRM1* and *SETD2* GA in over40 vs under40 ccRCC; increased C*DKN2A/B* and *TERT* and decreased *FH* GA in over40 vs under40 papRCC; increased *TP53* and decreased *VHL*, *BAP1*, *SETD2* and *PTEN* in over40 vs under40 chrRCC; increased *TP53*, *PTEN* and *TERT* GA with decreased NF2 GA in over40 vs under 40 sarcRCC; and increased *TP53*, *VHL* and *TERT* in over40 vs under40 nosRCC. Changes in GA in under40 vs over40 medRCC, cdRCC and RSC were noted but insufficient cases prevented further evaluation. **Conclusions:** When separately evaluated by under/over 40 years of age, CGP of clinically advanced RCC demonstrates differences in genomic landscapes with over40 cases featuring increasing male preponderance, higher GA/tumor, higher TMB and increases in a variety of GA. These findings may play important roles in the planning of future clinical trials designed to personalize the treatment of metastatic RCC. Research Sponsor: Foundation Medicine Inc.

5067 Poster Session (Board #136), Fri, 8:00 AM-11:00 AM

Quality-adjusted time without symptoms or toxicity (Q-TWiST) of lenvatinib plus everolimus versus everolimus monotherapy in patients with advanced renal cell carcinoma (RCC). *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the primary analysis of Study 205 phase II trial (NCT01136733), lenvatinib+everolimus (vs everolimus) significantly prolonged progression-free survival (median PFS; 14.6 vs 5.5 months, HR = 0.40, 95% CI [0.24, 0.68]) in advanced RCC patients who received one prior anti-angiogenic therapy. Overall treatment differences were evaluated in a post hoc analysis using a quality-adjusted time without symptoms of disease or toxicity of treatment (Q-TWiST) methodology. **Methods:** Patients' survival time was partitioned into three mutually exclusive health states: time spent with grade 3/4 toxicity (TOX), time prior to disease progression and without grade 3/4 toxicity (TWiST) and time post disease progression (REL). Mean time spent in each state was weighted by a health-state utility associated with that state and summed to calculate the Q-TWiST. Non-parametric bootstrapping method was used to generate 95% CI, which evaluates the between-treatment differences. At base case, utility for TWiST, TOX and REL were assigned as 1.0, 0.5 and 0.5, respectively. A sensitivity analysis was used, applying utilities across the range of 0 (similar to death) to 1.0 (perfect health). A relative gain in Q-TWiST of ≥10% and ≥15% has been established in previous literature as clinically important and clearly clinically important, respectively. **Results:** Patients receiving lenvatinib+everolimus (n = 51) vs everolimus (n = 50) had significantly longer mean time in TWiST (10.9 vs 6.4 months; difference 4.5 [95% CI: 1.4, 7.8]) and numerically longer in TOX (1.9 vs 0.7 months; difference 1.2 [95% CI: -0.3, 3.1]) but shorter in REL (5.8 vs 8.5 months; difference -2.8 [95% CI: -6.2, 0.6]). At base case, lenvatinib+everolimus patients had a significant mean Q-TWiST gain of 3.7 months (14.7 vs 11.0; 95% CI of difference [1.3, 6.3]), with a relative gain of 24% vs everolimus. In a sensitivity analysis using alternative utility values for TWiST (varied from 0.55 - 0.9) with utility of TOX and REL both set as 0.5, absolute mean Q-TWiST gain ranged from 1.7 to 3.3 months, with a relative gain ranging from 11.0% to 21.2% (all significant). With TWiST utility set as 1.0 and utility of TOX and REL varying from 0 to 1.0, Q-TWiST gain ranged from 1.7 to 5.8 months (mostly significant and became non-significant as the REL utility gets closer to 1.0 and TOX utility gets closer to 0). **Conclusions:** Within Study 205, lenvatinib+everolimus resulted in a statistically significant and clinically important gain in Q-TWiST vs everolimus alone. Clinical trial information: NCT01136733. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5068 Poster Session (Board #137), Fri, 8:00 AM-11:00 AM

Efficacy of immune-checkpoint inhibitors (ICI) in the treatment of older adults with metastatic renal cell carcinoma (mRCC): An international mRCC database consortium (IMDC) analysis. *First Author: Daniel Vilarim Araujo, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Anti-PD-1/PD-L1 immune-checkpoint inhibitors (ICI) are now a standard of care in metastatic renal cell carcinoma (mRCC). Older adults were underrepresented in registration trials and given that immunological senescence may affect the anti-tumor activity of ICIs, there is uncertainty about the efficacy of ICIs in this population. Here we provide real world data on outcomes of older adults with mRCC treated with ICIs. **Methods:** Patients with mRCC treated with a PD-1/PD-L1 ICI either as monotherapy or as a combination treatment from 2000 to 2019 were included. Older adult was defined as ≥ 70-years at the time of ICI treatment. Descriptive statistics were summarized in means, medians and proportions. Efficacy was assessed by survival analysis, including overall survival (OS), time to treatment failure (TTF), and overall response rate (ORR). Multivariate analyses adjusted for imbalances in IMDC risk factors. $P < 0.05$ was considered statistically significant. **Results:** Of 1427 patients, 397 (28%) were older adults. Mean age of older vs. younger adults was 74 (70-92) vs. 60 (22-69) years. Groups were comparable in terms of gender (Female 28.5% vs. 26.1%, p = 0.36), rates of nephrectomy (21% vs. 18.3%, p = 0.24) and presence of sarcomatoid features (12.3% vs. 17.8%, p = 0.14). Proportion of IMDC risk-groups between older vs. younger adults were as follows: 15.4% vs. 18.2% for favorable, 61.2% vs. 59.1% for intermediate, and 23.4% vs. 22.7% for poor; there was no statistical difference (p = 0.55). ICI was used as 1st line in 40%, 2nd line in 48.5% and 3rd line in 11.5% patients; older adults were less likely to be treated with ICI in 1st line (32.2% vs. 43%, $p < 0.01$). In terms of survival, older adults had poorer median OS (25.1m vs. 30.8m, $p < 0.01$) but similar median TTF (6.9m vs. 6.9m, p = 0.40) compared to younger adults. In multivariate analyses, older age was not a predictor of either worse OS (aHR = 1.02, p = 0.86) or TTF (aHR = 0.95, p = 0.59). Older adults had a lower ORR compared to younger (24% vs. 31%, p = 0.01), which was mainly driven by responses in 1st line (31% vs. 44%, p = 0.02) and not observed in 2nd/3rd line (20% vs. 20%, p = 0.86). **Conclusions:** On multivariate analyses, older adults with mRCC treated with ICI had no difference in OS and TTF when compared to younger adults, despite having lower ORR in 1st line. Our data supports that older age is not an independent risk factor for survival; thus, treatment selection should not be based solely on chronological age. Research Sponsor: None.

5069 Poster Session (Board #138), Fri, 8:00 AM-11:00 AM

First-line pembrolizumab (pembro) monotherapy in advanced clear cell renal cell carcinoma (ccRCC): Updated follow-up for KEYNOTE-427 cohort A. *First Author: David F. McDermott, Dana-Farber/Harvard Cancer Center, Boston, MA*

Background: KEYNOTE-427 (NCT02853344), an open-label, single-arm, phase 2 study, showed clinical activity of first-line pembro monotherapy in patients (pts) with ccRCC (cohort A). Previous studies in RCC and immune-oncology suggest depth of response may correlate with long-term benefit. Association between depth of response and OS, along with updated efficacy and safety for cohort A of KEYNOTE-427, are presented. **Methods:** Pts with histologically confirmed ccRCC, measurable disease (RECIST v1.1), and no prior systemic therapy received pembro 200 mg IV Q3W for 2 y or until progressive disease, unacceptable toxicity, or withdrawal. End points: ORR (primary), DOR, and PFS (RECIST v1.1); OS, and safety. Association between depth of response (maximum reduction from baseline in the sum of target lesions) and OS was evaluated using Cox proportional hazards model with target lesion reduction group as time-varying covariate. **Results:** 110 pts enrolled; median time from enrollment to data cutoff was 23.1 (range, 16.7-27.5) mo. Overall, 38.2% of pts had favorable and 61.2% had intermediate/poor IMDC risk. ORR was 36.4% (95% CI, 27.4-46.1; 3 CRs, 37 PRs); median (range) DOR was not reached (2.3-23.5+ mo); 64.0% had a DOR ≥12 mo. Median PFS was 7.1 mo (95% CI, 5.6-11.0) and median OS was not reached; 18-mo PFS and OS rates were 26.6% and 80.0%, respectively. 69.1% had some reduction in target lesions. Pts with > 60% reduction in target lesions had a greater probability of survival than pts with a ≤60% reduction (Table). ORR observed in IMDC favorable and intermediate/poor risk was 31.0% and 39.7%, respectively; 18-mo OS rate was 95.2% for favorable and 70.5% for intermediate/poor IMDC risk. Treatment-related AEs (TRAEs) occurred in 81.8% of pts, primarily fatigue (29.1%) and pruritus (28.2%). Grade ≥3 TRAEs occurred in 29.1% of pts; 1 pt died of treatment-related pneumonitis. **Conclusions:** First-line pembro monotherapy was tolerable and showed promising antitumor activity in advanced ccRCC. In general, pts who had greater reductions in target lesions demonstrated a trend toward improved OS; pts with reduction of tumor burden ≥80% had comparable long term outcomes to those who achieved a RECIST 1.1 defined CR. Clinical trial information: NCT02853344. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Outcomes of patients with metastatic renal cell carcinoma (mRCC) treated with first-line Immuno-oncology (IO) agents who do not meet eligibility criteria for clinical trials. *First Author: Chun Loo Gan, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: IO combination therapies [including IOIO and IO/vascular endothelial growth factor inhibitor (IOVE) combinations] in mRCC have been approved based on registration clinical trials that have strict eligibility criteria. The clinical outcomes of trial ineligible patients who are treated with first-line IOIO or IOVE combinations are unknown. **Methods:** Metastatic RCC patients treated with first-line IOIO or IOVE were retrospectively deemed ineligible for clinical trials (according to commonly used inclusion/exclusion criteria in IO trials) if they had a Karnofsky performance status (KPS) $< 70\%$, no clear-cell component, brain metastases, hemoglobin (Hb) < 9 g/dL, eGFR < 40 mL/min, platelet count of $< 100{,}000/mm^3$, and/or neutrophil count $< 1500/mm^3$. Time to treatment failure (TTF) and overall survival (OS) were calculated from time of starting first-line IO therapy. **Results:** Overall, 26% (155/592) of patients in the International mRCC Database Consortium (IMDC) were deemed ineligible for clinical trials by the above criteria. Baseline characteristics are listed in Table. The reasons for ineligibility were: no clear-cell component (34%, 53/155), Hb $<$ 9g/dL (28%, 44/155), eGFR $<$ 40 mL/min (19%, 30/155), brain metastases (19%, 29/155), KPS $< 70\%$ (14%, 21/155), platelet $< 100{,}000/mm^3$ (3%, 4/155) and neutrophil count $< 1500/mm^3$ (0%, 0/155). Between ineligible versus eligible patients, the response rate, median TTF and median OS of first-line IOIO or IOVE was 34% vs 46% ($p = 0.02$), 4.2 vs 9.7 months ($p < 0.01$), and 25.3 vs 44.4 months ($p < 0.01$), respectively. When adjusted by the IMDC prognostic categories, the HR for death between trial ineligible and trial eligible patients was 1.50 (95% CI 1.05-2.14). **Conclusions:** The number of patients that are ineligible for clinical trials is substantial and their outcomes are inferior. These data may guide patient counselling and specific trials addressing the unmet needs of protocol ineligible patients are warranted. Research Sponsor: None.

5071 Poster Session (Board #140), Fri, 8:00 AM-11:00 AM

Characterizing sites of metastatic involvement in metastatic clear-cell, papillary, and chromophobe renal cell carcinoma. *First Author: Shaan Dudani, Ottawa Hospital Cancer Centre, University of Ottawa, Ottawa, ON, Canada*

Background: There exists considerable biological and clinical variability between histologic variants of metastatic renal-cell carcinoma (mRCC). Data reporting on sites of metastatic involvement in less common histologies of mRCC are sparse. We sought to characterize the frequency of metastatic site involvement across the three most common histologies of mRCC: clear-cell (ccRCC), papillary (pRCC), and chromophobe (chrRCC). **Methods:** Using the International mRCC Database Consortium (IMDC) database, patients with mRCC starting systemic therapy between 2002-2019 were identified and sites of metastases at the time of systemic therapy initiation were documented. Patients with multiple sites of metastatic involvement were included in analyses of all groups to which they had metastases. The primary outcomes were prevalence of metastatic site involvement and overall survival (OS). Patients with mixed histology were excluded. **Results:** 10,105 patients were eligible for analysis. Median age at diagnosis was 60, 72% were male and 79% underwent nephrectomy. 92%, 7% and 2% of patients had ccRCC, pRCC, and chrRCC, respectively. Frequency of metastatic site involvement across the histologic subtypes is shown in Table. Lung, adrenal, brain and pancreatic metastases were more frequent in ccRCC, lymph node involvement was most frequent in pRCC, and liver metastases were most frequent in chrRCC. Median OS for ccRCC varied by site of metastatic involvement, ranging between 16 months (brain/pleura) and 50 months (pancreas). OS by site of metastatic involvement was compared between histologies for the four most common sites of metastases (lung, lymph nodes, bone, liver). As compared to patients with ccRCC, patients with pRCC had lower OS regardless of site of metastasis ($p < 0.05$). Power was limited and thus differences in OS between ccRCC and chrRCC were not detectable. **Conclusions:** Sites of metastatic involvement differ based on histology in mRCC. These data highlight the clinical and biologic variability between histologic subtypes of mRCC and constitute the largest cohorts of patients with metastatic pRCC and chrRCC to report on sites of metastases. Sites of Metastatic Involvement by Histology. Research Sponsor: None.

5072 Poster Session (Board #141), Fri, 8:00 AM-11:00 AM

Baseline and early change of systemic inflammation index (bSII and ΔSII) as prognostic factors in metastatic renal cell carcinoma (mRCC) patients treated with Nivolumab: Final results of the Meet-URO 15 (I-BIO-REC) study. *First Author: Sara Elena Rebuzzi, Medical Oncology Unit 1, IRCCS Ospedale Policlinico San Martino di Genova, Genoa, Italy*

Background: Biomarkers to select mRCC patients most likely to benefit to immunotherapy are still needed. The retrospective multicentre Meet-URO-15 study evaluated the prognostic role of peripheral blood cells in mRCC patients treated with Nivolumab. **Methods:** Complete blood count was collected at the first four cycles of Nivolumab. The primary endpoint was median overall survival (mOS) according to baseline neutrophil-to-lymphocyte ratio. Secondary analyses included bSII defined as platelet x NLR (cutoff = 1375) and ΔSII defined as the difference between SII at 2^{nd}cycle and bSII (median used as cutoff = 383). **Results:** From October 2015 to October 2019, 470 patients started Nivolumab as 2^{nd}(67%), 3^{rd}(22%) and $> 3^{rd}$(11%) line. Median age was 66 years, 71% were male and 83% had clear cell histology. Baseline IMDC group was favorable in 25%, intermediate in 63% and poor in 12%. Lymph-nodes, visceral and bone metastases were present in 54%, 91% and 36%. mOS and progression-free survival (PFS) were 34.8 and 7.5 months. Overall response rate (ORR) and disease control rate (DCR) were 30% and 61%. SII was available in 404 patients: SII $<$ 1375 (82%) correlated with statistically significant improvement of PFS [10.2 *vs* 4.1 months, HR 2.06 (1.54-2.76), $p< 0.001$], OS [46.2 *vs* 9.5 months, HR 3.16 (2.23-4.49), $p< 0.001$], ORR (35% vs 21%, $p= 0.035$) and DCR (67% *vs* 40%, $p< 0.001$). ΔSII was available in 360 patients: ΔSII $<$ 383 (75%) correlated with statistically significant improvement of PFS [11.3 *vs* 4.7 months; HR 1.64 (1.23-2.18), $p= 0.001$] and OS [NR *vs* 21.1 months; HR 1.76 (1.21-2.56), $p= 0.003$], ORR (37% *vs* 24%, $p= 0.023$) and DCR (68% *vs* 53%, $p= 0.01$). Multivariate analyses adjusted for IMDC group, line of therapy and metastatic sites, confirmed the statistically significant correlation of bSII and ΔSII with OS, PFS and DCR. **Conclusions:** Our study showed the statistically significant correlation of lower bSII and early ΔSII with longer OS, PFS and higher DCR in mRCC patients treated with Nivolumab. Research Sponsor: None.

5073 Poster Session (Board #142), Fri, 8:00 AM-11:00 AM

Phase I clinical trials as a therapeutic option for patients with metastatic renal cell carcinoma (mRCC). *First Author: Andrew W Hahn, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint inhibitors, multi-kinase VEGF agents, and mTOR inhibitors are approved for mRCC. Due to the overlapping mechanisms of action of the twelve approved therapies for mRCC, select patients are referred for phase I clinical trials after progression on multiple lines of treatment. We sought to evaluate the efficacy of phase I trials in patients with mRCC. **Methods:** Patients with all histologies of mRCC were included if they received treatment on a phase I clinical trial at MD Anderson Cancer Center. Baseline clinical characteristics and outcomes data were retrospectively collected. The historical control was a study of 1112 patients with mRCC who received third-line treatment in the IMDC database (PMID: 27318422). Time to event endpoints were calculated using Kaplan-Meier methods. Hazard ratios (HR) were calculated using the Cox proportional hazard model. **Results:** Between 2014 and 2019, there were 106 cases where 82 patients with mRCC were enrolled in a phase I clinical trials (40 unique trials). 30% (32/108) of the cases were in patients with non-clear cell RCC (nccRCC), and the most prevalent nccRCC histologies were papillary (n = 7) and renal medullary carcinoma (n = 7). The median number of prior systemic therapies was 2 (range 0-9). Across the entire cohort, median PFS was 5.9 months (m), median OS was 31.2 m, and the ORR was 23% (Table). In patients who received at least two prior lines of therapy (n = 70), the median PFS was 4.8 m and median OS was 24.9 m. In patients with metastatic nccRCC, median OS, PFS, and ORR were numerically lower, but statistically did not contradict the supposition that these outcomes did not differ from ccRCC (Table). **Conclusions:** In the largest pooled phase I clinical trial experience for patients with mRCC, phase I trials may have therapeutic value when compared to historical controls, where median PFS was 3.9 m, median OS was 12.4 m, and ORR was 10.5%. Patients with all histologies of mRCC may derive clinical benefit from phase I clinical trials, yet patients with ccRCC had numerically better outcomes. Patients with mRCC should be considered for phase I clinical trials. Research Sponsor: None.

5074 Poster Session (Board #143), Fri, 8:00 AM-11:00 AM

CT-based radiomic classifier of primary renal tumors to distinguish between metastatic and non-metastatic disease. *First Author: Sam O Kleeman, Barts Health NHS Trust, London, United Kingdom*

Background: Existing clinicopathological tools are unable to accurately identify renal cell carcinoma (RCC) patients who will develop metastases after surgery. As a result, it is unclear how long and how often to follow-up patients post-operatively. Tumor macropathology, as assayed by CT scanning, represents the sum product of tumor biology and microenvironment. We hypothesized that quantitative tumor features extracted from CT scans (termed radiomics) could discriminate between metastatic and non-metastatic RCCs. **Methods:** This retrospective study incorporated three cohorts of clear-cell RCC patients (n = 279, from TCGA, CPTAC and KiTS19 datasets) treated with nephrectomy. The study cohort was sub-divided into metastatic (n = 54, M1 at diagnosis or recurrence after surgery), high metastatic risk/HMR (n = 85, N1, T3-4, T2G3/4, T1G4) or low metastatic risk/LMR (n = 140, absence of these features) subsets. 3D primary tumor segmentation of arterial contrast CT scans was performed by trained investigators. Features were extracted using pyRadiomics 2.2.0 (n = 839) with gray value and voxel size normalization. For random forest (RF) model training, the cohort was randomly split into training (75%) and validation (25%) sets. **Results:** Multidimensional clustering of radiomic features by t-SNE analysis showed that metastatic and HMR tumors predominantly cluster together, while LMR tumors cluster separately. Consistent with this, there were no differentially regulated radiomic features (DR-features) between HMR and metastatic tumors. In contrast, we identified 26 DR-features (adjusted p-value < 0.05) between presumed-metastatic (n = 139, HMR and metastatic tumors) and LMR tumors, which were then used as input to a RF binary classifier. In the training set, the trained classifier discriminated between presumed-metastatic and LMR tumors with bootstrapped AUC = 0.81. In the validation set, the classifier discriminated subsets with AUC = 0.80. **Conclusions:** High-risk and metastatic tumors have similar radiomic properties, suggesting common biology driving metastasis in RCC. We propose a novel radiomic classifier that accurately distinguishes between presumed-metastatic and low-risk tumors. Further work will assess whether this tool can identify patients with micrometastatic disease at diagnosis, who may benefit from adjuvant therapy or closer, long-term surveillance. 5075 Poster Session (Board #144), Fri, 8:00 AM-11:00 AM

A phase II study of the selective MET kinase inhibitor INC280 in advanced papillary renal cell cancer. *First Author: Paul Denis Leger, National Institutes of Health, Bethesda, MD*

Background: There are currently no approved systemic agents for patients with advanced type 1 papillary renal cell carcinoma (pRCC). Type 1 pRCC can occur in a hereditary form with germline alterations of *MET* (hereditary papillary RCC: HPRC) or in a sporadic form. Both hereditary and sporadic forms have similar histologic features and somatic *MET* alterations have been found in 15-20% of patients with sporadic pRCC. Furthermore, gain of chromosome 7, where *MET* and the gene for its ligand HGF are located, has been reported in a majority of patients with type 1 pRCC and may represent an alternative means of activating the MET pathway. This is a phase II study evaluating the activity of INC280, a highly selective and potent MET inhibitor, in patients with pRCC. **Methods:** Patients with advanced type 1 pRCC were treated with INC280 at a starting dose of 600mg PO twice daily (capsules). Later in the study course, the capsules were replaced with exposure-equivalent tablets (400mg PO twice daily). Eligible patients had an ECOG PS 0-2, no active brain metastases, and less than 4 prior lines of therapy. The primary endpoint was overall response rate (ORR) assessed by RECIST 1.1. Secondary endpoints included progression-free survival, disease control rate, and tolerability. Exploratory endpoints included the correlation between *MET* alteration/copy number gain and response to INC280. **Results:** Twenty subjects were enrolled from January 2014 to October 2019. Median age was 62 years, 60% of patients were classified as IMDC good risk and 40% as IMDC intermediate risk. Three patients (15%) achieved a confirmed partial response and seven (35%) had stable disease, including 4 (20%) who maintained stable disease for over 6 months. The most common treatment-related adverse events (AEs) were of grade 1-2 including nausea (85%), increased creatinine(70%) diarrhea(60%), fatigue(55%), limb edema(40%), increase in amylase(20%), triglycerides(20%), LFTs(20%), lipase(10%) and leukopenia(10%). INC280-related Grade 3-4 AEs included asymptomatic increased lipase (20%), increased LFTs (10%), increased amylase(5%), leukopenia (5%), lymphopenia (5%) and syncope (5%). **Conclusions:** INC280 demonstrated clinical activity in patients with advanced type 1 pRCC with an acceptable toxicity profile. The correlation between the presence of *MET* alteration and/or copy number gain and response to INC280 is under evaluation. Research Sponsor: Novartis, Other Government Agency.

Genomic and transcriptomic correlates of clinical benefit from immunotherapy and targeted therapy among patients with metastatic renal cell carcinoma (mRCC). *First Author: Nicholas Salgia, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Previous studies have delineated *PBRM1* alterations as a prognostic indicator for response to nivolumab in mRCC (Miao *et al* Science 2018). However, further clinically-relevant biomarkers remain elusive in mRCC. Herein, we utilized genomic profiling to detect correlates of clinical benefit (CB) among patients (pts) with mRCC receiving VEGF-directed targeted therapy, immunotherapy, or both. **Methods:** Pts with mRCC who underwent clinical tumor-normal whole exome and whole transcriptome RNA sequencing (Ashion Analytics, Phoenix, AZ) were retrospectively identified at a single institution. Pts' demographics and clinical variables including treatment type, treatment response, and survival outcomes were collected from an institutional mRCC database. Pts who had received immunotherapy or VEGF-directed therapy (or both) were eligible for analysis. CB was defined as pts who experienced a complete response, partial response, or maintained stable disease for at least 6 months on therapy. Two-tailed Fisher's exact test was used to assess characteristics of genomic alterations and clinical benefit. **Results:** Out of 155 mRCC pts with genomic profiling, 58 pts with evaluable response and sufficient follow-up information were included in the analysis. The median age of the cohort was 63 years and 74% were male. The majority (81%) had clear cell histology. 43 pts received targeted therapy and 32 received immunotherapy (17 pts received both). No singular gene was associated with clinical benefit in the targeted therapy cohort. *PBRM1* loss of function mutations were more frequent in pts on immunotherapy who experienced CB ($p > 0.05$). *TERT* promoter mutations were enriched in pts who experienced no CB on immunotherapy ($p = 0.04$). Differential gene expression analysis of the transcriptomes found 135 genes that were significantly upregulated in *TERT*-mutated samples, including *SST, CYSLTR2, WNK2,* and *PTGES* (adjusted p-value < 0.05). ENRICHR analysis found that MYC and KAT2A were key transcription factor pathways significantly enriched in pts with *TERT* mutation who experienced no CB from immunotherapy. **Conclusions:** These data support previous observations regarding the prognostic nature of *PBRM1* in mRCC and offer novel findings associating *TERT* mutations with a lack of CB from immunotherapy. Our transcriptomic analysis implies that MYC-targeting agents and epigenetic modifiers (directed at KAT2A) could overcome immunotherapy resistance. Research Sponsor: None.

Use of immune checkpoint inhibitors (ICIs) after prior ICI in metastatic renal cell carcinoma (mRCC): Results from a multicenter collaboration. *First Author: Praful Ravi, Dana-Farber Cancer Institute, Boston, MA*

Background: Several ICIs are used in first and subsequent lines of therapy for mRCC, either alone or in combination with another ICI or targeted therapy (TT). There are no data on the efficacy and safety of using an ICI in patients who have already received an ICI in a prior line of therapy. **Methods:** We reviewed patients with mRCC at 8 institutions who received 2 separate lines of ICI therapy (ICI-1, ICI-2), including as a single-agent and/or combination with other agents. The primary outcomes were overall response rate (ORR) and time to progression (TTP) with ICI-1 and ICI-2. Immune-related adverse events (irAEs) were graded using CTCAEv5.0. **Results:** 65 patients were included. Median age at diagnosis of mRCC was 60 years (range 30-86) and the majority had clear cell RCC (n=56, 86%). Median follow-up was 3.5 years (95% CI 2.9-4.4). Median lines at which ICI-1 and ICI-2 were received were 1 (1-6) and 3 (2-8) respectively. Reasons for discontinuing ICI-1 were disease progression (n=47, 72%), toxicity (n=15, 23%) or other (n=3, 5%). Therapies received at ICI-2 were single-agent ICI (n=26, 40%), or combinations of ICI with another ICI (n=20, 31%), TT (n=11, 17%) or other agent (n=8, 12%). Responses to ICI-1 and ICI-2 are shown in the Table; ORR to ICI-2 was significantly lower than to ICI-1 (23% vs. 36%, p=0.044). Amongst those who responded to ICI-2 (n=14), 7 (50%) received single-agent ICI, and the remainder received ICI in combination with another ICI (n=4, 29%) or TT (n=3, 21%); 7 patients (50%) had previously responded to ICI-1. The ORR to ICI-2 was higher in responders to ICI-1 (32%) compared to those with SD (17%) or PD (15%) to ICI-1. Median TTP (mTTP) at ICI-2 was shorter compared to ICI-1 (5.3 months vs. 8.5 months, Wilcoxon p=0.024). 29 patients (45%) experienced an irAE with ICI-2; 8 (12%) and 3 (5%) had a grade 3 or 4 irAE respectively, with 3 (30%) of these patients having previously had ≥grade 3 irAE to ICI-1. There were no treatment-related deaths. **Conclusions:** The ORR to ICI-2 was 23%, which is comparable to that seen with ICI after prior TT. Responses were seen even amongst those receiving single-agent ICI at ICI-2 and the likelihood of response to ICI-2 was higher if a patient had previously responded to ICI-1. No increase in toxicity with ICI-2 was apparent. Additional data from prospective studies are needed to determine whether sequential ICI has a role in treatment of mRCC. Research Sponsor: None.

	ICI-1	ICI-2
Partial response (PR)	23/64 (36%)	14/60 (23%)
Stable disease (SD)	28/64 (44%)	23/60 (38%)
Progressive disease (PD)	13/64 (20%)	23/60 (38%)

5078 Poster Session (Board #147), Fri, 8:00 AM-11:00 AM

Randomized prospective trial assessing *Bifidobacterium*-containing probiotic supplementation in metastatic renal cell carcinoma (mRCC) patients receiving vascular endothelial growth factor-tyrosine kinase inhibitors (VEGF-TKIs). *First Author: Nazli Dizman, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Studies suggest a link between the gut microbiome and mRCC outcomes, including evidence that mRCC patients (pts) possess a lower abundance of *Bifidobacterium* spp compared to healthy adults (Pal *et al* Clin Cancer Res 2015). The aim of this study was to assess if *Bifidobacterium*-containing probiotics could modulate the gut microbiome and impact rates of clinical benefit (CB) from VEGF-TKIs. **Methods:** Pts initiating VEGF-TKI therapy for mRCC were randomized to probiotic supplemented (PSu) or probiotic restricted (PRe) treatment arms. Pts in the PSu arm consumed two 4 oz servings of Activia daily. Stool samples were collected prior to therapy and at wks 2, 3, 4 and 12. Gut microbiota composition was assessed using whole genome shotgun metagenomic sequencing (Zhu *et al* Microbiome 2018). The primary endpoint was change in *Bifidobacterium* spp with therapy. Microbiome composition was compared across pts with CB (complete/partial response or stable disease) versus no CB (NCB). **Results:** In total, 20 pts were enrolled. The most frequent VEGF-TKIs were cabozantinib (45%), sunitinib (25%) and lenvatinib (25%). Median progression-free survival (PFS) was 6.5 months (95%CI 0.3-12.9) and CB rate was 75%. *Bifidobacterium animalis,* the active ingredient of Activia, reached detectable levels in all pts in the PSu arm, but was only detectable in one pt in the PRe arm. CB rate was not significantly different in PSu vs PRe arms (70% vs 80%, $p > 0.05$), and there was no difference in PFS. LDA effect size (LEfSe) analysis of MetaPhlAn2 data captured 25 enriched species demonstrating an LDA score > 3 in either CB or NCB. Of those with high LDA scores, *Barnesiella intesitinihominis* and *Akkermansia municiphila* were the most significant members ($p = 7.4 \times 10^{-6}$ and $p = 5.6\ 10^{-3}$, respectively). While 92% of *B. intestinihominis* positive pts obtained a CB, only 50% of *B. intestinihominis* negative pts obtained CB ($p = 0.036$). **Conclusions:** This is the first prospective randomized study demonstrating modulation of the gut microbiome with probiotics in mRCC. While microbiome modulation by probiotics did not increase CB rates as intended, consecutive stool specimens allowed us to identify an association between *B. intesitinihominis, A. municiphila* and CB with VEGF-TKIs. In addition to the previously documented association between *A. municiphila* and immunotherapy outcome (Routy *et al*. Science 2018), this species may predict activity with VEGF-TKIs. Clinical trial information: NCT02944617. Research Sponsor: Pfizer Inc.

5079 Poster Session (Board #148), Fri, 8:00 AM-11:00 AM

Prediction of watchful waiting in newly diagnosed metastatic clear cell renal cell carcinoma patients with a good or intermediate prognosis. *First Author: Sarah Verhoeff, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: In metastatic clear cell renal cell carcinoma (mccRCC), the number of International Metastatic Database Consortium (IMDC) risk factors plus metastatic sites may identify patients with rapid or slow disease progression in a period of watchful waiting (WW) (median WW of 8.4 vs 22.2 months; Rini *et al*. Lancet Oncol. 2016). We aimed to validate this and prospectively assess the added value of baseline PET with [^{18}F]FDG and [^{89}Zr]Zr-DFO-girentuximab to predict the WW-period in the multicenter IMaging PAtients for Cancer drug selecTion (IMPACT)-RCC cohort study. (NCT02228954). **Methods:** Between February 2015 and March 2018, 40 treatment-naïve mccRCC patients with a good (n=13) or intermediate prognosis (n=25) according to IMDC, were enrolled. Following baseline CT, [^{18}F]FDG and [^{89}Zr]Zr-DFO-girentuximab-PET, CT scans (RECIST1.1) were acquired at 2, 4, 6, 9, 12 months and thereafter every 4 months. Primary endpoint was time to radiological and/or clinical disease progression, requiring systemic treatment. Patients were assigned to a favorable (<2 IMDC risk factors and <3 metastatic sites) or unfavorable for WW-group (all others; Rini *et al*). Maximum standardized uptake values (SUV_{max}) were measured in PET-positive lesions measuring $\geq$10mm, or 15mm in lymph nodes. High and low-uptake groups were defined based on median geometric mean (gm) SUV_{max} across patients. A one-sided test was used to validate observations by Rini *et al*; other tests were two-sided. **Results:** The median WW-period was 9.3 months in the unfavorable WW-group (n=19) vs 20.4 months in the favorable WW-group (n=21) (HR 1.89 95%CI 0.94-3.89; p=0.037), confirming observations of Rini *et al*. Patients with high [^{18}F]FDG uptake had a median WW-period of 8.5 months compared to 25.2 months in the low-uptake group (HR 4.08 95%CI 1.89-9.28; p=0.0002). Patients with high [^{89}Zr]Zr-DFO-girentuximab uptake had a median WW-period of 10.7 versus 16.4 months in the low-uptake group (HR 1.37; 95%CI 0.69-2.76; p=0.37). [^{18}F]FDG uptake groups improved a Cox-model for WW based on the prognostic groups of Rini *et al* (p=0.0015); [^{89}Zr]Zr-DFO-girentuximab did not (p=0.98). **Conclusions:** The IMPACT-RCC study validated the observations by Rini *et al.* and shows that adding baseline [^{18}F]FDG PET further improves the prediction of the duration of the WW-period in mccRCC patients. Clinical trial information: NCT02228954. Research Sponsor: Dutch Cancer Society (Alpe d'HuZes Grant RUG 2012-5400).

5080 Poster Session (Board #149), Fri, 8:00 AM-11:00 AM

Axitinib plus pembrolizumab in patients with advanced renal cell carcinoma: Long-term efficacy and safety from a phase Ib study. *First Author: Michael B. Atkins, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Axitinib (AXI) plus pembrolizumab (pembro) showed superior overall survival (OS), progression-free survival (PFS) and response rate compared with sunitinib in a randomized Phase 3 trial in advanced renal cell carcinoma (RCC). Here, we report long-term efficacy and safety data of the combination AXI/pembro from the Phase 1 trial, with almost 5 years of follow-up. **Methods:** 52 treatment-naïve patients with advanced RCC were enrolled between 23 September 2014 and 13 October 2015, and were treated with oral AXI 5 mg twice daily and intravenous pembro 2 mg/kg every 3 weeks. Planned treatment duration was 2 years for pembro and not limited for AXI. Based on International Metastatic Database Consortium (IMDC) criteria, 46.2%, 44.2% and 5.8% of patients were reported as having favourable, intermediate and poor risk. **Results:** At data cut-off date (July 3, 2019), median OS was not reached; 38 (73.1%) patients were alive. 14 (26.9%) patients had died, none were related to treatment. The probability of being alive was 96.1% (95% CI 85.2–99.0) at 1 year, 88.2% (95% CI 75.7–94.5) at 2 years, 82.2 % (95% CI 68.5– 90.3) at 3 years, and 66.8 % (95% CI 49.1–79.5) at 4 years. Median PFS was 23.5 (95% CI 15.4–30.4) months. Median duration of response was 22.1 (95% CI 15.1–not evaluable) months. Median time on treatment with the combination AXI/pembro was 14.5 months (n=52), median time on pembro after AXI discontinuation was 9.0 months (n=10), and median time on AXI after pembro discontinuation was 7.5 months (n=11). After stopping study treatment, 22 patients received subsequent systemic therapy, including nivolumab and cabozantinib (n=6 each). Grade 3/4 AEs were reported in 38 (73.1%) patients. 20 (38.5%) patients discontinued either drug due to AEs: 17 (32.7%) patients discontinued AXI, and 13 (25.0%) patients discontinued pembro with 10 (19.2%) discontinuing both drugs. Dose reduction of AXI due to AEs was reported in 16 (30.8%) patients. The most common AEs reported were diarrhea (84.6%), fatigue (80.8%), hypertension (53.8%), cough (48.1%), and dysphonia (48.1%). Increased alanine aminotransferase and aspartate aminotransferase occurred in 44.2% and 36.5% of patients, respectively. With this longer follow-up, there were no cumulative AEs or new AEs. OS by IMDC risk group will be presented. **Conclusions:** In patients with advanced RCC with almost 5 years of follow-up, the combination of AXI/pembro continues to demonstrate clinical benefit with no new safety signals. Clinical trial information: NCT02133742. Research Sponsor: Pfizer.

5081 Poster Session (Board #150), Fri, 8:00 AM-11:00 AM

FDA pooled analysis of time to treatment discontinuation (TTD) in frontline advanced renal cell carcinoma trials. *First Author: Elaine Chang, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Time to treatment discontinuation (TTD) has been proposed as a potential pragmatic real-world data (RWD) endpoint, and was closely correlated with progression-free survival (PFS) in pooled analyses of non-small cell lung cancer (NSCLC) and breast cancer trials across therapeutic classes (Blumenthal, Ann Onc 2019; Gao, SABCS Abstract P5-14-02). **Methods:** We analyzed data from all randomized patients (pts) in the phase 3 trials submitted to FDA 2016-18 evaluating a combination therapy (Rx) of an immuno-oncology agent and another systemic Rx (IO-X) versus sunitinib (SUN) for treatment-naïve advanced renal cell carcinoma (RCC). Protocols specified treatment until progression, but treatment beyond progression was allowed. TTD was defined as the time from the start of Rx to time of treatment discontinuation of both drugs in combination Rx or SUN. We measured TTD in treatment-defined subgroups (IO-X and SUN) and across all pts, and pt-level correlation (Pearson's *r*) between TTD and PFS and between TTD and overall survival (OS). We also determined rates of disparity between TTD and PFS greater than 3 months. **Results:** Of 3758 pts (IO-X, n=1878; SUN, n=1880), 3190 pts (85%) had a TTD event, and 1899 pts (51%) had a PFS event. Median TTD was longer among pts receiving IO-X than SUN (12.3 versus 8.0 months). Regardless of drug class, more pts had early (TTD shorter than PFS by $\geq$ 3 months) TTD events than late TTD (13.4% versus 6.4%, overall). We found higher correlation between TTD and PFS in pts receiving SUN ($r = 0.89$) than pts receiving IO-X ($r = 0.72$). Overall, TTD was more closely associated with PFS ($r = 0.80$) than with OS (0.61). **Conclusions:** Observed correlations of TTD to PFS were stronger compared to the correlation of TTD to OS. This may be expected because OS is farther removed in time from TTD than is PFS. In contrast to TTD in NSCLC, more than twice as many pts in RCC trials had early TTD than late TTD, regardless of Rx group, which may indicate earlier discontinuation with combination Rx due to additive toxicity. Limitations include the censoring of PFS and OS and the post-hoc nature of this analysis. Research Sponsor: FDA.

	IO-X	SUN	All

Immune infiltration and angiogenesis as markers of outcome in the post-nephrectomy setting: Transcriptomic data from patients receiving placebo on a randomized phase III trial (PROTECT). *First Author: A. Ari Hakimi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Defined stromal and immune features of the tumor microenvironment (TME) have proven relevant for outcomes with systemic therapy in advanced clear cell renal cell carcinoma (ccRCC). We hypothesized that these may matter beyond therapeutic applications and could be relevant much earlier in the disease course. We sought to study the TME in high risk ccRCC patients undergoing definitive surgery. **Methods:** Clinical, pathologic, immunohistochemical, and whole-genome microarray data were acquired on 236 out of 769 patients in the Placebo arm of PROTECT trial (NCT01235962 - pazopanib vs placebo). Transcriptomic scores assessing angiogenesis and myeloid infiltration with individual annotations above/below median were used to categorize patients into four groups (angiogenesis high vs. low; myeloid high vs. low). We tested categorical association with disease free (DFS) and overall survival (OS) using logrank testing and assessed interdependence with relevant clinicopathologic variables, including the UCLA Integrated Staging System (UISS) in a cox regression model. **Results:** Tumors from236 patients were available for analysis. Overall, 37% developed metastatic recurrence and 81% were alive at last follow up. On univariate analysis increasing tumor stage, higher UISS score, and angiogenesis/myeloid subgroups (high – H and low – L) were associated with worse DFS and OS (all p values <0.05). On multivariate analysis TME subgroups remained significant for worse DFS and OS (Table). **Conclusions:** Microenvironmental subgroups stratified into angiogenic and myeloid expression profiles carry independent prognostic significance and should be further explored to guide future biomarker-directed adjuvant trials. Clinical trial information: NCT01235962. Research Sponsor: Novartis, Philantropic.

5083 Poster Session (Board #152), Fri, 8:00 AM-11:00 AM

Patient preferences and expectations of systemic therapy in renal cell carcinoma. *First Author: Dena Battle, KCCure, Alexandria, VA*

Background: In metastatic renal cell carcinoma, the systemic therapy landscape has expanded to include multiple VEGF inhibitors, immunotherapies, and combination therapy. Little is known about patient expectations and preferences when making decisions about systemic therapy. We sought to gather independent data from online kidney cancer patient communities to assess patient perspectives on what matters most when considering treatment options. **Methods:** The KCCure online survey was performed between August 1, and September 30, 2019. Patients were recruited via the KCCure website, social media channels (Twitter, Facebook) and through fliers distributed at cancer centers. Those who agreed to participate were surveyed for demographics (age, gender, race, income, country) and clinical characteristics (date of the diagnosis, disease stage, treatment history). Key questions focused on treatment selection and side effect management. **Results:** Out of 1,136 patients responding, 411 patients were on systemic therapy with a median age of 57 years (range 28-86). 223 (54%) of patients on systemic therapy were male. Patients were primarily from the U.S. (83%). Median duration on therapy was 24.7+/-1.9 months. When asked to select the most important outcome for treatment selection, 58.8 % of patients chose complete response, followed by tumor control (10.2%), low risk of toxicity (5.7%) and the chance to discontinue therapy (3.7%). Patients ranked cost as the least important factor in selecting treatment (2.9%). 10.9% preferred infusion therapy and 42.1% oral therapy, whereas 47% were indifferent about the route of administration. Even if it would be safe to discontinue therapy, 62.8% of patients would be anxious about cancer progression. 23.2% would rather stay on treatment and 39.3% would want increased scanning intervals. Only 34.4% of patients would look forward to having more time off therapy. When asked to define treatment success, 86.3% selected reduction in tumor size, followed by stable disease (71.7%), freedom from symptoms (35.1%) and better quality of life (47.7%). **Conclusions:** Patients rank efficacy as the most important outcome when considering treatment options. Toxicity, time off therapy and cost are not significant priorities for patients. Further data is warranted investigating the impact of communicating treatment options, potential discontinuation of therapy and resulting expectations. Research Sponsor: None.

5084 Poster Session (Board #153), Fri, 8:00 AM-11:00 AM

Patient-reported use of marijuana and cannabinoid (CBD) oil in patients with renal cell carcinoma undergoing systemic therapy. *First Author: Dena Battle, KCCure, Alexandria, VA*

Background: The use of cannabis and cannabinoid related products has become increasingly common among cancer patients. We sought to gather independent data from online kidney cancer patient communities to assess frequency of use of marijuana and CBD-oil and estimate influence on treatment duration and side-effects. **Methods:** The KCCure online survey was performed between August 1, and September 30, 2019. Descriptive statistics were used to characterize patients who self-report using marijuana, their systemic treatments, and interactions with their oncologists. **Results:** Out of 1,136 patients responding, 411 patients were on systemic therapy with a median age of 57 years (28-86). Of the 441 patients with systemic therapy, 223 patients (54%) were male. There was no difference in gender distribution or race among patients who reported using or not using marijuana and or CBD oil. 93 patients (21%) reported using marijuana or CBD oil and 35 patients (8.5%) reported using both. Patients using marijuana and/or CBD oil had a median age of 55.7 +/- 1.1 years compared with patients not using (65.1 +/- 6.9 years). The median treatment duration was 23.9+/-2.4 months for patients using marijuana and/or CBD oil versus 26.4+/- 1.9 months for patients not using these supplements (p=0.437). Patients using marijuana and/or CBD oil were more likely to have bothersome side effects from therapy (p=0.001) and were less likely to talk to their doctor about their situation (p=0.044). The median NCCN distress score in patients using marijuana and/or CBD oil was 49.5+/-25.7 versus 51.4+/-24.0 (p n.s.). No correlation was seen with the use of steroids, anti-diarrhea drugs, anti-nausea-drugs, hormone substitution or other drugs used to manage side effects. **Conclusions:** Marijuana and/or CBD oil are used by a significant number of patients. No benefit/harm on treatment duration and use of concomitant drugs to control side effects and severity was seen. Patients using marijuana and/or CBD oil were more likely to report bothersome treatment related side effects and were more willing to report their side effects to their provider. As cannabinoids become more mainstream and legal in a number of states, more research is needed to better understand the impact these supplements may have on patients. Research Sponsor: None.

5085 Poster Session (Board #154), Fri, 8:00 AM-11:00 AM

Camrelizumab plus famitinib malate in patients with advanced renal cell cancer and unresectable urothelial carcinoma: A multicenter, open-label, single-arm, phase II trial. *First Author: Yuan-Yuan Qu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Camrelizumab (SHR-1210) is a humanised anti-PD-1 antibody. Famitinib malate is a tyrosine kinase inhibitor (TKI) against VEGFR-2, PDGFR, c-kit, and FGFR. This is an ongoing, open label, multi-center Phase II study to assess the preliminary efficacy and safety of camrelizumab in combination with famitinib malate in patients (pts) with genitourinary cancers and gynecologic cancers. Here we just report genitourinary cancers results. **Methods:** Eligible pts were aged 18 or older, who had advanced clear-cell renal-cell carcinoma with their primary tumour resected or unresectable urothelial carcinoma, had an ECOG performance status of 0-1and measurable disease. Previous system treatments were allowed (excluding prior PD-1/PD-L1 inhibitors or famitinib treatment). Famitinib 20 mg was administered orally once daily with SHR-1210 200 mg given intravenously every 3 weeks. We assessed antitumour activity and safety in all pts who received at least one dose treatment. The primary end point was objective response rate (ORR) per RECIST v1.1. **Results:** From 23 Jan 2019 to 24 Jun2019, 35 pts were enrolled (25 with RCC, 10 with UC). Median previous treatment line was 1 (range, 1-4), and 50.0% of pts had received ≥2 prior therapies in RCC, all pts received one or more-line therapies in UC. At the data cut-off date (Dec 31, 2019), after at least 6 months follow-up, 22 (63%) pts were still receiving study treatment. The most common reason for discontinuing treatments was disease progression (n = 10). 16 pts achieved a confirmed response, all were partial response, with 8 additional > 24 weeks stable disease. the ORR was 52.0% (13/25, 95% CI 31.3% to 72.2%) in RCC and 30.0% (3/10) in UC, the disease control rate was 84.0% (21/25) in RCC and 70.0% in UC. 13/16 confirmed PR pts were still on treatment, the median duration of response is not reached. The most common grade 3-4 treatment-related AEs (TRAEs) were hypertension (17.1%), proteinuria (11.4%), platelet count decreased (8.6%), hand-foot syndrome (8.6%) and anemia (5.7%). Immune-related adverse events were observed in 7 pts (20%) of 35 pts, 1 pt (2.9%) with grade 3 enteritis. **Conclusions:** The camrelizumab with famitinib combination appeared to show encouraging activity in pts with heavy-treated RCC and UC, and the safety profile of the combination seemed to be manageable and consistent with that of each drug alone. This combination represented a novel potential treatment option for these settings and warranted further investigation. Clinical trial information: NCT03827837. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

5086 Poster Session (Board #155), Fri, 8:00 AM-11:00 AM

Tipifarnib, a farnesyltransferase inhibitor, for metastatic urothelial carcinoma harboring HRAS mutations. *First Author: Jiyun Lee, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Tipifarnib is a farnesyltransferase inhibitor known to block RAS signaling and attenuate cancer cell proliferation. We tested the activity and safety of tipifarnib in patients with previously treated urothelial carcinoma (UC) carrying HRAS mutations. **Methods:** In a prospective phase II clinical trial, genetic screening was performed in 224 UC patients; those with missense HRAS mutations or STK11:rs2075606 received study treatment. Eligible patients received oral tipifarnib 900 mg twice daily on days 1–7 and 15–21 of 28-d treatment cycles. The primary endpoint was progression-free survival at 6 mo (PFS6). With two-stage design, at least 18 patients were required. **Results:** Among the 224 patients screened, we found 16 (7%) missense HRAS mutations (G13R, 7; Q61R, 4; G12S, 3; G12C, 2) and 104 (46%) STK11: rs2075606 carriers. In 21 patients enrolled, 14 and 7 patients had HRAS mutations and STK11:rs2075606, respectively. The most frequent adverse events included fatigue and hematologic toxicities. With a median follow-up of 28 months, 4 patients (19%) reached PFS6: 3 had missense HRAS mutations and one patient, enrolled as a STK11 carrier, had HRAS frameshift insertions at H27fs and H28fs rendering a nonsense HRAS mutation. Response rate was 24% (4 missense and one nonsense frameshift HRAS mutation); no response observed in UC patients with wild type HRAS tumors. **Conclusions:** Oral tipifarnib showed a manageable safety profile and encouraging anti-tumor efficacy against treatment-refractory UC containing HRAS mutations. Clinical trial information: NCT02535650. Research Sponsor: Kura Oncology.

5087 Poster Session (Board #156), Fri, 8:00 AM-11:00 AM

Comprehensive genomic profiling (CGP) of histologic subtypes of urethral carcinomas (UrthCa). *First Author: Petros Grivas, University of Washington, Seattle, WA*

Background: UrthCa is an uncommon GU malignancy that can progress to advanced metastatic disease. **Methods:** 127 metastatic UrthCa underwent hybrid-capture based CGP to evaluate all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on up to 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined on 114 loci. PD-L1 expression was determined by IHC (Dako 22C3). **Results:** 49 (39%) urothelial (UrthUC), 31 (24%) squamous (UrthSCC), 34 (19%) adenocarcinomas (UrthAC) and 13 (9%) clear cell (UrthCC) were evaluated along with a control cohort of 2,130 bladderUC cases. UrthUC and UrthSCC were more common in men; UrthAC and UrthCC more common in women. Age was similar in all 4 groups. GA in *PIK3CA* were the most frequent potentially targetable GA; MTOR pathway GA in *PTEN* also identified. GA in other potentially targetable genes were also identified including *ERBB2*(6% in UrthUC, 3% in UrthSCC and 12% in UrthAC), *FGFR1-3* (3% in UrthSCC), *BRAF* (3% in UrthAC), *PTCH1* (8% in UrthCC) and *MET* (8% in UrthCC). Higher TMB was seen in UrthUC and UrthCC compared to UrthAC and UrthSCC, possibly reflecting their higher GA/tumor status and suggesting potential for immunotherapy benefit. MSI high status was absent throughout. The bladderUC cases had similar genomic pattern as UrthUC with significantly lower frequency of HPV16/18 positive cases. **Conclusions:** CGP reveals GA that may be predictive of both targeted and immunotherapy benefit in patients with advanced UrthCa and that could potentially be used in future adjuvant, neoadjuvant and metastatic disease trials. Impact of human papillomavirus (HPV) infection on the outcome of perioperative treatments for penile squamous-cell carcinoma (PSCC). *First Author: Patrizia Giannatempo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: PSCC patients (pts) with palpable inguinal lymph node (ILN) disease have a poor overall survival (OS). Multimodal perioperative treatments are usually offered despite the lack of clinically meaningful efficacy. Pending the availability of novel effective systemic therapy, the optimization of conventional treatments in better selected pts is needed. **Methods:** Within an international, multicenter database of 924 PSCC pts who received ILN dissection from USA, Europe, Brazil and China, 494 had information on HPV, and 52 (10.5%) had HPV+ PSCC, predominantly assessed with immunohistochemistry (53%). Multivariable logistic regression analyses evaluated the association between pt factors and HPV status. Multivariable Cox analyses (MVA) assessed predictors of overall mortality (OM), including HPV status, pathologically-involved ILN ratio (ILNR), extranodal extension, margin status, vascular invasion (VI), perioperative RT (pRT) and perioperative chemotherapy (pCT). Comparisons between HPV status and ILNR were performed using interaction tests. Kaplan-Meier method was used to define the OS benefit related in HPV-stratified sub-groups. **Results:** Median age at diagnosis was 58yrs. Overall, pCT and pRT were used in 227 (46%) and 50 (10%) pts. The median follow-up was 62 months. Neither clinical factors nor country were associated with HPV status. On MVA, ILNR (HR: 1.01, p = 0.01) and extranodal extension (HR: 1.5, p = 0.02) were statistically significantly associated with OM, but HPV was not (p = 0.2). However, in the subgroup of pts who received pRT, HPV status was associated with favorable OM (HR: 0.11, 95%CI: 0.03-0.5, p = 0.004) together with negative VI (p = 0.03), and the use of adjuvant CT (p = 0.04). A significant interaction was found on OM between HPV+ status and increasing ILNR, with a cutoff at 50% (p = 0.05). Results are limited by their retrospective nature and small numbers in each subgroup. **Conclusions:** In the largest available dataset of ILND for PSCC, we observed that pRT seemed to be more effective in the subgroup of HPV+ PSCC. These results should be considered as hypothesis-generating and may inspire both the future prospective trials or the ongoing InPACT study. Research Sponsor: Fondazione IRCCS Istituto Nazionale dei Tumori.

5089 Poster Session (Board #158), Fri, 8:00 AM-11:00 AM

A pooled analysis of the efficacy and safety of cabozantinib post immunotherapy in patients with advanced renal cell carcinoma. *First Author: Mototsugu Oya, Department of Urology, Keio University School of Medicine, Tokyo, Japan*

Background: While studies have demonstrated survival benefits of first-line regimens including immuno-oncology agents (IO) in advanced renal cell carcinoma (aRCC), optimal treatment following IO is unknown. In the phase 3 METEOR trial, cabozantinib improved progression-free survival (PFS), objective response rate (ORR), and overall survival (OS) versus everolimus in patients (pts) with aRCC, after VEGFR-TKI therapy. The Japanese phase II C2001 study (NCT03339219), targeting a population similar to that of METEOR, showed similar efficacy and safety results. Here, we present a post-hoc pooled analysis of pts who had received prior IO therapy from METEOR and C2001. **Methods:** A pooled analysis was performed in pts who received 60mg/day of oral cabozantinib once daily enrolled in the METEOR or C2001. Patients were divided into two groups with previous IO treatment (pre-w/ IO subgroup) or without previous IO treatment (pre-w/o IO subgroup). Analyses of ORR, PFS, OS, and safety were performed as measures of clinical outcome in each subgroup. **Results:** 365 pts (pre-w/ IO subgroup: 33 pts, pre-w/o IO subgroup:332 pts) were included for efficacy analysis and 366 pts (pre-w/ IO subgroup: 33 pts, pre-w/o IO subgroup:333 pts) for safety analysis. Minor differences in baseline characteristics were noted between the analysis subgroups but are not expected to substantially affect efficacy outcomes. The ORR was 21.2% (95% CI: 9.0-38.9%) for pre-w/ IO subgroup, and 17.2% (95% CI: 13.3-21.7%) for pre-w/o IO subgroup. PFS rate and OS rate at 6 months pre-w/ IO was 65.5%, 90.8% and pre-w/o IO was 58.3%, 90.6%, respectively. Although there were some differences in the safety profile, almost all AEs were manageable by dose modifications. There were no differences in AEs associated with IO treatment, such as pneumonitis, endocrinolopathy or infusion related reaction. No new safety signals were noted in any subgroups. **Conclusions:** Safety and treatment efficacy of cabozantinib were maintained in the pooled analysis of pts from METEOR and C2001 irrespective of prior IO treatment. Funded by Takeda Pharmaceutical Company Limited, Tokyo, Japan. Clinical trial information: NCT03339219, NCT01865747. Research Sponsor: Takeda Pharmaceutical Company Limited and Exelixis, Inc.

TPS5090 **Poster Session (Board #159), Fri, 8:00 AM-11:00 AM**

A phase II, randomized study of nivolumab (NIVO), NIVO plus linrodostat mesylate, or NIVO plus intravesical bacillus Calmette-Guerin (BCG) in BCG-unresponsive, high-risk, nonmuscle invasive bladder cancer (NMIBC): CheckMate 9UT. *First Author: Noah M. Hahn, Departments of Oncology and Urology, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Immune checkpoint inhibitors, including NIVO (anti–PD-1), have demonstrated favorable tolerability and efficacy profiles, ushering in a new treatment (tx) paradigm for advanced bladder cancer (advBC). However, an unmet need exists for new effective tx options in earlier stages of disease, specifically for patients (pts) with BCG-unresponsive, high-risk NMIBC. Increased IDO and PD-L1 expression in NMIBC tumors (Inman, et al. *Cancer* 2007; Hudolin, et al. *Anticancer Res* 2017), support the combination of anti–PD-1 and IDO1 inhibition in NMIBC. Linrodostat mesylate, a selective, potent, once-daily IDO1 inhibitor, has demonstrated clinical activity in combination with NIVO in pts with immunotherapy-naive advBC who received ≥ 1 prior line of therapy (objective response rate, 37%; Tabernero, et al. *J Clin Oncol* 2018;36(suppl) [abstr 4512]). Furthermore, high levels of PD-L1 expression have been reported in patients not responding to BCG tx. These findings provide a rationale for investigation of NIVO ± linrodostat ± intravesical BCG therapy in BCG-unresponsive high-risk NMIBC. Here we describe a phase 2, randomized, open-label study assessing the safety and efficacy of NIVO ± linrodostat ± intravesical BCG in pts with BCG-unresponsive, high-risk NMIBC (NCT03519256). **Methods:** Pts aged ≥ 18 years with BCG-unresponsive (per February 2018 FDA guidance), high-risk NMIBC, defined as carcinoma-in-situ (CIS) with or without papillary component, any T1, or Ta high-grade lesions, will be enrolled. Pts must have urothelial carcinoma as the predominant histological component (> 50%). Key exclusion criteria include locally advanced or metastatic BC, upper urinary tract disease within 2 years, prostatic urethral disease within 1 year, and prior immunotherapy. Using a novel adaptive-type design, pts will be randomized to 1 of 4 tx arms with NIVO ± linrodostat ± BCG. Primary endpoints include proportion of pts with CIS with complete response (CR) and duration of CR in pts with CIS. Secondary endpoints are progression-free survival and safety. This global study in 14 countries is underway, with a target enrollment of 436 pts. Clinical trial information: NCT03519256. Research Sponsor: Bristol Myers Squibb.

TPS5091 **Poster Session (Board #160), Fri, 8:00 AM-11:00 AM**

A phase III randomized study of neoadjuvant chemotherapy (NAC) alone or in combination with nivolumab (NIVO) ± linrodostat mesylate, followed by adjuvant postsurgical NIVO ± linrodostat, in cisplatin-eligible muscle invasive bladder cancer (MIBC). *First Author: Guru Sonpavde, Department of Genitourinary Oncology, Dana Farber Cancer Institute, Boston, MA*

Background: Immuno-oncology (IO) therapies have revolutionized the treatment (tx) of pts with advanced bladder cancer (advBC). For pts with cisplatin-eligible, muscle invasive BC (MIBC), the recommended tx is cisplatin-based neoadjuvant chemotherapy (NAC) prior to radical cystectomy (RC). However, since only ≈ 30% of pts achieve a pathologic complete response (pCR) translating to improved long-term outcomes with approved regimens, new therapies are needed. PD-L1 expression is associated with aggressive BC and has been shown to increase in BC after NAC, supporting the therapeutic pursuit of the PD-1/PD-L1 axis. Additionally, expression of indoleamine 2,3-dioxygenase (IDO) is higher in BC than in normal bladder tissue and is associated with advanced disease and poor clinical outcome. Linrodostat mesylate, a selective, potent, once-daily oral IDO1 inhibitor that works to reduce kynurenine production, has demonstrated clinical activity in combination with NIVO (anti–PD-1) in pts with IO tx–naive advBC who had ≥ 1 prior line of therapy (ORR, 37%). Taken together, these data provide a rationale for investigating NAC + NIVO + linrodostat in MIBC. Here we describe a randomized, partially blinded, phase 3 study evaluating the efficacy and safety of NAC ± NIVO ± linrodostat followed by RC and continued IO tx in pts with MIBC (NCT03661320). **Methods:** Pts aged ≥ 18 years with previously untreated MIBC (clinical stage T2-T4a, N0, M0), creatinine clearance ≥ 50 mL/min, and predominant UC histology who are eligible for cisplatin-based NAC and RC will be enrolled. Pts with evidence of positive lymph node; metastatic BC; or prior systemic therapy, radiotherapy, or surgery for BC other than TURBT are not eligible. Pts will be randomized to receive NAC (gemcitabine/cisplatin; arm A), NAC + NIVO + oral placebo (arm B), or NAC + NIVO + linrodostat (arm C) followed by RC (all arms); arms B and C will receive continued IO tx. Primary endpoints include pCR after neoadjuvant tx and event-free survival (arms C vs A; arms B vs A). Secondary endpoints are overall survival and safety. This global study in 28 countries began accrual in Nov 2018 and has a target enrollment of 1200 pts. Clinical trial information: NCT03661320. Research Sponsor: Bristol Myers Squibb.

TPS5092 **Poster Session (Board #161), Fri, 8:00 AM-11:00 AM**

Study EV-103: New randomized cohort testing enfortumab vedotin as monotherapy or in combination with pembrolizumab in locally advanced or metastatic urothelial cancer. *First Author: Nataliya Mar, UC Irvine Medical Center, Orange, CA*

Background: Cisplatin-based chemotherapy is the standard for first-line (1L) patients (pts) with locally advanced/metastatic urothelial cancer (LA/mUC). PD-1/PD-L1 inhibitors have promising durability of responses but 1L use is restricted to pts ineligible for cisplatin-containing therapy and whose tumors express PD-L1 (CPS ≥10) or pts ineligible for platinum-containing chemotherapy regardless of PD-L1 status. Enfortumab vedotin (EV), an antibody-drug conjugate, delivers the microtubule-disrupting agent monomethyl auristatin E to cells expressing Nectin-4, which is highly expressed in UC. EV recently received FDA accelerated approval based on tumor response rates for adults with LA/mUC who have previously received a PD-1/PD-L1 inhibitor and a platinum-containing chemotherapy. In the ongoing phase 1b/2 study EV-103/KEYNOTE-869 (NCT03288545), the safety and antitumor activity of EV are investigated as monotherapy (mono) (for the first time in the 1L setting) and in combination with PD-1 inhibitor pembrolizumab (P) +/- chemotherapy in UC. An initial analysis of EV (1.25 mg/kg) + P (200 mg) (both drugs in investigational use here) in this study showed a 73.3% confirmed ORR in 45 1L cisplatin-ineligible LA/mUC pts (dose-escalation + expansion Cohort A) (Rosenberg ASCO 2020). **Methods:** A new Cohort K randomized 1:1 to 1.25 mg/kg EV mono or 1.25 mg/kg EV + 200 mg P provides additional information on EV + P and the contribution of activity from EV in cisplatin-ineligible pts with LA/mUC in the 1L setting. This cohort will enroll 150 adults (≥18 years) with LA/mUC and measurable disease per RECIST v1.1, and exclude pts with prior systemic treatment for LA/mUC, active CNS metastases, ongoing sensory or motor neuropathy (Grade ≥2), or uncontrolled diabetes. Cisplatin-ineligibility in this study is based on ≥1 of the following: ECOG of 2, creatinine clearance of ≥30 and < 60 mL/min, or hearing loss/dysfunction. In each 3-week cycle of this study, EV is administered on days 1 and 8, and P on day 1. The primary endpoint is ORR per RECIST v1.1 by BICR. Secondary endpoints include ORR per RECIST v1.1 by investigator assessment, DOR, DCR, PFS per RECIST v1.1 by BICR and investigator assessment, OS, safety, and tolerability. Sample size is not based on power calculation for formal hypothesis testing but is selected based on ORR estimate precision based on 95% CIs. Efficacy is summarized by treatment arm with no formal statistical comparisons between arms. The study opened in Oct 2017. Cohort K opened in Jan 2020. Clinical trial information: NCT03288545. Research Sponsor: Seattle Genetics, Astellas, Merck.

TPS5093 **Poster Session (Board #162), Fri, 8:00 AM-11:00 AM**

Phase III study of pembrolizumab (pembro) plus chemoradiotherapy (CRT) versus CRT alone for patients (pts) with muscle-invasive bladder cancer (MIBC): KEYNOTE-992. *First Author: Arjun Vasant Balar, NYU Langone Health Perlmutter Cancer Center, New York, NY*

Background: Pembro has shown clinical activity across many stages of bladder cancer (BC), including metastatic BC, MIBC, and NMIBC. Current NCCN and AUA/ASCO/ASTRO/SUO guidelines recommend CRT as a bladder-preserving treatment option for selected pts with MIBC. This phase 3 study was designed to investigate the safety and efficacy of pembro + CRT in pts with MIBC who opt for bladder preservation. Ongoing phase 2 studies (NCT02662062; NCT02621151) have shown that pembro + CRT may be a promising therapeutic option in MIBC. **Methods:** KEYNOTE-992 (NCT04241185) is a phase 3, global, multicenter, double-blind, placebo-controlled, randomized trial to evaluate the efficacy and safety of pembro + CRT versus placebo + CRT in pts with previously untreated MIBC. Adults (≥18 years) opting for bladder preservation with histologically confirmed cT2-T4a, nonmetastatic (NOM0) MIBC after maximal TURBT are eligible. An estimated 636 pts will be randomly assigned 1:1 to receive CRT + either pembro 400 mg IV every 6 weeks (Q6W) or placebo. Treatment will continue with pembro or placebo Q6W for up to 9 doses. CRT regimens will be decided by the investigator before randomization. Accepted radiotherapy regimens are conventional radiotherapy consisting of 64 Gy at 2 Gy/fraction over 6.5 weeks (whole bladder with or without pelvic nodes) or hypofractionated radiotherapy consisting of 55 Gy at 2.75 Gy/fraction over 4 weeks (whole bladder only). Accepted concurrent radiosensitizing chemotherapy regimens are cisplatin monotherapy (35 mg/m^2 IV weekly), 5-fluorouracil (500 mg/m^2 on days 1-5 and days 22-26) + mitomycin C (12 mg/m^2 on day 1), or gemcitabine monotherapy (27 mg/m^2 IV twice weekly). Randomization will be stratified by ECOG PS (PS 0/1 vs 2), PD-L1 combined positive score (< 10 vs ≥10), T stage (T2 vs T3/4), and geographic region (US vs Europe vs rest of world). Pts must provide tissue for biomarker analysis. Efficacy will be assessed by cystoscopy (± biopsy), CT or MRI (with blinded independent central review), and urine cytology at 10 weeks after CRT, then Q12W up to the end of year 2, and then Q24W thereafter. The primary end point is bladder-intact event-free survival, defined as time from randomization to residual/recurrent MIBC, nodal or distant metastasis, radical cystectomy, or death from any cause. Key secondary end points are OS, metastasis-free survival, time to occurrence of NMIBC, and safety. Clinical trial information: NCT04241185. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS5094 **Poster Session (Board #163), Fri, 8:00 AM-11:00 AM**

Phase III study of the hypoxia-inducible factor 2α (HIF-2α) inhibitor MK-6482 versus everolimus in previously treated patients with advanced clear cell renal cell carcinoma (ccRCC). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: In RCC, the Von Hippel-Lindau (*VHL*) tumor suppressor gene is inactivated in most cases, resulting in the accumulation and overactivation of HIF-2α. HIF-2α is a key oncogenic driver in RCC and is involved in the activation of genes associated with angiogenesis, tumor progression, and metastasis, such as vascular endothelial growth factor A (*VEGFA*), cyclin D1, and *CXCR4*. MK-6482 is a potent and selective small molecule inhibitor of HIF-2α, and it has shown antitumor activity in a phase 1/2 study in patients with previously treated advanced ccRCC. **Methods:** The current study (NCT04195750) is a phase 3, open-label, multicenter, randomized, active-controlled trial to compare the efficacy and safety of MK-6482 with everolimus in patients with previously treated advanced ccRCC. Adults aged ≥18 years will be eligible if they have unresectable, locally advanced, or metastatic ccRCC; have measurable disease per RECIST v1.1; and received ≤3 prior systemic regimens, which must include a PD-1/PD-L1 inhibitor (≥2 doses) and a VEGF-targeted therapy, for locally advanced or metastatic RCC. Approximately 736 patients will be randomly assigned 1:1 to receive MK-6482 120 mg orally once daily or everolimus 10 mg orally once daily. At randomization, patients will be stratified by International Metastatic RCC Database prognostic scores (0 vs 1-2 vs 3-6) and by the number of prior anti-VEGF–targeted therapies received for advanced RCC (1 vs 2-3). Responses will be assessed by CT or MRI per RECIST v1.1 by blinded independent central review at week 9 from the date of randomization, then every 8 weeks through week 49, and then every 12 weeks thereafter. Treatment will continue until documented disease progression, withdrawal of consent, or other discontinuation event. Dual primary endpoints are progression-free survival per RECIST v1.1 and overall survival. Key secondary endpoints include objective response rate, duration of response, patient-reported outcomes, and safety. Clinical trial information: NCT04195750. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS5095 **Poster Session (Board #164), Fri, 8:00 AM-11:00 AM**

PROOF 302: A randomized, double-blind, placebo-controlled, phase III trial of infigratinib as adjuvant therapy in patients with invasive urothelial carcinoma harboring susceptible *FGFR3* alterations. *First Author: Siamak Daneshmand, Keck School of Medicine of USC, Los Angeles, CA*

Background: Radical surgery ± cisplatin-based (neo)adjuvant chemotherapy (NAC) is the mainstay of treatment for invasive urothelial carcinoma of the upper urinary tract (UTUC) or bladder (UBC), but recurrence rates are high. Furthermore, many patients are unable to receive NAC due to cisplatin ineligibility. Fibroblast growth factor receptor 3 (FGFR3) genetic alterations occur in up to 70% of UTUC and up to 20% of UBC and may constitute a potential candidate for targeted therapy. Infigratinib (BGJ398), a FGFR1–3 selective oral tyrosine kinase inhibitor, has shown promising clinical activity and tolerability in patients with advanced urothelial carcinoma having *FGFR3* alterations [Pal et al. Cancer Discov 2018]. PROOF 302 has been designed to investigate the efficacy and safety of infigratinib versus placebo as adjuvant therapy in patients with high-risk invasive urothelial carcinoma and susceptible *FGFR3* alterations. **Methods:** PROOF 302 is a randomized, double-blind, placebo-controlled, phase III study of approx. 218 patients. Adults with high-risk invasive UTUC or UBC with susceptible *FGFR3* genetic alterations (i.e. activating mutations, gene fusions or translocations) who are ≤120 days following surgical resection and ineligible for or refusing cisplatin-based adjuvant chemotherapy or with residual disease after cisplatin-based NAC are eligible. Those who received non cisplatin-based NAC are eligible if they have residual disease and are ineligible for adjuvant cisplatin. Patients receive oral infigratinib 125 mg or placebo (1:1 ratio) once daily on days 1–21 every 28 days for up to 52 weeks or until disease recurrence, unacceptable toxicity or death. Primary endpoint: centrally reviewed disease-free survival (DFS). Secondary endpoints: DFS including intraluminal low-risk recurrence; metastasis-free survival; overall survival; DFS (per investigator); safety and tolerability. Exploratory endpoints include quality of life, pharmacokinetics, cell-free DNA (cfDNA) and/or RNA for resistance mechanisms. The study will involve approximately 120 centers worldwide. The study was initiated in late 2019 and is expected to end in 2024. Clinical trial information: NCT04197986. Research Sponsor: QED Therapeutics.

TPS5096 **Poster Session (Board #165), Fri, 8:00 AM-11:00 AM**

Cell cycLe inhibitiON to target the EVolution of urOthelial cancer (CLONEVO): A single-arm, open-label window-of-opportunity trial of neoadjuvant abemaciclib in platinum-ineligible muscle invasive bladder cancer patients. *First Author: Jones Nauseef, NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY*

Background: The standard of care for clinically localized muscle-invasive bladder cancer (MIBC) is neoadjuvant platinum-based combination chemotherapy followed by radical cystectomy (RC). Up to 40% of patients (pts) are ineligible to receive cisplatin and proceed to RC without any neoadjuvant therapy. We and others have demonstrated enrichment of molecular alterations in cell cycle genes in MIBC, including copy number losses of *CDKN2A* in 41% of pts. Abemaciclib is a unique CDK4/6 inhibitor with single agent activity and a target kinome distinct from other CDK4/6 inhibitors. We have demonstrated that CRISPR knockout of CDKN2A increases susceptibility to abemaciclib in bladder cancer cell lines. Beyond tumor-intrinsic effects, abemaciclib also modulates the tumor microenvironment (TME) via upregulating human endogenous retroviral elements and increasing T cell infiltration. **Methods:** Cell cycLe inhibitiON to target the EVolution of urOthelial cancer (CLONEVO) is a single arm, window-of-opportunity trial of neoadjuvant abemaciclib which will evaluate tumor cell and TME changes in response to abemaciclib. Enrolled pts must be ineligible for platinum-based neoadjuvant therapy for resectable MIBC. Pts receive abemaciclib (200 mg BID PO) for 4 weeks prior to RC. Tumor tissue collected via transurethral resection of bladder tumor (TURBT) and residual tumor at RC undergo single cell RNA sequencing and whole-exome sequencing. Patient-derived organoids and xenografts are generated for a co-clinical trial of abemaciclib alone or in combination. The primary endpoint is the measurement of changes in cell cycle dynamics. Secondary objectives are assessment of toxicity via NCI CTCAE v 5.0 and pathologic downstaging of MIBC. We will perform targeted sequencing of a panel of cell cycle genes in serial plasma and urine cell free DNA to evaluate changes in the variant allele fractions of somatic alterations. The novel design of this trial allows dynamic *in vivo* assessment of tumor changes and creates a new paradigm for studying tumor evolution in real time. Clinical trials information: NCT03837821. Clinical trial information: NCT03837821. Research Sponsor: Lilly.

TPS5097 **Poster Session (Board #166), Fri, 8:00 AM-11:00 AM**

Phase II trial of durvalumab plus tremelimumab with concurrent radiotherapy as bladder-sparing therapy in patients with localized muscle invasive bladder cancer: A SOGUG study. *First Author: M. Andres Cuellar, Catalan Institute of Oncology, Barcelona, Spain*

Background: Several studies have shown that long-term bladder preservation is feasible in selected patients with muscle-invasive bladder cancer, using a multimodal treatment, including transurethral resection (TUR), radiotherapy and chemotherapy. Durvalumab, a fully human monoclonal antibody against PD-L1, has shown activity in patients with advanced pretreated urothelial cancer. A preclinical study showed that the combination of radiation, anti-CTLA4 and anti-PD-L1 overcome- adaptive immune resistance and has superior activity than either therapy alone (Twyman-Saint Victor et al. Nature 2015). The purpose of the present study is to explore feasibility, toxicity and activity in terms of response and bladder preservation of the integration of TUR, immune double checkpoint inhibition with durvalumab and tremelimumab (a fully human monoclonal antibody against CTLA-4), and radiotherapy in the treatment of localized muscle-invasive. **Methods:** This is a multicenter prospective phase II study of multimodal therapy in patients with localized urothelial carcinoma of the bladder in clinical stages T2-4a N0 M0, ECOG 0- 1, without contraindications to immunotherapy, who either wish for bladder preservation or are ineligible for cystectomy. The primary endpoint is pathological response (≤T1) at post-treatment biopsy. A 2-stage sequential design (response rate P0=5, P1=0.7, α=0.10, β=0.20) requires at least 6 responses in the first 12 pts to expand to a second cohort of 20 patients. The treatment consists of initial TUR of the tumor, followed by durvalumab 1500 mg i.v. plus tremelimumab 75 mg i.v., every 4 weeks for 3 doses. Normofractionated external-beam radiotherapy is started 2 weeks later, at doses of 46 Gy to the minor pelvis and 64-66 Gy to the bladder. Patients with pathological response will be candidates to bladder preservation, whereas those with residual muscle invasive tumor will be candidates to salvage cystectomy. At present time, prespecified activity goal for the first stage of accrual was met; second stage accrual began in December 2019. Clinical trial information: NCT03702179. Research Sponsor: None.

TPS5098 Poster Session (Board #167), Fri, 8:00 AM-11:00 AM

Hcrn GU15-215: A phase II trial of atezolizumab (atezo) and bevacizumab (bev) in cisplatin-ineligible patients (pts) with advanced/unresectable urothelial cancer (UC). *First Author: Arjun Vasant Balar, Perlmutter Cancer Center at NYU Langone Health, New York, NY*

Background: Atezolizumab is a standard of care in selected cisplatin-ineligible pts with advanced UC. VEGF targeted therapies have activity in advanced UC and may lead to immune synergy when combined with anti-PD-1/L1 therapy. This phase II study is investigating the combination of bevacizumab and atezolizumab in untreated cisplatin-ineligible pts with advanced UC. **Methods:** HCRN GU15-215 (NCT03272217) is a phase 2, multicenter single arm trial to evaluate the efficacy and safety of atezolizumab and bevacizumab in pts with advanced UC. Cisplatin-ineligible pts (defined as any of estimated CrCl $<$ 60 cc/min, Grade $\geq$ 2 hearing loss or neuropathy, ECOG PS 2 or solitary kidney) with untreated, histologically confirmed locally advanced or metastatic UC irrespective of PD-L1 expression status and with sufficient pre-treatment tumor tissue available for biomarker analysis are eligible. Pts who have received perioperative chemotherapy are eligible, however prior treatment with a checkpoint inhibitor is excluded. Pts with NYHA Class II or greater heart failure, significant cerebrovascular or cardiac disease within 3 months, uncontrolled HTN, persistent gross hematuria, and GI obstruction or perforation within 6 months are excluded. 70 pts will receive treatment with atezolizumab 1200 mg IV plus bevacizumab 15 mg/kg IV every 21 days. All pts will undergo an on-treatment biopsy before cycle 2 if safe and feasible. Peripheral blood samples and stool samples will be collected before treatment and on-treatment for immune-relevant biomarker analyses. Cross-sectional imaging will be performed every 9 weeks on therapy for the first 12 months and then every 12 weeks thereafter to assess for response. Subjects will be eligible to continue treatment until RECIST v1.1 defined progression or unacceptable toxicity for up to 24 months. The primary endpoint is overall survival rate at 1 year and will be analyzed by the Kaplan Meier method. Key secondary endpoints include objective response rate, duration of response, disease control rate, progression-free survival and safety and toxicity as defined by CTCAE version 4.0. Clinical trial information: NCT03272217. Research Sponsor: Genentech.

TPS5099 Poster Session (Board #168), Fri, 8:00 AM-11:00 AM

A phase III, randomized, placebo-controlled trial of nivolumab or nivolumab plus ipilimumab in patients with localized renal cell carcinoma at high-risk of relapse after radical or partial nephrectomy (CheckMate 914). *First Author: Axel Bex, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Surgery is standard treatment for nonmetastatic renal cell carcinoma (RCC). Unfortunately, patients (pts) with stage II or III RCC have high risk of relapse with 5-year disease-free survival rates of ~51%–56%; prevention of recurrence is an unmet need. In CheckMate 214, first-line nivolumab plus ipilimumab (NIVO+IPI) demonstrated significant overall survival improvements in pts with advanced/metastatic RCC, with a manageable safety profile. Moreover, while not yet confirmed in randomized controlled trials, evidence suggests that anti-PD-(L)1 monotherapy may provide sufficient clinical activity in some pts with advanced RCC. These findings indicate a potential for improved clinical outcomes in the early-stage adjuvant RCC setting. As such, the phase 3, double-blind CheckMate 914 study will evaluate NIVO and NIVO+IPI vs placebo in pts with high risk of relapse after nephrectomy (NCT03138512). **Methods:** Key inclusion criteria: radical or partial nephrectomy with negative surgical margins $>$ 4 weeks and $\leq$12 weeks before randomization; predominantly clear cell histology; pathologic TNM staging T2a (grade [G] 3 or 4), T2b (any G), T3 (any G), or T4 (any G) N0M0, or any T (any G) N1M0; Eastern Cooperative Oncology Group performance status $\leq$1; no clinical/radiological evidence of macroscopic residual disease or distant metastases post-nephrectomy; and tumor tissue obtained $\leq$3 months pre-enrollment. Key exclusion criteria: conditions requiring corticosteroid or immunosuppressive systemic treatment, autoimmune disease, prior treatment with drugs specifically targeting T-cell co-stimulation or checkpoint pathways, and prior systemic treatment for RCC. In part A, pts are randomized 1:1 to receive NIVO+IPI or placebo infusions; in part B, pts are randomized 1:1:2 to receive NIVO+IPI, placebo infusions, or NIVO with IPI placebo. All treatments are given for 24 weeks or until disease recurrence, unacceptable toxicity, or withdrawal of consent. Stratification factors: TNM staging and type of nephrectomy procedure. Primary endpoint: disease-free survival per blinded independent central review (part A: NIVO+IPI vs placebo; part B: NIVO vs placebo). Secondary endpoints: overall survival (part A: NIVO+IPI vs placebo; part B: NIVO vs placebo and NIVO+IPI vs NIVO), disease-free survival (part B: NIVO+IPI vs NIVO), and safety. Enrollment in the study is ongoing. Total target enrollment across parts A and B is 1600 pts. Clinical trial information: NCT03138512. Research Sponsor: Bristol-Myers Squibb.

TPS5100 Poster Session (Board #169), Fri, 8:00 AM-11:00 AM

PDIGREE: An adaptive phase III trial of PD-inhibitor nivolumab and ipilimumab (IPI-NIVO) with VEGF TKI cabozantinib (CABO) in metastatic untreated renal cell cancer (Alliance A031704). *First Author: Tian Zhang, Duke Cancer Institute, Durham, NC*

Background: First-line treatment of mRCC has rapidly changed to include IPI-NIVO or CABO, with clinical benefit of each based on the Checkmate 214 and CABOSUN (A031203) trials. Combination immunotherapy with VEGF therapies has shown benefit over sunitinib in the JAVELIN 101 and KEYNOTE 426 trials. It is yet unclear which patients (pts) benefit most from combination immunotherapy-VEGF inhibitors, and the optimal sequence of drugs. **Methods:** In an adaptive, randomized, multicenter phase 3 trial (Alliance A031704, PDIGREE), pts start treatment with induction IPI 1 mg/kg and NIVO 3 mg/kg intravenously (IV) once every 3 weeks. Key inclusion criteria include clear cell mRCC, International Metastatic RCC Database Consortium (IMDC) intermediate or poor risk, Karnofsky performance status $>$ 70, and no prior treatments for mRCC. Based on 3-month radiographic assessment (after completing IPI-NIVO combination), pts with complete responses (CR) undergo maintenance NIVO 480 mg IV every 4 weeks; pts with progression of disease (PD) switch to CABO 60 mg oral daily; pts with non-CR/non-PD are randomized to NIVO 480 mg IV every 4 weeks versus NIVO 480 mg IV every 4 weeks with CABO 40 mg oral daily. Randomization is stratified by IMDC risk criteria and presence of bone metastases. The primary endpoint of the study is overall survival (OS). We hypothesize that 3-year OS will improve to 70% for NIVO-CABO compared to 60% for NIVO alone; to achieve 85% power with a two-sided alpha of 0.05 and exponential distribution, 696 patients will be randomized. Accounting for 30% patients with either CR or PD, and 5% dropout from toxicity, up to 1046 pts will be enrolled. Key secondary endpoints include progression-free survival, 12-month CR rate, overall response rate based on RECIST 1.1 and irRECIST criteria, and toxicity profiles. Quality of life will be assessed based on the FKSI-19, PROMIS-fatigue, and EQ5D-5L questionnaires. Biomarkers associated with CR, tissue-based and plasma-based biomarkers will be assessed. Updated enrollment through May 2020 will be presented. Clinical trial information: NCT03793166. Research Sponsor: U.S. National Institutes of Health.

TPS5101 Poster Session (Board #170), Fri, 8:00 AM-11:00 AM

PROSPER: Phase III randomized study comparing perioperative nivolumab versus observation in patients with renal cell carcinoma (RCC) undergoing nephrectomy (ECOG-ACRIN EA8143). *First Author: Naomi B. Haas, Abramson Cancer Ctr, Philadelphia, PA*

Background: There is no standard adjuvant systemic therapy that increases overall survival (OS) over surgery alone for non-metastatic RCC. Anti-PD-1 nivolumab (nivo) improves OS in metastatic RCC and is well tolerated. In mouse models, priming the immune system prior to surgery with anti-PD-1 results in superior OS compared to adjuvant dosing. Remarkable pathologic responses have been seen with neoadjuvant PD-1 in multiple ph 2 studies in bladder, lung and breast cancers. Phase 2 neoadjuvant RCC trials of nivo show preliminary feasibility and safety with no surgical delays. PROSPER RCC seeks to improve clinical outcomes by priming the immune system with neoadjuvant nivo prior to nephrectomy followed by continued immune system engagement with adjuvant blockade in patients (pts) with high risk RCC compared to standard of care surgery alone. **Methods:** This global, unblinded, phase 3 National Clinical Trials Network study is accruing pts with clinical stage $\geq$T2 or $T_{any}N+$ RCC of any histology planned for radical or partial nephrectomy. Select oligometastatic disease is permitted if the pt can be rendered 'no evidence of disease' within 12 weeks of nephrectomy ($\leq$3 metastases; no brain, bone or liver). In the investigational arm, nivo is administered 480mg IV q4 weeks with 1 dose prior to surgery followed by 9 adjuvant doses. The control arm is nephrectomy followed by standard of care surveillance. There is no placebo. Baseline tumor biopsy is required only in the nivo arm but encouraged in both. Randomized pts are stratified by clinical T stage, node positivity, and M stage. 805 pts provide 84.2% power to detect a 14.4% absolute benefit in recurrence-free survival at 5 years assuming the ASSURE historical control of ~56% to 70% (HR = 0.70). The study is powered to evaluate a significant increase in OS (HR 0.67). Critical perioperative therapy considerations such as safety, feasibility, and quality of life metrics are integrated. PROSPER RCC embeds a wealth of translational studies to examine the contribution of the baseline immune milieu and neoadjuvant priming with anti-PD-1 on clinical outcomes. As of February 2020, 396 patients have been enrolled. Clinical trial information: NCT03055013. Research Sponsor: U.S. National Institutes of Health.

TPS5102 Poster Session (Board #171), Fri, 8:00 AM-11:00 AM

A phase III study (COSMIC-313) of cabozantinib in combination with nivolumab and ipilimumab in patients with previously untreated advanced renal cell carcinoma of intermediate or poor-risk. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Cabozantinib (C) inhibits tyrosine kinases involved in tumor growth, angiogenesis, and immune regulation, including MET, VEGFR, and TAM kinases (Tyro3, AXL, MER), and may promote an immune-permissive tumor environment, resulting in enhanced response to immune checkpoint inhibitors. C has shown preliminary clinical activity and tolerability in combination with the PD-1 inhibitor nivolumab (N) and as part of a triplet combination with N and the CTLA-4 inhibitor ipilimumab (I) in patients (pts) with advanced renal cell carcinoma (aRCC) (Nadal et al. ASCO 2018). C is approved for pts with aRCC, and N+I is approved as a combination therapy in pts with previously untreated aRCC of intermediate or poor risk. We present the study design of a phase 3 trial of C+N+I vs N+I in previously untreated pts with aRCC of IMDC intermediate or poor risk (NCT03937219). **Methods:** This randomized, double-blind, controlled phase 3 study evaluates the efficacy and safety of C+N+I vs N+I in previously untreated pts with IMDC intermediate or poor risk aRCC. Eligible pts are randomized 1:1 to receive C+N+I or N+I in combination with placebo, stratified by IMDC prognostic score and geographic region. Pts receive C (40 mg oral QD) + N (3 mg/kg IV Q3W) x 4 doses + I (1 mg/kg IV Q3W) x 4 doses, followed by C (40 mg oral QD) + N (480 mg IV flat dose Q4W). Control pts receive C-matched placebo and the same treatment regimen for N+I as the experimental arm. N will be administered for a maximum of 2 years. Eligibility criteria include histologically confirmed metastatic or aRCC with a clear cell component, intermediate or poor risk RCC per IMDC criteria, measurable disease per RECIST 1.1, KPS $\geq$70%, adequate organ and marrow function and age $\geq$18 years. Exclusion criteria include prior systemic therapy for aRCC and uncontrolled significant illnesses. The primary endpoint is PFS per RECIST 1.1 by BICR; the secondary endpoint is OS. Additional endpoints include ORR, safety, correlation of biomarkers with outcomes, and pharmacokinetics of C in combination with N+I. The first patient was enrolled in June 2019 and enrollment is ongoing. Clinical trial information: NCT03937219. Research Sponsor: Exelixis Inc.

TPS5103 Poster Session (Board #172), Fri, 8:00 AM-11:00 AM

A randomized phase II study of nivolumab plus ipilimumab versus standard of care in previously untreated and advanced non-clear cell renal cell carcinoma (SUNIFORECAST). *First Author: Marit Ahrens, Medical Clinic II, University Hospital, Frankfurt Am Main, Germany*

Background: Non-clear cell renal cell carcinomas (nccRCC) are a heterogeneous group of tumors accounting for approximately 25% of RCC patients (pts.). Since most clinical trials focus on clear-cell RCC (ccRCC) only, data on treatment strategies for nccRCC are limited. The combination of Nivolumab and Ipilimumab (IO/IO) has recently been approved for treatment in RCC showing a significant improvement in overall response rate (ORR), progression free (PFS), and overall survival (OS) in intermediate and high-risk pts. compared to sunitinib in a phase-III trial. Furthermore retrospective analysis in nccRCC patients have shown promising results for IO/IO as well in these entities. **Methods:** In this prospective randomized phase-II multicenter European trial adults with advanced or metastatic nccRCC without prior systemic therapy are eligible. Other key inclusion criteria include: available tumor tissue, Karnofsky $>$ 70% and measurable disease per RECIST 1.1. All histological diagnoses are reviewed by a central pathologist. The study plans to randomize ~306 pts. stratified for papillary or non-papillary non-clear cell histology and by the International Metastatic RCC Database Consortium (IMDC) risk score. Pts. will be randomized 1:1 to either i) Nivolumab 3mg/kg intravenously (IV) plus Ipilimumab 1mg/kg IV every 3 weeks for 4 doses followed by Nivolumab fixed dose 240mg IV every 2 weeks or ii) standard of care therapy according to the approved schedule. Treatment will be discontinued in case of unacceptable toxicity or withdrawal of informed consent. Pts may continue treatment beyond progression, if clinical benefit is achieved and treatment is well tolerated. Primary endpoint is the OS rate at 12 months. Secondary endpoints include OS rate at 6 and 18 months, median OS, PFS, ORR and quality of life. The trial is in progress and 122 patients (78 pts with papillary, 37 pts with non-papillary histology) have been enrolled until now. Clinical trial information: NCT03075423. Research Sponsor: Goethe University, Frankfurt, Germany, Pharmaceutical/Biotech Company.

5500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

TheraP: A randomised phase II trial of ^{177}Lu-PSMA-617 (LuPSMA) theranostic versus cabazitaxel in metastatic castration resistant prostate cancer (mCRPC) progressing after docetaxel: Initial results (ANZUP protocol 1603). *First Author: Michael S Hofman, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: LuPSMA is a radiolabeled small molecule that delivers therapeutic β-radiation to PSMA-expressing tumors. Encouraging efficacy and safety has been shown in non-randomized studies of mCRPC. TheraP is a randomized phase II trial comparing LuPSMA vs cabazitaxel in men with mCRPC progressing after docetaxel. **Methods:** Men with mCRPC, and imaging with ^{68}Ga-PSMA-11 and ^{18}F-FDG PET/CT that confirmed high PSMA-expression and no sites of FDG-positive/PSMA-negative disease, were randomly assigned (1:1) to LuPSMA (6-8GBq q6weeks up to 6 cycles) vs cabazitaxel (20mg/m^2 q3weeks up to 10 cycles); stratified by disease burden (>20 vs ≤20 sites), prior novel antiandrogens (NAA; abiraterone or enzalutamide), and study site. The primary endpoint was PSA response rate (PSA50-RR) defined by ≥50% reduction. Secondary efficacy endpoints included PSA-progression-free survival (PSA-PFS) and overall survival (OS). Data cut-off was 31DEC19 at this first pre-specified analysis. **Results:** 200 (median age 72 y, prior NAA 91%, >20 lesions 78%) of 291 PET screened men were randomised to LuPSMA (N=99) or cabazitaxel (N=101). 17 patients withdrew or died before receiving study treatment (1 LuPSMA vs 16 cabazitaxel). The PSA50-RR was higher in those assigned LuPSMA than cabazitaxel (65/99 [66%; 95%CI 56-75] vs 37/101 [37%; 95%CI 27-46]; P<0.001). At a median follow-up of 11.3 months, LuPSMA significantly improved PSA-PFS (HR 0.63, 95%CI 0.45-0.88, P=0.007; 143 events with next pre-specified analysis planned after 170 events). Efficacy results were similar when analyses were restricted to per-protocol treated men. OS data remains immature (57 deaths). Grade III-IV adverse events (AEs) occurred in 31/98 (32%) LuPSMA-treated men vs 42/85 (49%) in cabazitaxel-treated men. Discontinuations for toxicity occurred in 1/98 (1%) LuPSMA vs 3/85 (4%) cabazitaxel-treated. There were no treatment-related deaths. **Conclusions:** In men with docetaxel-treated mCRPC, LuPSMA was more active (PSA50-RR) than cabazitaxel with relatively fewer G3-4 AEs and PSA-PFS favoring LuPSMA. Clinical trial information: NCT03392428. Research Sponsor: None.

5501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Impact of PSMA-targeted imaging with 18F-DCFPyL-PET/CT on clinical management of patients (pts) with biochemically recurrent (BCR) prostate cancer (PCa): Results from a phase III, prospective, multicenter study (CONDOR). *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Current imaging modalities are inadequate for localizing and characterizing occult disease in men with BCR PCa, particularly in pts with low PSAs (<2 ng/mL). There is a need for improved diagnostic imaging to better inform treatment planning. ^{18}F-DCFPyL (PyL) is a novel PET imaging agent that binds selectively with high affinity to PSMA, which is overexpressed in PCa cells. **Methods:** Men ≥18 years- with rising PSA after definitive therapy and negative or equivocal standard of care imaging (e.g., CT/MRI, bone scintigraphy) were enrolled. A single 9 mCi (333 MBq) ± 20% dose of PyL was injected, followed by PET/CT 1-2 hours later. Primary endpoint was correct localization rate (CLR), defined as percentage of pts with a 1:1 correspondence between at least one lesion identified by PyL-PET/CT and the composite standard of truth: pathology, correlative imaging, or PSA response. The trial was successful if the lower bound of the 95% confidence interval (LLCI) for CLR exceeded 20% for two of three independent, blinded central PyL-PET/CT reviewers. The secondary endpoint, impact of PyL-PET/CT on clinical management of pts was based on the treating physician's documented clinical plans before and after PyL-PET/CT. **Results:** 208 men (median PSA 0.8 [0.2 - 98.4] ng/mL) underwent PyL PET/CT. The study achieved its primary endpoint: CLR of 84.8% to 87.0% among the three PyL-PET/CT readers; the LLCI for CLR by all three reviewers was >77%. Here we report the clinical impact. Based on local radiology assessment, PSMA-avid lesion(s) were identified in 69.3% (142/208) of pts. 63.9% (131/205) had a change in intended management after PyL-PET/CT, of which 78.6% (103/131) were attributable to positive PyL finding(s) and 21.4% (28/131) to negative PyL scans. Changes included: salvage local therapy to systemic therapy (n=58); observation before initiating therapy (n=49); noncurative systemic therapy to salvage local therapy (n=43); and planned treatment to observation (n=9). PyL was well tolerated with one drug-related SAE (hypersensitivity) and the most common AE being headache (n=4; 1.9%). **Conclusions:** PSMA-targeted PyL-PET/CT detected and localized occult disease in most men with BCR presenting with negative or equivocal conventional imaging. PyL-PET/CT led to changed management plans in the majority of pts, thus providing evidence that clinicians find PSMA PET imaging useful in men with recurrent or suspected metastatic PCa. Clinical trial information: NCT03739684. Research Sponsor: Progenics Pharmaceuticals, Inc.

5502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Accuracy of 68Ga-PSMA-11 for pelvic nodal metastasis detection prior to radical prostatectomy and pelvic lymph node dissection: A multicenter prospective phase III imaging study. *First Author: Thomas A Hope, University of California, San Francisco, San Francisco, CA*

Background: To determine the accuracy of 68Ga-PSMA-11 PET for the detection of pelvic nodal metastases (N1) compared to histopathology at time of radical prostatectomy (RP). **Methods:** This is a prospective multicenter single-arm open-label phase 3 imaging trial. Patients with intermediate to high risk prostate cancer (PCa) considered for RP with lymph node dissection (PLND) were enrolled at the University of California, Los Angeles (UCLA) and at the San Francisco (UCSF) (NCT03368547, NCT02611882, NCT02919111), and underwent one 68Ga-PSMA-11 PET. The primary endpoint was the sensitivity (Se) and specificity (Sp) of 68Ga-PSMA-11 PET for the N1 detection compared to PLND histopathology (reference-standard) on a per patient basis using nodal region-based correlation. Each scan was read by three blinded independent central readers (BICR). Consensus was based on majority rule. **Results:** From December 2015 to August 2019, 633 patients underwent one 68Ga-PSMA-11 PET for primary staging, and 277/633 (44%) subsequently underwent RP and PLND. The median initial PSA was 11.1 [0.04-147]. 75/277 patients (27%) had N1 disease per histopathology. Using a regional based analysis, Se, Sp, positive predictive value (PPV) and negative predictive value (NPV) for N1 detection was 0.40 [0.34, 0.46], 0.95 [0.92, 0.97], 0.75 [0.70, 0.80], 0.81 [0.76, 0.85], respectively. Se was higher for patients with higher PSA: 0.29 [0.24, 0.35] for PSA < 11 ng/ml versus 0.48 [0.42, 0.54] for PSA > 11. Se was higher when the nodes were larger: 0.30 [0.25, 0.36] for nodes < 10 mm versus 0.68 [0.63, 0.74] for nodes > 10. The average node size in true positive patients was 10 mm versus 4 mm in false negative patients. **Conclusions:** In intermediate to high risk PCa patients who underwent RP and PLND, 68Ga-PSMA-11 PET detected pelvic nodal metastases with a sensitivity of 0.40 and a specificity of 0.95. Higher PSAs and larger node size correlated with increased sensitivity. Clinical trial information: NCT03368547, NCT02611882, NCT02919111. Research Sponsor: Prostate Cancer Foundation.

5503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results of a phase II trial of intense androgen deprivation therapy prior to radical prostatectomy (RP) in men with high-risk localized prostate cancer (PC). *First Author: Rana R. McKay, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients with high-risk localized PC have an increased risk of recurrence and death despite treatment. Abiraterone acetate (AA), a potent CYP17 inhibitor, and apalutamide, a next generation anti-androgen, have each demonstrated improved overall survival in metastatic PC. In this multicenter randomized phase II trial we investigate the impact of intense androgen deprivation on RP pathologic response (NCT02903368). **Methods:** Eligible patients had a Gleason score ≥4+3=7, PSA >20 ng/mL or T3 disease (by prostate MRI) and lymph node <20 mm. During Part 1 of the study, patients were randomized 1:1 to AA + prednisone + apalutamide + leuprolide (APAL) or AA + prednisone + leuprolide (APL) for 6 cycles (1 cycle=28 days) followed by RP. All RPs underwent central pathology review. The primary endpoint was the rate of a pathologic complete response (pCR) or minimum residual disease (MRD, tumor ≤5 mm). Secondary endpoints include PSA response, surgical staging at RP, positive margin rate, and safety. **Results:** 118 patients were enrolled at four sites. Median age was 61 (range 46-72) years. The majority of patients had NCCN high-risk disease [n=111, 94%; T3 n=73 (62%), Gleason 8-10 n=84 (71%), PSA >20 ng/mL n=28 (24%)]. 114 (97%) patients completed 6 therapy cycles followed by RP. Median PSA nadir was <0.01 versus 0.02 ng/mL and time to nadir was 4.2 versus 4.6 months in the APAL and APL arms, respectively. RP outcomes are displayed in Table. The combined pCR or MRD rate was 21.8% in the APAL arm and 20.3% in the APL arm (p=0.85). 13 (11%) patients (8 in APAL; 5 in APL) experienced grade 3 treatment-related adverse events (TrAEs). The most common grade 3 TrAEs were hypertension (5%), elevated ALT (3%) and elevated AST (3%). No grade 4 or 5 TrAE was reported. **Conclusions:** Intense neoadjuvant hormone therapy followed by RP in men with high-risk PC resulted in favorable pathologic responses (<5 mm residual tumor) in 21% of patients. Pathologic responses were similar between the treatment arms. Follow-up is necessary to evaluate the significance of a pathologic response on recurrence rates. Part 2 of this trial will investigate the impact of an additional 12 months of APAL post-RP on biochemical recurrence. A phase 3 trial investigating neoadjuvant apalutamide + leuprolide prior to RP is ongoing. Clinical trial information: NCT02903368. Research Sponsor: Janssen.

Pathologic outcomes at RP.

	APAL (N=55)	APL (N=59)
ypT2	21 (38%)	19 (32%)
ypT3	27 (49%)	34 (58%)
Positive Margins	4 (7%)	7 (12%)
Positive Seminal Vesicles	15 (27%)	16 (27%)
Positive Lymph Nodes	4 (7%)	10 (17%)
pCR	7 (13%)	6 (10%)
MRD	5 (9%)	6 (10%)

5504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Neoadjuvant apalutamide (APA) plus leuprolide (LHRHa) with or without abiraterone (AA) in localized high-risk prostate cancer (LHRPC). *First Author: Eleni Efstathiou, Department of Genitourinary Medical Oncology, Division of Cancer Medicine, Houston, TX*

Background: Novel androgen signaling inhibitors (ASI) with medical castration may improve outcomes in LHRPC. We previously reported relapse free survival association with pathologic measures of tumor regression. However a wide range of persistent cancers was recorded. To build on our findings and test candidate predictors of outcome, we conducted a study examining APA effect in LHRPC. **Methods:** This is a phase II neoadjuvant study of 6 months APA+LHRHa +/- AA (randomized 1:1) in LHRPC ($\geq$ cT2 + Gleason Score $\geq$ 8 or $\geq$ cT2b + Gleason $\geq$ 7 + PSA $>$ 10 ng/mL) followed by radical prostatectomy (RP). We studied treatment effect by pathology measures [path. stage, tumor volume (TV), tumor cellularity % (TC), tumor epithelial volume (TEV: TC x TV)]. Tumor expression of candidate markers of outcome was assessed in the diagnostic biopsy by IHC [AR signaling (AR-N, ARC19, ARV7, PSA), PTEN, glucocorticoid receptor (GR), Ki67, p53, RB] and DNA/RNA seq. A previously identified candidate predictive molecular signature (AR-N overexpression, nARV7 absence, no GR overexpression, Ki67 $\leq$10%) was tested. Univariate (Fisher's exact, Wilcoxon) and multivariate (logistic, linear models) analyses employed. **Results:** Sixty three -of 65 pts enrolled- had RP. PS-ECOG 0, median age 65 (43-77). Treatment was well tolerated with Grade 3 hypertension in 7 (2 APA + LHRHa). Presurgical PSA was $\leq$0.1 in 62/63 (98%). Organ confined disease ($\leq$ypT2N0) found in 13/32(41%) APA+LHRHa vs. 12/31 (39%) APA+AA+LHRHa treated. 2 (3%) had pathologic complete remission (APA+AA+LHRHa), 6 (10%) minimal residual disease (5 on APA +LHRHa). Despite uniformity in PSA response, we recorded heterogeneity in measures of tumor viability: TV (0-11.5cc), TC (1-80%), TEV (0-6.1cc). $\leq$ypT2N0 associates with diagnostic biopsy positivity for the prespecified molecular signature (p $<$0.0001), PTEN expression (p: 0.004), absence of cribriform/ intraductal spread (p 0.002) but not with Gleason Score. On multivariate analysis only the prespecified biopsy signature associates with outcome (p 0.003). Findings were replicated when analyzed by TV, TC and TEV measures. **Conclusions:** Neoadjuvant Apalutamide plus LHRHa is tolerable and results in tumor regression in a subset of LHRPC patients. Dual ASI treatment does not further improve outcomes. Biopsy positive for a prespecified molecular signature, associated with response. Study results emphasize the need to consider biologic heterogeneity and pursue validation of predictors of response in order to improve therapeutic outcomes in LHRPC. Clinical trial information: NCT03279250. Research Sponsor: Prostate Cancer Foundation, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

5505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II randomized study of abiraterone acetate plus prednisone (AAP) added to ADT versus apalutamide alone (APA) versus AAP+APA in patients with advanced prostate cancer with noncastrate testosterone levels: (LACOG 0415). *First Author: Fernando C. Maluf, Beneficência Portuguesa de São Paulo, São Paulo, Brazil*

Background: ADT combined with AAP, APA, enzalutamide or docetaxel are among the standard treatment options to patients (pts) with hormone sensitive advanced/metastatic prostate cancer (PC). However, treatment-related adverse events (TRAEs) due to ADT impact negatively on the quality of life of these patients. Effective options with fewer TRAEs are required. **Methods:** LACOG 0415 is a phase II, randomized trial (1:1:1) evaluating the use of AA 1000mg po + prednisone 5mg po BID + ADT versus APA 240mg po alone versus AA 1000mg po + prednisone 5mg po BID + APA 240mg po in patients with advanced PC with noncastrate testosterone levels and indication of ADT (N+ or M+ or biochemical relapse combined with PSA $\geq$ 20 ng/ml or with PSA$\geq$4 ng/ml and PSA doubling-time $<$ 10 months). Stratification factors: metastatic disease (+/-). Primary endpoint was the percentage of pts who achieved PSA $\leq$ 0.2 ng/mL at Week 25, we estimated a PSA response rate of 65% in each of the three arms with a null hypothesis of 45%, power of 80% and alfa 5%, using Fleming one-stage method. Secondary endpoints were percentage of pts with $\geq$ 80% and $\geq$ 50% decline in PSA at week 25, radiographic progression-free survival (rPFS) and safety. **Results:** 128 patients were randomized between Oct 2017 and Apr 2019, and 122 pts were evaluable for PSA response. Median age was 69y (range, 53-88); most pts had ECOG PS0-1(99%). 17% of pts had biochemical relapse only, 9% N+ and 74% M+ disease. At week 25 the PSA was $\leq$ 0.2 ng/mL in 76% of pts in AAP+ADT arm, 59% in APA, and 80% in APA+AAP. All pts had a decline of $\geq$ 50% in PSA at week 25. 97% had a decline of $\geq$ 80% in PSA at week 25: 100% of pts in AAP+ADT arm, 95% in APA and 98% in APA+AAP. A total of 3 pts had clinical progressive disease, one in each arm. Two of them also had radiological progression at week 25, 1 pt in AAP+ADT arm and 1 pt in APA. TRAEs rates of any grade were 71% in AAP+ADT arm, 64% in APA, and 65% in APA+AAP. TRAEs rates of Grade$\geq$3 were 12% in AAP+ADT arm, 9% in APA and 16% in APA+AAP. 9 pts (7%) discontinued the treatment before the week 25, 5(4%) of them due to toxicity: 1 pt from AAP+ADT, 2 pts from APA, and 6 pts from APA+AAP. **Conclusions:** The AAP+ADT and APA+AAP groups showed high effectiveness in terms of PSA response. Radiologic disease control and the decline of $\geq$ 80% in PSA at week 25 were similar among all treatment arms. APA alone had less toxicity. APA+AAP and APA alone are promising regimens in this setting. No new safety signal was detected in the study. Clinical trial information: NCT02867020. Research Sponsor: Janssen.

5506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Baseline circulating tumor cell (CTC) count as a prognostic marker of PSA response and progression in metastatic castrate sensitive prostate cancer (mCSPC): Results from SWOG S1216, a phase III randomized trial of androgen deprivation plus orteronel (cyp17 inhibitor) or bicalutamide. *First Author: Amir Goldkorn, Division of Medical Oncology, Department of Medicine, Keck School of Medicine and Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

Background: In mCSPC, androgen deprivation therapy (ADT) combined with chemotherapy or androgen receptor signaling inhibition (ARSI) is the new standard of care. Biomarkers that predict clinical outcomes with these therapies are needed. We hypothesized that CellSearch CTC count, an FDA-cleared biomarker in metastatic castrate resistant PC (mCRPC), may be a valuable biomarker in mCSPC. **Methods:** In S1216, peripheral blood was drawn with informed consent at registration (baseline), and CTCs were enumerated on the FDA-cleared CellSearch platform (Menarini) per standard manufacturer protocol. CTC counts were analyzed centrally for associations with 2 pre-specified trial intermediate endpoints: 7-month PSA (7mPSA) $\leq$ 0.2 ng/ml vs. 0.2–4.0 vs. $>$ 4.0, (intermediate endpoint for overall survival, OS); and progression-free survival (PFS) $<$ vs. $>$ 2 years. Because OS data have not matured, analysis was pooled and equal numbers of samples were analyzed from each treatment arm and outcome measure (7mPSA and PFS) as stipulated by the Data Safety Monitoring Committee. **Results:** From 2014 to 2017, 523 baseline samples were collected. In the 7mPSA analysis (n = 264), CTCs were detected in 38% of men, with a median of 4 CTCs in those with detectable CTCs. In the PFS analysis (n = 336), CTCs were detected in 37% of men, with a median of 3 CTCs in those with detectable CTCs. Adjusting for disease burden (minimal vs. extensive) and ADT status (already initiated or not) at the time of CTC measurement, men with undetectable CTCs were 6.1-fold more likely to attain 7mPSA $\leq$ 0.2 (OR 6.1, 95% CI 2.1-17.2, p $<$ 0.001) and 3.7-fold more likely to achieve $>$ 2 years PFS (OR 3.7, 95% CI 1.7-8.1, p $<$ 0.001) compared to men with baseline CTCs $\geq$ 5. Other cutpoints previously validated in mCRPC studies (CTC $<$ 5 vs. $\geq$5 and CTCs 0 vs. $\geq$1) also strongly discriminated 7mPSA and PFS with statistical significance in this mCSPC cohort. **Conclusions:** CTC count at the start of treatment for mCSPC was highly prognostic of 7-month PSA response (intermediate endpoint for OS) and of PFS at 2 years. To our knowledge, this is the first such strong evidence from a prospective phase 3 trial of this magnitude. Additional analyses are planned when the trial is fully reported. Baseline CTC count may serve as a valuable prognostic marker to discriminate men likely to respond favorably to hormonal therapies from those who may benefit from early alternate interventions. Research Sponsor: U.S. National Institutes of Health.

5507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

The comprehensive methylation landscape of metastatic castration-resistant prostate cancer (mCRPC) identifies new phenotypic subtypes: Results from the West Coast Prostate Cancer Dream Team (WCDT). *First Author: Eric Jay Small, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: While recent studies have delineated the genomic landscape of mCRPC, its epigenomic landscape has not been as well characterized. The goal of this study was to define the comprehensive methylation landscape of mCRPC. **Methods:** mCRPC patients (pts) underwent a metastasis biopsy as part of a multi-institutional study (NCT02432001). Deep whole-genome bisulfite sequencing (mean depth 46x) was performed on fresh frozen tissue from 100 mCRPC patients; data was paired with deep whole-genome and transcriptome sequencing from the same samples. Unbiased hierarchical clustering of the mCRPC methylome was undertaken, and the survival of patients in each cluster was calculated using the Kaplan Meier method. **Results:** Unbiased hierarchical clustering revealed several distinct subtypes. 22% of mCRPC samples exhibited a novel epigenomic subtype associated with hypermethylation. This hypermethylated (HM) cluster was significantly associated with somatic mutations in genes known to be involved in methylation, eg *TET2* and *DNMT3B*, as well as in genes in which mutations have been associated with hyper-methylation in other cancer types (*IDH1* in glioblastoma and *BRAF* in colon cancer). mCRPC survival was 56.1 mos in pts with HM cancers compared to 35.6 mos in non-HM (p = .055). Methylome clustering also identified a unique cluster comprised of all patients with treatment-induced small cell/neuroendocrine cancer, a subtype previously associated with poor survival. **Conclusions:** This integrated study of whole-genome, whole methylome and whole-transcriptome sequencing provides the first comprehensive overview of the important regulatory role of methylation in metastatic castration-resistant prostate cancer, and has identified at least two distinct subtypes. The clinical and therapeutic implications of methylation subtypes should be explored in future studies. Clinical trial information: NCT02432001. 5508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Circulating tumor DNA (ctDNA) dynamics associate with treatment response and radiological progression-free survival (rPFS): Analyses from a randomized phase II trial in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Jane Goodall, The Institute of Cancer Research, London, United Kingdom*

Background: ctDNA can inform on prognosis, treatment response and survival. We evaluated ctDNA in serial plasma samples from patients enrolled in A.MARTIN (NCT01485861), a randomized phase II study of abiraterone with or without ipatasertib in patients with mCRPC. **Methods:** Blood was collected in cell-free DNA Streck tubes from 216 patients at 3 time points; baseline, C3D1 and end of treatment. Cell-free DNA (cfDNA) was extracted from plasma using a Circulating DNA Kit (Qiagen) on a QIASymphony machine (Qiagen). 25ng of extracted cfDNA was used in library preparation, constructed with a custom designed, 58 gene, QIAseq Targeted DNA panel (Qiagen) enriched for PI3K/AR pathway genes. Samples were sequenced to mean depth of 3394x on a NextSeq500 machine. Unless otherwise noted, all analyses combine patients across the 3 study arms, and reported p-values are unadjusted. **Results:** Baseline (BL) ctDNA positivity correlated with radiological progression-free survival (rPFS; HR: 1.8 [95% CI 1.3-2.6], $p < 0.01$); this association with rPFS was maintained in a multivariate cox model with > 5 baseline clinical variables (HR: 1.6 [95% CI 1.1-2.4]; $p = 0.011$). Patients with a C3D1 reduction in ctDNA had superior rPFS compared to patients with a C3D1 increase in ctDNA (HR: 2 [95% CI 1.3-3.2], $p < 0.01$). The rate of ctDNA clearance at C3D1 was higher in the Ipatasertib 400mg arm compared to placebo (56.3% versus 24.4%, $p < 0.01$). We find that changes in ctDNA associated with best confirmed overall response ($p = 0.024$); CR patients had the greatest reduction in ctDNA (mean of -23.4%), followed by PR (-16.3%), then SD (-4.1%), and lastly PD patients (-1.3%). Changes in ctDNA levels correlated with SLD changes ($rs = 0.289$, $p = 0.05$), and also PSA changes ($rs = 0.33$, $p < 0.01$). Changes in ctDNA were associated with rPFS in a multivariate cox analysis that included PSA change ($p < 0.01$), as well as in a separate multivariate analysis that included SLD change ($p < 0.01$). Lastly, we explored CNVs and observed emerging resistance mutations in progression samples, including alterations in *TP53*, *AR*, *FOXA*, *PTEN*, and *PI3K/AKT* pathway genes. **Conclusions:** ctDNA analyses may help (i) identify poorer prognosis disease at baseline, (ii) inform on treatment response (CR/PR/SD/PD) and radiological progression free survival (rPFS) in on-treatment (C3D1) samples, and (iii) can elucidate emerging resistance mechanisms at disease progression. Clinical trial information: NCT01485861. Research Sponsor: Roche.

Prostate cancer relative survival by stage and race/ethnicity, United States, 2001 to 2015. *First Author: David A Siegel, Centers for Disease Control and Prevention, Atlanta, GA*

Background: Prostate cancer is the most common cancer diagnosed and the second leading cause of cancer-related deaths among U.S. men. Incidence rates for distant stage cancer increased during 2010–2014, and survival at all stages was lower for black men than white men. We examined temporal changes in survival by race/ethnicity. **Methods:** Five-year relative survival (RS) (cancer survival in the absence of other causes of death) was calculated for men with prostate cancer aged ≥40 years using National Program of Cancer Registries data (93% U.S. population coverage). Cancers were diagnosed during 2001–2015 with follow-up through 2015. RS was estimated by race/ethnicity (non-Hispanic white, non-Hispanic black, and Hispanic), stage, and year (2001–2007 and 2008–2015). Differences were determined by non-overlapping 95% confidence intervals (CI). **Results:** During 2001–2015, 2,234,233 cases were recorded. Five-year RS was 100% for localized disease in all race/ethnicities and time periods. Overall, RS improved from 29.0% (95% CI, 28.5–29.5) to 31.3% (30.8–31.9) for distant stage and 83.4% (83.0–83.8) to 84.7% (84.2–85.1) for unknown stage. For regional stage, RS improved for white men (table). For distant stage, RS was highest for black and Hispanic men. For unknown stage, RS was highest for white and Hispanic men. **Conclusions:** RS improved for regional, distant, and unknown stage, but disparities by race/ethnicity persist. The disparity between black and white men for distant stage reversed compared to past studies. Further investigation of diagnosis patterns and clinical characteristics of men with distant and unknown stage cancer could inform interventions to address disparities in outcomes. Research Sponsor: None.

Stage	Race/ethnicity	No., 2001–2007	RS (95% CI), 2001–2007	No., 2008–2015	RS (95% CI), 2008–2015
Regional	White	100,214	97.9 (97.7–98.2)	132,175	99.4 (99.1–99.6)
	Black	15,966	98.4 (97.6–98.9)	23,094	99.1 (98.2–99.5)
	Hispanic	7,544	96.8 (95.9–97.5)	11,547	98.1 (97.2–98.7)
Distant	White	36,398	27.5 (27.0–28.1)	53,859	29.4 (28.8–30.1)
	Black	10,784	29.9 (28.9–30.9)	14,774	32.2 (31.1–33.4)
	Hispanic	3,835	35.4 (33.7–37.1)	6,310	38.7 (36.9–40.5)
Unknown	White	83,667	83.2 (82.7–83.6)	61,482	81.1 (80.5–81.7)

Assessment and management of cardiovascular risk factors among U.S. Veterans with newly diagnosed prostate cancer. *First Author: Lova Sun, UPHS, Philadelphia, PA*

Background: Cardiovascular disease (CVD) is a leading cause of death in men with prostate cancer (PC). Androgen deprivation therapy (ADT) is associated with increased CVD risk, and American Heart Association guidelines recommend CVD risk factor assessment and management in PC patients starting ADT. We characterized rates of guideline-concordant assessment and management of CVD risk factors for US Veterans with newly diagnosed PC, according to ADT use and prior atherosclerotic CVD diagnosis. **Methods:** We used cross-sectional data from VA Corporate Data Warehouse to identify Veterans with an incident diagnosis of PC from 2001-2017. Primary outcomes were guideline-concordant baseline CVD risk factor assessment (defined as ≥1 blood pressure, cholesterol, and HbA1c or fasting glucose measurement within 1 year prior to 6 months after ADT start or PC diagnosis), CVD risk factor control, and CVD risk-reducing medication use. Risk difference multivariable regression analyses adjusting for age, race, poverty, PC risk category, and year were used to evaluate the effect of ADT on study outcomes. **Results:** Of 191,829 Veterans with newly diagnosed PC, 27% (n = 51,419) were treated with ADT within 1 year of diagnosis, and 18% (n = 34,110) had a pre-existing diagnosis of atherosclerotic CVD. From 2001-2017, annual rates of guideline-concordant CVD risk factor assessment increased from 26% to 77%. In adjusted analyses, pre-existing atherosclerotic CVD diagnosis was associated with higher CVD risk factor assessment rate (64% vs 53%), better control of baseline LDL (94 vs 108 mg/dL), and higher rates of anti-hypertensive (90% vs 66%), lipid-lowering (83% vs 49%), and glucose-lowering (32% vs 20%) medication use. Treatment with ADT was associated with similar to minimally higher rates of CVD risk factor assessment (58% vs 54%), LDL control (104 vs 105 mg/dL), and anti-hypertensive (73% vs 69%), lipid-lowering (55% vs 55%), and glucose-lowering (25% vs 21%) medication use. Sixty percent of men starting ADT had at least one sub-optimally controlled CVD risk factor, and 1 in 4 of these men were not receiving a corresponding risk-reducing medication. One third of men starting ADT had BMI > 30 kg/m2. **Conclusions:** CVD risk factor assessment in Veterans with PC has increased over time. However, ADT does not appear to meaningfully impact CVD assessment or management, despite its known association with CVD risk. Over half of patients initiating ADT had elevated CVD risk factor(s). Multidisciplinary efforts to improve CVD risk mitigation are needed among men initiating ADT. Research Sponsor: U.S. National Institutes of Health, VA Center for Health Equity Research and Promotion.

PROREPAIR-A: Clinical and molecular characterization study of prostate cancer (PC) patients with and without previously known germline *BRCA1/2* mutations. *First Author: Rebeca Lozano, Spanish National Cancer Research Centre, Prostate Cancer Clinical Research Unit, Madrid, Spain*

Background: Germline *BRCA1/2* (g*BRCA1/2*) mutations are associated with poor clinical outcomes in PC. Previous studies showed that g*BRCA2* carriers present more CNV in several genes associated with more aggressive disease. These aberrations may explain the poor clinical outcomes of these patients, but larger studies are needed to confirm these findings. **Methods:** PROREPAIR-A is a multicenter case-control study in which g*BRCA2* carriers with available diagnostic timor-tissue were matched 1:2 by Gleason and stage at diagnosis (M0 vs M1) with known non-carriers (NC). A minimum of 120 controls-60 cases were required to prove a 5yr Cause Specific Survival (CSS)-rate of 85% vs 60%. The primary endpoint was to confirm the independent prognostic value of g*BRCA2* in PC CSS. In addition, we explored the prognostic role of g*BRCA1* and somatic events in *BRCA2*, *RB1*, *MYC*, *PTEN* and *TMPRSS2-ERG* by FISH. X^2, Kaplan-Meier, log-rank and cox-regression models were carried out to identify associations with baseline characteristics and outcomes: Metastases Free Survival (MFS), Time to Castration-Resistance (TTCR) and CSS. **Results:** A total of 80:160 matched cases-controls were initially included, but tumor tissue and clinical data were only available in 73 g*BRCA2* and 127 NC. 14 g*BRCA1* were also included. At diagnosis, g*BRCA2* were younger (median 62.6 vs 64.5, $p = 0.02$) and had cT3-4 disease more often than NC (31.5% vs 9.4%, $p < 0.01$), but no other significant differences were found. Somatic *BRCA2-RB1* codeletion (40.8% vs 11.8%, $p < 0.01$) and *MYC* amplification (51.4% vs 22.8%, $p < 0.01$) were more frequent in g*BRCA2* compared to NC, but no significant differences in *PTEN* and *TMPRSS2-ERG* were observed. g*BRCA2* mutations as well as somatic *BRCA2-RB1* codel and *MYC* amplif were significantly associated with shorter CSS, MFS and TTCR (Table). MVA model confirmed the independent prognostic value of g*BRCA2* (HR 1.94, $p = 0.03$), *BRCA2-RB1* codel (HR 3.16, $p < 0.01$), *MYC* amplif (HR 2.36, $p < 0.01$), Gleason ≥8 ($p < 0.01$) and M1 at diagnosis ($p < 0.01$) for CSS. **Conclusions:** PROREPAIR-A confirmed the independent prognostic value of g*BRCA2* for CSS. Somatic *BRCA2*, *RB1* and *MYC* aberrations were more frequent in g*BRCA2* carriers. Those alterations are associated with shorter CSS, MFS and TTCR, and may contribute to poor clinical outcomes in g*BRCA2* and NC. Research Sponsor: Prostate Cancer Foundation.

	CSS	MFS	TTCR
g*BRCA2* vs NC	110 vs 211 m $p < 0.01$	105 vs NR m $p < 0.01$	105 vs NR m $p < 0.01$

Late toxicities and recurrences in patients with clinical stage I nonseminomatous germ cell tumor after one cycle of adjuvant BEP versus primary retroperitoneal lymph node dissection: A 13-years follow-up analysis of a phase III trial cohort. *First Author: Andreas Hiester, Department of Urology, Heinrich-Heine-University, Düsseldorf, Germany*

Background: One cycle of adjuvant BEP has shown superiority in recurrence free survival over RPLND in patients (pts) with clinical stage (CS) I nonseminomatous germ cell tumor of the testis (NSGCT) (JCO 2008). We report recurrences and late toxicities of this randomized trial after 13 yrs of follow-up (FU). **Methods:** Questionnaires of 382 unselected pts with CS I NSGCT treated within a phase III trial comparing recurrence rate after 1 cycle of adjuvant BEP (arm A) vs. RPLND (arm B) were evaluated regarding recurrences and late toxicity. Overall (OS) and progression free survival (PFS) was calculated by Kaplan-Meier and arms were compared using logrank test. Categorial data were analyzed by chi-square test (PRISM v8). **Results:** In each arm 191 pts were analyzed as intention-to-treat with a median FU of 13.75 yrs (0-22.9 yrs); 3/191 pts (1.6 %) in arm A and 16/191 pts (8.4 %) in arm B had a recurrence. 20-yrs PFS in arm A / B was 97 % (CI 96-99 %) / 92 % (CI 90-95 %), (*p = .0049*). 20-yrs OS in arm A / B was 90 % (CI 86-94 %) / 88 % (CI 86-94 %), (*p = .83*). 23/382 (6 %) pts have died, 22/23 not related to testis cancer, 1/23 died of a recurrence in arm B. 8/191 pts (4.2 %) in arm A and 4/191 pts (2.1 %) in arm B showed metachronous secondary testis cancer (*p = .26*). 5/191 pts (2.6 %) in arm A and 4/191 pts (2.1 %) in arm B developed other malignancies. 170/382 questionnaires were evaluable (arm A: 95; arm B: 75). 45 pts were lost to FU. There were no significant differences comparing both treatment arms regarding potentially treatment-related late toxicities. However, excluding pre-existing complaints, ototoxicity (9/95 (9 %) vs. 4/75 (5 %) pts, *p = .31*) was reported more frequently in arm A. Excluding pre-existing neurological conditions, peripheral neuropathy of all grades was more frequently reported in arm A (15/95 pts; 16 % vs. 9/75 pts; 12 % pts; *p = .48).* Retrograde ejaculation occurred more frequently after RPLND (9/95 pts; 9% vs. 18/75 pts; 24 %, *p = .01*). **Conclusions:** After more than 13 yrs of FU, recurrences in non-risk factor selected pts with CS I NSGCT remain to be significantly more frequent with RPLND. No excess mortality due to secondary malignancies was observed. Late toxicities did not differ between 1 cycle of BEP and RPLND. Only retrograde ejaculation was observed significantly more frequent after RPLND. With long-term observation, 1 cycle of BEP has not only a high efficacy to prevent recurrence but also seems to be tolerated without clinically relevant long-term toxicity. Research Sponsor: None.

Population-based prostate cancer screening using a prospective, blinded, paired screen-positive comparison of PSA and fast MRI: The IP1-PROSTAGRAM study. *First Author: David Eldred-Evans, Imperial Prostate, London, United Kingdom*

Background: The prostate-specific antigen (PSA) test can lead to under- and over-diagnosis of prostate cancer and has not been recommended for population screening. A fast MRI scan might overcome the limitations of PSA. IP1-PROSTAGRAM is the first study to evaluate the performance of a 15-minute non-contrast MRI for prostate cancer screening in comparison to PSA. **Methods:** IP1-PROSTAGRAM was a prospective, population-based, screen-positive paired-cohort study. Men aged 50-69 years in the UK were invited for prostate cancer screening through seven primary care practices or community-based recruitment. Participants underwent a PSA and MRI scan (T2-weighted and diffusion). MRI was scored using PIRADS version 2.0 without knowledge of PSA; screen-positive MRI (defined as either PIRADS score 3-5 or 4-5) were compared against a screen-positive PSA defined as ≥3ng/ml. If any test was screen-positive, a systematic 12-core biopsy was performed with MRI-ultrasound image-fusion targeted biopsy to MRI suspicious areas, as appropriate. Clinically-significant cancer was defined as any Gleason score ≥3+4. The primary outcome was the proportion of screen-positive MRI at different scores; important secondary outcomes were the number of clinically-significant and insignificant cancers detected. **Results:** 2034 men were invited to participate of whom 408 consented and 406 were screened by both PSA and MRI (10/Oct/2018-15/May/2019). The proportion with a screen-positive MRI (score 3-5) was higher than the proportion with a screen-positive PSA (17.7% [95%CI 14.3-21.8] vs. 9.9% [95%CI 7.3-13.2]; $p < 0.001$). A screen-positive MRI (score 4-5) was similar to a screen-positive PSA (10.6% [95%CI 7.9-14.0] vs. 9.9% [95%CI 7.3-13.2], $p = 0.71$). An MRI score 3-5 or 4-5 used to denote a screen-positive MRI, compared to PSA alone, detected 14, 11 and 7 clinically-significant cancers, respectively. There were 7, 5 and 6 clinically-insignificant cancers detected, respectively. No serious adverse events occurred. **Conclusions:** When screening the general population for prostate cancer, MRI using a score of 4-5 to define a screen-positive test, compared to PSA alone at ≥3ng/ml, could lead to more men diagnosed with clinically-significant cancer without increasing the number of men biopsied or diagnosed with clinically-insignificant cancer. Clinical trial information: NCT03702439. Research Sponsor: Wellcome Trust, Other Foundation, The Urology Foundation.

Overall survival (OS) results of phase III ARAMIS study of darolutamide (DARO) added to androgen deprivation therapy (ADT) for nonmetastatic castration-resistant prostate cancer (nmCRPC). *First Author: Karim Fizazi, Institut Gustave Roussy and University of Paris Sud, Villejuif, France*

Background: DARO is a structurally distinct androgen receptor inhibitor with a favorable safety profile, approved for treating men with nmCRPC after demonstrating significantly prolonged metastasis-free survival, compared with placebo (PBO), in the phase III ARAMIS trial: median 40.4 vs 18.4 months, respectively (HR 0.41; 95% CI 0.34–0.50; $P < 0.0001$). We report final analyses of OS and prospectively collected, patient-relevant secondary endpoints, and updated safety results. **Methods:** 1509 patients (pts) with nmCRPC were randomized 2:1 to DARO 600 mg twice daily (n = 955) or PBO (n = 554) while continuing ADT. Secondary endpoints included OS, and times to pain progression, first cytotoxic chemotherapy, and first symptomatic skeletal event. The OS analysis was planned to occur after approximately 240 deaths. Secondary endpoints were evaluated in a hierarchical order. **Results:** Final analysis was conducted after 254 deaths were observed (15.5% of DARO and 19.1% of PBO patients). After unblinding at the primary analysis, 170 pts crossed over from PBO to DARO. DARO showed a statistically significant OS benefit corresponding to a 31% reduction in the risk of death compared with placebo. All other secondary endpoints were significantly prolonged by DARO, regardless of the effect of crossover and subsequent therapies on survival benefit. Incidences of treatment-emergent adverse events (AEs) with ≥5% frequency were generally comparable between DARO and PBO, similar to the safety profile observed at the primary analysis. Incidences of AEs of interest (including falls, CNS effects, and hypertension) were not increased with DARO compared with PBO when adjusted for treatment exposure. AEs in the crossover group were consistent with those for the DARO treatment arm. **Conclusions:** DARO showed a statistically significant OS benefit for men with nmCRPC. In addition, DARO delayed onset of cancer-related symptoms and subsequent chemotherapy, compared with PBO. With extended follow-up, safety and tolerability were favorable and consistent with the primary ARAMIS analysis (Fizazi et al, *N Engl J Med* 2019;380:1235-46). Clinical trial information: NCT02200614. Research Sponsor: Bayer AG and Orion Pharma.

Final overall survival (OS) from PROSPER: A phase III, randomized, double-blind, placebo (PBO)-controlled study of enzalutamide (ENZA) in men with nonmetastatic castration-resistant prostate cancer (nmCRPC). *First Author: Cora N. Sternberg, Englander Institute of Precision Medicine, Weill Cornell Medicine, New York, NY*

Background: PROSPER previously demonstrated a statistically significant and clinically meaningful improvement in metastasis-free survival (MFS) (hazard ratio [HR] 0.29; 95% CI 0.24-0.35; $P < .001$) in men with nmCRPC and rapidly rising prostate-specific antigen (PSA) who received ENZA. When first reported, OS was immature with only 165 of 596 (28%) prespecified deaths. Here we report results from the final OS analysis. **Methods:** Men with nmCRPC, PSA doubling time ≤ 10 mo, and PSA ≥ 2 ng/mL at screening continued androgen deprivation therapy (ADT) and were randomized 2:1 to ENZA 160 mg or PBO. OS treatment effect was assessed using a group sequential testing procedure with O'Brien-Fleming-type alpha spending function ($P \leq .021$ required for statistical significance). Medians were estimated using the Kaplan-Meier method; 95% CIs using a stratified Cox regression model. **Results:** As of Oct 15, 2019 (median follow-up ≈ 48 mo), there were 466 deaths (288 [30.9%] and 178 [38.0%] in the ENZA and PBO arms, respectively). ENZA significantly prolonged OS compared with PBO (HR 0.73; 95% CI 0.61-0.89; $P = .0011$). Median OS was 67.0 mo (95% CI 64.0-not reached) in the ENZA arm and 56.3 mo (95% CI 54.4-63.0) in the PBO arm. Subsequent antineoplastic therapies were initiated after treatment discontinuation by 310 (33%) men in the ENZA arm vs 303 (65%) in the PBO arm. Median duration of treatment was 33.9 mo vs 14.2 mo with ENZA vs PBO, respectively. Grade ≥ 3 adverse events (AEs) were reported by 48% of men in the ENZA arm vs 27% in the PBO arm (16% vs 6% were drug related, respectively). AEs with event rates per 100 patient-yr that were ≥ 2 points higher with ENZA vs PBO were falls (9 vs 4), fatigue (14 vs 12), and hypertension (7 vs 5). **Conclusions:** ENZA treatment resulted in a statistically significant 27% reduced risk of death compared with PBO, demonstrating that initiation of ENZA + ADT before the onset of detectable metastasis improves OS in men with CRPC and rapidly rising PSA. This OS benefit ensues despite crossover from the PBO arm to ENZA and higher rates of subsequent antineoplastic therapies in men from the PBO arm. Safety was consistent with previous clinical trials. This final OS analysis from PROSPER provides prospective validation of MFS as a potential surrogate endpoint for OS in nmCRPC and supports the continued use of ENZA + ADT as a standard of care in men with nmCRPC and rapidly rising PSA. Clinical trial information: NCT02003924. Research Sponsor: Pfizer Inc. and Astellas Pharma, Inc.

Final survival results from SPARTAN, a phase III study of apalutamide (APA) versus placebo (PBO) in patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC). *First Author: Eric Jay Small, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: SPARTAN evaluated APA vs PBO in pts with nmCRPC and a prostate-specific antigen doubling time of ≤ 10 mo receiving androgen deprivation therapy (ADT). At primary end point analysis of metastasis-free survival (MFS), APA significantly improved median MFS by 2 yrs, as well as time to metastasis, progression-free survival, and time to symptomatic progression vs PBO (Smith, et al. *NEJM* 2018); overall survival (OS) results were immature. SPARTAN was unblinded upon meeting the primary end point; pts still on PBO were allowed to cross over to APA. Final survival results are reported herein. **Methods:** 1207 nmCRPC pts were randomized 2:1 to APA (240 mg QD) or PBO plus ongoing ADT. At progression, pts could receive open-label sponsor-provided abiraterone acetate + prednisone. After the primary efficacy end point (MFS) was met, 76 PBO pts (19%) crossed over to APA. OS and time to cytotoxic chemotherapy (TTCx) were tested by group sequential testing procedure with O'Brien-Fleming (OBF)-type alpha spending function. Time-to-event end points were analyzed by Kaplan-Meier method and Cox model. A sensitivity analysis for OS, accounting for crossover using a naïve censoring approach, was conducted. **Results:** With follow-up of 52.0 mo, 428 (of 427 required) OS events had occurred. Median treatment duration: APA, 32.9 mo; PBO, 11.5 mo. Median OS was significantly longer with APA + ADT vs PBO + ADT (73.9 vs 59.9 mo), (hazard ratio [HR], 0.784, Table). APA significantly lengthened TTCx (HR, 0.629). Discontinuation rates (APA vs PBO) due to progressive disease were 42.7% vs 73.9%, and due to adverse events (AE) 15.2% vs 8.4%. Safety was consistent with previous reports; grade 3/4 treatment-emergent (TE) AEs of special interest were rash 5.2%, fractures 4.9%, falls 2.7%, ischemic heart disease 2.6%, hypothyroidism 0%, and seizures 0%. 1 TEAE leading to death (myocardial infarction) was considered potentially APA related. **Conclusions:** In pts with nmCRPC, APA + ADT significantly improved OS compared with PBO + ADT, with median OS > 6 yr in the APA + ADT group and 14 mo improvement over PBO + ADT. Benefit from APA was observed despite a 19% crossover from PBO. The safety profile of APA was consistent with prior interim analyses. Clinical trial information: NCT01946204. Research Sponsor: Janssen Research & Development.

End point, median mo	APA + ADT (n = 806)	PBO + ADT (n = 401)	HR	p Value[a]
OS	73.9	59.9	0.784	0.0161[b]
OS (naïve censoring crossover)	73.9	52.8	0.685	0.0002

TRANSFORMER: Bipolar androgen therapy (BAT) versus enzalutamide (E) for castration-resistant metastatic prostate cancer (mCRPC). *First Author: Samuel R. Denmeade, Johns Hopkins University Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Rapid cycling between high and low testosterone (T) (i.e BAT) produces tumor response in mCRPC, and may overcome resistance to newer AR therapies. Here we report a randomized study comparing BAT to E in men with mCRPC progressing on abiraterone (A). **Methods:** In this phase 2 trial, men received either T cypionate 400mg IM (BAT) once every 28 days or daily oral E 160mg. Primary endpoint was clinical/radiographic PFS; crossover was permitted at progression. Secondary endpoints were OS, PSA progression to primary and crossover therapy, PSA and objective responses (OR), time to PSA progression from randomization through crossover (PFS2), quality of life (QoL), and AEs. **Results:** 195 men were randomized (94 to BAT, 101 to E). Results are presented in table. Although diametrically opposed therapies, median PFS and PSA response in the intent-to-treat (ITT) population was not significantly different between BAT and E. OR and OS favored BAT. For those who received BAT and then crossed over to E the PSA50 response was 77.8% and time to PSA progression was 10.9 mo compared to 25.3% and 3.8 mo for those receiving E immediately after A. The sequence of treatment had a significant effect on median PSF2 which was 28.2 mo for men receiving BAT→E vs. 19.6 m for E→BAT. For men who crossed over from BAT to E, OS was 37.3 mo vs. 28.6 months for those receiving E without crossover. AEs were primarily grade 1-2 in the BAT arm and included fatigue, generalized pain, and lower extremity edema. BAT improved QoL (fatigue, physical functioning, sexual function) vs. E. **Conclusions:** BAT could be safely administered to asymptomatic men with mCRPC. BAT produced a comparable PFS to E in A-refractory mCRPC pts. However, PSA50 and OR after crossover, as well as PFS2, were significantly improved in men who received BAT→E versus E→BAT. OS in men receiving BAT→E was 37.3 mo, exceeding historical expectations. These results support the hypothesis that treatment with BAT is safe, has efficacy and can restore sensitivity to antiandrogens. Clinical trial information: NCT02286921. Research Sponsor: Department of Defense Prostate Cancer Research Program.

A phase I, open-label, multicenter study to assess the safety, pharmacokinetics, and preliminary antitumor activity of AZD4635 both as monotherapy and in combination in patients with advanced solid malignancies: Results from prostate cancer patients (NCT02740985). *First Author: Emerson A. Lim, Columbia University-Herbert Irving Comprehensive Cancer Center, New York, NY*

Background: AZD4635 inhibits adenosine 2a receptor (A2aR) signaling and improves immune activation and anti-tumor activity in preclinical models. This phase I study assessed the safety, pharmacokinetics, pharmacodynamics and efficacy of AZD4635 monotherapy (mono) and in combination (combo) with durvalumab (durva) in patients (pts) with refractory solid tumors. Here we present data for immune checkpoint-naïve pts with metastatic castrate-resistant prostate cancer (mCRPC). **Methods:** Pts with refractory mCRPC received AZD4635 mono (75 mg or 100 mg QD oral nanosuspension [(RP2D]) or in combination (75 mg or 100mg QD) with durva 1.5g IV q4wk. **Results:** Between 30Aug16 and 20Jun19 (data cutoff [DCO]) 94 mCRPC pts were treated with mono (n = 49) or combo (n = 45): median age 70.5 yrs; ECOG 0-1 = 99%. The median number of prior treatment regimens was 5 (range = 1-10); 61% of pts (57/94) had prior chemotherapy, 90% had prior new hormonal therapy. PK data suggest AZD4635 concentrations at 75-100 mg QD are above the *in vitro* IC_{50} for A2aR inhibition throughout the dosing interval. Modeling predicts 80-90% A2aR occupancy at steady state for doses at ≥75 mg QD. Most common treatment-related AEs (> 10%) were nausea, vomiting, fatigue, decreased appetite, dizziness, and diarrhea. At the DCO in this ongoing study, 70 pts were evaluable for response by RECIST v1.1 (mono = 33, combo = 37). Confirmed response occurred in 8 pts: mono = ORR 6.1% (2PRs) and combo = 16.2% (2CRs, 4PRs). The duration of response across cohorts ranged from 1-18.5 mo (5 pts ongoing). PSA response (defined as ≥50% decrease from baseline of ≥1ng/ml) was observed in 6.4% (3/47 pts; 95% CI, 1.3-17.5) of mono-treated patients and 20% (9/45 pts; 95% CI, 9.6-34.6) of combo-treated patients. Patients with high adenosine (ADO) gene expression signature (N = 46) in peripheral blood, showed a median PFS of 21 weeks v. 8.7 weeks in ADO signature low patients (N = 46) (HR 0.5, CI 0.3-0.9) (DCO 20Jun19). In addition, baseline TCR clonality and diversity were linked with response. **Conclusions:** In mCRPC pts, AZD4635 alone or in combination with durva was tolerable and associated with clinical benefit. A mCRPC phase II trial is ongoing with continued exploration of predictors of response to treatment. Clinical trial information: NCT02740985. Research Sponsor: Astra Zeneca.

5520 Poster Discussion Session; Displayed in Poster Session (Board #101), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

ProCAID: A randomized double-blind phase II clinical trial of capivasertib (C) in combination with docetaxel and prednisolone chemotherapy (DP) in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Simon J. Crabb, Southampton Clinical Trials Unit, University of Southampton, University Hospital Southampton NHS Foundation Trust and Southampton Experimental Cancer Medicine Centre, Southampton, United Kingdom*

Background: DP extends survival in mCRPC, but clinical benefit is modest. PI3K/AKT/PTEN pathway activation is common in mCRPC contributing to disease progression and DP resistance. C is a pan-AKT inhibitor. Pre-clinical data indicate activity in prostate cancer and synergism with DP. This phase II trial combined C with DP in mCRPC. **Methods:** Key eligibility criteria: histologically or cytologically proven measurable or evaluable mCRPC, suitable for treatment with DP for PSA and/or radiographic disease progression, ECOG performance status 0-1, no prior chemotherapy for mCRPC, not requiring insulin or > 2 oral hypoglycaemic drugs for diabetes mellitus. Treatment: up to 10 cycles of DP (D: 75 mg/m^2 IV, day 1; P: 5 mg bd oral, day 1 – 21) and random assignment (1:1, double blind) to oral C (320 mg twice daily, 4 days on/3 days off, from cycle 1, day 2) or matched placebo to disease progression. Primary endpoint: progression free survival (PFS; comprising PSA, radiographic or clinical progression, new cancer therapy or death; PCWG2 criteria) in the intent to treat (ITT) population. Secondary endpoints included overall survival (OS) and safety. PFS and OS were also assessed by composite biomarker (B) subgroup for PI3K/AKT/PTEN pathway activation status (NGS/IHC on archival tumour, contemporaneous ctDNA). Statistics: designed to detect a 50% increase in median PFS (6 to 9 months (mo)) between the placebo and C arms (90% power, 20% 1-sided alpha) by Cox proportional hazards model. Registration: ISRCTN 69139368. **Results:** 150 patients were randomised to 01/2019. Median follow up 16.77 months (IQR 12.0-26.5). PFS and OS by ITT and B status, are shown in the table (NR, not reached; CI confidence interval). Grade 3–4 adverse events (AE) were equally common between arms (62.2%). The most common AEs were diarrhoea, fatigue and nausea. **Conclusions:** Adding C to DP did not extend PFS. The OS secondary endpoint was significantly increased. PFS and OS results were consistent irrespective of PI3K/AKT/PTEN pathway activation status. Clinical trial information: 69139368. Research Sponsor: Cancer Research UK, Pharmaceutical/Biotech Company.

5521 Poster Session (Board #102), Fri, 8:00 AM-11:00 AM

Molecular determinants of prostate specific antigen (PSA) kinetics and clinical response to apalutamide (APA) in patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC) in SPARTAN. *First Author: Fred Saad, Centre Hospitalier de l'Université de Montréal, Université de Montréal, Montréal, QC, Canada*

Background: In SPARTAN, APA + androgen deprivation therapy (ADT) prolonged metastasis-free survival (MFS) and improved PSA kinetics over placebo (PBO) + ADT in high-risk nmCRPC. All molecular subtypes derived benefit in MFS from APA (Feng FY, et al. ASCO GU 2019; abstract 42). We evaluated the association of PSA decline and efficacy outcomes in SPARTAN pts with different molecular subtypes. **Methods:** Gene expression from archival primary tumors (biomarker population) was assessed with the DECIPHER platform (Decipher Biosciences, Inc.) and stratified into genomic classifier (GC) high- and low-to-average risk using GC score > 0.6 and ≤ 0.6, respectively, and ADT-resistant or -sensitive basal or luminal A/B (PAM50 classifier) subtypes. PSA nadir and confirmed PSA decline (Table) were assessed in APA pts overall and at 3, 6, and 12 mo. Associations between molecular subtypes and outcomes were assessed. **Results:** Of 233 available samples, 154 were from APA pts; 49% of APA pts had high GC score and 66% had basal subtype. PSA levels at baseline were similar across all subtypes. Regardless of GC score or basal/luminal subtype, $> 50\%$ of patients achieved $\geq 90\%$ reduction in PSA with APA. PSA declined faster and PSA reduction was deeper at 6 mo (Table) in GC low to average vs GC high risk and luminal vs basal subtypes. Overall, only luminal vs basal subtypes had a significantly higher % of pts with $\geq 90\%$ PSA decline (Chi square p = 0.037). In luminal pts, deeper PSA decline with APA was consistent with improved MFS vs basal pts. In GC high pts, MFS benefit with APA was similar to that in GC low to average pts despite lower PSA decline. Although GC low to average and luminal pts had more rapid and deeper PSA responses than GC high or basal pts, respectively, all pts derived MFS benefit. Association of long-term outcomes with PSA decline in these molecular subtypes will be presented. **Conclusions:** In SPARTAN, all molecular subtypes of pts with nmCRPC treated with APA + ADT had MFS benefit and rapid and sustained PSA decline. PSA responses were deepest and most rapid in GC low to average and luminal subtypes. Clinical trial information: NCT01946204. Research Sponsor: Janssen Research & Development.

A urine exosomal circRNA classifier for detection of high-grade prostate cancer at initial biopsy: A multicenter, retrospective study. *First Author: Liaoyuan Li, Sun Yat-sen University, Guangzhou, China*

Background: The low specificity of prostate-specific antigen (PSA) has resulted in the overdiagnosis and overtreatment of clinically indolent prostate cancer (PCa). We aimed to identify a urine exosomal circular RNA (circRNA) classifier that could detect high-grade (Gleason score [GS]7 or greater) PCa. **Methods:** We did a three-stage study that enrolled eligible participants, including PCa-free men, 45 years or older, scheduled for an initial prostate biopsy due to suspicious digital rectal examination findings and/or PSA levels (limit range, 2.0-20.0 ng/mL), from four hospitals in China. We used RNA sequencing and digital droplet polymerase chain reaction to identify 18 candidate urine exosomal circRNAs that were increased in 11 patients with high-grade PCa compared with 11 case-matched patients with benign prostatic hyperplasia. Using a training cohort of eligible participants, we built a urine exosomal circRNA classifier (Ccirc) to detect high-grade PCa. We then evaluated the classifier in discrimination of GS7 or greater from GS6 and benign disease on initial biopsy in two independent cohorts. We used the sensitivity, specificity, and area under the receiver operating characteristic curve (AUC) to evaluate diagnostic performance, and compared Ccirc with standard of care (SOC) (ie, PSA level, age, race, and family history). **Results:** Between June 1, 2016, and July 31, 2019, we recruited 356 participants to the training cohort, and 442 and 325 participants to the two independent validation cohorts. We identified a Ccirc containing five differentially expressed circRNAs (circ_0049335, circ_0056536, circ_0004028, circ_0008475, and circ_0126027) that could detect high-grade PCa. Ccirc showed higher accuracy than SOC to distinguish individuals with high-grade PCa from controls in both the training cohort and the validation cohorts. (AUC 0.831 [95% CI 0.765-0.883] *vs* 0.724 [0.705-0.852], P = 0.032 in the training cohort; 0.823 [0.762-0.871] *vs* 0.706 [0.649-0.762], P = 0.007 in validation cohort 1; and 0.878 [0.802-0.943] *vs* 0.785 [0.701-0.890], P = 0.021 for validation cohort 2). In all three cohorts, Ccirc had higher sensitivity (range 71.6-87.2%) and specificity (82.3-90.7%) than did SOC (sensitivity, 42.3-68.2%; specificity, 40.1-62.3%) to detect high-grade PCa. Using a predefined cut point, 202 of 767 (26.3%) biopsies would have been avoided, missing only 6% of patients with dominant pattern 4 high-risk GS 7 disease. **Conclusions:** Ccirc is a potential biomarker for high-grade PCa among suspicious men. 5523 Poster Session (Board #104), Fri, 8:00 AM-11:00 AM

Bone metabolism biomarkers (BMB) and progression-free survival (PFS) in men with metastatic hormone-sensitive prostate cancer (HSPC): SWOG S1216, a phase III trial of androgen deprivation therapy (ADT) with or without orteronel. *First Author: Primo Lara, University of California, Sacramento, CA*

Background: We previously reported that baseline BMB are independently prognostic for overall survival (OS) in men with castration resistant prostate cancer. We correlated BMB with outcomes in mHSPC as part of S1216, a phase III trial of ADT +/- the novel CYP17 inhibitor orteronel. **Methods:** Blood was obtained at study entry for bone resorption [C-telopeptide(CTx) & Pyridinoline(PYD)] & formation markers [C-terminal collagen propeptide(CICP) & bone alkaline phosphatase(BAP)]. With prior DSMC approval, patients were sampled to mask potential treatment effect. Logistic regression was used to assess if BMB elevation above median was prognostic for a PFS event w/in 2 years across pooled study treatment arms, adjusting for baseline variables (including disease extent, PSA, age, pre-randomization ADT, & presence of bone mets). An additional interaction term between BMB elevation & presence of bone mets was included; if significant, separate models were developed for men +/- bone mets. **Results:** Of 1,313 men, 656 were included in this analysis. All 4 BMB levels were higher in men with a PFS event w/in 2 years vs. those with no PFS event. The odds ratio (OR) for a PFS event was significantly higher in men w/ elevated baseline BMB (see table). For BAP, a significant interaction between marker elevation and bone mets was seen (p = 0.003); men w/ bone mets and BAP elevation had an OR of 1.83 for a PFS event in 2 years. **Conclusions:** In men with newly diagnosed HSPC, elevated baseline levels of BMB were significantly associated with PFS, with about a two-fold increased risk of a progression event w/in 2 years. For CICP, CTx, & PYD, this association was independent of the presence of bone metastases. Baseline BMB levels have strong prognostic value in the mHSPC context. Correlative analysis of BMB & OS is planned. Clinical trial information: NCT01809691. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Bone metabolism biomarker	Population	Odds Ratio (95% CI)	p-value	Bone marker X presence of bone mets interaction p-value
CICP	Full cohort	1.73 (1.21, 2.47)	0.003	0.73
CTx	Full cohort	1.90 (1.35, 2.69)	0.0003	0.66
PYD	Full cohort	2.22 (1.56, 3.14)	< 0.0001	0.34
BAP	Full cohort	---	---	0.003
	Men with bone mets	1.83 (1.23, 2.73)	0.003	---
	Men without bone mets	0.47 (0.22,1.02)	0.06	---

5524 Poster Session (Board #105), Fri, 8:00 AM-11:00 AM

Ability of cell-cycle progression score to predict risk for progression to metastatic disease and disease-specific mortality in prostate cancer patients after prostatectomy. *First Author: Gregory P. Swanson, Baylor Scott and White Health, Temple, TX*

Background: Prostate cancer treatment aims to prevent metastatic disease (METS) and disease-specific mortality (DSM). A major challenge is to identify those at highest risk so additional intervention can be initiated earlier when it has a better chance of success. Pathologic parameters alone have limited ability to predict METS and DSM, but data suggests biomarkers can improve risk discrimination. **Methods:** Eligible patients had: (1) prostate cancer treated with radical prostatectomy (RP; 1988-1995); (2) available tissue for cell-cycle progression (CCP) testing that resulted in a valid score; (3) preoperative prostate-specific antigen (PSA); (4) no neoadjuvant therapy; and (5) clinical follow-up (N = 360). Cancer of the prostate risk assessment post-surgical (CAPRA-S) was combined with CCP into a combined cell-cycle risk score (CCR = $0.38 \times$ CAPRA-S + $0.57 \times$ CCP). **Results:** Median follow-up was 23.5 years for patients alive at last follow-up. Overall, 11% (41/360) developed METS and 9% (33/360) had DSM. CCP score added significant information to CAPRA-S when predicting METS (p = 0.001) and DSM (p = 0.001). CCR score was also a significant predictor of METS and DSM (p-values $< 1\times10^{-8}$). CCP and CCR scores were prognostic of METS in patients with rising post-RP PSA. Of patients with biochemical recurrence (BCR), 25% (41/163) developed METS. CAPRA-S alone was predictive of these events (p = 0.01) but was significantly improved with the addition of CCP (Hazard Ratio [HR] = 1.69 [95% Confidence Interval (CI) 1.13, 2.52], p = 0.014). CCR was also highly prognostic (HR = 1.56 [95% CI 1.20, 2.03], p = 0.001). CCR score discriminated risk of METS both post-RP and after post-RP BCR (Table). **Conclusions:** Overall, the CCR score significantly predicted METS and DSM in prostate cancer post-RP and was also highly prognostic in those with a post-RP rising PSA. It is therefore a useful tool for determining who is at greatest risk of treatment failure and may benefit from earlier intervention. Research Sponsor: Myriad Genetics.

5525 Poster Session (Board #106), Fri, 8:00 AM-11:00 AM

***HSD3B1* (1245A>C) polymorphism and clinical outcomes in metastatic castration-resistant prostate cancer (mCRPC) patients treated with abiraterone acetate (AA) and enzalutamide (ENZA): Results from two prospective studies.** *First Author: Isabel Aragon, Genitourinary Cancer Traslational Research Unit, Institute of Biomedical Research in Málaga (IBIMA), Málaga, Spain*

Background: The common HSD3B1 (1245A > C) germline variant is associated with increased *de-novo* synthesis of androgens and worse outcomes in men treated with androgen-deprivation therapy in metastatic hormone sensitive prostate cancer. The aim of this study is to determine the role of this polymorphism on treatment outcomes for AA and ENZA in patients with mCRPC. **Methods:** A total of 547 patients treated with AA or ENZA for mCRPC from two prospective cohorts; cohort 1 included 202 from British Columbia (Canada) and cohort 2 enrolled 345 patients from the Spanish study PROREPAIR-B. HSD3B1 genotype was determined by targeted sequencing in cohort 1 and by Taqman SNP genotyping assay in cohort 2. Associations between HSD3B1 genotypes and (TTPP), time to progression (TTP) and overall survival (OS) were evaluated via univariate COX regression. Multivariate analysis was performed to determine the independent association of each covariate. **Results:** The proportions of patients with a homozygous wild-type HSD3B1 (AA), heterozygous (AC) and homozygous variant (CC) genotype were respectively 45.6%, 39.4% and 15%. As expected, known prognostic factors for mCRPC such as hemoglobin, alkaline phosphatase (ALP), LDH, PSA at baseline as well as site of metastasis were significantly associated with TTPP and TPP. In the combined cohort, HSD3B1 (CC) genotype was associated with worse TTP (HR 1.31, 95%CI 1.02-1.67, p = 0.032) and PSA response rates (48% for CC vs 62% and 65% for AA and AC, respectively (p = 0.019, χ^2)). Similar trend was observed for TTPP (HR 1.28, 95%CI 0.99-1.66, p = 0.064). OS was not different among genotypes, but was significantly shorter for patients with CC genotype in cohort 1 (HR 1.97, 95%CI 1.14-3.40, p = 0.016). There was no association between HSD3B1 genotype and time to castration-resistance in either of the two cohorts. Multivariable analysis showed that LDH, ALP, hemoglobin and use of AA or ENZA as first-line therapy for mCRPC were independent prognostic factors for TTP and TTPP; non-significant association was observed for genotype and TTP. **Conclusions:** HSD3B1 homozygous variant genotype (CC) was associated with shorter TTP and lower PSA response rate in mCRPC patients treated with AA or ENZA. However, the CC genotype did not provide prognostic information beyond that conferred by standard clinical variables, suggesting that it may not be a suitable stand-alone biomarker in mCRPC. 5526 Poster Session (Board #107), Fri, 8:00 AM-11:00 AM

Biomarker analysis from the KEYNOTE-199 trial of pembrolizumab in patients (pts) with docetaxel-refractory metastatic castration-resistant prostate cancer (mCRPC). *First Author: Emmanuel S. Antonarakis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: In the phase II KEYNOTE-199 study (NCT02787005), pembrolizumab monotherapy demonstrated antitumor activity in pts with docetaxel-refractory mCRPC (n = 258). Here we evaluated the association between prespecified molecular biomarkers and clinical outcomes. **Methods:** Cohorts 1 (C1) and 2 (C2) enrolled pts with RECIST-measurable PD-L1–positive (combined positive score [CPS] ≥1 using immunohistochemistry) and PD-L1–negative (CPS <1) disease, respectively. C3 enrolled pts with nonmeasurable, bone-predominant disease, irrespective of PD-L1 status. Biomarkers evaluated in this analysis were tumor mutational burden ([TMB; mutations/exome] n = 155), PD-L1 CPS (n = 255), tumor microenvironment–based 18-gene RNA expression profile ([GEP] n = 196), and microsatellite instability ([MSI] as determined by Promega PCR analysis; n = 147). Outcomes evaluated for C1 and C2 (n = 200) were ORR, disease control rate (DCR), and radiographic PFS (rPFS) per blinded, independent central review per PCWG-modified RECIST v1.1. Outcomes evaluated for C1-C3 (n = 258) were prostate-specific antigen (PSA) response, time to PSA progression, and OS. Significance of continuous biomarkers (CPS; TMB; GEP) was prespecified at 0.05 for one-sided *P* values from logistic (ORR; DCR; PSA response) and Cox proportional hazard regression (rPFS; OS; PSA progression) adjusted for Eastern Cooperative Oncology Group performance status. Binary biomarkers (MSI) were analyzed using Fisher's exact test (ORR; DCR; PSA response). Clinical data cutoff date: Jun 24, 2019. **Results:** Median TMB was 53.0 (interquartile range [IQR], 40.5 to 78.0), median CPS was 1 (IQR, 0 to 5), and median GEP was –0.64 (IQR, –0.88 to –0.46); 6 pts (2.3%) had MSI-high tumors. In C1-C3, TMB was associated with PSA response (one-sided nominal *P* = 0.0016) and time to PSA progression (one-sided nominal *P* = 0.00092). In C1-C3, PD-L1 CPS was associated with PSA response (one-sided nominal *P* = 0.046) and time to PSA progression (one-sided nominal *P* = 0.021). In C1-C3, GEP was not significantly associated with response. In C1-C3, MSI was associated with PSA response (one-sided nominal *P* = 0.019). **Conclusions:** In this biomarker analysis from KEYNOTE-199 C1-C3, TMB and PD-L1 CPS were associated with better PSA response; however, small pt numbers limit definitive conclusions on ORR, DCR, and OS. Further evaluation of molecular biomarkers in pts with mCRPC treated with pembrolizumab is warranted. Clinical trial information: NCT02787005. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5527 Poster Session (Board #108), Fri, 8:00 AM-11:00 AM

Association of BRCA alteration (alt) type with real-world (RW) outcomes to PARP inhibitors (PARPi) in patients (pts) with metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Emmanuel S. Antonarakis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Inactivating alts in *BRCA1/2* result in homologous recombination deficiency and are predictive of PARPi response in mCRPC. *BRCA* reversion mutations, which restore the protein function, are frequently observed in acquired resistance to PARPi. In tumors harboring homozygous gene deletions (*BRCA*del) reversions cannot develop; thus, we hypothesize that *BRCA*del pts may have prolonged benefit from PARPi compared to pts harboring other BRCA alterations. **Methods:** Pts were included from the Flatiron Health (FH)-Foundation Medicine (FMI) de-identified clinico-genomic database (CGDB). Inclusion criteria were diagnosis of mCRPC, treatment in the FH network and an FMI comprehensive genomic profiling result between 1/1/2011 - 9/30/2019. Time to therapy discontinuation (TTD) and overall survival (OS) from start of PARPi were estimated with Kaplan-Meier analysis and unadjusted/adjusted (age at PARPi initiation, line number, practice type) hazard ratios (HR/aHR) from Cox proportional hazards models adjusted for survival bias. **Results:** Out of 829 mCRPC cases, *BRCA1/2* alts were detected in 15 (1.8%) and 71 (8.6%) respectively, with 2 cases included in both groups. 26% of *BRCA*alts were *BRCA*del, 67% were coding mutations, and 7% were genomic rearrangements. 25 (28%) *BRCA*alt pts were treated with PARPi, 11/25 in the 1st or 2nd line setting including 43% of *BRCA*del and 44% of other *BRCA*alt cohorts. Median age at PARPi initiation was 70 yrs and 88% were treated in community practices. TTD was significantly longer in the *BRCA*del (n = 7) cohort vs. other *BRCA*alt cohort (n = 18) (22.7 vs. 9.2 months; HR: 0.16 [0.03-0.74]; aHR: 0.13 [0.02 – 0.92]) while a statistically nonsignificant difference in median OS was observed (31.5 vs. 11.9 months; HR: 0.20 [0.02-1.58]; aHR: 0.24 [0.02-3.15]). In comparison, no statistically significant difference in TTD was observed for *BRCA*del (n= 7) vs. other BRCAalts (n=19) pts treated with 1st line hormonal therapies (abiraterone or enzalutamide) (3.4 vs. 5.7 months; HR: 1.16 [0.45-2.98]; aHR: 0.72 [0.25-2.10]). Follow up analysis with more pts and somatic/germline status and zygosity of *BRCA*alts will be presented. **Conclusions:** These data suggest a differential benefit from PARPi therapy across *BRCA*alt subgroups. This observation may in part be explained by the inability to develop reversion mutations to restore BRCA function in tumors with *BRCA*del. Further studies are warranted to fully assess the association of *BRCA*alt type with outcomes to PARPi-based treatments. Research Sponsor: Foundation Medicine, Inc.

5528 Poster Session (Board #109), Fri, 8:00 AM-11:00 AM

Association of polymorphisms in androgen production, uptake, and conversion chain (APUC) genes with mortality of prostate cancer patients. *First Author: Sean Thomas McSweeney, University of Minnesota Medical Center, Minneapolis, MN*

Background: Genes involved in APUC may affect prognosis in PC. We tested the association of four SNPs involved in the APUC pathway: hydroxy-delta-5-steroid dehydrogenase, 3 beta-and steroid delta-isomerase 1 (*HSD3B1*), 5α reductase enzyme (*SRD5A*), and solute carrier organic ion (*SLCO2B1*) with all-cause and PC mortality 596 in the Atherosclerosis Risk in Communities (ARIC) study. **Methods:** Between 1987 & 2015 596 men were diagnosed with PC. Median age at diagnosis was 70 (range 53-86) years; 21% of all PC patients were African American. After diagnosis, follow-up was median 8.4 years (max 26.7 years) until PrC death (N = 60), death from any cause (N = 253), or end of 2015. SNPs were genotyped using the Affymetrix Genome-Wide Human SNP Array 6.0 and imputed to the 1000 Genomes Phase 3 reference panel. To examine survival, we used Kaplan-Meier curves and Cox proportional hazards regression. Hazard ratios (HR) and 95% confidence intervals (CI) were adjusted for age, field center, stage and grade at diagnosis. We also controlled for confounding by ancestry by adjusting for genetic principal components. The analyses were conducted in all PrCa patients and in Whites PrCa patients only. Polymorphisms tested included rs1047303 (A = > C, also called 1245C); rs523349 (C = > G); and rs1789693 (A = > T) and rs12422149 (G = > A), located in the aforementioned genes. **Results:** The A allele for *SLCO2B1* rs1789693 (A = > T) was significantly associated with an increased risk of PC mortality (versus T): multivariable-adjusted HRs (95%CI) were (2.06, 1.14-3.74; p = 0.02) and all-cause mortality (1.29, 1.00-1.66; p = 0.05) among Whites. The associations were similar when Whites and African-Americans were combined and when accounting for ancestry. The C allele for *HSD3B1* rs1047303 (C = > A) was not statistically significantly associated with either PC or all-cause mortality in the whole cohort (which included localized disease), although HRs were increased for men diagnosed with stage 4 disease (n = 35) in both additive and dominant models. For carriers of the C allele (gain of function) versus AA, HRs were 5.32 (1.16-24.33; p = 0.03) and 6.13 (1.51-24.86; p = 0.01) for PC and all-cause mortality, respectively. All associations with *SRDA2* (rs12422149) and *SLCO2B1* (rs12422149) were not significant. **Conclusions:** The gain of function allele in *HSD3B1* rs1047303 (1245C) was associated with increased PC and all-cause mortality in men diagnosed with metastatic PC, paralleling prior findings. Associations with *SLCO2B1* SNP rs1789693 require validation in larger studies. Research Sponsor: None.

5529 Poster Session (Board #110), Fri, 8:00 AM-11:00 AM

AR enhancer and locus genomic alterations as cell-free DNA biomarkers of primary resistance to AR-directed treatment of metastatic prostate cancer. *First Author: Chris Maher, Washington University in St. Louis, St. Louis, MO*

Background: Predicting primary resistance to androgen receptor (AR)-directed therapies is critical for personalizing treatment of metastatic prostate cancer (mPCa). Analyses of liquid biopsies are potential tools but remained underutilized due to limited sensitivity. We developed a cell-free DNA (cfDNA) assay (EnhanceAR-Seq) to monitor genomic alterations in mPCa including *AR* enhancer duplication, a resistance marker recently discovered in ~81% of mPCa patients. Here we show that applying EnhanceAR-Seq to plasma cfDNA to monitor alterations of *AR* gene and enhancer (*AR*/enhancer) predicted primary resistance with high sensitivity and outperformed the clinically validated CTC AR-V7 assay. **Methods:** Forty mPCa patients were prospectively enrolled at the Washington University School of Medicine Siteman Cancer Center with plasma cfDNA analyzed by EnhanceAR-Seq. Twenty-five of them also had the Oncotype DX AR-V7 Nucleus Detect CTC assay performed at a similar timepoint at the discretion of the treating oncologist. All patients received AR-directed therapy (eg. abiraterone, enzalutamide) and underwent standard-of-care clinical and laboratory follow-up. Primary resistance was defined as PSA progression, change of treatment or death within 4 months of treatment initiation, or radiographic progression within 6 months. **Results:** Median clinical follow up after diagnosis was 50 months. EnhanceAR-Seq detected alterations targeting *AR*/enhancer in 18 patients (45%), *TP53* in 8 patients (20%), and *PTEN* in 6 patients (15%). We found that *AR*/enhancer alterations (copy gain, tandem duplication, and point mutation) in cfDNA were strongly predictive of primary resistance to AR-directed therapy (PPV = 100%, Sens. = 89%). Our assay outperformed the CTC AR-V7 assay, which was positive in only two patients (PPV = 50%, Sens. = 6%). Furthermore, patients with *AR*/enhancer alterations had significantly worse progression-free survival (P = 0.0015; HR = 11.5) and overall survival (P = 0.0002; HR = 6.8). Finally, serial cell-free DNA analysis of 10 patients showed that *AR*/enhancer copy number gain was maintained or acquired in 5 of 6 AR-resistant cases, and neutrality maintained in 4 of 4 AR-sensitive cases. **Conclusions:** cfDNA-based *AR*/enhancer locus genomic alterations could potentially be used to predict primary resistance to AR-directed therapy with higher sensitivity than the clinically validated CTC AR-V7 assay, be used for serial timepoint monitoring and guiding personalized clinical decision-making. 5530 Poster Session (Board #111), Fri, 8:00 AM-11:00 AM

Clinical analysis of the extracellular vesicle-fingerprint score blood test to refine the prediction of clinically significant prostate cancer and avoid prostate biopsy. *First Author: Adrian S. Fairey, University of Alberta, Edmonton, AB, Canada*

Background: The accuracy of the extracellular vesicle-fingerprint score (EV-FPS) test to predict clinically significant prostate cancer (PCa; Gleason grade (GG) ≥ 3) from indolent disease (GG ≤ 2) and avoid unnecessary prostate biopsies was determined at the point of prostate biopsy decision. **Methods:** Clinical data, health information, and blood samples were collected from a prospective validation cohort of 415 men, without prior PCa diagnosis, referred to urology clinics for prostate biopsy or transurethral prostate surgery (June 2014-Dec 2016). The patient's EV-FPS risk score was calculated by combining machine learning model-analyzed microflow cytometry data from EV biomarkers with logistic regression-analyzed patient-centric clinical features. The plasma-derived EV biomarkers were prostate-specific membrane antigen, polysialic acid and ghrelin-growth hormone receptor. The patient clinical features were; age, ethnicity, PCa family history, PSA levels, abnormal digital rectal examination (DRE) and prior negative prostate biopsy. Together, the biomarkers and clinical features provided specificity for clinically significant PCa. **Results:** The EV-FPS test identified clinically significant PCa patients with high accuracy (0.81 area under curve) at 95% sensitivity and 97% negative predictive value. Using a 7.85% probability cut-off after test validation; 95% of the patients with GG ≥ 3 would have been found before biopsy, 35% biopsies would have been avoided and diagnosis of GG ≥ 3 PCa would have been missed in only 5% of the cohort. **Conclusions:** This minimally invasive EV-FPS test accurately predicted clinically significant PCa in men with high EV-FPS risk scores, high PSA level and/or abnormal DRE. Therefore, men with low EV-FPS risk scores could potentially avoid unnecessary prostate biopsies. Clinical care cut-offs to calculate the number of biopsies that could have been avoided, and the percentage of GG ≥ 1 to GG ≥ 3 PCa that could have had a delayed diagnosis. 5531 Poster Session (Board #112), Fri, 8:00 AM-11:00 AM

Prevalence and tissue concordance of BRCA2 copy number loss evaluated by single-cell, shallow whole genome sequencing of circulating tumor cells (CTCs) in castration-resistant prostate cancer (CRPC). *First Author: Ethan Barnett, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Genomic studies have shown that up to 25% of prostate cancer tissue specimens harbor alterations in DNA Damage Repair (DDR) genes, which may sensitize the tumor to poly ADP-ribose polymerase inhibitors (PARPi). Trials evaluating PARPi in patients with DDR deficiencies have shown varied response rates and differences regarding which genomic alterations predict for sensitivity to these agents, with the majority of objective responses seen in BRCA2-altered tumors. These results highlight the need to develop biomarker assays which can predict benefit from PARPi therapy. Tissue and cell-free DNA (cfDNA) have been the most utilized sources of tumor material for analysis in this setting, but success rates of obtaining sufficient tumor for analysis from bone are low and detecting tumor-derived copy number variants (CNVs) in cfDNA is challenging. Circulating tumor cells (CTCs) represent an alternate source of genetic information, for which assays are available to isolate and sequence individual cells in a manner that eliminates background noise from stroma and healthy cells, while capturing inter-cellular heterogeneity. **Methods:** Blood samples, collected from 138 progressing metastatic CRPC patients within 30 days of a pre-treatment biopsy intended for sequencing using MSK-IMPACT, were sent to EPIC Sciences for CTC analysis. Detected CTCs underwent single cell, low pass whole genome sequencing. Prevalence and concordance of BRCA2 copy-loss, regardless of whether single copy or homozygous, was compared in matched tissue and CTC samples. **Results:** BRCA2 copy-loss was identified in 21% (23/108) and 50% (58/115) of successfully sequenced tissue and CTC samples, respectively. In the 58 patients with CTC-detected BRCA2 loss, BRCA2 loss was detected in 36% (220/565) of the sequenced CTCs, representing a median of 46% (range 4-100%) of CTCs found in each individual sample. When both sequencing assays were successful, BRCA2 loss was detected in CTCs in 84% (16/19) of the tissue-positive cases, whereas tissue sequencing detected BRCA2 loss in 35% (16/46) of CTC-positive cases. **Conclusions:** Data from this study supports the notion that single-cell CTC sequencing can detect BRCA2 copy-loss at a high frequency, including cases that were negative in tissue, while also characterizing inter-cellular heterogeneity. Further studies will investigate whether CTC BRCA2 copy-loss can predict the likelihood of response to PARPi. Research Sponsor: EPIC Sciences.

5532 Poster Session (Board #113), Fri, 8:00 AM-11:00 AM

Comparative effectiveness of systemic treatments for metastatic castration-sensitive prostate cancer: A parametric survival network meta-analysis of randomized controlled trials. *First Author: Lin Wang, Johns Hopkins School of Public Health, Baltimore, MD*

Background: Treatment decision-making for metastatic castration-sensitive prostate cancer (mCSPC) is complicated by the unclear comparative effectiveness and widely varying costs of competing strategies. Objective: To compare the effectiveness and safety of systemic treatments for mCSPC. **Methods:** We searched bibliographic databases, regulatory documents, and trial registries for randomized controlled trials testing active drugs added to androgen deprivation therapy (ADT) for mCSPC. We used Cochrane risk-of-bias tool (version 2) to assess trial quality and Bayesian network meta-analysis (NMA) to estimate the relative effects of competing treatments. In addition to combing published time-invariant hazard ratios (HRs), we reconstructed survival data from Kaplan Meier curves to enable parametric survival NMA that allows time-varying HR. **Results:** Seven trials with 7,236 patients were included comparing six treatments (Table). Risk of bias is a concern for trials with open label (N=4), missing data (N=3), or unprespecified analysis (N=3). Ordered from the most to the least effective, treatments significantly improving overall survival (OS) include abiraterone acetate, apalutamide, and docetaxel; treatments significantly improving radiographic progression-free survival (rPFS) include enzalutamide, abiraterone, apalutamide, and docetaxel. (see HRs in Table) Allowing time-varying HR produced similar treatment rankings. Serious adverse events (SAE) were substantially increased for docetaxel (odds ratio [OR] 104.17, 95% credible interval [CI] 24.85-1012.32) and slightly increased for abiraterone (OR 1.42, 95% CI 1.11-1.83). **Conclusions:** Abiraterone provided the largest OS benefit with slightly increased risk of SAE. Apalutamide offered comparable OS benefit with abiraterone without increasing SAE risk. Although enzalutamide delayed rPFS to the greatest extent, longer follow-up is needed to examine its OS benefit. Research Sponsor: None.

Treatment rankings based on overall survival and radiographic progression-free survival.

Treatment strategy (plus ADT)	HR of OS vs ADT (95% CI)	Median rank for OS	HR of rPFS vs ADT (95% CI)	Median rank for rPFS
Abiraterone acetate	0.62 (0.54-0.71)	1	0.45 (0.40-0.51)	2
Apalutamide	0.67 (0.51-0.88)	2	0.48 (0.39-0.59)	3
Docetaxel	0.80 (0.71-0.89)	3	0.68 (0.61-0.75)	4
Enzalutamide	0.81 (0.53-1.23)	4	0.39 (0.30-0.51)	1
Standard non-steroid antiandrogen (bicalutamide, nilutamide, or flutamide)	1.21 (0.74-1.97)	5	0.97 (0.70-1.35)	5

5533 Poster Session (Board #114), Fri, 8:00 AM-11:00 AM

Phase I study of a novel S1P inhibitor, NOX66, in combination with radiotherapy in patients with metastatic castration-resistant prostate cancer. *First Author: Paul L. de Souza, University of Western Sydney School of Medicine, Liverpool, Australia*

Background: NOX66 is a new formulation of the small molecule, idronoxil. The primary mechanism of action of idronoxil stems from its binding to the transmembrane enzyme ENOX2 expressed on cancer cells, resulting in reduced S1P and increased ceramide levels, thereby promoting apoptosis. Additional intracellular effects include the inhibition of DNA repair mechanisms. There is growing evidence that S1P is a promotor of tumour resistance to immune cell infiltration, highlighting NOX66's potential to modulate the immune response against cancer. **Methods:** This two-part phase 1b open-label study enrolled patients with late-stage progressive mCRPC. Part 1 was a dose-escalation safety assessment of three doses of NOX66 (400 mg, n = 4; 800 mg, n = 6 and 1200 mg, n = 15) administered daily for 14 days with radiation therapy (20 Gy) delivered in 5 fractionated doses to one or more symptomatic lesion/s. Part 2 was an expansion cohort with NOX66 at 1200 mg in conjunction with radiation therapy. The primary endpoint of safety was assessed by the frequency and grade of treatment-emergent adverse events (TEAEs). At 6 weeks, 3- and 6-month follow up, treatment response was assessed radiographically by RECIST1.1 and by PSA >50% reduction. **Results:** 25 patients received and completed treatment. TEAEs considered related to NOX66 alone were mild (Grade 1) cases of dry mouth and oral mucositis; mild (Grade 1) fatigue was considered related to both NOX66 and radiation. None of the 21 Grade ≥3 TEAEs were considered related to NOX66. At 6 months, of the 15 evaluable patients by RECIST1.1, 9 had SD and 1 had PR and these same patients had maintained this response from 3 months. Five of the 16 PSA-evaluable patients achieved a PSA response (61-98% PSA reduction) at 6 months, which again was maintained from 3 months. **Conclusions:** NOX66 in combination with low-dose radiation therapy was found to be safe and well tolerated with promising signals of durable efficacy in patients with late-stage mCRPC. Responses of lesions outside the radiation field are being reviewed. Clinical trial information: NCT03307629. Research Sponsor: Noxopharm Limited.

5534 Poster Session (Board #115), Fri, 8:00 AM-11:00 AM

Contrasting genomic profiles in post-systemic treatment metastatic sites (MET), pretreatment primary tumors (PT), and liquid biopsies (LB) of clinically advanced prostate cancer (PC). *First Author: Andrea Necchi, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Comprehensive genomic profiling (CGP) was done on pre-systemic treatment (pre) PT, post-treatment (post) MET sites and LB in PC to uncover differences in genomic alterations (GA) and potential impact on therapy selection. **Methods:** 1,294 PC tissues and 782 LB underwent hybrid-capture based CGP. PT biopsies and resections were compared with post-treatment MET biopsies from bone (BO), liver (LIV), lung (LU), brain (BN), lymph node (LN) and soft tissue (ST) sites and LB. TMB was determined on up to 1.1 Mbp of sequenced DNA for tumor samples. Tumor cell PD-L1 IHC was measured (Dako 22C3). **Results:** Differences in alteration frequencies between PT, MET and LB for selected genes are shown in the Table. *TMPRSS2:ERG* fusion frequencies were similar between PT and MET (35% vs 33%) but varied between MET sites (27% in BO and ST to 40% in LN). GA in *AR* were lowest in pre PT (2%) and highest in MET (24% in LU to 50% in LIV). BN had the highest GA/tumor (8) and the most *PTEN* GA. *BRCA2* GA frequency varied from 0% in BN to 15% in LI. Potential predictors of IO response included *CDK12* GA (16% in LU) and MSI high status (29% in BN). High PD-L1 expression was found in only two cases (LN) and low PD-L1 expression was relatively uncommon. *ERBB2* amplifications were increased in MET compared with PT. *RB1* GA were increased in LIV cases. LB GA had a similar increase in *AR* and *TP53* GA to MET and appeared to be a blend of MET site biopsies across alteration frequencies. **Conclusions:** CGP of PT, MET and LB in PC demonstrates differences most likely associated with exposure to systemic therapies. Differences identified in the MET GA landscape suggest that liquid biopsies may capture a broader range of therapeutic opportunities for PC patients. Research Sponsor: Foundation Medicine Inc.

Molecular determinants of outcome for metastatic castration-sensitive prostate cancer (mCSPC) with addition of apalutamide (APA) or placebo (PBO) to androgen deprivation therapy (ADT) in TITAN. *First Author: Felix Y Feng, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: In TITAN, addition of APA to ADT improved radiographic progression-free survival (rPFS) and overall survival (OS) versus PBO plus ADT in patients (pts) with mCSPC. In this post hoc analysis, we performed transcriptome-wide profiling of tumor samples and assessed association of molecular subtypes with rPFS. **Methods:** The DECIPHER platform (Decipher Biosciences, Inc.) was used to assess gene expression in archival primary prostate tumors from TITAN. Samples were classified into high versus low to average risk of metastases (DECIPHER genomic classifier [GC] > 0.6 and ≤ 0.6, respectively), basal and luminal A/B (PAM50 classifier), and androgen receptor activity (AR-A) signature high and low. Associations between subtypes with rPFS were assessed with Cox proportional hazards model. **Results:** The biomarker population included 222 pts (APA, 110; PBO, 112). Benefit in rPFS from APA in the biomarker population (HR [95% CI]; p value; 0.49 [0.31-0.78]; 0.002) resembled that in the overall study population (0.49 [0.40-0.61]; < 0.0001). The majority of TITAN pts had GC high scores (n = 166, 75%). GC high risk subtype in the PBO group had poorer prognosis for rPFS than GC low to average risk subtype (median rPFS 18.2 mos for GC high vs not reached [NR] for GC low to average, 0.28 [0.11-0.69]; 0.006), but there was no difference in prognosis between high and low to average GC risk subtypes in the APA group (GC high NR vs GC low to average NR; 0.81 [0.35-1.89]; 0.625). Pts were further stratified based on basal/luminal and AR-A signatures. Basal (n = 112, 50%) and AR-A low (n = 96, 43%) subtypes, known to be nonresponsive to ADT, both showed significant benefit from APA vs PBO (0.30 [0.16-0.57]; < 0.001 and 0.25 [0.12-0.52]; < 0.001, respectively). The majority of AR-A low subtype (74%, 71/96) overlapped with basal subtype. Further conclusions for risk of rPFS in GC low, luminal, and AR-A high subtypes and OS across all subtypes will be assessed as more events occur. **Conclusions:** In TITAN, addition of APA to ADT improved rPFS for all subtypes of pts with mCSPC. APA overcame the poor prognosis of GC high risk subtype and prolonged rPFS in ADT-resistant AR-A low and basal molecular subtypes, suggesting APA is beneficial especially for the highest risk molecular subtypes. Clinical trial information: NCT02489318. Research Sponsor: Janssen Research & Development.

5536 Poster Session (Board #117), Fri, 8:00 AM-11:00 AM

Clinical, genetic, and pathologic determinants of prostate cancer brain metastasis. *First Author: Mira Patel, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Prostate cancer (PCa) brain metastasis (BM) is a rare event occurring in 0.16-0.63% of PCa patients. Current clinical data on this phenomenon is limited to small retrospective cohorts and our understanding of it is incomplete. We sought to identify clinical and molecular predictors of PCa BM in a large retrospective cohort treated at our institution. **Methods:** Men diagnosed with Pca from 1995-2017 with ≥6 months of follow-up were included. Data was collected on clinical and tumor characteristics at diagnosis, PCa treatment, brain and bone metastasis, and tumor genetic profile based on Integrated Mutation Profiling of Actionable Cancer Targets (IMPACT) analysis. Results were examined using Kyoto Encyclopedia of Genes and Genome (KEGG) pathway. Genes altered in ≥5% of patients were included. Time to brain metastasis (TTBM) and overall survival (OS) were analyzed with univariable (UVA) Fine-Gray competing risks regression and Cox proportional hazards. TTBM and OS were landmarked at 6 months after PCa diagnosis. False discovery rate (FDR) adjustment accounted for multiple comparisons. **Results:** 27,887 men met inclusion criteria; 74 developed BM. Clinical variables associated with increased hazard of TTBM in UVA were high-clinical and pathologic-* (p<.001) T stage, node-positive disease* (p<.001), primary* and total* Gleason (p<.001), receipt of abiraterone* (HR 52.51 (95% CI 7.1-389.8), p<.001), and receipt of leuprolide* (HR 3.0 (95% CI 1.7-5.4), p<.001). Tumor alterations associated with BM include mutations in BRCA2 (HR 2.94 (95% CI 1.1-8.0), p=.04), MYC (HR 3.41 (95% CI 1.2-9.5), p=.02), PTEN (HR 2.90 (95% CI 1.2-6.9), p=.02), RB1 (HR 3.09 (95% CI 1.2-8.0), p=.02), and pathways involving homologous recombination (HR 2.70 (95% CI 1.1-6.4), p=.02), Fanconi anemia* (HR 4.22 (95% CI 1.8-10.0), p<.001), Ras signaling* (HR 4.6 (95% CI 1.5-13.9), p=.006), mTOR signaling (HR 2.88 (95% CI 1.1-7.9), p=.04), VEGF signaling* (HR 3.60 (95% CI 1.5-8.8), p=.005), and GnRH signaling* genes (HR 3.93 (95% CI 1.6-9.6), p0.003). Variables associated with increased hazard of BM after FDR adjustment are denoted with an asterisk. Variables associated with reduced OS after FDR adjustment were neuroendocrine or blastoma histology, node-positive disease, high-T stage, high initial PSA, receipt of leuprolide, and alterations in AR, TP53, and CDK12 genes. **Conclusions:** PCa BM is significantly associated with high-stage and grade disease, receipt of androgen deprivation agents such as abiraterone and leuprolide, and alterations in the Fanconi anemia, Ras, VEGF, and GnRH pathways. Research Sponsor: None.

5537 Poster Session (Board #118), Fri, 8:00 AM-11:00 AM

Overall survival (OS) with docetaxel (D) vs novel hormonal therapy (NHT) with abiraterone (A) or enzalutamide (E) after a prior NHT in patients (Pts) with metastatic prostate cancer (mPC): Results from a real-world dataset. *First Author: Umang Swami, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: NHT (A and E) are approved first-line (1L) treatment (Rx) for mPC. After progression on NHT, Rx include either alternate NHT or D. However, OS from a randomized trial comparing NHT vs D after progression on 1L NHT has not been reported. **Methods:** Pts data were extracted from the Flatiron Health EHR-derived de-identified database. Inclusion: diagnosis of mPC; 1L Rx with single agent A or E only, single-agent Rx with alternate NHT (E or A) or D in second line (2L). Exclusion: > 180 days between date of diagnosis of mPC and date of next visit to ensure Pts were actively engaged in care at data-providing site; Rx with NHT in non-metastatic setting, any prior exposure to D. OS was compared using Cox proportional hazards model stratified by Rx propensity score. Each Pts' probability of receiving D (rather than NHT) was modeled via a random forest based on Pts and disease characteristics which may drive treatment selection. These included pre-2L Rx ECOG scores, PSA, LDH, ALPH, Hb, age, ICD codes for liver metastasis, diabetes, neuropathy, and heart failure; insurance payer, year of start of 2L Rx, time on 1 L NHT, Gleason score, PSA at the original diagnosis of mPC. Subgroup analyses included 1L Rx duration < 12 mos. **Results:** 1165 Pts between 2/5/2013 to 9/27/2019 were eligible. Median follow up 8 mos (range 0.1-64.5). Median OS after 1L A was higher with E as compared to D (15.7 vs. 9.4 mos). Median OS after 1L E was higher with A as compared to D (13.3 vs. 9.7 mos) (table). Propensity distributions were overlapping among Rx arms and showed only modest imbalance. In 2L, D had a worse adjusted hazard ratio of 1.29 and 1.35 as compared to E and A respectively ($p < 0.05$). Similar results were seen with 1L Rx duration of < 12 mos ($p < 0.05$). **Conclusions:** These hypothesis-generating data provide real-world OS estimates with 2L D & NHT in mPC. In propensity-stratified analyses, mPC Pts who progressed on NHT had a worse OS with 2L D as compared to alternate NHT. Results were consistent in unadjusted analysis & subgroup analyses of 1L Rx < 12 mos. Results are subject to residual confounding and missingness. After prospective validation these data may aid in Rx sequencing, Pts counselling, and design of future clinical trials in this setting. Research Sponsor: None.

5538 Poster Session (Board #119), Fri, 8:00 AM-11:00 AM

Impact of olaparib vs physician's choice of new hormonal agent (pcNHA) on burden of pain in metastatic castration-resistant prostate cancer (mCRPC): PROfound. *First Author: Fred Saad, Centre Hospitalier de l'Université de Montréal/CRCHUM, Montreal, QC, Canada*

Background: In the Phase III PROfound study (NCT02987543) olaparib significantly improved radiographic progression-free survival (primary endpoint) vs pcNHA (enzalutamide or abiraterone) in patients (pts) with mCRPC and homologous recombination repair (HRR) gene alterations. In pts with alterations in *BRCA1*, *BRCA2* and/or *ATM* (cohort A), time to pain progression was also significantly improved by olaparib vs pcNHA. We report additional pain analyses evaluated in the overall study population (cohort A and B). **Methods:** Pts were randomized to olaparib tablets (300 mg bid; n=256) or pcNHA (n=131). Pts completed the Brief Pain Inventory-Short Form (BPI–SF) questionnaire (electronic administration) every 4 weeks up to 6 months after progression or treatment crossover. Responses were analysed to determine time to progression to worst pain, pain severity and first opiate use for cancer-related pain (Kaplan-Meier), and also pain interference in daily activity (mixed model for repeated measures). **Results:** 85% and 76% of olaparib pts were free of pain progression (worst pain item) compared with 75% and 51% in the pcNHA arm, respectively at 6 and 12 months. The proportion of pts without pain progression (overall pain severity) also favoured olaparib (Table). Median time to first opiate use was significantly prolonged in olaparib arm compared with pcNHA arm; 18 months for olaparib vs 9 months for pcNHA (Table). BPI-SF pain interference scores were also more favourable for olaparib than pcNHA; difference in overall adjusted mean change from baseline score −0.75 (95% CI: −1.14, −0.36) *P*=0.0002. Further pain burden results for cohort A will also be presented. **Conclusions:** Olaparib reduced the burden of pain and time to first opiate use in pts with mCRPC and HRR gene alterations vs pcNHA, demonstrating a clinical and symptomatic patient benefit. Clinical trial information: NCT02987543. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Time to pain progression and first opiate use (overall population).

	Endpoint	Events n (%)	6-month event free rate (%)	12-month event free rate (%)	Median (m)	HR (95% CI)	*P* value (nominal)

5539 Poster Session (Board #120), Fri, 8:00 AM-11:00 AM

Health-related quality of life (HRQoL) for olaparib versus enzalutamide or abiraterone in metastatic castration-resistant prostate cancer (mCRPC) with homologous recombination repair (HRR) gene alterations: PROfound. *First Author: Antoine Thiery-Vuillemin, Centre Hospitalier de Besancon, Besancon, France*

Background: In the randomized Phase III PROfound trial (NCT02987543), olaparib significantly prolonged radiographic progression-free survival compared with physician s choice of new hormonal agent (pcNHA, enzalutamide or abiraterone) in men with mCRPC and HRR gene alterations, whose disease had progressed on prior NHA. Olaparib significantly improved time to pain progression in Cohort A. We report additional patient reported outcome measures of HRQoL in the overall study population (Cohorts A+B). **Methods:** HRQoL was assessed in the overall study population using the Functional Assessment of Cancer Therapy-Prostate (FACT-P) questionnaire, comprising 5 subscales: physical wellbeing (PWB), functional wellbeing (FWB), emotional wellbeing, social wellbeing, and prostate cancer subscale (PCS). The Trial Outcome Index (TOI; PWB+FWB+PCS) and FACT Advanced Prostate Symptom Index (FAPSI-6: derived from 6 FACT-P items) were also calculated. Adjusted mean change and time to deterioration in scores were statistically analyzed. **Results:** Baseline FACT-P total score was similar for both treatment arms. FACT-P total and subscale scores during treatment were all higher for olaparib vs pcNHA, with clinically meaningful differences between treatment arms in the adjusted least square (LS) mean changes from baseline in all but FWB and FAPSI-6 (Table). The time to deterioration in FACT-P total and TOI, FAPSI-6, PWB and PCS scores favored olaparib but were not statistically significant, with hazard ratios ranging from 0.68 to 0.94. Further HRQoL results for cohort A will also be presented. **Conclusions:** Olaparib delayed deterioration in HRQoL scores vs pcNHA and was associated with better HRQoL functioning over time compared with pcNHA in men with mCRPC and HRR gene alterations. Clinical trial information: NCT02987543. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Comparison of change from baseline.

	LS means		
	Olaparib N = 162	**pcNHA N = 74**	**Difference in LS means**
FACT-P total	**-8.01**	**-14.67**	**6.67**
TOI	**-5.05**	**-12.21**	**7.16**
FAPSI-6	**-0.54**	**-2.92**	**2.38**

*Olaparib n = 160. A clinically meaningful change was an increase (improvement) or decrease (deterioration) of ≥6 (FACT-P total), ≥5 (TOI), ≥3 (FAPSI-6, PCS), or ≥2 points (PWB, FWB)

5540 Poster Session (Board #121), Fri, 8:00 AM-11:00 AM

Radium-223 (Rad) and niraparib (Nira) treatment (tx) in castrate-resistant prostate cancer (CRPC) patients (pts) with and without prior chemotherapy (chemo). *First Author: William Kevin Kelly, Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA*

Background: Despite multimodality txs such as surgery, radiotherapy, hormonal tx and chemo, metastatic CRPC (mCRPC) prognosis remains poor. Research suggests PARP-1 is a key regulator of androgen receptor (AR) signaling and transition to lethal CRPC. Nira is a safe, potent and selective PARP-1/2 inhibitor that has shown single agent clinical activity in CRPC, and Rad is an alpha particle emitter. Addition of PARP inhibition may further enhance the clinical benefit of Rad. Nira has a favorable safety profile however, data on safety, tolerability and efficacy of Nira plus radiotherapy is limited. We hypothesize that targeting the PARP-1/AR axis in combination with radiation is safe and will improve mCRPC management. **Methods:** This is a phase (ph) Ib dose finding study (NCT03076203) of pts with progressive mCRPC using Time-to-Event Continual Reassessment Method (TITE-CRM). The primary objective is to determine the optimum ph II dose of Nira plus Rad (55 kBq/kg of body weight) in pts with and without prior chemo. Secondary endpoints include PSA reduction at 12 weeks (wks) and radiographic progression-free survival at 6 months. Pts enrolled to one of three dose levels of Nira (100, 200, and 300 mg PO daily). After completing 6 cycles of Rad, pts continued on Nira alone until objective progression, tx intolerance or pt decision. TITE-CRM identifies the maximum tolerated dose (MTD) based on toxicities observed over 12 wks of tx. **Results:** Between Oct 2017 and Jan 2020, 30 pts were enrolled (15 per stratum). Median age was 70 years; ECOG performance status was 0. The MTD of Nira was 100 mg in the chemo-exposed arm and 200 mg in the chemo-naïve arm. 19 Grade ≥ 3 adverse events were possibly related to tx: lymphocyte count decrease (n = 4, 13%), neutrophil count decrease (n = 3, 10%), anemia (n = 3, 10%), hypertension (n = 3, 10%), platelet count decrease (n = 2, 7%), creatinine increase (n = 1, 3%), hydronephrosis (n = 1, 3%), nausea (n = 1, 3%), white blood cell count decrease (n = 1, 3%). Tx duration and PSA response are shown in the table. **Conclusions:** Nira plus Rad was determined to be safe and tolerable. The MTD of Nira was identified and is pending ph II investigation. Managed by: Prostate Cancer Clinical Trials Consortium; Funded by: Janssen Scientific Affairs and Bayer Healthcare Pharmaceuticals, Inc Clinical trial information: NCT03076203. Research Sponsor: Janssen Scientific Affairs, Pharmaceutical/Biotech Company.

Cohort	**Median Tx Duration (wks)**	**Proportion of Pts with ≥50% PSA Decline at 12 wks (%)**
100 mg Chemo-naïve (n = 3)	21	33
Chemo-exposed (n = 10)	18	0

5541 Poster Session (Board #122), Fri, 8:00 AM-11:00 AM

Prostate-specific antigen (PSA) kinetics in patients (pts) with advanced prostate cancer treated with apalutamide: Results from the TITAN and SPARTAN studies. *First Author: Kim N. Chi, BC Cancer and Vancouver Prostate Centre, Vancouver, BC, Canada*

Background: The phase III TITAN and SPARTAN studies demonstrated improved outcomes with the addition of apalutamide (APA) to androgen deprivation therapy (ADT); outcomes included prolonging overall survival and radiographic progression-free survival (rPFS) in metastatic castration-sensitive prostate cancer (mCSPC) in TITAN, and metastasis-free survival (MFS) in nonmetastatic castration-resistant PC (nmCRPC) in SPARTAN. A post hoc analysis of PSA kinetics in pts from both studies is reported. **Methods:** Baseline PSA at randomization, time to PSA nadir, and proportion of pts achieving a PSA decline of ≥ 90% (PSA90) and of pts achieving a PSA ≤ 0.2 ng/mL at 3 and 12 months and at any time after treatment in the APA arms of the TITAN and SPARTAN studies were evaluated. Within each study, rPFS/MFS were compared between pts achieving a PSA90 or PSA ≤ 0.2 ng/mL response vs not. **Results:** 525 TITAN pts and 806 SPARTAN pts treated with APA were included in the analysis. Median baseline PSA, time to PSA nadir, median PSA nadir, and maximum percentage changes from baseline PSA are shown in the table. PSA90 and confirmed PSA ≤ 0.2 ng/mL were evident as early as 3 months in both TITAN and SPARTAN, and percentage of confirmed response continued to increase at 12 months. Pts treated with APA who achieved PSA90 were at lower risk of rPFS events in TITAN and of MFS events in SPARTAN, with a hazard ratio (95% confidence interval) of 0.46 (0.321-0.653) and 0.36 (0.271-0.489) in each respective study (both $p < 0.0001$), compared with APA pts who did not achieve PSA90. Pts with confirmed PSA ≤ 0.2 ng/mL had similar rPFS and MFS benefits. **Conclusions:** Pts with advanced PC, whether mCSPC or nmCRPC, treated with APA + ADT demonstrated rapid PSA declines that continued over time. There was a high rate of pts with PSA90 and with PSA ≤ 0.2 ng/mL responses, with a majority of pts reaching PSA90 by 12 months. Pts achieving PSA90 and/or PSA nadir of ≤ 0.2 ng/mL had a prolonged rPFS and MFS in TITAN and SPARTAN, respectively. Clinical trial information: NCT02489318; NCT01946204. Research Sponsor: Janssen Research and Development.

5542 Poster Session (Board #123), Fri, 8:00 AM-11:00 AM

Safety and overall survival (OS) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with radium-223 (Ra-223) plus subsequent taxane therapy. *First Author: Celestia S. Higano, Department of Medicine, University of Washington and Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Ra-223, a targeted alpha therapy, showed a survival benefit and favorable safety profile over 3 years' (yrs) follow-up in mCRPC pts (ALSYMPCA trial). REASSURE (NCT02141438) is a global, prospective, single-arm, observational study of long-term Ra-223 safety in routine clinical practice in mCRPC pts (planned 7-yr follow-up). **Methods:** This analysis, based on the second prespecified interim analysis (data cutoff 3-20-2019) of REASSURE (N = 1465), evaluated safety/OS in the pt subset that was chemotherapy-naïve at Ra-223 administration but received subsequent taxane therapy any time after Ra-223 completion. **Results:** 182 pts received taxane therapy after Ra-223. Most (58%) had unresected primary tumors, 69% had ≥6 metastases, 99% received prior systemic anticancer therapy (Table). 143 (79%) completed 5 or 6 Ra-223 injections. Subsequent anticancer therapies included docetaxel (95%), enzalutamide (25%), cabazitaxel (24%), abiraterone (12%), lutetium-177-prostate-specific membrane antigen (4%), and sipuleucel-T (1%). During/up to 30 days after taxane therapy, 15 pts (8%) had grade 3/4 hematologic adverse events: anemia (erythropenia) (n = 11, 6%), neutropenia (n = 3, 2%), and thrombocytopenia (n = 2, 1%). Median OS was 24.3 (95% CI: 20.9–27.5) months from Ra-223 initiation and 11.8 (95% CI: 10.6–14.1) months from subsequent taxane initiation. **Conclusions:** In this cohort where Ra-223 was integrated prior to taxane therapy, most pts received multiple subsequent anticancer therapies. It appears that sequencing of multiple treatment modalities with different mechanisms of action may contribute to improved OS. Taxane therapy in routine clinical practice in pts previously treated with Ra-223 had acceptable hematologic safety/tolerability profiles. Clinical trial information: NCT02141438. Research Sponsor: Bayer.

5543 Poster Session (Board #124), Fri, 8:00 AM-11:00 AM

KEYNOTE-199 cohorts (C) 4 and 5: Phase II study of pembrolizumab (pembro) plus enzalutamide (enza) for enza-resistant metastatic castration-resistant prostate cancer (mCRPC). *First Author: Christopher J. Hoimes, Duke Cancer Institute, Durham, NC*

Background: Initial evidence suggests activity of pembro + enza in patients (pts) resistant to enza. We present results from the multicohort phase II study KEYNOTE-199 (NCT02787005) in chemotherapy-naive pts with mCRPC treated with pembro + enza after progression with enza and who had RECIST-measurable (C4) or bone-predominant (C5) disease. **Methods:** Pts who did or did previously receive abiraterone and for whom enza treatment failed after clinically meaningful response received pembro 200 mg Q3W, with continuation of enza for up to 2 y or until progression, toxicity, or withdrawal. End point was ORR per RECIST v1.1 (C4) by blinded independent central review (primary); DOR (C4), time to PSA progression, rPFS, OS, and safety. **Results:** A total of126 pts (C4, 81; C5, 45) were treated. Median (range) PSA was 31 ng/mL (0.4-1667) in C4 and 19 ng/mL (1-1750) in C5.Median (range) time from enrollment to data cut off was 15 mo (7-21) in C4 and 19 mo (7-21) in C5. In C4, ORR (95% CI) was 12% (6-22; 2 CRs, 8 PRs) and median (range) DOR was 6 mo (3+ to 13); 60% of pts had DOR ≥6 mo. DCR (CR + PR + SD) was 51% in C4 and C5. Median (95% CI) time to PSA progression was 4 mo (4-4) in C4 and 4 mo (4-4) in C5. Median (95% CI) rPFS was 4 mo (3-6) for C4 and 4 mo (3-6) for C5; 12-mo rPFS rate was 17% in C4 and 23% in C5. Median (95% CI) OS was NR (16-NR) in C4 and 19 (14-NR) mo in C5; 12-mo OS rate was 70% in C4 and 75% in C5. Shorter median OS was more associated with prior enza treatment <6 mo than with prior enza treatment ≥6 mo. Liver metastasis was associated with shorter median OS however, median OS in visceral disease subgroups appeared longer than expected. Any-grade/grade ≥3 treatment-related AEs occurred in 75%/26% of pts in C4 and 69%/24% in C5. Two pts in C5 died of immune-related AEs (Miller Fisher syndrome and myasthenia gravis). Any-grade/grade 3/4 rash (regardless of relatedness) was higher than that in prior reports for individual agents (33%/6%). **Conclusions:** Pembro + enza after enza resistance had manageable safety and showed antitumor activity for RECIST-measurable and bone-predominant mCRPC. This combination is being evaluated in an ongoing phase III combination trial. Clinical trial information: NCT02787005. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5544 Poster Session (Board #125), Fri, 8:00 AM-11:00 AM

Pembrolizumab (pembro) plus olaparib in patients (pts) with docetaxel-pretreated metastatic castration-resistant prostate cancer (mCRPC): KEYNOTE-365 cohort A efficacy, safety, and biomarker results. *First Author: Evan Y. Yu, University of Washington, Seattle, WA*

Background: Pembro + olaparib has shown antitumor activity and acceptable safety in docetaxel-pretreated pts with mCRPC enrolled in cohort A of the phase I/II KEYNOTE-365 study (NCT02861573). Updated results with new biomarker data are reported. **Methods:** Pts with docetaxel-pretreated mCRPC who progressed within 6 mo of screening received pembro 200 mg IV Q3W + olaparib 400-mg capsule or 300-mg tablet PO BID. Pts might have received 1 other chemotherapy and ≤2 second-generation androgen-receptor targeted therapies. Primary end points: PSA response rate (decrease ≥50% from baseline, confirmed by a second value ≥3 wks later), ORR per RECIST v1.1, and safety. Key secondary end points: DCR, DOR, rPFS, and OS. Biospecimens (eg, blood, tissue) were collected for biomarker analysis (tissue PD-L1 expression, androgen receptor variant 7 [AR-v7] expression in circulating tumor cells [CTCs], and a T-cell–inflamed gene expression profile [GEP]). ctDNA was analyzed by Guardant Health 360 (GH360) and Omni (GH Omni) assays. FFPE tissue was analyzed by FoundationOne CDx (F1CDx) assay. **Results:** 84 of 87 enrolled pts were treated; 48/84 (57.1%) had measurable disease. Median (range) time from enrollment to data cutoff was 3.6 mo (0.0-29.2) for all pts and 26.7 mo (21.2-29.2) for 41 pts with ≥27 wks' follow-up. Confirmed PSA response rate was 9% (95% CI, 3.5-16.8) in 82 pts with a baseline PSA assessment. Median time to PSA progression: 3.8 mo (95% CI, 2.9-4.4). In 24 pts with measurable disease and ≥27 wks' follow-up, ORR was 8.3% (95% CI, 1.0-27.0; 2 PRs) and DCR ≥6 mo was 20.8% (95% CI, 7.1-42.2). Median (range) DOR was NR (12.0+ to 21.4+ mo); 2 pts had DOR ≥12 mo. In all pts, median rPFS was 4.3 mo (95% CI, 3.4-7.7) and median OS was 14.4 mo (95% CI, 8.1-18.5). Grade ≥3 TRAEs occurred in 29 pts (35%); 2 pts died of TRAEs (1 myocardial infarction, 1 unknown). Overall, 26% had PD-L1$^+$ tumors (combined positive score ≥1). Of 31 pts with CTC data, 12.9% were AR-v7$^+$. No *BRCA1/2* mutation was detected by GH360 (n=42). Of 57 pts analyzed by GH Omni, 2 had *BRCA2* mutations, 1 had a *BRCA1* mutation, 4 had *ATM* mutations, 1 had a *CHEK1* mutation, and 6 had *CDK12* mutations. Of 49 pts analyzed by F1CDx, 4 had *BRCA* mutations; 1 pt had a copy number loss mutation not detected by ctDNA analysis. GEP was not associated with ORR or PSA response. **Conclusions:** Pembro + olaparib continued to show activity and acceptable safety in pts with docetaxel-pretreated mCRPC. A phase III study of this combination is ongoing (KEYLYNK-010, NCT03834519). Clinical trial information: NCT02861573. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5545 Poster Session (Board #126), Fri, 8:00 AM-11:00 AM

Pembrolizumab (pembro) plus enzalutamide (enza) in patients (pts) with abiraterone acetate (abi)-pretreated metastatic castration-resistant prostate cancer (mCRPC): KEYNOTE-365 cohort C efficacy, safety, and biomarker results. *First Author: Henry Jacob Conter, University of Western Ontario, Brampton, ON, Canada*

Background: Pembro + enza (cohort C) has shown antitumor activity and acceptable safety in abi-pretreated pts with mCRPC in the phase I/II KEYNOTE-365 study (NCT02861573). Updated results with new biomarker data from cohort C are reported. **Methods:** Pts who became intolerant to or for whom ≥4 weeks of abi failed in the prechemotherapy mCRPC state and who progressed within 6 mo of screening were enrolled. Pts received pembro 200 mg IV Q3W + enza 160 mg/day orally. Primary end points were PSA response rate (PSA decrease ≥50%; confirmed by a second value ≥3 weeks later), ORR per RECIST v1.1 by blinded independent central review, and safety. Key secondary end points were DCR per RECIST v1.1 (CR+PR+SD or non-CR/non-PD ≥6 mo), DOR per RECIST v1.1, radiographic PFS (rPFS) per PCWG-modified RECIST v1.1, and OS. Biospecimens (eg, blood, tissue) were collected at baseline and during the study for biomarker analysis, including tissue PD-L1 expression, androgen receptor variant 7 (AR-v7) expression in circulating tumor cells (CTCs), and a T-cell-inflamed gene expression profile (GEP). **Results:** Of 103 enrolled pts, 102 were treated; 39% of treated pts had measurable disease. Median (range) time from enrollment to data cutoff was 19.1 mo (1.1-28.8) for all pts and 21.4 mo (15.1-28.8) for pts with ≥27 wks' follow-up (n=69). Confirmed PSA response rate was 22% in 101 pts with a baseline PSA assessment. Median time to PSA progression was 3.5 mo (95% CI, 2.9-4.0). In pts with measurable disease and ≥27 wks' follow-up (n=25), confirmed ORR was 12% (2 CRs, 1 PR) and DCR was 32%. Median DOR was not reached (range, 0.0+ to 24.4+ mo); 2 pts had a response for ≥6 mo. In all pts, median (95% CI) rPFS was 6.1 mo (4.4-6.5) and median OS was 20.4 mo (15.5-NR). At 6 mo, rPFS rate was 55.1% and OS rate was 88.2%. Treatment-related AEs occurred in 92 pts (90%); most frequent (≥20%) were fatigue (38%), nausea (22%), and rash (20%). Grade 3-5 treatment-related AEs occurred in 40 pts (39%). Three pts died of AEs (1 AE was treatment related [cause unknown]). Of all pts, 29% had PD-L1$^+$ tumors (combined positive score ≥1). Of 51 pts with AR-v7 data, 13.7% were AR-v7$^+$ and 86.3% were AR-v7$^-$. GEP was not significantly associated with ORR or PSA response. **Conclusions:** Pembro + enza continued to show activity in pts with abi-pretreated mCRPC. Safety of the combination was consistent with the known profiles of pembro and enza. A phase III study of this combination is ongoing (KEYNOTE-641, NCT03834493). Clinical trial information: NCT02861573. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5546 Poster Session (Board #127), Fri, 8:00 AM-11:00 AM

Use of plasma androgen receptor (AR) testing to optimize docetaxel chemotherapy in castration-resistant prostate cancer (CRPC): A multicenter biomarker study. *First Author: Vincenza Conteduca, IRCCS-IRST (Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori), Meldola, Italy*

Background: Plasma *AR* status has been identified as a potential biomarker of response in CRPC patients receiving docetaxel or the *AR*-targeted therapies abiraterone or enzalutamide. However, the relevance of plasma *AR* in the overall management of CRPC patients (pts) receiving docetaxel at different dose due to the toxicity profiles and physician-patient preferences is unknown. **Methods:** This was a multi-institution study of associations between baseline plasma *AR*-copy-number status assessed by droplet digital PCR and outcome in 325 CRPC pts. Between September 2011 and July 2019 pts started treatment with docetaxel administered at standard regimen 75mg/m^2 every three weeks or adapted regimen (75-80% of standard recommended dose or 30mg/m^2 weekly administration) at the discretion of the treating physician. Patients were assigned randomly into 2 sets with a ratio 2:1 to either training (n=217) and internal validation (n=108) cohorts. **Results:** In our study, adapted regimen of docetaxel was administered in 68 (31.3%) and 35 (32.4%) of training and validation cohorts, respectively. Based on plasma *AR* status, 67 (30.9%) and 39 (36.1%) validation and training set pts were classified as *AR* gain, respectively. In men treated with standard docetaxel regimen, no difference in progression-free/overall survival (PFS/OS) was seen between plasma *AR* normal and gain in both cohorts. In patients treated with adapted docetaxel regimen, we observed a significantly shorter median PFS (3.9 vs. 6.4 months, HR 4.77, 95%CI 1.48-3.80, p=0.0003) and median OS (11.2 vs. 20.4 months, HR 2.87, 95%CI 1.73-2.13, p=0.0008) in the training cohort. This finding was confirmed in the validation cohort (median PFS: 4.8 vs. 7.4 months, HR 2.54, 95%CI 1.40-4.58, p=0.005, and median OS: 11.8 vs. 26.4 months, HR 5.00, 95%CI 2.59-9.65, p<0.0001). In addition, *AR*-gained patients were less likely than *AR* normal to have a PSA decline when receiving an adapted regimen in both cohorts (p=0.010 e p=0.003, respectively). **Conclusions:** This study suggests that plasma *AR* may improve clinical decision making in choosing not only between *AR*-directed therapies and taxanes, but also between adapted and standard regimen of docetaxel in first- and subsequent-therapy lines, providing promising clinical implications to select the proper timing and dose of docetaxel. Prospective trials to validate these findings are warranted. Research Sponsor: None.

5547 Poster Session (Board #128), Fri, 8:00 AM-11:00 AM

Efficacy of enzalutamide (ENZA) + androgen deprivation therapy (ADT) in metastatic hormone-sensitive prostate cancer (mHSPC) by pattern of metastatic spread: ARCHES *post hoc* analyses. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: ENZA + ADT significantly reduced the risk of radiographic progression or death in men with mHSPC (NCT02677896). Here, we assess how pattern of metastatic spread impacts the efficacy of ENZA + ADT in patients enrolled in ARCHES. **Methods:** Patients with mHSPC were randomized 1:1 to ENZA (160 mg/day) + ADT or placebo (PBO) + ADT, stratified by disease volume and prior docetaxel treatment. The primary endpoint was radiographic progression-free survival (rPFS). Secondary endpoints included time to prostate-specific antigen (PSA) progression, time to first symptomatic skeletal event (SSE), time to castration resistance, and time to initiation of new antineoplastic therapy. *Post hoc* analyses were performed by pattern of metastatic spread at study entry. **Results:** Of the overall population with known metastases at screening (n=1146), the largest patient subgroups were those with bone metastases only (n=513) and those with bone and soft-tissue metastases only (n=351); there were fewer M0 patients or patients with soft-tissue metastases only (n=154) and patients with visceral ± bone metastases (n=128). ENZA + ADT reduced the risk of rPFS and other secondary endpoint measures versus PBO + ADT across all subgroups, with greater relative efficacy observed in patients without visceral metastases (Table). **Conclusions:** ENZA + ADT provides improvements in rPFS and other secondary endpoints versus PBO + ADT in patients with mHSPC regardless of pattern of metastatic spread, particularly in patients without visceral metastases. These results highlight the importance of patient/physician discussion regarding the use of ENZA in the treatment of mHSPC. Clinical trial information: NCT02677896. Research Sponsor: This study was funded by Astellas Pharma Inc. and Pfizer Inc., the co-developers of enzalutamide. Medical writing and editorial assistance were provided by Lianne Young, BSc (Hons), and Jane Beck from Complete HealthVizion, funded by the study sponsors.

Prognostic markers for overall survival and outcome to LuPSMA radionuclide treatment in patients with metastatic castration-resistant prostate cancer. *First Author: Andrei Gafita, University of California, Los Angeles, CA*

Background: The aim of this international multicenter retrospective analysis was to identify prognostic markers for the clinical outcome in late-stage mCRPC patients treated with ^{177}Lutetium-prostate-specific membrane antigen (LuPSMA) radionuclide treatment. **Methods:** Patients with progressive mCRPC treated with LuPSMA at six centers in Germany, USA, and Australia were considered for inclusion. Eligible patients had 24 predefined, pretherapeutic covariates (demographics, prior mCRPC treatments, and PSMA PET/CT derived parameters) and survival data available. Endpoints included overall survival (OS) and PSA progression-free survival (PSA-PFS). Covariates were tested using univariate and mulitvariate proportional hazards regression Cox models. **Results:** 267/414 (64%) patients met inclusion criteria and were analyzed. 113 patients participated in clinical trials (ACTRN12615000912583, NCT03042312), while 154 were enrolled in compassionate-access programs. After a median follow-up of 22.5 months, median OS was 13.0 months (95%CI 11.6-14.4); 83% of the patients died. Median PSA-PFS was 4.0 months (95%CI 3.2-4.7). In the multivariate analysis, factors associated with shorter OS were: shorter time since diagnosis of prostate cancer (HR=2.04; p=0.002), lower number of prior systemic therapies (≤3; HR=1.56; p=0.006), prior exposure to chemotherapy (HR=1.42; p=0.05), lower hemoglobin levels (HR=1.13; p=0.002), higher number of lesions (≥20: HR=1.53; p=0.009), multiple sites of metastases (bone/LN only vs. bone + LN; HR=1.39; p=0.03) and visceral involvement (M1c) (HR=1.45; p=0.01). Factors associated with longer PSA-PFS were: longer time since diagnosis of prostate cancer (HR=0.44; p<0.001), higher hemoglobin levels (HR=0.32; p=0.03), presence of pelvic lymph nodes (LN) metastasis (N1) (HR=0.68; p=0.01), no distant lymph node metastases (M1a) (HR=0.66; p=0.01), no skeleton involvement (HR=0.44; p=0.01), no visceral metastases (M1c) (HR=0.51; p<0.001), higher PSMA-positive tumor volume (HR=0.87; p=0.04), and higher SUVmean (HR=0.94; p=0.002). **Conclusions:** This retrospective analysis identified prognostic factors for survival and treatment response to LuPSMA. Along with the conventional risk factors in mCRPC, PSMA PET/CT can be a useful tool for stratifying patients and guide patient's selection for LuPSMA radionuclide treatment. Research Sponsor: Prostate Cancer Foundation.

5549 Poster Session (Board #130), Fri, 8:00 AM-11:00 AM

Overall survival after ^{177}Lu-PSMA-617 molecular radiotherapy in patients with metastatic castrate-resistant prostate cancer: Post-hoc analysis of a prospective phase II trial. *First Author: Jeremie Calais, University of California, Los Angeles, CA*

Background: This was an open-label randomized prospective bi-centric single-arm phase II clinical trial of ^{177}Lu-PSMA-617 molecular radiotherapy in patients with progressive metastatic castrate-resistant prostate cancer (mCRPC) conducted at University of California Los Angeles (USA) and Excel Diagnostics & Nuclear Oncology Center (Houston, TX, USA) (NCT03042312). The study was investigator-initiated under an investigational new drug approval protocol (IND#133661) with authorization of charging for investigational drug (cost-recovery, Title 21 CFR 312.8). We report here the post-hoc analysis of overall survival (OS) in a single-study site cohort (UCLA). **Methods:** Patients with progressive mCRPC (biochemical, radiographic, or clinical) after ≥1 novel androgen axis drug (NAAD), either chemotherapy (CTX) naïve or post-CTX, with sufficient bone marrow reserve, normal kidney function, and sufficient PSMA-target expression by PET were eligible. Patients received up to 4 cycles of ^{177}Lu-PSMA-617 every 8±1 weeks and were randomized into 2 treatment activities groups (6.0 or 7.4 GBq). Efficacy was defined as serum PSA decline of ≥50% from baseline and served as primary endpoint (hypothesis: ≥40% of responders after 2 cycles). **Results:** 43 patients were randomized to the 6.0 GBq (n= 14) and 7.4 GBq (n=29) treatment arms. 11/43 (26%) were CTX naïve while 10/43 (23%), 12/43 (28%), 5/43 (12%) and 5/43 (12%) had received 1, 2, 3 or 4 CTX regimens. Median baseline PSA was 29.2 ng/ml (mean 228.8, range 0.5-2082.6). 21/43 (49%) completed 4 cycles of ^{177}Lu-PSMA-617 whereas 4/43 (9%), 13/43 (30%) and 5/43 (12%) underwent 1, 2 and 3 cycles. PSA decline of ≥50% was observed in 11/43 of patients (26%) after 2 cycles and in 16/43 (37%) at any time (best PSA response). 9/43 (21%) had a PSA decline of ≥90% and 23/43 (53%) had any PSA decline (>0%). After a median follow-up of 19.5 months the median OS was 14.8, 15.7 and 13.5 months in the whole cohort, the 6.0 GBq and 7.4 GBq treatment arms, respectively (p=0.68). Patients showing a PSA decline of ≥50% after 2 cycles and at any time had a longer OS: median 20.1 months vs. 13.6 (p=0.091) and 20.1 vs. 11.6 (p=0.002), respectively. **Conclusions:** In this post-hoc analysis of a single-site cohort of 43 patients included in a prospective phase II trial the median OS after 177Lu-PSMA-617 molecular radiotherapy in patients with progressive mCRPC was 14.8 months. There was no difference of efficacy between the 6.0 GBq and 7.4 GBq treatment arms. Clinical trial information: NCT03042312. Research Sponsor: None.

5550 Poster Session (Board #131), Fri, 8:00 AM-11:00 AM

Pembrolizumab (pembro) plus docetaxel and prednisone in patients (pts) with abiraterone acetate (abi) or enzalutamide (enza)-pretreated metastatic castration-resistant prostate cancer (mCRPC): KEYNOTE-365 cohort B efficacy, safety and, biomarker results. *First Author: Srikala S. Sridhar, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Pembro + docetaxel and prednisone (cohort B) has shown anti-tumor activity in pts with mCRPC in the phase I/II KEYNOTE-365 study (NCT02861573). Updated efficacy and safety and new biomarker data from cohort B are reported. **Methods:** Pts who received at least 4 wk of abi or enza in the prechemotherapy mCRPC setting and whose disease progressed within 6 mo of screening were eligible. Pts received pembro 200 mg IV + docetaxel 75 mg/m^2 IV Q3W and prednisone 5 mg orally twice daily. Primary end points were PSA response rate (PSA decrease ≥50%; confirmed by a second value ≥3 weeks later), ORR per RECIST v1.1 by blinded independent central review, and safety. Key secondary end points were DCR per RECIST v1.1 (CR+PR+SD or non-CR/non-PD ≥6 mo), DOR per RECIST v1.1, radiographic PFS (rPFS) per PCWG-modified RECIST, and OS. Biospecimens (blood, tissue) were collected for biomarker analysis, including tissue PD-L1 expression, androgen receptor variant 7 (AR-v7) expression in circulating tumor cells, and a T-cell-inflamed gene expression profile (GEP). **Results:** Of 105 enrolled pts, 104 were treated, and 50% had measurable disease. Median (range) time from enrollment to data cutoff was 19.9 mo (1.4-27.8) for all pts and 21.8 mo (17.9-27.8) for pts with ≥27 wks follow-up (n=72). Confirmed PSA response rate was 28% in 103 pts with a baseline PSA assessment. Median time to PSA progression was 6.2 mo (95% CI, 3.7-7.4). In pts with measurable disease and ≥27 wks follow-up (n=39), ORR was 18% (7/39, all PRs) and DCR was 51%. Median DOR was 6.7 mo (range, 3.4-9.0+ [+ indicates ongoing responder]); 5 pts had a response for ≥6 mo. In all pts, median rPFS was 8.3 mo (95% CI, 7.6-10.1) and OS was 20.4 mo (16.9-NR). At 6 mo, the rPFS rate was 72.8% and OS rate was 95.3%. Treatment-related AEs (TRAEs) occurred in 96% of all pts; most frequent were alopecia (39%), diarrhea (38%), and fatigue (38%). Grade 3-5 TRAEs occurred in 40% of pts; 2 pts died of TRAEs (pneumonitis). Overall, 24% of pts were PD-L1$^+$ (combined positive score ≥1). Of 57 pts with AR-v7 data, 17.5% were AR-v7$^+$, 77% were AR-v7$^-$, and 5% were undetermined. GEP was not significantly associated with ORR or PSA response. **Conclusions:** Pembro + docetaxel and prednisone showed activity in pts with abi or enza-pretreated mCRPC. Safety of the combination was consistent with the known profiles of the individual agents. A phase 3 study of this combination is ongoing (KEYNOTE-921, NCT03834506). Clinical trial information: NCT02861573. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

5551 Poster Session (Board #132), Fri, 8:00 AM-11:00 AM

Prostate cancer biomarker enrichment and treatment selection (PC-BETS) study: A Canadian cancer trials group phase II umbrella trial for metastatic castration-resistant prostate cancer (mCRPC). *First Author: Kim N. Chi, BC Cancer and Vancouver Prostate Centre, Vancouver, BC, Canada*

Background: Genomic characterization of mCRPC has identified commonly occurring alterations but also recurrently mutated genes at much lower frequencies. To efficiently evaluate anti-tumor activity of novel targeted therapies in mCRPC patients (pts) we initiated an umbrella trial using circulating tumour DNA (ctDNA) to enrich accrual for cancers with alterations that may predict response. **Methods:** mCRPC pts that have progressed after treatment with a next generation AR-pathway inhibitor (ARPI) were enrolled to this multi-center, multi-arm, 2-stage phase II trial. Plasma cell-free DNA was subjected to targeted sequencing and pts allocated to a treatment arm by a Tumor Board (TB) based on *a priori* criteria (biomarker positive, BM+) or by randomization if biomarker negative (BM-). Primary objective was to determine the clinical benefit rate (CBR: PSA decline ≥50% (PSA50), CR/PR, or stable disease ≥12 weeks). We report on 1st-stage activity of arms evaluating inhibitors of CDK4/6 (palbociclib), WEE1 kinase (adavosertib), cMET (savolitinib) and the AR inhibitor darolutamide. Additional planned arms include inhibitors of AKT (ipatasertib), Polo-like Kinase 4 (CFI-400945), immune checkpoints (durvalumab, tremelimumab) and carboplatin. **Results:** 250 pts were screened from two sequential trials over 29 months at 11 centers. Median time from blood draw to TB decision was 35 days. 169 pts (68%) had detectable ctDNA (≥1%) with a mean ctDNA fraction of 24% (range 1-95%). Commonly detected genomic alterations involved AR (49% gain, 24% mutation), TP53 (49%), PTEN/PI3K pathway (35%), DNA repair (23%: mismatch repair (5%), BRCA2 (8%), ATM (3%), CDK12 (5%), other (2%)) and CTNNB1/APC (14%). To date, 46 BM+ pts and 37 BM- patients were enrolled: median age 70 years (53-88), 100% had prior ARPI, 45% had prior docetaxel, 17% with visceral metastases. Accrual and CBR are presented in table. Adverse events were as expected. **Conclusions:** Prospective centralized screening of ctDNA to stratify mCRPC pts into a precision oncology trial is feasible. Activity was seen in 4 of 7 evaluable cohorts with darolutamide and adavosertib, meeting the threshold for expansion of these arms. Clinical trial information: NCT03385655, NCT02905318. Research Sponsor: Canadian Cancer Clinical Trials Network, Other Foundation, Pharmaceutical/Biotech Company, Canadian Cancer Society.

5552 Poster Session (Board #133), Fri, 8:00 AM-11:00 AM

First-in-human phase I study of HPN424, a tri-specific half-life extended PSMA-targeting T-cell engager in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Johanna C. Bendell, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: HPN424 is a first-in-class, prostate-specific membrane antigen (PSMA)-targeting T-cell engager designed as a small, globular protein to enable efficient solid-tumor penetration with prolonged half-life. HPN424 is derived from the TriTAC platform (Tri-specific T-Cell-Activating Construct) and engineered with three binding domains: anti-PSMA for tumor cell engagement, anti-albumin for half-life extension and anti-CD3 for T-cell engagement. **Methods:** This Ph I study is evaluating HPN424 in progressing mCRPC patients (pts) who have received >2 prior systemic therapies. Primary endpoints are safety, tolerability and determination of MTD/RP2D. Secondary objectives are pharmacokinetics (PK), pharmacodynamics, immunogenicity, and preliminary anti-tumor activity. HPN424 is administered IV once weekly. Tumor assessments include PSA, CT, and bone scans every 9 weeks. **Results:** As of 1/17/20, 27 pts were dosed in 8 cohorts ranging from 1.3 to 72ng/kg. Pts received a median of 6 prior systemic regimens, including >1 novel AR therapy, and 59% received prior chemotherapy for mCRPC. Median PSA at baseline was 251 ng/mL (range: 0.05 – 5000). No DLTs have been observed. The most common grade >3 TRAEs were cytokine release syndrome (CRS) (3 pts) and transient elevated liver transaminases (2 pts) that occurred concurrently with CRS. All CRS events resolved and pts were successfully re-treated. Short-term steroid premedication was effective in limiting CRS and allowing long-term weekly treatment. HPN424 demonstrated dose proportional increase in Cmax and AUC with a geometric mean T1/2 of 30.5 hours. Dose-dependent, transient increases in peripheral cytokine and chemokine levels were observed. Reduction in circulating tumor cells (CTCs) was seen in 11 of 19 pts with measurable CTC at baseline. Six pts had PSA decreases from baseline ranging from -3.8% to -76%, including 2 pts with PSA decline ≥50%. Ten of 20 pts (50%) with > 18 weeks follow-up remained on study beyond week 18 and includes 8 pts on study > 24 weeks. **Conclusions:** HPN424 represents a novel half-life extended PSMA-targeting T-cell engager that can be safely administered once weekly. AEs have been transient and manageable. Cytokine increases indicate T-cell activation. CTC reductions in subset of pts suggest target engagement. Early signs of clinical activity include PSA reductions and time on study, including 8 pts on study > 24 weeks. Dose escalation is ongoing, including exploration of step dosing. Clinical trial information: NCT03577028. Research Sponsor: Harpoon Therapeutics.

5553 Poster Session (Board #134), Fri, 8:00 AM-11:00 AM

Primary analysis of a phase II study of metastasis-directed ablative therapy to PSMA (^{18}F-DCFPyL) PET-MR/CT defined oligorecurrent prostate cancer. *First Author: Rachel Glicksman, Department of Radiation Oncology, University of Toronto, Toronto, ON, Canada*

Background: Despite maximal local therapies (MLT) (radical prostatectomy followed by radiotherapy [RT]), 20-30% of men will progress to incurable prostate cancer (PCa). Most recurrences in this scenario are characterized by rise in PSA with negative bone scan (BS) and computed tomography (CT). We conducted a phase II trial for men with rising PSA after MLT using ^{18}F-DCFPyL (PSMA) PET-MR/CT followed by metastasis-directed therapy (MDT) to PET positive foci. We report the results of our primary analysis. **Methods:** Patients with rising PSA (0.4-3.0 ng/mL) after MLT, negative BS/CT and no prior salvage ADT were eligible. All patients underwent PSMA PET-MR and PET-CT. Those with limited disease burden amenable to MDT underwent either stereotactic ablative RT (SABR) or surgery (lymph node dissection). No ADT was used. The primary endpoint was biochemical response rate (complete [undetectable PSA] or partial [PSA decline ≥50% from baseline]) following MDT. A Simon's two-stage study design was employed. Estimated time of delay in salvage ADT was calculated using the Kaplan-Meier method. Toxicity was prospectively recorded (CTCAE v4.0). **Results:** After a median of 63 months (range 3-180) post MLT, 72 patients underwent PSMA PET-MR/CT with median PSA 0.98 ng/mL (range 0.4-3.1). Sixteen patients had negative and 56 had positive PET-MR/CT scans, of which 37 (51%) were amenable to MDT. The median number of treated lesions was 2 (range 1-5). Of the treated patients, 30 (81%) had miT0N1M0 disease, 2 (5.5%) had miT0N1M1a, 2 (5.5%) had miT0N0M1a and 3 (8%) had miT0N0M1b. Twenty-seven patients underwent SABR (median 30 Gy in 3 fractions) and 10 had surgery. At a median of 11 months (range 1-29) post MDT, 8 patients (22%) had complete (CR) and 14 (38%) had partial (PR) responses. Among the 8 CRs, 5 had surgery and 3 had SABR; of the 14 PRs, 2 had surgery and 12 had SABR. The estimated median delay in salvage ADT for the entire cohort, PR and CR subgroups was 13 months (IQR 8-20), 16 months (IQR 13-20) and 30 months (IQR not reached), respectively. Two grade 2+ toxicities were observed, both in surgical patients: deep venous thrombosis and ureteric injury requiring stent placement. **Conclusions:** ^{18}F-DCFPyL PET-MR/CT has high detection rates (78%) in men with rising PSA after MLT. We observed a favorable therapeutic index with MDT (60% response rate) for patients with metachronous PSMA-unveiled oligometastatic PCa following MLT. Phase III studies using validated intermediate clinical endpoints are needed before integration into routine practice. Clinical trial information: NCT03160794. Research Sponsor: Terry Fox Canadian Comprehensive Cancer Centre Network (TF4CN) Pilot Project, Terry Fox Research Institute (TFRI); Abbvie CARO Uro-Oncologic Radiation Awards (ACURA); Astellas Prostate Cancer Innovation Fund, University of Toronto, Other Foundation.

5554 Poster Session (Board #135), Fri, 8:00 AM-11:00 AM

Cabazitaxel versus enzalutamide/abiraterone in CARD eligible mCRPC patients with or without germline HRR defects. *First Author: Nuria Romero-Laorden, Hospital Universitario La Princesa, Madrid, Spain*

Background: The CARD trial proved that in mCPRC patients (pts), previously treated with docetaxel and an androgen-receptor signaling inhibitor (ARSi), cabazitaxel (CBZ) significantly improves progression-free (PFS) and Overall Survival (OS) compared with the alternative ARSi. Concurrently, the PROFOUND study showed the superiority of olaparib vs. ARSi in pts with similar prior treatment history and genetic alterations in Homologus Recombination DNA repair related genes (HRR). **Methods:** PROREPAIR-B (NCT03075735) is a prospective study which aimed to demonstrate the prognostic role of germline deleterious mutations in (g)HRR genes and the benefit of first (1L), second (2L) and subsequent therapy lines for mCRPC. Outcomes with 1-2L have been previously reported. Here we evaluated radiographic (r)-PFS, clinical (c)-PFS, and OS in PROREPAIR-B pts who meet CARD study eligibility criteria and who received CBZ and/or ARSi. Survival analysis were performed using Kaplan Meier method and Cox regression models. **Results:** 95 out of 419 mCRPC pts included in PROREPAIR-B meet CARD eligibility criteria and received CBZ (n=60) or ARSi (n=35) including 14 gHRR carriers, 8/6 treated with CBZ/ARSi, respectively. Visceral metastases were more frequent among pts treated with CBZ (p=0.01). ECOG 2, M1 at diagnosis, Abiraterone as 1st ARSi and prior radiographic PD (all $p<0.05$) were more frequent in our pts than in the CARD study. Overall, CBZ was superior to ARSi in terms of rPFS (median 6.0 vs. 3.7 months (m), p=0.03), cPFS (median 4.4 vs. 3.4 m, p=0.01) and PSA50 responses (39% vs. 17%, p=0.027). Differences in OS were not observed, although approximately 60% of patients in ARSi had crossed to CBZ at the time of the analyses. Results of subgroups analyses were similar to those reported by CARD. In this series, gHRR carriers had a significant worse prognosis (OS HR 1.9; rPFS HR 2.4; cPFS HR 2.6) than non-carriers. In gHRR carriers CBZ was not superior to ARSi in terms of rPFS (2.5 vs. 3.0 m, p=0.8), cPFS (2.5 vs. 2.4 m, p=0.8) and OS (4.5 vs. 3.7, p=0.8). Cox MVA models adjusted for unbalances and CARD grouping factors confirmed a significant interaction between treatment and gHRR status for rPFS and cPFS, suggesting that the benefit of CBZ was not observed in gHRR. **Conclusions:** Our results confirm the benefit of CBZ treatment over a second ARSi (either abiraterone or enzalutamide) in unselected mCRPC population. However, the outcomes in gHRR carriers are poor with either CBZ or ARSi supporting the need of novel therapies in this setting. Clinical trial information: NCT03075735. Research Sponsor: Spanish Society of Medical Oncology (SEOM), Spanish Oncology Genitourinary Group (SOGUG), Pharmaceutical/Biotech Company.

5555 Poster Session (Board #136), Fri, 8:00 AM-11:00 AM

Detection of prostate cancer and determination of its significance using explainable artificial intelligence. *First Author: Okyaz Eminaga, Department of Urology, Stanford University School of Medicine, Stanford, CA*

Background: The variation of the human perception has limited the potential of multi-parametric magnetic resonance imaging (mpMRI) of the prostate in determining prostate cancer and identifying significant prostate cancer. The current study aims to overcome this limitation and utilizes an explainable artificial intelligence to leverage the diagnostic potential of mpMRI in detecting prostate cancer (PCa) and determining its significance. **Methods:** A total of 6,020 MR images from 1,498 cases were considered (1,785 T2 images, 2,719 DWI images, and 1,516 ADC maps). The treatment determined the significance of PCa. Cases who received radical prostatectomy were considered significant, whereas cases with active surveillance and followed for at least two years were considered insignificant. The negative biopsy cases have either a single biopsy setting or multiple biopsy settings with the PCa exclusion. The images were randomly divided into development (80%) and test sets (20%) after stratifying according to the case in each image type. The development set was then divided into a training set (90%) and a validation set (10%). We developed deep learning models for PCa detection and the determination of significant PCa based on the PlexusNet architecture that supports explainable deep learning and volumetric input data. The input data for PCa detection was T2-weighted images, whereas the input data for determining significant PCa include all images types. The performance of PCa detection and determination of significant PCa was measured using the area under receiving characteristic operating curve (AUROC) and compared to the maximum PiRAD score (version 2) at the case level. The 10,000 times bootstrapping resampling was applied to measure the 95% confidence interval (CI) of AUROC. **Results:** The AUROC for the PCa detection was 0.833 (95% CI: 0.788-0.879) compared to the PiRAD score with 0.75 (0.718-0.764). The DL models to detect significant PCa using the ADC map or DWI images achieved the highest AUROC [ADC: 0.945 (95% CI: 0.913-0.982; DWI: 0.912 (95% CI: 0.871-0.954)] compared to a DL model using T2 weighted (0.850; 95% CI: 0.791-0.908) or PiRAD scores (0.604; 95% CI: 0.544-0.663). Finally, the attention map of PlexusNet from mpMRI with PCa correctly showed areas that contain PCa after matching with corresponding prostatectomy slice. **Conclusions:** We found that explainable deep learning is feasible on mpMRI and achieves high accuracy in determining cases with PCa and identifying cases with significant PCa. Research Sponsor: Department of Defense.

5556 Poster Session (Board #137), Fri, 8:00 AM-11:00 AM

Prospective evaluation of ^{18}F-DCFPyL PET/CT in biochemically recurrent prostate cancer: Analysis of lesion localization and distribution. *First Author: Hong Song, Stanford University, Stanford, CA*

Background: ^{18}F-DCFPyL, a promising PET agent targeting prostate specific membrane antigen (PSMA), is prospectively evaluated in a single academic center for detecting recurrent lesions in prostate cancer patients with biochemical recurrence (BCR). **Methods:** We prospectively enrolled 150 men (51-91 years old, mean ± SD: 70.3±7.5) with biochemical recurrence (PSA median 2.38 ng/mL, range 0.12 to 698.4) after primary definitive treatment with prostatectomy (65%), radiotherapy (35%) or both (19%). The ^{18}F-DCFPyL positive lesions compatible with prostate cancer were evaluated by two independent readers. Impact of ^{18}F-DCFPyL PET/CT on patient management was recorded from clinical chart review. **Results:** ^{18}F-DCFPyL PET/CT had an overall positivity rate of 83% (125 scans), which increased with higher prostate specific antigen (PSA) levels (ng/mL): 63% (PSA $<$ 0.5), 75% (0.5≤PSA $<$ 1), 91% (1≤PSA $<$ 2), 95% (2≤PSA $<$ 5) and 98% (PSA≥5), respectively. In the cohort who underwent prostatectomy, ^{18}F-DCFPyL PET/CT had higher positivity rate in patients with shorter PSA doubling time (PSAdt) (94% in PSAdt 0-3 months vs. 53% in PSAdt $>$ 12 months, $P<0.01$). No difference of ^{18}F-DCFPyL positivity rate was observed in post-radiation patients with different PSAdt, nor were there differences between patients with low grade (Gleason 6) or higher-grade prostate cancer (Gleason 7-10). 20 patients (13%) had lesions in the prostate bed only and 41 patients (27%) had oligometastatic disease (1-3 lesions), making them candidates for locally targeted therapy. We identified a total of 1455 ^{18}F-DCFPyL positive lesions, including 51 lesions in the prostate bed, 271 pelvic and 463 extrapelvic lymph nodes, approximately 585 osseous lesions, including 5 patients with diffuse osseous metastases, and 85 lesions in other organs (most commonly in the lungs). 91 out of 150 patients (61%) had change in treatment after ^{18}F-DCFPyL PET and, most noticeably, 48 of these patients (32% total) had lesions only localized on ^{18}F-DCFPyL PET/CT despite negative conventional imaging. **Conclusions:** ^{18}F-DCFPyL PET/CT holds great potential to be a "one-stop shop" diagnostic tool in the work-up of BCR prostate cancer, with high (61%) impact on the management of these patients. Clinical trial information: NCT03501940. Research Sponsor: Progenics provided DCFPyL as part of a research access program. No other financial support.

5557 Poster Session (Board #138), Fri, 8:00 AM-11:00 AM

Updated results of a phase I/II prospective dose escalation trial evaluating safety and efficacy of combination ^{177}Lu PSMA 617 and idronoxil in men with mCRPC post androgen signalling inhibition and taxane chemotherapy (LuPIN trial). *First Author: Louise Emmett, Department of Theranostics and Nuclear Medicine, St. Vincent's Hospital, Sydney, Australia*

Background: There is no established standard of care post cabazitaxel in men with mCRPC. Ongoing trials in ^{177}LuPSMA-617 have demonstrated good efficacy and safety, but synergistic combinations may further improve treatment responses. Idronoxil (NOX66) inhibits external NADH oxidase type 2 with downstream pro-apoptotic actions including radio-sensitization. Herein we present updated results and an additional cohort of a prospective single arm phase I/II dose escalation/expansion trial of LuPSMA-617 and NOX66 in mCRPC. **Methods:** Men with progressive mCRPC post androgen signalling inhibition (ASI) and 2 lines of taxane chemotherapy were considered eligible. Key inclusion criteria included PSMA PET/CT intensity SUV max > 15 with no discordant disease on FDG PET/CT, Hb >10, Platelets >100 and GFR >40mls/min. Enrolled patients received up to 6 doses of ^{177} Lu-PSMA 617 (7.5Gbq) day 1 every 6 weeks in combination with NOX66 days 1-10 each cycle. Cohort 1 (n=8) received 400mg NOX66. Cohorts 2 and 3 subsequently received 800mg and 1200mg of NOX66, respectively, following safety reviews. Data regarding safety, efficacy, pain scores, and QOL were collected. **Results:** 32 men were enrolled in cohorts 1&2 (November 2017 – June 2019) and 24 in cohort 3 (August 2019-February 2020). To date there have been no dose-limiting toxicities. Data for cohort 3 are immature. For cohorts 1 & 2: 31/32 men received ≥2 cycles, with 12/32 (47%) completing 6 cycles. Any PSA response was seen in 84% (27/32), with a PSA response > 50% in 62.5% (20/32). Median PSA PFS is 6.1 months Of men with increased baseline pain scores ≥3 (24/32), 50% (12/24) had a clinically significant reduction in pain indicators. Adverse events are summarized below. Updated results for cohorts 1 and 2 and preliminary results of cohort 3 will be presented. **Conclusions:** Combination LuPSMA-617 + NOX 66 appears safe and efficacious in men with heavily pre-treated end stage mCRPC. Clinical trial information: ACTRN12618001073291. Research Sponsor: Noxopharm.

5558 Poster Session (Board #139), Fri, 8:00 AM-11:00 AM

Pain progression at initiation of cabazitaxel in metastatic castration-resistant prostate cancer (mCRPC) is associated with a poor prognosis: a post-hoc analysis of PROSELICA. *First Author: Nicolas Delanoy, Department of Medical Oncology, Georges Pompidou European Hospital, Paris, France*

Background: PROSELICA phase III trial (NCT01308580) showed that cabazitaxel 20 mg/m2 (C20) is non-inferior to C25 in mCRPC patients (pts) post-docetaxel (DOC) *(Eisenberger JCO 2017)*. Pts enrolled were symptomatic or not. This post-hoc analysis evaluates the influence of progression type at randomization on outcomes. **Methods:** Progression type at randomization was defined as follows: PSA progression only (PSA-p; no radiological progression (Radio-p), no pain), Radio-p (± PSA-p, no pain) or pain progression (pain-p, ±PSA-p, ±Radio-p). The relationship between progression type and overall survival (OS), radiological progression-free survival (rPFS) and PSA response (confirmed PSA decrease ≥ 50%) was analyzed. **Results:** All patients randomized (n = 1200) had received prior DOC and 25.7% had received prior abiraterone or enzalutamide. Progression type was evaluable in 1065 pts (PSA-p = 24.5%, radio-p = 20.9%, pain-p = 54.6%). Pain progression was associated with clinical and biological features of aggressive disease and worse outcomes (decreased PSA response, rPFS and OS) vs PSA-p or radio-p (Table). The survival (rPFS and OS) on C25 was numerically higher than on C20 in pts with radio-p and pain-p. Conversely, C20 and C25 equally benefited pts with PSA-p only. In multivariate analysis (all arms combined), pain progression was an independent predictor of poor OS. **Conclusions:** This post-hoc analysis of PROSELICA shows that pain progression at initiation of cabazitaxel in mCRPC pts previously treated with DOC is prognostic. The activity of C25 was numerically higher than C20 in patients with radiological or pain progression. Clinical trial information: NCT01308580. Research Sponsor: None.

5559 Poster Session (Board #140), Fri, 8:00 AM-11:00 AM

Efficacy and safety in older patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) receiving cabazitaxel (CBZ) versus abiraterone (ABI) or enzalutamide (ENZ) in the CARD study. *First Author: Cora N. Sternberg, Englander Institute of Precision Medicine, Weill Cornell Medicine, New York, NY*

Background: In the CARD (NCT02485691) study, radiographic PFS (rPFS), PFS and OS were significantly improved with CBZ vs. androgen-signaling-targeted agents (ARTA; ABI or ENZ) in pts with mCRPC who had received docetaxel (DOC) and progressed within 12 months (mo) on an alternative ARTA. This analysis evaluated the impact of age (< 70 vs. ≥ 70 years) on the efficacy and safety of CBZ and ARTAs in CARD. **Methods:** 255 pts with mCRPC were randomized 1:1 to CBZ (25 mg/m^2 IV Q3W + prednisone [P] + G-CSF) vs. ABI (1000 mg PO + P) or ENZ (160 mg PO) until disease progression, unacceptable toxicity or pt request. Pts were eligible if they had received ≥ 3 cycles of DOC and progressed ≤ 12 mo on the previous alternative ARTA. Primary endpoint was rPFS. Subgroup analysis of older (≥ 70 years; n = 135) and younger (< 70 years; n = 120) pts was pre-specified for rPFS; others were post hoc. **Results:** rPFS was significantly improved vs. ARTA in both older (median 8.2 vs. 4.5 mo; HR 0.58; 95% CI 0.38–0.89) and younger pts (median 7.4 vs. 3.2 mo; HR 0.47; 95% CI 0.30–0.74). Median OS for CBZ vs. ARTA was 13.9 vs. 9.4 mo (HR 0.66; 95% CI 0.41–1.06) in older pts and 13.6 vs. 11.8 mo (HR 0.66; 95% CI 0.41–1.08) in younger pts. PFS, tumor, PSA and pain responses also favored CBZ, regardless of age. Grade ≥ 3 adverse events (AEs) occurred in 57.8% vs. 49.3% of older pts receiving CBZ vs. ARTA and 48.4% vs. 42.1% in younger pts. AEs leading to death were more frequent with ARTA, mainly due to disease progression. **Conclusions:** CBZ had improved efficacy outcomes vs. ARTA in pts with mCRPC previously treated with DOC and the alternative ARTA, regardless of age. Grade ≥ 3 cardiac AEs were more frequent in older pts treated with ARTA. A higher rate of AEs was reported in older vs. younger pts, for ARTA and CBZ. CBZ and ARTA had different safety profiles in older compared with younger pts. Clinical trial information: NCT02485691. Funding: Sanofi. Research Sponsor: Sanofi.

5560 Poster Session (Board #141), Fri, 8:00 AM-11:00 AM

Phase I dose-escalation study of PSMA-targeted alpha emitter ^{225}Ac-J591 in men with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Scott T. Tagawa, Weill Cornell Medicine, New York, NY*

Background: Antibodies (Abs) or small molecules can target PSMA with different biodistribution. Certain sites of PSMA expression (e.g. salivary/lacrimal glands, kidneys, small bowel) are not accessible to Abs. Given radiosensitivity of PC and potency of alpha emitters plus the ability to minimize targeting off tumor PSMA+ sites with J591, we performed a 1st in human study of ^{225}Ac-J591. **Methods:** Men with progressive mCRPC following at least 1 potent AR-pathway inhibitor (ARPI) and chemo (or unfit/refuse) without limit of # prior therapies (Ra-223 and ^{177}Lu-PSMA allowed) with ECOG PS 0-2 and adequate organ function were eligible. Baseline ^{68}Ga-PSMA11 PET was performed, but not used for eligibility. Initially 1-subject cohorts treated until transition to 3+3 at dose level 5 (predicted by dosimetry to have moderate toxicity) with a single infusion of ^{225}Ac-J591 (13.3 KBq/kg with planned escalation up to 93.3 KBq/kg). Dose-limiting toxicity (DLT) defined as attributable grade (Gr) 4 heme toxicity or Gr 3/4 non-heme tox. Imaging, genomic, patient-reported outcomes (PRO), and immune correlates embedded. **Results:** 22 men treated on 7 dose levels; median age 72.5 (range 58-89), PSA 147 (5-7168); 82% with >2 prior ARPI, 64% chemo, 23% Ra-223, 55% ^{177}Lu-PSMA. 1 (5%) CALGB (Halabi) good prognostic risk, 10 (45%) intermed, 11 (50%) poor risk. 1 of 6 in cohort 6 (80 KBq/kg) had DLT (Gr 4 anemia and platelets); no others had attributable Gr > 2 non-heme or Gr > 3 heme AE (including 0 of 6 at the highest dose level 93.3 KBq/Kg). Gr 1/2 AE's: 17 (77%) fatigue, 11 (50%) pain flare, 10 (45%) anemia (+1 Gr 3), 10 (45%) platelets, 6 (27%) nausea, 6 (27%) xerostomia (5 of 6 with prior ^{177}Lu-PSMA), 5 (23%) neutropenia, 4 (18%) AST elevation. Despite prior treatment including ^{177}Lu-PSMA and no selection for PSMA expression, 14 (64%) with any PSA decline, 9 (41%) with > 50% PSA decline. 15 (68%) had initial PSA rise followed by decline from peak (delayed effect). 2 with response > 1 year despite prior ^{177}Lu-PSMA. Of 15 with paired baseline and 12-wk CTC counts, 8 declined, 4 remained undetectable, 3 increased. In subset with complete PRO data (baseline to 12 wks), pain was improved or absent by BPI-SF in 63% and by FACT-P in 89%. Social and emotional well-being domains of FACT-P improved or stabilized in majority; physical well-being improved in most responders. **Conclusions:** Alpha-emitter ^{225}Ac targeting PSMA via J591 Ab is tolerable with early evidence of clinical activity in a pre-treated population with favorable PRO's. Enrollment to expansion cohort being completed. Clinical trial information: NCT03276572. Research Sponsor: Weill Cornell Medicine, Other Foundation, Other Government Agency, U.S. National Institutes of Health.

5561 Poster Session (Board #142), Fri, 8:00 AM-11:00 AM

Safety outcomes of darolutamide versus apalutamide and enzalutamide in nonmetastatic castration-resistant prostate cancer (nmCRPC): Matching-adjusted indirect comparisons. *First Author: Shan Jiang, Bayer U.S. LLC, Whippany, NJ*

Background: Randomized nmCRPC trials comparing darolutamide (D), apalutamide (A) and enzalutamide (E) have not been reported. Safety of these therapeutics has important implications in assessing patient risk-benefit concerns. Matching-adjusted indirect comparison (MAIC) is a method to perform indirect treatment comparisons adjusting for cross-trial heterogeneity. Objective: To compare the safety outcomes of D vs. A or E using MAIC. **Methods:** Data from the ARAMIS (D vs. placebo [PBO]), SPARTAN (A vs. PBO) and PROSPER (E vs. PBO) trials were used. Key safety outcomes including adverse events (AEs) that have central nervous system relevance were compared using anchored MAIC. Individual patient level data (IPD) from ARAMIS were selected and re-weighted to match the inclusion criteria and baseline characteristics published in SPARTAN and PROSPER (no access to their IPD). The Benjamini-Hochberg approach was applied to adjust for multiplicity. The D vs A MAIC matched on 7 covariates: age, prostate-specific antigen (PSA) level and doubling time, Eastern Cooperative Oncology Group (ECOG), Gleason score, bone-sparing agent use and prior surgery. Sensitivity analyses were conducted matching on different sets of covariates. D vs. E were matched on age, region, PSA level and doubling time, ECOG, Gleason score and bone-sparing agent use. Risk difference (RD) ([DARO – PBO_{ARAMIS}] – [ENZA – $PBO_{PROSPER}$]) and odds ratio (OR) ($OR_{ARAMIS}/OR_{PROSPER}$) were calculated. RD<0 or OR<1 indicate lower AE risk for D. **Results:** For D vs. A, the effective sample sizes (ESS) of D and its placebo (PBO) arm were 604 and 391 after matching. Fall, fracture, and rash were statistically significantly lower for D vs. A (Table). For D vs. E, the ESS of D and PBO arm were 580 and 395, respectively. Fall, dizziness, mental impairment, hypertension, fatigue and severe fatigue were statistically significantly lower for D vs. E. **Conclusions:** After adjusting for trial differences, D showed favorable safety profile in fall, dizziness, mental-impairment, hypertension, rash, fatigue, and fracture. Research Sponsor: Bayer U.S. LLC.

5562 Poster Session (Board #143), Fri, 8:00 AM-11:00 AM

Association of detectable levels of circulating tumor DNA (ctDNA) with disease burden in prostate cancer (PC). *First Author: Gerhardt Attard, University College London Cancer Institute, London, United Kingdom*

Background: PC is characterized by a relatively low prevalence of recurrent somatic point mutations. ctDNA is shed from PC and can be analyzed to profile somatic point mutations and copy number changes. We evaluated a computational approach to detect ctDNA (ie. ctDNA+) in PC based on allele frequencies of polymorphisms and mutations. We then sought to confirm the association of this biomarker with disease burden and clinical outcome. **Methods:** Customized, hybrid capture, high-depth next-generation sequencing was performed on pre-treatment (PT) plasma samples from a phase 2 line 3+ metastatic castration-resistant PC (mCRPC) study (NCT02854436, GALAHAD) and PT and end of treatment (EOT) samples from randomized Phase 3 study in non-metastatic (nm) CRPC (NCT01946204, SPARTAN) and from metastatic castration-sensitive PC (mCSPC) (NCT02489318, TITAN). Associations of ctDNA+ with bone lesions (number), visceral metastases (+/-), circulating tumor cells count (CTCc), and serum prostate specific antigen (PSA), alkaline phosphatase (AP) and lactate dehydrogenase (LD) were tested. Also, associations of ctDNA+ with overall survival (OS) and second progression free survival (PFS2) were evaluated in randomized studies using Cox regression. **Results:** ctDNA+ at PT was 7.5% in nmCRPC, 23.7% in mCSPC and 66% in heavily pre-treated mCRPC. ctDNA+ increased from PT to EOT in nmCRPC (7.5% to 27%) and mCSPC (23.7% to 63.6%). Disease burden metrics were evaluated in ctDNA+ vs ctDNA- patients. ctDNA+ was associated with higher disease burden in mCRPC (Table), nmCRPC and mCSPC. At EOT, ctDNA+ patients had shorter OS and PFS2 in nmCRPC (HR [95% CI] OS: 2.73 [1.83, 4.08], $p < 0.0001$; PFS2: 2.00 [1.38, 2.90], $p = 0.0002$) and mCSPC (HR [95% CI] OS: 7.59 [3.22, 17.91], $p < 0.0001$; PFS2: 4.84 [2.47, 9.47], $p < 0.0001$). **Conclusions:** ctDNA+ assessed using our novel, composite biomarker increases with advanced disease state and disease progression, is significantly associated with disease burden and poor clinical outcome in PC and could be a clinically relevant metric for monitoring response to therapy. Clinical trial information: NCT02854436. Research Sponsor: Janssen Research and Development, LLC.

5563 Poster Session (Board #144), Fri, 8:00 AM-11:00 AM

Results of the randomized phase II study of sipuleucel-T (Sip-T) +/- Radium-223 (Ra-223) in men with bone-metastatic castration resistant prostate cancer. *First Author: Catherine Handy Marshall, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: It has been suggested that immune modulation can be augmented by radiation, possibly by enhancing tumor-antigen display. SipT-induced antigen-specific immune responses in mCRPC patients correlate with survival. We hypothesized that the combination of Ra223 and SipT would enhance SipT-related immune response and improve outcomes compared to SipT alone. **Methods:** Patients with asymptomatic, bone-predominant mCRPC, without visceral mets >1.0 cm, were randomized (1:1) to SipT alone or with 6 doses of Ra223 (NCT02463799). Men in the SipT+Ra223 arm started SipT between the 2nd and 3rd dose of Ra223. The primary immunologic endpoint was PA2024-specific T-cell proliferation 6 wks after the first SipT infusion. Secondary immune endpoints were PA2024-specific ELISPOT response, PAP-specific proliferation and ELISPOT, humoral responses against both antigens, and antigen spread. Clinical endpoints were radiographic PFS, PSA response (≥50% decline), AlkPhos response (≥30% decline), and safety. **Results:** 32 men were randomized, 16 per arm. Baseline characteristics in SipT+Ra223 and SipT arms were similar: age (median 71 vs. 70 yrs), Gleason (8-10: 69% vs. 69%), baseline PSA (med 25 vs. 33 ng/mL), AlkPhos (med 89 vs. 92 U/L) and ECOG score (≥1: 31% vs. 19%). There was no significant difference in prior use of abi/enza (38% vs. 44%), or chemo (0% vs. 25%). At 6 weeks, absolute PA2024-specific T-cell proliferation was 2.1-fold higher in the Sip-T arm compared to the SipT+Ra223 arm (35.6 vs. 16.6; *P*=0.03) and remained higher through week 26. Relative to baseline, the 6-week PA2024-specific T-cell proliferation change was 3.6 times greater in the Sip-T arm compared to the SipT+Ra223 arm (*P*=0.007) and remained higher through week 14. There were no significant differences in antigen spread or humoral responses. Median radiographic PFS was longer in the SipT+Ra223 arm (9.3 vs. 3.2 months; HR 0.26, 95% CI 0.11–0.61; *P*=0.007). PSA and AlkPhos responses were better in the SipT+Ra223 arm (PSA50: 5/15=33% vs. 0/14=0%; *P*=0.04; AlkPhos30: 9/15=60% vs. 1/15=7%; *P*=0.01). There was no difference in SREs (13% vs. 7%). **Conclusions:** SipT+Ra223 was associated with improved clinical outcomes and a higher rate of PSA responses compared to SipT alone, although surprisingly, the SipT arm demonstrated higher peripheral PA2024-specific T-cell proliferation. Since neither agent reliably induces PSA responses alone, these data suggest a synergistic effect of the combination. Larger randomized studies of this combination are planned. Clinical trial information: NCT02463799. Research Sponsor: Dendreon, Bayer.

5564 Poster Session (Board #145), Fri, 8:00 AM-11:00 AM

Cabozantinib in combination with atezolizumab in patients with metastatic castration-resistant prostate cancer: Results of cohort 6 of the COSMIC-021 study. *First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Cabozantinib (C) may enhance response to immune checkpoint inhibitors (ICIs) by promoting an immune-permissive microenvironment and has shown encouraging activity in combination with ICIs in tumor types including RCC and HCC. C and atezolizumab (A) have shown low objective response rates as monotherapy in metastatic castration-resistant prostate cancer (mCRPC) (Smith JCO 2012; Kim JCO 2018). COSMIC-021 (NCT03170960), a multinational phase 1b study, is evaluating the combination of C + A in various solid tumors. We report results for Cohort 6 in mCRPC. **Methods:** Eligible patients (pts) were required to have radiographic progression in soft tissue after enzalutamide and/or abiraterone, measurable disease, and an ECOG PS of 0 or 1. Prior chemotherapy for mCSPC was permitted. Pts received C 40 mg PO QD and A 1200 mg IV Q3W. CT/MRI scans were performed Q6W for the first year and Q12W thereafter. The primary endpoint is ORR per RECIST 1.1. Other endpoints include safety, ORR per irRECIST, duration of response (DOR), PFS, and OS. Results are presented for the first 44 pts enrolled. **Results:** Median follow-up as of Dec 20, 2019 was 12.6 mo (range 5, 20) for the 44 mCRPC pts. Median age was 70 y (range 49, 90), 50% had ECOG PS 1, 34% had visceral metastases, and 61% had extrapelvic lymph node metastases. 27% had prior docetaxel and 52% had 2 prior novel hormonal therapies. The most common any grade treatment-related adverse events (TRAEs) were fatigue (50%), nausea (43%), decreased appetite (39%), diarrhea (39%), dysgeusia (34%), and PPE (32%). One grade 5 TRAE of dehydration was reported in a 90 y/o. Median duration of treatment was 6.3 mo. ORR per RECIST 1.1 among all 44 pts was 32% (2 CRs [4.5%] and 12 PRs [27%]); 21 (48%) pts had SD resulting in a disease control rate of 80% in all pts. One pt with PD per RECIST 1.1 had an irPR per irRECIST. ORR per RECIST 1.1 was 33% in 36 pts with high-risk disease (visceral and/or extrapelvic lymph node metastases). Median DOR for all pts with response per RECIST 1.1 was 8.3 mo (range 2.8, 9.8+). 17 (50%) of 34 pts with post-baseline PSA evaluation had a decrease in PSA. In 12 responders with post-baseline PSA evaluation, 8 (67%) had a PSA decrease ≥50%. Tumor PD-L1 expression will also be reported. **Conclusions:** The combination of C + A had a tolerable safety profile and demonstrated clinically meaningful activity with durable responses in men with mCRPC. Given the encouraging activity in these pts, especially in those with high-risk disease, further evaluation of C + A in men with mCRPC is being pursued. Clinical trial information: NCT03170960. Research Sponsor: Exelixis Inc.

5565 Poster Session (Board #146), Fri, 8:00 AM-11:00 AM

Safety and clinical activity of atezolizumab (atezo) + radium-223 dichloride (r-223) in 2L metastatic castration-resistant prostate cancer (mCRPC): Results from a phase Ib clinical trial. *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: mCRPC patients (pts) tend to have a poor prognosis and limited treatment (tx) options, especially those with concomitant bone metastases (mets). We explored the ability of combination tx with atezo (anti–PD-L1) and r-223 (α-particle emitter) to stimulate anti-tumor immunity in mCRPC pts. **Methods:** This Phase Ib study evaluated the safety and tolerability of atezo + r-223 in pts with mCRPC and multiple bone mets, visceral mets and/or lymphadenopathy who progressed after androgen pathway inhibitor tx. The initial cohort phase evaluated the safety and tolerability of a concurrent dosing schedule (CDS), in which atezo and r-223 were administered on the same day. Following assessment of CDS, pts were randomized 1:1:1 to CDS or 1 of 2 staggered dosing schedules (atezo or r-223 introduced a full cycle before the other). This was followed by an expansion of enrollment (randomized 1:1:1). Pts got atezo 840 mg IV q2w and r-223 at 55 kBq/kg IV 6 times at 4-wk intervals until unacceptable toxicity or loss of clinical benefit. Exploratory measures of efficacy included investigator-assessed ORR (RECIST 1.1), PSA response rate, time to PSA progression, radiographic PFS (rPFS; PCWG2 criteria) and OS. Biopsy samples were collected at baseline and prior to cycle 2 to evaluate changes in the tumor microenvironment during tx. **Results:** As of Oct 4, 2019, 45 pts were enrolled and 44 had evaluable data. Baseline characteristics were generally similar across groups. All 44 evaluable pts had $\geq$ 1 all-cause AE; 23 (52.3%) had Gr 3-4 AE. Eight pts (18.2%) had Gr 5 AE as per protocol reporting of deaths; 4 (9.1%) were from disease progression. Median follow-up was 13.9 mo (range, 1.7–34.2). Confirmed ORR was 6.8% (95% CI: 1.43, 18.66). Confirmed PSA response rate was 4.5% and median time to PSA progression was 3.0 mo (95% CI: 2.8, 3.3). Median rPFS was 3.0 mo (95% CI: 2.8, 4.6) and median OS was 16.3 mo (95% CI: 10.9, 22.3). Changes in PD-L1 and CD8 IHC were consistent with the known mechanism of action of atezo, as were changes in alkaline phosphatase with radium. **Conclusions:** No dose-limiting toxicities, safety signals, or changes in serum biomarkers were observed beyond the known safety profiles of atezo and r-223. This Phase 1b study did not seem to show clinical benefit from combination tx. Ongoing subgroup and biomarker analyses may provide additional insights. Studies of PD-1/PD-L1 targeted therapies in combination with tumor-directed radiation in molecularly selected mCRPC pts are planned or underway. Clinical trial information: NCT02814669. Research Sponsor: F. Hoffmann-La Roche, Ltd.

TALAPRO-1: Phase II study of talazoparib (TALA) in patients (pts) with DNA damage repair alterations (DDRm) and metastatic castration-resistant prostate cancer (mCRPC) – updated interim analysis (IA). *First Author: Johann S. De Bono, The Royal Marsden Hospital and The Institute of Cancer Research, London, United Kingdom*

Background: PARP inhibitors (PARPi) show antitumor activity in mCRPC/DDRm pts treated with novel hormonal therapy (NHT). TALAPRO-1 is an open-label study evaluating TALA (potent PARP inhibitor/trapper) in men with mCRPC/DDRm. We report a planned IA (Dec 2019). **Methods:** TALAPRO-1 (NCT03148795) is enrolling pts (N $\approx$ 100) with measurable soft tissue disease, progressive mCRPC, and DDRm likely to sensitize to PARPi (*ATM*, *ATR*, *BRCA1/2*, *CHEK2*, *FANCA*, *MLH1*, *MRE11A*, *NBN*, *PALB2*, *RAD51C*), who received 1–2 chemotherapy regimens ($\geq$1 taxane-based) for metastatic disease and progressed on $\geq$1 NHT (enzalutamide/abiraterone acetate) given for mCRPC. DDRm are defined as known/likely pathogenic variants or homozygous deletions. Pts receive oral TALA 1 mg/day (moderate renal impairment 0.75 mg/day) until radiographic progression, unacceptable toxicity, consent withdrawal or death. Primary endpoint is objective response rate (ORR). Secondary endpoints: time to OR; response duration; PSA decrease $\geq$50%; circulating tumor cell (CTC) count conversion (to CTC = 0 and $<$5 per 7.5 mL blood); time to PSA progression; radiographic PFS (rPFS); overall survival; safety. A planned efficacy/safety IA was done when 60 pts with DDRm and measurable disease completed $\geq$6 months of TALA/no longer followed (DDR population [DDRp]). Radiographic responses are based on investigator assessments. **Results:** 113 pts received TALA (cutoff Dec 12, 2019); 75 pts were DDRp, had measurable disease, received $\geq$16 wk treatment, and were evaluable for ORR (54.7% *BRCA1/2*, 4.0% *PALB2*, 22.7% *ATM*; 18.7% other DDRm).All DDRp pts had prior docetaxel; 45.3% cabazitaxel. Confirmed ORR, rPFS, and composite response (investigator-assessed) in pts who received TALA for $\geq$16 weeks are in the table. Most common treatment-emergent adverse events: anemia (42.5%); nausea (32.7%). **Conclusions:** TALA monotherapy has encouraging antitumor activity in docetaxel-pretreated mCRPC pts with *BRCA1/2* alterations and was generally well tolerated. Clinical trial information: NCT03148795. Research Sponsor: Pfizer Inc.

Olaparib (O) in patients (pts) with prostate cancer with BRCA1/2 inactivating mutations: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Evan P. Pisick, Cancer Treatment Centers of America, Zion, IL*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Advanced prostate cancer (PC) pts with germline or somatic BRCA1/2 inactivating mutations treated with O are reported. **Methods:** Eligible pts had advanced PC, no remaining standard treatment (tx) options, measurable disease, ECOG Performance Status (PS) 0-2, and adequate organ function. Tumor genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts received O tablets or capsules dosed at 300 mg (n=24) or 400 mg (n=5), respectively, orally twice daily until disease progression. Simon 2-stage design tested the null disease control (DC) (objective response (OR) or stable disease at 16+ weeks (wks) (SD16+) according to RECIST) rate of 15% vs. 35% (power = 0.85; α = 0.10). If $\geq$2 of 10 pts in stage 1 have DC, 18 more pts are enrolled. If $\geq$7 of 28 pts have DC, the tx is worthy of further study. Pts had radiographic evaluations at 8 and 16 wks and then every 12 wks. Secondary endpoints are progression-free survival (PFS), overall survival (OS) and safety. **Results:** 29 pts with *BRCA1/2* inactivating mutations were enrolled from Aug 2016 to Jul 2019; 4 were identified as ineligible after enrollment due to bone only disease and removed from analyses. Demographics and investigator-reported outcomes are summarized in the Table. Nine pts with OR and 8 with SD16+ were observed for DC and OR rates of 68% (90% CI: 53% - 77%) and 36% (95% CI: 18% - 57%), respectively. Six pts had at least one grade 3 AE or SAE at least possibly related to O including anemia, aspiration, dehydration, diabetic ketoacidosis, fatigue, and neutropenia. **Conclusions:** Monotherapy with O showed anti-tumor activity in heavily pre-treated PC pts with germline (1/2 pts with OR or SD16+) or somatic (16/23 pts with OR or SD16+) *BRCA1/2* inactivating mutations. These findings extend results from recent trials of O in advanced prostate cancer pts with germline only BRCA1/2 mutations. Clinical trial information: NCT02693535. Research Sponsor: AstraZeneca, Pharmaceutical/Biotech Company.

Comparison of germline mutations in African American and Caucasian men with metastatic prostate cancer. *First Author: Elisa Marie Ledet, Tulane University Cancer Center, New Orleans, LA*

Background: The relevance of germline mutations in metastatic prostate cancer is well established; however, comparison of germline genetics in African American (AA) versus Caucasian (CA) men with metastatic prostate cancer (PCa) is limited. **Methods:** Germline data from self-identified AA and CA metastatic PCa patients (pts) were collected from 5 academic cancer centers. Various commercial cancer-specific germline testing panels were used to evaluate 12-86 genes. Pathogenic (P) or likely pathogenic (LP) mutations, and variants of unknown significance (VUS), were reported according to ACMG guidelines. Self-reported family history (FH) was annotated for 99% of pts. Statistical analyses included Chi-squared and Fischer's exact tests. **Results:** A total of 821 metastatic PCa pts were assessed: 152 AAs and 669 CAs. For P/LP alterations, AAs had a frequency of 11.2% (17/152) as compared to a frequency of 14.6% (98/669) in CAs (p = 0.302). AA pts were more likely to have a VUS than CA pts, 61% vs 43% respectively (OR = 2.09, 95%CI [1.45, 2.99], p $<$ 0.001). BRCA mutations were similar between races, but AA were more likely to have a BRCA1 P/LP alteration (OR = 6.00, 95% CI [1.33, 27.09], p = 0.025). AA pts were less likely to have a P/LP alteration in a non-BRCA gene (OR = 0.34, 95% CI [0.15, 0.80], p = 0.013). Among DNA repair genes, there were no significant difference between AA and CA pts (p = 0.574); however, there was a trend toward AA pts having fewer P/LP alteration in a non-BRCA DNA repair genes (OR = 0.26, 95% CI [0.06, 1.08], p = 0.071). In pts with $>$1 first degree relative (FDR) with ovarian cancer, P/LP germline alterations were more likely in CAs (OR = 2.33, 95% CI [1.05, 5.17], p = 0.043); but there were no significant differences in AAs (p = 0.098). Those with $>$2 FDRs with PCa were more likely to have a P/LP change in CAs (OR = 2.32, 95% CI [1.04, 5.15], p = 0.043), but there were no difference in AAs (p = 0.700). In pts with $\geq$2 FDRs with breast cancer, P/LP germline alterations were more likely in both AAs (OR = 9.36, 95% CI [1.72, 50.84], p = 0.019) and CAs (OR = 3.92, 95% CI [1.79, 8.59], p = 0.001). **Conclusions:** We did not observe a difference in the overall frequency of germline P/LP alterations between AA and CA men with metastatic PCa but VUSs were more common in AA men. These AA men have an overall frequency of BRCA mutations similar to CA men; however, BRCA1 mutations were more prevalent in these AAs. Non-BRCA P/LP mutations are significantly less frequent in AA pts. A positive family history of $>$2 FDRs with breast cancer was associated with P/LP alterations in both AA and CA pts. Research Sponsor: None.

5569 Poster Session (Board #150), Fri, 8:00 AM-11:00 AM

CARD: Overall survival (OS) analysis of patients with metastatic castration-resistant prostate cancer (mCRPC) receiving cabazitaxel versus abiraterone or enzalutamide. *First Author: Bertrand F. Tombal, Institut d Recherche Clinique, Université Catholique de Louvain, Brussels, Belgium*

Background: The CARD trial (NCT02485691) compared cabazitaxel vs. an androgen receptor targeted agent (ART; abiraterone/enzalutamide) in mCRPC previously treated with docetaxel and the alternative ART (abiraterone/enzalutamide), in any order. These post hoc analyses assessed OS from various time points and the impact of prognostic factors. **Methods:** Patients with mCRPC previously treated with docetaxel and progressing ≤ 12 months on prior abiraterone/enzalutamide were randomized 1:1 to cabazitaxel (25 mg/m^2 IV Q3W + daily prednisone + prophylactic G-CSF) vs. abiraterone (1000 mg PO + daily prednisone) or enzalutamide (160 mg PO). OS was calculated from date of diagnosis of metastatic disease, date of mCRPC, and start of 1st, 2nd or 3rd life-extending therapy (LET). A stratified multivariate Cox regression analysis assessed the impact of 14 prognostic factors on OS using a stepwise model selection approach with a significance level of 0.10 for entry into the model and 0.05 for removal. **Results:** In the CARD study (N = 255), median OS was longer with cabazitaxel vs. abiraterone/enzalutamide (13.6 vs 11.0 months; HR 0.64, 95% CI 0.46–0.89; p = 0.008). OS was numerically improved for cabazitaxel vs. abiraterone/enzalutamide when assessed from the time of diagnosis of metastatic disease or mCRPC, or from start of 1st or 2nd LET (Table). In the multivariate analysis, low hemoglobin, high baseline neutrophil to lymphocyte ratio, and high PSA values at baseline were associated with worse OS. In presence of these factors, the OS benefit observed with cabazitaxel versus abiraterone/enzalutamide remained significant (HR 0.63, 95% CI 0.42–0.94, p = 0.022). **Conclusions:** Cabazitaxel numerically improved OS vs. abiraterone/enzalutamide in patients with mCRPC previously treated with docetaxel and the alternative ART (abiraterone/enzalutamide), whatever the time point considered. The robustness of this OS benefit was confirmed by stratified multivariate analysis. Sanofi funded. Clinical trial information: NCT02485691. Research Sponsor: Sanofi.

Survival outcome in patients with metastatic castration-resistant prostate cancer according to first-line treatment. *First Author: Marine Gross-Goupil, University Hospital, Bordeaux, France*

Background: Therapeutic strategy in metastatic castration-resistant prostate cancer (mCRPC) has evolved significantly with the introduction of abiraterone acetate in association with prednisone/prednisolone in first-line treatment in December 2012. This work aimed to compare the effectiveness of abiraterone acetate and docetaxel as first-line treatments for mCRPC, in real-life setting. **Methods:** Patients with mCRPC were identified in the main scheme of the National Healthcare System database (SNDS), which covers about 86% of the French population, and capturing all reimbursed healthcare expenditures and hospital discharge summaries. Those initiating docetaxel or abiraterone acetate in 1st line in 2014 were included and 1:1 matched on the previous prostate cancer stage before mCRPC status, the delay from the date of initial diagnosis and a high-dimensional propensity score. The 36-month overall survival and the 36-month discontinuation-free survival (i.e. survival time until treatment switch or death) were compared using Cox proportional hazards risk model. **Results:** In 2014, out of the 12,951 patients with prevalent mCRPC, 1,214 initiated docetaxel in 1st line and 2 444 initiated abiraterone. A total of 716 patients per group were matched with good comparability (C-statistic = 0.6). The median duration of docetaxel–defined as the time between the first and the last infusion–was 7.3 months with a median of 6 infusions. The median duration of abiraterone acetate–corresponding to the period covered by the dispensed drug–was 9.1 months. Near 70% of the docetaxel and 62% of the abiraterone acetate patients received a 2nd line of treatment. Results related to the main survival outcomes are presented in the table below. **Conclusions:** First-line treatment with abiraterone acetate in mCRPC patients results in a better 36-month overall survival and discontinuation-free survival compared to docetaxel in real-life setting. Research Sponsor: JANSSEN.

	Docetaxel n=716	Abiraterone acetate n=716	*p-value*
Overall Survival			
36-month survival probability, % [95%CI]	27.9 [25.0 – 31.2]	34.6 [31.5 – 38.1]	<0.003

5571 Poster Session (Board #152), Fri, 8:00 AM-11:00 AM

Clinical significance of CTC enumeration on the Epic Sciences platform in metastatic castration-resistant prostate cancer (mCRPC) patients treated with AR signaling inhibitors (ARSi). *First Author: Joseph Schonhoft, Epic Sciences, Inc., San Diego, CA*

Background: Circulating Tumor Cell (CTC) number, enumerated using the analytically valid FDA cleared Cell Search (Menarini Silicon Biosystems) platform has been shown to be prognostic for survival pre- and post-therapy, and used as an aid to monitoring breast, colorectal and prostate cancers. The assay uses antibody-based capture and defines a CTC as an EpCAM+ and CD45- intact cell. In contrast, with the Epic sciences CTC detection platform red blood cells are first lysed and all nucleated cells deposited on pathology slides, fixed, and imaged. There is no affinity selection and CTCs for this analysis were defined *in silico* as any cytokeratin (CK)+, CD45- cell with an intact DAPI+ nucleus. Here we report the prognostic significance of the CK+ CTCs detected on the EPIC Sciences platform in mCRPC patients prior to treatment with an AR signaling inhibitor. **Methods:** A pre-treatment blood sample was collected from 181 unique patients with progressing mCRPC about to start an ARSI as 1st, 2nd or 3rd line therapy at MSKCC. CTCs were enumerated on the Epic Sciences platform and verified by a trained human technician. **Results:** At least 1 CTC was detected (median = 1, 0-711 CTCs/ml) in 134 (74%) of cases, with higher counts observed in patients with visceral or multiple osseous sites relative to those with lymph node only disease. Counts increased by line of therapy. The table shows the associated risk of death for CTCs modeled as a continuous variable. **Conclusions:** The results support the clinical validity of CTC number determined on the Epic Sciences platform as a significant baseline prognostic factor. In multivariate modeling CTC number was found to be the most significant blood-based predictor of poor OS with each doubling representing a 20% greater risk of death observed with adjustment for therapy line, LDH, PSA, and ALK. Research Sponsor: Epic Sciences, Other Government Agency.

Cox proportional hazards models for assessing the prognostic value of CTCs detected on the Epic Sciences platform with association to overall survival.

Model	PSA		CTC		CTC + PSA		ALK + LDH + PSA		ALK + LDH + PSA + CTC	
Continuous Blood Based Measurement	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P
CTC	1.4 (1.3, 1.6)	<0.0001	-	-	1.3 (1.2, 1.5)	<0.0001	-	-	1.2 (1.1, 1.4)	0.002
PSA	-	-	1.3 (1.2, 1.4)	< 0.0001	1.2 (1.1, 1.3)	0.0002	1.1 (1.0, 1.3)	0.0168	1.1 (1.0, 1.2)	0.064
ALK	-	-	-	-	-	-	1.3 (1, 1.6)	0.0614	1.2 (0.9, 1.6)	0.13
LDH	-	-	-	-	-	-	1.9 (1.4, 2.7)	0.0001	1.6 (1.1, 2.3)	0.012

Each continuous covariate was log2 transformed and all models adjust for line of therapy and patient age.

5572 Poster Session (Board #153), Fri, 8:00 AM-11:00 AM

Circulating tumor cells (CTCs) with small-cell like pathology are prevalent in metastatic castration-resistant prostate cancer (mCRPC) and show selective pharmacodynamic reductions in patients treated with platinum but not ARSI or taxane. *First Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The increasing availability and earlier use of life prolonging drugs targeting the androgen receptor signaling axis (ARSI) has resulted in an increase in the frequency of late state tumors with "small cell/neuroendocrine (NESC) phenotypes" similar to small-cell lung cancer (SCLC). Definitive pathologic criteria to diagnose the "entity" are lacking, and the eligibility criteria across trials are inconsistent, limiting the ability to relate outcomes between studies. We hypothesized that an analytically valid assay for a rigorously defined "small-cell CTC" phenotype might serve as a unifying biomarker for the presence of NESC-like tumors in an individual for use in clinical trials. **Methods:** Using the WHO guidelines for small-cell diagnosis in tissue as reference, we defined an equivalent set of single-cell CTC criteria for defining a CTC with small-cell histology: a small and circular CD45-, CK+ cell with high N/C ratio lacking detectable nucleoli. Small-cell subtype pharmacodynamic changes were studied in 233 patients with progressing mCRPC about to start an AR signaling inhibitor ARSi (N=111), taxane (N=89), or platinum (N=33). **Results:** CTCs with small-cell morphology had lower AR protein expression compared with non-small-cell CTCs (P<0.0001) and increased with therapy line. The small-cell CTC subtype decreased in number from baseline to on-therapy in patients treated with platinum but not in those treated with ARSi or taxane (Table). **Conclusions:** Digital pathology analysis of CTCs defined a CTC subtype consistent with that of small-cell carcinoma that were only reduced in number with platinum-based therapy. The tracking of CTC subtypes after treatment with different drug classes may help assess drug activity in heavily treated patients that often have heterogeneous disease that of which may not be captured using standard measures of response. Research Sponsor: Epic Sciences, Other Government Agency.

5573 Poster Session (Board #154), Fri, 8:00 AM-11:00 AM

Clinical outcomes and markers of treatment response in a randomized phase II study of androgen deprivation therapy with or without palbociclib in RB-intact metastatic hormone-sensitive prostate cancer (mHSPC). *First Author: Phillip Lee Palmbos, University of Michigan Rogel Cancer Center, Ann Arbor, MI*

Background: Targeted therapies based on tumor molecular markers are not currently used in mHSPC. Palbociclib, a CDK4/6 inhibitor, blocked proliferation and promoted G1 arrest in a Rb-and Cyclin D-dependent manner in preclinical models of HSPC. We hypothesized that co-targeting AR (ADT) and cell cycle (palbociclib) would improve outcomes in mHSPC pts. **Methods:** mHSPC pts with Rb intact tumors based on IHC of metastatic tumor biopsy were stratified and randomized (1:2) to Arm A: ADT or Arm B: ADT+ palbociclib (125mg 3 weeks on, 1 week off). Primary endpoint was confirmed PSA RR (≤ 4 ng/mL) after 28 weeks of therapy. Secondary endpoints included safety/tolerability, PFS, PSA and radiographic RR. Metastatic biopsy and primary tumors were subjected to whole exome and transcriptomic sequencing where available. CTC's were enumerated at various time points. **Results:** 72 eligible pts (median age 67 years, PSA 73ng/mL) with newly diagnosed mHSPC were registered and underwent biopsy. 97% retained RB expression (IHC). 62 pts were stratified by disease extent and early initiation of ADT, and randomized. 60 pts initiated therapy (Arm A: 20; Arm B: 40). Adverse events were reported previously. 80% of pts (Arm A: 16/20, Arm B: 32/40; p = 0.87) on both arms met primary PSA endpoint (≤4ng/mL at 28 weeks). PSA undetectable rate at 28 weeks was Arm A: 50% (10/20) and Arm B: 43% (17/40; p = 0.5). Measurable disease RR: Arm A: 89% and Arm B: 89%. 12-month biochemical PFS was Arm A 69% (95%CI: 44-85%), Arm B 74% (95%CI: 57-85%). 41 patients on trial underwent sequencing of metastatic biopsy and 10 patients had matched primary prostate tumor sequencing results. CCND1 amp, 8q gain, PTEN and KMT2C mutations were each observed in metastatic, but not paired prostate primary tumors. TP53, PIK3 pathway (PIK3CA, AKT1, PTEN) mutations and 8q gains were associated with reduced PSA PFS [HR (95%CI): 3.0 (1.2-7.2), p = 0.018; 3.2(1.03-10),p = 0.044; 4.96 (1.8-12), p = 0.001, respectively]. Pretreatment CTCs were associated with lower PSA CR (p = 0.04) and shorter PFS (12-month PFS: 58% vs. 86%, p = 0.031). **Conclusions:** A tissue based biomarker preselected trial is feasible in mHSPC. ADT + palbociclib did not impact outcomes. Pretreatment CTC counts, TP53 and PIK3 pathway mutations, and 8q gain may offer prognostic value in mHSPC. Support: Movember-PCF Challenge Award, Pfizer. Clinical trial information: NCT02059213. Research Sponsor: Movember-PCF Challenge Award, Pharmaceutical/Biotech Company.

5574 Poster Session (Board #155), Fri, 8:00 AM-11:00 AM

A blood-based multi-mRNA liquid biopsy with >90% accuracy for diagnosis and assessment of prostate cancers. *First Author: Kambiz Rahbar, University Hospital Münster, Münster, Germany*

Background: There are a paucity of blood-based biomarkers with clinical utility for prostate cancer (PCa). We developed a circulating mRNA (27-gene) prostate cancer signature to diagnose and manage PCa. **Methods:** Gene identification: Publicly available PCa transcriptome sets (n= 1,159 samples) were evaluated and compared with normal blood-based transcriptomes using gene co-expression network enrichment, differential expression and functional enrichment analyses to identify candidate markers. Gene expression evaluation: Seven PCA cell lines and two normal prostate epithelial lines were used to assess candidate genes. Marker genes were determined in PCa tumor tissue (n= 50) and validated in the TCGA-PRAD (n= 500) dataset. Blood gene expression: Set #I: PCA: n= 132, BPH: n= 44, controls n= 55. Set #II: n= 50 (biochemical recurrence [BCR]). We constructed an artificial intelligence PCa model using classification algorithm analyses. Scoring: normalized algorithmically analyzed gene expression (0 to 100), positive score >20. PSA: BPH (n= 44) and PCa (n= 132). Clinical score assessment: Surgical cohort: (n= 47), samples: pre-surgical and post: 1 week - 14 months. Statistics: Kruskal-Wallis, Pearson-correlation, Fisher's and AUROC analyses (Mean±SEM). **Results:** Transcriptomic analysis identified 27 candidates. Cell lines/tissue: Expression levels were significantly elevated ($p< 0.001$, 2.1-35.8-fold) in cell lines and PCa surgical samples. All 27 markers were confirmed in TCGA-PRAD samples (average TPM: 58 to 10,366). *Blood*: In Set#I, levels in PCa were 47±2 ($p< 0.0001$) compared to BPH (19±1) and controls (18±0.5); AUROC: 0.92 (BPH) and 0.94 (controls), with an accuracy of 85-88%, a sensitivity of 86% and specificities 82 and 93%. For PSA, the AUROC (PCa vs. BPH) was 0.51 (p= 0.88). PSA was positive in 86% of BPH and was > 10ng/ml in 30%. PSA was positive in 83% of PCa and > 10ng/ml in 40% (Fisher's p= 0.28). PSA accuracy (> 10ng/ml) was 48%. Levels in Set#II (BCR) were 44±3. ProstaTest-was positive in 48 (96%). Surgical cohort (n= 47): Prostatest accuracy 100% pre-surgery. Resection decreased levels (KW-statistic: 57.4, $p< 0.0001$) from 52±1 to 23.5±2. **Conclusions:** A 27-gene blood signature was developed for PCa that exhibited a diagnostic accuracy of 92%; significantly better than PSA (48%, $p< 0.0001$). Surgical resection significantly ($p< 0.0001$) decreased levels. Biochemical recurrence was accurately detected (96%). A multi-gene prostate cancer liquid biopsy is likely to have clinical utility in both diagnosis and monitoring of PCa. Research Sponsor: None.

5575 Poster Session (Board #156), Fri, 8:00 AM-11:00 AM

Osteonecrosis of the jaw (ONJ) in radium 223 (Ra223)-treated metastatic castration-resistant prostate cancer (mCRPC) patients (pts) with exposure to zoledronic acid and/or denosumab. *First Author: Yen Thi Kim Hong Cao, University of Nevada Las Vegas, Las Vegas, NV*

Background: Bone health agents (BHA) including denosumab, a monoclonal antibody, and Zoledronic acid (ZA), a bisphosphonate, are recommended for men with CRPC and bone metastases to prevent skeletal-related complications. ONJ occurs in about 5% of patients (pts) on BHA. The incidence of ONJ in pts treated with Ra223 and BHA remains unknown, particularly in those who receive sequential treatment of BHAs. Here we describe the rate of ONJ in a real-world setting in mCRPC pts treated with Ra223 in 3 groups: 1) denosumab alone, 2) ZA alone, and 3) sequential ZA /denosumab or vice versa. **Methods:** A retrospective analysis of a cohort of mCRPC pts with bone metastases who received Ra223. Follow-up was until date of death or last data entry. Chart inclusion criteria included patients who received Ra223 between November 2010 to August 2018 with documentations of data points. **Results:** A total of 177 pts received Ra223 between 11/2010 and 8/2018. Median age 73 at 1st Ra223 (range 40-93); Median PSA 15.8- at 1st Ra223 (range 0.1-1952); Demographics-AA-10, C-130, Asian-9, unspecified-28; Median Alk Phos 95 at 1st Ra233 (range 25-1515). 93 % (164/177) received BHA. Of the 164 who received BHA, 45% (73/164) received denosumab only, 37% (61/164) received ZA only, and 18% (30/164) received sequential treatment. ONJ developed in 9.7% (16/164) of all patients on BHA. Denosumab alone caused ONJ in 7 of 73 pts (9.6%). ZA alone caused ONJ in 6 of 61 pts (9.8%). ONJ occurred in 3 of 30 pts (10%) in the sequential group. The median number of doses of BHA before development of ONJ was 10 with denosumab, 20 with ZA, and 19.5 (denosumab) and 22 (ZA) in the sequential group. **Conclusions:** In patients treated with Ra223 and a BHA, the rate of ONJ is 9.7%. The rate of ONJ was similar in groups treated with denosumab alone, ZA alone, and sequential treatment of ZA and denosumab However, ONJ developed more quickly in patients on denosumab. We conclude that the risk of ONJ is increased in patients treated with Ra223 and BHA. ZA or sequential therapy appears to delay time to onset of ONJ compared to denosumab. Clinicians should be mindful of the toxic synergy between Ra223 and BHA. ZA may be the preferred BHA partner with Ra223. Research Sponsor: None.

5576 Poster Session (Board #157), Fri, 8:00 AM-11:00 AM

RESTORE: A single-arm, open-label phase II trial of bipolar androgen therapy (BAT) in men with metastatic castration resistant prostate cancer (mCRPC)—A comparison of post-abiraterone (Abi) versus post-enzalutamide (Enza) patients (Pts). *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: A paradoxical inhibition of cell growth has been observed in both androgen-sensitive and castration resistant prostate cancer cell lines following the addition of high-dose testosterone.We have conducted several clinical trials investigating a mode of supraphysiologic testosterone therapy termed, BAT, in which testosterone levels are rapidly driven to the supraphysiologic range followed by a return to near-castrate levels over 28-day treatment cycles with favorable results. We previously reported the efficacy of BAT in mCRPC pts that were progressing on enza. In this study, we compared the effect of BAT in mCRPC pts whose last therapy was abi vs. enza. In addition, we examined the benefit of abi or enza rechallenge after progression on BAT. **Methods:** 59 mCRPC pts (n = 29 post abi; n = 30 post enza) were enrolled and received at lease one dose of BAT monotherapy, 400mg intramuscularly every 28 days. After clinical or radiographic progression on BAT, pts were rechallenged with the AR targeted therapy to which they were most recently resistant. The co-primary endpoints were a 50% decline in PSA from baseline (PSA50) for BAT and for enza/abi rechallenge. **Results:** 5/29 (17.2%) of post-abi pts compared to 9/30 (30%) in the post enza group achieved a PSA50 response (P = 0.36). Post BAT rechallenge with abi (n = 19) or enza (n = 22) resulted in a PSA50 response rate of 15.8% (n = 3) and 68.2% (n = 15), respectively (P = 0.001). The total duration of benefit (i.e. PFS on BAT + PFS on rechallenge = "PFS2") was significantly longer in the post enza vs. post-abi patients (Median PFS2: 12.75 vs. 8.125 months; P = 0.04. Lastly, AR-V7 negative (n = 42) pts has a significantly longer median PFS2 compared to AR-V7 positive (n = 10) pts. (10.3 vs. 7.1 months, P = 0.005). **Conclusions:** Our data suggest that BAT may be more effective at resensitizing mCRPC to direct AR antagonists (i.e. enza) compared to abi. Detection of AR-V7 portended a worse outcome on BAT/rechallenge. Further clinical study is warranted. Clinical trial information: NCT02090114. Research Sponsor: U.S. National Institutes of Health.

	Post Abi N = 29	Post Enza N = 30	P-value
BAT PSA50 RR	17.2% (N = 5/29)	30.0% (N = 9/30)	0.360
BAT Objective RR	28.6% (N = 2/7)	50.0% (N = 6/12)	0.361
Rechallenge PSA50 RR	15.8% (N = 3/19)	68.2% (N = 15/22)	0.001

5577 Poster Session (Board #158), Fri, 8:00 AM-11:00 AM

Radiographic paradoxical response in patients with metastatic castrate-resistant prostate cancer (mCRPC) undergoing treatment with second-generation hormone therapy (second-HT). *First Author: Jamal Alamiri, Mayo Clinic Rochester, Rochester, MN*

Background: Prostate specific antigen (PSA) has well-recognized limitations as a marker for treatment response and disease progression. A post hoc analysis of the PREVAIL trial reported 24.5% of chemotherapy naïve mCRPC patients on enzalutamide had radiographic progression on conventional imaging with non-rising PSA. In this study, we sought to retrospectively compare PSA levels with C-11 choline positron emission tomography/computed tomography (PET/CT) images in patients with m-CRPC on 2nd-HT with prior use of chemotherapy. **Methods:** We identified 123 patients with mCRPC on 2nd-HT following prior use of docetaxel chemotherapy (Abiraterone, n = 106; Enzalutamide, n = 17). Patients underwent serial PSA testing and C-11 choline PET/ CTs every 3–6 months. Disease progression was defined by the increase in blood pool corrected maximum standardized uptake value (SUVmax) of the index lesion on C-11 choline PET/CT scan. Suspicious lesions were confirmed by biopsy and/or conventional imaging. **Results:** Approximately 43% (n = 53) of patients had radiographic disease progression while on 2nd-HT. At time of radiographic progression, 60.4% of patients showed a parallel rise in PSA (Group-A), while 39.6% showed a paradoxical response; defined as radiographic progression with stable or down-trending PSA (Group-B). Median PSA at time of progression was 3.1 ng/ml for Group-A, and 1.3 ng/ml for Group-B (p-value = 0.0176). Median SUVmax was the same (4.9 Group-A, 4.6 Group-B; p-value = 0.6072). Bone-predominance progression was more significant in Group-B (90%) versus Group-A (65%) (p-value = 0.0309). The median time for radiographic progression was 9.5 months versus 3.9 months for Group-A and Group-B, respectively (Log-Rank = 0.0063). **Conclusions:** Metabolic imaging is a useful tool that should complement PSA in the evaluation of treatment response and disease progression in mCRPC patients on 2nd-HT, especially considering the paradoxical response observed in our data. Research Sponsor: None.

5578 Poster Session (Board #159), Fri, 8:00 AM-11:00 AM

Quality of life (QOL) for the treatment sequence of abiraterone acetate plus prednisone (AAP) followed by enzalutamide (ENZ) versus the opposite sequence for metastatic castration-resistant prostate cancer (mCRPC): Results from a phase II randomized clinical trial. *First Author: Daniel J Khalaf, BC Cancer Agency-Vancouver Centre, Vancouver, BC, Canada*

Background: A randomized cross-over phase II trial (Lancet Oncol 20(12):1730, 2019) showed the sequence of AAP followed by ENZ is associated with a better time to PSA progression compared with the opposite sequence and superior 2nd line activity of ENZ. It is unknown whether one treatment sequence is associated with better QOL than the other. **Methods:** 202 Patients were randomized (1:1) to receive either AAP followed by ENZ at PSA progression (arm A) or the opposite sequence of ENZ followed by AAP (arm B). FACT-P questionnaires were completed at baseline, cross-over and every 4 weeks on treatment. Time to QOL deterioration (TTQOLD) for the treatment sequence was determined from start of 1st line treatment to first questionnaire with a clinically meaningful decrease from baseline and compared between arms using the log-rank test. TTQOLD was also determined for 1st line and 2nd line separately. The proportion of patients with QOL deterioration for total FACT-P score and FACT-P subscores from baseline to week 12 of 1st and 2nd line treatment was compared between arms using X^2 test. **Results:** Median follow-up for 1st and 2nd line and whole sequence were 9.3, 6.6 and 22.0 months (mos) respectively and questionnaire completion rate was 81%. TTQOLD for total FACT-P score for the whole sequence for arm A vs B was 10.5 mo (95% CI 5.0-15.5) vs 10.8 mo (5.5-13.1), p = 0.74. For 1st-line AAP vs ENZ, median TTQOLD was 15.5 mo (5.5-21.2) vs 11.0 (5.5-13.3) respectively (p = 0.23). For 2nd line ENZ vs ABI, median TTQOLD was 3.7 mo (2.0-5.4) vs 5.8 (2.8-12.1), p = 0.13. There was a higher rate of deterioration in physical well-being (PWB) for 1st line ENZ (arm B) and 2nd line ENZ (arm A) (Table). **Conclusions:** There was no difference in TTQOLD between the two treatment sequences of AAP and ENZ. Although treatment with second line ENZ has been associated with greater anti-cancer effects, ENZ was associated worse PWB QOL scores. Clinical trial information: NCT02125357. Research Sponsor: Canadian Cancer Society Research Institute, Other Foundation, Pharmaceutical/Biotech Company.

Clinically significant deterioration at 12 weeks (%).

5579 Poster Session (Board #160), Fri, 8:00 AM-11:00 AM

Association between BRCA2 status and histologic variants (intraductal [IDC] and cribriform [CRIB] histology) in prostate cancer (PC). *First Author: Elena Castro, Hospitales Virgen de la Victoria y Regional de Málaga, Instituto de Investigación Biomédica de Málaga, Málaga, Spain*

Background: IDC histology in PC has been suggested to associate with germline *BRCA2* mutations *(gBRCA2)* in small series, leading to the potential recommendation of genetic testing for all PC patients with IDC in the primary tumor. **Methods:** We conducted a case-control study in which primary PC from 58 germline *BRCA2* mutation carriers (*gBRCA2*) and 116 from non-carriers (NC) were matched 1:2 by Gleason score and specimen type (core biopsy/prostatectomy). Samples were independently reviewed by two expert pathologists blinded to genetic status who established the presence of IDC and/or CRIB morphology with supportive immunohistochemical stains in a subset of cases. Next-generation sequencing, aCGH and/or FISH were used to assess for somatic mono-/bi-allelic *BRCA2* alterations. PTEN protein loss was determined by IHC, and *TMPRSS2-ERG* was detected by FISH/qRT-PCR. Chi-square tests were used to compare the frequency of IDC and cribriform histology in *gBRCA2* vs NC, as well as to assess the associations with other variables. Logistic regression models were built to identify independent factors associated with IDC and CRIB histology. **Results:** *gBRCA2* cases were younger at diagnosis (median 61.3 vs 64, $p < 0.01$) and had T3-4 disease more often than NC cases (31% vs 10.5%, $p < 0.01$), but the two groups did not differ in any other clinical-pathologic characteristics. After independent histopathological review, 79 cases demonstrated IDC histology and 81 had CRIB histology. No differences in the prevalence of IDC (50% NC vs 36% *gBRCA2*, p = 0.09) or CRIB (43% NC vs 53% *gBRCA2*, p = 0.20) patterns were observed. The probability of IDC was higher in PC with bi-allelic *BRCA2* alterations (OR 5.1, 95%CI 2.1-12.6), PTEN loss (OR 5.1, 95% CI 1.9-13.5) or both (OR 23.0, 95%CI 4.9-107.2) compared to those without these alterations. Bi-allelic *BRCA2* alteration was also associated with higher probability of CRIB histology (OR 7.2, 95%CI 3.1-16.4). *TMPRSS2-ERG* fusions were not associated with IDC or CRIB histology. MVA confirmed the independent association of bi-allelic *BRCA2* alteration ($p < 0.01$) and PTEN loss ($p < 0.01$) with IDC histology. Bi-allelic *BRCA2* alteration ($p < 0.01$) and Gleason >8 ($p < 0.01$) were independent risk factors for CRIB histology. **Conclusions:** Primary PC with bi-allelic *BRCA2* alterations was significantly associated with IDC and CRIB histology, independent of other clinical-pathologic factors (while *gBRCA2* status alone was not). PTEN loss in primary PC was also independently associated with IDC, but not CRIB, histology. Research Sponsor: Prostate Cancer Foundation; Instituto de Salud Carlos III.

5580 Poster Session (Board #161), Fri, 8:00 AM-11:00 AM

Obesity and metabolic syndrome correlate with a higher risk of biochemical recurrence in high risk and intermediate risk prostate cancer patients who underwent robotic-assisted laparoscopic prostatectomy. *First Author: Shifeng Mao, Allegheny Health Network Cancer Institute, Pittsburgh, PA*

Background: Obesity and metabolic syndrome (MS) is prevalent in our society, and have been linked to a higher incidence of prostate cancer (PCa). The relationship of obesity or MS and cancer control has yielded mixed results in previous studies. We examined the correlation between the incidence of biochemical recurrence (BCR) with MS and BMI in a cohort of patients with PCa who underwent robotic-assisted laparoscopic prostatectomy (RALP). **Methods:** A retrospective study of patients who underwent RALP at a single center from 2007 to 2015 was conducted. Parameters including preoperative BMI, fasting glucose, lipid profile, blood pressure, PSA, Gleason score, pathologic stage, time to BCR, and surgical margin status were analyzed. Patients were categorized in high (HR), intermediate (IR), and low-risk (LR) groups based on the National Comprehensive Cancer Network (NCCN) guidelines. WHO classification was used for MS criteria, and BCR was defined as two consecutive postoperative PSA volume of $\geq$ 0.2 ng/mL. Obesity is defined as BMI $\geq$30 kg/m^2. **Results:** A total of 726 patients with 189 in HR, 471 in IR and 66 patients in LR groups were included in this study with the median age of 59 (interquartile range [IQR] 55-64) years old. The median follow-up from surgery was 38 (IQR 22-46) months. More obese patients were found in the HR group compared to IR/LR group (46.5% vs. 33.1%, $p<0.01$). There were also more patients with MS in the HR group compared to IR/LR group (36.5% vs. 12.0%, $p<0.01$). Obese patients had a higher rate of BCR across risk groups in comparison to non-obese patients 32.1% vs. 15.4% ($P<0.001$), specifically 68% vs. 40%($p<0.01$) in HR group and 21.3% vs. 12.7% (p=0.035) in the IR group. Similarly, patients with MS had a higher rate of BCR in HR and IR groups in comparison to the patients without MS, 39.1% vs. 18.7% ($P<0.01$); specifically, 67.7% vs. 42.2% ($p<0.01$) in HR and 29% vs. 11.6% ($p<0.01$) in the IR group. No correlation between MS or obesity and BCR was observed in LR group. There was no statistically significant difference in the positive surgical margin rate between obese and non-obese cohorts in each risk group. **Conclusions:** Among HR and IR-PCa patietns who underwent RALP, both obesity and MS correlate with increased risk of BCR. There were significantly more obesity and MS in HR-PCa patients, suggesting a potential pathophysiologic interplay between obesity or MS and cancer progression. 5582 Poster Session (Board #163), Fri, 8:00 AM-11:00 AM

Oncological outcomes of 356 patients undergoing salvage focal ablative HIFU or cryotherapy following radiation failure. *First Author: Deepika Reddy, Imperial College London, London, United Kingdom*

Background: Patients that have previously failed radiotherapy for prostate cancer is usually limited to systemic therapy due to morbidity from salvage prostatectomy. We reviewed the outcomes following focal salvage ablative therapy with HIFU or cryotherapy within the UK's HEAT and ICE registries. **Methods:** 356 consecutive patients underwent focal ablative treatment after initial radiation treatment failure (28/1/2004-1/10/2019, 194 (54.5%) underwent HIFU (posterior recurrence) and 162 (45.5%) underwent cryotherapy (mostly anterior or T3b). Primary outcome was failure-free survival (FFS) defined as no systemic therapy, whole-gland treatment, metastases or prostate cancer-specific death. Secondary outcomes were adverse events and overall survival. **Results:** Median (IQR) age was 69years (65-73) and PSA (IQR) was 4.0ng/ml (1-7-7.2). Overall median (IQR) follow-up was 41.3 months (21.4-58.5). Quadrant ablation was performed in 128 (36.0%), hemi-ablation performed in 64 (18.0%), hockey-stick in 5 (1.4%) and 159 (43.8%) had unknown ablative patterns. Due to histological or MRI proven recurrence/residual disease, 31 (8.7%) underwent further focal salvage re-treatment. FFS (95%CI) at 3 and 6 years were 81% (76-87%) and 75% (68-83%) respectively. Median (IQR) time to failure was 15.5 months (19.7). Overall survival (95%CI) at 3 and 6 years were 97% (95-100%) and 88% (81-96%) respectively. Prostate-specific mortality was 2.8%. Overall 3 (0.8%) patients were managed for fistula formation, 16 (4.5%) were treated for UTIs. **Conclusions:** Salvage focal ablative therapy for radio-recurrent prostate cancer is safe and provides good short to medium-term oncological control. The FORECAST study is awaited to further determine oncological outcomes in this cohort. Research Sponsor: None.

5583 Poster Session (Board #164), Fri, 8:00 AM-11:00 AM

Cost-effectiveness of novel antiandrogens (AAs) for treatment of nonmetastatic castrate-resistant prostate cancer (nmCRPC). *First Author: Irbaz Bin Riaz, Mayo Clinic, Rochester, MN*

Background: FDA has approved three novel AAs [Apalutamide(A), Darolutamide(D) and Enzalutamide(E)] in combination with Androgen deprivation therapy (ADT) for treatment of (nmCRPC) patients (pts). We report the cost-effectiveness of these drugs from the US perspective to help facilitate the choice of these agents for clinical practice. **Methods:** A life time Markov state-transition model was constructed with three health states (Metastasis-Free Survival[MFS], Metastatic disease, and Death) to compare cost-effectiveness of AA therapies for treatment of nmCRPC based on US healthcare payer perspective. A network meta-analysis of MFS and OS was conducted due to the lack of head to head trials. An approximation of the original individual-level patient time-to-event data were derived from digitized Kaplan-Meier curves for OS and MFS. Weibull distributions was selected as the best fitted model fitted and extrapolated as per the NICE decision support unit recommendations. Medication costs were based on wholesale acquisition cost. Adverse event (AE) grades 3/4 management costs were incorporated in the model. Discount rate of 3% per year was applied to costs and effects. Life years (LYs) and quality adjusted life years (QALYs) for each treatment as well as the incremental cost effectiveness (ICER) and cost utility (ICUR) ratios were estimated. Base case analyses (BCA) and probabilistic sensitivity analyses (PSA) were estimated. **Results:** The table summarizes the results form BCA analyses. A+ADT offers best gain in LYs (8.37yrs) and QALYs (5.30 yrs) but at higher cost. **Conclusions:** Apalutamide was associated with gains in LYs and QALYs traded off with higher lifetime cost relative to other AA alternatives. ADT was associated with lower gains in LYs and QALYs traded off with lower lifetime cost relative to other alternatives. Based on a $150,000/QALY threshold pay off, A+ADT is likely more cost effective compared to E+ADT or ADT alone; while E+ ADT may be more cost effective compared to D+ ADT. Research Sponsor: None.

Base case analyses for MFSLY and QALY.

Treatment	Cost	LY	QALY
Apalutamide	$512,620	8.37	5.30
Enzalutamide	$458,640	6.99	3.05
Darolutamide	$379,932	7.49	4.68
ADT	$187,264	6.48	3.07
Incremental Cost Effectiveness Ratio (ICER)/Incremental Cost Utility Ratio (ICUR)			
Apalutamide	$39,116	$150,782	$172,146
$23,991	Enzalutamide	$157,416	$532,110
$214,013	$48,287	Darolutamide	$190,760
$145,900	$13,568,800	$119,670	ADT

Short-term adjuvant versus neoadjuvant hormone therapy in localized prostate cancer: A pooled individual patient analysis of two phase III trials. *First Author: Daniel Eidelberg Spratt, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The timing of systemic therapy in relation to radiotherapy (RT) is important in most malignancies. In contrast, androgen deprivation therapy (ADT) has largely been investigated in relation to its duration rather than its sequencing with RT. Herein, we conduct the first combined individual patient analysis of two phase III randomized trials to determine the optimal timing of ADT with RT in localized prostate cancer (PCa). **Methods:** Individual patient data was obtained from the Malone et al trial (JCO 2019), which randomized patients to receive neoadjuvant/concurrent or concurrent/adjuvant ADT for 6 months with prostate only RT. This was combined with the prostate only RT arms of RTOG 9413 that randomized patients to 4 months of neoadjuvant/concurrent or adjuvant ADT. The neoadjuvant/concurrent arms of both trials were combined into the "neoadjuvant" group, and the concurrent/adjuvant (Malone) and adjuvant arm (RTOG 9413) were combined in the "adjuvant" group. The Kaplan-Meier method was used to estimate overall survival (OS) and progression-free survival (PFS). Cumulative incidence of distant metastasis (DM), PCa-specific mortality (PCSM) and biochemical failure (BF) were calculated using the Fine-Gray method with non-PCa deaths as competing events. Late genitourinary (GU) and gastrointestinal (GI) toxicity are also reported. **Results:** The median follow-up was 14.9 years (yrs) and 1065 patients were included (n=531 neoadjuvant, 534 adjuvant). Groups were well balanced for all baseline characteristics. Adjuvant ADT was superior to neoadjuvant ADT in terms of BF (15yr: 33% vs 43%, HR: 1.37 (95%CI: 1.12-1.68), p=0.002), DM (15yr: 12% vs 18%, HR: 1.40 (95%CI: 1.00-1.95), p=0.04), and PFS (15yr: 36% vs 29%, HR: 1.25 (95%CI: 1.07-1.47), p=0.01). Adjuvant ADT yielded lower PCSM (15yr: 15% vs 20%, HR: 1.29 (95%CI: 0.95-1.75), p=0.10), but did not reach statistical significance. This approached statistical significance in high risk PCa (HR 1.39 (95%CI 1.00-1.93), p=0.053). OS was not significantly different between arms (15yr: 39% vs 34%, HR: 1.11 (95%CI: 0.95-1.30), p=0.20). There was no significant difference in either late grade $\geq$3 GI (p=0.21) or GU (p=0.98) toxicity. **Conclusions:** We demonstrate for the first time that sequencing of ADT with RT significantly impacts long-term oncologic outcomes in localized PCa, favoring an adjuvant rather than neoadjuvant approach, without increasing late toxicity. This data has important implications to ongoing and future clinical trial design. Clinical trial information: NCT00769548. Research Sponsor: Prostate Cancer Foundation.

5585 Poster Session (Board #166), Fri, 8:00 AM-11:00 AM

Treatment patterns and outcomes of patients with penile squamous-cell carcinoma (PSCC) undergoing inguinal lymph node dissection (ILND): An analysis of a multicenter contemporary database. *First Author: Marco Bandini, Vita-Salute San Raffaele University, Milan, Italy*

Background: PSCC is a rare tumor and the administration of guidelines-based therapies is still problematic in real-world practice. Survival outcomes remain suboptimal in patients (pts) with ILN involvement. Multinational analyses of real-world patterns are needed. **Methods:** Within an international, multicenter database of 965 PSCC pts who received ILND from 1980-2019, 630 had complete information for the variables of interest, from USA (N=81), Europe (EU, N=355), South America (SA, N=90), and China (Ch, N=104). Descriptive analyses according to geographical and ethnicity/race distribution were made. Comparisons of outcomes were made with Kaplan-Meier analyses and corresponding logrank tests. **Results:** Median age at diagnosis was 59 yrs, with no differences worldwide and according to ethnicity/race. Pts from SA presented with more advanced cT-stage (cT3-4: 26.7% vs. 17.3% USA vs. 7.6% EU) while EU pts presented with more advanced cN-stage (cN3: 14.9% vs. 11% USA vs. 7.8% SA vs. 5.8% Ch) as well as pathological (p)N-stage: pN3 pts were 53% in EU, 33.3% in USA, 20% in SA, and 18.3% in Ch. Perioperative chemotherapy (pCT) was more frequently administered in EU (53.8%) vs. USA (34.6%) SA (5.6%) Ch (7.7%). cT-stage was more frequently advanced in black pts (cT3-4: 33.3% vs. 12% Caucasian, 6.2% Hispanic/latino, 0% Asian) and the same was for cN-stage (cN3: 25% in black, 13% in Caucasian, 6.2% in Hispanic/latino, 6% in Asian). Conversely, pN3 pts were more frequently Caucasian (45.6%) vs. black (25%), Hispanic/latino (19%), and Asian (18%). pCT was more frequently administered in Caucasian pts (45%) vs. black (8.3%), Hispanic/latino (0), and Asian (8%). No significant differences in overall survival (OS) were observed according to geographical region or ethnicity/race, in the total pts and in the subgroups according to cT, cN, pN-stages and pCT. Median OS after pCT and ILND was 95 months. Bilateral ILN involvement was equally observed regardless of geographical region and ethnicity/race. In the total population, pCT significantly prolonged OS in pts with bilateral ILN (p=0.04), but not in pts with pelvic LN. **Conclusions:** Treatment patterns for PSCC undergoing ILND remain heterogeneous worldwide, and adherence to guidelines is seemingly poor. However, long-term outcomes with pCT remain uniformly suboptimal with $<$50% pts alive at 10 yrs. Further collaborative efforts are needed in this orphan disease to harmonize the therapeutic paradigm. Research Sponsor: Fondazione IRCCS Istituto Nazionale dei Tumori.

TPS5586 **Poster Session (Board #167), Fri, 8:00 AM-11:00 AM**

A phase II randomized trial of RAdium-223 dichloride and SABR versus SABR for oligomEtastatic prostate caNcerS (RAVENS). *First Author: Matthew Pierre Deek, Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins Hospital, Baltimore, MD*

Background: Metastasis directed therapy (MDT) is able to prolong progression free survival (PFS) and forestall initiation of androgen deprivation therapy (ADT) in men with hormone-sensitive, oligometastatic prostate cancer (HSOPCa) compared to observation. While MDT appears to be effective in HSOPCa, a large percentage of men will have disease recurrence. Patterns of failure demonstrate patients tend to recur in the bone following MDT, raising the question of subclinically-apparent osseous disease. Radium-223 dichloride is a radiopharmaceutical with structural similarity to calcium, allowing it to be taken up by bone where it emits alpha particles, and therefore might have utility in the treatment of micrometastatic osseous disease. Therefore, the primary goal of the phase II RAVENS trial is to evaluate the efficacy of Stereotactic ablative radiation (SABR) + radium-223 dichloride in prolonging PFS in men with HSOPCa. **Methods:** Patients with HSOPCa and 3 or less metastases with at least 1 bone metastasis (by conventional imaging) will be randomized 1:1 to SABR alone vs. SABR + radium-223 dichloride. Eligibility criteria include PSA doubling time of < 15 months and ECOG performance status of < 2. Patients cannot be on ADT and must have normal testosterone levels at the time of randomization. Patients randomized to the combination arm will receive six doses of Radium-223 dichloride at four week intervals. A sample size using a 1:1 randomization scheme of 30 patients per arm will provide 80% power to detect an increase of median PFS from 10 months to 20 months with type I error = 0.1, using a one-sided log-rank test. To account for 5% early drop out, we will randomize a total of 64 patients (32 per arm). The primary end point is PFS with a primary hypothesis that SABR + radium-223 dichloride will increase median PFS from 10 months in the SABR arm to 20 months in the SABR + radium-223 dichloride arm. Progression is a composite endpoint including PSA progression per Prostate Cancer Working Group 2 (PCWG2), symptomatic progression, radiologic progression per RECIST 1.1 criteria, initiation of ADT, or death due to any cause. Secondary clinical endpoints include toxicity and quality of life assessments, local control at 12 months, locoregional progression, time to distant progression, time to new metastasis, and duration of response. Biological correlates will be evaluated including changes in circulating tumor cells following therapy, deep sequencing of circulating tumor DNA, and T-cell repertoire profiling before and after therapy. Clinical trial information: NCT04037358. Research Sponsor: Bayer.

TPS5587 **Poster Session (Board #168), Fri, 8:00 AM-11:00 AM**

DaroACT: Darolutamide and enzalutamide effects on physical and neurocognitive function and daily activity in patients with castration-resistant prostate cancer (CRPC). *First Author: Tomasz M. Beer, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: The androgen receptor inhibitors (ARIs) apalutamide and enzalutamide (Enza) are approved for the treatment of men with advanced prostate cancer. These ARIs are associated with adverse events (AEs) including fatigue, neurocognitive dysfunction, and falls. Darolutamide (Daro) is a structurally distinct ARI approved by the FDA to treat nonmetastatic CRPC, based on significantly improved metastasis-free survival vs placebo in the ARAMIS Phase III clinical trial. Daro was not associated with a significant increase in AEs beyond that of concomitant androgen deprivation therapy, compared with placebo. DaroAcT is the first prospective trial to compare the effects of Daro to those of Enza on physical and neurocognitive function, and daily physical activity, in men with CRPC. **Methods:** This randomized, open-label, multicenter, Phase IIb trial (NCT04157088), involving ~20 sites across the US, is open for enrollment. After a lead-in phase of 30 pts treated with Daro alone, approximately 120 pts will be randomized 1:1 to receive Daro (600 mg twice daily) or Enza (160 mg once daily). Eligibility criteria include CRPC (metastatic and non-metastatic); age $\geq$18 years; Karnofsky performance status $\geq$80; no prior abiraterone within 6 months of enrollment, and no prior immunotherapy or apalutamide. All patients will continue luteinizing hormone-releasing hormone agonist or antagonist treatment for the duration of the study. The primary endpoint is the proportion of pts with slowed Timed Up and Go (TUG) time during the 24-week period from baseline. Secondary endpoints include the proportion of pts with worsening in short Physical Performance Battery (sPPB), mean change from baseline in daily physical activity, the proportion of pts with a decline in neurocognitive function or worsening of fatigue, and AEs. This study uses objective measures to assess physical function, including TUG and sPPB, measurements of daily activity levels with an accelerometry device for $\geq$7 days at designated time points, and neurocognitive tests. Fatigue is measured using the Brief Fatigue Inventory. Primary completion is estimated to be December 31, 2022. Clinical trial information: NCT04157088. Research Sponsor: Bayer.

TPS5588 **Poster Session (Board #169), Fri, 8:00 AM-11:00 AM**

A phase III randomized, placebo-controlled, double-blind study of niraparib plus abiraterone acetate and prednisone versus abiraterone acetate and prednisone in patients with metastatic prostate cancer (MAGNITUDE). *First Author: Kim N. Chi, BC Cancer and Vancouver Prostate Centre, Vancouver, BC, Canada*

Background: Preclinical data suggest synergistic antitumor activity when the PARP inhibitor (PARPi) niraparib is combined with the androgen pathway inhibitor abiraterone acetate[1]. The addition of a PARPi to abiraterone acetate plus prednisone (AAP) showed improved radiographic progression-free survival (rPFS) vs AAP alone in patients with mCRPC regardless of DNA repair gene defect (DRD) status[2]. Interim results from a phase I study support safety and tolerability of niraparib 200 mg combined with AAP in patients with mCRPC[3]. The objective of this Phase III study is to compare the efficacy and safety of niraparib plus AAP versus AAP with placebo as first-line therapy for mCRPC. **Methods:** This ongoing multicenter MAGNITUDE study (NCT03748641) will open in approximately 300 sites across 28 countries and will enroll patients with mCRPC who have not received treatment in the metastatic castrate resistant setting other than ongoing androgen deprivation therapy [ADT] and $\leq$4 months of AAP. DRD status will be determined by plasma and tissue assays. The cohort with DRD (n=400) and the cohort without DRD (n=600) will each be randomized 1:1 to niraparib + AAP or placebo + AAP. The first patient was consented in February 2019 and enrollment is ongoing. The primary objective of the study is to compare radiographic progression-free survival (rPFS) as assessed by blinded independent central radiology review in each cohort and treatment group. To test superiority of the combination vs AAP, sample sizes were estimated to provide 92% power to detect HR$\leq$0.65 rPFS in the cohort with DRD and 94% power to detect HR$\leq$0.67 in rPFS in the cohort without DRD, both at a 2-tailed level of significance of 0.05. The secondary objectives are time to symptomatic progression, time to cytotoxic chemotherapy, and overall survival. Safety and pharmacokinetic profiles will be evaluated. [1]Rajendra N, et al. Cancer Res 2019;79(13 Suppl):Abstract nr 2134. [2]Clarke N, et al. Lancet Oncol. 2018;(7):975-986. [3]Saad, et al. Ann Oncol, 2018;29 (suppl 8), mdy284.043, https://doi.org/10.1093/annonc/mdy284.043) Clinical trial information: NCT03748641. Research Sponsor: Janssen Research and Development.

TPS5589 **Poster Session (Board #170), Fri, 8:00 AM-11:00 AM**

Phase I study of AMG 509, a STEAP1 x CD3 T cell-recruiting XmAb 2+1 immune therapy, in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: W. Kevin Kelly, Thomas Jefferson University, Philadelphia, PA*

Background: Six transmembrane epithelial antigen of the prostate 1 (STEAP1) is a cell surface antigen that is highly expressed in prostate cancer. AMG 509 is a potent bispecific XmAb 2+1 immune therapy designed to direct T-effector cells to STEAP1-expressing cells. AMG 509 contains two identical humanized anti-STEAP1 Fab domains that bind STEAP1-expressing cells, an anti-CD3 scFv domain that binds T cells, and an Fc domain, engineered to lack effector function, that extends serum half-life. In preclinical studies, AMG 509 induced potent and specific T-cell-mediated lysis of STEAP1-expressing cancer models. **Methods:** This open-label, phase I, first-in-human study will evaluate the safety, tolerability, pharmacokinetics (PK), and efficacy of AMG 509 in patients with relapsed/refractory mCRPC. The dose exploration phase (n=40) will estimate the maximum tolerated dose (MTD) or recommended phase II dose (RP2D) using a Bayesian logistic regression model. The dose expansion phase (n=30) will confirm safety, PK, and pharmacodynamics at the MTD or RP2D and collect further safety, efficacy, and biomarker data. Efficacy will be assessed by prostate-specific antigen response, circulating tumor cell response, and objective tumor response per RECIST 1.1 with Prostate Cancer Working Group 3 modifications. Key inclusion criteria: men $\geq$18 years with histologically/cytologically confirmed mCRPC who are refractory to novel hormonal therapy (e.g., abiraterone and/or enzalutamide) and have failed 1–2 taxane regimens or are medically unsuitable for or have refused taxanes; ongoing castration with total serum testosterone $\leq$50 ng/dL; evidence of progressive disease; ECOG performance status 0–1; life expectancy $\geq$3 months; and adequate hematologic, renal, hepatic, and cardiac function. In the dose exploration phase, novel antiandrogen therapy must have been given in the metastatic setting. Key exclusion criteria: pure small-cell or neuroendocrine carcinoma of the prostate; untreated CNS metastases or leptomeningeal disease; any anticancer therapy or immunotherapy, radiation therapy, or major surgery $<$4 weeks from first dose; history of or current autoimmune disease or any disease requiring immunosuppressive therapy ($\leq$10 mg/d prednisone permitted); prior STEAP1-targeted therapy; infection requiring IV antimicrobials $<$7 days from first dose. The study opened in January 2020 and is recruiting patients. Clinical trial information: NCT04221542. Research Sponsor: Amgen Inc.

TPS5590 **Poster Session (Board #171), Fri, 8:00 AM-11:00 AM**

Phase I study of AMG 160, a half-life extended bispecific T-cell engager (HLE BiTE immune therapy) targeting prostate-specific membrane antigen, in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Ben Tran, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Prostate-specific membrane antigen (PSMA) is a clinically validated therapeutic target for the imaging and treatment of mCRPC. AMG 160 is an HLE BiTE immune therapy designed to redirect T cells to cancer cells by binding to PSMA on cancer cells and CD3 on T cells. BiTE immune therapy leads to direct tumor cell killing, T-cell activation and expansion, and the creation of a pro-inflammatory tumor microenvironment. Combining AMG 160 with a PD-1 inhibitor may enhance antitumor activity by enabling sustained T-cell-dependent killing of tumor cells in the inflamed tumor microenvironment. **Methods:** NCT03792841 is a phase I study of AMG 160 as monotherapy (part 1) and in combination with pembrolizumab (part 2) in men with histologically/cytologically confirmed mCRPC who are refractory to a novel hormonal therapy (abiraterone, enzalutamide, and/or apalutamide) and have failed 1–2 taxane regimens (or are medically unsuitable or have refused taxanes), who have ongoing castration with total serum testosterone $\leq$ 50 ng/dL, and have evidence of progressive disease. Patients who received prior PSMA radionuclide therapy may be eligible. Patients with CNS metastases, leptomeningeal disease, spinal cord compression, or active autoimmune disease will be excluded. Primary objectives are to evaluate safety and tolerability and determine the maximum tolerated dose (MTD) or recommended phase II dose (RP2D) of AMG 160 given as monotherapy or in combination with pembrolizumab. Secondary objectives are to characterize pharmacokinetics and preliminary antitumor activity. Exploratory objectives include evaluation of potential pharmacodynamic and patient selection biomarkers, immunogenicity, and patient-reported pain and functional outcomes. The part 1 dose exploration will determine the MTD/RP2D of AMG 160. The part 1 dose expansion will confirm the safety and tolerability of the MTD/RP2D. The part 2 dose exploration will estimate the MTD/RP2D of AMG 160 in combination with pembrolizumab. Evaluation of preliminary antitumor activity will be based on RECIST 1.1 with Prostate Cancer Working Group 3 modifications, PSA response, CTC response, progression-free survival (radiographic and PSA), and overall survival. PSMA PET/CT and FDG PET/CT imaging will be used for evaluation of exploratory objectives. The study opened in February 2019 and is currently recruiting patients into both part 1 and part 2. Clinical trial information: NCT03792841. Research Sponsor: Amgen Inc.

TPS5591 **Poster Session (Board #172), Fri, 8:00 AM-11:00 AM**

CYCLONE 2: A phase II, randomized, placebo-controlled study of abiraterone acetate plus prednisone with or without abemaciclib in patients with metastatic castration-resistant prostate cancer. *First Author: Matthew Raymond Smith, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Despite recent advances, nearly all patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) experience disease progression and cancer-specific mortality. Persistent or reactivated androgen receptor (AR) signaling and/or activation of pathways in cross-talk with AR signaling are key drivers of mCRPC progression. Evidence suggests that AR signaling promotes translation of D-type cyclins resulting in cyclin-dependent kinase 4 and 6 (CDK4&6) activation and cell cycle progression. Abemaciclib is an oral selective inhibitor of CDK4&6 dosed on a continuous schedule, that is FDA-approved in combination with endocrine therapy or as monotherapy to treat HR+, HER2- metastatic breast cancer pts. Preclinical studies with prostate cancer cell lines and xenograft models showed that abemaciclib induces cell cycle arrest and tumor growth inhibition. The hypothesis is that addition of abemaciclib to AR targeted therapy may be an effective treatment for mCRPC pts. **Methods:** CYCLONE 2 (NCT03706365) is a phase II, randomized, double-blind, multicenter, placebo-controlled study to assess the safety and efficacy of abemaciclib in combination with abiraterone acetate plus prednisone (AA+P) as first-line treatment of pts with mCRPC. The study is designed in two parts. Part 1 is a 30-patient safety lead-in to determine the recommended phase II dose (RP2D; 150 mg or 200 mg, twice daily) of abemaciclib in combination with AA (1000 mg, once daily) + P (5 mg, twice daily). In part 2, 150 pts are randomized 1:1 to abemaciclib at the RP2D with AA+P or placebo with AA+P. Pts who received prior AA+P, enzalutamide, apalutamide, darolutamide, radiopharmaceuticals, or sipuleucel-T are excluded. Prior docetaxel for metastatic hormone-sensitive prostate cancer, but not for mCRPC, is allowed. Pts must have progressive mCRPC (by PSA and/or imaging) and an accessible metastatic lesion for tumor biopsy. The co-primary objectives are radiographic PFS (per RECIST1.1 for soft tissue and PCWG3 for bone) and time to PSA progression. Secondary objectives include safety, objective response rate, duration of response, OS, time to symptomatic progression, and pharmacokinetics. Assuming hazard ratios of 0.64 (rPFS) and 0.6 (PSA progression), the study is powered to 80% and 85%, respectively, to test the superiority of abemaciclib plus AA+P vs. placebo plus AA+P at one-sided α=0.1 using stratified log-rank tests. Part 1 is completed and part 2 is enrolling in 70 sites worldwide. Clinical trial information: NCT03706365. Research Sponsor: Eli Lilly and Company.

TPS5592 **Poster Session (Board #173), Fri, 8:00 AM-11:00 AM**

A phase I/II study of REGN5678 (Anti-PSMAxCD28, a costimulatory bispecific antibody) with cemiplimab (anti-PD-1) in patients with metastatic castration-resistant prostate cancer. *First Author: Charles G. Drake, Department of Medicine and Division of Hematology/Oncology, Columbia University Medical Center, New York, NY*

Background: Bispecific antibodies (bsAbs) are emerging as a protein-based therapeutic strategy for directing T-cell-mediated cytotoxicity in a tumor antigen-specific manner, typically by binding to both tumor antigen and the CD3 receptor on T cells. REGN5678 is a human IgG4-based, first-in-class costimulatory bsAb designed to target prostate tumors by bridging prostate specific membrane antigen expressing tumor cells with the costimulatory receptor, CD28, on T cells, and providing amplified T-cell receptor-CD3 complex-mediated T-cell activation within the tumor through the activation of CD28 signaling. At the tumor site, REGN5678 may synergize with PD-1 inhibitors. In mouse models, REGN5678 in combination with PD-1 antibody has improved anti-tumor activity compared with either therapy alone (Skokos et al CRI/CICON 2019; oral, session 3). This study evaluates the safety and anti-tumor activity of REGN5678 alone and in combination with cemiplimab in patients with metastatic castration-resistant prostate cancer (mCRPC) who progressed after prior therapy. **Methods:** This is an open label, Phase I/II, first-in-human study evaluating safety, tolerability, pharmacokinetics (PK), and anti-tumor activity of REGN5678 alone and in combination with cemiplimab in treatment-experienced mCRPC (NCT03972657). For inclusion, patients must have received at least two approved therapies for metastatic disease, including a second-generation hormonal agent. REGN5678 is administered weekly and cemiplimab (350 mg) is administered once every 3 weeks. During dose escalation, a 3-week safety lead-in of REGN5678 monotherapy will be administered prior to the addition of cemiplimab. Study therapies are administered until disease progression, intolerable adverse events, withdrawal of consent, or study withdrawal criterion is met. The primary objectives in dose escalation are to evaluate safety, tolerability, and PK of REGN5678 alone and in combination with cemiplimab. Expansion cohort(s) will be enrolled once a REGN5678/cemiplimab recommended Phase II dose is determined. During the expansion phase, the primary trial objective is to assess clinical activity, as measured by objective response rate of REGN5678 in combination with cemiplimab per modified Prostate Cancer Working Group 3 criteria. This study is currently open to enrollment. Clinical trial information: NCT03972657. Research Sponsor: Regeneron Pharmaceuticals Inc.

TPS5593 **Poster Session (Board #174), Fri, 8:00 AM-11:00 AM**

DAROL: DARolutamide ObservationaL study patients in nonmetastatic castration-resistant prostate cancer (nmCRPC) patients. *First Author: Evan Y. Yu, Division of Oncology, Department of Medicine, University of Washington, Seattle, WA*

Background: Patients (pts) with prostate cancer treated with prolonged androgen deprivation therapy (ADT) will eventually develop castration-resistant disease. Treatment of pts with nmCRPC with darolutamide (DARO) delays the development of metastases, which are associated with cancer-related morbidity. DARO is a structurally unique oral androgen receptor inhibitor approved by the FDA for the treatment of nmCRPC, based on prolonged metastasis-free survival (MFS) compared with placebo (median 40.4 months vs.18.4 months, respectively) in the ARAMIS phase III clinical trial. DARO showed a similar incidence of adverse events (AEs) compared to ADT alone and has a low potential for drug-drug interactions. However, phase III clinical trials cannot fully reflect all the facets of real-world pts. Therefore, non-interventional studies in the real-world setting, such as DAROL, are able to provide additional insight into the patterns of use and real-world safety profile of recently approved drugs. **Methods:** (NCT04122976) will enrol participants in the US, Brazil, Japan, and the EU. Eligible pts include men with histologically confirmed nmCRPC aged $\geq$18 yrs, life expectancy $\geq$3 months, and initiated on DARO treatment as per investigators' decision within 3 days prior to enrollment. DAROL opened for enrollment in December 2019 in the US with a projected enrollment of 1000 pts. The primary endpoint of DAROL is safety. Treatment-emergent AEs will be collected during the study. Secondary endpoints to measure clinical effectiveness are MFS, time to symptomatic skeletal event, time to prostate-specific antigen progression, survival rate, and duration of DARO therapy. Other endpoints include pt demographics and characteristics, and prior and subsequent therapy. The estimated primary completion date is December 30, 2024. Clinical trial information: NCT04122976. Research Sponsor: Bayer.

TPS5594 Poster Session (Board #175), Fri, 8:00 AM-11:00 AM

A phase III trial of docetaxel versus docetaxel and radium-223 (Ra-223) in patients with metastatic castration-resistant prostate cancer (mCRPC): DORA. *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ra-223, a bone-targeted alpha therapy, prolongs survival in patients (pts) with symptomatic mCRPC to bone. Docetaxel targets microtubule trafficking improving survival in the mCRPC and metastatic hormone-sensitive settings. We hypothesized that simultaneously targeting the tumor and bone compartment yields superior outcomes than targeting either alone. We previously determined the dose and schedule of co-administering Ra-223 + docetaxel in a randomized phase I/IIa trial. The combination appeared to have improved declines in prostate specific antigen (PSA) and bone markers, delayed PSA progression, and was better tolerated (with adjusted dose/schedule) relative to standard docetaxel alone. We are now conducting a phase III study to determine the clinical benefit of the regimen. **Methods:** Randomization (1:1) of 738 men with mCRPC to docetaxel or docetaxel + Ra-223 is planned with a projected hazard ratio for treatment effect (15 vs 20 months median survival) of 0.75. Pts with ≥2 bone lesions and progression by Prostate Cancer Working Group 3 criteria are eligible. Other key inclusion criteria are an Eastern Cooperative Oncology Group performance status of 0-1 and normal organ function. Key exclusion criteria are: use of anticancer therapy ≤4 weeks (wks) before randomization and use of bone-seeking radiopharmaceuticals or chemotherapy in the castration-resistant setting, and bulky visceral metastases (≥3 lung and/or liver or a lesion ≥2 cm in the previous 8 wks). Subjects receive docetaxel 75 mg/m^2 IV q3w for 10 doses or docetaxel 60 mg/m^2 IV q3w for 10 doses + Ra-223 55 kBq/kg IV q6w for 6 doses. The primary endpoint is overall survival. Secondary and exploratory endpoints include: radiographic progression-free survival, symptomatic skeletal event-free survival, safety, markers of bone metabolism, alterations in circulating tumor cells and DNA, detection of androgen-receptor splice variant 7, changes in automated bone scan index (aBSI), and assessment of patient-reported outcome instruments (FACT-P, Brief Pain Inventory, Brief Fatigue Inventory). The study is open at 25 sites in the US and Netherlands, sponsored by Memorial Sloan Kettering Cancer Center, and managed by the Prostate Cancer Clinical Trials Consortium. Clinical trial information: NCT03574571. Research Sponsor: Memorial Sloan Kettering Cancer Center, Other Government Agency, Pharmaceutical/Biotech Company.

TPS5595 Poster Session (Board #176), Fri, 8:00 AM-11:00 AM

Phase III study of pembrolizumab (pembro) plus enzalutamide (enza) and androgen deprivation therapy (ADT) for patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC): KEYNOTE-991. *First Author: Christian Gratzke, University Medical Center Freiburg, Freiburg, Germany*

Background: Pembro, an anti–PD-1 antibody, has shown antitumor activity as monotherapy and in combination with other agents in metastatic castration-resistant prostate cancer (mCRPC). As the antitumor effects of enza may be pro-immunogenic, we hypothesized that combining pembro and enza could show additive or synergistic antitumor activity. Furthermore, pembro + enza previously showed antitumor activity in pts with mCRPC for whom abiraterone failed (KEYNOTE-365, NCT02861573) and in pts with mCRPC for whom enza monotherapy failed (KEYNOTE 199, NCT02787005). These data warrant further evaluation of the combination of pembro + enza when given at the initiation of ADT. **Methods:** KEYNOTE-991 (NCT04191096) is a phase III trial to evaluate the efficacy and safety of enza + ADT + either pembro or placebo in patients with mHSPC. Approximately 1232 pts will be randomly assigned 1:1 to receive enza 160 mg orally once daily + ADT + pembro 200 mg IV every 3 weeks (Q3W) or enza 160 mg orally once daily + ADT + placebo IV Q3W. ADT is receipt of an LHRH agonist or antagonist during study treatment or bilateral orchiectomy. Treatment will be stratified by prior docetaxel therapy (yes or no) and presence of high-volume disease (yes or no). Pts with mHSPC, with ≥2 bone lesions and/or visceral disease, who are naive to next-generation hormone agents, and who have ECOG PS 0 or 1 are eligible. Pts must provide tissue for biomarker analysis. Responses will be assessed by CT or MRI and radionuclide bone imaging per Prostate Cancer Working Group 3 (PCWG3)–modified RECIST v1.1 by blinded independent central review (BICR) Q12W from the date of randomization. Treatment will continue with pembro for up to 35 cycles, and treatment with enza will proceed continuously from day 1 of cycle 1 until disease progression, unacceptable toxicity, or withdrawal of consent. Dual primary end points are radiographic progression-free survival (PFS) per PCWG3-modified RECIST v1.1 assessed by BICR and overall survival. Secondary end points are time to first subsequent anticancer therapy, time to symptomatic skeletal-related event, PFS2 (progression after next line of therapy or death), prostate-specific antigen (PSA) response rate, time to PSA progression, PSA undetectable rate, objective response rate, duration of response, and time to radiographic soft tissue progression. Other end points are safety and patient-reported outcomes (eg, time to pain progression). Clinical trial information: NCT04191096. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS5596 Poster Session (Board #177), Fri, 8:00 AM-11:00 AM

A multicenter, randomized, controlled phase II study: Efficacy and safety of PSMA-targeted radioligand therapy I-131-1095 (1095) plus enzalutamide (enza) in 18F-DCFPyL PSMA scan avid, metastatic castration-resistant prostate cancer (mCRPC) patients post-abiraterone (abi) progression (ARROW). *First Author: Evan Y. Yu, University of Washington, Seattle, WA*

Background: PSMA is a transmembrane glycoprotein expressed in normal human prostate epithelium at low levels, but highly upregulated in metastatic prostate cancer (PC). ^{18}F-DCFPyL is a novel PSMA-targeted PET imaging agent that has shown highly promising diagnostic performance for detection of metastatic disease, with potential to identify disease amenable to theranostic targeting. 1095 is a novel PSMA-targeted small molecule that binds to the extracellular domain of PSMA selectively with high affinity. The complex is internalized, allowing the beta emitter, I-131, to kill PC cells. **Methods:** ARROW is an open-label, randomized (2:1) trial of enza plus 1095 or enza alone in pts with progressive mCRPC who previously received abi. ~120 pts (80: 1095 + enza; 40: enza alone) will be treated at ~40 sites in the US and Canada. Eligible male pts must be at least 18 yo with metastatic disease documented by bone scan or soft tissue lesions measurable per RECIST 1.1 on CT/MRI, be PSMA-avid as determined by ^{18}F-DCFPyL PET/CT, have evidence of biochemical or radiographic progression on abi, and be ineligible for or refuse to receive chemotherapy. Pts will receive enza (prescribed per approved labeling) with or without 1095 (100 mCi dose, followed by up to 3 additional dose(s) administered at least 8 weeks apart, as determined by dosimetry evaluation and occurrence of dose-limiting events). The primary objective is to determine the efficacy of 1095 plus enza compared to enza alone, based on PSA response (confirmed PSA decline ≥50%) rate according to Prostate Cancer Clinical Trials Working Group 3 (PCWG3) criteria. Additional objectives include objective response rate based on PCWG3-modified RECIST 1.1, progression-free survival (PFS) defined as the first occurrence of radiographic progression (PCWG3-modified RECIST 1.1), unequivocal clinical progression, or death from any cause, duration of response, overall survival, and the safety and tolerability of 1095 radioligand therapy. Clinical trial information: NCT03939689. Research Sponsor: Progenics Pharmaceuticals, Inc.

TPS5597 Poster Session (Board #178), Fri, 8:00 AM-11:00 AM

A phase II study of M6620 in combination with carboplatin compared with docetaxel in combination with carboplatin in metastatic castration-resistant prostate cancer. *First Author: Atish Dipankar Choudhury, Dana-Farber Cancer Institute, Boston, MA*

Background: Alterations in DNA damage repair genes are common in metastatic castration-resistant prostate cancer (mCRPC), and are implicated in responses to carboplatin, PARP inhibitors and immunotherapeutics. The ATR kinase is involved in the DNA damage response, and ATR inhibitors have been demonstrated in preclinical models to have synergistic activity with platinum compounds due to induction of replication stress. **Methods:** This is a randomized open-label Phase 2 study of the ATR inhibitor M6620 + carboplatin vs. docetaxel + carboplatin in mCRPC. Patients (pts) previously treated with at least one secondary hormonal therapy and taxane-based chemotherapy undergo mandatory pre-treatment biopsy and are randomized 1:1 to receive Arm A (docetaxel 60 mg/m2 day 1 + carboplatin AUC 4 day 1) or Arm B (M6620 90 mg/m2 days 2,9 + carboplatin AUC 5 day 1) every 21 days. Pts randomized to Arm A who are not candidates for docetaxel receive carboplatin AUC 5 monotherapy. Stratification factors are 1) prior PARP inhibitor (yes vs. no) and 2) evaluable disease by RECIST 1.1 (yes vs. no). Pts on Arm A crossover to Arm B (M6620+carboplatin) at the earlier of PSA or radiographic progression. For the primary endpoint of overall response rate (ORR; PSA reduction by ≥ 50% or radiographic response by RECIST 1.1), with 65 pts on each arm (total N = 130), there will be 80% power to distinguish ORR of 40% vs. 20% using a chi-square test (one sided $\alpha = 0.05$). 136 pts will be enrolled to account for 5% dropout. Secondary endpoints include time to PSA progression, radiographic PFS, PFS by PCWG3 criteria, safety and adverse events in each arm. Biomarker studies include whole exome sequencing, RAD51 focus formation, and ATM IHC from tumor specimens. Circulating cell-free DNA from pre-treatment and progression plasma specimens will undergo ultra-low pass whole genome sequencing and deep targeted sequencing. The goal of this study is to expand therapeutic options in mCRPC through a novel approach to targeting the DNA damage response, and to identify biomarkers associating with response and resistance to both standard and trial therapy. Enrollment began June 2019 (NCI/ETCTN #10191, NCT03517969). Clinical trial information: NCT03517969. Research Sponsor: U.S. National Institutes of Health.

TPS5598 **Poster Session (Board #179), Fri, 8:00 AM-11:00 AM**

TALAPRO-2: a placebo-controlled phase III study of talazoparib (TALA) plus enzalutamide (ENZA) for patients with first-line metastatic castration-resistant prostate cancer (mCRPC). *First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: TALA blocks poly(ADP-ribose) polymerase (PARP) activity and traps PARP on single-strand DNA breaks, preventing DNA damage repair (DDR) and causing death of cells with DDR alterations (eg *BRCA1/2*).[a] TALA has been approved in multiple countries as monotherapy for germline *BRCA1/2*-mutated human epidermal growth factor receptor 2-negative advanced breast cancer. ENZA is an androgen receptor (AR) inhibitor and an established therapy for mCRPC. As PARP activity has been shown to support AR function, inhibition of PARP is expected to reduce AR signaling and increase sensitivity to AR-directed therapies. In addition, AR blockade downregulates homologous recombination repair gene transcription which induces '*BRCAness*'. Therefore, combining TALA with ENZA in mCRPC may be efficacious regardless of DDR alterations. TALAPRO-2 (NCT03395197) is a Phase III, 2-part study to evaluate efficacy, safety, pharmacokinetics, and patient-reported outcomes (PROs) of TALA combined with ENZA. **Methods:** Enrollment goal is 1037 patients (19 patients, part 1 dose-finding; 1,018 patients, part 2 placebo-controlled). Key eligibility criteria: age $\geq$18 years; asymptomatic/mildly symptomatic mCRPC; ECOG performance status $\leq$1; metastatic disease (no brain metastases); and no prior life-prolonging systemic therapy for nonmetastatic CRPC or mCRPC. Prior therapies (excluding novel AR inhibitors) in the castration-sensitive (CSPC) setting are allowed. ADT must continue throughout the study. The randomized double-blind portion (part 2) will evaluate safety, efficacy, and PROs of TALA (0.5 mg QD) + ENZA (160 mg QD) vs placebo + ENZA (160 mg QD). Patients are stratified by prior novel hormonal therapy or docetaxel for CSPC (yes or no) and DDR alteration status (deficient vs nondeficient/unknown). The primary endpoint is radiographic progression-free survival (rPFS), defined as time to progression in soft tissue per RECIST v.1.1 or in bone per PCWG3 criteria by independent review or death. The key secondary endpoint is overall survival. Efficacy will be assessed radiographically every 8 weeks up to Week 25 and every 8–12 weeks thereafter. rPFS will be compared between the two arms by a 1-sided stratified log-rank test. Patient recruitment is ongoing in multiple regions including US, Europe/Eastern Europe, Israel, South America, South Africa, and Asia-Pacific region. [a]DDR alterations are defined as known/likely pathogenic variants or homozygous deletions. Funding: Pfizer Inc. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc.

TPS5599 **Poster Session (Board #180), Fri, 8:00 AM-11:00 AM**

A phase Ib trial of enzalutamide with venetoclax in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Dharmesh Gopalakrishnan, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Androgen receptor (AR) signaling plays an important role in prostate cancer (PCa) cell survival and proliferation. Xenograft and PDX models demonstrate that untreated PCa harbors $AR^{-/lo}$ stem cells not critically dependent on androgens for survival.[1] Furthermore, castration and enzalutamide (enza) leads to expansion of both $AR^{-/lo}$ and $AR^{+/hi}$ resistant clones in xenograft tumors, resulting in two distinct CRPC-propagating populations.[2] However, most current CRPC treatments are directed towards $AR^{+/hi}$ cells. RNAseq revealed that BCL-2 is highly up-regulated in $AR^{-/lo}$ tumors post-castration and in $AR^{+/hi}$ CRPC tumors post-enza.[2] Strikingly, BCL-2, but not BCL-X_L and MCL-1, was selectively up-regulated in these xenograft tumors. These results were subsequently validated in patient CRPC datasets.[2,3] Venetoclax (ven), a potent and selective BCL-2 inhibitor, inhibits enza resistance in $AR^{+/hi}$ CRPC and tumor growth in $AR^{-/lo}$ xenograft models.[2] A recent phase I trial of ven combined with tamoxifen showed promising activity in ER^+ and $BCL2^+$ metastatic breast cancer.[4] We hypothesize that co-targeting $AR^{-/lo}$ and $AR^{+/hi}$ PCa clones with ven and enza will prevent the emergence of enza resistance in human mCRPC. **Methods:** This is a phase Ib, single-center, single-arm trial of enza (160mg/d) with ven in patients with mCRPC that has progressed on previous therapies which may include anti-androgens. Three dose-levels of ven (400mg, 600mg and 800mg/d q28d) will be evaluated using a 3+3 study design. Fifteen to 18 patients will be enrolled in this phase to assess dose-limiting toxicities, maximum tolerated dose, and recommended phase II dose. Aims of correlative studies include (1) assessing the pharmacokinetic interaction between enza and ven, (2) identification of potentially predictive blood and tissue biomarkers (including pre- and post-treatment CTC levels, expression of BCL2, AR, ARv7 in pre-and post-treatment biopsies and CTCs), (3) measurement of pre- and post-treatment BCL2 expression in peripheral blood mononuclear cells as a surrogate for ven activity, and (4) the development of 3D organoid models from CTCs and biopsies. The trial is open with 3 patients enrolled to dose-level 1, and 2 patients currently at dose-level 2. Correlative studies are ongoing. TPS5600 **Poster Session (Board #181), Fri, 8:00 AM-11:00 AM**

Initial experience of the adjuvant treatments to the local tumor for metastatic prostate cancer: Assessment of novel treatment algorithms, a multicenter, phase II randomized controlled trial (IP2-ATLANTA). *First Author: Martin John Connor, Imperial College London, London, United Kingdom*

Background: Local cytoreductive and metastasis-directed interventions are hypothesised to confer additional survival benefit beyond standard systemic therapy in patients with *de novo* synchronous metastatic prostate cancer. There is accumulating prospective evidence for local cytoreductive therapy. In particular, the phase III study STAMPEDE which demonstrated improved overall survival in a low burden subgroup of men following cytoreductive radiotherapy. Cytoreductive prostatectomy and minimally invasive ablative therapies (MIAT) are now subject to similar trial evaluation. IP2-ATLANTA will evaluate progression-free and overall survival outcomes with the addition of sequential multi-modal local and metastasis-directed treatments in patients with newly diagnosed metastatic prostate cancer compared to standard care alone. **Methods:** Phase II, multicentre, three-arm randomised controlled trial using a positive comparator arm (n=918). An internal pilot (n=80) feasibility phase is incorporated. All men with new histologically diagnosed, hormone sensitive, metastatic prostate cancer, within three months of commencing ADT and of PS 0-2 are eligible. Patients are randomised (1:1:1) to: Control (Standard of Care) OR Intervention 1 (Minimally invasive ablative therapy to the prostate +/- pelvic lymph node dissection [PLND]) OR Intervention 2 (prostate radiotherapy +/- lymph nodes OR Radical prostatectomy +/- PLND). Metastatic burden pre-specified by CHAARTED definition. Men with low-burden disease in intervention arms are eligible for metastasis-directed therapy (stereotactic ablative radiotherapy [SABR] or surgery). Standard systemic therapy given in all arms (incl. docetaxel). Follow-up: min. 2-years; max. 4 years. Primary outcome: progression-free survival (PFS). Secondary outcomes: Overall survival; urinary, sexual & rectal side-effects; patient reported outcome measures. HRA ethical approval (Ref: 19/WA0005). To date, 28/80 (35%) patients have been recruited and randomised across 9 open sites in the internal pilot. Median recruitment rate is 85.7% (IQR 55–86). Internal pilot recruitment expected to be complete by April 2020. IP2-ATLANTA addresses an important research gap in the role of local and metastasis-directed therapy in men with newly diagnosed metastatic prostate cancer. Clinical trial information: NCT03763253. Research Sponsor: Wellcome Trust Charity.

TPS5601 **Poster Session (Board #182), Fri, 8:00 AM-11:00 AM**

RTOG 3506 (STEEL): A study of salvage radiotherapy with or without enzalutamide in recurrent prostate cancer following surgery. *First Author: Edwin Melencio Posadas, Cedars-Sinai Cancer, Los Angeles, CA*

Background: Salvage radiotherapy (SRT) is an important intervention for men with prostate cancer (PCa) who experience biochemical recurrence (BCR) after radical prostatectomy (RP). These patients are in need of cure or else they will develop metastatic disease. NRG/RTOG 9601 (WU Shipley, N Eng J Med 2017) identified a survival benefit from the addition of androgen receptor (AR) inhibition to SRT that was most prominent in men with high-risk features. Enzalutamide (Enza) is a non-steroidal anti-androgen that improves survival in castration-resistant and -sensitive PCa. We hypothesized that enhanced AR suppression with Enza would augment the benefit of SRT + androgen deprivation therapy (ADT) in BCR with high risk features. **Methods:** RTOG 3506 (STEEL, NCT03809000) is a randomized phase II study of SRT in BCR after RP with a serum PSA $\geq$ 0.2 ng/mL active in the USA and Canada. Patients are stratified by number of high-risk features including Gleason score (8-10), locoregional node involvement at RP, seminal vesicle invasion, persistently elevated PSA after RP, and PSA $>$ 0.7 ng/mL. All patients receive SRT with 2 years of ADT. The experimental arm also receives Enza 160 mg daily for 2 years. Patients are followed by PSA every 3 months. SRT can be highly individualized per treating physician beyond the mandatory treatment of the prostatic fossa. Treatment of the pelvis and/or para-aortic nodes, as well as sequential or concurrent boosts to a prostatic fossa mass and/or suspicious lymph nodes, are allowed options. This permits individualization of radiotherapy guided by CT, MRI, PET, and/or biopsy findings. The primary goal of this study is to determine whether SRT enhanced ADT with Enza, will improve progression-free survival (PFS) compared to SRT with standard ADT. PFS defined as the first occurrence of biochemical failure, clinical failure, or initiation of new anticancer treatment. STEEL is designed to demonstrate a 35% reduction in the risk of progression at 5 years. An accrual goal of 242 patients will provide 80% power with a one-sided alpha = 0.10. Secondary endpoints include disease control rates, acute and late physician- and patient-reported toxicity, and quality of life. This study was activated in February 2019. Site recruitment and activation are underway. **Conclusions:** There is an unmet and urgent need for individualized strategies to optimize systemic therapy used with SRT for men with BCR. Outcomes from this study will further clarify the approach to systemic therapy for SRT in high-risk BCR patients. Support: Provided by Pfizer. Clinical trial information: NCT03809000. Research Sponsor: RTOG Foundation.

5602 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

HERO phase III trial: Results comparing relugolix, an oral GnRH receptor antagonist, versus leuprolide acetate for advanced prostate cancer. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: LHRH agonists are the mainstay for medical castration in advanced prostate cancer; however, they cause an initial testosterone (T) surge with a delayed onset of castration and require depot injection. Relugolix is the first oral GnRH receptor antagonist, which was previously shown to rapidly suppress T levels. The HERO trial compared the safety and efficacy of relugolix with leuprolide acetate in advanced prostate cancer patients. **Methods:** HERO is a 48-week, global, pivotal phase III trial that randomized 934 patients with androgen-sensitive advanced prostate cancer in a 2:1 ratio to receive relugolix 120 mg orally QD after a single l or leuprolide acetate 3-month depot injection. The primary endpoint was to achieve and maintain serum T suppression to castrate levels (< 50 ng/dL) through 48 weeks. Key secondary endpoints included castration rates at Day 4, profound castration (< 20 ng/dL) rates at Days 4 and 15, PSA response rate at Day 15 and FSH levels at Week 25. Testosterone recovery was evaluated in a subset of 184 patients. Results: A total of 96.7% (95% CI: 94.9%, 97.9%) of men on relugolix achieved and maintained castration through 48 weeks compared to 88.8% on leuprolide. The difference of 7.9% (95% CI: 4.1%, 11.8%) demonstrated non-inferiority (margin -10%) and superiority ($P < 0.0001$) of relugolix to leuprolide. All key secondary efficacy endpoints tested demonstrated superiority over leuprolide ($P < 0.0001$) (Table). In the testosterone recovery subset, median T levels were 270.76 ng/dL in the relugolix compared to 12.26 ng/dL in the leuprolide group 90 days after discontinuation of therapy. In a prespecified analysis, the incidence of major adverse cardiovascular events (MACE) was lower in the relugolix group than in the leuprolide group (2.9% vs. 6.2%, respectively); otherwise the safety and tolerability profiles were generally similar. Conclusion: Relugolix achieved castration as early as Day 4 and demonstrated superiority over leuprolide in sustained T suppression through 48 weeks, faster T recovery after discontinuation and a 50% reduction in MACE. Relugolix has the potential to become a new standard for T suppression for patients with advanced prostate cancer. Clinical trial information: NCT03085095. Research Sponsor: None.

	Endpoint	Relugolix (N= 622)	Leuprolide (N= 308)	P-value
		%	%	
Primary Endpoint	Sustained castration rate from Day 29 to Day 337	96.7	88.8	<0.0001
Key Secondary Endpoints	Testosterone suppression to < 50 ng/dL at Day 4	56.04	0.00	<0.0001
	Testosterone suppression to < 50 ng/dL at Day 15	98.71	12.05	<0.0001
	Confirmed PSA response at Day 15 followed with confirmation at Day 29	79.4	19.8	<0.0001

6000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized phase III study to evaluate the impact of secondary cytoreductive surgery in recurrent ovarian cancer: Final analysis of AGO DESKTOP III/ENGOT-ov20. *First Author: Andreas Du Bois, AGO & Ev. Kliniken Essen-Mitte, Essen, Germany*

Background: The role of secondary cytoreductive surgery in recurrent ovarian cancer (ROC) has been under debate for decades. A recent trial in unselected patients (pts) failed to show an OS benefit. **Methods:** Pts with ROC and 1st relapse after 6+ months (mos) platinum-free interval (TFIp) were eligible if they presented with a positive AGO-score (PS ECOG 0, ascites ≤500 ml, and complete resection at initial surgery) and were prospectively randomized to second-line chemotherapy alone vs. cytoreductive surgery followed by the same chemotherapy; platinum combination therapy was recommended. OS was primary endpoint in this superiority trial. **Results:** 407pts were randomized 2010-2014. The TFIp exceeded 12 mos in 75% of pts. 206 pts were allocated to the surgery arm of whom finally 187 (91%) were operated. A complete resection was achieved in 75%; almost 90% in both arms received a platinum-containing second-line chemo. Primary endpoint analysis showed median OS of 53.7 mos with and 46.2 mos without surgery (HR 0.76, 95%CI 0.59-0.97, p=0.03); median PFS was 18.4 and 14 mos (HR: 0.66, 95%CI 0.54-0.82, p<0.001), median time to start of first subsequent therapy (TFST) was 17.9 vs. 13.7 mos in favor of the surgery arm (HR 0.65, 95%CI 0.52-0.81, p<0.001). An analysis according to treatment showed an OS benefit exceeding 12 mos for pts with complete resection (CR) compared to pts without surgery (median 60.7 vs. 46.2 mos); pts with surgery and incomplete resection even did worse (median 28.8 mos). 60 d mortality rates were 0 and 0.5% in the surgery and no-surgery arm. Re-laparotomies were performed in 3.7% of operated pts. Further grade 3/4 adverse events did not differ significantly between arms. **Conclusions:** This is the first surgical study demonstrating a meaningful survival benefit in OC: Surgery in pts with first relapse and TFIp of 6+ mos and selected by a positive AGO-Score resulted in a significant increase of OS, PFS and TFST with acceptable morbidity and, therefore, should be offered to suitable pts. The benefit was exclusively seen in pts with CR indicating the importance of both the optimal selection of pts (eg. by AGO score) and of centres with expertise and a high chance of achieving a CR. Clinical trial information: NCT01166737. Research Sponsor: None.

6001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A randomized phase III trial of secondary cytoreductive surgery in later recurrent ovarian cancer: SOC1/SGOG-OV2. *First Author: Rongyu Zang, Fudan University Zhongshan Hospital, Shanghai, China*

Background: In China, secondary cytoreductive surgery (SCR) has been standard of care in some high volume cancer centers for ovarian cancer (OC) and most pts prefer surgery over the past two decades. Although GOG213 showed no OS benefit, the debate on selected pts and the conflict with certain local clinical care is still open. **Methods:** Pts with 1st relapsed OC after 6m+ platinum-free interval (PFI) were eligible if predicted to be a potential R0 by iMODEL score combined with PET-CT image and were randomized to SCR followed by chemotherapy (surgery arm) vs 2nd line chemotherapy alone (no surgery arm). Co-primary endpoint is PFS and OS. The 2nd endpoint is accumulated treatment-free survival (TFSa), which was defined as the overall survival time minus the time of surgery and chemotherapy after randomization. We report analysis of PFS and interim analysis of TFSa. **Results:** 357 pts were randomized 2012-2019. 6.3% of 175 pts were operated in no surgery arm and cross-over rate was 36.9% in 2nd+ relapsed pts of no surgery arm. 97% and 96% of pts received a platinum-containing 2nd line therapy. Complete resection (R0) rate was 76.7% in overall and 61.1% in pts with iMODEL>4.7. 60 d mortality rates were 0 % in both surgery and no surgery arm. Postoperative 30 d complication rate with ≥ grade 3 was 5.2%. The median follow-up was 36.0 m. Median PFS was 17.4 m and 11.9 m in surgery and no surgery arm, respectively (HR 0.58, 95% CI 0.45-0.74, p < 0.001). Median time to start of first subsequent therapy (TFST) was 18.1 m vs 13.6 m in favor of the surgery arm (HR 0.59, 95%CI 0.46-0.76). 1.1% and 10.1% of pts underwent Bevacizumab and PARPi maintenance in the 2nd line therapy. The OS and TFSa was immatured. The median TFSa was unreached and 39.5 m in R0 subgroup and no surgery arm, respectively (HR0.59, 95%CI 0.38-0.91). TFSa in surgery arm showed a better long-term survival than that in no surgery group (restricted mean survival time from 60 to 72m: 6.2m vs 4.2m). **Conclusions:** SCR in selected pts resulted in a dramatically significant extension of PFS. The interim analysis of TFSa indicate that SCR might contribute to long-term survival. Research Sponsor: Talent Funding from Zhongshan Hospital Fudan University (No. 016).

6002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Final overall survival (OS) results from SOLO2/ENGOT-ov21: A phase III trial assessing maintenance olaparib in patients (pts) with platinum-sensitive, relapsed ovarian cancer and a BRCA mutation. *First Author: Andres Poveda, Initia Oncology, Hospital Quirónsalud and GEICO, Valencia, Spain*

Background: SOLO2 (ENGOT ov-21; NCT01874353) showed that maintenance therapy with the PARP inhibitor olaparib in pts with platinum-sensitive relapsed ovarian cancer (PSROC) and a BRCA mutation (BRCAm) led to a statistically significant improvement in median progression-free survival (PFS) of 13.6 months vs placebo (hazard ratio [HR] 0.30). Time to second progression or death significantly improved (Pujade-Lauraine *et al Lancet Oncol* 2017) and a quality-adjusted PFS benefit was seen (Friedlander *et al Lancet Oncol* 2018) with maintenance olaparib vs placebo. We report the preplanned final OS analysis for SOLO2. **Methods:** Pts with PSROC and a BRCAm who had received ≥2 lines of treatment and were in response to their most recent platinum-based chemotherapy received maintenance olaparib (300 mg bid tablets) or placebo. Pts were stratified by response to previous chemotherapy (complete vs partial) and length of platinum-free interval (>6–12 months vs >12 months). OS was a secondary endpoint. The only preplanned OS sensitivity analysis was an OS analysis in the Myriad germline BRCAm subset (Myriad BRAC *Analysis* test). **Results:** At final data cut-off (Feb 3, 2020), median follow-up was 65 months in both treatment arms. A long-term treatment benefit was seen with olaparib vs placebo with an OS HR of 0.74 (95% confidence interval [CI] 0.54–1.00) in the full analysis set (FAS; unadjusted for crossover; 38.4% of placebo pts crossed over to a PARP inhibitor) (Table). At 5 years: by Kaplan-Meier estimates, 28.3% of pts in the olaparib arm vs 12.8% of pts in the placebo arm were alive and had still not received subsequent treatment; 42.1% of olaparib pts vs 33.2% of placebo pts were alive. The long-term tolerability profile of olaparib was generally consistent with that reported previously. **Conclusions:** In the final analysis of SOLO2, maintenance olaparib provided an unprecedented improvement of 12.9 months in median OS vs placebo. This is the first study with olaparib tablets, and the first since Study 19 (NCT00753545), to provide long-term follow-up and final OS data in pts with PSROC and a BRCAm. Clinical trial information: NCT01874353. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp, a subsidiary of Merck & Co, Inc, Kenilworth, NJ, USA.

6003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase III study comparing single-agent olaparib or the combination of cediranib and olaparib to standard platinum-based chemotherapy in recurrent platinum-sensitive ovarian cancer. *First Author: Joyce F. Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: Combination cediranib (C) and olaparib (O) improved progression-free survival (PFS) in patients (pts) with relapsed platinum (plat)-sensitive high-grade ovarian cancer (ovca) compared to O alone in a Phase 2 trial (NCT01116648). We conducted this randomized, open-label Phase 3 trial (NCT02446600) to assess whether combination C+O, or O alone, was superior to standard of care (SOC) plat-based therapy in relapsed plat-sensitive ovca. **Methods:** Eligible pts had recurrent plat-sensitive [> 6-month plat-free interval (PFI)] high-grade serous or endometrioid, or BRCA-related, ovca. One prior non-plat therapy and unlimited prior plat-therapies were allowed; prior anti-angiogenics in the recurrent setting or prior PARP inhibitor were exclusions. Pts were randomized 1:1:1 to SOC (carboplatin/paclitaxel; carboplatin/gemcitabine; or carboplatin/liposomal doxorubicin), O (300mg twice daily), or C+O (C 30mg daily + O 200mg twice daily). Randomization was stratified by g*BRCA* status, PFI (6-12 vs > 12 months), and prior anti-angiogenic therapy. Target sample size was 549 pts; primary analysis occurred 2 years after the last pt enrolled. The primary endpoint was PFS. Type 1 error = 0.025 was controlled by a gatekeeping hierarchy that assessed C+O vs SOC, then O alone vs SOC, and finally C+O vs O. All maintenance therapy was prohibited. **Results:** Between 4FEB2016 and 13NOV2017, 565 pts enrolled (187 SOC, 189 O, 189 C+O), and 528 pts initiated treatment (166 SOC, 183 O, 179 C+O). 23.7% of patients had g*BRCA*mut. Median follow-up was 29.1 months. 53 pts on SOC initiated non-protocol therapy (predominantly PARP inhibitor maintenance) before disease progression. The hazard ratio (HR) for PFS was 0.856 (95% CI 0.66-1.11, p = 0.08, 1-tail) between C+O and SOC and 1.20 (95% CI 0.93-1.54) between O and SOC, with median PFS of 10.3, 8.2, and 10.4 months for SOC, O, and C+O, respectively. Response rates were 71.3% (SOC), 52.4% (O), and 69.4% (C+O). In *gBRCA* pts, HR for PFS was 0.55 (95% CI 0.73-1.30) for C+O vs SOC, and 0.63 (95% CI 0.37-1.07) for O vs SOC. In non-g*BRCA* pts, HR for these comparisons was 0.97 (95% CI 0.73-1.30) and 1.41 (1.07-1.86). No OS differences between arms were observed at 44% events. Pts receiving C+O (vs SOC) had more frequent Grade 3 or higher gastrointestinal (30.1% vs 8.4%), hypertension (31.7% vs 1.8%), and fatigue events (17.5% vs 1.8%). **Conclusion:** C+O demonstrated similar activity to SOC in relapsed plat-sensitive ovca but did not meet the primary endpoint of improved PFS. Clinical trial information: NCT02446600. Research Sponsor: U.S. National Institutes of Health.

6004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Mirvetuximab soravtansine, a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC), in combination with bevacizumab in patients (pts) with platinum-agnostic ovarian cancer. *First Author: Lucy Gilbert, McGill University Health Centre, Royal Victoria Hospital, Montréal, QC, Canada*

Background: Mirvetuximab soravtansine (MIRV) is an ADC comprising a FRα-binding antibody, cleavable linker, and the maytansinoid DM4, a potent tubulin-targeting agent. As part of the Phase 1b FORWARD II trial (NCT02606305), the combination of MIRV with bevacizumab (BEV) was evaluated in pts with FRα-positive (medium/high expression; ≥ 50%/ ≥75% of cells with PS2+ staining intensity), platinum agnostic ovarian cancer, defined as pts with either platinum resistant (PR) (recurrence within 6 months after last platinum dose) or platinum sensitive (PS) responded to the last platinum therapy received before study entry and did not progress within 6 months) disease for whom a non-platinum based doublet would be appropriate. **Methods:** Pts received MIRV (6 mg/kg; adjusted ideal body weight) and BEV (15 mg/kg) on Day 1 of a 21-day cycle. Responses were assessed by investigator according to RECIST 1.1 and adverse events (AEs) evaluated by CTCAE v4.03. **Results:** In total, 60 pts received the combination, with a median age of 60 years, and a median of 2 prior lines of systemic therapy (range 1-4). Platinum status was determined for 56 pts, with 30 (50%) considered PR and 26 (43%) considered PS; platinum status data were incomplete for 4 pts. The most common treatment related AEs (percent all grade/grade 3+) were diarrhea (65/2), blurred vision (62/3), nausea (55/0), and fatigue (55/5). The most common treatment related grade 3+ AEs were hypertension and neutropenia, (10% each); all other grade 3+ events occurred in ≤ 5% of pts. Serious AEs regardless of relationship to study drug were infrequent, with the most common events being small intestinal obstruction in 3 pts, 5% (grade 3) and pneumonitis in 3 pts, 5% (2 grade 1; 1 grade 2). Objective responses were seen in 26 pts for a confirmed overall response rate (ORR) of 43% (95% CI, 31, 57). In a subset analysis of pts with high FRα expressing tumors (n = 33), the confirmed ORR was 61% (95% CI, 42, 77), with an ORR of at least 50% in each of the PR and PS subsets. With a median follow-up of 5.5 months, the duration of response and progression free survival data are immature. **Conclusions:** The combination of MIRV with BEV demonstrates an encouraging ORR with a favorable tolerability profile in pts with recurrent ovarian cancer regardless of platinum sensitivity, particularly in those with tumors that express high levels of FRα. Clinical trial information: NCT02606305. Research Sponsor: ImmunoGen.

6005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Final results from the KEYNOTE-100 trial of pembrolizumab in patients with advanced recurrent ovarian cancer. *First Author: Ursula A. Matulonis, Dana-Farber Cancer Institute, Boston, MA*

Background: Pembrolizumab (pembro) showed modest clinical activity in patients (pts) with recurrent advanced ovarian cancer (AOC) after a median follow-up of 16.9 mo in an interim analysis of KEYNOTE-100 (NCT02674061). We present the protocol-specified final analysis based on a data cutoff of 18-SEP-2019. **Methods:** Key eligibility criteria included epithelial ovarian, fallopian tube, or primary peritoneal cancer, confirmed recurrence following front-line platinum-based therapy, ECOG PS 0-1, and provision of a tumor sample for biomarker analysis. Pts in cohort A received ≤2 prior chemotherapy lines for recurrent AOC and had a platinum-free or treatment-free interval (PFI/TFI) of ≥3 to 12 mo. Pts in cohort B received 3-5 prior chemotherapy lines and had a PFI/TFI of ≥3 mo. Pts received pembro 200 mg Q3W for 2 yr or until progression, death, or unacceptable toxicity. Tumor imaging was performed every 9 wk for 1 yr and every 12 wk thereafter. Primary study endpoint was ORR per RECIST v1.1 by independent central review in both cohorts and by tumor PD-L1 expression using the combined positive score (CPS). Secondary endpoints included DOR, DCR (CR+PR+SD≥24 wk), PFS, OS, and safety. **Results:** 376 pts were enrolled and treated, 285 in cohort A and 91 in cohort B. Median age (range) was 61 (25 to 89) yr, 64.4% had ECOG PS 0, and 75.3% had high grade serous disease. In cohorts A and B, ORR (95% CI) was 8.1% (5.2, 11.9) and 9.9% (4.6, 17.9) in the total population, 6.9% (2.8, 13.8) and 10.2% (3.4, 22.2) in pts with CPS ≥1, and 11.6% (3.9, 25.1) and 18.2% (5.2, 40.3) in pts with CPS ≥10. Median DOR (range) was 8.3 (3.9 to 35.4+) mo in cohort A and 23.6 (3.3+ to 32.8+) mo in cohort B. DCR (95% CI) was 22.1% (17.4, 27.4) and 22.0% (14.0, 31.9). Median PFS was 2.1 mo in both cohorts. In cohorts A and B, median OS was 18.7 mo (17.0, 22.5) and 17.6 mo (13.3, 24.4) in the total population, 20.6 mo (15.2, 23.2) and 20.7 mo (13.6, 27.4) in pts with CPS ≥1, and 21.9 mo (12.9, 26.8) and 24.0 mo (14.5, NR) in pts with CPS ≥10. 73.7% of pts had treatment-related AEs and 20.2% were grades 3-4. There were 2 treatment-related deaths (Stevens-Johnson syndrome and hypoaldosteronism). Immune-mediated AEs occurred in 23.7% of pts. **Conclusions:** Pembro monotherapy was associated with modest antitumor activity in pts with recurrent AOC. There appeared to be a trend toward increased ORR with higher PD-L1 expression in both cohorts. Responses were durable and typically lasted ≥6 months. Median OS was 18.7 months overall, with a trend toward a longer OS with increasing PD-L1 expression in both cohorts. No new safety signals were identified. Clinical trial information: NCT02674061. Research Sponsor: Merck & Co., Inc.

6006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Long-term oncological safety of sentinel lymph node biopsy in early-stage cervical cancer. *First Author: Vincent Balaya, Hopital Européen Georges Pompidou, Paris, France*

Background: The goal of this study was to assess disease-free survival (DFS) and disease-specific survival (DSS) in patients with early-stage cervical cancer who underwent bilateral sentinel lymph node (BSLN) biopsy alone versus bilateral pelvic lymphadenectomy (BPL). **Methods:** An ancillary analysis of two prospective multicentric trials on SLN biopsy for cervical cancer (SENTICOL I and II) was performed. All patients with early stage cervical cancer (IA to IIB FIGO stage), negative SLN after ultrastaging and negative non-SLN after final pathologic examination were included. Risk-factors of recurrency and disease-specific deaths were determined by Cox proportional hazard models. Kaplan-Meier survival curves were compared by applying log-rank test. **Results:** Between January 2005 and July 2012, 259 patients met the inclusion criteria: 85 patients underwent only bilateral SLN biopsy whereas 174 patients underwent BPL. None had positive SLN at ultrastaging or positive non-SLN at final pathologic examination. Between the both groups, there was no differences in histology, final FIGO stage and type of surgical approach. In the BPL group, patients had more frequently tumor size larger than 20 mm (22.9% vs 10.7%, p = 0.02) and postoperative radiochemotherapy (10.7% vs 1.6%, p = 0.01). The median follow-up was 47 months (4-127). During the follow-up, 21 patients (8.1%) experienced reccurencies, including 4 nodal recurrences (1.9%), and 9 patients (3.5%) died of cervical cancer. The 5-year DFS and the DSS were similar between BSLN and BPL groups, 94.1% vs 97.7%, p = 0.14 and 88.2% vs 93.7%, p = 0.14 respectively. After controlling for final FIGO stage and margin status, BSLN compared to BPL was not associated with DFS (HR = 1.76, 95%CI = [0.69 – 4.53], p = 0.24) and DSS (HR = 2.5, 95%CI = [0.64 – 9.83], p = 0.19). Only final FIGO stage was independent predictor of DSS. **Conclusions:** SLN biopsy alone is oncologically safe in early-stage cervical cancer. Full lymphadenectomy could be omitted in case of bilateral negative SLN. Worse prognosis was associated with higher FIGO stage disease. Research Sponsor: None.

6007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Sequential chemoradiation versus radiation alone or concurrent chemoradiation in adjuvant treatment after radical hysterectomy for stage IB1-IIA2 cervical cancer (STARS Study): A randomized, controlled, open-label, phase III trial. *First Author: He Huang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: There are limited data from previous studies regarding whether the addition of chemotherapy to adjuvant radiation after radical surgery improves outcomes among patients with early-stage cervical cancer and adverse pathological factors. **Methods:** This was a prospective randomized trial including patients with FIGO 2009 stage IB1-IIA2 cervical cancer and squamous-cell, adenocarcinoma, or adenosquamous carcinoma with at least one adverse factor after radical hysterectomy. Patients were randomized 1:1:1 to receive adjuvant radiation alone, concurrent chemoradiation with weekly cisplatin (30-40 mg/m^2), or sequential chemoradiation with cisplatin (60-75 mg/m^2) plus paclitaxel (135-175 mg/m^2) in 21 day cycles, given 2 cycles before and 2 cycles after radiotherapy respectively. The primary outcome was the rate of disease-free survival at 3 years. **Results:** A total of 1,048 patients were included in the study (350, radiation alone; 345, concurrent chemoradiation; and 353, sequential chemoradiation). Overall, the median follow-up was 56 months and the median age of patients was 48 years. Most patients (75%) had stage IB1 or IIA1 disease. The three groups were similar with respect to histologic subtypes, the rate of lymphovascular invasion, parametrial, surgical margin and deep stromal involvement, tumor grade, rate of use of minimally invasive surgery, and neoadjuvant chemotherapy, except for lymph-node involvement that was lowest in radiation alone arm. In the intention-to-treat population, sequential chemoradiation was associated with a higher rate of disease-free survival than radiation alone (3-year rate, 90·0% vs. 82·0%; HR 0·52; 95% CI, 0·35 to 0·76) and concurrent chemoradiation (90·0% vs. 85·0%; HR 0·65; 95% CI, 0·44 to 0·96), differences remained after adjustment for lymph-node involvement. Sequential chemoradiation was also associated with a higher rate of overall survival than radiation alone (5-year rate, 92·0% vs. 88·0%; HR for death from cancer, 0·58; 95% CI, 0·35 to 0·95). However, neither disease-free survival nor cancer death risk was different between patients treated with concurrent chemoradiation or radiation alone. **Conclusions:** In this trial, sequential chemoradiation, rather than concurrent chemoradiation, resulted in a higher disease-free survival and lower risk of cancer death than radiation alone among women with early-stage cervical cancer after radical surgery. Clinical trial information: NCT00806117. Research Sponsor: Sun Yat-sen University Clinical Research 5010 Program.

A phase II trial of the Wee1 inhibitor adavosertib (AZD1775) in recurrent uterine serous carcinoma. *First Author: Joyce F. Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: Uterine serous carcinoma (USC) is an aggressive subtype of endometrial carcinoma characterized by TP53 mutations (> 90%), often concomitantly with oncogenic mutations or amplifications that can increase replication stress. As such, USC may therefore be uniquely sensitive to further interference of cell cycle regulation by Wee1 inhibition. This two-stage single arm Phase 2 study was conducted to assess the activity of the Wee1 inhibitor adavosertib as monotherapy in recurrent USC. **Methods:** Women with recurrent USC (defined as non-carcinosarcoma uterine cancers with any serous component) were eligible. Patients (pts) were required to have had at least one prior platinum-based chemotherapy regimen; those with known MSI-H/MMRd disease were required to have received prior PD1/PDL1 therapy or to be ineligible for such therapy. There was no upper limit on the number of prior lines pts could have received. All pts were required to have RECIST measurable disease. Pts received adavosertib 300mg daily on days 1 through 5 and 8 through 12 of a 21-day cycle. Coprimary endpoints were objective response and progression-free survival at 6 months (PFS6). **Results:** Between OCT-11-2018 and SEP-30-2019, 35 pts enrolled on study. Median follow-up is 4.6 months. The median number of prior lines was 3 (range 1-8). 34 pts were considered evaluable for response. In these pts, 9 confirmed and 1 unconfirmed responses were observed, for an ORR of 29.4% (95% CI 15.1-47.5%). The PFS at 6 months was 58.7% (95% CI: 39.5-73.7%). The median PFS is 6.1 months and the median duration of response is 9.0 months. Frequently observed Grade 3 or higher related adverse events included neutropenia (32.3%), anemia (20.6%), and fatigue (23.5%). Immunohistochemistry and targeted next-generation sequencing were performed to investigate potential biomarkers of response. **Conclusions:** Adavosertib monotherapy demonstrates promising clinical activity in women with USC. The observed monotherapy activity is higher than in other diseases, and additional exploration of the biology of Wee1 inhibition in USC is needed. Further studies of adavosertib in this patient population are planned. Clinical trial information: NCT03668340. Research Sponsor: AstraZeneca.

6010 **Clinical Science Symposium, Fri, 8:00 AM-9:30 AM**

A randomized phase II study of cabozantinib and nivolumab versus nivolumab in recurrent endometrial cancer. *First Author: Stephanie Lheureux, Princess Margaret Hospital, Toronto, ON, Canada*

Background: The efficacy of treatment for recurrent endometrial cancer (EC) remains limited. Vascular endothelial growth factor and inflammatory chemokines are proangiogenic factors and immune modulators involved in immune suppression. Reprogramming the tumor microenvironment by combining antiangiogenic and immunotherapy (IO) could enhance antitumor responses. **Methods:** A 2:1 randomized phase 2 trial compared the combination of cabozantinib and nivolumab (Arm A) versus nivolumab (Arm B) in recurrent EC. Primary endpoint was progression free survival (PFS) assessed by RECIST 1.1 (NCT03367741). Women with recurrent measurable EC were eligible. There were no limits on prior therapy, but at least one prior platinum-based chemotherapy was required. Patients (pts) were stratified according to MSI status and assessed by CT every 8 weeks. Cabozantinib was given at 40 mg daily (Arm A) and nivolumab at 240 mg, on D1 and D15 of a 28-day cycle for 4 cycles, followed by 480 mg every 4 weeks (Arms A & B). Pts with carcinosarcoma or prior IO were enrolled in an exploratory cohort and received combination treatment (Arm C). A baseline biopsy was required for all pts. CyTOF analysis was performed on fresh biopsies. **Results:** 76 evaluable pts were enrolled (Arm A: 36, Arm B: 18, Arm C: 9 carcinosarcoma, and 20 post IO including 7 pts crossed over from Arm B). 55% of pts had received ≥3 prior lines of therapy. Two pts were MSI high in Arm A and none in Arm B. The Kaplan-Meier estimated median PFS was 5.3 (95% CI: 3.5-9.5) months in Arm A and 1.9 (95% CI: 1.6-3.8) months in Arm B, with a log-rank p = 0.07, which met the significance level of 0.1 used for sample size calculation. Objective response rate (ORR) was 25% for Arm A and 16.7% for Arm B; stable disease (SD) was seen in 44.4% *vs* 11.1%, respectively. Clinical benefit (ORR+SD) was significantly higher in arm A *vs* B ($p < 0.001$). In Arm C-carcinosarcoma, one patient had a partial response (11.9 months duration) and four SD. In Arm C-prior IO, six pts responded and eight had SD. The most common related AEs in Arm A were diarrhea (47.2%), elevated liver enzymes (44.4%), fatigue (38.9%), anorexia, hypertension, and nausea (30.6%), mainly grade 1/2. Preliminary CyTOF analysis across treatment arms identified multiple immune subsets for further interrogation including activated CD8+ and CD4+ T cells. **Conclusions:** Cabozantinib plus nivolumab demonstrates improved PFS compared to nivolumab in heavily pre-treated women with recurrent EC. In-depth CyTOF analysis of the tumor microenvironment to identify predictive immune biomarkers of response is ongoing. Clinical trial information: NCT03367741. Research Sponsor: U.S. National Institutes of Health, Conquer Cancer Foundation of the American Society of Clinical Oncology.

6011 **Clinical Science Symposium, Fri, 8:00 AM-9:30 AM**

Impact of chemotherapy alone or in combination with an anti-angiogenic on the immune tumor microenvironment (TME) of ovarian cancer: Data from the randomized CHIVA trial (a GINECO –GINEGEPS study). *First Author: Elisa Yaniz, Gustave Roussy Cancer center, INSERM U981, Villejuif, France*

Background: The neoadjuvant setting is an excellent opportunity to study '*in vivo*' the biological impact of treatment on tumor cells and the immune TME. Both chemotherapy and anti-angiogenics may have immunomodulatory properties which could prime the TME and increase effectiveness of immunotherapeutic agents. We performed comprehensive multiplexed immune biomarker analyses on paired tumor samples at diagnosis and after 3 cycles of neoadjuvant carboplatin+paclitaxel (CP) +/- the anti-angiogenic tyrosine kinase inhibitor nintedanib (N) in the randomized CHIVA trial. **Methods:** Patients were randomized 2:1 to CP + N or placebo for 3 cycles prior to interval debulking, samples were evaluable for immune profiling for 124 pts at diagnosis and 107 at surgery from the CHIVA trial. For 86 patients matched paired samples were available. Multiplexed IF or IHC panels were performed for CD4, CD3, CD8, CK, Granzyme B, FOXP3, CD68, CD163 and DC-Lamp. Wilcoxon tests were used to compare measurements. **Results:** At diagnosis the most abundant cells were CD8+ and CD4+ cells (median=118 and 119cells/mm2, respectively) compared to Foxp3+ TRegs (median=30/mm2). Among the myeloid lineage, the proportion of CD68+ (M1) and CD163+ (M2) macrophages was balanced, while mature dentritic cells (DC) represented <5% of myeloid cells. In the whole population, regardless of arm, neoadjuvant platinum-based treatment significantly increased CD4+ (p=0.03) and CD8+ infiltration (p=0.009), decreased FOXP3+ cells (p=0.01), and these differences pre- and post-treatment remained significant when analysis was restricted to pts with paired samples. Mature DC also increased significantly with neoadjuvant treatment (p=0.0003), there was no significant modification in CD68+ or CD163+ macrophages. Changes in immune parameters did not differ significantly between the CP+B vs CP+placebo arms. **Conclusions:** Neoadjuvant treatment has a profound impact on the immune cell composition of the TME in advanced OC. However this change seems to be mainly mediated by platinum+paclitaxel chemotherapy rather than the anti-angiogenic tyrosine kinase inhibitor nintedanib. Research Sponsor: Maria Pia Award.

Final survival analysis of NSGO-AVANOVA2/ENGOT-OV24: Combination of niraparib and bevacizumab versus niraparib alone as treatment of recurrent platinum-sensitive ovarian cancer—A randomized controlled chemotherapy-free study. *First Author: Mansoor Raza Mirza, The Finsen Centre 5073, Copenhagen, Denmark*

Background: We previously reported significantly improved progression-free survival (PFS) with the chemotherapy-free regimen of niraparib and bevacizumab compared to niraparib alone, in women with platinum-sensitive relapsed ovarian cancer (PSROC), regardless of homologous recombination deficiency (HRD) status (MyChoice HRD), duration of chemotherapy-free interval (CFI) and number of previous lines of therapy (Mirza MR et al, Lancet Oncol 2019). We now present the updated PFS, overall survival (OS) and other efficacy and safety endpoints. **Methods:** In this randomized, open-label, phase 2 study, women with measurable/evaluable, high-grade serous or endometrioid PSROC were randomized to niraparib 300mg once daily or the combination of niraparib 300mg once daily and bevacizumab 15mg/kg IV every 3 weeks until disease progression (1:1 randomization). The primary endpoint was PFS. Stratification was according to HRD status and CFI (6-12months (mo) vs. > 12mo). First-line maintenance bevacizumab was permitted. **Results:** Of 97 enrolled patients, 48 were randomized to niraparib monotherapy and 49 to the chemotherapy-free combination. The combined treatment significantly improved PFS compared to niraparib alone: updated median PFS 12.5 mo vs. 5.5 mo; hazard ratio (HR) adjusted for stratification factors 0.34; 95% confidence interval (CI) [0.21 to 0.55]; P < 0.0001. Preplanned exploratory subgroup analyses: patients with HRD-positive tumors (n = 54) HR 0.41 (CI, 0.23-0.76); HRD-negative disease (n = 43) HR, 0.40 (CI, 0.20-0.79); Time to First Subsequent Therapy (TFST) (n=97) HR, 0.4 (CI, 0.25-0.64); PFS2 (n=97) HR 0.55 (CI, 0.35-0.88); Time to Second Subsequent Therapy (TSST) (n=97) HR, 0.56 (CI, 0.35-0.90); OS (49 events only) HR, 0.77 (CI, 0.42-1.41). There was no difference in treatment-emergent grade 3-4 adverse events except for the rate of hypertension (22.9% vs. 0%) and neutropenia (8.3% vs. 2.0%). Patient-reported outcomes measured using EORTC QLQ-C30 and OV28 were similar for both treatment arms. **Conclusions:** Updated PFS consistently demonstrates that the niraparib-bevacizumab combination had clinically and statistically meaningful activity in PSROC. This phase 2 study was not powered to detect differences in OS or any other efficacy endpoints however TFST, PFS2 & TSST are significantly improved while there is a trend towards OS improvement with niraparib-bevacizumab combination. Clinical trial information: NCT02354131. Research Sponsor: research grant + niraparib from Tesaro Inc for this Invest. Initiated Trial (sponsor Nordic Society of Gynaecological Oncology NSGO).

6013 Poster Discussion Session; Displayed in Poster Session (Board #184), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Olaparib treatment in patients (pts) with platinum-sensitive relapsed (PSR) ovarian cancer (OC) by BRCA mutation (BRCAm) and homologous recombination deficiency (HRD) status: Phase II LIGHT study. *First Author: Karen Anne Cadoo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In Study 19 (NCT00753545), olaparib capsules demonstrated improvement in progression-free survival (PFS) vs placebo in the PSR OC maintenance setting, irrespective of BRCAm status (Ledermann *et al. Lancet Oncol* 2014). LIGHT is the first prospective study to evaluate olaparib tablet treatment in PSR OC pts by BRCAm and HRD status. **Methods:** This is an open-label, non-randomized study (NCT02983799) that assessed efficacy and safety of olaparib monotherapy (300 mg BID) in pts with PSR, high-grade serous/endometrioid epithelial OC and ≥1 prior line of platinum chemotherapy. Pts were assigned to one of four cohorts: germline (g) BRCAm; somatic (s) BRCAm; HRD+ve (non-BRCAm); HRD–ve; by Myriad BRACAnalysis CDx and myChoice tests. HRD+ve was a score ≥42. Primary endpoint was objective response rate (ORR). Secondary endpoints included: disease control rate (DCR) and investigator-assessed PFS (RECIST v1.1). Primary analysis was to be ~6 months (mo) after the last pt was enrolled. **Results:** Data cut off was 8/27/19. Of 271 pts treated (median of 31.7 weeks [2.1–96.0]), 270 had measurable disease at baseline and were included in efficacy analyses (Table). The most common treatment-emergent adverse events (AEs) were nausea (66%) and fatigue (62%).Serious AEs and Grade ≥3 AEs were experienced by 25% and 44% of pts, respectively. AEs leading to olaparib dose interruptions, reductions and discontinuations occurred in 33%, 24% and 4% of pts, respectively. **Conclusions:** Olaparib treatment demonstrated activity across all cohorts. As observed in the maintenance setting, similar efficacy was seen in the gBRCAm and sBRCAm cohorts. For non-BRCAm pts, longer median PFS and higher ORR were observed in the HRD+ve cohort. Olaparib treatment was well tolerated with no new safety signals identified and a safety profile consistent with that seen in the PSR and first-line settings. Clinical trial information: NCT02983799. Research Sponsor: AstraZeneca Pharmaceuticals LP.

Concordance between CA-125 and RECIST progression (PD) in patients with germline BRCA-mutated platinum-sensitive, relapsed ovarian cancer treated with a PARP inhibitor (PARPi) as maintenance therapy after response to chemotherapy. *First Author: Angelina Tjokrowidjaja, NHMRC Clinical Trials Centre, Camperdown, NSW, Australia*

Background: There are no data to support CA-125 as a surrogate biomarker for ovarian cancer PD in patients on maintenance therapy with a PARPi. We aimed to assess the concordance of PD by CA-125 with RECIST PD in patients treated with maintenance PARPi. **Methods:** We extracted data on PD as defined by GCIG CA-125 and investigator-assessed RECIST from the SOLO2/ENGOT-Ov21 (NCT01874353) trial. Patients were categorized into: (i) CA-125 and RECIST non-PD concordant; (ii) CA-125 and RECIST PD concordant; and (iii) CA-125 and RECIST discordant. We excluded those with PD other than by RECIST, PD on date of randomization, and no repeat CA-125 beyond baseline. To assess the concordance of CA-125 PD with RECIST PD and CA-125 non-PD with RECIST non-PD, we computed the positive predictive value (PPV), i.e. the probability that patients with CA-125 PD also had RECIST PD, and negative predictive value (NPV), i.e. probability that patients with no CA-125 PD also did not have RECIST PD, respectively. **Results:** Of 295 randomised patients, 275 (184 olaparib, 91 placebo) were included in the primary analysis. 80 (29%) had CA-125 PD and 77 had concordant RECIST PD, resulting in a PPV of 96% (95% CI 90%-99%). Of 195 patients without CA-125 PD, 101 also did not have RECIST PD, resulting in a NPV of 52% (95% CI 45%-59%; Table). Among those with RECIST PD (n = 171), a greater proportion of patients with RECIST-only PD had a normal baseline CA-125 than those with both CA-125 and RECIST PD (94% *vs* 69%; $p< 0.001$). Of 94 patients without CA-125 PD but had RECIST PD, 65 (69%) had CA-125 that remained within normal range, while 27 (29%) had rising and elevated CA-125 that did not meet the criteria for GCIG CA125-PD. Discordance between RECIST PD and CA-125 non-PD was similar in early (≤12 weeks) and late (> 12 weeks) PD (56% *vs* 55%, respectively; $p= 0.96$). **Conclusions:** Almost half the patients with RECIST PD did not have CA-125 PD and most had CA-125 still within the normal range. Regular imaging should be considered as part of surveillance in patients on maintenance olaparib rather than relying on CA-125 alone. Research Sponsor: Astra Zeneca.

Disease status by CA-125 criteria	RECIST-defined disease progression (n = 171)	No RECIST-defined disease progression (n = 104)	Total (n = 275)
Progressive disease, n (%)	77 (96%)	3 (4%)	80
Non-progressive disease, n (%)	94 (48%)	101 (52%)	195

Characterization of patients (pts) with long-term responses to rucaparib in recurrent ovarian cancer (OC). *First Author: Elizabeth M. Swisher, University of Washington, Seattle, WA*

Background: Pts who derive durable benefit from PARP inhibitor treatment may provide insights into improving outcomes. Here we describe long-term responders from Study 10 (NCT01482715) and ARIEL2 (NCT01891344), studies of the PARP inhibitor rucaparib for the treatment of high-grade recurrent OC. **Methods:** This analysis included pts enrolled in Study 10 (Part 2A: *BRCA1* or *BRCA2* [*BRCA*]-mutant OC, platinum sensitive, 2–4 prior chemotherapies; Part 2B: any platinum status, 3–4 prior chemotherapies) and ARIEL2 (Part 1: *BRCA*-mutant or wild-type OC, platinum sensitive; Part 2: any platinum status, 3–4 prior chemotherapies). Final results from Study 10 (n = 54) and ARIEL2 (n = 491) were pooled. Long-term responders were defined as pts with duration of response (DOR) > 1 y, and short-term responders as pts with DOR ≤ 20 weeks; responses were evaluated using RECIST. Targeted next-generation sequencing was used to detect deleterious mutations and loss of heterozygosity (LOH) in tumors. *BRCA1* methylation was quantified by digital droplet PCR. **Results:** Overall, 25% (138/545) of enrolled pts were responders. Of these, 29% (40/138) had long-term responses, including 16/138 (12%) with DOR > 2 y; 21% (29/138) were short-term responders. Both groups received a median of 3 prior anticancer therapies. Among patients with *BRCA* mutations, *BRCA* homozygous deletion or rearrangement was detected in 15% (4/27) of long-term responders vs 0% (0/15) of short-term responders. In an expanded analysis of the 95 pts with *BRCA* mutations and confirmed response, pts with *BRCA* homozygous deletion or rearrangement had significantly longer DOR than pts with other mutation types (median 3.5 vs 0.6 y; HR = 0.30; p = 0.024). There was no apparent difference in *BRCA* gene or mutation location for long- vs short-term responders. Ten of the 13 long-term responders with *BRCA* wild-type OC had high genome-wide LOH (≥16% LOH), a genomic scar indicative of homologous recombination deficiency, including OC associated with *BRCA1* hypermethylation (n = 2) and *RAD51C/D* mutations (n = 2). **Conclusions:** Long-term responders to rucaparib include OC with *BRCA* mutation, particularly homozygous deletion or rearrangements, which would not be susceptible to somatic reversion mutations, as well as *BRCA1* hypermethylation, and *RAD51C/D* mutations. Clinical trial information: NCT01482715; NCT01891344. Research Sponsor: Clovis Oncology, Inc.

A randomized phase II trial of secondary cytoreductive surgery (SCS) +/- carboplatin hyperthermic intraperitoneal chemotherapy (HIPEC) in patients (pts) with recurrent platinum-sensitive ovarian cancer (EOC). *First Author: Oliver Zivanovic, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: The role of HIPEC for recurrent EOC is not well defined. The aim of this phase II study was to determine the proportion of pts without evidence of disease progression at 24 months post SCS +/- intraoperative carboplatin HIPEC. **Methods:** After SCS to ≤ 0.5 cm residual visible disease pts were intraoperatively randomized to carboplatin HIPEC (800mg/m^2 for 90 minutes) or no HIPEC. The HIPEC arm received 5 additional and the standard arm received 6 postoperative cycles of IV platinum-based chemotherapy without maintenance treatment. Based on an exact binomial single stage "pick the winner" design, each arm is considered "winner" if ≥ 17/49 pts are without evidence of disease progression at 24 months post SCS. Secondary objectives include postoperative grade ≥ 3 toxicity and complications within 4 weeks post SCS, and pharmacokinetics of carboplatin HIPEC. **Results:** Of 98 pts, 49 (50%) were randomized to the HIPEC arm. The arms were well balanced for age, stage, histology, BRCA mutation status, prior chemotherapy, and disease-free interval. Complete gross SCS was achieved in 94% of the standard and 82% of the HIPEC arm (p = 0.12). Bowel resection was performed more frequently in the standard (65%) compared to the HIPEC arm (37%; p = 0.008). Median operative time was shorter in the standard (296 minutes) compared to the HIPEC arm (475 minutes; p < 0.001). There was no perioperative mortality and no difference in use of ostomies, length of stay or postoperative toxicity. At a median follow-up of 27.7 months (range: 8.8-81.8 months) 70 of 98 pts progressed and 26 died with a median progression free survival (PFS) of 14.3 months (12.1-16 months) and a median overall survival (OS) of 55.2 months (47.7-not reached). At 24 months post SCS 32 pts progressed within 24 months in the standard versus 35 in the HIPEC arm. There was no statistically significant difference in median PFS (15.4 vs 12.3 months, p = 0.173) or median OS (69.2 vs 53.1 months, p = 0.317) between arms. These are preliminary efficacy estimates as 83/98 pts have a minimum of 24 months follow-up. **Conclusions:** The HIPEC arm did not reach the predefined "winner" endpoint; the standard arm is still undetermined as 6 pts did not reach 24 months follow-up. No perioperative mortality, and no increased perioperative morbidity or toxicity was seen with HIPEC. SCS with carboplatin HIPEC followed by 5 cycles of platinum-based chemotherapy was not superior to SCS without HIPEC followed by 6 cycles of platinum-based chemotherapy. Clinical trial information: NCT01767675. Research Sponsor: Gail Baird Foundation, Other Foundation.

Randomized double-blind placebo-controlled trial of primary maintenance vigil immunotherapy (VITAL study) in stage III/IV ovarian cancer: Efficacy assessment in *BRCA1/2*-wt patients. *First Author: Rodney Paul Rocconi, University of South Alabama, Mobile, AL*

Background: Vigil is an autologous tumor cell vaccine constructed from autologous harvested tumor tissue transfected with a DNA plasmid encoding GMCSF and bi-shRNA-furin thereby creating TGFβ expression control. **Methods:** A randomized double-blind placebo-controlled trial of Vigil vs. placebo was performed in advanced stage frontline OC patients. Relapse-free survival (RFS) and safety were endpoints. Patients who achieved complete clinical response were randomized [1:1 to placebo (control group, CG) or Vigil (Vigil group, VG)] after completion of frontline surgery and chemotherapy. All patients received 1 x 10e7 cells/ml of Vigil or placebo intradermally once a month for up to 12 doses. **Results:** Ninety-two patients were randomized with 91 patients in the per-protocol population (PP), (VG n=46; CG n=45). 62 patients were tested for *BRCA1/2* status. VG showed no added overall toxicity compared to CG and no grade 4/5 toxicities were observed. Grade 2/3 toxic events were observed in 18% of CG patients (most common bone pain, fatigue) compared to 8% of VG patients (most common nausea, musculoskeletal pain). From time of randomization median RFS for all 91 patients was favorable in the VG (HR 0.69, one-sided p 0.088).Stratified by BRCA status, an advantage in RFS was seen in the *BRCA1/2*-wt patients in VG (19.4 mo) compared to CG (8 mo) (HR 0.51, 90% CI 0.26 – 1.01, one-sided p 0.050) from time of randomization and HR of 0.49 (90% CI 0.25 – 0.97, one-sided p 0.038) from time of surgery. Median time from surgery to randomization was 208.5 days (6.9 mo) in VG vs. 200 days (6.6 mo) in CG. 37.5% BRCA1/2-wt Vigil treated patients relapsed compared to 71% of placebo at time of data snap for analysis (HR 0.51, one-sided p 0.05), (median follow-up of 34.3 mo for all n=91 subjects). Germline and somatic *BRCA1/2* molecular testing via central third party is underway on all 91 patients under continued blinded conditions to validate activity in *BRCA1/2*-wt. **Conclusions:** Vigil immunotherapy as frontline maintenance in Stage III/IV ovarian cancer is well tolerated and showed RFS clinical benefit, particularly in *BRCA1/2*-wt disease. Clinical trial information: NCT02346747. Research Sponsor: None.

RFS in BRCA1/2-wt population from time of surgery/procurement.

Group	N	Number of events	Median RFS in mo (95% CI)	HR	One-sided p-value
Vigil	24	9/24 (37.5%)	Not reached (14.5 – N/A)	**0.49** (90% CI 0.25 – 0.97)	**0.038**
Placebo	24	17/24 (71%)	14.8 (12 - 21.2)

Association of chronotype and pain at baseline in ovarian cancer survivors participating in a lifestyle intervention (NRG/GOG 0225). *First Author: Tracy E Crane, University of Arizona Cancer Center, Tucson, AZ*

Background: Chronotype is defined as an individual's propensity to sleep at a specific time in a 24-hour cycle with late chronotype associated with poorer health outcomes including cancer. Chronotype remains relatively undefined in ovarian cancer. The Lifestyle Intervention for oVarian cancer Enhanced Survival (LIVES) study is testing whether 1205 women randomized to a diet and physical activity intervention for 24-months will have longer progression-free survival versus an attention control. Here we determine the association of late and early vs mid chronotypes and patient reported outcomes (PROs), lifestyle behaviors and biomarkers of metabolic health and inflammation in ovarian cancer survivors post-treatment (≤ 6.5 months). **Methods:** Chronotype was determined using self-reported time to bed (early < 9 pm; mid ≥ 9 pm - ≤12 am; late > 12 am) captured through the Pittsburg Sleep Quality Index and PROs were measured using subscales of the Rand-36 questionnaire. Validated questionnaires for diet and physical activity were used and biomarkers were collected at routine clinic visits. A total subsample of 438 ovarian cancer survivors enrolled in NRG/GOG 0225- LIVES study with all available baseline measures were included in analyses. Descriptive statistics, general linear mixed models, and Pearson correlations were performed. **Results:** Reported pain was significantly higher in late chronotypes (P < 0.05) when compared to early and mid-chronotypes. Total sleep duration was significant between the 3 chronotypes (P < 0.05) with late chronotype experiencing less sleep (6.77 ± 1.67 hrs) than mid chronotype (7.04 ± 1.31 hrs) and early chronotype (7.56 ± 1.33 hrs). Higher reported pain was significantly correlated to poorer CRP levels (r = -0.198, P < 0.001) suggesting higher systemic inflammation and poorer blood insulin levels (r = -0.116, P < 0.05) independent of chronotype classification. All other subscales of the RAND 36 and physical activity were not associated with chronotype. Diet quality trended towards significance with a positive association observed in early and an inverse association in late chronotypes (P = 0.06). **Conclusions:** Late chronotypes reported higher levels of pain which was associated with poorer sleep and diet quality and higher levels of inflammation and insulin. More robust data, including actigraphy, are being analyzed and will provide additional insight of the role of circadian rhythm and phenotype on pain and key biomarkers in ovarian cancer survivors. Clinical trial information: NCT00719303. Research Sponsor: U.S. National Institutes of Health.

Beyond Sedlis: A novel, histology-based nomogram for predicting recurrence risk and need for adjuvant radiation in cervical cancer—A NRG/GOG ancillary analysis. *First Author: Kimberly Levinson, The Johns Hopkins School of Medicine, Baltimore, MD*

Background: In GOG 49, factors associated with a 3-year, 30% recurrence risk in squamous cell carcinoma of the cervix (SCC) after surgery alone were defined. These "intermediate" risk factors [tumor size (TS), depth of tumor invasion (DOI), and lymphvascular space invasion (LVSI)] were then studied in GOG 92, which demonstrated the utility of treating patients (pts) with ≥2 intermediate risk factors with adjuvant radiation (RT), Sedlis Criteria. However, pts with < 30% recurrence risk were not eligible and few pts with adenocarcinoma (AC) were included. Our study purpose was 1) to evaluate recurrence risk factors for AC vs SCC, and 2) to define contemporary nomograms for adjuvant treatment in pts with both histologies. **Methods:** We performed an ancillary analysis of GOG 49, 92, and 141, and included Stage I pts who received no neoadjuvant/adjuvant therapy. Multivariable Cox proportional hazards models were created separately for AC and SCC to evaluate independent risk factors for recurrence. Model accuracy was tested with ROC curves. Prognostic nomograms were generated for 2-year recurrence risk for AC and SCC. **Results:** We identified 715 with SCC and 105 pts with AC; 142 with SCC (19.9%) and 18 with AC 17.1%) recurred. For SCC, factors associated independently with recurrence were: LVSI [HR 1.58 (CI 1.12-2.22)], DOI [middle 1/3, HR 4.31 (CI 1.81-10.26); deep 1/3, HR 7.05 (CI 2.99-16.64)] and TS [≥4cm HR 2.67 (CI 1.67-4.29)]. In contrast, for AC, only TS ≥4cm was independently associated with recurrence [HR 4.69 (CI 1.25-17.63)]. At 3 years, ROC curves for these models predicted recurrence with 76% and 75% accuracy for SCC and AC, respectively. Utilizing a nomogram generated from these models, for SCC, DOI had the greatest impact on recurrence, with mid 1/3 conferring an 18% risk and deep 1/3 a 32% risk, while LVSI and TS increased risk by 4-10%, respectively. In contrast, for AC, TS alone had the greatest impact on recurrence risk with TS 2-4cm conferring a 20% risk over 3 years and TS ≥4cm, a 28% risk. **Conclusions:** Our nomogram differs from the Sedlis Criteria in demonstrating that single, as well as a combination of risk factors predict substantial 3-year recurrence rates in Stage I cervical cancer. Furthermore, these factors differ by AC and SCC subtypes, suggesting that distinct, histology-specific nomograms may have greater utility in identifying pts who will most benefit from adjuvant therapy. Camrelizumab plus apatinib in patients with advanced cervical cancer: A multicenter, open-label, single-arm, phase II trial. *First Author: Chunyan Lan, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Camrelizumab is a fully humanized, monoclonal antibody against PD-1. We aimed to assess the efficacy and safety of camrelizumab plus apatinib, a tyrosine kinase inhibitor targeting VEGFR2, in patients with advanced cervical cancer. **Methods:** In this open-label, single-arm, phase 2 study done at four centres in China, eligible patients were aged 18–70 years, had an ECOG performance status of 0 or 1, progressed after at least one line of systemic chemotherapy for metastatic, recurrent or persistent cervical cancer, and had measurable disease. Patients received camrelizumab 200 mg every 2 weeks and apatinib 250 mg once daily. Treatment continued until disease progression, unacceptable toxicity, and withdrawal of consent. The primary endpoint was the objective response rate (ORR) assessed by RECIST version 1.1. An optimal Simon two-stage design was employed to test the null hypothesis of a 17% ORR versus 35% alternative (1-sided alpha 0.10, 80% power), if >3 responses out of the first 16 patients were observed, then the study would continue to enroll a total of 44 patients. **Results:** Between Jan 21st, 2019, and Aug 1st, 2019, 45 patients were enrolled and received study treatment (safety population). The median age was 51 (range, 33–67) years. Median previous treatment lines were 2 (range, 1–4). As of Jan 22, 2020, median follow-up was 9.2 months (range, 2.4–12.2). 25 (59.5%; 95%: CI 44.7–74.4) of 42 patients who had at least one post-baseline tumor assessment (efficacy evaluable population) achieved an objective response, including two (4.8%) complete response, and 23 (54.8%) partial response. Median duration of response was not reached. The disease control rate was 88.1% (37/42). Median progression-free survival (PFS) was 7.6 months (95% CI: 5.8–not reached). 31 (68.9%) patients had grade ≥ 3 treatment-related adverse events (TRAEs). Grade ≥ 3 TRAEs occurring in $\geq 5\%$ of patients were hypertension (24.4%), anemia (20.0%), fatigue (15.6%), γ-glutamyltransferase increased (13.3%), neutropenia (6.7%), and thrombocytopenia (6.7%). In post-hoc analyses, objective response was noted in 20 (69%) of 29 patients with PD-L1-positive tumors, and in 5 (50.0%) of 10 patients with PD-L1-negative tumors (Chi-square test, P = 0.281). PFS was longer in patients with PD-L1-positive tumors than patients with PD-L1-negative tumors (median PFS: 9.6 versus 5.3 months; log-rank test, P = 0.017). **Conclusions:** Camrelizumab plus apatinib showed promising antitumor activity and tolerable toxicities in patients with advanced cervical cancer. Clinical trial information: NCT03816553. Research Sponsor: Jiangsu Hengrui Medicine Co. Ltd., National Natural Science Foundation of China

A Big Ten Cancer Research Consortium phase II trial of pembrolizumab with carboplatin and paclitaxel for advanced or recurrent endometrial cancer. *First Author: Mario Javier Pineda, Ironwood Cancer and Research Centers, Gilbert, AZ*

Background: There are limited chemotherapeutic options for patients (pts) with advanced or recurrent endometrial cancer (EC). Reported objective response rates (ORR) for first-line doxorubicin/cisplatin/ paclitaxel combination therapy was 57%; with a median progression-free survival (PFS) of 8.3 months. The goal of this phase II study was to assess the efficacy and safety of pembrolizumab in combination with standard carboplatin/paclitaxel in pts with measurable advanced or recurrent EC. **Methods:** This was a single-arm, open-label, multicenter phase II study for pts with RECIST measurable advanced or recurrent EC coordinated by the Big Ten Cancer Research Consortium. Patients may have had received 1 prior platinum-based regimen, with a platinum free interval $>$ 6 months, $<$ one non-platinum chemotherapy, or prior hormonal therapy. Pts received carboplatin AUC 6, paclitaxel 175mg/m^2 (CT) and pembrolizumab 200mg IV every 3 weeks for up to 6 cycles; with dose reduced for prior radiation. The primary endpoint was ORR per immune-related RECIST. Planned sample size of 46 subjects provided 77% power to detect 15% ORR improvement compared to historical controls, with one-tailed test and 10% type I error rate. **Results:** 46 pts were enrolled. Median age was 67 (range: 43-86). 32 pts had recurrent and 14 had primary metastatic EC. Histological types were: 26 endometrioid, 11 serous, 3 clear cell, 6 other. 19 patients had received prior carboplatin/paclitaxel, 23 pelvic EBRT, 14 brachytherapy, 1 adriamycin and 1 hormonal therapy. Grade 3-4 adverse events (AEs) included: laboratory abnormalities (20), hematological (8), metabolism (6), nervous system (4), gastrointestinal (2), and others (6). There were 15 grade 3-4 SAEs occurring in 7 pts: vomiting (1), anaphylaxis (3), fever (2), dehydration (1), syncope (2), vascular (2), fatigue (1), neurological (2), thrombocytopenia (1), and no grade 5 SAEs. 36 patients were evaluable for response at the time of abstract submission. ORR was 77.8% (28/36) and median PFS was 10.55 months. **Conclusions:** The addition of pembrolizumab to standard of care CT chemotherapy for advanced or recurrent EC induced a clinically significant improvement in ORR compared to historical outcomes and toxicity did not exceed anticipated toxicity with standard treatment, supporting further testing in a phase III trial. Clinical trial information: NCT02549209. Research Sponsor: Merck.

Effect of high-dose chemotherapy with autologous stem cell rescue (HDC-aSCR) on outcome in ovarian small-cell carcinoma, hypercalcemic type (SCCOHT): Prospective series from the French Rare Gynecologic Malignant Tumors Network (TMRG). *First Author: Felix Blanc, Institut Gustave Roussy, Villejuif, France*

Background: Small cell carcinoma of the ovary, hypercalcemic type (SCCOHT), is a rare and rapidly lethal disease affecting young women with over half dying within 2 years of diagnosis. We previously reported improved outcomes with cytoreductive surgery followed by HDC-aSCR in a prospective study, but these encouraging results needed to be confirmed in an independent and larger cohort. **Methods:** Between 2008 and 2019, out of 44 patients (pts) diagnosed with centrally confirmed SCCOHT in 16 referent centers of the TMRG network, 38 were treated prospectively according to the French recommendations of the network with complete surgery (primary or after neoadjuvant chemotherapy), 4 to 6 cycles of PAVEP chemotherapy (cisplatin, doxorubicin, vepeside, and cyclophosphamide), and for pts with complete response (CR), HDC-aSCR, followed by pelvic radiotherapy. The 6 patients who could not receive PAVEP (unfit or diagnostic delay) relapsed and died rapidly. The primary endpoint was the event-free survival (EFS) in the intention-to-treat cohort. **Results:** Median age at diagnosis was 33 years (14-76). 13 pts presented with FIGO stage I, 17 stage III and 6 stage IV, 2 unknown. Median follow-up was 55.5 months. 34 patients achieved CR with CT + surgery and 30 received HDC-aSCR (40%, 47% and 10% with stages I, III and IV diseases respectively) and 21 received also pelvic radiotherapy. Median overall and event-free survival was 36.4 and 15.9 months respectively, and 2-years event-free survival rate was 40% (CI95% 25-56). Median OS was respectively not reached, 18 and 9.6 months for FIGO I, III and IV patients. Among the pts (N = 14) who did not receive HDC-aSCR (rapid progression during or after PAVEP), the 2-yr EFS was 0% compared to 50.5% for the 30 patients receiving HDC. In multivariate analysis, HDC was significantly correlated with better outcomes ($p < 0.001$). For the 21 patients receiving also pelvic radiotherapy, 57% (12/21) are free of recurrence at 4 years. Grades 3/4 adverse events were frequent (78%) but, in most cases, manageable, although one toxic death (3%) occurred during HDC (fungal septic shock). **Conclusions:** Treatment of SCCOHT, with intensive multimodal therapy, is associated with a 40% 2-yr event-free survival. However, this protocol is associated with significant toxicity and should be restricted to good performance status patient and expert centers. Research Sponsor: None.

6025 Poster Session (Board #196), Fri, 8:00 AM-11:00 AM

Phase II trial of guadecitabine priming and pembrolizumab in platinum resistant recurrent ovarian cancer. *First Author: Daniela Matei, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Platinum resistant ovarian cancer (PROC) remains a disease of high need. Immune checkpoint inhibitors (ICI) have modest activity. We hypothesized that priming with a hypomethylating agent (HMA) guadecitabine (G) will improve the anti-tumor activity of ICI in PROC by enhancing tumor cell recognition by CD8+ T cells. **Methods:** This open-label phase II study used a Simon's two-stage design. Eligible patients (pts) had recurrent PROC; ECOG PS of 0-1; normal end organ function; and measurable disease. Up to 5 prior cytotoxic regimens were allowed. Treatment consisted of G 30mg/m2 sq D1-4 and pembrolizumab (P) 200mg iv D5. Each cycle was 21 days. The primary endpoint was response rate (RR). Secondary endpoints were progression-free survival (PFS), clinical benefit rate (CBR), and toxicity assessment. Translational endpoints were LINE1 methylation in PBMCs, global tumor methylation, and immune endpoints. Tumor biopsies were obtained at baseline and after 2 cycles. If 2 patients experienced clinical benefit in stage I [n = 16], enrollment proceeded to stage II. The null hypothesis was rejected for ≥ 6 responses in 35 evaluable patients. **Results:** 48 pts were enrolled, 43 were treated, and 33 were evaluable for response. Histology was serous (35), endometrioid (2), clear cell (3) and other (3). Median age was 63 (range 40-88) and median number of prior regimens was 4 [range 1-8]. Two PRs were recorded in the first stage, allowing second stage of enrollment. Overall, there were 2 PRs (RR = 6.6%) and 16 pts had stable disease (SD) [48%]. The clinical benefit rate (PR + SD $>$ 3 months) was 27%. One patient continued treatment for $>$ 2 yrs. Grade 3-4 related toxicities were neutropenia [20], lymphopenia, (9), anemia (2), neutropenic fever (1), rash (1), and others (8). There were 13 grade 3-4 SAEs and 4 grade 5 SAEs, assessed as being unrelated to treatment. LINE1 was hypomethylated in PBMCs D5 vs. D1 (n = 21, p = 0.001). Epic arrays measured global tumor methylation, with 39579 CpG sites (0.05%) being differentially methylated (C2D5 vs. C1D1, n = 11, paired t-test; $p < 0.01$). Main pathways affected included *endosomal transport, K+ transport, cathecolamine secretion, etc.* PDL1 staining in archival tissue showed tumor staining > 0 in 16 of 35 and tumor/stroma interface staining > 0 in 20 of 35 specimens. Antigen-specific cytotoxic T cell activity was increased in CD8+ cells from ascites (C2D5 vs. C1D1). **Conclusions:** G+P has modest anti-tumor activity in patients with PROC, but some patients experienced prolonged disease stabilization. Biomarkers of response are being investigated. Clinical trial information: NCT02901899. Research Sponsor: Department of Defense, Pharmaceutical/ Biotech Company.

6027 Poster Session (Board #198), Fri, 8:00 AM-11:00 AM

A randomized phase II/III trial of conventional paclitaxel and carboplatin with/without bevacizumab versus dose-dense paclitaxel and carboplatin with/without bevacizumab, in stage IVB, recurrent, or persistent cervical carcinoma (JCOG1311): Results of the phase II part. *First Author: Mitsuya Ishikawa, Department of Gynecology, National Cancer Center Hospital, Tokyo, Japan*

Background: A randomized controlled trial was conducted to assess the efficacy and safety of dose-dense, weekly paclitaxel plus carboplatin (ddTC) with or without bevacizumab (Bmab) compared to conventional, tri-weekly paclitaxel plus carboplatin (cTC) with or without Bmab, in metastatic or recurrent cervical carcinoma not amenable to curative treatments with local therapy. **Methods:** Patients were randomly assigned to either a cTC or a ddTC regimen. After Bmab was approved in Japan (in May 2016) the protocol was amended, and patients on both arms received Bmab if not contraindicated. The cTC was paclitaxel 175 mg/m^2 intravenously (IV) for 3 h on day 1 followed by carboplatin at an area under the curve of five IV for 1 h on day 1. The ddTC was paclitaxel 80 mg/m^2 IV for 1 h on day 1 followed by carboplatin at an area under the curve of five IV for 1 h on day 1 and paclitaxel 80 mg/m^2 IV for 1 h on day 8 and day 15. Both cTC and ddTC treatments were repeated every three weeks, for up to nine cycles. Bmab 15 mg/kg IV was repeated until progression or unacceptable toxicity. The primary endpoint of phase II was the response rate (RR) in patients with measurable lesion, who had received Bmab. If the RR of the ddTC + Bmab arm was greater than that of the cTC + Bmab arm for more than 5%, the study would proceed to phase III, which had overall survival (OS) as its primary endpoint. The planned sample size in the phase II part was 56 to select the ddTC arm with a probability of at least 75% if the difference of RR was 15% or more (45% vs. 60%). **Results:** Patient accrual started in October 2015. It was suspended in May 2019 because the number of Bmab-treated patients with measurable lesions reached 56. In total, 122 patients were enrolled and randomly assigned to either the cTC arm (cTC: 29 patients; cTC + Bmab: 32 patients) or the ddTC arm (ddTC: 30 patients; ddTC + Bmab: 31 patients). The primary analysis of the phase II part was conducted in November 2019. The RRs of each regimen were 67.9% [95% CI, 47.7-84.1] (19/28, cTC + Bmab), 60.7% [40.6-78.5] (17/28, ddTC + Bmab), 55.2% [35.7-73.6] (16/29, cTC), and 50.0% [29.9-70.1] (13/26, ddTC). **Conclusions:** The study did not meet the primary endpoint of phase II. Dose-dense, weekly paclitaxel plus carboplatin is not promising for metastatic or recurrent cervical carcinoma. Clinical trial information: jRCTs031180007. 6028 Poster Session (Board #199), Fri, 8:00 AM-11:00 AM

Histopathologic validation of the sentinel node technique in early-stage cervical cancer patients. *First Author: Patrice Mathevet, University Hospital of Lausanne, Lausanne, Switzerland*

Background: Sentinel lymph node biopsy (SLN) could be an alternative to systematic lymphadenectomy in early cervical cancer. SLN is less morbid and had shown a high sensitivity for metastasis detection. However, sensitivity of the SLN technique could be over evaluated because SLN are examined with ultrastaging and non sentinel nodes are only examined with routine techniques. The aim of this study was to validate the negative predictive value (NPV) of the SLN technique, with ultrastaging of SLN and non sentinel nodes (NSLN). **Methods:** We used the SENTICOL 1 study data, published in 2011. All nodes, SLN and NSLN have been secondarily subjected to ultrastaging. The ultrastaging consisted in sectioning every 200 μm and immunohistochemistry. A central reviewing of the positive slides and 10% of the negative slides was undertaken. **Results:** One hundred thirty-nine patients were included. SLNs were detected in 136 (97.8%) of the 139 patients. SLNs were found bilaterally in 104 (76.5%) of the 136 patients. 2056 NSLNs were identified (median = 13 NSLNs per patient [range 1-54]). Of 136 patients with SLNs detection, 23 had positive SLNs, after serial sectioning and IHC. NSLNs were metastatic in 8 patients. However, in case of bilateral SLN detection, the FN rate was 1/99 (1%) with detection of ITC in one NSLN from 99 bilateral negative SLNs. The NPV was 99% (0,99 [IC 95% = 0,97-1,00]). **Conclusions:** The pelvic SLN technic is a safe and trustfully technic to determine the nodal status in patients with early-stage cervical cancer. In case of optimal mapping with bilateral detection, NPV is 99% (IC 95% = 0,97-1,00). Research Sponsor: the National French Cancer Institute (PHRC 2004).

6029 Poster Session (Board #200), Fri, 8:00 AM-11:00 AM

Survival differences by race after minimally invasive versus open radical hysterectomy. *First Author: Rebekah Summey, University of Texas at Austin, Austin, TX*

Background: Black patients with cervical cancer have historically experienced worse survival compared with white women, as well as decreased rates of minimally invasive surgery (MIS) including radical hysterectomy. The goal of our study is to evaluate if this disparity in survival outcomes reverses in light of new findings favoring an open approach for patients with stage IA2 and IB1 cervical cancer compared to MIS. **Methods:** The National Cancer Database was queried, and all black and white women with stages IA2 and IB1 cervical cancer who underwent radical hysterectomy from 2010 to 2015 were included. Patients without survival data or documented surgical approach were excluded. Demographic factors were compared using student t-tests and Z-test of proportions as appropriate. Hazard ratios (HR) for the event of mortality were calculated by race and by route of surgery. Kaplan-Meier plots were created to compare survival between groups, and the Cox proportional hazards model was used to adjust for covariates. **Results:** 4915 patients were identified for inclusion, 12.1% black and 87.9% white. 43.0% of patients underwent open surgery (84.9% white and 15.1% black) and 57.0% underwent MIS (90.1% white and 9.9% black). Average follow up time between groups was 39.5 months for black patients and 40.6 months for white patients. Black patients who underwent open surgery had a hazard ratio (HR) for mortality of 1.44 (95% CI: 1.03-2.00), and those who underwent MIS had a HR of 1.48 (95% CI: 1.03-2.12), when compared to white patients. Mortality rates for black patients undergoing open radical hysterectomy remained higher than those for white patients who underwent MIS. When adjusted for age, insurance status, neighborhood income and educational level, tumor type, Hispanic ethnicity, node positivity and tumor size, these hazard ratios were no longer significant. **Conclusions:** Following discoveries of improved outcomes following abdominal radical hysterectomy as compared with MIS, we have identified that the discrepancy in ability to undergo MIS did not resolve previously identified disparities in the outcome of death for black women. Research Sponsor: None.

6030 Poster Session (Board #201), Fri, 8:00 AM-11:00 AM

Gastric-type adenocarcinoma of the cervix: Genomic drivers and clinical outcomes. *First Author: Dib Sassine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cervical Gastric-type adenocarcinoma (CGA) is a non-HPV-associated adenocarcinoma, comprising 10% of all cervical adenocarcinomas (Park et al, 2019). The optimal management approach is unclear, given that most data in advanced cervical cancer is driven by HPV-positive disease. We summarize our experience with this rare tumor type at a large cancer center. **Methods:** A retrospective review was performed for all women diagnosed with CGA 6/1/2002- 7/1/2019. Patients who did not follow up after a single visit were excluded. Kaplan-Meier survival analysis was performed to determine progression-free survival (PFS) and overall survival (OS) from date of diagnosis. Tumors from a subset of patients were subjected to MSK-IMPACT targeted sequencing and analysis (Zehir et al, 2017). **Results:** A total of 68 women were identified; 47 met inclusion criteria. The median age at diagnosis was 52 years (range 27-83). The majority of patients were white (70%), an additional 19% were Asian. The majority of patients (60%, n=28) presented with advanced disease (FIGO 2018, stage II-IV), while 40% (n=19) were Stage I. Of note, 26% (n=12) had positive pelvic lymph nodes and 13% (n=6) had ovarian metastases at time of surgical resection. For upfront treatment: 13% (n=6) had surgery alone of whom 83% had stage 1 disease, 36% (n=17) had surgery followed by adjuvant therapy, 30% (n =14) received definitive chemoradiation (CRT). All patients with stage IV disease 15% (n=7) received chemotherapy alone. At completion of primary treatment, 19% (n=9) of patients had persistent disease. In patients who received CCRT, 65% (n=22) recurred, the majority (64%) within 12 months of completion of upfront therapy. Pelvic recurrence was the most common site (n=14, 64%). With a median follow up time of 30 months (range 1-159), the median PFS for Stage I was 34.4 months, compared to 17.5 months in patients with Stage II-IV disease (p= 0.29). Of the 24 patients that had MSK-IMPACT, the most common mutation was TP53 (n=16, 64%) followed by mutations in the RAS pathway (n=8, 33%), PIK3CA (n=3, 12.5%), STK11 (n=3, 12.5%), and ERBB2 alterations (n=2, 8.3 %). 2 (8.3%) women enrolled on a clinical trial based on their NGS results, one targeting ERBB2 and one targeting PIK3CA. **Conclusions:** Consistent with prior published literature, CGA is an aggressive form of cervical cancer with poor median OS in the advanced setting. With universal HPV vaccination, HPV negative cervical cancer will represent a larger percentage of newly diagnosed cancers and further research is needed to identify the optimal management approach. Research Sponsor: None.

6031 Poster Session (Board #202), Fri, 8:00 AM-11:00 AM

Adjuvant chemotherapy after concurrent chemoradiation therapy for locally advanced cervical cancer. *First Author: Lingna Kou, Department of Oncology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China*

Background: Standard treatment nowadays for locally advanced cervical cancer (LACC) is concurrent chemoradiation therapy (CCRT). However, due to distant metastasis, survival outcomes are still not optimistic. We tried to evaluate the clinical efficacy and safety of adjuvant chemotherapy for patients with LACC after treated with concurrent chemoradiation therapy (CCRT). **Methods:** Patients diagnosed between May, 2013 to May, 2018 with stage IIA-IIIB LACC were retrospectively analyzed. All the patients received platinum-based radical concurrent chemoradiotherapy and were divided into two groups: adjuvant chemotherapy after CCRT (CCRT+ACT group) and observation after CCRT (CCRT group). Overall survival (OS), progression free survival (PFS) and adverse effects were recorded and analyzed. Kaplan–Meier method and log-rank test were used to calculate and compare differences between survival outcomes. Toxicities were analyzed using chi-square test. **Results:** In total, 375 patients were included in this study, and 262 patients accepted ACT after CCRT while the remaining 113 patients chose to observe. With a median follow-up of 40 months (range 5-73 months), no significant differences were found in both overall survival (OS) and progression free survival (PFS) between two groups referring as 88.5% vs. 90.3% (P= 0.904) and 83.2% vs. 87.6% (P= 0.374). OS rates for patients in CCRT+ACT and CCRT groups at 1 year and 3 years were 97.3% vs. 94.7% (P= 0.195) and 90.2% vs. 88.4% (P= 0.694), respectively. Meanwhile, PFS rates at 1 year and 3 years were 92% vs. 94.7% (P= 0.371) and 87.5% vs. 85.5% (P= 0.761) for two arms separately. 3-4 grades acute adverse events happened more frequently in CCRT+ACT group than in CCRT group, with significant differences in neutropenia and anemia (P< 0.05). **Conclusions:** In this study, adjuvant chemotherapy after concomitant chemoradiotherapy did not show benefit of survival but do induce adverse effects. We do not suggest it unless further large scale randomized controlled trials are executed to verify it. Research Sponsor: None.

6032 Poster Session (Board #203), Fri, 8:00 AM-11:00 AM

Gls-010, a novel anti-PD-1 mAb in Chinese patients with recurrent or metastatic cervical cancer: Results from a multicenter, open-label and single-arm phase II trial. *First Author: Xiaohua Wu, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: GLS-010 is a novel fully human anti-PD-1 mAb. Previous Phase I study exhibited favorable result of tolerance, preliminary efficacy and 240mg fixed dose q2w was selected as Recommended Phase II Dose (RP2D). This Phase II clinical trial is aimed to further evaluate the safety and anti-tumor activity of GLS-010 in patients with recurrent or metastatic cervical cancer. **Methods:** PD-L1 positive (combined positive score (CPS) ≥1) patients with recurrent or metastatic cervical cancer who had received one or more lines of chemotherapy were enrolled and received GLS-010 240mg every 2 weeks. Primary endpoint was the objective response rate (ORR) per RECIST 1.1, secondary endpoints included duration of response (DoR) and safety. **Results:** From May 16th 2019 to December 24th 2019, 44 pts were enrolled and treated in the study. As of December 24th 2019,the median line of prior systemic chemotherapy was 2(range: 1~4) , and 59% (26/44) of pts had received ≥2 previous lines of chemotherapy. The median number of GLS-010 doses was 1.5(range: 1~4). 25 pts received response evaluation per investigator review. With a median follow-up of 2.9 months, 7 of 25 evaluable pts achieved a partial response (PR). The ORR was 28% (95% CI, 12.07-49.39), with 7 pts achieving a PR (3 of 7 confirmed), 3 pts achieving stable disease (SD) and 15 pts with progressive disease (PD), 1 of which was assessed as dissociated response with treatment ongoing. Median duration of response had not been reached yet. 33 of 44 patients (75%) experienced one or more treatment-related adverse events (TRAEs) per NCI CTCAE v4.03, most of which were grade 1 or 2. The most common TRAEs were Anaemia (15/44), and 73.3% of them were grade 1 or 2. The most common ≥grade 3 TRAE included Anaemia (4/44). As data cut off, only 1 pt discontinued treatment due to adverse event. **Conclusions:** GLS-010 showed impressive therapeutic activity and manageable safety profile in Chinese recurrent or metastatic cervical cancer patients. Current evidence support further development of GLS-010 in this and more indications. This trial is still ongoing, and we are looking forward to further results. Clinical trial information: NCT03972722. Research Sponsor: Guangzhou Gloria Biosciences Co., Ltd.

6033 Poster Session (Board #204), Fri, 8:00 AM-11:00 AM

Genome-wide association analysis in host genetic characteristics of progression to high-grade cervical intraepithelial neoplasia or higher for women with human papillomavirus infection and normal cytology. *First Author: Chyong-Huey Lai, Department of OB/GYN, Chang Gung Memorial Hospital, Taoyuan, Taiwan*

Background: Human papillomavirus (HPV) testing is widely used for cervical cancer screening. The hazard ratio of developing cervical intraepithelial neoplasia grade 2 or higher (CIN2+) in HPV-positive/ normal cytology women is 20–34 fold as compared to those with HPV-negative/normal cytology. HPV-positivity would cause substantial anxiety. Apart from viral factors such as high-risk (hr) types, it is important to identify host characteristics for predicting outcome. **Methods:** An initial genome-wide association study (GWAS) of single nucleotide polymorphisms (SNPs) by Affymetrix Axiom™ Genome-Wide Human Arrays was conducted on 505 cases with histological diagnosis of CIN2+ (group D1) versus 920 female controls. An additional set of 2315 female controls from the Taiwan Biobank genotype array were added in the discovery stage. The identified 29 CIN2+ -associated SNPs from GWAS ($p < 5 \times 10^{-6}$) were verified in an independent cohort (group D2 [n = 306] versus group N [n = 600]). Group N were HPV-negative/normal cytology women from a population-based cervical cytology and HPV co-test study. A cohort with HPV-positive/normal cytology (group P, n = 755) underwent follow-up and was served as the prediction set. The predictive validity was analyzed by logistic regression and receiver operating characteristic (ROC) curve analysis. **Results:** Thirty-three individuals of the group P progressed to CIN2+ (median follow-up: 23.7 months, range 4.0–122.1). A risk-predictive panel of 8 SNPs rs3097662, rs35979982, rs7763822, rs4282438, rs3128927, rs7759943, rs213194, rs17835649 which were significant in the replication ($p < 0.05$) was used to train models for disease risk prediction using the combination of GWAS and verification sets. Two prediction models were finalized and determined using 7 SNPs for hr- and low-risk (lr) HPV groups respectively (sensitivity 0.72 and 0.75, specificity 0.651 and 0.884, area under the ROC curve 0.703 and 0.701). Among group P with hr-HPV, those carried < 6 risk-alleles had significantly decreased hazard (log-rank $p < 0{\cdot}001$) of progression to CIN2+ than those with ≧6 risk-alleles, while among group P with lr-HPV, those with predictive probability of ≥ 0·095 had a cumulative risk of progression of 10% at 3 years. **Conclusions:** Two risk-predictive SNP panels including 7 SNPs with hr- or lr-HPV groups can assist risk stratification among HPV-positive/ normal cytology women. These panels could be further tested in other ethnic populations. Research Sponsor: Supported by grants from Chang Gung Medical Foundation (OMRPG3B0041, CMRPG371151-3, CMRPG380731, CMRPG391451, and CRRPG3D0021/2/3), and the Ministry of Health and Welfare-Taiwan (DOHW105-TDU-B-212-113003, MOHW106-TDU-B-212-113005, and MOHW107-TDU-B-212-11.

Anlotinib in patients with recurrent advanced cervical cancer: A prospective single-arm, open-label, phase II trial. *First Author: Xiaohua Wu, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Anlotinib is a novel multi-target tyrosine kinase inhibitor that has previously shown clinical antitumor activity in various cancers, including the phase I study on female genital tumors. This phase II study (ChiCTR1800020116) aims to further evaluate the safety and efficacy of anlotinib, in those patients with recurrent advanced cervical cancer. **Methods:** Eligible patients were advanced cervical cancer who had received at least two previous lines of chemotherapy. Patients were given anlotinib (12 mg/day) from day 1 to day 14 in a 21-day cycle until disease progression or had unacceptable toxic effects. The primary endpoint of this study was objective response rate (ORR) and the secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. **Results:** Between 2018 December and 2019 October, 41 patients (female) were enrolled. As of January 15, 2020, median follow-up duration, from randomization to data cutoff, was 2.6 months (range, 0.7-10.3). Therapeutic evaluation showed the ORR was 32.1% (95%CI, 13.7%-50.6%) and the median PFS was 3.9 months (95% CI, 1.3%-6.5%). The most frequently reported adverse events were lymphocyte count decreased, anemia, hand-foot syndrome, blood uric acid increased, blood creatinine increased, blood thyroid stimulating hormone increased. All frequently occurring AEs were grade 1 or 2. High grade AE was only observed in 1 patient with white blood cells urine positive of grade 3. Neither unexpected safety signals nor treatment related death occurred. **Conclusions:** Anlotinib showed a promising activity with an acceptable safety profile for patients with recurrent advanced cervical cancer. Clinical trial information: ChiCTR1800020116. Research Sponsor: Chia-Tai Tianqing Pharmaceutical Group Co Ltd.

6035 Poster Session (Board #206), Fri, 8:00 AM-11:00 AM

Photodynamic therapy for preinvasive cervical cancer. *First Author: Viktoria A. Ivanova, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation*

Background: Photodynamic therapy (PDT) is an effective treatment for various cancers ensuring maximum preservation of the viability of healthy tissues surrounding the tumor. The purpose of the study was to reveal the effectiveness of PDT in treatment for preinvasive cervical cancer. **Methods:** The study included 45 patients aged 22-53 years with preinvasive cervical cancer. The patients were divided into two groups depending on the type of the transformation area and the tumor site: group 1–on the exocervix (type I-II), n=24; group 2–on the endocervix (type III), n=21. Infection with high-risk genotypes of HPV (16, 18, 31, 33, 35, 45, 56) was detected with PCR in 37 (82%) women. All patients received PDT with the semiconductor Latus laser up to 3 W, a single-use diffusing fiber for the exocervix irradiation and a single-use cylindrical diffusing fiber for tumors in the cervical canal. Photoditazine and photolon were used as photosensitizers. Effectiveness criteria included the normalization of the colposcopic picture, the absence of atypical cells, and the pathogen elimination confirmed by PCR. **Results:** A normal cytogram profile was observed after PDT in 84% of group 1 and in 88% of group 2. PCR 3 months after PDT showed a positive HPV reaction in 9.1%. Neither group of patients had negative changes in cytogram after 6 and 12 months. Repeated HPV DNA tests detected HPV DNAs in 2.8% in group 1 and 3.2% in group 2. The effectiveness of PDT did not depend on the photosensitizer. The maximum follow-up period has lasted for 4.5 years, with no recurrences registered. During this period, three young women successfully gave birth to healthy children. **Conclusions:** PDT is an alternative treatment for pre-tumor and initial tumor pathology of the cervix with preservation of the anatomical and functional integrity of the organ, which is important for the female reproductive function. The results support the use of PDT in treatment for preinvasive cervical cancer. Research Sponsor: None.

6036 Poster Session (Board #207), Fri, 8:00 AM-11:00 AM

Gut microbiome diversity as an independent predictor of survival in cervical cancer patients receiving chemoradiation. *First Author: Travis T. Sims, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Diversity of the gut microbiome is associated with response rates for patients receiving immunotherapy. Studies investigating the gut microbiome and outcomes in cancer patients often do not adjust for confounding patient and tumor characteristics. We sought to identify independent gut microbial risk factors in cervical cancer (CC) patients receiving chemoradiation (CRT) and to evaluate their impact on survival. **Methods:** We analyzed baseline 16S rDNA fecal microbiomes of CC patients receiving standard CRT. Patient and tumor characteristics were analyzed by univariate and multivariate Cox regression models for Recurrence-free survival (RFS) and Overall survival (OS) based on univariate p-value>0.2. Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status, and max tumor size. Alpha (within sample) diversity was evaluated using Shannon diversity index (SDI). Kaplan-Meier curves were generated for patients with normal BMI and overweight/obese BMI based on Cox analysis. **Results:** 55 CC patients were included. Univariate analysis identified older age (Hazard Ratio (HR) of 0.93 (95% CI = 0.87-0.98, p = 0.0096)), SDI (HR of 0.51 (95% CI = 0.23-1.1, p = 0.087)) and BMI (HR of 0.92 (95% CI = 0.84-1, p = 0.096)) as risk factors for RFS. Multivariate survival analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87 (95% CI = 0.77-0.98, p = 0.02) and 0.36 (95% CI = 0.15-0.84, p = 0.018) respectively. For OS, multivariate survival analyses again identified BMI and SDI as independent prognostic factors with a HR of 0.78 (95% CI = 0.623-0.97, p = 0.025) and 0.19 (95% CI = 0.043-0.83, p = 0.028) respectively. **Conclusions:** Gut diversity is a significant factor for predicting OS in CC patients undergoing CRT when BMI is accounted for, and may help explain the "obesity paradox" in cancer response. Studies exploring the relationship between gut diversity, CRT, and treatment efficacy are needed to further understand the role of the gut microbiome in treatment outcomes. Research Sponsor: U.S. National Institutes of Health, The University of Texas MD Anderson Cancer Center HPV-related Cancers Moonshot.

Delayed adjuvant radiotherapy in early-stage cervical cancer with intermediate-risk features has a detrimental effect on survival that cannot be corrected by adjuvant chemotherapy. *First Author: Joyson Kodiyan, NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY*

Background: GOG-0263 is currently investigating the role of adjuvant chemotherapy (CT) concurrently with radiotherapy (RT) in patients with early stage cervical cancer that underwent radical hysterectomy and pelvic lymphadenectomy harboring intermediate risk features. We used a retrospective database to investigate whether adjuvant chemotherapy significantly influenced overall survival (OS), and whether its effectiveness is influenced by delays in radiotherapy. **Methods:** All data was obtained from the NCDB (National Cancer Database) and initially contained 115,747 cases of cervical cancer diagnosed between 2004 and 2015. Analyzed patients had early stage disease, received radical hysterectomy with pathologic stage I to IIA, and had intermediate risk features including size greater than 4 cm or lymphovascular invasion. All patients received adjuvant RT with or without CT. Cases with positive margin or nodes, with parametrial extension, or metastasis were excluded. Cases were weighted by inverse probability of treatment (CT) using clinical and socioeconomic variables, and analyzed for OS using multivariate models. Predictors of receiving CT were determined using multivariate logistic regression. **Results:** The final cohort was 557 patients with median follow-up of 43 months (range, 1.54-143.7). Median survival without CT (n = 244) versus with CT (n = 313) was 42.2 versus 43.9 months (HR 0.81, 95%CI 0.661-0.995, p = 0.045). Median time from diagnosis to RT was 91 days (range, 21-691), and predicted for inferior OS (p = 0.007). No significant interaction existed between RT delay and receipt of CT (p = 0.997). Cases with squamous histology were less likely to receive CT than adenocarcinoma histology (OR 0.345, 95% CI 0.159-0.725, p = 0.006). **Conclusions:** Poor survival outcomes are observed in patients with early stage cervical cancer harboring intermediate risk features when adjuvant radiotherapy is delayed. This outcome was not corrected by addition of chemotherapy. Research Sponsor: None.

6038 Poster Session (Board #209), Fri, 8:00 AM-11:00 AM

Prexasertib, a cell cycle checkpoint kinase 1 inhibitor, in *BRCA* mutant recurrent high-grade serous ovarian cancer (HGSOC): A proof-of-concept single arm phase II study. *First Author: Erika Joelle Lampert, Women's Malignancies Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Preclinical data suggest cell cycle checkpoint inhibition induces greater cell death in *BRCA* mutant HGSOC by causing replication stress and dysregulation of DNA damage responses. We hypothesized that prexasertib, a cell cycle checkpoint kinase 1 (CHK1) inhibitor, would be active in *BRCA* mutated HGSOC patients. **Methods:** We conducted a single center, two-stage phase II study of prexasertib (105mg/m^2 IV every 2 weeks) in HGSOC patients with known germline or somatic *BRCA* mutations. The primary endpoint was RECIST response rate (RR). Progression-free survival (PFS) and safety (CTCAE v4) were secondary endpoints. Baseline research biopsies and blood samples were collected for exploratory biomarker endpoints. **Results:** Between February 2015 and July 2019, 22 heavily pretreated (median 5 prior systemic therapies [1-12]) women with *BRCA* mutant HGSOC (median age 58.7 [44-74.8]) received at least one dose of prexasertib. 13 (59%) patients were secondary platinum-resistant (median 8 [3-12] prior therapies) and 9 (41%) maintained platinum-sensitivity (median 4 [1-5] prior therapies). All but one received prior PARP inhibitor (PARPi) either in combination (10 [48%]) or as monotherapy (11 [52%]), with a median 5 month [mo; 1-29] PARPi-free interval prior to study entry. There was one complete response (41+mo, platinum-sensitive, no prior PARPi) and one partial response (9+mo, platinum-sensitive, 13.5mo PARPi-free interval) yielding an 11% RR (2/18 evaluable). No response was seen in platinum-resistant patients with prior PARPi. Median duration on study treatment was 4mo [1-9] among 21 patients with prior PARPi and 4mo [1.5-9] among 17 evaluable patients with prior PARPi. Common (>10%) grade 3/4 adverse events were neutropenia (82%), leukopenia (64%), and thrombocytopenia (14%); only one patient had grade 3 febrile neutropenia. 16 of 18 (89%) patients with grade 3/4 neutropenia received prophylactic growth factors for subsequent treatments. **Conclusions:** Prexasertib is tolerable and has modest activity in heavily pretreated *BRCA* mutant HGSOC patients. Further evaluation of predictive biomarkers for exceptional responders is ongoing. Clinical trial information: NCT02203513. Research Sponsor: U.S. National Institutes of Health, Stand Up To Cancer – Ovarian Cancer Research Fund Alliance – National Ovarian Cancer Coalition Dream Team Translational Research Grant.

6039 Poster Session (Board #210), Fri, 8:00 AM-11:00 AM

Maintenance olaparib plus bevacizumab (bev) after platinum-based chemotherapy plus bev in patients (pts) with newly diagnosed advanced high-grade ovarian cancer (HGOC): Efficacy by BRCA1 or BRCA2 mutation in the phase III PAOLA-1 trial. *First Author: Domenica Lorusso, Fondazione IRCCS Istituto Nazionale Tumori and Multicenter Italian Trials in Ovarian Cancer and Gynecologic Malignancies (MITO), Milan, Italy*

Background: In PAOLA-1/ENGOT-ov25 (NCT02477644), adding the PARP inhibitor olaparib to maintenance bev after first-line platinum-based chemotherapy plus bev led to a statistically significant progression-free survival (PFS) benefit in pts with advanced HGOC (HR 0.59; 95% CI 0.49–0.72) (Ray-Coquard *et al.* 2019). Retrospective subgroup analysis in GOG-0218 (Norquist *et al.* 2018) suggested BRCA mutation (BRCAm) status did not significantly impact the PFS benefit provided by bev. We explored the efficacy of olaparib plus bev by *BRCA1* mutation (*BRCA1*m) or *BRCA2* mutation (*BRCA2*m) in PAOLA-1. **Methods:** PAOLA-1 is a randomized, double-blind, Phase III trial in pts with newly diagnosed, FIGO stage III–IV, high-grade serous or endometrioid OC, fallopian tube or primary peritoneal cancer receiving platinum-based chemotherapy plus bev then maintenance bev. Pts unrestricted by surgical outcome or BRCAm status and in response to first-line therapy were randomized to maintenance olaparib tablets (300 mg bid for up to 24 months) plus bev (15 mg/kg q3w for up to 15 months in total) or placebo plus bev, stratified by first-line treatment outcome and tumor BRCAm status. Investigator-assessed PFS (modified RECIST v1.1) by BRCAm was a predefined analysis. **Results:** Of 806 randomized pts, 160 (20%) had tumor *BRCA1*m, 76 (9%) had tumor *BRCA2*m and 1 (<1%) had both. Median PFS follow-up was 24.1 and 27.4 months in *BRCA1*m and *BRCA2*m pts, respectively. At primary data cutoff, PFS was prolonged with olaparib plus bev versus placebo plus bev in *BRCA1*m pts and *BRCA2*m pts (Table). The percentage of *BRCA1*m pts who received olaparib plus bev and were progression-free at 1 and 2 years was 95% and 73% (vs. 70% and 29% for placebo plus bev) and for *BRCA2*m pts was 89% and 84% (vs. 84% and 53%) (Kaplan-Meier estimates). **Conclusions:** In PAOLA-1, maintenance olaparib plus bev provided a significant PFS benefit versus placebo plus bev in all pts analysed, regardless of whether they had *BRCA1*m or *BRCA2*m. The median PFS in the control arm suggests a role for bev in this subgroup and the hazard ratio versus an active control arm shows the value of adding maintenance olaparib to bev. Clinical trial information: NCT02477644. Research Sponsor: Funded by AstraZeneca, Merck Sharp & Dohme Corp, and F. Hoffmann La Roche, ARCAGY Research.

6040 Poster Session (Board #211), Fri, 8:00 AM-11:00 AM

A randomized multicenter phase II trial to evaluate the safety and efficacy of vaccination with folate receptor alpha (FRα) peptides admixed with GM-CSF as an adjuvant versus GM-CSF alone in patients with platinum-sensitive ovarian cancer (EOC). *First Author: Roisin Eilish O'Cearbhaill, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: FRα is overexpressed on > 90% of high-grade EOC. We conducted a randomized double-blind multicenter phase II clinical trial to evaluate the safety and efficacy of TPIV200 (a multi-epitope FRα peptide vaccine admixed with GM-CSF adjuvant) versus GM-CSF alone as a control in patients with stage III-IV high-grade platinum-sensitive epithelial ovarian, fallopian tube, or primary peritoneal carcinoma in first complete or partial remission, irrespective of baseline level of FRα expression. **Methods:** Patients with stage III-IV high-grade serous, high-grade endometrioid, carcinosarcoma or poorly differentiated EOC who had previously completed standard upfront therapy without evidence of disease progression and who were within a year of last platinum were randomized 1:1 to intradermal vaccination of TPIV200 versus intradermal GM-CSF alone. The vaccination period included 6 administrations of the study drug at 4-week intervals. Up to 6 booster vaccinations at 12-week intervals were permitted for patients who did not have disease progression. AEs were assessed using CTCAE. Tumor response was assessed via RECIST every 12 weeks. The primary endpoint, progression free survival (PFS), was calculated from date of first vaccination to the date of progression, death or study termination. **Results:** Of 120 patients randomized, 63 (53%) were treated on the TPIV200 arm. The median age at study entry was 63 years (range 37-88). AEs were generally mild. Injection site reaction was more frequent in the TPIV200 (63%) versus GM-CSF arm (39%). The other most common AEs, abdominal pain (25%) and fatigue (23%), were comparable in both arms. At study termination with a median follow-up of 15.2 months (range: 1.2-28.3 months), 68 of 119 intention-to-treat patients had progressed (55% in the TPIV200 arm and 59% in the GM-CSF arm). The median PFS was 11.1 months (95% CI: 8.3-16.6 months) and there was no statistically significant difference in median PFS between the arms (10.9 months with TPIV200 versus 11.1 months with GM-CSF, HR = 0.85 [upper 90% CI = 1.17]). **Conclusions:** Although TPIV200 had a manageable safety profile, the study was terminated for futility after the planned interim analysis. Future development of FRα-targeted therapy will likely focus on the careful selection of patients whose cancers show high FRα expression. Clinical trial information: NCT02978222. Research Sponsor: Marker Therapeutics, Inc.

6041 Poster Session (Board #212), Fri, 8:00 AM-11:00 AM

Low rates of *BRCA1* and *BRCA2* testing for patients with ovarian cancer in ASCO's CancerLinQ, a real-world database. *First Author: Summer Dewdney, Rush University Medical Center, Chicago, IL*

Background: Ovarian cancer is the deadliest gynecological cancer and has limited screening options for early stage diagnosis. Genetic mutations in genes such as *BRCA1* and *BRCA2* increase the risk of ovarian cancer, and if identified, patients can undergo risk-reducing surgery. It is recommended and well accepted to test any new ovarian cancer patient for genetic mutations, particulary *BRCA1* and *BRCA2*. If a *BRCA1/2* mutation is found in a patient (somatic or germ line), this information can be used to guide therapy. We sought to analyze the characteristics of genetic testing in a real-world database, ASCO's CancerLinQ. **Methods:** We performed a retrospective cohort study using the CancerLinQ Discovery database. Women with ovarian, fallopian tube, or primary peritoneal cancer were identified using ICD9 and ICD10 codes. We included patients diagnosed between 1/1/11 to 12/31/18 and age >18. We included all epithelial histologies including carcinosarcomas and excluded patients without a known histology. **Results:** Of the 2654 patients meeting inclusion criteria, 600 had been tested for a *BRCA1/2* mutation (22.6%). Of those tested, 63% were stage III/IV, 14% stage I/II, and 21.8% an unknown stage. The majority of the histologies were serous (76%), followed by undifferentiated (21.2%). The majority of patients tested were white (69.9%), with 18.8% unknown, and 9.9% black. The rate of a positive *BRCA1* or *BRCA2* mutation in this population was 17.2%. Of the patients with a *BRCA1/2* mutation, the majority had serous histology (87%), followed by 18.5% undifferentiated, and 3.9% transitional cell. The majority of the patients found to have a *BRCA1/2* mutation were age >50 (57.3%). **Conclusions:** Since 2008 evidence-based guidelines have recommended that all ovarian cancer patients be tested for *BRCA1* and *BRCA2* mutations, but in this real-world database only 22.6% have a recorded test. Of those tested, we found a *BRCA1* or *BRCA2* mutation rate of 17.2%. Our data is limited by what is recorded in the database and may not represent the true number of patients tested because of data missing from the EHR; however, these percentages appear similar to previous studies. Not only is testing important for cancer prevention for family members of patients, it now impacts the type of treatments for which these patients are eligible. Since genetic testing remains low at only 22.6% in this population, significant opportunities exist to impact cancer prevention and treatment. Research Sponsor: None.

6042 Poster Session (Board #213), Fri, 8:00 AM-11:00 AM

Low expression of gamma-glutamyl transpeptidase 1 is an independent poor prognostic factor in ovarian clear cell carcinoma, in relation to up-regulation of immune suppressive genes and EMT-related genes. *First Author: Hiroshi Asano, Department of Obstetrics and Gynecology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan*

Background: Ovarian clear cell carcinoma (OCCC) is a distinct entity from other epithelial ovarian cancers such as the most prevalent high-grade serous cancer (HGSC), and often exhibit less sensitivity to platinum-based chemotherapy. Several studies using cell lines have reported that glutathione (GSH) metabolism plays an important role in chemo-resistance of OCCC. Here, we aimed to correlate the prognosis of OCCC and the expression of gamma-glutamyltransferase 1 (GGT1), one of the key enzymes in GSH metabolism. **Methods:** We prepared a FFPE-tissue microarray, and analyzed 56 OCCC patients with the follow-up periods over 3 years. Expression level of GGT1 was evaluated by immunohistochemistry (IHC) using H-score (0-300), and was correlated with clinical outcomes. The prognostic significance was assessed by multivariate analysis using Cox regression model. To investigate the possible related pathways, we performed transcriptome analysis using Ion AmpliSeq Transcriptome Human Gene Expression Kit (Thermo Fisher Scientific) from the frozen tissue specimens collected from 33 ovarian cancer patients including 15 OCCC patients and 18 HGSC patients. **Results:** The OCCC patients were divided into two populations in the histogram of H-score in IHC staining, and the cut-off value was 90; 44 cases showed GGT1-high, and remaining 12 cases were GGT1-low. Follow-up periods, FIGO stage, and optimal surgery rate were not significantly different between two groups. However, platinum-resistant recurrent rate was significantly higher (42% vs. 14%, p=0.027), and overall survival (OS) was significantly shorter (5-year OS; 42% vs. 72%, p=0.0226) in GGT1-low OCCC. Multivariate analysis revealed that low expression of GGT1 was one of the independent poor prognostic factors as well as platinum-drug resistance. In enrichment analysis, the genes related to GSH metabolism, such as SLC3A1, GGT1, CSE, and GPX3 were up-regulated and positively correlated with HNF1B expression in OCCC. The expression level of GGT1 was inversely correlated with that of immune suppressive genes (TGF-b, IFNG, IL10, FOXP3, PD-L1, CTLA4) and epithelial-mesenchymal transition (EMT)-related genes (CDH2, VIM, TWIST1, ZEB1, ZEB2) in OCCC samples. **Conclusions:** Low expression of GGT1 is an independent poor prognostic factor probably in part due to suppression of tumor immunity and induction of EMT in OCCC. 6043 Poster Session (Board #214), Fri, 8:00 AM-11:00 AM

A phase I trial a FR alpha targeted thymidylate synthase inhibitor CT900 exploring four schedules of treatment in expansion cohorts of patients with high-grade serous ovarian cancer. *First Author: Susana N. Banerjee, The Royal Marsden and The Institute of Cancer Research, London, United Kingdom*

Background: CT900 (BTG945/ONX-0801) is a novel small molecule that binds to folate receptor alpha (FRα), is internalized and causes cytotoxicity by thymidylate synthase inhibition. **Methods:** The aims of the expansion cohorts were to determine toxicity, response rates and correlation of the response to FRα expression in patients with HGSOC (NCT02360345). Four expansion cohorts were studied which included: schedule A (6 mg/m^2/q every 2 weeks), schedule B (12 mg/m^2/q every 2 weeks), schedule C (12 mg/m^2/q every 2 weeks with 12 mg dexamethasone IV and 8 mg of dexamethasone for 2 days) and schedule D (12 mg/m^2/q every 3 weeks). Response rates were assessed by RECIST V1.1 and GCIG CA125 response criteria. Patients who were withdrawn for reasons other than toxicity within 8 weeks (cohorts A, B, C) and 12 weeks (cohort D) were not assessable for efficacy. FRα expression was quantified using immunohistochemistry. **Results:** A total of 67 patients were treated in the 4 cohorts (14, 25, 15 and 13 for cohorts A, B, C and D). The median age was 62 (IQR 57 - 68) and the median lines of previous treatment was 5 (range 1 to 13). A majority of patients were platinum resistant. The most common toxicities across all expansion cohorts were: fatigue (51%), nausea (36%), anemia (27%), fever (25%), AST elevation (21%), most of which were grade 1 - 2. Toxicity of special interest included radiological changes of pneumonitis and was 15% in all cohorts (7%, 16%, 27% and 8% in cohorts A, B, C and D, respectively). These changes were grade 1 - 2 in all but one case. RECIST response rates in evaluable patients across the different cohorts were: A 1/8 (13%), B 6/21 (29%), C 5/12 (42%) and D 2/12 (17%). FRα expression in archival tumor tissue was measured in 59/67 patients. Expression was found to be high/medium in 43/59 (73%), low in 7/59 (12%) and negative/very low in 9/59 (15%). In patients with high/medium FRα expression, the RECIST response rates in different cohorts were: A 0/9 (0%), B 6/16 (38%), C 4/12 (33%) and D 1/6 (17%). The CA125 response rate in all patients within cohort B was 13/25 (52%) and 10/16 (63%) in patients with high/medium FRα expression. **Conclusions:** CT900 has shown clinical activity in patients with heavily pre-treated platinum-resistant, high/medium FRα expressing HGSOC. Based on toxicity and efficacy, the schedule of 12 mg/m^2/q2 weekly (schedule B) is the recommended phase II dose for further evaluation in patients with relapsed high/medium FRα expressing HGSOC. Clinical trial information: NCT02360345. Research Sponsor: Carrick Therapeutics;BTG; Onyx.

6044 Poster Session (Board #215), Fri, 8:00 AM-11:00 AM

APOLLO: A phase I study of adaptive memory natural killer (NK) cells in recurrent ovarian cancer. *First Author: Melissa Ann Geller, University of Minnesota, Minneapolis, MN*

Background: Human cytomegalovirus (CMV) infection induces a subset of long-lived CD57$^+$NKG2C$^+$ adaptive NK cells that exhibit enhanced antibody-dependent cellular cytotoxicity and resistance to tumor-suppressive mechanisms. We developed a 7-day culture process using a GSK3 inhibitor and IL-15 to manufacture modulated adaptive NK cells (FATE-NK100) from CMV$^+$ haploidentical donors for adoptive transfer. The phase I Apollo trial tests the maximum tolerated dose/maximum feasible dose (MTD/MFD) of FATE-NK100 administered intraperitoneally (IP) to treat platinum-sensitive or -resistant recurrent ovarian, fallopian tube, and primary peritoneal cancer. **Methods:** FATE-NK100 via IP port was tested using 3 dose cohorts ([DC]; 1×10^7 cells/kg; $>1 \times 10^7$ cells/kg to $\leq 3 \times 10^7$ cells/kg; or $>3 \times 10^7$ to $\leq 10 \times 10^7$ cells/kg) after lympho-conditioning with fludarabine 25 mg/m^2 IV and cyclophosphamide 300 mg/m^2 IV on days -6 and -5. After FATE-NK100 infusion on day 0, rhIL-2 at 6 million IU was given IP 3 times a week for 6 doses for in vivo NK activation. IP fluid and peripheral blood were collected regularly until response assessment (day 28). Patients with stable disease or better were eligible for retreatment. Pre- and post-treatment tumor biopsies were collected. **Results:** Nine patients were treated with no dose-limiting toxicities (DLTs) to date. Retreatment based on clinical benefit was performed on 3 patients (33%), 2 following stable disease (DC 2) and 1 with partial remission (48% tumor reduction, DC 3). IP samples were collected for PK and functional analysis. FATE-NK100 product was detected by flow cytometry in 5 of 6 patients with evaluable samples (range 4.8%–91.2% donor NK cells at day +5-7). Retreatment samples were available in 1 patient, where FATE-NK100 persisted to day +21, demonstrating that repeated IP dosing did not accelerate clearance of the donor NK cells. In that same patient, measurement of NK cell CD107a degranulation or IFNg production in response to K562 targets demonstrated sustained enhanced in vivo function of FATE-NK100 compared to endogenous patient NK cells (e.g. at Day +12 CD107a$^+$ NK were 39.0% vs. 22.5% cycle 1, and 40.3% vs. 18.2% retreatment cycle 2, and IFNg$^+$ NK were 12.3% vs. 5.9% cycle 1, and 2.4% vs. 0.2% retreatment cycle 2). **Conclusions:** IP delivery of FATE-NK100 is safe, with clinical benefit in 3/9 patients treated. The allogeneic product cells persist and have enhanced function compared to patient NK cells for up to 21 days, even after retreatment. This phase I study in recurrent/refractory ovarian cancer shows promise for IP NK cell delivery. Clinical trial information: NCT00652899. Research Sponsor: Fate Therapeutics.

6045 Poster Session (Board #216), Fri, 8:00 AM-11:00 AM

A clinical study of tremelimumab alone or in combination with olaparib in patients with advanced epithelial ovarian cancer. *First Author: Stephanie Gaillard, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Single agent immunotherapy (IO) has shown only modest clinical activity for the treatment of ovarian cancer. The combination of anti-programmed death-1 and PARP inhibitors showed promising activity in early trials. Here, we report the results of an open-label, parallel arm, dose escalation study of tremelimumab (T) alone or in combination with olaparib (O) in patients (pts) with advanced epithelial ovarian cancer (EOC). **Methods:** Pts with recurrent/persistent EOC who had progression $<$ 12 months from last platinum exposure were enrolled. Prior therapy with IO (except anti-CTLA-4) or PARP inhibitor was allowed. Pts were randomized to either T 10mg/kg every 4 weeks (wks) x 7 then every 12 wks (Arm A) or T with O twice daily at three planned dose levels (Arm B). The primary objectives were safety, pharmacodynamic (PD) change in CD4$^+$ICOS^{hi} peripheral T cells by flow cytometry, and identification of the optimal dose combination of T with O. Secondary objectives included 6-month progression-free survival (PFS6) and objective response rate (ORR). **Results:** A total of 24 pts were treated, 12 on Arm A, and 12 on two Arm B dose levels. Pts had a median age of 60 years (range 44-81). Histologic subtypes included high-grade serous EOC (20 pts, 83%), clear cell (3 pts, 13%), and moderately-differentiated adenocarcinoma (1 pt, 4%). BRCA1 mutation (mt) was present in 2 cases, BRCA2 mt in 1. Median number of prior regimens was 3.5 (range 1-9). Most adverse events (AEs) were attributable to T, the most common grade 3 toxicities were rash (13%), immune-mediated hepatitis (8%), and colitis (8%). No grade $\geq$4 toxicities were identified. Immune-mediated AEs also included acute kidney injury, hypophysitis, and hypothyroidism. No dose limiting toxicities were identified on Arm B. Two pts in Arm B had $>$PFS6. Of 20 pts evaluable for response, there was 1 partial response (Arm B), and 9 pts had stable disease (6 on Arm A, 3 on Arm B). Mean percentage of CD4+ICOS^{hi} T cells was significantly increased on Days 15 and 22 compared to Day 1 at both T dose levels (Table).T at 3 mg/kg with O at 150mg is the optimal dose of those tested. **Conclusions:** T and T with O was tolerable, with modest clinical activity in this pt population. AEs were as expected, and peripheral CD4$^+$ICOS^{hi} T cells increased on therapy. Clinical trial information: 02485990. Research Sponsor: AstraZeneca.

Long-term survival outcomes of intravenous versus intraperitoneal chemotherapy in the treatment of advanced ovarian cancer. *First Author: Rachel Soyoun Kim, University of Toronto, Toronto, ON, Canada*

Background: The role of intraperitoneal (IP) chemotherapy in the management of advanced ovarian cancer has been questioned given emerging evidence showing lack of survival benefits. The objective of this study was to compare the long-term survival associated with IP chemotherapy at a tertiary cancer center. **Methods:** We reviewed the long-term survival records of 271 women with stage IIIC or IV high-grade serous ovarian cancer treated with primary cytoreductive surgery (PCS) followed by IP or intravenous (IV) chemotherapy between 2001-2015 with a minimum follow-up of 4 years. 5-year progression free (PFS) and overall survival (OS) rates were compared using Kaplan-Meier survival analysis and covariates were evaluated using Cox regression analysis. **Results:** Women who received IP chemotherapy after PCS (n = 91) were more likely to have undergone aggressive surgery ($p < 0.001$), longer surgery ($p < 0.001$), and had no residual disease ($p < 0.001$) compared to the IV arm (n = 180). Median follow-up was 51.6 months. Five-year PFS was 19% vs. 18% (p = 0.63) and OS was 73% vs. 44% (p = 0.00016) in the IP vs. IV arms, respectively. After controlling for covariates in a multivariable model, the use of IP was no longer a significant predictor of OS in the entire cohort (p = 0.12). In patients with 0mm residual disease, PFS was 28% vs. 26% (p = 0.67) and OS was 81% vs. 60% (p = 0.059) in IP (n = 61) vs. IV (n = 69), respectively. In patients with residual of 1-9mm, PFS was 30% vs. 48% (p = 0.076) and OS was 60% vs. 43% (p = 0.74) in IP (n = 29) vs. IV (n = 31), respectively. **Conclusions:** IP chemotherapy showed a trend towards improved survival over conventional IV chemotherapy, especially in patients with no residual disease. Given the retrospective nature and small numbers in this study, prospective non-randomized cohort studies are warranted to evaluate the role of IP chemotherapy in advanced ovarian cancer. Research Sponsor: None.

6047 Poster Session (Board #218), Fri, 8:00 AM-11:00 AM

Phase I study to assess the safety, tolerability, pharmacokinetics/ pharmacodynamics and preliminary efficacy of SC10914 in patients with advanced solid tumors. *First Author: Jifang Gong, Gastrointestinal Medical Oncology, Beijing Cancer Hospital, Beijing, China*

Background: SC10914 is a highly selective inhibitor of PARP enzymes, including PARP1 and PARP2. SC10914 has a similar structure with olaparib. We conducted a phase I study to assess the safety, tolerability, PK/PD and preliminary efficacy of SC10914 in patients with advanced solid tumors. **Methods:** This is a phase I dose-escalation study with 3+3 design, we enrolled patients at 4 sites in China. Eligible patients were diagnosed with advanced solid malignancies who are refractory to standard therapies or for which no standard therapy exists; had measurable disease; had adequate organ function. Patients received SC10914 daily at ten escalating doses from 30 mg QD to 500 mg TID in a 28-day cycle. We obtained blood for PK and CA125 assessments. Toxic effects were assessed by CTCAE 4.03 criteria and tumour responses ascribed by RECIST 1.1 and CA125 was assessed by GCIG criteria. **Results:** As of January 2020, 52 patients were enrolled, of which 14 were males and 38 were females. Ten doses were escalated to 500mg TID, and no DLT was observed, and MTD was not obtained. The incidence of grade 3/4 AEs and SAEs that were related to SC10914 were 34.6% (18/52) and 13.5% (7/52). Grade 3/4 adverse reaction happened in at least two patients were anaemia/reduced hemoglobin (10/52, 19.2%), decreased WBC count (5/52, 9.6%), neutropenia (3/52, 5.8%), thrombocytopenia (2/52, 3.8%), and decreased lymphocyte count (2/52, 3.8%). A total of 17 gBRCAm evaluable ovarian cancer patients were enrolled, 6 of them had PR, the ORR was 35.3% (6/17). 10 gBRCAm ovarian cancer patients were enrolled in TID groups (including 2 patients who received BID doses at the beginning and changed to 300 mg TID dose after several cycles of treatment), 5 of them had PR, the ORR was 50% (5/10). The ORR of 400 mg TID group was 66.7%(4/6). PK data showed that the exposure of SC10914 was increased with dose increasing at the dose of 30 mg to 250 mg. The half-life of SC10914 was about 2-5 hours. **Conclusions:** SC10914 was safe in patients with advanced solid tumors. The main toxicity was blood-related adverse reactions. SC10914 was effective in gBRCAm ovarian cancer patients. 400 mg TID might be RP2D. Clinical trial information: NCT02940132. Research Sponsor: Jiangxi Qingfeng Pharmaceutical Co., Ltd, Other Government Agency.

6048 Poster Session (Board #219), Fri, 8:00 AM-11:00 AM

Quality of life, vascular endothelial growth factor inhibition, and survival outcomes with combination oral metronomic therapy in platinum refractory epithelial ovarian carcinoma: Results from a randomized study. *First Author: Aparna Sharma, Dr. B.R. A. IRCH, All India Institute of Medical Sciences, Delhi, India*

Background: Patients with recurrent and refractory epithelial ovarian cancer (EOC) have dismal outcomes. We evaluated a combination of oral metronomic therapy in platinum refractory EOC vis-à-vis angiogenic marker expression and its impact on patient reported outcomes. **Methods:** Between October 2017 and September 2019, 75 patients were randomized to receive etoposide (VP-16) (50 mg daily for 14 days) cyclophosphamide (50 mg daily for 28 days) (Arm A, n = 38) or etoposide (VP-16) (50 mg daily for 14 days) cyclophosphamide (50 mg daily for 28 days) and pazopanib (400 mg daily 28 days) every 28 days (Arm B, n = 37). Eligibility criteria included histopathological diagnosis of EOC, platinum refractory disease and ECOG performance status 0-2. Primary endpoint was serological progression free survival (PFS) as defined by Rustin criteria. Quality of Life (QoL) (evaluated using the EORTC QLQC30 and OV 28 questionnaires) and serum vascular endothelial growth factor (VEGF) were ascertained at baseline and after 3rd and 6th cycle. Intention to treat analysis was done. **Results:** Baseline characteristics were well matched in 2 arms. At a median follow up 14.4 months (95% CI 13.2-15.7), the median serological PFS is better for patients in Arm B 5.1 months (95%CI 3.13-10.33) compared to 3.4 months (95%CI 3-6.53) in arm A (P= 0.045). Median overall survival (OS) is not reached in arm B versus 11.2 months (95%CI 5.66-NR) in arm A (P= 0.032). Disease progression was seen in 42.1% (n = 16) in Arm A versus 40.5 %(n = 15) in arm B (P= 0.40). Sixteen patients are maintaining response. Mucositis (29.7% n = 11) and fatigue (13.5%, n = 5) were more in the pazopanib-containing arm (P= 0.36). Serum VEGF demonstrated significant decline with subsequent cycles of therapy {median values (range): Arm A, baseline; 466.0 pg/mL(123.9-1930) vs. 6 cycles; 92.05pg/ mL(42.34-279.5) P< 0.0001; Arm B, baseline; 382.0 pg/mL(49.44-2054.0) vs 6 cycles; 119.7 pg/mL(18.20-367.5) P= 0.013} without any difference between the two arms (P= 0.18). QoL symptom scales in both QLQC 30 and OV 28 questionnaires indicated small but significant improvement in pazopanib arm (P= 0.02) without differences in global (p = 0.96) and physical functioning scales. (P= 0.68). **Conclusions:** Addition of pazopanib to etoposide and cyclophosphamide resulted in improvement in serological PFS and OS with a well-tolerated toxicity profile and modest improvement in QoL.Serum VEGF expression requires validation in a larger cohort. Clinical trial information: CTRI/ 2017/10/010219. Research Sponsor: Department of Health resources (DHR) Grant in Aid scheme, Government of India (Project number R.11012/04/2018).

6049 Poster Session (Board #220), Fri, 8:00 AM-11:00 AM

Phase I/II trial assessing hydroxychloroquine and itraconazole in women with advanced platinum-resistant epithelial ovarian cancer (EOC) (HYDRA-01). *First Author: Ainhoa Madariaga, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Autophagy is a mechanism of resistance to platinum chemotherapy. Itraconazole (Itr), an antifungal agent, can alter cholesterol-trafficking, leading to accumulation of cholesterol in endosomes/lysosomes and resulting in cancer cell death. Itr is also involved in regulation of angiogenesis, mTOR and Hedgehog pathways. In preclinical studies the Itr effect can be enhanced by combining it with the autophagy inhibitor hydroxychloroquine (H). Drug repurposing studies with Itr have shown a signal of activity in prostate, lung and basal cell carcinoma. **Methods:** A rolling-6 phase I design was used to enroll patients (pts) with platinum-resistant/refractory EOC. Pts received Itr 300mg twice daily (BID) with H as per dose escalation schedule (range 200mg BID- 600mg BID), continuously in a 28-day cycle. Primary objective was establishment of MTD; secondary objective was objective response rate, progression free survival (PFS). Pre- and on-treatment biopsies were mandatory to evaluate exploratory objectives assessing effect on apoptosis/proliferation, angiogenesis, cholesterol metabolism and mechanism of cytotoxicity. RNAseq and IHC was performed in the sequential biopsies. **Results:** 11 pts were enrolled, 9 evaluable for efficacy. Histology was high 91% and low-grade serous 9%. Median lines of prior therapy was 7. RP2D was Itr 300mg BID and H 600mg BID. 1 DLT was seen in dose-level 2 was grade 3 hypertension. Other grade ≥3 related toxicity were grade 3 hypokalemia and grade 4 QTc prolongation (1 pt, dose-level 3). No objective responses were observed and 1 pt had stable disease. Median PFS was 1.6 months (1-1.7). Pre- and on-treatment biopsy was available for 10 pts. Increase in autophagy related protein, LC3, P62 and lysosomal marker, LAMP1, expression by IHC was identified in 3 pts. RNAseq revealed no differences between pre and on treatment samples in cholesterol homeostasis, angiogenesis, lysosomal-autophagy, PI3K-mTOR pathways. **Conclusions:** The combination of Itr and H was feasible but did not show antitumour activity in this heavily pre-treated platinum resistant EOC population. Increase of IHC expression in autophagy related proteins was detected in 30% of pts but did not correlate with patient benefit. Clinical trial information: NCT03081702. Research Sponsor: OICR Ovarian TRI grant.

6050 Poster Session (Board #221), Fri, 8:00 AM-11:00 AM

Evaluation of an individualized starting-dose of niraparib in the PRIMA/ ENGOT-OV26/GOG-3012 study. *First Author: Mansoor Raza Mirza, Nordic Society of Gynecologic Oncology (NSGO) and Rigshospitalet–Copenhagen University Hospital, Copenhagen, Denmark*

Background: Niraparib is approved at a fixed starting dose (FSD) of 300 mg QD for maintenance treatment of patients (pts) with recurrent ovarian cancer (OC) achieving a complete or partial response to platinum-based chemotherapy based in the ENGOT-OV16/NOVA study. A post-hoc analysis of NOVA showed baseline bodyweight (BW) and platelet count (PC) were predictive for hematologic toxicities and dose reductions. Following this analysis, the PRIMA/ENGOT-OV26/GOG-3012 study was amended to prospectively evaluate the safety and efficacy of an individualized starting dose (ISD) regimen. **Methods:** This double-blind, placebo-controlled, phase III study randomized 733 pts with newly diagnosed advanced OC with a complete or partial response to first-line (1L) platinum-based chemotherapy. The protocol was amended to change the dose from 300 mg FSD for all patients to an ISD regimen: 200 mg QD in pts with BW <77 kg and/or PC <150,000/μL or 300 mg QD in pts with BW ≥77 kg and PC ≥150,000/μL. Exposure, efficacy, and safety data were compared between patients treated with FSD vs ISD. **Results:** Efficacy in the ISD subgroup was comparable to the FSD subgroup relative to placebo (Table). An interaction test showed no treatment difference between ISD and FSD at the pre-specified 0.10 significance level (p=0.30). Medians for dose intensity and relative dose intensity in pts who received niraparib were similar. The overall safety profile among pts in the niraparib arm (n=484), including grade ≥3 hematologic toxicities, improved with the ISD. **Conclusions:** The ISD in the 1L maintenance setting provides comparable efficacy to the FSD while reducing the risk of hematologic toxicities. No new safety signals were identified. Clinical trial information: NCT02655016. Research Sponsor: GlaxoSmithKline.

Niraparib exposure-response relationship in patients (pts) with newly diagnosed advanced ovarian cancer (AOC). *First Author: Bradley J. Monk, Arizona Oncology (US Oncology Network), University of Arizona College of Medicine, Phoenix, AZ*

Background: Niraparib improves progression-free survival (PFS) in pts with newly diagnosed AOC after complete or partial response to first-line, platinum-based chemotherapy. In the PRIMA/ENGOT-OV26/GOG-3012 (PRIMA) trial, pts were treated with a fixed starting dose (FSD) of 300 mg QD until a protocol amendment introduced the individualized starting dose (ISD) regimen: 200 mg QD for pts with baseline bodyweight (BW) $<$ 77 kg and/or platelet count (PC) $<$ 150,000/μL, or 300 mg QD for pts with baseline BW $\geq$77 kg and PC $\geq$150,000/μL. Here, we developed a population pharmacokinetic (PopPK) model for niraparib and evaluated exposure-response relationships for pts receiving niraparib using safety and efficacy data from PRIMA. **Methods:** The PopPK model for niraparib was developed based on 7418 plasma samples from 1442 pts from 4 studies: PN001, NOVA, QUADRA, and PRIMA. PRIMA PK samples were collected on cycle 1, day 1 (C1D1), C2D1 pre-dose and 2 h post-dose, C4D1, and C8D1 pre-dose (or EOT if patient discontinued before C8D1). The relationship between PopPK model-based prospective exposure (average concentration [C_{ave}] until progression/death) and efficacy (PFS) were evaluated in pts receiving niraparib in both the homologous-recombination deficient (HRd) and overall population. The relationship between model-predicted exposure metrics and incidence of clinically relevant adverse events (AEs) was analyzed using univariate logistic regression in pts receiving niraparib. **Results:** Of 484 pts receiving niraparib in PRIMA, 480 had PK data and were included in the efficacy and safety analysis. The safety exposure-response showed significant associations ($p \leq 0.0128$) between increasing niraparib exposure and increasing probability of experiencing any-grade and grade $\geq$3 AEs, except grade $\geq$3 hypertension. The incidence of AEs, including thrombocytopenia, was lower in pts who received a 200-mg ISD. Efficacy was not compromised in these pts. **Conclusions:** Niraparib exposure was associated with increased risk of select AEs. However, the ISD regimen decreased AE risk without compromising efficacy. Clinical trial information: NCT02655016. Research Sponsor: GlaxoSmithKline.

6052 Poster Session (Board #223), Fri, 8:00 AM-11:00 AM

Population-adjusted indirect treatment comparison (PAITC) of maintenance PARP inhibitor (PARPi) with or without bevacizumab versus bevacizumab in women with newly diagnosed ovarian cancer (OC). *First Author: Robert Hettle, AstraZeneca, Cambridge, United Kingdom*

Background: In patients (pts) with newly diagnosed OC, bevacizumab (B), PARPi, and PARPi + B have shown benefit as maintenance treatment options after platinum chemotherapy response. Phase III trials have demonstrated longer median progression-free survival (PFS) with PARPi + B (PAOLA-1, olaparib [O]; NCT02477644) vs placebo (P) + B and with PARPi alone (PRIMA, niraparib [N]; NCT02655016) vs P. As there are no randomized head-to-head trials comparing PARPi + B vs PARPi, or PARPi vs B, we performed indirect treatment comparison across these regimens. **Methods:** Unanchored PAITC was performed with individual pt data (IPD) from a PAOLA-1 subset comprising pts with stage IV disease, stage III with residual disease after primary surgery, inoperable stage III disease, or any patient who received neoadjuvant chemotherapy. Propensity weights were used to match the baseline (BL) characteristics of the PRIMA population. PRIMA dataset was reconstructed using published PFS curves. Both datasets were pooled; treatment efficacy was assessed by weighted Cox regression and Kaplan–Meier methods. PAITC was performed in all pts (biomarker unselected) and the homologous recombination repair deficiency positive (HRD+; cut-off 42) subgroup. **Results:** 595/806 (266/387 HRD+) PAOLA-1 pts were included. After matching, the effective sample size (ESS) for PAOLA-1 was 532 (242 HRD+; weights 0.241–2.37). Weighted BL data were balanced across cohorts. **Conclusions:** In biomarker-unselected and HRD+ pts, PAITC suggests that adding O to B significantly improved PFS vs. N or B alone. In biomarker-unselected pts, PAITC results show no significant difference in PFS between N and B. In HRD+, improved efficacy with N appears to translate into improved PFS vs. B alone, although follow-up was $<$2 years (14 vs 22 months, respectively). Results are hypothesis generating and could guide randomized trial design. Clinical trial information: NCT02477644 and NCT02655016. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp, a subsidiary of Merck & Co, Inc, Kenilworth, NJ, USA.

Hypersensitivity to platinum salts according to BRCA status in ovarian cancer: Retrospective analysis of clinical outcomes. *First Author: Gaia Giannone, Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy*

Background: Hypersensitivity reactions (HSRs) to platinum salts are an important issue in the treatment of ovarian cancer (OC) patients (pts). Few data suggest that, along with number of previous cycles, germline BRCA mutations could be a risk factor. We aimed at evaluating the incidence and severity of HSRs to platinum salts in a large group of OC pts with known BRCA status and correlated them with drug exposure time. **Methods:** Between March 2003 and September 2019, 432 pts with a diagnosis of OC and a known BRCA status, were recorded in our 5 Institutions and retrospectively analyzed. The following data were collected: histology, BRCA status, type of surgery and first line therapy, number of total lines and cycles received, line and cycle of HSR onset, symptoms, history of other allergies and if desensitization was attempted. We graded the severity of HSRs according to CTCAE v5.0. We calculated the total duration of exposure to platinum salts, summing up the duration of all platinum lines received by the pts. **Results:** Four hundred nine of 432 (94.7%) pts were treated with at least one platinum-based line of therapy and were eligible for the analysis. Among them, 314 pts were BRCA wild type (BRCAwt) (76.8%) and 95 were BRCA mutated (BRCAmut) (23.2%). There was no statistical difference in number of prior lines of therapy [median 1 (2-6) for BRCA wt and 2 (1-6) for BRCAmut pts (p = 0.194)] and duration of exposure to platinum [median 126 (42 – 893) and 197 (42 – 896) days for BRCAwt and BRCAmut pts, respectively (p = 0.145)]. Incidence of any grade HSRs was 29 / 314 (9.2%) among BRCAwt pts vs. 17/ 95 (17.9%) among BRCAmut pts (Odds ratio [OR] 0.47, 95% CI 0.24 – 0.89, p= 0.019). All recorded HSRs to platinum salts were related to carboplatin. We observed a numerically higher incidence of Grade 3-4 HSRs in BRCAmut pts (5.1% in BRCAwt vs. 10.5% in BRCAmut cohort, OR 0.46, 95% CI 0.20 – 1.04, p = 0.057). The risk to develop HSRs increases with duration of exposure to platinum, particularly in BRCAmut pts. The cumulative incidence of any grade HSRs was 20.6% vs. 23.3% after 12 months and 38.4% vs. 59.7% after 18 months in BRCAwt and BRCAmut pts, respectively (Hazard Ratio [HR] 1.72, 95% CI 0.94 – 3.12, p = 0.073). The cumulative incidence of severe HSRs was 10.9% vs. 15.7% after 12 months and 26.5% vs. 41.0% after 18 months in BRCAwt and BRCAmut pts, respectively (HR 1.88, 95% CI 0.85 – 4.16, p = 0.11). **Conclusions:** In BRCAmut OC pts, there is a significantly higher incidence of HSRs to carboplatin, that seems not justified by longer drug exposure only. Research Sponsor: None.

6054 Poster Session (Board #225), Fri, 8:00 AM-11:00 AM

Pharmacokinetics and safety following a single oral dose of niraparib in patients with moderate hepatic impairment. *First Author: Mehmet Akce, Department of Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Niraparib is approved for the maintenance treatment of adult patients (pts) with recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer who are in a complete or partial response to platinum-based chemotherapy, or with similar cancers but advanced, associated with homologous recombination deficiency (HRD) and have been treated with ^{3}3 prior chemotherapy regimens. Niraparib is extensively metabolized in the liver and eliminated via both hepatobiliary and renal routes. Objectives of this study included characterization of niraparib pharmacokinetics (PK) and safety in pts with normal hepatic function vs. pts with moderate hepatic impairment. **Methods:** This phase I, open-label, parallel-group, single-dose study enrolled pts with advanced solid tumors into 2 groups: normal hepatic function and moderately impaired hepatic function, defined as bilirubin $>$1.5 to 3 times the upper limit of normal and any aspartate aminotransferase elevation. Pts received a single 300-mg dose and underwent PK sampling for 7 days. Exposure parameters included maximum concentration (C_{max}), area under the concentration-time curve calculated to last measured concentration (AUC_{last}), and extrapolated to infinity (AUC_{inf}). PK parameters were determined using a non-compartmental analysis in WinNonlin. **Results:** Seventeen pts were enrolled; 9 with normal hepatic function and 8 with hepatic impairment. Niraparib C_{max} was 7% lower in pts with moderate hepatic impairment compared with pts with normal hepatic function (Table). Overall exposure was increased in pts with moderate hepatic impairment, with niraparib AUC_{last} and AUC_{inf} increased 45% and 60%, respectively. Safety data during the PK phase of the study is consistent with the known profile for niraparib. **Conclusions:** Pts with moderate hepatic impairment experienced increased niraparib exposure which did not noticeably alter the toxicity profile in this population. Clinical trial information: NCT03359850. Research Sponsor: GlaxoSmithKline.

	NHF GLSM	MHI GLSM	NHF/MHI Ratio, %	90% CI

Laboratory cross-comparison of tumor BRCA1/2 analysis in a multicenter epithelial ovarian cancer series: The BORNEO GEICO60-0 study. *First Author: Ignacio Romero, Instituto Valenciano de Oncología, Valencia, Spain*

Background: Epithelial ovarian cancer (EOC) identification of *BRCA1* and *BRCA2* mutations is usually carried out in germline, representing around 17% in high grade serous ovarian cancer (HGSOC) and further 5-7% are only identified in the tumor (somatic). The aim of this study was to identify in EOC tumor BRCA mutation frequency and inter-laboratory reproducibility using different Next-generation Sequencing (NGS) approaches. **Methods:** In an ambispective study design, a population of unselected consecutive non mucinous EOC was clinically annotated and Formalin-Fixed Paraffin-Embedded (FFPE) tumor *BRCA1/2* mutation analysis was undertaken in two laboratories (Lab-1 and Lab-2) simultaneously. Both laboratories used their own validated NGS panels; variant allele frequency threshold was 5% for single nucleotide polymorphism and 10% for indels. Each laboratory classified variants into three categories based on ACMG criteria: non-mutated (class 1-2), Variants of Uncertain Significance (VUS: class 3) and likely pathogenic/pathogenic (class 4-5). Germline *BRCA* analysis was available according to local clinical practice or centralized in Lab-1 if histology was low grade. **Results:** Ninety FFPE samples were received, 8 had insufficient material to be analyzed in both laboratories and 6 cases were discarded due to tumor cellularity below 20% leaving 76 cases to be sequenced. The population had a median age of 58 (25-84) years, 87% (66/76) of HGSOC histology and 70% of advanced stages (III-IVB: 53) and 14.5% (11) germline *BRCA* mutations (3 with not available results). Lab-1 identified 17 class 4-5 mutations, 11 correspond to germline, 4 (5.3%) are just somatic and 2 have germline results not available yet. Lab-2 had one not valuable analysis and identified 16 class 4-5 mutations, 10 corresponding to germline and 4 somatic variants. Percentage of concordance between both laboratories was 96% (kappa coefficient 0.883; p value < 0.0001). Three discordant out of 18 class 4-5 mutations included 2 undetected (VAF of 14.9% and 60.3% respectively) and one class 4 in Lab-2 classified as VUS in Lab-1 due to different interpretation criteria. **Conclusions:** The global *BRCA* mutation frequency in our series was 22.3% for Lab-1 and 21.0% for Lab-2. Concordance between tumor *BRCA* mutation analysis was high (96%). Nevertheless, further effort is required on harmonizing the technical and analytical aspects in tumor mutational analysis. Research Sponsor: Astra Zeneca.

6056 Poster Session (Board #227), Fri, 8:00 AM-11:00 AM

Cediranib in combination with olaparib in patients without a germline BRCA1/2 mutation with recurrent platinum-resistant ovarian cancer: Phase IIb CONCERTO trial. *First Author: Jung-min Lee, National Cancer Institute, Bethesda, MD*

Background: A Phase I trial (NCT01116648) of cediranib (cedi) in combination with olaparib (ola) (cedi + ola) demonstrated an overall response rate of 44% in patients (pts) with recurrent ovarian cancer (OC), including pts without a deleterious or suspected deleterious gBRCAm (non-gBRCAm; Liu *et al. Eur J Cancer* 2013). The subsequent Phase II trial (NCT01116648) showed significant improvement in progression-free survival (PFS) with cedi + ola versus ola monotherapy in recurrent platinum-sensitive OC pts, notably in non-gBRCAm pts (Liu *et al. Lancet Oncol* 2014). We report data from the Phase IIb, single-arm, open-label CONCERTO study investigating cedi + ola in non-gBRCAm pts with recurrent platinum-resistant OC who had received ≥3 previous lines of therapy for advanced OC (NCT02889900). **Methods:** Pts with disease progression <6 months from the last receipt of platinum-based chemotherapy received cedi tablets (30 mg once daily) plus ola tablets (200 mg twice daily) until progression or unacceptable toxicity. gBRCAm pts were ineligible. Primary endpoint: objective response rate (ORR) by independent central review (ICR; RECIST 1.1). Key secondary endpoints: PFS and safety. **Results:** 60 pts from the USA were included (median age: 64.5 years; median number of previous systemic treatment regimens: 4 [range: 2–9]; previous bevacizumab: 53). All pts had high-grade OC (90% serous; 3.3% clear cell; 3.3% endometrioid; 3.3% other). 7% of pts had tumor *BRCA2* (confirmed somatic) mutations, 80% of pts had no tumor BRCA mutation (non-tBRCAm) and 13% of pts were not evaluable for tBRCAm. Five (8%) pts who were non-tBRCAm carried somatic homologous recombination repair gene mutations (FoundationOne Clinical Trial Assay, Foundation Medicine, Inc). The Table shows results of key endpoints. Most common grade ≥3 adverse events (AEs) that occurred in pts were hypertension (30%), fatigue (22%) and diarrhea (13%). 37% of pts reported serious AEs, of which nausea (7%) was most common. Dose interruptions, reductions and discontinuations were caused by AEs in 55%, 18% and 18% of pts, respectively, who received cedi + ola. **Conclusions:** Cedi + ola showed evidence of antitumor activity in heavily pretreated non-gBRCAm pts with recurrent platinum-resistant OC. Toxicity was manageable with dose modifications. Clinical trial information: NCT02889900. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp, a subsidiary of Merck & Co, Inc, Kenilworth, NJ, USA.

Olaparib maintenance monotherapy for non-germline BRCA1/2-mutated (non-gBRCAm) platinum-sensitive relapsed ovarian cancer (PSR OC) patients (pts): Phase IIIb OPINION interim analysis. *First Author: Andres Poveda, Initia Oncology, Hospital Quirónsalud, Valencia, Spain*

Background: In the Phase II Study 19 trial (NCT00753545; Ledermann *et al. Lancet Oncol* 2014), maintenance olaparib improved progression-free survival (PFS) vs placebo in PSR OC pts, including those in the non-BRCAm subgroup. A significant PFS benefit was also seen with maintenance olaparib vs placebo in gBRCAm PSR OC pts in the Phase III SOLO2 trial (NCT01874353; Pujade-Lauraine *et al. Lancet Oncol* 2017). To investigate olaparib maintenance monotherapy in non-gBRCAm PSR OC pts who had received ≥2 previous lines of platinum-based chemotherapy, we performed the Phase IIIb, single-arm, OPINION study (NCT03402841). **Methods:** Pts had high-grade serous or endometrioid OC and had responded to platinum-based chemotherapy. Pts initiated maintenance olaparib tablets (300 mg bid) until disease progression or unacceptable toxicity. Primary endpoint was investigator-assessed PFS (modified RECIST 1.1). Secondary endpoints included PFS by homologous recombination repair deficiency (HRD; assessed with the Myriad myChoice HRD plus test; HRD+ve: score ≥42) and somatic BRCA mutation (sBRCAm) status. An interim analysis was planned after ~135 PFS events. **Results:** 279 pts were enrolled from 17 countries (mean age: 64 yrs); 94.3% were confirmed non-gBRCAm by local testing. At data cut-off (Nov 15, 2019), the median PFS was 9.2 months (95% confidence interval [CI]: 7.6–10.9 months), with 152 PFS events (54.5% maturity). The Table presents PFS outcomes by key subgroups. The median exposure to olaparib was 8.1 months. Grade ≥3 adverse events (AEs) occurred in 72 (26%) pts. 19% of pts reported serious AEs. No deaths related to AEs were reported. AEs led to dose interruption, dose reduction and treatment discontinuation in 39%, 15% and 7% of pts, respectively. **Conclusions:** Maintenance olaparib demonstrated activity in non-gBRCAm PSR OC pts. There were no new safety signals. Clinical trial information: NCT03402841. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

PFS outcomes by key subgroups.

	Subgroup	Events, n (%)	Median PFS, months (95% CI)
HRD/BRCAm status	HRD+ve including sBRCAm, n=128	63 (49)	10.9 (9.1–14.5)
	HRD+ve excluding sBRCAm, n=94	51 (54)	9.7 (8.1–11.1)
	sBRCAm, n=34	12 (35)	14.5 (9.2–NE)
	HRD-ve, n=115	72 (63)	7.3 (5.5–9.1)
Prior platinum regimens	2, n=172	97 (56)	9.2 (7.4–10.9)
	>2, n=107	55 (51)	9.0 (7.2–NE)
Response to last platinum therapy	CR/NED, n=96	45 (47)	10.8 (9.2–13.8)
	PR, n=179	104 (58)	7.4 (7.2–10.8)

CR, complete response; NE, not evaluable; NED, no evidence of disease; PR, partial response

The safety and efficacy of weekly paclitaxel and cisplatin chemotherapy for patients with ovarian cancer who developed carboplatin hypersensitivity reaction in previous chemotherapy. *First Author: Kyoko Nishikimi, Departments of Reproductive Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background: Carboplatin (CBDCA) hypersensitivity reactions (HSR) often occur in patients with ovarian cancer. Once CBACA HSR occurs, it is difficult to use platinum even though the patients had platinum-sensitive disease and consequently the survival of the patients cannot be prolonged. We had administered weekly paclitaxel and cisplatin (CDDP) chemotherapy (wTP) for patients with ovarian cancer who developed CBDCA HSR in previous chemotherapy. We investigated the safety and efficacy of wTP. **Methods:** We investigated 86 patients with ovarian, fallopian tube, and peritoneal carcinoma who developed CBDCA HSR in previous chemotherapy (paclitaxel/CBDCA) at our institution between 2011 and 2019. After premedication was administered, paclitaxel and sequentially CDDP were administered as one hour infusion, respectively (paclitaxel 80 mg/m^2, CDDP 25 mg/m^2; 1, 8, 15 day/4 weeks). **Results:** The median cycle of the previous chemotherapy of CBDCA was 8 (interquartile range [IQR], 6–11). The grade of CBDCA HSR was 1 in 57 (66%), 2 in 26 (30%), and, 3 in 1 (1%) patient(s). WTP was administered for the first line in 21 (24%), second line in 35 (41%) and third or more line in 30 patients (34%). The median cycles of wTP administration was 4 (IQR, 3–7). We observed that severe CDDP HSR did not occur in any patients and 15 patients (17.4%, grade 1, 10 patients; grade 2, 5) developed CDDP HSR. All CDDP HSR were successfully managed with infusion interruption and Hydrocortisone Sodium Phosphate administration. There was no relation between the grade of CBDCA HSR in the previous chemotherapy and the rate of CDDP HSR ($p = 0.363$). Progression-free survival and overall survival after administration of wTP were 10.9 months (95% CI: 7.7–17.7) and 25.9 months (95%Ci: 19.0–50.2), respectively. **Conclusions:** 71 patients (82%) who developed CBDCA HSR in previous chemotherapy were able to continue administration of wTP without CDDP HSR. WTP was safe and effective for the patients who developed CBDCA HSR. Research Sponsor: None.

Patient characteristics.

No. of Cycles in previous CBDCA	n (%)	Grade of previous CBDCA HSR	n (%)	Line of cisplatin	n (%)
2–6	28 33%	1	57 66%	First	21 24%

Phase I/II study of weekly topotecan and gefitinib in patients with platinum-resistant ovarian, peritoneal, or fallopian tube cancer. *First Author: Anca Chelariu- Raicu, MD Anderson, Houston, TX*

Background: The epidermal growth factor receptor (EGFR) is expressed in many types of cancer. Fifty to 70% of epithelial ovarian can overexpress EGFR, and its expression has been correlated with poor prognosis features in many cases. While these tumors are chemosensitive to platinum-based therapy, chemoresistance often develops. We conducted a phase I/II trial to examine the efficacy, safety, and toxicity of gefitinib, a tyrosine kinase inhibitor, combined with topotecan in women with recurrent ovarian cancer with EGFR receptor positivity (1+ or greater). **Methods:** Patients with measurable, recurrent or persistent cancer after treatment with a platinum and paclitaxel-containing regimen were eligible for this study (n = 19). We first used "run-in" dose escalation, in which a conventional 3+3 algorithm was used. Initial treatment was gefitinib 250 mg oral dose daily and topotecan at a dose of 2.0 mg/m^2 on days 1, 8, and 15, with cycles repeated every 28 days. Dose escalations were planned for topotecan (Dose Levels 1–3: 2, 3, 4 mg/m^2) until the MTD was reached. Next, an additional 10 patients with refractory or progressive ovarian cancer were enrolled in the phase II study. **Results:** 19 patients received a total of 61 cycles. Median age was 60 years. Histological types of treated patients included 73% serous (n = 14), 12.5% mixed (n = 2), 12.5% transitional (n = 2) and 6.3% clear cell (n = 1). There were 3 patients treated at dose level 1, 3 patients at dose level 2, and 3 patients treated at dose level 3. The maximum tolerated dose was topotecan 4.0mg/m^2 IV days 1, 8 and 15, and gefitinib 250mg p.o. QD x28 days. Therefore, dose level 3 was used for the Phase II portion of the trial. Of the 19 patients included in the phase I/II, 3 patients were inevaluable for response to therapy due to toxicity, missed therapy or decline in performance status. Of the 16 patients, 81% patients (n = 13) had progressive disease, 12.5% stable disease (n = 2), and 6% partial response (n = 1). We assessed all 19 patients for adverse events; 60% had treatment-related grade 3 events, primarily blood disorders such as anemia (n = 3, 16%), neutrophil count decrease (n = 4, 21%). **Conclusions:** This prospective phase I/II clinical trial failed to show sufficient clinical activity of topotecan in combination with gefitinib in patients with EGFR-positive recurrent ovarian, fallopian tube, or peritoneal cancers. The drug combination was relatively well-tolerated in this cohort. As such, the study did not proceed to the next accrual goal secondary to the lack of response. Clinical trial information: NCT00317772. Research Sponsor: MD Anderson.

6060 Poster Session (Board #231), Fri, 8:00 AM-11:00 AM

Whole transcriptome changes correlate to exceptional ovarian cancer responders: A sub-analysis of a HIPEC Phase I trial. *First Author: Thanh Hue Dellinger, City of Hope Natl Comp Cancer Ctr, Duarte, CA*

Background: Advanced stage ovarian cancer patients benefit from hyperthermic intraperitoneal chemotherapy (HIPEC), prolonging overall survival by nearly 12 months. However, molecular changes triggered by HIPEC are not well characterized, and no molecular signatures of response are known. We analyzed early gene expression changes after HIPEC treatment in ovarian tumors. **Methods:** This is an interval subgroup analysis of a single institution Phase I trial using HIPEC with cisplatin 75 mg/m^2 at time of optimal cytoreduction. Snap-frozen biopsies from tumor and normal peritoneum from 20 patients with ovarian cancer before and after HIPEC underwent whole-transcriptome sequencing using Illumina's NovaSeq 6000 for paired 100 base-pair reads. Differential expression analysis comparing post and pre-samples was done to identify significantly changed genes, and pathway analysis was conducted using GSEA. **Results:** Sixty-three genes were differentially expressed ($P < 0.05$, fold change ≥ 2) between pre- and post-HIPEC tumors. Hierarchical clustering analysis of these genes confirmed that all tumors and normal tissues clustered based on pre-HIPEC versus post-HIPEC status, and not based on their patient source. Gene set enrichment analysis using a collection of 50 "hallmark" gene sets revealed that post-HIPEC tumors demonstrate significant upregulation in immune pathways (TNFA signaling via NFKB, coagulation, complement), followed by epithelial-mesenchymal transition, inflammation, apoptosis, hypoxia, angiogenesis, KRAS signaling and JAK/STAT3 signaling. In contrast, post-HIPEC normal tissues exhibited upregulation in cell cycle pathways (Myc targets V2, G2M checkpoint). As expected, both post-HIPEC tumor and normal samples shared upregulation of genes related to inflammatory response. Lastly, post-HIPEC normal samples revealed downregulation of growth and metabolism pathways; in contrast, cell cycle or DNA repair pathways were downregulated in post-HIPEC tumors. Two exceptional-responders with recurrent platinum-sensitive disease (ongoing PFS 47 and 12+ months) demonstrated the most substantial changes in gene expression. **Conclusions:** Exceptional ovarian cancer responders to HIPEC are characterized by extensive gene expression changes; specifically, early HIPEC-induced molecular changes are strongly associated with immune pathways changes, implicating a role for immunotherapy after HIPEC in ovarian cancer. Clinical trial information: NCT01970722. Research Sponsor: None.

6061 Poster Session (Board #232), Fri, 8:00 AM-11:00 AM

Anlotinib in patients with recurrent platinum-resistant or refractory ovarian carcinoma: A prospective, single-arm, single-center, phase II clinical study. *First Author: Boer Shan, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: Recurrent platinum-resistant or refractory ovarian carcinoma is difficult to treat, and how to improve the treatment effect of these patients is still an urgent problem to solve. Anlotinib is a new multi-target tyrosine kinase inhibitor and its anti-tumor vascular targets include VEGFR, PDGFR and FGFR. Previous researches have shown clinical antitumor activity of anlotinib in various cancers, including the phase I study on gynecologic tumor. This phase II study (ChiCTR2000029654) aims to further evaluate the safety and efficacy of anlotinib in patients with recurrent or refractory ovarian carcinoma. **Methods:** Patients who have previously received second-line or more chemotherapy, with histopathologically confirmed ovarian high-grade serous gonadal carcinoma (including salpingocarcinoma and peritoneal carcinoma), ECOG 0-2 were considered eligible for enrollment. Anlotinib was administered orally (12 mg qd, d1-14; 21 days per cycle) till disease progression, death or intolerant toxicity. Therapeutic effects are evaluated every 6 weeks. The primary endpoint was objective response rate (ORR) and the secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), safety and quality of life (QOL). **Results:** Between 2019 March to 2020 January, 15 patients (female) with FIGO histopathological stage IA(6.7%), IIIA (73.3%), IIIC (6.7%) and IV (13.3%) were enrolled and 14 patients were evaluable with a median age of 59 years (range: 47-69). The mean follow-up period is 3.5 months (95% CI: 2.1-4.8). Therapeutic evaluation showed the incidence of partial response, stable disease and progression disease was 14.3%, 57.1% and 28.6% respectively, yielding the ORR of 14.3% (2/14; 95% CI: 1.8%-42.8%) and the DCR of 71.4% (10/14; 95% CI: 41.9%-91.6%). The median PFS was not reached. Most of the occurring AEs were grade 1, including hypertention (57.1%), fatigue (50.0%), hand-foot syndrome (35.7%), hoarseness (14.3%), diarrhea (7.1%), gum-pain (7.1%), decrease in leukocyte count (6.7%) and urine protein (7.1%). Only cancer pain (7.1%) was grade 2. No high grade AE was observed in these 14 patients. Neither unexpected safety signals nor treatment related death occurred. **Conclusions:** Anlotinib showed a promising efficacy with a favourable toxicity profile for patients with recurrent platinum-resistant or refractory ovarian carcinoma. And we will report more results ahout anlotinib in the future. Clinical trial information: ChiCTR2000029654. Research Sponsor: Chia-Tai Tianqing Pharmaceutical Group Co Ltd.

6062 Poster Session (Board #233), Fri, 8:00 AM-11:00 AM

Risk stratified multidisciplinary ambulatory management of malignant bowel obstruction (MAMBO) program for women with gynecological cancers: Preliminary results from a prospective single-center study. *First Author: Shiru Lucy Liu, Princess Margaret Cancer Centre-University Health Network, Toronto, ON, Canada*

Background: Malignant Bowel Obstruction (MBO) is one of the most common and devastating complications in women with gynecological cancer (GC). There is currently no consensus guideline to improve patient (pt) care in this setting. MAMBO (NCT03260647) is an ongoing prospective study evaluating the clinical implementation of a novel management algorithm for multidisciplinary management of MBO in GC pts. We report preliminary patient outcomes. **Methods:** All GC pts at Princess Margaret Cancer Centre with a confirmed diagnosis of or are at risk of MBO are eligible for enrollment. Participants follow a low fiber diet titrated by severity of symptom and their monthly weight and albumin levels are recorded, along with standardized patient-reported outcome measures (PROMs) at different time points. For pts who develop MBO, inpatient and ambulatory management algorithms are applied using a multidisciplinary and interprofessional care model consisting of nurses, surgeons, oncologists, radiologists, nutritionists, total parenteral nutrition team, social work, and palliative care. Decisions regarding most optimal management strategies are made by this team with regular MAMBO rounds. A retrospective analysis of pts hospitalized with MBO between 2012 and 2017 was performed in order to have a historical comparison for outcome and survival analysis using Kaplan Meier methods. **Results:** Since August 2017, 70 pts have been enrolled in MAMBO. Most had high-grade serous ovarian carcinoma (75%), of whom 68% are platinum-resistant. So far, 36 (51%) developed MBO, 6 of whom had multiple sequential episodes. Mean number of days in hospital with MBO was 10 days (median 7, range 0-45), compared to 18 days (median 9, range 0-134) for historical control ($p = 0.009$). There was no significant loss in weight 6 months from MBO diagnosis but a significant reduction in albumin level by 2.75 g/L after 3 months ($p = 0.005$). PROMs suggest fatigue and general lack of wellbeing were the symptoms with highest distress. Most patients (78%) received chemotherapy following MBO and most received weekly paclitaxel (36%). Median time from first MBO to death was 219 days (95% CI: 101-not reached) for all-comers in MAMBO and 174 days (95% CI: 98-363) for MBO requiring hospitalization, compared to 108 days (95% CI: 79-160) for historical controls ($p = 0.007$ and $p = 0.062$, respectively). **Conclusions:** Patient care and outcomes from MBO seem to be improved in GC pts enrolled in MAMBO compared to historical controls. Clinical trial information: NCT03260647. Research Sponsor: Clinical Cancer Research Unit, Princess Margaret Cancer Centre.

6063 Poster Session (Board #234), Fri, 8:00 AM-11:00 AM

Are symptoms distinguishable in ovarian cancer? A nested case control study of insurance claims. *First Author: Denise Manon Langabeer, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Over 60% of ovarian cancer cases are diagnosed with Stage III and IV disease. The US healthcare system does not support a standard screening method for ovarian cancer. Our goal was to determine whether certain symptoms based on ICD-9 categories are distinguishable among women diagnosed with ovarian cancer and women without ovarian cancer. **Methods:** Women diagnosed with ovarian cancer were randomly matched 1:1 to women without cancer to support a nested case-control analysis of health insurance claims between 2008 through 2013 from a commercial payer. The following eligibility criteria were applied: 1) 24 years of age or older; 2) continuously enrolled in healthcare plan for a minimum period of 6 months; 3) experienced more than 1 symptom over the observation period; and 4) an observation period of a minimum of 6 months. Symptoms were based on 47 ICD-9 diagnosis codes and categorized specific to pain, abdominal and pelvic, digestive, and bladder. The analysis was based on 1,578 women (789 cases; 789 controls). **Results:** Overall, 90% (n = 1,421) of the women experienced abdominal and pelvic symptoms, and 92% (n = 725) of the women with ovarian cancer visited their physician for this complaint 6-70 months prior to diagnosis, OR 1.66 (CI 1.14 to 2.41; p = .008). Pain was reported as a complaint by cases at nearly 60% (n = 464) and controls at 48% (n = 376); OR 1.75 (CI 1.39 to 2.19; $p < .001$). Symptoms for bladder and digestive combined represented 68% of complaints for both cases (n = 507) and controls (n = 555), p = .024 and p = .298, respectively. Of the 1,578 women, 77% (cases = 621; controls = 595) experienced more than one category of symptoms. Both cases (n = 206) and controls (n = 153) complained of abdomen and pelvic symptoms along with pain; OR 1.54 (CI 1.19 to 1.99; p = .001). A second combination included abdomen and pelvic symptoms with pain and digestive symptoms in 14% of women (cases n = 99; controls n = 67); OR 1.58 (CI 1.13 to 2.22; p = .008). Sixty percent (n = 473) of women with ovarian cancer experienced the majority of associated prediagnosed symptoms analyzed for the study. **Conclusions:** Certain recurring symptoms associated with abdomen and pelvic as well as pain appear to indicate an association with ovarian cancer, signifying that symptom awareness remains relevant to this disease that is diagnosed at a late stage and currently does not have routine screening methods to support early detection. Research Sponsor: None.

6064 Poster Session (Board #235), Fri, 8:00 AM-11:00 AM

Juvenile granulosa cell tumor: An interim report from the international ovarian and testicular stromal tumor (OTST) registry. *First Author: Anne Harris, Children's Hospitals and Clinics of Minnesota, Minneapolis, MN*

Background: Juvenile granulosa cell tumors (JGCT) are rare sex cord-stromal tumors which occur primarily in children and adolescents. **Methods:** All individuals or proxy caregivers provided informed consent/assent for participation in the International OTST Registry. Clinical data was collected. When available, pathology was centrally reviewed. Staging was evaluated using the International Federation of Gynecology and Obstetrics (FIGO) classification. Kaplan-Meier survival analyses and exact permutation tests were performed. **Results:** Forty-two individuals with ovarian JGCT were enrolled. Median age at diagnosis was 9 years (range 0-27). Most individuals had Stage I disease (Stage Ia=16; Stage Ib=1; Stage Ic=16). Seven individuals presented with higher stage (Stage II=2; Stage III=5). Stage was unknown for 2 individuals. Three-year overall survival (OS) was 88% (CI 77%, 100%) and event-free survival (EFS) was 69% (CI 54%, 88%). At median follow-up time of 25 months (range 0-416), 9 patients (Stage Ia=1, Stage Ic=5, Stage III=3) had recurrent disease. Use of post-operative adjuvant chemotherapy varied by stage and timing of rupture. Of those with Stage Ic JGCT, 2/7 with preoperative rupture and 3/9 with intraoperative rupture recurred. Among individuals with recurrence, median time to recurrence was 11.5 months (range 3-19). Four of 9 individuals with recurrence survived (no evidence of disease n=2; alive with disease n=2). All individuals who died presented with extrapelvic recurrence. Median time from recurrence to death was 10 months (range 2-53). In individuals with recurrence, advanced stage at diagnosis (HR 5.1; p-value 0.087) and recurrence outside the tumor bed (HR Infinity; p-value 0.048) were associated with inferior OS. Three-year OS for individuals with recurrence was 57% (CI 30%, 100%). **Conclusions:** Low stage JGCT is associated with a favorable prognosis, however, recurrence is associated with lower survival rate. Within this series, recurrences presented within 2 years of diagnosis. Novel strategies are needed to address recurrent and extrapelvic disease. Research Sponsor: Pine Tree Apple Tennis Classic Foundation.

6066 Poster Session (Board #237), Fri, 8:00 AM-11:00 AM

ctDNA from ascites as an alternative to tumor sampling for HRD (homologous recombination deficiency) testing in ovarian cancer (OC). *First Author: Alexandra Leary, Gustave Roussy Cancer Center, Villejuif, France*

Background: Knowledge regarding HRD status is becoming crucial to guide maintenance strategies for patients with newly diagnosed OC. Unfortunately, for patients (pts) treated with neoadjuvant chemotherapy (NACT), HRD testing on small biopsies from diagnostic laparoscopies (Dx Lap) or interval debulking has a high failure rate. At relapse, biopsies may not be feasible. Aim: Evaluate the feasibility and usefulness of HRD testing on cfDNA from ascites **Methods:** Pts enrolled in a prospective biological study (OvBIOMark) consented to analysis of biological samples obtained as part of routine diagnosis. cfDNA was extracted from 1-2ml of double-centrifuged fresh ascites and subjected to 1) targeted NGS including the most common somatic mutations in high grade ovarian cancer (*TP53*) to confirm presence of tumor cfDNA and 2) SNParray for copy number (CN) analyses to calculate a genomic instability score (GIS) for HRD. **Results:** Thirty four ascites samples were collected from 25 pts with suspected or confirmed OC. For 15/25 pts samples were obtained at Dx Lap, and for 10 pts samples were obtained at relapse. Seven pts underwent repeat ascitic drains during treatment or at relapse. 97% (33/34) of ascitic samples had detectable cfDNA (median = 980ng, range:80-5730ng) even when obtained during chemotherapy. A deleterious mutation was identified in 87% (29/33) of samples with high allelic frequencies (median allelic frequency, AF = 60%; 3.3-87%), confirming that most of detected cfDNA was tumoral. The most common mutation was a *TP53m (*86%; 25/29). We have performed CN analysis on cfDNA from ascites on 17 of these patients to evaluate their HRD status. Ten pts had a high GIS (HRD+), and 7 pts a low GIS (HRD-). The 4 pts with confirmed *BRCA*m included in this study had a high GIS on ascites. When available from the same patient, the CN profiles derived from ascites cfDNA and tumor sampling were superimposable. **Conclusions:** Ascites yields large amounts of cfDNA, which can be confirmed as tumoral based on *TP53* mutation detection. CN analysis on ascitic cfDNA is feasible and can be used to detect the same HRD scar as tumor testing. Ascites is frequent at diagnosis, especially in pts with inoperable disease planned for NACT and could provide a useful alternative to tumor for HRD and *BRCA* testing. Research Sponsor: Institut National du Cancer TransCAN european grant.

6067 Poster Session (Board #238), Fri, 8:00 AM-11:00 AM

Laparoscopy compared with laparotomy for comprehensive surgical staging of early ovarian cancer: Results of a retrospective multicenter case-control study. *First Author: Julia Caroline Radosa, Department of Obstetrics and Gynecology, Homburg, Germany*

Background: The objective of this study was to compare laparoscopy and laparotomy for comprehensive surgical staging of early ovarian cancer in terms of efficacy and oncologic safety. **Methods:** Patients who had laparoscopic staging for early stage (I/II) ovarian cancer between 01/2000 and 10/2018 at the participating sites (Gynecologic comprehensive cancer centers with respective expertise in minimal invasive surgery) were included in this retrospective case-control study. The control group consisted of all patients treated via laparotomy during the study period. Clinical data were abstracted from medical record and recent follow up information were obtained. Comparisons were made between patients regarding surgical parameters and oncologic outcome and multivariate models were used to identify factors independently associated with disease recurrence. **Results:** Among 313 patients, staging was performed via laparoscopy in 208 (66 %) patients and via laparotomy in 105 (34 %) patients. Patients staged laparoscopically were younger (median 52 (15-86) vs. 59 (17-92) vears, $p \leq 0.01$) and had a lower BMI (24.4 (16.5-46.8) vs. 26 (15.5-53.8), $p \leq 0.01$). Regarding surgical parameters, duration of surgery was longer (291 (159-778) vs. 277 (159-690) minutes, $p \leq 0.01$), postoperative hospitalization was shorter (7 (0-27) vs. 9 (0-92) days, $p \leq 0.01$) and postoperative complications were lower in the laparoscopy group. On univariate analysis there were no differences in rates of tumor stage according to FIGO, intraoperative rupture of ovarian cysts (14 % vs. 13 %, p=0.87), number of lymph nodes removed (24 (0-89) vs. 22 (0-96), p=0.81) or any recurrence of disease (14 % vs. 16 %, p=0.52). At a median follow-up of 46 months (0-227), there were no differences in DFS and OS by surgical technique (5yr DFS 82 % (SE 0.04) vs. 83 % (SE 0.05), p=0.43; OS 91 % (SE 0.03) vs. 87 % (SE 0.04), p=0.87). On multivariate analysis route of surgery was not associated with an increased risk of recurrence. **Conclusions:** According to this preliminary analysis, laparoscopic surgical staging in patients with early ovarian cancer seems to be adequate and safe, but a longer follow-up and prospective data are needed to enhance evidence on oncologic outcomes. Research Sponsor: None.

6068 Poster Session (Board #239), Fri, 8:00 AM-11:00 AM

Efficacy and safety of olaparib according to age in BRCA-1/2 mutated patients with recurrent platinum-sensitive ovarian cancer: Analysis of the phase III SOLO2 (AGO-OVAR 2.23/ENGOT-Ov21) study. *First Author: Fabian Trillsch, AGO and Department of Obstetrics and Gynecology, University Hospital, LMU Munich, Munich, Germany*

Background: Adding olaparib as maintenance treatment to BRCA-1/2 mutated patients (pts) with recurrent platinum-sensitive ovarian cancer (PSOC) has significantly improved progression-free survival (PFS) as well as patient-centered endpoints. As BRCA mutated pts tend to be younger, specific information on efficacy and safety of olaparib for elderly pts is of special interest. **Methods:** 295 pts from the SOLO2 trial that randomly assigned to olaparib or placebo were categorized according to age cutoff at 65 years. The efficacy and tolerability of olaparib relative to placebo within in each age group was assessed based on PFS and toxicity outcomes. Quality of life (QoL) was assessed using EQ-5D-5L descriptive system score and FACT Trial Outcome Index (TOI) and evaluated using generalized estimating equations (GEE) and time without significant symptoms of toxicity (TWiST) analysis. **Results:** Baseline characteristics were similar in pts ≥65 years (N=62; 21%) compared to pts <65 years (N=233; 79%), except for more BRCA2 mutations in elderly pts (39% vs. 23%). There was no significant difference in the magnitude of PFS benefit from olaparib in elderly as compared with younger pts (interaction P=0.33). The PFS adjusted hazard ratio (HR) of olaparib vs. placebo arms were respectively $HR_{\geq 65}$ 0.43 (95%-confidence interval [CI] 0.24-0.81) and $HR_{<65}$ 0.31 (95%-CI 0.22-0.43). Elderly and younger pts also had comparable safety profiles with no significant differences in median time on olaparib treatment (≥65: 27 vs. <65: 33 months), percentage of pts experiencing at least one grade >2 adverse event with olaparib (≥65: 73% vs. <65: 79%), or requiring at least one dose interruption or dose reduction (≥65: 77.5 vs. <65: 77.6%). No differences were found with regards to QoL scores. Quality adjusted TWiST analysis showed only non-significant differences in duration of good QoL under olaparib (≥65: 8.02 vs. <65: 9.24 months, P=0.48). **Conclusions:** In this large cohort of BRCA mutated PSOC pts treated with a PARP inhibitor within a phase III trial, no significant differences were detected in terms of efficacy, safety, and QoL with olaparib treatment for pts ≥65 years compared to younger pts. This information supports the use of PARP inhibitors as maintenance therapy for PSOC pts irrespective of age. Clinical trial information: NCT01874353. Research Sponsor: AstraZeneca.

6069 Poster Session (Board #240), Fri, 8:00 AM-11:00 AM

Ovarian cancer clinical trials: Study the studies to terminate the terminations. *First Author: Daniel Spinosa, Division of Gynecologic Oncology, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: Clinical trials safely expand the arsenal of treatments available to future patients while providing hope to current patients, particularly ovarian cancer patients who often have poor prognoses. Trial termination for lack of efficacy or unacceptable toxicity are consistent with the aim of protecting patients in the pursuit of knowledge, but those are not the only reasons trials terminate early. Understanding why some clinical trials do not achieve their stated goals may aid in the design of future trials. **Methods:** Data were gathered from clinical trials registered to ClinicalTrials.gov. Included trials were interventional (as opposed to observational), were closed between 2004 and 2019, enrolled ovarian cancer patients, had submitted results, and were open at one or more domestic sites. For each trial, data were captured regarding study completion, reason for non-completion (if applicable), sites, phase, sponsor (defined as the study initiator, not necessarily the funder), and intervention type. **Results:** A total of 313 trials were examined, of which 262 met inclusion criteria. Of the 262 evaluable trials, 189 (72%) were completed and 72 (27%) terminated early. The most common reasons for early termination were low accrual (27 trials, 38%), lack of efficacy (15 trials, 21%), or insufficient funding (9 trials, 13%). Five trials (7%) were terminated early due to toxicity. Early phase trials are less likely to complete enrollment, with 11 out of 16 (65%) phase 1 trials, 135 out of 180 (75%) phase 2 trials, and 15 out of 16 (94%) phase 3 trials completed. Trials initiated by an academic center were twice as likely to be terminated early (41/103, 40%) as those initiated by industry (16/80, 20%), with remaining trials initiated by consortia, NCI, or non-academic oncology practices. Terminated trials were open at an average of 11 sites (range 1-317), while completed trials were open at an average of 27 sites (range 1-632). Trials that had multiple types of interventions, for instance a drug and a procedure, had a 34% early termination rate which was higher than the rate for trials with any single type of intervention. **Conclusions:** More than one in four ovarian cancer clinical trials are terminated early, rarely due to treatment efficacy or tolerability. Trials terminated for reasons other than patient outcomes represent a misallocation of resources or a missed opportunity for innovation. Further research is needed to understand the circumstances that allow for clinical trial completion such that available resources maximize patient benefit. Research Sponsor: None.

6070 Poster Session (Board #241), Fri, 8:00 AM-11:00 AM

Patterns of progression and subsequent management of patients with *BRCA1/2* mutated platinum-sensitive recurrent epithelial ovarian cancer (EOC) progressing on olaparib versus placebo: the SOLO2/ENGOT Ov-21 trial (NCT01874353). *First Author: Jean-Sebastien Frenel, GINECO & Institut de Cancerologie de l'Ouest, Centre René Gauducheau, Saint-Herblain, France*

Background: Olaparib maintenance is a standard treatment of *BRCA1/2* mutated platinum-sensitive recurrent EOC. Despite improvement in PFS, olaparib (O) resistance often occurs and the optimal management of post-olaparib progression remains undefined. **Methods:** Data of patients who participated in the SOLO-2 trial and progressed were analyzed. Primary objective was to depict the patterns of progression of patients treated with O compared to placebo (P). Secondary objectives include description of post-progression treatments. **Results:** 106/195 (54%) and 80/99 (81%) patients had a RECIST progression in the O and P arms respectively. As permitted in the protocol, 37 (35%) pts continued O despite a RECIST progression and 10 remained on treatment at the date of data base cut-off of the primary endpoint. Median duration of O post progression was 3.2 months (range: 1 to 19.4). In the placebo arm, only 20% of the patients with progressive disease continued placebo during a median of 1.6 months (range:1.1 to 16.1). Patterns of sites of progressive disease were similar in the O and P arms respectively in terms of liver (21% vs 18%), lung (4% vs 3%), lymph node (20% vs 16%) peritoneal (48% vs 32%) or brain metastases (0% vs 2%). Number of sites of relapsing disease were similar in the O and P arm respectively (1 (68% vs 64), ≥2 (32% vs 36%). A total of 54 (51%) patients in the O arm and 42 (53%) in the P arm received subsequent platinum-based therapy. In both arms, 8% received bevacizumab and 6% received no further treatment. Median PFS with first post-study platinum-based and non platinum-based therapy were 7.1 months and 5.6 months respectively. In the P arm, 18 (23) patients received PARP inhibitors following the first subsequent chemotherapy. **Conclusions:** Patterns of disease progression and subsequent chemotherapy were similar in patients receiving O or P in the SOLO2 trial. Instead of switching to chemotherapy, continuing O at the time of RECIST progression was an option for 35% of the patients. Clinical trial information: NCT01874353. Research Sponsor: ASTRA ZENECA.

6071 Poster Session (Board #242), Fri, 8:00 AM-11:00 AM

Combined regimen of inhalable STING agonist plus chemoimmunotherapy in platinum-resistant or platinum-refratory ovarian cancer: A randomized, open-label, phase II trial. *First Author: Yan Zhang, Chinese PLA General Hospital, Beijing, China*

Background: Approximately 70% patients with advanced ovarian cancer have a relapse and ultimately succumb to their disease. Treatment options are limited in this context with an unacceptable low response (less than 20%). Immunotherapy with checkpoint inhibitors presented to date are not very convincing with 10-15% response because of inadequate immunity. We previously discovered the critical role of manganese in innate immune sensing of tumors by activating STING signaling. This ongoing, randomized, phase II study is to assess STING agonist plus nPP chemotherapy and anti-PD-1 antibody sintilimab in platinum-resistant/refractory ovarian cancer. **Methods:** Enrolled patients were 2:1 randomizedly assigned to receive nab-paclitaxel (180-220mg/m^2), cisplatin (60-80mg/m^2) and sintilimab 200mg per 3 weeks with (cohort 1) or without (cohort 2) inhalable $MnCl_2$ (0.4mg/kg) daily. Safety was assessed by CTCAE v5.0, and clinical response by MRI or CT every 2 cycles referred to RECIST version 1.1. The primary endpoints were objective response rate (ORR) and safety. Key secondary end points were disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). **Results:** 27 patients were enrolled, and 21 were included in efficacy population by the end of Jan. 2020. All enrolled patients were with heavily treated history, median 4 lines of prior therapy, median 19 cycles of multiagent regimens. The addition of $MnCl_2$ to the combined chemo-immunotherapy did not appear to exacerbate treatment-related adverse events (AEs). The most common AEs are hematological toxicity (87%), nausea (56%) and vomiting (47%) in both two cohorts. All 14 evaluable patients (14/19) from cohort 1 had an effective control (11 PR [78.6%], 3 SD [21.4%]) . Ten patients (71.4%) achieved PR at the first tumor scan assessment. For 8 cases from cohort 2, 7 were assessable and all showed SD, 4 of whom exhibited SD with enlarged lesions and disease progression after 4-cycle treatment. **Conclusions:** $MnCl_2$ administration induced encouraging objective clinical responses (78.6%) and disease control (100%) in relapsed/refractory ovarian cancer. The combined regimen showed accepted and manageable safety profile. Clinical trial information: NCT03989336. 6072 Poster Session (Board #243), Fri, 8:00 AM-11:00 AM

Methylated DNA markers for plasma detection of ovarian cancer: Discovery, validation, and clinical feasibility. *First Author: Jamie Nadine Bakkum-Gamez, Mayo Clinic, Rochester, MN*

Background: Effective screening tests for ovarian cancer (OC) are lacking; most cases present at advanced stage and portend poor prognosis. DNA methylation is an early event in carcinogenesis and can be detected in blood plasma samples from cancer patients. In DNA extracted from tissues, we first discovered, then validated discriminant methylated DNA marker (MDM) candidates for OC and subsequently tested independent plasma from women with and without OC. **Methods:** For discovery, DNA from 67 frozen tissues (18 high grade serous (HGS), 18 endometrioid, 15 clear cell (CC), 6 mucinous OCs; 10 benign fallopian tube epithelium (FT); and 19 buffy coats from cancer-free women underwent reduced representation bisulfite sequencing (RRBS) to identify MDMs associated with OC. Candidate MDM selection was based on receiver operating characteristic (ROC) discrimination, methylation fold change, and low background methylation among controls. Blinded biological validation was performed using methylated specific PCR on DNA extracted from independent FFPE tissues from OCs (36 HGS, 22 endometrioid, 21 CC, and 14 mucinous) and 29 FT. Top performing MDMs in tissue were tested using long-probe quantitative amplified signal assays in independent pre-treatment plasma samples from women newly-diagnosed with OC and population-sampled healthy women. A random forest modeling analysis was performed to generate predictive probability of disease; results were 500-fold in silico cross-validated. **Results:** After RRBS discovery and biological validation, 33 MDMs showed marked methylation fold changes (10 to > 1000) across all OC histologies vs FT. The top 11 MDMs (*GPRIN1, CDO1, SRC, SIM2, AGRN, FAIM2, CELF2, DSCR6, GYPC, CAPN2, BCAT1*) were tested on plasma from 91 women with OC (76 (84%) HGS) and 91 without OC; the cross-validated 11-MDM panel highly discriminated OC from controls (96% (95%CI 89-99%) specificity; 79% (69-87%) sensitivity, and AUC 0.91 (0.86 - 0.96)). Among HGS, the panel correctly identified 83%, including 5/6 stage I/II, and the majority of other subtypes (Table). **Conclusions:** Whole methylome sequencing, stringent filtering criteria, and biological validation yielded outstanding candidate MDMs for OC that performed with promisingly high sensitivity and specificity in plasma. Larger plasma-based OC MDM testing studies, with larger numbers of non-HGS histologies are warranted. Research Sponsor: Mayo Clinic Transform the Practice Grant, Other Foundation, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

Risk of venous thromboembolism in patients receiving neoadjuvant chemotherapy for ovarian cancer. *First Author: Derman Basaran, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: To identify the incidence of newly occurring venous thromboembolism (VTE) in patients with ovarian cancer receiving neoadjuvant chemotherapy (NACT). **Methods:** Using our prospectively maintained ovarian cancer database, we identified all ovarian cancer patients who received NACT at our institution from 4/15-9/18. VTE events included clinically diagnosed deep venous thrombosis (DVT) or pulmonary embolism (PE). Patients who presented with VTE prior to induction of NACT or patients on anticoagulation therapy prior to diagnosis were excluded. The incidence of newly occurring thrombotic events were categorized according to treatment phases, defined as 1) NACT prior to interval debulking surgery (IDS); 2) intraoperative and 30-day post-IDS; and 3) adjuvant chemotherapy. **Results:** 290 patients underwent NACT during the study period. Thirty-eight patients (13%) who presented with VTE, 12 (4%) on anticoagulation at presentation, and 4 (1.4%) seeking only a second opinion were excluded from analysis. Of the 236 evaluable patients, the overall rate of VTE during all treatment phases was 15% (35/236). In treatment phase I, 11% (27/236) of patients experienced VTE during NACT. In phase II, an additional 2.5% (6/236) developed VTE in the intraoperative and 30-day postoperative period. In phase III, an additional 0.8% (2/236) experienced a thrombotic event >30 days postoperatively. Sevety-seven percent (27/35) of VTE events occured during phase I. **Conclusions:** Patients receiving NACT for advanced ovarian cancer are at high risk for the development of clinically detectable thromboembolic events. The highest rate of new VTE events was seen during induction of NACT, a phase of treatment traditionally without any prophylactic anticoagulation. Further research regarding the timing of thromboprophylaxis for this patient population is warranted. Research Sponsor: None.

Computerized features of spatial arrangement of tumor-infiltrating lymphocytes from H&E images predicts survival and response to checkpoint inhibitors in gynecologic cancers. *First Author: Sepideh Azarianpour Esfahani, Case Western Reserve University, Cleveland Heights, OH*

Background: Immune checkpoint inhibitors (ICI) have demonstrated success in solid tumors. In gynecologic cancers (GC), the response rate is still low (~10-15%) except in MSI-H endometrial cancer (~ 50%). Current biomarkers (e.g. PDL1 expression) have limited utility in identifying benefit from ICI in GC. In this work we evaluated the ability of computational measurements of spatial arrangement of tumor infiltrating lymphocytes (TIL) from H&E slide images in predicting overall survival (OS) and response to ICI in ovarian, cervical and endometrial cancers. **Methods:** The study included 151 patients, including 102 ovarian carcinomas treated with surgery and chemotherapy (D1) and another set (D2) of n=49 patients (n=14 ovarian, n=27 endometrial and n=8 cervical), treated with different ICI agents (Pembrolizumab, Nivolumab, Ipilimumab, Avelumab) in the second line setting. Progressors and non-progressors in D2 were classified according to clinical improvement and radiologic assessment by RECIST. A machine learning approach was employed to identify tumor regions on the diagnostic slides from D1 and D2 and then used to automatically identify TILs within the tumor regions. Subsequently machine learning was used to define TIL clusters based on TIL proximity, and graph network theory was used to capture measurements relating to spatial arrangement of TIL clusters. The multivariable Cox regression model (MCRM) was trained on n=51 patients from D1 to predict OS and then independently evaluated in predicting (1) OS on the hold-out n=51 patients in D1 and (2) response and progression-free survival (PFS) in D2. **Results:** Statistical analysis identified 7 prognostic features relating to interaction of TIL clusters with cancer nuclei. MCRM was prognostic of OS on the n=51 hold out patients in D1 (hazard ratio (HR)=2.06, 95% confidence interval [1.04- 4.07], p=0.008) and predictive of PFS in D2 (HR=2.24, CI=[1.13-4.44], p=0.03). The AUC for MCRM in predicting progression in D2 was 82%. **Conclusions:** Computerized features of spatial arrangement of TILs on H&E images were prognostic of OS and PFS and predicted response to ICI in three gynecological cancers. These findings need to be validated in larger, multi-site validation sets. Research Sponsor: U.S. National Institutes of Health.

Infiltration of tumor by T cells following treatment with DPX-Survivac and intermittent low dose cyclophosphamide (CPA) leads to clinical responses in advanced recurrent ovarian cancer (OvCa). *First Author: Oliver Dorigo, Stanford Cancer Institute, Stanford, CA*

Background: DPX-Survivac is a novel T-cell activating therapy designed to elicit an effective immune response against survivin expressing tumors. Its unique mechanism of action (MOA) facilitates active and sustained uptake of target peptides by APC at the injection site. APCs subsequently present the antigen in local lymph nodes generating survivin-specific T cells that traffic to distant tumor sites and elicit effective tumor cell death. DPX-Survivac is used in combination with intermittent low dose CPA which acts as an immunomodulator of T-cell responses. **Methods:** The study enrolled 22 patients with recurrent, advanced platinum-sensitive and -resistant ovarian cancer. Patients received 2 subcutaneous injections of DPX-Survivac 3 weeks apart and every 8 weeks thereafter, and intermittent low dose CPA for up to 1 year. Paired tumor biopsies were performed prior to treatment and on treatment. Primary endpoints were ORR, DCR and safety. Secondary endpoints include cell mediated immunity, immune cell infiltration in paired biopsy samples, DOR, TTP, OS and biomarker analyses. **Results:** Twenty-two patients were enrolled in the study. Three patients were discontinued prematurely due to early progression leaving 19 patients for response evaluation. The population is heavily pre-treated with a median of 3 lines of prior treatment [range 1 to 8]; 77.3% of patients are platinum-resistant. At the time of data cut-off, 3/19 patients (15.8%) achieved PR and one additional patient met PR on target lesions but had a newly detected lesion; 10/19 patients (52.6%) showed tumor regression on target lesions at > 1 scan. The median time on study (N=19) is 131 days [63 to ˚295]. Six patients are still on trial. The clinical responses and benefits observed with treatment are associated with an increase in systemic survivin-specific T cells and tumor immune-infiltration. Moreover, RNAseq analysis on paired tumor tissue revealed an enrichment in cytolytic T-cell signature. The most common AEs were grade 1-2 injection site reactions; 4 treatment-related SAEs were reported. **Conclusions:** DPX-Survivac and intermittent low dose CPA shows promising clinical activity in heavily pre-treated patients with recurrent OvCa. The preliminary results, supported by strong translational data, link the observed clinical benefits with the unique MOA of DPX-Survivac. These clinical results suggest that DPX-Survivac/CPA is an active regimen in OvCa and warrant testing in an expanded cohort of patients. Clinical trial information: NCT02785250. Research Sponsor: IMV Inc.

6076 Poster Session (Board #247), Fri, 8:00 AM-11:00 AM

Influence of BRCA pathogenic variants in the benefit of secondary cytoreductive surgery. *First Author: Felipe Leonardo Estati, AC Camargo Cancer Center, São Paulo, Brazil*

Background: Germline BRCA pathogenic variants are present in 15% to 25% of ovarian carcinoma patients. These tumors are more sensitive to platinum and PARP inhibitor therapy and have a better prognosis. Two retrospective studies with limited number of patients have shown conflicting results regarding the benefit of secondary cytoreductive surgery (SCS) in patients with BRCA mutations. Our aim was to evaluate the impact of SCS in recurrent ovarian cancer according to BRCA status. **Methods:** All patients with ovarian carcinoma with recurrent disease and who were tested for BRCA pathogenic variants treated at a tertiary Cancer Center in Brazil were included. Patients characteristics were compared between patients treated with SCS and not treated with SCS. Cox regression analysis was used to evaluate the impact of SCS on progression free survival (PFS) and the influence of BRCA pathogenic variants on the effect of SCS. **Results:** One hundred and forty patients were included, 49.6% were treated with SCS and chemotherapy and 50.4% treated with chemotherapy only. Patients treated with SCS were younger, presented better performance status, lower CA 125 and longer platinum free interval. After adjusting for relevant covariables SCS was associated with longer PFS (HR 0.53, 95%CI 0.29-0.97, p = 0.039). Germline BRCA pathogenic variants were found in 37 patients (26.4%). No patient was treated with PARP inhibitors. Among non-carriers of pathogenic variants in BRCA, SCS lead to a longer PFS (HR 0.48, 95%CI 0.28-0.81, p = 0.006) but among carriers there was no benefit of SCS (HR 0.84, 95%CI 0.30-2.34, p = 0.735). Test for interaction was not statistically significant (p = 0.359). **Conclusions:** Our study is the second to demonstrate no benefit of SCS among patients with BRCA pathogenic variants and not treated with PARP inhibitor. The only other study to show a benefit of SCS in this group of patients included a limited number of patients and all of them were treated with PARP inhibitors. BRCA germline status might influence the efficacy of SCS, and should be evaluated as a potential biomarker to be assessed together with clinical factors to better select patients for SCS. 6077 Poster Session (Board #248), Fri, 8:00 AM-11:00 AM

PFS by blinded independent central review (BICR) in the VELIA trial of veliparib (V) plus carboplatin/paclitaxel (CP) and as monotherapy in newly diagnosed patients (pts) with high-grade serous ovarian cancer (HGSC). *First Author: Carol Aghajanian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The phase III VELIA trial (NCT02470585) demonstrated statistically significant improvement in PFS per investigator (INV) for V added to CP and continued as maintenance (CPV-V) vs. CP alone in pts with newly diagnosed HGSC in the *BRCA* mutated (*BRCA*m), homologous recombination deficient (HRD), and whole populations. Here we present pre-specified analyses of PFS per BICR. **Methods:** Pts with Stage III-IV HGSC received V or Placebo (PL) with CP (6 cycles) and as maintenance (30 additional cycles). Primary analysis of PFS by INV compared CPV-V to CP alone in the *BRCA*m, HRD, and whole populations. Exploratory analyses of PFS in *BRCA* wildtype (wt) and non-HRD HGSC were performed. Radiologic tumor assessments were also prospectively submitted to an independent central reviewer for blinded assessment per RECIST v 1.1. PFS per BICR and rates of concordance between INV and BICR for determination of disease progression were analyzed. Safety data from the primary analysis were previously reported. **Results:** 1140 total pts were enrolled (CPV-V 382; CP 375). In the whole population, 26% of HGSCs were *BRCA*m and 55% were HRD. Concordance rates between INV and BICR were 68-85% by arm for each population. Analyses of PFS per BICR and per INV were consistent (Table). PFS was prolonged in the CPV-V vs. CP arm in all primary and exploratory populations assessed. **Conclusions:** Analyses of PFS per BICR supported the primary analysis of PFS per INV in the *BRCA*m, HRD, and whole populations, as well as exploratory *BRCA*wt and non-HRD populations. Median PFS per BICR was longer compared to PFS per INV assessments in all populations and in both arms. These findings support the reliability of PFS by INV in ovarian cancer trials. Alternate strategies like audits may be appropriate to support PFS by INV with less time and expense than full BICR. Clinical trial information: NCT02470585. Research Sponsor: AbbVie.

Elucidating resistance mechanism to PARP inhibitors for the development of novel therapeutic approaches in high-grade serous ovarian cancer. *First Author: Hagen Kulbe, Charité Medizinische Universität Berlin, Berlin, Germany*

Background: PARP inhibitors (PARPi) have been established as a targeted therapeutic approach not only in patients with high-grade serous ovarian cancer (HGSOC) that have genetic loss of function of BRCA1/2-associated DNA repair. However, treatment efficacy varies and neither BRCA mutation, nor homolog recombination deficiency (HRD) status seem to be optimal predictors. Moreover, mechanisms of treatment resistance are poorly understood and novel approaches are urgently required. **Methods:** Here we created gene expression data of HGSOC patients (n = 52) before PARPi treatment to elucidate key signaling pathways of resistance to increase their efficacy in combinatorial therapeutic strategies. We performed a comprehensive bioinformatics analysis of the differentially expressed genes between the 25% extreme responders (n = 26; 13 each group), including gene set enrichment analysis (GSEA) and causal inference analysis with the CARNIVAL pipeline to elucidate the underlying molecular and regulatory mechanisms governing treatment efficacy and resistance. **Results:** In accordance with recent publications, we found higher levels of MYC activity in non-responders and deregulation of the Wnt/ß-catenin signaling pathway resulting in PARPi treatment resistance. The pathway enrichment analysis also revealed specific pathways especially PDGFR, FGFR, PI3K/mTOR and MAPK signaling pathway associated with resistant phenotype. Furthermore, we have identified key kinases, particularly JAK1/2 and SRC that might mediate resistance to PARP inhibition. In addition, differential gene expression analysis revealed folate receptor 1 (FOLR1) to be significantly higher expressed in non-responders (logFC = 2.66; $p < 0.0026$) with the potential as a serum-based biomarker not only for ovarian cancer, as it correlates closely with CA125, but also PARPi treatment efficacy. **Conclusions:** In conclusion, these findings define a network of pathways, that are crucial to mediate mechanism of PARPi resistance and identified key signaling kinases as therapeutic targets in ovarian cancer. Research Sponsor: Institutional research funds, Pharmaceutical/Biotech Company.

6079 Poster Session (Board #250), Fri, 8:00 AM-11:00 AM

Financial toxicity and patient-reported outcomes over time: A longitudinal study of women with recurrent ovarian cancer. *First Author: Larissa Meyer, The University of Texas - MD Anderson Cancer Center, Houston, TX*

Background: The chronic nature of treatment for ovarian cancer (OC) can place women at increased risk of financial toxicity (FT) from ongoing direct and indirect costs coupled with potential loss of income. We explored FT and its association with anxiety, depression, and quality of life over time in women with recurrent OC. **Methods:** Women with recurrent OC enrolled in a longitudinal study were given the following validated instruments at baseline and every 3 months: FACIT Comprehensive Score for Financial Toxicity (COST), GAD-7 (anxiety), CES-D (depression) and FACT-Ovary. Mixed models were performed on longitudinal data over 12 months of follow-up. Multivariable analysis of demographic data was performed. **Results:** 225 patients were divided into low FT (top 2 terciles, n = 152) and high FT (bottom tercile, n = 73,) by baseline COST scores. The median age was 59 (range 22.9-78.9). There were no significant differences between the groups in regards to marital status, number of people in household or education level. There were significant differences between the low and high financial toxicity groups in terms of median age (low FT = 61 yrs vs. high FT = 54 yrs, $p < 0.0001$); race (5.4% black in low FT vs. 15.1% in high FT, p = 0.04), number of children < 18 years in the home ((p = 0.02), employment status p(< 0.0001) and annual income p(< 0.0001). On multivariable analysis, only income and age remained significantly associated with FT. The mean baseline COST score in the low FT group was 34 vs. 16 in the high FT group. Interestingly, pts with low baseline FT had significant worsening of FT over the 12 month time period while those with high FT had slight improvement over time. Consistently, the high FT group had higher scores on screening measures for anxiety and depression, as well as lower overall quality of life which persisted over time. **Conclusions:** Financial toxicity is a measurable and clinically relevant patient reported outcome. The cohort of women with high FT demonstrated higher mean scores on screening measures for depression and anxiety as well as persistently lower quality of life. Targeted interventions to decrease financial toxicity may provide more global improvements in mental health and quality of life. Research Sponsor: AstraZeneca, U.S. National Institutes of Health.

Effect on response to neoadjuvant chemotherapy in high-grade serous ovarian cancer by inhibiting the GAS6/AXL pathway and inducing homologous recombination deficiency. *First Author: Mary M Mullen, Washington University in St. Louis School of Medicine, St. Louis, MO*

Background: Less than 10% of patients with high grade serous ovarian cancer (HGSC) have a complete pathologic response to neoadjuvant chemotherapy. We aimed to identify a biomarker predictive of response to neoadjuvant chemotherapy and to determine if GAS6/AXL inhibition with AVB500 (AVB) could increase platinum response. **Methods:** AVB was supplied by Aravive Biologics. HGSC tumor samples were obtained pre- and post-neoadjuvant chemotherapy. GAS6 expression was measured by tissue immunohistochemistry (IHC) and serum ELISA. Four HGSC cell lines were used for all experiments. Immunofluorescent (IF) assays targeting γH2AX for DNA damage, RAD51, BRCA1, and BRCA2 for homologous recombination (HR) and 53BP1 for non-homologous end joining (NHEJ) were performed. Flow cytometry was used to evaluate RPA binding. DNA fiber assays were performed. In vitro clonogenic assays were done on chemoresistant ovarian tumor cells treated with carboplatin (carbo) +/- AVB and olaparib +/- AVB. Synergy assays were analyzed using Combenefit software. Mouse models were used to evaluate the combination of carboplatin + AVB and olaparib + AVB on tumor burden. **Results:** Patients with high pretreatment tumor GAS6 IHC expression ($>$ 85%) or serum GAS6 concentrations ($>$ 25ng/mL) were more likely to have a poor response to neoadjuvant chemotherapy than those with low GAS6 (P = 0.002). Additionally, high GAS6 concentration was associated with decreased overall survival (24.4 months versus undefined, P = 0.009). Carbo + AVB resulted in decreased clonogenic colonies compared to carbo alone ($p < 0.05$). In vivo tumor mouse models treated with chemotherapy + AVB had significantly less tumor burden than those treated with chemotherapy alone (50mg vs 357mg, P = 0.003). We identified an induction in HR deficiency by a decrease in RAD51, BRCA1, and BRCA2 foci and RPA binding in cells treated with carbo + AVB compared to carbo ($P < 0.05$). There was increase in γH2AX and 53BP1 foci as well as replication fork slowing in tumor cells treated with carboplatin + AVB ($P < 0.01$). We also AVB and carboplatin were synergistic. Olaparib + AVB resulted in decreased clonogenic colonies ($P < 0.05$) and decreased tumor burden in mouse models (76mg vs 171mg, P = 0.03) compared to olaparib alone. **Conclusions:** GAS6 is a potential biomarker predictive of poor response to neoadjuvant chemotherapy in HGSC. Inhibition of this GAS6/AXL pathway with AVB improves sensitivity to traditional neoadjuvant chemotherapy by inducing a homologous recombination deficiency. 6081 Poster Session (Board #252), Fri, 8:00 AM-11:00 AM

Sacituzumab govitecan (SG) in patients (pts) with previously treated metastatic endometrial cancer (mEC): results from a phase I/II study. *First Author: Alessandro Santin, Yale University School of Medicine, New Haven, CT*

Background: Unselected pts with EC who progressed on prior chemotherapy have a poor prognosis with limited treatment options. SG is a novel antibody-drug conjugate that targets Trop-2, a cell surface glycoprotein highly expressed in many epithelial tumors. It is conjugated to deliver SN-38, the active metabolite of irinotecan, via a proprietary hydrolyzable linker. Preclinical studies show SG has activity against chemotherapy-resistant EC and significant bystander effect against EC with heterogenous Trop-2 expression (Perrone E. *Mol Oncol.* 2019). **Methods:** The phase I/II basket study (NCT01631552) evaluated pts unselected for Trop-2 with advanced solid tumors who received intravenous SG (days 1 and 8 of 21-day cycles), until progression or unacceptable toxicity. CT/MRI scans were obtained at 8-week intervals for response assessment by RECIST 1.1. We report results for mEC pts who progressed after $\geq$1 prior systemic therapy and were treated with SG 10 mg/kg. Endpoints include safety, objective response rate (ORR), clinical benefit rate (CBR), duration of response (DOR), progression-free survival (PFS), and overall survival (OS). **Results:** 18 mEC pts (all women; 17 white and 1 black; median age 69 years [range, 41–76]) had a median 3.5 (range 2–6) prior lines of therapy. All pts received prior treatment with platinum therapies. At a median follow-up of 12.7 months, the ORR (95% CI) was 22.2% (6.4–47.6), with 4 partial responses. CBR (95% CI) was 44.4% (21.5–69.2), with 8 of 18 pts having either an objective response or stable disease $\geq$6 months. The DOR of responders ranged from 9.1 to 26.6 months, with 2 of 4 responders having a duration of $\geq$18 months. Median PFS (95% CI) was 3.2 months (1.9–9.4), and median OS (95% CI) was 11.9 months (4.7–not calculable). Key grade $\geq$3 TRAEs in the overall basket study safety population (n=495) included neutropenia (28%), neutrophil count decrease (14%), anemia (10%), diarrhea (8%), fatigue (6%), and febrile neutropenia (5%). A similar safety profile was seen in the mEC cohort. **Conclusions:** Median OS in unselected pts with mEC who progressed on prior platinum therapy is ~10 months with an ORR of ~10%. SG monotherapy showed clinical activity in pts with relapsed/refractory mEC, consistent with previous preclinical findings, and support further clinical investigation (NCT04251416). The phase II TROPiCS-03 (NCT03964727) study in pts with metastatic solid tumors selected based on elevated Trop-2 expression by a validated IHC assay will also provide further insights. Clinical trial information: NCT01631552. Research Sponsor: Immunomedics, Inc.

Mutation in homologous recombination to predict a better prognosis in endometrial cancer. *First Author: Luyang Zhao, Department of Gynecology and Obstetrics,Peking University People's Hospital, Beijing, China*

Background: Endometrial cancers have been categorized into four genomic classes by The Cancer Genome Atlas Research Network (TCGA) with comprehensive genomic analysis. However, TCGA molecular subtypes are hard to utilize in clinic as the expensive cost and a simply version of POLE, TP53 genes cannot fully differentiate the four subtypes. Therefore, more convenient and reliable biomarkers need to be identified for clinical practice. **Methods:** Whole-exome sequencing and RNA sequencing data for 515 patients with endometrial carcinomas were downloaded from TCGA. Mutations in 48 genes of homologous recombination repair (HR) signaling were defined as HR mutation. Associations between HR mutation and survival and RNA expression were analyzed.Gene set enrichment analysis (GSEA) were used to invesgate the gene signaling. **Results:** HR mutation was associated with a prolonged disease specific survival (DSS) (HR, 0.39; 95% CI, 0.22-0.71; P = 0.002), progression-free survival (PFS) (HR, 0.46; 95% CI, 0.31-0.68; $P < 0.001$) and overall survival (OS) (HR, 0.45; 95% CI, 0.28-0.72; P = 0.001) in endometrial cancers. HR mutation was related with clinical characteristics including histological types ($P < 0.05$). In the multivariable cox proportional hazards regression model including FIGO 2008, histology types, tumor grade and TCGA subtypes, TP53 mutation, POLE mutation, the association between HR mutation and PFS was still significant (HR, 0.48; 95% CI, 0.27-0.86; $P < 0.05$), which indicating the HR mutation is an independent prognostic factor for PFS. HR mutations were associated with a higher tumor mutation burden. GSEA suggested that HR mutation was involved with the increase of genes related to activated T cells, immune cytolytic activity, and IFN-γ release. In MSS endometrial cancers, *HR* mutation still showed a longer PFS (HR, 0.57; 95% CI, 0.34-0.98; P = 0.04), suggested HR mutation may help predict the effect of immunotherapy in MSS endometrial carcinoma. **Conclusions:** HR mutation was related with a favorable prognosis through increasing T cells signature. Identification of HR mutation by genomic profiling provides a potentially novel and convenient approach for endometrial cancer patients to predict the prognosis independent of TCGA four subtype classifications and provides an inspiration for screening patients who may benefit from ICBs in endometrial cancer in the future. Lenvatinib (LEN) plus pembrolizumab (PEMBRO) for early-line treatment of advanced/recurrent endometrial cancer (EC). *First Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: As part of an ongoing phase Ib/II study (NCT02501096) in patients (pts) with selected solid tumors, LEN (20 mg PO QD) + PEMBRO (200 mg IV Q3W) displayed substantial and durable antitumor activity in advanced EC. In previously treated EC that was not microsatellite instability high (MSI-H) or mismatch repair deficient (dMMR; n=94 pts), the objective response rate (ORR) by independent imaging review (IIR) per RECIST 1.1 was 38.3% (95% CI 28.5–48.9). In this post hoc analysis, we assessed 2 subgroups of pts with previously treated, advanced, non MSI-H or dMMR EC who received LEN + PEMBRO in an early-treatment setting. **Methods:** Pts were examined in 2 subgroups: (1) Pts with only 1 prior line of cytotoxic therapy regardless of surgical stage or setting (adjuvant treatment for local-regional disease or treatment for metastatic disease); and (2) pts from subgroup 1 with local-regional disease at diagnosis who received only adjuvant cytotoxic therapy. There were no restrictions on prior hormonal or chemoradiation therapies in either subgroup. Tumor responses were assessed by IIR per RECIST 1.1. **Results:** Subgroup 1 included 63 pts and subgroup 2 had 21 pts. ORR (95% CI) was 41.3% (29.0–54.4) for subgroup 1 and 57.1% (34.0–78.2) for subgroup 2. Additional efficacy outcomes are summarized in the table. In subgroup 1, treatment-related adverse events (TRAEs) occurred in 62 (98%) pts (42 [67%] $\geq$ grade 3). TRAEs led to study-drug interruption of one or both drugs in 43 (68%) pts and dose reductions of LEN in 42 (67%) pts; 12 (19%) pts discontinued one or both drugs due to a TRAE. Serious TRAEs occurred in 18 (29%) pts and 2 (3%) pts died from a TRAE. The safety profile for subgroup 2 was generally similar to the profile for subgroup 1. **Conclusions:** The efficacy of LEN + PEMBRO for early-line treatment of advanced non MSI-H or dMMR EC appears promising. No new safety signals have emerged. A phase III study of LEN + PEMBRO vs paclitaxel + carboplatin for first-line treatment in advanced or recurrent EC is underway. Clinical trial information: NCT02501096. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

	Subgroup 1 (n=63)	Subgroup 2 (n=21)

Human epidermal growth factor 2 (HER2) in early stage uterine serous carcinoma: A multi-institutional cohort. *First Author: Britt Kristina Erickson, University of Minnesota, Minneapolis, MN*

Background: Uterine serous carcinoma (USC) is a rare and aggressive malignancy, accounting for 40% of all endometrial cancer deaths. Human Epidermal Growth Factor Receptor 2 (HER2) has emerged as an important prognostic and therapeutic target in USC. Given recent randomized trial results, HER2-directed therapy is now recommended in advanced-stage or recurrent, HER2-positive disease. The significance of tumoral HER2 expression in early-stage disease has not yet been established. **Methods:** In this IRB-approved, retrospective, multi-institutional cohort, women diagnosed with stage I USC from 2000-2018 were identified. Patient demographic, treatment, and survival data were collected. Immunohistochemistry (IHC) was performed for HER2 and scored 0-3+. Equivocal IHC results (2+) were further tested with in-situ hybridization (ISH) per the 2007 ASCO-CAP HER2 breast cancer guidelines. HER2 overexpression ("positive") was defined as 3+ IHC or ISH positive. Kaplan-Meier analyses and Cox-proportional hazards were used to compare survival between the cohorts. **Results:** In total, 173 patients with stage I USC were tested for HER2; 25% were HER2-positive, 77.4% had stage IA and 22.6% had stage IB disease. Adequate clinical follow up was available for 168 patients. There were no significant differences in age, race/ethnicity, body mass index, surgical management, sub-stage, tumor size, adjuvant therapy, or follow-up duration between the HER2-positive and negative cohorts. On univarite analysis, presence of lymph-vascular space invasion was correlated with HER2-positive tumors (p=0.003). After a median follow-up of 50 months, there were 41 (24.4%) recurrences. Significantly more recurrences were observed in the HER2-positive cohort (47.6% vs. 16.7%, $p<0.001$). HER2 overexpression was also associated with poorer progression-free (PFS) and overall survival (OS) ($p<0.001$ and p=0.012). After adjusting for prognostic factors including sub-stage and adjuvant treatment, those with HER2-positive tumors experienced inferior PFS (aHR 3.67, 95%CI 1.92-6.98; $p<0.001$) and OS (aHR 2.03, 95%CI 1.03-4.01; p=0.042) compared to HER2-negative tumors. **Conclusions:** Uterine serous carcinoma is a poor prognostic tumor, even in patients with early-stage disease. Given its significant association with worse survival outcomes, tumoral HER2 overexpression appears to be a prognostic biomarker in women with stage I disease. These data provide rationale for clinical trials with HER2-directed therapy in early-stage uterine serous carcinoma. Research Sponsor: U.S. National Institutes of Health.

6085 Poster Session (Board #256), Fri, 8:00 AM-11:00 AM

An open-label, multicenter, phase Ib/II study of rebastinib in combination with paclitaxel in a dose-expansion cohort to assess safety and preliminary efficacy in patients with advanced or metastatic endometrial cancer. *First Author: Filip Janku, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX*

Background: Rebastinib is a switch control inhibitor targeting tunica interna endothelial cell kinase (TIE2). TIE2 is primarily expressed in endothelial cells playing a role in angiogenesis. TIE2 is also expressed in a subset of macrophages with pro-metastatic and immunosuppressive properties and linked to chemoresistance. This study is a 2-part open-label, phase Ib/II, multicenter study of rebastinib orally administered, in combination with paclitaxel. In Part 1, we observed encouraging antitumor activity of rebastinib with 5 PRs in 24 patients (pts) at 50 mg BID and 3 PRs in 19 pts at 100 mg BID from a heavily pretreated heterogeneous patient population. Here we summarize preliminary results from the endometrial cancer (EC) cohort of Part 2. **Methods:** Part 2 of this study has four disease-specific cohorts (TNBC, inflammatory breast cancer, ovarian cancer and EC). Pts were evaluated for safety (CTCAE v5.0) and efficacy (RECIST v1.1). According to the Simon 2-stage design of this study, for each cohort, 15 additional pts will be enrolled if more than 4 PRs are observed. **Results:** As of Jan 21, 2020, 19 EC pts were enrolled with a median age of 66 years. All pts received at least one prior line of paclitaxel and 12 (63%) pts received >3 prior anti-cancer therapies. Sixteen pts were treated with rebastinib starting dose 100 mg BID (reduced to 50 mg BID due to a higher frequency of muscular weakness) and 3 pts with 50 mg BID, in combination with 80 mg/m^2 weekly paclitaxel with a median duration of treatment 85 days (6, 225). In 15 evaluable pts, there were 5 PRs (4 confirmed) and 6 $SD_{8\ weeks}$ for an ORR of 33% and clinical benefit rate of 73%. Treatment-emergent AEs (>20%) were mostly ≤ grade 2: constipation, fatigue (each n=9); alopecia, peripheral edema (each n=8); dysgeusia, peripheral sensory neuropathy, arthralgia (each n=6); diarrhea, hypomagnesaemia, vomiting, dry mouth (each n=5); anemia, decreased appetite, dyspnea, nausea, and muscular weakness (each n=4). Serious AEs possibly related or related to rebastinib included muscular weakness (n=2, at 100 mg BID), head discomfort (n=1) and increase troponin (n=1) which resolved after dose interruption. **Conclusions:** Preliminary activity of rebastinib in combination with paclitaxel was encouraging in heavily pretreated EC pts, all of whom received prior paclitaxel. The safety profile of rebastinib at 50 mg BID was generally well tolerated. The EC cohort is enrolling at 50 mg BID in stage 2 of the study. Clinical trial information: NCT03601897. Research Sponsor: Deciphera Pharmaceuticals, Inc.

6086 Poster Session (Board #257), Fri, 8:00 AM-11:00 AM

Clinical outcomes of MSI-high (MSI-H) versus stable (MSS) endometrial carcinoma (EC) after front-line platinum chemotherapy and subsequent matched therapy. *First Author: Natalie Ngoi, Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore*

Background: Precision oncology approaches in EC patients (pts) are evolving with emerging targeted therapy. We reviewed the effect of genomic findings on treatment choice and outcome in an Asian EC cohort. **Methods:** Recurrent or metastatic ECs were prospectively profiled with next-generation sequencing (NGS) and relevant immunohistochemistry. Clinical data were collected to assess outcomes. **Results:** Between 12/2014 to 12/2019, 51 Asian EC pts of endometrioid (26/51), serous (7/51), carcinosarcoma (4/51), clear cell (4/51) and mixed (10/51) histology were enrolled. 35/51(69%) of tumors were high grade. The median age at diagnosis was 56 (range 37-77), and the median lines of treatment received was 3 (range 1-8). 45/51(88%) of pts had successful NGS profiling, 31/45(69%) using FoundationOne CDx, and 14/45 (31%) on an in-house platform. Frequent mutations (>20%) occurred in *PTEN* (60%), *PIK3CA* (49%),*TP53* (46%), *ARID1A* (27%), *CTNNB1* (24%) and *KRAS* (22%). There were 12/51(24%) MSI-H, 25/51(49%) MSS, and 14/51(27%) MSI-unknown tumors. The 6 mth progression free survival (PFS) rate for MSS versus MSI-H pts treated with front-line carboplatin+paclitaxel (CP) was 83% versus 50% (RR 1.67, fisher's exact 2-sided p=0.09), with a shorter median PFS after 1st line CP for MSI-H versus MSS pts (median 5.2 mth vs. 8.3 mth, not sig). Upon progression, 29/51(57%) of pts were matched to therapy based on tumor profiles. Of these, 7/29(24%), 13/29(45%) and 9/29(31%) matched to anti-PD1/PD-L1, endocrine therapy and other targeted therapy, respectively. Among 7 MSI-H pts matched to anti-PD1/PD-L1 therapy, median PFS was 14.6 mth (95% CI 0.4-29), and objective response rate was 57%(4/7). In subsequent-line, matching to endocrine therapy (HR 4.3 95% CI 0.95-19.0, p=0.06) or other targeted therapy (HR 5.1, 95% CI 1.1-24.5, p=0.04) was associated with worse PFS compared to anti-PD1/PD-L1 therapy. Despite a short median PFS after front-line CP, median overall survival (OS) was not reached for MSI-H pts, compared to 38 mth (95% CI 30.7-46.0) for MSS and MSI-unknown pts. **Conclusions:** MSI-H EC pts appear to have shorter PFS to front-line CP chemotherapy compared with MSS pts, but may derive durable responses from immunotherapy in subsequent-line therapy. Early use of immunotherapy in advanced MSI-H EC pts should be considered. Further optimisation of therapy is urgently needed in advanced MSS EC. Research Sponsor: National Medical Research Council Singapore, NMRC/CSA-INV-0016/2017.

6087 Poster Session (Board #258), Fri, 8:00 AM-11:00 AM

Randomized phase II study of sapanisertib (SAP) + paclitaxel (PAC) versus PAC alone in patients (pts) with advanced, recurrent, or persistent endometrial cancer. *First Author: Giovanni Scambia, Fondazione Policlinico Universitario A. Gemelli IRCCS Roma, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: SAP (TAK-228, MLN0128) is a selective dual inhibitor of mammalian target of rapamycin complexes 1 and 2. In endometrial tumor xenograft models, SAP+PAC exhibited stronger antitumor efficacy than PAC alone. **Methods:** Female pts with histologic/cytologic diagnosis of endometrial cancer were randomized to receive SAP 4 mg by mouth (days [d] 2–4, 9–11, 16–18, 23–25) plus PAC 80 mg/m^2 intravenously (d 1, 8, 15), or PAC alone, in 28-day cycles until unacceptable toxicity or disease progression. Randomization was stratified by histologic subtype, lines of prior chemotherapy (1 vs. 2), and prior taxane therapy. The primary endpoint was progression-free survival (PFS); secondary endpoints included overall survival (OS), overall response rate (ORR), clinical benefit rate (CBR; ORR + stable disease), and safety. Additional treatment arms of SAP alone (weekly dosing) and SAP+TAK-117 were closed after futility analyses. **Results:** 180 pts were randomized to SAP+PAC (n=90) or PAC (n=90); 86 and 87 pts received SAP+PAC and PAC, respectively; 3 pts from each arm were ongoing on treatment at data cut (30 July 2019). Baseline characteristics were balanced between arms. After a median follow-up of 17.2 vs. 14.4 mos with SAP+PAC vs. PAC, median PFS was 5.6 mos vs. 3.7 mos (hazard ratio [HR] 0.82; 95% CI 0.58–1.15). In pts with endometrioid histology (n=116), median PFS was 5.7 mos with SAP+PAC vs 3.3 mos with PAC (HR 0.66; 95% CI 0.43–1.03). In pts with nonendometrioid histology (n=64), median PFS was 3.6 mos with SAP+PAC vs. 5.4 mos with PAC (HR 1.09; 95% CI 0.62–1.90). Median OS was 13.7 mos with SAP+PAC vs. 14.6 mos with PAC (HR 1.01; 95% CI 0.67–1.53). Confirmed ORR was 24% with SAP+PAC vs. 18% with PAC (endometrioid, 23% vs. 16%; nonendometrioid, 28% vs. 22%); CBR was 80% vs. 58% (endometrioid, 84% vs. 55%; nonendometrioid, 72% vs. 63%). Median number of cycles received was 5 (range 1–23) with SAP+PAC and 4 (range 1–37) with PAC. Rates of grade ≥3 treatment-emergent adverse events (TEAEs) were 90% with SAP+PAC vs. 54% with PAC; the most common included anemia (21% vs.12%), neutropenia (12% vs. 3%), fatigue (12% vs. 5%), hypophosphatemia (12% vs. 1%), and pulmonary embolism (11% vs. 3%). **Conclusions:** Median PFS was longer with SAP+PAC vs. PAC in pts with endometrial cancer but did not reach statistical significance. PFS was particularly longer in the endometrioid subtype but again was not significant, and further studies are warranted. Incidence of grade ≥3 TEAEs was higher with SAP+PAC vs. PAC, but SAP+PAC toxicity was manageable, with no new safety signals. Clinical trial information: NCT02725268. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

6088 Poster Session (Board #259), Fri, 8:00 AM-11:00 AM

Preoperative chemotherapy for advanced endometrial cancer-registry analysis of outcomes. *First Author: Samer Salamekh, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Hysterectomy followed by risk-adjusted adjuvant treatment is the standard of care for staging and treatment of locally advanced endometrial cancer. Up-front surgery is difficult in some locally advanced cases with extensive local invasion since negative margins may not be achievable. Preoperative systemic treatment may be used to shrink the tumor and facilitate resection, echoing the experience from ovarian cancer. There is limited data for this paradigm in endometrial cancer. **Methods:** The National Cancer Database (NCDB) was queried for cases with FIGO stage III/IV endometrial cancer (serous, clear cell, or endometrial histology) who underwent surgery and had known chemotherapy/radiation sequencing. Those who received pre-operative chemotherapy +/- post-operative chemotherapy (PreCT) were compared to those who received post-operative chemotherapy alone (PostCT). PreCT cases were considered to be initially borderline resectable or unresectable. Downstaging was determined by comparing clinical and pathologic T-stage. Univariable (UV) and multivariable (MV) analyses were performed, with statistically significant values reported. **Results:** 12,310 cases in PostCT and 1,059 cases in PreCT were included in the analysis. Pre-CT cases were more likely to have higher AJCC T-stage, clinically positive nodes, serous histology, higher grade, and positive surgical margins (28% compared to 16%). Overall survival (OS) was lower for PreCT compared to PostCT (HR = 2.18 UV; HR = 1.87 MV). 20% of patients who received PreCT were down-staged compared to 2% in PostCT group. Patients who were downstaged with PreCT were more likely to achieve negative margins (OR 0.36 UV) and had improved OS compared to those whose stage did not change (HR = 0.61 UV; HR = 0.37 MV). Positive margins portended worse OS for both PreCT (HR = 1.93 UV) and PostCT (HR = 2.63 UV). Negative margins in PreCT had improved OS compared to positive margins in PostCT (HR = 1.2 UV; 2.67 MV). Post-operative radiation benefited both PreCT (HR = 0.45 UV; HR = 0.34 MV) and PostCT groups (HR = 0.48 UV; HR 0.64 MV). **Conclusions:** Preoperative chemotherapy increased the number of patients who were downstaged and those who were downstaged were more likely to achieve a negative margin. Patients who achieved negative margins in PreCT had improved OS compared to those with positive margins in PostCT. Adjuvant radiation further improved OS in both cohorts. Pre-operative chemotherapy can be considered for patients with unresectable/borderline resectable locally advanced endometrial cancer. Research Sponsor: None.

6089 Poster Session (Board #260), Fri, 8:00 AM-11:00 AM

Uterine cancer histology and stage at presentation in black and white women: A cohort study of 488,000 patients. *First Author: Mary Kathryn Abel, UCSF School of Medicine and Department of Surgery, San Francisco, CA*

Background: Although mortality among black women diagnosed with uterine cancer is higher than in white women, the reason for this difference is not completely understood. We proposed to investigate the differences in the incidence and presentation of uterine cancer histology among black women compared to white women. **Methods:** Data were obtained from the United States Cancer Statistics (USCS) and the National Cancer Database (NCDB) between 2004 and 2016. Chi-squared tests were used for statistical analyses. **Results:** Of 488,811 patients with uterine cancer, 411,904 (84.3%) were white and 51,093 (10.5%) were black. Based on USCS data, the incidence of endometrioid carcinoma in white women was 19.63 (per 100,000 per year) compared to 12.53 in black women. However, the incidence of high-risk histologies was higher in black women, particularly for serous tumors (3.32 vs. 1.29), clear cell tumors (0.59 vs. 0.31), carcinosarcoma (2.88 vs. 1.05), and leiomyosarcoma (1.02 vs. 0.48). Using the NCDB database, we evaluated the proportion of these histologies based on race. Compared to white women, black women have a higher proportion of serous (14.2% vs. 5.6%), clear cell (2.4% vs. 1.3%), carcinosarcoma (12.3% vs. 4.5%), and leiomyosarcoma (4.3% vs. 1.7%). black women were less likely to have endometrioid (52.7% vs. 75.9%) and mucinous (0.4% vs. 0.8%) tumors. In addition, black women were more likely to have stage III or IV disease at presentation when all histological subtypes were combined (22.8% vs. 17.7%). However, of those with endometrioid and grade 1 tumors, black women did not have more advanced stage at presentation compared to white women (3.8% vs. 4.7%). **Conclusions:** Compared to white women, black women are more likely to be diagnosed with serous, clear cell, carcinosarcoma, and leiomyosarcomas at a more advanced stage upon presentation, but they are less likely to have endometrioid tumors. More research is needed to understand why this disparity exists. Research Sponsor: None.

6090 Poster Session (Board #261), Fri, 8:00 AM-11:00 AM

Evaluation of treatment patterns and prognosis in correlation with age in patients with vulvar cancer: A subset analysis of the AGO-CaRE-1 study. *First Author: Katharina Prieske, Department of Gynecology and Gynecologic Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Despite an increasing incidence with simultaneous decreasing age of onset, the impact of age on prognosis and treatment patterns in primary squamous cell vulvar cancer (VSCC) has not extensively been studied yet. **Methods:** This is a subgroup analysis of the AGO-CaRE-1 study. Patients (pts) with VSCC (FIGO stage ≥1B), treated at 29 cancer centers in Germany from 1998-2008, were included in a centralized database (n = 1618). In this subgroup analysis pts were analyzed according to age (< 50yrs (n = 220), 50–69yrs (n = 506), ≥70yrs (n = 521)) with regard to treatment patterns and prognosis. Only pts with documented age, surgical groin staging and known nodal status were included (n = 1247). Median follow-up was 27.5 months. **Results:** At first diagnosis, women ≥70yrs presented with more advanced tumor stages (< 0.001), larger tumor diameter (< 0.001), poorer ECOG status (< 0.001), higher tumor grading (0.048), as well as a higher rate of nodal involvement (< 0.001). Older women ≥70yrs showed more commonly HPV negative tumors compared to the other age groups (54% vs. 36.5% in < 50yrs vs. 47.9% in 50-69yrs, p = 0.03). Disease recurrence occurred significantly more often in elderly women (48% vs. 21% in < 50yrs vs. 37.4% in 50-69yrs, p = 0.001). Particularly isolated vulvar recurrence was more frequent in the elderly in comparison to the younger groups (18.2% vs. 15.2% in 50-69yrs vs. 12.7% in < 50yrs, p = 0.001). Age was an independent prognostic factor for disease-free survival (DFS) (HR: 1.7, 95%CI: 1.24-2.46, p = 0.001) with 2-year DFS being 81.1% (< 50yrs), 65.8% (50–69yrs), and 59.3% (≥70yrs), respectively. Elderly women (age group ≥70) had a 221% higher risk for death or recurrence, compared to the youngest group (HR: 3.21, p < 0.001). In a multivariate analysis ECOG, tumor stage, grading, and receipt of (chemo)radiation were further independent prognostic factors for recurrence. **Conclusions:** Older women with VSCC present with advanced tumor stages at first diagnosis and have an increased risk of recurrence as well as a decreased 2-year PFS in comparison to younger pts groups. Potential reasons for delayed time of diagnosis could be self-awareness and/or more aggressive tumor biology due to HPV negative disease. Research Sponsor: None.

6091 Poster Session (Board #262), Fri, 8:00 AM-11:00 AM

Combination immunotherapy with ipilimumab and nivolumab in patients with rare gynaecological malignancies. *First Author: Oliver Klein, Medical Oncology Unit, Austin Health, Heidelberg, Australia*

Background: Up to 50% of gynecological cancers are considered rare. The outcome of these patients (pts) is poor given a lack of scientific and clinical knowledge. Immunotherapy using single agent anti- PD-1/PD-L1 treatment (tx) has shown only modest activity in patients with common gynecological malignancies, such as high grade serous ovarian cancer (ca) and microsatellite stable endometrial ca. Combined CTLA-4/PD-1 blockade using ipilimumab (ipi) and nivolumab (nivo) has demonstrated superior efficacy compared to single agent anti-PD-1 therapy in pts with advanced melanoma and renal cell ca. To date, no trials have been undertaken with ipi/nivo in patients with rare gynecological malignancies. **Methods:** 41 pts with advanced rare gynecological malignancies were enrolled into the CA209-538 trial. Pts received nivo 3mg/kg and ipi 1mg/kg q 3 weekly for four doses, followed by nivo 3mg/kg q 2 weekly. Tx continued for up to 96 weeks, or until disease progression or the development of unacceptable toxicity. Response (RECIST 1.1) was assessed every 12 weeks. The primary endpoint was clinical benefit rate (CBR = CR + PR + SD). Exploratory endpoints include correlation of efficacy with biomarkers (incl PD-L1/TMB). **Results:** Pts with 10 rare tumor types were enrolled (Table). 39/41 pts have received prior therapy (1-7 lines). Objective responses were observed in 11 pts (27%) including pts with vaginal SCC, ovarian clear cell and low grade serous ca, ovarian and uterine carcinosarcoma, uterine clear cell, uterine serous ca and leiomyosarcoma. A further 9 pts had SD as their best radiological response resulting in a CBR of 49%. The median duration of response had not been reached (range 3.5 – 25+ months) with seven responses being ongoing. 63% of pts experienced an immune related adverse event (irAEs) with 4 pts developing Grade 3/4 irAEs. **Conclusions:** Ipi/Nivo tx demonstrates efficacy in a range of different rare gynecological cancers with a significant number of durable responses being observed. Tumor agnostic biomarkers are required to assist with better patient selection. Clinical trial information: NCT02923934. Research Sponsor: Australian Federal Department of Health.

6092 Poster Session (Board #263), Fri, 8:00 AM-11:00 AM

Efficacy and safety of laterally extended endopelvic resection for the pelvic side wall gynecologic tumors: A four-year prospective cohort study with historical comparison. *First Author: Haerin Paik, Seoul National University Hospital, Seoul, South Korea*

Background: Although laterally extended endopelvic resection (LEER) has been introduced to control the pelvic sidewall tumors, there is a lack of evidence about its efficacy and safety despite high skillful procedure, compared with the other treatments. Thus, we performed a prospective cohort study with historical comparison for four years. **Methods:** One gynecologic oncologist performed LEER consecutively for patients with the pelvic sidewall tumors between March 2014 and July 2018. We compared clinicopathologic characteristics and survival between patients who received primary LEER and with those treated with other treatments. **Results:** We enrolled 37 patients treated with LEER. Among them, 22 (59.5%) and 15 (40.5%) had recurrent and primary disease. Among perioperative outcomes, there was more estimated blood loss, and hospitalization was longer in recurrent disease and previous surgery ($p < 0.05$). In recurrent disease, previous progression-free survival < 8 months was related to poor recurrence-free survival after LEER (median, 5.4 vs. 10.2 months; $p < 0.05$). When LEER was applied for the first recurrence of cervical cancer, recurrence-free survival and overall survival after treatment seemed to be longer in LEER (n = 9) than in palliative chemotherapy (n = 27) without statistical significance (median, 12.2 vs. 4.7 months and 23.2 vs. 12.4 months; $p = 0.13$ and $p = 0.63$). In 15 patients with primary locally advanced cervical cancer, LEER after partial response to neoadjuvant chemotherapy showed longer progression-free survival than LEER after stable or progressive disease to neoadjuvant chemotherapy and primary radiotherapy ($p = 0.012$). After LEER, grade 3 and 4 complications developed in 15 (23.1%) and 2 (3.1%) patients. **Conclusions:** Compared with palliative chemotherapy, LEER followed by palliative chemotherapy may improve progression-free survival in patients with recurrent cervical cancer located in the pelvic sidewall. If possible, it is more effective to apply LEER without preceding palliative chemotherapy for recurrent cervical cancer located in the pelvic sidewall. Research Sponsor: None.

6093 Poster Session (Board #264), Fri, 8:00 AM-11:00 AM

Genomic and transcriptomic profiles of gynecologic neuroendocrine carcinoma are distinct from pulmonary neuroendocrine small cell carcinoma. *First Author: Haider Mahdi, Cleveland Clinic, Cleveland, OH*

Background: High-grade neuroendocrine carcinoma (NEC) of the cervix and other gynecologic origins are rare and aggressive cancers that unfortunately affect young women with high mortality. Treatment recommendations are often extrapolated from their counterpart, small cell carcinoma of the lung (SCLC). In the present study, we have performed comprehensive genomic and transcriptomic analyses in a cohort of patients with NEC of the cervix and other gynecologic origins and compared them to SCLC. **Methods:** We have identified 27 patients diagnosed with NEC of gynecologic origin from 1998-2019. Of them, we were able to obtain archival tissue from 14 patients (17 samples), including seven cervical NEC, three ovarian NEC, and two endometrial NEC. Two ovarian and one cervical patient have recurrent tumors. Whole exome sequencing (WES) and RNA-seq were successfully performed in 14 and 13 samples, respectively. BWA-MEM was used for mapping (hg38), and GATK Haplotype Caller was used for WES analysis. Ensemble-VEP was used for variant annotation, and SIFT and PolyPhen-2 were used for pathogenic prediction of missense mutations. Stranded pair-end RNA-seq data were analyzed using STAR and DESeq2. SCLC data from cBioPortal and EBI (accession number EGAS00001000334) were used to compare mutation and transcriptomic profiles. **Results:** We found that TP53 is not mutated in our cohort, and RB1 is mutated only in 1 (7%) tumor. TP53 and RB1 are the most frequently mutated genes in small cell lung carcinoma. However, LRP1B, the third most mutated gene in SCLC was also mutated in 4 (29%) tumors. We observed that WNT, RTK-RAS, NOTCH, and MYC are among the top mutated pathways in our cohort. Among the top 20 mutated genes, only four genes, MUC4, KMT2C, MAP3K1, and HLA-A, were common in cervical, ovarian, and endometrial tumors suggesting a high diversity within the NEC of gynecologic origin. Our RNA-seq analysis revealed a distinct transcriptional signature when compared to SCLC, especially the expression pattern of SCLC molecular subtypes defining ASCL1, NEUROD1, POU3F2, and YAP1 genes. Surprisingly, we observed a high expression of the YAP1 gene in all of the 13 tumors. However, the YAP1+ subtype represents a minority in SCLC and known to predict chemotherapy resistance and lower survival. **Conclusions:** Our results suggest a unique mutational profile and transcriptional signature that are distinct compared to SCLC tumors. Therefore, there is an urgent need to re-evaluate the therapeutic options and targets for NEC of gynecologic origin. Research Sponsor: None.

TPS6094 Poster Session (Board #265), Fri, 8:00 AM-11:00 AM

A randomized phase III trial of adjuvant chemotherapy versus concurrent chemoradiotherapy (CCRT) for postoperative cervical cancer: Japanese Gynecologic Oncology Group study (JGOG1082). *First Author: Akiko Furusawa, Department of Gynecology, Tokyo Metropolitan Cancer and Infectious Disease Center Komagome Hospital, Tokyo, Japan*

Background: Cervical cancer is one of the common gynecologic cancer and the incidence of invasive cervical cancer has increased over the past few decades, particularly in younger women. The standard treatment for stage IB to IIB cervical cancer is a radical hysterectomy. In Japan, more than 80% of institutions, radical hysterectomy is chosen as the primary treatment for patients with stage IB1 and IIA1 cervical cancer. Patients with high-risk factors would be recommend adjuvant concurrent chemoradiotherapy (CCRT). However, adjuvant CCRT might not reduce distant metastasis and might cause of severe gastrointestinal and urinal toxicity. To avoid those adverse events of adjuvant CCRT, many Japanese gynecologic oncologists perform chemotherapy as adjuvant therapy. In the first multi-institutional phase II trial conducted in stage IB-IIA cervical cancer with pelvic lymph node metastasis (JGOG1067), we found a 5-years disease free-survival rate of 86.5%, suggesting the adjuvant chemotherapy had promising efficacy and would be feasible for a long time. No prospective study reported that adjuvant chemotherapy would improve overall survival in patients with the high-risk cervical cancer. **Methods:** High risk stage IB-IIB cervical cancer patients who underwent radical hysterectomy are eligible for the study. Patients with high risk are defined as those with pelvic lymph-node metastasis and/or parametrial invasion. Patents with SCC, adenocarcinoma, adenosquamous cell carcinoma are eligible for the study. After providing informed consent, patients are randomized on a 1:1 basis to receive CCRT or chemotherapy. Randomization is stratified by the faculty, FIGO stage, and pathological subtype (SCC or non-SCC). Treatment have to be started within 6 weeks after surgery. CCRT group is given whole pelvis irradiation 50.4Gy and cisplatin ($40mg/m^2$/week). Chemotherapy group is given paclitaxel ($175mg/m^2$) plus cisplatin ($50mg/m^2$) or paclitaxel ($175mg/m^2$) plus carboplatin(AUC of 6). The primary endpoint is overall survival (OS). Secondary endpoints are disease free survival (DFS), adverse events and QOL. This study began in November 2019 and a total of 290 patients will be accrued within 5 years. The study is coordinated by of the JGOG cervical cancer committee. Clinical trial information: 041190042. Research Sponsor: None.

TPS6095 Poster Session (Board #266), Fri, 8:00 AM-11:00 AM

Phase Ib/II trial of tisotumab vedotin (TV) ± bevacizumab (BEV), pembrolizumab (PEM), or carboplatin (CBP) in recurrent or metastatic cervical cancer (innovaTV 205/ENGOT-cx8/GOG-3024). *First Author: Ignace Vergote, Belgium and Luxembourg Gynaecological Oncology Group, University of Leuven, Leuven Cancer Institute, Leuven, Belgium*

Background: Patients (pts) with recurrent/metastatic cervical cancer (r/mCC) receive paclitaxel/platinum or paclitaxel/topotecan ± BEV as first-line standard-of-care therapy. Tissue factor (TF) expression has been associated with poor prognosis in solid tumors, and TF is highly expressed in r/mCC. TV is an investigational antibody-drug conjugate composed of a fully human, TF-directed monoclonal antibody covalently attached to the microtubule-disrupting agent monomethyl auristatin E (MMAE) via a protease-cleavable linker. Upon internalization, MMAE is released resulting in cell cycle arrest and apoptotic cell death. In pts with previously treated r/mCC, TV monotherapy (IV 2.0 mg/kg Q3W) demonstrated a manageable safety profile and encouraging antitumor activity (investigator-assessed confirmed ORR, 24%; median DOR, 4.2 mo) [Hong DS et al. *Clin Cancer Res.* 2019. doi: 10.1158/1078-0432.CCR-19-2962]. The preliminary safety and efficacy data for TV monotherapy suggest a positive benefit/risk profile and warrant further investigation of TV in combination with therapies commonly administered to pts with r/mCC. The global, open-label, phase Ib/II trial innovaTV 205/ENGOT-cx8/GOG-3024 (NCT03786081) evaluates the safety and antitumor activity of TV monotherapy and TV in combination with BEV, PEM, or CBP in pts with untreated or previously treated r/mCC. This abstract presents the new TV monotherapy weekly dosing schedule. Results from this study will inform the further clinical development of TV in the treatment of r/mCC. **Methods:** Approximately 170 adult pts with recurrent or stage IVB squamous, adenosquamous, or adenocarcinoma of the cervix; measurable disease; and ECOG PS 0-1 will be enrolled. The phase I part of the study will consist of 3 dose-escalation arms for identification of the recommended phase II dose (RP2D) of TV administered Q3W with BEV, PEM, or CBP. In this part, previously treated pts will receive escalating doses of TV (IV Q3W) in combination with escalating doses of BEV (IV Q3W), a fixed dose of PEM (IV Q3W), or a fixed dose of CBP (IV Q3W). The phase II part will include 4 expansion arms. In this phase, pts who have not received prior systemic therapy for r/mCC will receive 1) TV RP2D + PEM or 2) TV RP2D + CBP; pts who received 1-2 prior treatments for r/mCC will receive 3) TV RP2D + PEM or 4) TV monotherapy with weekly dosing (IV 3Q4W). The primary endpoint of phase II is ORR by RECIST v1.1. Secondary endpoints include DOR, time to response, PFS, OS, and safety. Clinical trial information: NCT03786081. Research Sponsor: Genmab A/S.

TPS6096 **Poster Session (Board #267), Fri, 8:00 AM-11:00 AM**

ENGOT-cx11/KEYNOTE-A18: A phase III, randomized, double-blind study of pembrolizumab with chemoradiotherapy in patients with high-risk locally advanced cervical cancer. *First Author: Domenica Lorusso, Fondazione IRCCS, Foundation Policlinico Universitario Agostino Gemelli IRCCS, Istituto Nazionale dei Tumori, Milan, Italy*

Background: High-risk locally advanced cervical cancer has a poor prognosis, and more than half of patients recur in 2 y. External beam radiotherapy (EBRT) with concurrent chemotherapy followed by brachytherapy is the standard of care for locally advanced cervical cancer. The immunostimulatory activity of the PD-1 inhibitor pembrolizumab (pembro) may be enhanced by concurrent chemoradiotherapy (CRT). After the KEYNOTE-158 study, in which pembro showed durable antitumor activity, pembro monotherapy was approved for patients with PD-L1–positive recurrent or metastatic cervical cancer who progressed during or after chemotherapy. ENGOT-cx11/KEYNOTE-A18 (NCT04221945) is a phase III, randomized, placebo-controlled study evaluating pembro with concurrent CRT for the treatment of locally advanced cervical cancer. **Methods:** Approximately 980 patients with high-risk (FIGO 2014 stage IB2-IIB with node-positive disease or stage III-IVA), locally advanced, histologically confirmed cervical cancer who have not received systemic therapy, immunotherapy, definitive surgery, or radiation will be randomized 1:1 to receive either 5 cycles of pembro 200 mg every 3 wk (Q3W) + CRT followed by 15 cycles of pembro 400 mg Q6W or 5 cycles of placebo Q3W + CRT followed by 15 cycles of placebo Q6W. The CRT regimen includes 5 cycles (with optional 6th dose) of cisplatin 40 mg/m^2 Q1W + EBRT followed by brachytherapy. Randomization is stratified by planned EBRT type (intensity-modulated radiotherapy [IMRT] or volumetric-modulated arc therapy [VMAT] vs non-IMRT or non-VMAT), cancer stage at screening (stage IB2-IIB vs III-IVA), and planned total radiotherapy dose. Treatment will continue until the patient has received 20 cycles of pembro (5 cycles 200 mg Q3W, 15 cycles 400 mg Q6W) vs placebo (~2 y) or until disease progression, unacceptable toxicity, or withdrawal. Primary endpoints are PFS per RECIST v1.1 by blinded independent central review and OS. Secondary endpoints are PFS at 2 y, OS at 3 y, complete response at 12 wk, ORR, PFS and OS in PD-L1–positive patients, EORTC QLQ-C30 and QLQ-CX24, and safety. Enrollment is ongoing. Clinical trial information: NCT04221945. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS6097 **Poster Session (Board #268), Fri, 8:00 AM-11:00 AM**

Clinical trial in progress: Pivotal study of VB-111 combined with paclitaxel versus paclitaxel for treatment of platinum-resistant ovarian cancer (OVAL, VB-111-701/GOG-3018). *First Author: Rebecca Christian Arend, University of Alabama at Birmingham, Birmingham, AL*

Background: Ofranergene obadenovec (VB-111) is a targeted anti-cancer gene therapy with a dual mechanism: a broad antiangiogenic effect and induction of a tumor directed viral immune response. In a phase II trial in platinum resistant ovarian cancer VB-111 in combination with weekly paclitaxel showed a CA-125 response rate (RR) of 58% and median overall survival (OS) of 498 days compared to 172.5 days in the sub-therapeutic dose ($p = 0.028$). The combination treatment was well tolerated. Favorable outcomes were associated with induction of an immunotherapeutic effect of tumor infiltration with CD-8 T cells. Based on these observations, a phase III randomized controlled trial, VB-111-701/GOG-3018 (OVAL) was initiated in collaboration with the GOG Foundation, Inc. **Methods:** The OVAL study, NCT03398655, is an international, randomized, double-blind, placebo-controlled, phase III study. Patients with recurrent platinum-resistant epithelial ovarian cancer, who have measurable disease (RECIST 1.1) and were previously treated with up to 5 lines are randomized 1:1 to receive VB-111 ($1x10^{13}$ VPs) with weekly paclitaxel (80mg/m^2), or weekly paclitaxel with placebo. Randomization is stratified by number of prior treatment lines, prior antiangiogenic therapy and platinum refractory disease status. Treatment beyond asymptomatic RECIST progression may continue until progression is confirmed by follow up imaging. The primary endpoints are OS, safety and tolerability. Secondary endpoints include progression free survival, and objective RR by CA-125 (per GCIG criteria) and RECIST 1.1. The sample size calculation of 400 patients (event driven) provides 92% power to detect a difference in survival at the two-sided 5% significance level using the logrank test. A pre-planned interim analysis will take place in Q1 2020 to assess whether the CA-125 RR per GCIG criteria in the treatment arm is sufficiently larger than in the control arm and is comparable to the positive results of the phase II study. Study enrolment is ongoing and over 80 patients were enrolled in the US and Israel. Enrollment expansion to Europe is planned in 2020. Clinical trial information: NCT03398655. Research Sponsor: VBL Therapeutics.

TPS6098 **Poster Session (Board #269), Fri, 8:00 AM-11:00 AM**

Basket study of the oral progesterone antagonist onapristone ER in women with progesterone receptor positive (PR+) recurrent granulosa cell tumor (GCT), low-grade serous ovarian cancer (LGSOC), or endometrioid endometrial cancer (EEC). *First Author: Rachel N. Grisham, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Onapristone extended release (ER) is a type I full progesterone antagonist that inhibits progesterone mediated PR activation and stabilizes PR association with corepressors. Onapristone has shown activity across multiple preclinical models of hormonally driven cancer. A phase I dose escalation study of onapristone ER in PR+ breast, endometrial and ovarian cancer patients found all doses tested to be well tolerated, with 50mg PO BID determined to be the recommended phase 2 dose (RP2D). GCT (98% of cases PR+), LGSOC (58% of cases PR+) and EEC (67% of cases PR+) are hormonally driven cancers which generally have poor responses to chemotherapy and limited treatment options in the recurrent setting. **Methods:** This is an open-label, investigator-initiated basket study of onapristone ER in patients with PR+ recurrent GCT, LGSOC, or EEC currently enrolling patients at Memorial Sloan Kettering Cancer Center in NY, USA (NCT03909152). The primary objective is to evaluate the efficacy, in terms of response rate by RECIST 1.1 criteria, within 36 weeks of treatment. Eligible patients must have received at least 1 prior line of chemotherapy, have measurable disease by RECIST 1.1 criteria, and have tumor tissue collected within 3 years prior to enrollment with PR expression $\geq$ 1% by IHC. Patients are allowed to have unlimited additional prior lines of chemotherapy, biologic therapy, immunotherapy or hormonal therapy. Enrolled patients are treated with onapristone ER 50mg PO BID until time of progression or intolerable toxicity. The 3 disease cohorts are currently enrolling to Stage I in parallel with expansion from stage I to stage II planned when the prespecified response criteria are met for each cohort as described in the table below. Clinical trial information: NCT03909152. Research Sponsor: Context.

Histology	Stage I	Stage II (expansion)	Response rate to be deemed worthy of further study
PR+ Granulosa Cell Tumor	Enroll 14 patients, if $\geq$ 1 response(s) expand to stage II	Expand to a total of 23 patients	$\geq$ 3/23
PR+ Low Grade Serous Ovarian Cancer	Enroll 16 patients, if $\geq$ 2 responses expand to stage II	Expand to a total of 25 patients	$\geq$ 5/25
PR+ Endometrioid Endometrial Cancer	Enroll 19 patients, if $\geq$ 4 responses expand to Stage II	Expand to a total of 36 patients	$\geq$ 11/36

TPS6099 **Poster Session (Board #270), Fri, 8:00 AM-11:00 AM**

A phase Ib/II, multicenter, open-label study of DSP-7888 dosing emulsion in combination with immune checkpoint inhibitors (CPI) nivolumab or pembrolizumab in adult patients (pts) with advanced solid tumors, including platinum-resistant ovarian cancer (PROC). *First Author: Makoto Origuchi, Boston Biomedical, Inc., Cambridge, MA*

Background: DSP-7888 is a therapeutic cancer vaccine composed of two synthetic peptides derived from Wilms' tumor 1 (WT1) to promote both cytotoxic and helper T-lymphocyte-mediated immune responses against *WT1*-expressing tumors. *WT1* is overexpressed in various solid tumors, including ovarian cancer. Combining cancer vaccines like DSP-7888 with a CPI may reduce resistance to immunomodulators and improve clinical benefit. A phase Ib/II study is being conducted to evaluate DSP-7888 in combination with a CPI in pts with advanced solid tumors, including PROC (NCT03311334). **Methods:** This phase Ib/II, open-label, multicenter, two-part dose-search/dose-expansion study investigates DSP-7888 + nivolumab or pembrolizumab in pts with advanced solid tumors (phase Ib), including PROC (phase II). The phase Ib primary objectives are safety, tolerability, and identification of the recommended phase II dose (RP2D). The phase II primary objective is evaluation of objective response rate (ORR); secondary objectives are clinical activity, safety, and tolerability. Pts aged $\geq$18 years with unresectable, metastatic cancer approved for treatment with nivolumab (phase Ib, Arm 1, n=6–12, 7 enrolled) or pembrolizumab (phase Ib, Arm 2, n=6–12, 6 enrolled), or with PROC (phase II) are eligible. Phase II will enroll ~40 pts into two groups based on programmed death-ligand 1 status (combined positive score of $\geq$10 [Group 1] or $<$10 [Group 2]). Clinical activity will be assessed continuously using Bayesian analysis and actual enrollment may increase by ~20 pts/group based on this analysis. Pts in phase II will receive DSP-7888 intradermally (RP2D from phase Ib) once a week (wk) for 6 wks in the induction phase then every 3 wks in the maintenance phase. Beginning Day 1, pembrolizumab will be administered intravenously every 3 wks. In phase II, objective disease will be assessed every 6 wks for 24 wks, then every 12 wks until progression. Endpoints include ORR (per RECIST v1.1) (primary), duration of response, disease control rate (DCR), progression-free survival (PFS), 6-month PFS rate (per RECIST v1.1), and overall survival, immune (i)ORR, iDCR, and iPFS (per iRECIST) (secondary). Exploratory endpoints include blood and tumor tissue biomarkers. Safety and tolerability, assessed by adverse events, will be evaluated throughout the duration of the study and follow-up. This study is currently recruiting patients. Clinical trial information: NCT03311334. Research Sponsor: Boston Biomedical, Inc.

TPS6100 Poster Session (Board #271), Fri, 8:00 AM-11:00 AM

Primary cytoreductive surgery with or without Hyperthermic Intraperitoneal Chemotherapy (HIPEC) for FIGO stage III epithelial ovarian cancer: The OVHIPEC-2 trial in progress. *First Author: Ruby M. van Stein, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The addition of Hyperthermic Intraperitoneal Chemotherapy (HIPEC) to interval cytoreductive surgery improves recurrence-free and overall survival in patients with FIGO stage III ovarian cancer who are ineligible for primary cytoreductive surgery due to extensive intraperitoneal disease. The effect of HIPEC remains undetermined in patients who are eligible for primary cytoreductive surgery. We hypothesize that the addition of HIPEC to a complete or near-complete (residual disease $\leq$2.5 mm) primary cytoreductive surgery improves overall survival in patients with FIGO stage III ovarian cancer. **Methods:** This international, randomized, open-label, phase III trial enrolls patients with newly diagnosed, histological proven FIGO stage III epithelial ovarian, fallopian tube, or primary peritoneal cancer. Patients with resectable umbilical, spleen or local bowel lesions may be included. Following complete or near-complete primary cytoreduction, patients are intra-operatively randomized (1:1) to receive HIPEC or no HIPEC. Patients in both study arms will receive six courses of adjuvant carboplatin-paclitaxel and maintenance PARP-inhibitor or bevacizumab according to current guidelines. The primary endpoint is overall survival. To detect a Hazard Ratio of 0.67 in favor of HIPEC, 200 overall survival events are required. Assuming that accrual will be completed in 60 months, and 12 months additional follow-up, 538 patients need to be randomized. All randomized patients will be included in the analysis for overall survival according to the intention to treat principle. Pre-specified subgroup analyses will be performed based on stratification factors (peritoneal cancer index at start of surgery, completeness of surgery), histologic subtype (high-grade serous versus other), and BRCA mutation (BRCA1/2 mutation versus wildtype). Secondary endpoints are recurrence-free survival, time to first subsequent anticancer treatment, and treatment related complications and toxicity. Exploratory endpoints are time to second subsequent anticancer treatment, health-related quality of life, and cost-effectiveness. The Institutional Review Board of the Netherlands Cancer Institute approved the trial, which is actively enrolling patients since January 2020. Clinical trial information: NCT03772028. Research Sponsor: Dutch Cancer Society (DCS), Other Foundation, Other Government Agency, French PHRC (programme hospitalier de recherche Clinique) program for participation of French centers.

TPS6101 Poster Session (Board #272), Fri, 8:00 AM-11:00 AM

ENGOT-OV44/FIRST study: a randomized, double-blind, adaptive, phase III study of standard of care (SOC) platinum-based therapy $\pm$ dostarlimab followed by niraparib $\pm$ dostarlimab maintenance as first-line (1L) treatment of stage 3 or 4 ovarian cancer (OC). *First Author: Anne-Claire Hardy-Bessard, Medical Oncology Department, CARIO-HPCA and Cooperative Gynecological Cancer Research Group (GINECO), Plerin, France*

Background: Despite surgery and CT (paclitaxel + carboplatin $\pm$ bevacizumab [bev]), 5-year survival rates remain low for patients (pts) with FIGO stage 3 or 4 OC. Niraparib is a poly (ADP-ribose) polymerase (PARP) inhibitor that has recently demonstrated efficacy in 1L therapy. Dostarlimab (TSR-042) is an anti-programmed death (PD)-1 humanized monoclonal antibody that has shown clinical activity as monotherapy in early phase trials. The currently enrolling ENGOT-OV44/FIRST study will compare efficacy and safety of CT + dostarlimab + niraparib $\pm$ bev (Arm 3) vs CT + niraparib $\pm$ bev (Arm 2). **Methods:** Eligible pts are $\geq$18 years of age, with FIGO stage 3 or 4 non-mucinous epithelial OC, ECOG performance status $<$ 2, and tumor tissue available for PD-1 ligand (PD-L1) testing. After cycle 1 of CT, pts are stratified by concurrent bev use, *BRCA* mutation/homologous recombination repair status, and disease burden, then randomized 1:2 into trial Arms 2 and 3 (Table). Dostarlimab is administered at 500 mg IV Q3W during the CT period, then 1000 mg IV Q6W during the maintenance period. Niraparib dosing is 200 mg PO QD for pts with baseline bodyweight (BW) $<$ 77 kg and/or platelet count (PC) $<$ 150,000/μL, or 300 mg QD for pts with baseline BW $\geq$77 kg and PC $\geq$150,000/μL. The dual primary endpoints are PFS, based on investigator assessment per RECIST v1.1, in both PD-L1+ and all patients. Initially the study enrolled pts to Arm 1. This arm was discontinued following positive results from the PRIMA/ENGOT-OV26/GOG-3012 and PAOLA-1/ENGOT-OV25 studies. This allows investigators to offer the current standard of care to all patients. Clinical trial information: NCT03602859, EUDRACT 2018-000413-20. Research Sponsor: GlaxoSmithKline.

	Randomization Scheme 0:1:2		
Treatment period	**Arm 1 (discontinued)**	**Arm 2**	**Arm 3**
CT*	CT + IV placebo	CT + IV placebo	CT + IV dostarlimab
Maintenance up to 3 years*	Oral placebo + IV placebo	Oral niraparib + IV placebo	Oral niraparib + IV dostarlimab

*Bev is optional in all arms.

TPS6102 Poster Session (Board #273), Fri, 8:00 AM-11:00 AM

NOGGO Ov-42/MAMOC: Rucaparib maintenance after bevacizumab maintenance following carboplatin-based first line-chemotherapy in ovarian cancer patients. *First Author: Elena Ioana Braicu, Department of Gynecology, Charité Medical University, Berlin, Germany*

Background: Ovarian cancer (OC) is associated with the highest mortality rates among gynecological malignancies, with most patients being diagnosed in advanced stages. The most common histological subtype is high grade serous OC, which is characterized by deficiency in homologous recombination. Debulking surgery, followed by platinum based chemotherapy and bevacizumab (bev), followed by maintenance therapy with bev, is the standard therapy for advanced BRCA wild type (BRCAwt) OC patients in Germany. BRCA mutant patients will receive maintenance with olaparib, according to SOLO1 data. The anticancer effects of PARP inhibitors (PARPi) seem to be increased by the addition of antiangiogenic drugs. Preclinical data showed increased HRD in tumors pretreated with bev, and clinical trials showed a benefit of the combination of antiangiogenic drugs and PARPi vs. PARPi alone. NOGGO Ov-42/MAMOC trial (NCT04227522) is a phase III, randomized, placebo-controlled study evaluating rucaparib maintenance following bevacizumab maintenance for the treatment of advanced primary high grade BRCAwt OC. **Methods:** 190 patients with histologically confirmed advanced (FIGO stage IIIA- IV of the 2014 FIGO classification) high grade serous or high grade endometrioid (based on local histopathological findings) OC, fallopian tube cancer, primary peritoneal cancer or clear cell carcinoma of the ovary will be randomized 2:1 to receive either rucaparib 600mg BID or placebo as maintenance therapy following first line chemotherapy with 6 cycles of Carboplatin/Paclitaxel and at least 12 cycles of bev, given together with chemotherapy and as maintenance. Only BRCAwt patients will be included in the trial. Randomization is stratified by surgery planned timepoint (neoadjuvant vs. adjuvant), surgical outcome (no residual tumor mass vs. residual tumor mass), response to chemotherapy followed by bev (CR/NED vs. PR/SD) and study center. Treatment will continue for 24 months or until disease progression, unacceptable toxicity, or withdrawal. Primary endpoint is PFS in BRCAwt patients per RECIST v1.1. Secondary endpoints are PFS2, quality of life (EORTC QLQ-C30/OV28, FSI, SF-12, PROC-CTCAE, every day memory questionnaire), daily activity, time to next medical intervention, time to next subsequent therapy, safety assessments and OS. Clinical trial information: NCT04227522. Research Sponsor: CLOVIS.

TPS6103 Poster Session (Board #274), Fri, 8:00 AM-11:00 AM

MIRASOL (GOG 3045/ENGOT OV-55): A randomized, open-label, phase III study of mirvetuximab soravtansine versus investigator's choice of chemotherapy in advanced high-grade epithelial ovarian, primary peritoneal, or fallopian tube cancers with high folate-alpha (FRα) expression. *First Author: Kathleen N. Moore, University of Oklahoma Medical Center, Oklahoma City, OK*

Background: Elevated FRα expression is a characteristic of several solid tumors, including epithelial ovarian cancer (EOC), thereby providing an attractive candidate for targeted therapeutic approaches. Mirvetuximab soravtansine is an antibody-drug conjugate (ADC) comprising a FRα-binding antibody, cleavable linker, and the maytansinoid DM4, a potent tubulin-targeting agent that has shown consistent and meaningful single agent clinical activity, along with favorable tolerability, in patients with high FRα expressing tumors. **Methods:** MIRASOL is a randomized phase III study designed to evaluate the efficacy of mirvetuximab soravtansine compared with that of standard-of-care chemotherapy in adult patients with platinum-resistant EOC, primary peritoneal cancer, or fallopian tube cancer. Confirmation of high FRα positivity by immunohistochemistry (high expression; $\geq$ 75% of cells with PS2+ staining intensity) and $\leq$ 3 prior lines of therapy are required for inclusion. MIRASOL is designed to randomize 430 patients, 1:1 to Arm 1 (intravenous mirvetuximab soravtansine at a dose of 6 mg/kg, calculated using adjusted ideal body weight, on Day 1 of a 21-day cycle) or Arm 2 (investigators' choice chemotherapy: paclitaxel, pegylated liposomal doxorubicin, or topotecan). The primary efficacy endpoint is progression-free survival (PFS; by investigator) and secondary endpoints include objective response rate, quality of life, overall survival, and safety and tolerability. MIRASOL opened for enrollment in December 2019. Clinical trial information: NCT04209855. Research Sponsor: ImmunoGen.

TPS6104 **Poster Session (Board #275), Fri, 8:00 AM-11:00 AM**

DUETTE: A randomized phase II study to assess a second maintenance treatment with olaparib (ola) or ola+ceralasertib (cer), in patients (pts) with platinum-sensitive relapsed (PSR) epithelial ovarian cancer who have previously received PARP inhibitor maintenance treatment (NCT04239014). *First Author: Amit M. Oza, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Ovarian cancer is the leading cause of death from gynecological cancers in the USA, and the fifth most common cause of cancer death in women. Ola is a PARPi approved for first-line maintenance treatment of *BRCA*-mutated advanced ovarian cancer in women who achieve a complete or partial response to platinum-based chemotherapy. Ola is also efficacious in combination with bevacizumab in the same population, independent of BRCA mutation status. Cer is a potent, oral, selective inhibitor of ATR. ATR is a critical DDR kinase that is activated in response to replication stress and stalled replication forks. There is no second maintenance standard of care for patients with PSR ovarian cancer who have previously received a PARPi in the maintenance setting. Pre-clinical models have shown that several mechanisms of PARPi resistance may be overcome by ATR inhibition, such as BRCA reversion, replication fork protection and DDR rewiring. DUETTE will select pts with tumor response or stable disease after second or third-line platinum-based treatment, with the expectation to enrich for non-BRCA reversion PARPi resistance mechanisms. The study will address the role of a second maintenance treatment following prior 1L or 2L maintenance, an emerging population of unmet need, and includes translational studies that aim to further our knowledge of clinical PARPi resistance mechanisms and predictors of treatment response. **Methods:** DUETTE is a global, multi-center, phase II study. 192 pts with PSR epithelial ovarian cancer who have previously received PARPi maintenance treatment, will be retreated with platinum and those who have not progressed after $\geq$ 4 cycles will be randomized (1:1:1) to 3 treatment arms: Arm 1, open-label: cer 160 mg once daily (qd) days 1 to 7 plus ola 300 mg twice daily (bd); Arm 2, blinded: ola monotherapy 300 mg bd and Arm 3, blinded: ola-placebo. Treatment is administered in 28-day cycles. All pts will be stratified by BRCA status (mutation or wildtype) and response to most recent line of platinum-based chemotherapy (CR/PR or SD). The primary endpoint is to assess the efficacy of maintenance ola monotherapy and cer+ola combination therapy compared with placebo by PFS using blinded, independent central review. Secondary endpoints are overall survival, PFS2, ORR, DoR, safety and tolerability. Enrolment is planned to start in April 2020. Research Sponsor: Astra Zeneca.

TPS6105 **Poster Session (Board #276), Fri, 8:00 AM-11:00 AM**

SIENDO/ENGOT-EN5: A randomized phase III trial of maintenance with selinexor/placebo after combination chemotherapy in patients with advanced or recurrent endometrial cancer. *First Author: Ignace Vergote, BGOG and University Hospitals Leuven, Leuven Cancer Institute, Leuven, Belgium*

Background: Endometrial cancer is one of the most common gynecologic malignancies with increasing incidence and mortality. Patients with advanced disease that has relapsed or received prior platinum-based therapy or radiotherapy have limited options and the prognosis remains poor. Selinexor is a novel, oral selective inhibitor of nuclear export (SINE) which forces nuclear retention and activation of tumor suppressor proteins. Selinexor in combination with low dose dexamethasone was recently approved for patients with multiple myeloma. In addition, single agent selinexor has demonstrated broad activity in other hematologic malignancies and solid tumors. In a phase II study, 50 mg/m^2 (~80 mg) selinexor administered twice weekly demonstrated a disease control rate of 35% with 2 confirmed partial responses among 23 patients with heavily pretreated endometrial cancer (Vergote I et al. Gynecol Oncol 2020). In the absence of approved maintenance therapies, we conducted this study to evaluate the efficacy of selinexor compared with placebo as maintenance therapy in patients with advanced or recurrent endometrial cancer. **Methods:** This is a multicenter, double-blind, placebo-controlled, randomized phase III study in patients in partial or complete remission after completing at least 12 weeks of taxane-platinum combination therapy for primary Stage IV disease and recurrent disease (i.e., relapse after primary therapy for early stage disease including surgery and/or adjuvant therapy). A total of 192 patients will be enrolled at 80 sites in Europe, North America, and Israel. Patients will be randomized in a 2:1 ratio to either maintenance therapy with 80 mg oral selinexor once weekly or placebo. Stratification factors include primary Stage IV versus first recurrent disease at the time of taxane-platinum therapy and disease status after chemotherapy (partial versus complete response). Treatment will continue until disease progression. The primary endpoint is progression free survival (PFS) per RECIST v1.1. Secondary endpoints include disease-specific survival, overall survival, time to first subsequent therapy, time to second subsequent therapy, PFS on subsequent therapy and safety and tolerability. The study is currently open and enrolling patients. Clinical trial information: NCT03555422. Research Sponsor: Karyopharm Therapeutics Inc.

TPS6106 **Poster Session (Board #277), Fri, 8:00 AM-11:00 AM**

ENGOT-en9/LEAP-001: A phase III study of first-line pembrolizumab plus lenvatinib versus chemotherapy in advanced or recurrent endometrial cancer. *First Author: Christian Marth, Department of Gynecology and Obstetrics, Medical University of Innsbruck, Innsbruck, Austria*

Background: The prognosis for endometrial cancer (EC) can be favorable when diagnosed in early stages, but prognosis and overall survival are poor in patients with advanced or recurrent EC. First-line standard of care for patients with advanced or recurrent EC is paclitaxel and carboplatin chemotherapy; however, there is a need for more effective and tolerable therapies. In the phase Ib/II trial KEYNOTE-146, which assessed the PD-1 inhibitor pembrolizumab (pembro) in combination with the multikinase inhibitor lenvatinib, an objective response rate (ORR) of 38% was observed (N=108) in patients with previously treated advanced EC. ENGOT-en9/LEAP-001 (NCT03884101) is a randomized, open-label, active-controlled, phase III study investigating pembro + lenvatinib vs chemotherapy in patients with newly diagnosed advanced or recurrent EC. **Methods:** Patients with newly diagnosed advanced (stage III-IV) or recurrent EC not previously treated with antiangiogenic agents; systemic chemotherapy (unless within a chemoradiation regimen); PD-1, PD-L1, or PD-L2 inhibitors; or other T-cell receptor–targeted therapies will be eligible. Patients will be randomized 1:1 to receive pembro 200 mg every 3 wk (Q3W) + lenvatinib 20 mg daily or paclitaxel 175 mg/m^2 Q3W + carboplatin AUC 6 Q3W. Randomization will be stratified on the basis of proficient vs deficient mismatch repair (pMMR vs dMMR) status. The pMMR population will be further stratified by prior chemoradiation (yes vs no), measurable disease (yes vs no), and ECOG performance status (0 vs. 1). Patients will continue on treatment for up to 35 cycles of pembro vs 7 cycles of chemotherapy or until initiation of a new anticancer treatment, unacceptable adverse events, or withdrawal of consent. Primary study endpoints are progression-free survival (per RECIST v1.1 by blinded independent central review) and overall survival. Secondary study endpoints are ORR, health-related quality of life, safety and tolerability, and lenvatinib pharmacokinetics. Exploratory endpoints will include disease control rate, clinical benefit rate, and duration of response. Enrollment is ongoing. Clinical trial information: NCT03884101. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA and Eisai Inc., Woodcliff Lake, NJ, USA.

TPS6107 **Poster Session (Board #278), Fri, 8:00 AM-11:00 AM**

ENGOT-EN6/NSGO-RUBY: A phase III, randomized, double-blind, multicenter study of dostarlimab + carboplatin-paclitaxel versus placebo + carboplatin-paclitaxel in recurrent or primary advanced endometrial cancer (EC). *First Author: Mansoor Raza Mirza, Nordic Society of Gynecologic Oncology (NSGO) and Rigshospitalet–Copenhagen University Hospital, Copenhagen, Denmark*

Background: Carboplatin-paclitaxel is considered standard systemic anticancer therapy for recurrent or advanced EC for which surgery and/or radiation are not curative. Dostarlimab (TSR-042) is an anti-programmed cell death (PD)-1 humanized monoclonal antibody that has demonstrated antitumor activity and an acceptable safety profile in patients (pts) with recurrent or advanced EC in the GARNET trial. The RUBY trial was designed to evaluate the efficacy and safety of dostarlimab in combination with carboplatin-paclitaxel in recurrent or primary advanced EC compared with carboplatin-paclitaxel alone. **Methods:** This is a global, randomized, double-blind, multicenter, placebo-controlled study. Eligible pts must have first recurrent or primary stage III or stage IV EC with a low potential for cure by radiation therapy or surgery alone or in combination. Pts with carcinosarcoma are eligible for enrollment. 470 pts will be enrolled from approximately 160 sites in the ENGOT countries, United States, and Canada. Stratification factors are microsatellite instability (MSI) status (MSI-high [MSI-H] or microsatellite stable [MSS]), prior external pelvic radiotherapy (yes or no), and disease status (recurrent, primary stage III, or primary stage IV). Pts will be randomized 1:1 to receive combination dostarlimab 500 mg or placebo + carboplatin AUC 5 + paclitaxel 175 mg/m^2 every 3 weeks for 6 cycles followed by dostarlimab 1000 mg or placebo monotherapy every 6 weeks for up to 3 years in the absence of progressive disease, death, unacceptable toxicity, or patient/physician decision to withdraw from the study. The primary endpoint is progression-free survival (PFS) as assessed by the investigator in the all-comers population and the MSI-H population per RECIST version 1.1. Secondary efficacy endpoints are PFS assessed by blinded independent central review per RECIST version 1.1, overall survival, objective response rate, duration of response, disease control rate, safety and tolerability, and patient-reported outcomes. Clinical trial information: NCT03981796. Research Sponsor: GlaxoSmithKline.

TPS6108 Poster Session (Board #279), Fri, 8:00 AM-11:00 AM

DUO-E/GOG-3041/ENGOT-EN10: a randomized phase III trial of first-line carboplatin (carb) and paclitaxel (pac) in combination with durvalumab (durva), followed by maintenance durva with or without olaparib (ola), in patients (pts) with newly diagnosed (nd) advanced or recurrent endometrial cancer (EC). *First Author: Shannon Neville Westin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There is a high unmet need for advances in EC treatment that provide progression-free survival (PFS) and overall survival (OS) benefits. EC tumors are sensitive to carb/pac (Pectasides *et al. Gynecol Oncol* 2008). Maintenance therapy with the poly(ADP-ribose) polymerase inhibitor (PARPi) ola (with or without bevacizumab) led to significant PFS benefits in advanced ovarian cancer pts with either nd (SOLO1, Moore *et al. NEJM* 2018; PAOLA-1, Ray-Coquard *et al. NEJM* 2019) or recurrent (SOLO2, Pujade-Lauraine *et al. Lancet Oncol* 2017; Study 19, Friedlander *et al. Br J Cancer* 2018) platinum-sensitive disease, regardless of BRCA mutation status (PAOLA-1; Study 19), and in BRCA-mutated metastatic pancreatic cancer pts (POLO, Golan *et al. NEJM* 2019). Molecular features of EC could predict sensitivity to PARPi (de Jonge *et al. Clin Cancer Res* 2019; Auguste *et al. Mod Pathol* 2018). PARPi has been shown to prime the immune microenvironment in a preclinical *BRCA1* mutant ovarian model (Higuchi *et al. Cancer Immunol Res* 2015). Clinical trials have demonstrated antitumor activity of the anti-programmed cell death ligand-1 (anti-PD-L1) blocker durva (Antill *et al. J Clin Oncol* 2019) and anti-programmed cell death-1 (anti-PD-1) antibody therapies (Makker *et al. ESMO* 2019; Oaknin *et al. SGO* 2019) in EC pts. The DUO-E trial (EUDRACT 2019-004112-60, D9311C00001, NCT04269200) will investigate whether the addition of durva to carb/pac, followed by durva (with or without ola) maintenance treatment, improves PFS in pts with nd advanced or recurrent EC. **Methods:** Eligible pts for this multicenter, double-blind, Phase III trial must have nd Stage III/IV or recurrent EC and be naïve to first-line chemotherapy. Pts will be randomized (1:1:1; n=~233 per arm) to: arm A) carb/pac + placebo (pbo) (q3w for six cycles) followed by pbo maintenance treatment; arm B) carb/pac + durva (1120 mg; q3w for six cycles) followed by maintenance treatment with durva (1500 mg q4w) + pbo (tablets bid); or arm C) carb/pac + durva (1120 mg; q3w for six cycles) followed by maintenance treatment with durva (1500 mg q4w) + ola (300 mg bid tablets). Pts received maintenance treatment until disease progression. Primary endpoint: investigator-assessed PFS (RECIST 1.1) of arm B vs. arm A. Key secondary endpoints: PFS of arm C vs. arm A; OS of arm B vs. arm A, and of arm C vs. arm A. Enrollment began in Q1 2020. Clinical trial information: 2019-004112-60. Research Sponsor: AstraZeneca.

TPS6109 Poster Session (Board #280), Fri, 8:00 AM-11:00 AM

Multicentre randomized phase II trial of olaparib as maintenance therapy in platinum-sensitive advanced endometrial carcinoma: The GINECO-UTOLA study. *First Author: Florence Joly, Department of Medical Oncology, Centre François Baclesse, Caen, France*

Background: Advanced endometrial cancer (EC) patients relapse despite treatment with combination chemotherapy and have a short progression-free survival (PFS). Data from the TGCA suggest opportunities to targeting DNA repair in women with EC. Particularly type 4 (High copy number or serous like, with frequent TP53 mutations) and type 2 (microsatellite instability hyper-mutated) EC can be associated with defects in double strand break DNA repair by homologous recombination (HR) and could potentially be targeted by olaparib. We propose a placebo-controlled, multicenter, two-arm, phase II trial comparing olaparib versus placebo in maintenance therapy after chemotherapy in patients with advanced/metastatic EC. **Methods:** The primary objective of this trial is to evaluate the efficacy of maintenance olaparib in comparison to placebo after platinum based chemotherapy, defined by PFS according to Recist. Key eligibility criteria include: advanced/metastatic histologically confirmed EC (excepted carcino-sarcoma, small cells& neuroendocrine); prior surgery, adjuvant chemotherapy, radiation and hormonal therapy are permitted; objective or stable response after first-line chemotherapy is mandatory. 147 patients are randomized (2:1) after chemotherapy to receive Olaparib 300mg twice daily or placebo in maintenance after at least 4 cycles of platinum based chemotherapy. Olaparib/placebo is continued until disease progression, unacceptable toxicity, or withdrawal. Stratification is on IHC P53 and MMR status. Primary hypothesis is a 66.7% relative increase in the median PFS rate in the olaparib arm (from 4.5 to 7.5 months), corresponding to a 0.60 Hazard Ratio. Secondary endpoints include PFS according to P53, MMR and NGS HRD status, PFS2, disease specific survival, time to subsequent therapy, overall survival, objective response, disease control rate, patient reported outcomes (assessed via EORTC QLQ-C30 and EORTC QLQ-EN24, EORTC-FA, EQ5D) and safety. Trial is recruiting in France (in February n= 40 randomization). **Conclusion:** this will be the first study that evaluate the efficacy of olaparib in maintenace after chemotherapy in advanced/metastastic EC, stratified on molecular profil. Clinical trial information: NCT03745950. Research Sponsor: Astrazeneca.

6500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Transoral robotic surgical resection followed by randomization to low- or standard-dose IMRT in resectable p16+ locally advanced oropharynx cancer: A trial of the ECOG-ACRIN Cancer Research Group (E3311). *First Author: Robert L. Ferris, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: ECOG-ACRIN 3311 examines reduced postoperative therapy in patients with "intermediate risk" p16+ oropharynx cancer (OPC) undergoing primary transoral surgical management. We report the primary endpoint of 2-year progression free survival (PFS) for patients randomized to 50Gy vs 60Gy without chemotherapy. **Methods:** Between December 2013 and July 2017, 82 credentialed surgeons performed transoral resection (TOS) for 519 OPC patients (cT1-2 stage III/IV AJCC7 without matted neck nodes); post-operative management was determined by pathologically assessed risk. Among 353 eligible and treated patients, Arm A enrolled 10% (N=37) for clear margins, 0-1 nodes, no extranodal extension (ENE)), Arms B (50Gy, N=102) or C (60Gy, N=104) randomized 58%, for clear/close margins, 2-4 + nodes, or ENE ≤1mm, while Arm D (N=110, 60-66Gy plus weekly cisplatin, 40 mg/m2, positive margin with any T stage, >4 + nodes, or >1mm ENE) enrolled 31%. Arm D assignment was based on >1mm ENE (76%), > 4 nodes (27%), and/or positive margins (11%). Intermediate-risk patients were stratified by smoking history (>10 pk-yr). Of the 80 pts (15%) deemed ineligible, 28 had scans/labs not done per protocol, however treatment arm distribution for all patients mirrored that for the 353 pts eligible and treated. **Results:** Median follow-up was 31.8 months. 2 yr PFS for Arms A, B and C were 93.9% (90% CI=87.3%, 100%), 95.0% (90% CI=91.4%, 98.6%) and 95.9% (90% CI=92.6%, 99.3%) respectively, while Arm D was 90.5% (90% CI=85.9%, 95.3%). The regimen of TOS + low-dose radiation is considered worthy of further study, since the primary endpoint of the upper bound of the 90% CI (in the intermediate risk group) exceeding 85% was met. Of 17 progression events, 7 were locoregional. There were 10 distant recurrences: Arm A=1, Arm B=2, Arm C=4, Arm D=3. Grade III/IV treatment-related AE rates were 15%/2% during surgery, 13%/2% for Arm B and 25%/0% for Arm C. There were 2 treatment-related deaths (one surgical and one Arm D). **Conclusions:** Transoral resection of p16+ OPC is safe and results in good oncologic outcome, presenting a promising deintensification approach. For patients with low-risk disease, 2-yr PFS is favorable without post-operative therapy. For those with uninvolved surgical margins, <5 involved nodes, and minimal (<1mm) ENE, reduced dose post-operative RT without chemotherapy appears sufficient. Transoral surgery plus 50Gy should be compared to optimal non-surgical therapy in a phase III trial. Clinical trial information: NCT01898494. Research Sponsor: Eastern Cooperative Oncology Group, U.S. National Institutes of Health.

6501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Equivalence randomized trial comparing treatment based on sentinel node biopsy versus neck dissection in operable T1-T2N0 oral and oropharyngeal cancer. *First Author: Renaud Garrel, Head Neck Departement CHU Montpellier, Montpellier, France*

Background: Although sentinel node (SN) biopsy is known to be accurate in operable oral and oropharyngeal cT1-T2N0 squamous cell carcinomas (OC), the oncological equivalence of a treatment based on SN compared to that based on neck dissection (ND) has to be evaluated. **Methods:** A prospective multicenter randomized medico economic study included patients with OC operated of primary tumor and systematic neck dissection in ND-arm (standard treatment) versus patients operated of primary tumor and SN biopsy only if negative or ND if SN biopsy positive (SN-arm, experimental treatment). Primary endpoint was neck-relapse-free survival at 2 years and 5 years. Hypothesis of equivalence was tested with a delta of 10%. Functional outcomes were assessed by comparing the length of the hospital stay, the number of physiotherapy prescriptions and dysfunctions in neck and shoulder scales during the 2 post-operative years. **Results:** Out of 307 included patients in 10 hospital centers, 279 evaluable cases showed a neck-relapse-free survival at 2 years and 5 years respectively of 89,6% (95%CI: 0.827; 0.938) and 89,6 %, (95%CI: 0.827; 0.938) in the ND-arm (14 neck relapses out of 139 patients) and of 90,7% (95%CI: 0.842; 0.946) and 89,4% (95%CI: 0.823; 0.938) in the SN-arm (13 neck relapses out of 140 patients). The survival difference between the two arms was less than the 10% expected interval, confirming the equivalence with p = 0.008. The median length of hospital stay was 7 days (ext. 3-30) in SN-arm and 8 days (ext. 2-94) in ND-arm (Wilcoxon's test, p = 0.001). The other functional outcomes were statistically worse in the ND-arm at the 2nd, 4th and 6th postoperative months. There was no more difference at 12 months and later. **Conclusions:** This study demonstrated the oncological equivalence of the SN approach compared to the ND approach in a multicenter study with a lower morbidity and care consumption in the SN approach during the 6 first post-operative months. Treatment based on sentinel node biopsy is established as a standard of care in OC. Clinical trial information: NCT02855723. Research Sponsor: French National Institute of Cancer.

6502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II/III trial of post-operative chemoradiotherapy comparing 3-weekly cisplatin with weekly cisplatin in high-risk patients with squamous cell carcinoma of head and neck (JCOG1008). *First Author: Naomi Kiyota, Medical Oncology and Hematology, Cancer Center, Kobe University Hospital, Kobe, Japan*

Background: The standard treatment for post-operative high-risk patients (pts) with locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN) is chemoradiotherapy with 3-weekly cisplatin (CDDP) (100 mg/m^2, q3wk, 66 Gy/33Fr; 3-weekly CDDP+RT). However, one concern with 3-weekly CDDP+RT is insufficient CDDP compliance due to high-dose-related toxicities. Weekly CDDP+RT (40 mg/m^2, qwk, 66 Gy/33Fr; weekly CDDP+RT) is an alternative regimen with better compliance. Here, we conducted a phase II/III trial of weekly CDDP+RT in post-operative high-risk LA-SCCHN. **Methods:** This is a multi-institutional randomized phase II/III trial to confirm the non-inferiority of weekly CDDP+RT (Arm B) compared with 3-weekly CDDP+RT (Arm A). The trial enrolled pts aged 20-75 years with post-operative high-risk features (microscopically positive margin and/or extranodal extension) and ECOG-PS 0-1. Pts were randomized in a 1:1 ratio to Arm A or Arm B. Primary endpoint of phase II was the proportion of treatment completion and that of phase III was overall survival (OS). A non-inferiority margin of hazard ratio (HR) was set at 1.32. **Results:** Between Oct 2012 and Dec 2018, 261 pts were enrolled (Arm A 132 pts, Arm B 129 pts). At the planned second interim analysis in phase III with 76/161 events, the Data and Safety Monitoring Committee recommended terminating the trial and publishing the results because the statistical boundary for OS non-inferiority had met the pre-specified stop criteria. With a median follow-up of 2.2 years in all randomized pts, 3-year OS was 59.1% in Arm A and 71.6% in Arm B with a HR of 0.69 (99.1% CI, 0.374-1.273 [< 1.32], one-sided p for non-inferiority = 0.00272 < 0.00433). 3-year RFS was 53.0% in Arm A and 64.5% in Arm B with a HR of 0.71 (95% CI, 0.48-1.06). Regarding acute adverse events, neutropenia (≥ grade 3), increased creatinine (≥ grade 2), hearing impairment (≥ grade 2) and mucositis (≥ grade 2) occurred in 48.8%, 8.5%, 7.8% and 55.0% in Arm A and 35.3%, 5.7%, 2.5% and 59.0% in Arm B, respectively. For compliance, median total dose of CDDP was 280 mg/m^2 (IQR, 250-299) in Arm A and 239 mg/m^2 (IQR, 199-277) in Arm B. Total radiation dose was 66 Gy (IQR, 66-66) in both arms. Proportion of treatment completion was 93.2% in Arm A and 86.8% in Arm B. **Conclusions:** Weekly CDDP+RT is non-inferior to 3-weekly CDDP+RT for post-operative high-risk LA-SCCHN pts and has a favorable toxicity profile. Weekly CDDP+RT should be considered the new standard treatment option for these pts. Clinical trial information: 000009125. 6503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized phase II study of axitinib versus observation in patients with recurred or metastatic adenoid cystic carcinoma. *First Author: Bhumsuk Keam, Seoul National University Hospital, Seoul, South Korea*

Background: Adenoid cystic carcinoma (ACC) does not respond to cytotoxic chemotherapy. Several anti-angiogenic agents were evaluated in single arm phase II trials. However, the role of chemotherapy is still controversial, because of natural stable disease course without chemotherapy and lack of randomized trial. We firstly conducted a randomized trial to evaluate the efficacy of axitinib compared to observation. **Methods:** In this multicenter, prospective phase II trial, we enrolled recurred, metastatic ACC patients who progressed within 9 months. Patients were randomly assigned either axitinib (5mg twice daily) or observation arm with 1:1 ratio. Crossover to the axitinib arm was permitted for patients in the observation arm who had disease progression. The primary endpoint was 6-month progression-free survival (PFS) rate. The secondary endpoints included objective response rate (ORR), overall survival (OS), PFS, duration of response and adverse events. **Results:** A total of 60 patients randomly allocated to axitinib (N=30) and observation arm (N=30) and response evaluation was conducted in 57 patients. With a median follow-up of 25.4 months, the 6-month PFS rate was 73.2% (95% confidence interval [CI], 54.8 to 88.1%) in the axitinib arm and 23.2% (95% CI, 9.3 to 41.1%) in the observation arm (hazard ratio, 0.19; 95% CI, 0.08 to 0.45; $P < 0.001$). Median PFS was 10.8 months in axitinib arm and 2.8 months in observation arm ($P < 0.001$). The ORR was 3.3% (95% CI, 0.1 to 17.2%) in the axitinib arm, and 0% (95% CI, 0 to 12.8%) in the observation arm. The disease control rate was 100% (95% CI, 88.4 to 100%) in the axitinib arm and 51.9% (95% CI, 32.0 to 71.3%) in the observation arm. After crossover, ORR of axitinib in the observation arm was 11.1% (95% CI, 2.4 to 29.2%). Median OS was not reached in axitinib arm, 28.5 months in observation arm ($P = 0.688$). The most frequently reported adverse events of axitinib were grade 1 or 2 oral mucositis and fatigue. Detailed data of adverse events and mutational profile data will be presented. **Conclusions:** In this first randomized trial in patients with recurred or metastatic ACC, axitinib significantly increased 6-month PFS rate compared to observation. Clinical trial information: NCT02859012. Research Sponsor: Adenoid cystic carcinoma research foundation.

6504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Preliminary activity of tipifarnib in tumors of the head and neck, salivary gland and urothelial tract with HRAS mutations. *First Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HRAS is a proto-oncogene overexpressed and mutated in some human carcinomas. Tipifarnib is a potent and highly selective inhibitor of farnesyltransferase, a critical enzyme for proper HRAS function. **Methods:** We report data from two phase 2 clinical trials investigating the activity of tipifarnib in HRAS mutant (HRASm) solid tumors: KO-TIP-001 (NCT02383927: Squamous carcinomas [SCC], thyroid and salivary gland tumors, among others) and IST-01 (NCT02535650: Urothelial carcinomas, UC).Primary endpoints were overall response rate (ORR, KO-TIP-001) and progression free survival (PFS) rate at 6 months (IST-01). All pts had RECIST v1.1. measurable disease at study entry. Pts receive a starting dose of tipifarnib of either 600 or 900 mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease (PD) or unacceptable toxicity. **Results:** Proof of concept was achieved in studies KO-TIP-001 and IST-01. Based on preliminary efficacy results (Ho, et. al, ESMO 2018), KO-TIP-001 was amended to continue enrolling only in Head & Neck SCC (HNSCC) pts (Cohort 2) and other SCC pts (Cohort 3) with tumors carrying high HRASm variant allele frequency (VAF) >20%. As of 17 October 2019, 21 HNSCC pts meeting the high HRASm VAF criteria had been treated with tipifarnib of whom 18 were efficacy evaluable at data cut off. Pts had received a median of 2 prior systemic regimens. Ten objective responses were observed in 18 evaluable pts for an ORR of 56%. No responses were observed on last therapy prior to study entry. PFS on tipifarnib and on prior last therapy were, respectively, 6.1 and 2.8 months. In addition, 13 pts with recurrent/metastatic salivary gland tumors (SGT) were treated in KO-TIP-001 or in extended access programs. One objective response was observed in 12 (8%) evaluable pts and an additional 7 (58%) had stable disease as best response. Median PFS in SGT pts was 7 months. In IST-01, 224 UC pts were screened of whom 16 (7%) carried HRAS mutations and 15 of those were enrolled into the study. Five responses were observed in 12 evaluable UC pts (42%) and 3 additional pts had tumor size reduction. Median PFS was 5.1 months. **Conclusions:** Encouraging activity of tipifarnib was observed in HRASm solid tumors. Clinical trial information: NCT02383927, NCT02535650. Research Sponsor: Kura Oncology.

6505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

KEYNOTE-048: Progression after the next line of therapy following pembrolizumab (P) or P plus chemotherapy (P+C) vs EXTREME (E) as first-line (1L) therapy for recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). *First Author: Kevin Joseph Harrington, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust National Institute of Health Research Biomedical Research Centre, London, United Kingdom*

Background: 1L P vs E improved OS in PD-L1 CPS ≥20 and CPS ≥1 populations, and led to noninferior OS in the total population, with favorable safety; 1L P+C vs E had superior OS in CPS ≥20, CPS ≥1, and total populations with comparable safety in the phase 3 KEYNOTE-048 study (NCT02358031) in patients with R/M HNSCC. Neither P vs E nor P+C vs E improved PFS in the PD-L1 CPS ≥20, CPS ≥1, or total populations. Here, we present the progression after the next line of therapy (PFS2) to assess the effect of 1L P or P+C and subsequent anticancer therapy on patient outcomes. **Methods:** Patients with locally incurable R/M HNSCC and no prior systemic therapy in the R/M setting were randomly assigned 1:1:1 to P, P+C, or E. PFS2 was defined as time from randomization to objective tumor progression on next-line therapy or death from any cause. PFS2 was estimated using the Kaplan-Meier method as an exploratory outcome confined to those receiving subsequent therapy after 1L P. HR and 95% CIs were based on a Cox regression model with Efron's method of tie handling with treatment as a covariate (stratified by ECOG performance status [PS], HPV status, and PD-L1 for CPS ≥1 and total populations; by ECOG PS and HPV status for CPS ≥20 population). Data cutoff: Feb 25, 2019. **Results:** Of 882 (301 [P]; 281 [P+C]; 300 [E]) treated patients,422 (P: 148 [49.2%]; P+C: 115 [40.9%]; E: 159 [53.0%]) received subsequent anticancer therapy after 1L P, most commonly C (P: 135 [44.9%]; P+C: 88 [31.3%]; E: 102 [34.0%]); EGFR inhibitor (P: 59 [19.6%]; P+C: 37 [13.2%]; E: 19 [6.3%]); and immune checkpoint inhibitor (P: 6 [2.0%]; P+C: 12 [4.3%]; E: 50 [16.7%]); patients may have received more than one type of subsequent therapy. Median PFS2 is reported in Table. **Conclusions:** In patients with R/M HNSCC, longer median PFS2 was observed in the CPS ≥20 and CPS ≥1 populations for P vs E, and in the CPS ≥20, CPS ≥1, and total populations for P+C vs E. These data further support use of 1L P or P+C in patients with R/M HNSCC. Clinical trial information: NCT02358031. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Population	Treatment	Median PFS2, month	HR (95% CI)	24-mo PFS2 rate, %
CPS ≥20	P (n=133) vs E (n=122)	11.7 vs 9.4	0.64 (0.48-0.84)	27.0 vs 12.5
CPS ≥1	P (n=257) vs E (n=255)	9.4 vs 8.8	0.80 (0.66-0.96)	22.0 vs 9.9
Total	P (n=301) vs E (n=300)	9.0 vs 9.0	0.90 (0.75-1.07)	19.7 vs 11.4
CPS ≥20	P+C (n=126) vs E (n=110)	11.3 vs. 9.7	0.63 (0.47-0.84)	28.9 vs 12.0
CPS ≥1	P+C (n=242) vs E (n=235)	10.3 vs 8.9	0.66 (0.54-0.80)	23.7 vs 9.0
Total	P+C (n=281) vs E (n=278)	10.3 vs 9.0	0.74 (0.62-0.88)	21.4 vs 10.5

6506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Low-cost oral metronomic versus intravenous chemotherapy in recurrent, inoperable and metastatic head and neck cancer: Phase III Metro-CIS study. *First Author: Nandini Sharrel Menon, Tata Memorial Hospital, Mumbai, India*

Background: The NCCN preferred regimens for palliation in head and neck cancer, either EXTREME or KEYNOTE-048 are the only two regimens which have improved outcomes over chemotherapy, but they have limited applicability (1-3%) in low and middle-income countries due to the cost. Oral metronomic chemotherapy (OMC) has shown better outcomes than intravenous cisplatin; these results were obtained with a low incidence of adverse events and the cost of 1/100th of NCCN-preferred regimens in a Phase II study. **Methods:** This was a randomized Phase III non-inferiority open-label study. Adult patients with relapsed-recurrent or metastatic upfront palliatively treated squamous cell carcinoma of head and neck and ECOG PS 0-1 were eligible. Patients were randomized 1:1 between OMC (oral methotrexate 15 mg/m^2 weekly with celecoxib 200 mg once daily or intravenous cisplatin (IVC) 75 mg/m^2, 3-weekly for 6 cycles. CTCAE version 4.0 was used for adverse event recording. Response assessment (RECIST version 1.1) was performed every 2 months. EORTC QLQ-C 30 and EORTC QLQ -H&N 35 questionnaires were self-administered at baseline and 2-monthly thereafter. The primary endpoint was overall survival (OS) and was measured from the date of randomization to death. Assuming a 6-month OS in IVC arm of 40%, the non-inferiority margin of 13%, type 1 error of 5% (2-sided), type 2 error of 20% and lost-to-follow up rate of 20%, a total sample size of 422 subjects was required. Kaplan Meier method was used for the estimation of OS and progression-free survival (PFS). To determine non-inferiority the upper limit of 95% CI of difference between 6 months OS of the 2 arms had to be below 13%. **Results:** In the intention to treat analysis, the 6-months OS was 50.89% (95% CI, 43.3-57.97) and 62.26% (95% CI, 54.72-68.9) in the IVC and OMC arm respectively. The difference in 6-months OS between the 2 arms was - 11.37% (95% CI, -20.77 to -0.97). The median OS was 6.1 (95% CI, 5.33-6.93) versus 7.5 (95% CI, 6.5-8.8) months in IVC arm and OMC arm respectively (P= .026). The unadjusted hazard ratio for death was 0.773 (95% CI, 0.615-0.97, P= .026). The median PFS was 1.67 (95% CI, 1.47-2.03) versus 3.23 (95% CI, 2.57-4.13) months in IVC and OMC arms respectively (P< 0.001). Any grade 3 or above adverse events were seen in 61 (30.2%) versus 37 (18.9%) patients in IVC and OMC arm respectively (P= .01). **Conclusions:** OMC improves outcomes in palliatively treated head and neck cancer and is a new standard of care in this setting, in addition to the EXTREME and KEYNOTE-048 regimen. Clinical trial information: CTRI/2015/11/006388. Research Sponsor: Tata Memorial Center Research Administration Council.

6507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

TPExtreme randomized trial: Quality of Life (QoL) and survival according to second-line treatments in patients with recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). *First Author: Joel Guigay, Centre Antoine Lacassagne, FHU OncoAge, Université Côte d'Azur, Nice, France*

Background: TPExtreme trial comparing EXTREME regimen to the taxane-based TPEx confirmed the encouraging survival results of the TPEx regimen, despite lack of significant overall survival (OS) increase, with a significantly lower toxicity than the EXTREME regimen. Herein, the QoL and exploratory analyses of survival according to 2nd line treatments focusing on immunotherapy (IO) are presented. **Methods:** Randomized (1:1), open-label trial. Main inclusion criteria were R/M HNSCC not suitable for loco-regional treatment, age 18-70 years, PS < 2, creatinin clearance > 60ml/min, prior cisplatin < 300 mg/m^2. 539 pts were enrolled over a period of 37 months (mo). QoL was evaluated with QLQ-C30 questionnaire at baseline, week(W)12, W18, W26 and analyzed by linear mixed model. The primary QoL endpoint was the Global Health Status score. 2nd line treatments were collected for 501 (93%) patients (pts), 256 in the EXTREME arm and 245 in the TPEx arm. **Results:** The percentage of QLQ-C30 questionnaires filled at baseline, W12, W18 and W26 were similar in the 2 arms, 89%, 52%, 43%, and 39% in the EXTREME arm and 91%, 59%, 40%, and 37% in the TPEx arm, respectively.. Higher scores of Global Health Status (p = 0.02), physical functioning (p = 0.009) and role functioning (p = 0.013) and lower scores of appetite loss (p = 0.041) were observed in the TPEx arm than in the EXTREME arm. No significant difference was observed for the other scores. In 2nd line treatment, 120 (47%) pts in the EXTREME arm and 109 (44%) in the TPEx arm received chemotherapy +/- cetuximab (CT); 41 (16%) pts in the EXTREME arm and 41 (17%) in the TPEx arm received IO, mainly anti-PD-1/PD-L1. 79% and 85% of these 2nd line treatments were given after progression in EXTREME and TPEx arms respectively. Median OS (95%CI) since randomization was 17.6 (15.2 – 19.5) mo with CT and 19.4 (13.4 – 22.3) mo with IO in the EXTREME arm vs 14.9 (13.0 – 16.3) and 21.9 (15.9 – 35.0) mo in the TPEx arm (interaction test p = 0.077) respectively. Median OS since start of 2nd line was 9.3 mo with CT and 8.3 mo with IO in the EXTREME arm, and 7.1 and 11.6 mo respectively in the TPEx arm. **Conclusions:** An improvement in the QoL of patients was observed in the TPEx arm compared to that of the EXTREME arm. Exploratory analysis showed that the taxane-based TPEx regimen followed by IO in 2nd line could provide interesting median OS for pts who need CT in 1st line, with less toxicity than EXTREME. This sequential treatment deserves to be compared to a strategy that starts with Platinum+5FU+pembrolizumab. Clinical trial information: NCT02268695. Research Sponsor: Merck SERONO, GORTEC.

6508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results of a randomized phase III study of dysphagia-optimized intensity modulated radiotherapy (Do-IMRT) versus standard IMRT (S-IMRT) in head and neck cancer. *First Author: Christopher Nutting, Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Most newly diagnosed oro- & hypopharngeal cancers (OPC, HPC) are treated with (chemo)RT with curative intent but at the consequence of adverse effects on quality of life. CRUK/14/014 investigated if using Do-IMRT to reduce RT dose to the dysphagia/aspiration related structures (DARS) improved swallowing function compared to S-IMRT. **Methods:** Patients with T1-4, N0-3, M0 OPC/HPC were randomised 1:1 to S-IMRT (65 Gray (Gy)/30 fractions (f) to primary & nodal tumour; 54Gy/30f to remaining pharyngeal subsite & nodal areas at risk of microscopic disease) or Do-IMRT. The volume of the superior & middle pharyngeal constrictor muscle (PCM) (OPC) or inferior PCM (HPC) lying outside the high-dose target volume was set a mandatory mean dose constraint in Do-IMRT. Treatment allocation was by minimisation balanced by centre, use of induction/concomitant chemotherapy, tumour site & AJCC stage. Primary endpoint was mean MD Anderson Dysphagia Inventory (MDADI) composite score 12 months after RT with 102 patients needed to detect a 10 point improvement (assuming S-IMRT score of 72, standard deviation (SD) 13.8; 90% power, 2-sided 5% alpha). Patients were blind to treatment allocation. Secondary endpoints included local control. **Results:** 112 patients (56 S-IMRT, 56 Do-IMRT) were randomised from 22 UK centres from 06/2016 to 04/2018. Mean age was 57 years; 80% were male; 97% had OPC; 90% had AJCC stage 3&4 disease; 86% had concomitant chemotherapy only, 4% induction & concomitant and 10% no chemotherapy. 111/112 had RT doses as prescribed (1 patient died before RT). Median of the mean inferior PCM dose was S-IMRT 49.8Gy (IQR 47.1-52.4) vs. Do-IMRT 28.4Gy (21.3–37.4), $p < 0.0001$; superior & middle PCM dose was S-IMRT 57.2Gy (56.3–58.3) vs. Do-IMRT 49.7Gy (49.4–49.9), $p < 0.0001$. Do-IMRT had significantly higher MDADI scores: S-IMRT 70.3 (SD 17.3) vs. Do-IMRT 77.7 (16.1), $p = 0.016$. 3 local recurrences (1 S-IMRT, 2 Do-IMRT) have been reported. **Conclusions:** Do-IMRT reduced RT dose to the DARS and improved patient reported swallowing function compared with S-IMRT. This is the first randomised study to demonstrate functional benefit of swallow-sparing IMRT in OPC. Clinical trial information: 25458988. Research Sponsor: Cancer Research UK and the National Institute for Health Research.

6509 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Evaluation of the correlation between antibiotic use and survival in patients with recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC) treated with immune checkpoint inhibitors (ICIs). *First Author: Paz J. Vellanki, US Food and Drug Administration, Silver Spring, MD*

Background: Recent evidence suggests that treatment with systemic antibiotics (Abx) disrupts the intestinal microbiome and may be associated with decreased survival for patients receiving treatment with ICIs for advanced cancers, including R/M HNSCC. However, a potential confounder is that Abx use identifies a subgroup of patients with a worse prognosis. The FDA examined the association between Abx use and survival for ICIs and other drugs used for the treatment of patients with R/M HNSCC. **Methods:** Data submitted to the FDA from three randomized controlled trials with ICI as a single agent or with chemotherapy (ICI group) compared to chemotherapy and/or cetuximab (Control group) were pooled. The association between systemic Abx use within 30 days of initiating anticancer therapy and survival for the ICI and Control groups was evaluated using Kaplan-Meier (KM) estimates and compared using Cox proportional hazards regression models, controlling for ECOG performance status, line of therapy, HPV status, PD-L1 expression, and other important prognostic factors. **Results:** In the ICI and Control groups, 36% and 46% of patients received Abx, respectively. For the ICI group, the difference in KM-estimated median overall survival (OS) was 5.6 months based on receipt of Abx (hazard ratio [HR] 1.70). Abx had no impact on OS for the Control group. Similar trends were observed for progression-free survival (PFS). **Conclusions:** In this exploratory analysis, systemic Abx within 30 days of initiating treatment for R/M HNSCC was associated with decreased survival for patients treated with ICIs compared with patients who did not receive Abx. Use of Abx had no apparent difference in survival in the control group. Further examination of the association between Abx use and clinical outcomes for patients with R/M HNSCC treated with ICIs is needed. Research Sponsor: None.

6511 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Plasma-based tumor mutational burden (bTMB) as predictor for survival in phase III EAGLE study: Durvalumab (D) ± tremelimumab (T) versus chemotherapy (CT) in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) after platinum failure. *First Author: Weimin Li, AstraZeneca, Cambridge, MD*

Background: In NSCLC, bTMB assessed from circulating tumor DNA shows promise as a predictive survival biomarker for immunotherapy, but its value in R/M HNSCC is uncertain. We evaluated bTMB as a predictor of survival in R/M HNSCC. **Methods:** EAGLE (NCT02369874) was a randomized, open-label, phase 3 trial evaluating D (anti-PD-L1), or D+T (anti-CTLA-4), vs CT in R/M HNSCC. Patients (pts) with disease progression after platinum-based CT were randomized (1:1:1) to D (10 mg/kg intravenous [IV] every 2 weeks [Q2W]), D (20 mg/kg IV Q4W) + T (1 mg/kg IV Q4W for up to 4 doses, followed by D at 10 mg/kg Q2W) or CT. bTMB was assessed in pretreatment plasma samples using the Guardant Health OMNI platform. Association of somatic loss of function mutations with OS was assessed. **Results:** 736 intent-to-treat pts were randomized; 247 were evaluable for bTMB (BEP). bTMB expression was not linked to HPV status, PD-L1 status, age, gender, tumor location, or ECOG PS. Smoking and progression within 6 months on multi-modality CT in localized disease trended with higher bTMB. OS and PFS HRs were significantly improved for D or D+T vs CT in pts with high bTMB (≥16 mut/Mb) vs low (<16 mut/Mb; Table). The benefit of D or D+T vs CT in pts with high bTMB generally improved with increasing cutoff. 74 pts (27 D, 20 D+T, 27 CT pts) were bTMB high. 18-month OS rates were higher for D+T (22%; 95% CI 7%–42%) and D (33%; 95% CI 17%–51%) vs CT (0%; 95% CI 0%–0%) in pts with high bTMB. Pts with mutations in *KMT2D*, a HNSCC tumor suppressor gene, showed improved OS for D+T vs CT (HR 0.39; 95% CI 0.18–0.85). A trend of improved OS for D+T vs CT (HR 0.19; 95% CI 0.03–1.03) was also seen in pts with *ATM* mutations. **Conclusions:** This is the first retrospective analysis of a phase 3 trial to show bTMB may be predictive of outcomes for checkpoint inhibitors in R/M HNSCC. In pts with high bTMB, D or D+T improved OS hazards by at least 60%, vs CT at cutoffs ≥16 mut/Mb. Validation of bTMB as a predictive biomarker is ongoing. Clinical trial information: NCT02369874. Research Sponsor: AstraZeneca.

Lenvatinib plus pembrolizumab combination therapy in patients with radioiodine-refractory (RAIR), progressive differentiated thyroid cancer (DTC): Results of a multicenter phase II international thyroid oncology group trial. *First Author: Bryan Haugen, University of Colorado, Aurora, CO*

Background: Lenvatinib is an approved therapy for patients with RAIR DTC. While the overall response rate (ORR) is high, few patients achieve a complete response (CR) and most patients eventually have progressive disease (PD). Combination lenvatinib and pembrolizumab is being explored in many different cancers, and this combination has been approved for advanced endometrial carcinoma. **Methods:** Patients with RAIR DTC with Response Evaluation Criteria in Solid Tumor (RECIST v1.1) measurable PD (<14 months (mo) prior to registration) were enrolled in this single-arm multicenter phase II study. Patients were excluded if they had received previous VEGFR-directed multikinase therapy. The lenvatinib starting dose was 20 mg/day orally and pembrolizumab was 200mg IV every 3 weeks. The primary endpoint was CR. ORR, progression-free survival (PFS) and safety graded by Common Terminology Criteria for Adverse Events v4.0 were secondary endpoints. **Results:** Thirty patients were enrolled. The median age was 62.5 years, and 53% of the patients were women. Seventy percent of patients had grade 3 adverse events (AEs) and 10 percent had grade 4 AEs. There were no treatment-related deaths. The most common > grade 3 AEs were hypertension (47%), weight loss (13%), maculopapular rash (13%), leukopenia (7%), diarrhea (7%) and oral mucositis (7%). Twenty-one patients (70%) required lenvatinib dose reduction. Of 29 evaluable patients, 18 (62%) had a partial response (PR) and 10 (35%) had stable disease (SD). The clinical benefit rate (ORR +SD) was 97%. Median time to tumor nadir was 7.4 mo (1.6-17.8 mo). Median PFS was not yet reached. The PFS at 12 months was 74%. Median time on therapy was 9.9 mo (3.2-18.9 mo). Fourteen patients are continuing therapy (7.6-18.9 mo). Six of these patients (43%) have not yet reached tumor size nadir. Three patients (10%) had > 80% target tumor shrinkage. **Conclusions:** Lenvatinib plus pembrolizumab is reasonably tolerated in patients with RAIR DTC. To date, there have been no documented complete responses. Combination lenvatinib plus pembrolizumab therapy has a high ORR in patients with RAIR DTC. Continuation of this study will help determine the depth and length of the responses. Clinical trial information: NCT02973997. Research Sponsor: Merck and Eisai, International Thyroid Oncology Group.

A phase II study of nivolumab (N) plus ipilimumab (I) in radioidine refractory differentiated thyroid cancer (RAIR DTC) with exploratory cohorts in anaplastic (ATC) and medullary thyroid cancer (MTC). *First Author: Jochen H. Lorch, Dana-Farber Cancer Institute, Boston, MA*

Background: Treatment options for aggressive TC are limited. Pre-clinical data suggests efficacy of CTLA-4 plus PD-1 blockade in aggressive RAIR TC. **Methods:** This investigator initiated phase II study tested N (3mg/kg every 2 weeks) plus I (1mg/kg every 6 weeks) until disease progression or completion of 24 mo of treatment in RAIR differentiated TC including poorly differentiated TC (PDTC) with exploratory cohorts in anaplastic (ATC) and medullary TC (MTC). Radiographic response rate by RECIST v1.1 (CR+PR) was primary endpoint. At least 6 pts with disease response among n=32 DTC provided 84% power to distinguish between a 10% and a 25% RR (one-sided 9% binomial test). **Results:** Accrual is complete with n=32 patients with DTC, 10 with ATC and 7 with MTC enrolled between October 2017 and May 2019. Thirty-two DTC included: n=17 papillary, n=7 Hurthle, n=4 follicular TC, n=4 PDTC. Among n=49, median (range) age was 65 (30-88), 51% (25/49) were female. To date, in DTC, 3/32 achieved a PR (n=2 Hurthle and n=1 PDTC), 9.4% RR (.95CI:2%-25%). One near complete response has been observed. Among pts w ATC, 3/ 10 profound PR by RECIST occurred (30% RR, .95CI: 7%-65%). Among them, two remain without clear evidence of disease at 26 and 13 mo after treatment start. No PR's were observed in MTC. Most frequent grade 3-4 TRAEs were as expected and included increased lipase (n=8), increased serum amylase (n=4). There was an unexpected number of treatment related adrenal insufficiency (AI) (n=4) which was associated with long PFS (range 10.1—16.4+mo). **Conclusions:** N+I appears to have considerable activity in ATC. In unselected RAIR DTC, activity was low but responses were seen in PDTC and Hurthle cell TC. Exceptional responses with prolonged remissions were observed. Clinical trial information: NCT03246958. Research Sponsor: Bristol-Myers-Squibb.

Atezolizumab combinations with targeted therapy for anaplastic thyroid carcinoma (ATC). *First Author: Maria E. Cabanillas, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ATC is a rare/aggressive cancer with dismal outcome. Dabrafenib/trametinib is approved for BRAF-mutated ATC but pts eventually develop resistance. There are no approved drugs for pts with BRAF-wild type ATC. Better treatments (tx) are needed. **Methods:** ATC pts with PS $<$ 3 enrolled on a prospective trial at a single center, and tx was assigned by driver mutation: BRAF (cohort 1), RAS, NF1, or NF2 (cohort 2), or none of these (cohort 3). Cohort 4 with paclitaxel was exploratory for pts who did not qualify for 1-3. All pts received atezolizumab (A) IV + targeted therapy. Cohort 1 had run-in with vemurafenib (V) 960mg BID/cobimetinib (C) 60mg QD po for 28 days, followed by A 840mg Q2 weeks, at which time V dose was decreased to 720mg BID. Cohort 2: A + C (same doses as cohort 1); cohort 3: A 1200 mg Q3 weeks + bevacizumab 15 mg/kg q3 weeks. Pts unable to swallow used alternative drug preparation (ADP; crushed vemurafenib, suspension cobimetinib). Primary objective is to determine whether the tx in cohorts 1-3 leads to improved overall survival (OS). The trial was designed to enroll 36 pts but we are reporting early due to positive findings. Response rate (RR) was measured by RECISTv1.1. Median OS was estimated by Kaplan-Meier method. cfDNA and biopsy were obtained at baseline, course 2 and progression. Pts were allowed to undergo surgery and radiation while on trial. **Results:** From August 2017-January 2020, 34 ATC pts were enrolled in cohorts 1-3 and 9 in cohort 4. Cohort 3 closed early for futility. 3 pts had ADP. Median follow-up time was 7.51 mos (range: 0.43 – 27.37). Median OS in cohorts 1-3 was 18.23 mos (CI 10.45-NE) and 1-year OS was 67% (95%CI: 45%, 82%). See table. Response rate (RR) in cohort 1 was 71%: CR 1/17 (6%), PR 11/17 (65%), SD 4/17 (23%), 1 never restaged; in cohort 2 RR was 7%: PR 1/14 (7%), SD 7/14 (50%), PD 4/14 (29%), 2 died early. 8 (24% of cohort 1-3) pts had complete tumor resection after tx with VCA (n = 7) or CA (n = 1); all but 1 of these pts are alive. AEs as expected. cfDNA data will be reported at meeting. **Conclusions:** Atezolizumab + vemurafenib/cobimetinib for BRAF-mutated or + cobimetinib for NF1/2 or RAS-mutated ATC is effective, as evidenced by the long OS in these pts (13 mos $>$ historical control). A significant number of patients, particularly in cohort 1, were able to undergo complete tumor resection due to a favorable response to tx. Clinical trial information: NCT03181100. Research Sponsor: Genentech.

Female [N (%)]	17 (50%)	
Age, in yrs [median (range)]	66 (44-74)	
	N	Median OS in mos (95%CI)

Concurrent cetuximab (CTX) and nivolumab (NIVO) in patients with recurrent and/or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC): Results of phase II study. *First Author: Christine H. Chung, Moffit Cancer Center, Tampa, FL*

Background: While anti-Programmed Death-1 (anti-PD-1) inhibitors have efficacy, only some patients (pts) with R/M HNSCC achieve clinically significant benefits. We designed the study to determine the 1-year overall survival (OS) rate of concurrent CTX and NIVO in patients who had progressed on at least one prior treatment for their R/M HNSCC. **Methods:** Pts were treated with CTX 500 mg/m2 IV on Day (D) -14 as a lead-in followed by CTX 500 mg/m2 IV and NIVO 240 mg/m2 IV on D1 and D15 every 28-D cycle (C). Pts with CTX infusion reaction or who did not receive C1D1 for any reason were non-evaluable and replaced. NIVO dose reduction was not allowed but withheld/discontinued based on adverse event (AE) severity. **Results:** Total 47 pts are enrolled. 2 pts are non-evaluable. 45 evaluable pts are analyzed. Median age is 64 (24-77). ECOG performance status at baseline is 0 (9, 20%), 1 (33, 73%), and 2 (3, 7%). Primary sites are oral cavity 10 (22%), oropharynx 24 (53%), hypopharynx 3 (7%), larynx 6 (13%), and unknown primary 2 (4%). p16 status is available in 33 (73%). Prior treatments before the study enrollment are: chemotherapy (CT) 42 (93%), no CT 3 (7%), radiotherapy (RT) 38 (84%), no RT 7 (16%), checkpoint inhibitors (CPI) 23 (51%), and no CPI 22 (49%). PD-L1 combined positive scores (CPS) is available in 30 (67%). Median follow up time for overall survival (OS) is 12.6 months. The most common grade 3 treatment-related AE (TRAE) occurring $\geq$2 are fatigue 6 (13%) and rash-acneiform 2 (4.4%). The only grade 4 TRAE is CTX infusion reaction in 1 (2.2%). The most common grade 3 immune-related AE (IRAE) occurring $\geq$2 is fatigue 3 (6.7%). No grade 4 IRAE is observed. The median progression-free survival (PFS) and median OS are summarized in Table. Pts with no prior exposure to CPI have favorable PFS and OS relative to pts with prior CPI (PFS: HR 0.49, 95% CI 0.25-0.97, p=0.04 and OS: HR 0.5, 95% CI 0.22-1.14, p=0.09). **Conclusions:** Our data suggest the combination of CTX and NIVO is active in pts without prior CPI exposure and overall well tolerated in all pts. These preliminary results support further evaluation of the combination in CPI naïve pts. Clinical trial information: NCT03370276. Research Sponsor: Eli Lilly, Bristol Myers-Squibb, James and Esther King Biomedical Research Program.

Combination of monalizumab and cetuximab in recurrent or metastatic head and neck cancer patients previously treated with platinum-based chemotherapy and PD-(L)1 inhibitors. *First Author: Roger B. Cohen, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Monalizumab is a first-in-class immune checkpoint inhibitor targeting Natural Killer Group 2A (NKG2A), which is expressed on subsets of Natural Killer (NK), gd T and tumor-infiltrating $CD8^+$T cells. NKG2A blockade promotes innate anti-tumor immunity mediated by NK and $CD8^+$T cells and enhances NK cell antibody-dependent cell-mediated cytotoxicity induced by cetuximab. In a Phase I study, the combination of monalizumab and cetuximab was well tolerated. In an initial expansion cohort 1 of 40 patients (pts) who had progressed after platinum-based therapy, we reported an overall response rate (ORR) of 27.5%, a 4.5 month median PFS and an 8.5 month median OS. In a subset of patients (n=18) previously treated with PD-(L)1 inhibitors (IO), corresponding results were 17%, 5.1, and 14.1 months, respectively (ESMO 2019). Here we present data from a second expansion cohort 2 (n=40) conducted specifically in the post-IO setting to independently confirm the cohort 1 results. **Methods:** Eligible patients had R/M SCCHN previously treated with platinum and a PD-(L)1 inhibitor. Pts received monalizumab 750 mg q2weeks and cetuximab according to the label until progression or toxicity. Cohort 2 was designed as a confirmatory multicenter single arm phase II study, with a pre-planned total of 40 patients. The primary endpoint was ORR assessed per RECIST 1.1. **Results:** As of January 31, 2020, 40 pts have been treated in cohort 2. Median follow-up is 7.3 months (range, 1.9-13.6+). Eight (8) pts have a confirmed partial response (PR); ORR is 20% [95% confidence interval: 11-35]. Median time to response is 1.6 months [1.6-5.3]. At the time of data analysis, 3 pts were still in PR and 3 pts had stable disease continue on treatment. PFS and OS are still immature. **Conclusions:** In pts previously treated with platinum and PD-(L)1 inhibitors, the combination of monalizumab and cetuximab demonstrated promising activity. The second extension cohort confirmed prospectively the ORR reported in cohort 1. A randomized phase III trial of monalizumab and cetuximab is planned in this platinum and IO-pretreated SCCHN population. Clinical trial information: NCT02643550. Research Sponsor: INNATE PHARMA, Pharmaceutical/Biotech Company.

6517 Poster Discussion Session; Displayed in Poster Session (Board #178), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Updated analysis of the inducible T-cell co-stimulatory receptor (ICOS) agonist, GSK3359609 (GSK609), combination with pembrolizumab (PE) in patients (pts) with anti-PD-1/L1 treatment-naïve head and neck squamous cell carcinoma (HNSCC). *First Author: Eric Angevin, Gustave Roussy Institut de Cancérologie, Villejuif, France*

Background: INDUCE-1 (NCT02723955) is a first-in-human study investigating GSK609, an IgG4 ICOS agonist non-T-cell depleting antibody, as monotherapy and combination therapy with anti-cancer agents that includes PE. A range of GSK609 dose levels (≥0.1–1 mg/kg) having biological and clinical activity were identified and evaluated in the expansion phase with GSK609 0.3 mg/kg selected as the dose for further investigation. Results from the HNSCC expansion cohorts (ECs) showed GSK609 has single agent activity in pts with relapsed/refractory disease, and early clinical activity in combination with PE in pts with anti-PD-1/L1 treatment-naïve disease (Rischin, et al. *Annals of Oncol* 2019;30[Supplement_5]:v454–5). Updated results from the GSK609/PE HNSCC EC are presented. **Methods:** Eligible pts for the HNSCC EC had anti-PD-1/L1 treatment-naïve disease, ≤5 prior lines of therapy, measurable disease, and no active autoimmune disease. Pts received GSK609 0.3 mg/kg + PE 200 mg every 3 weeks (wks) until disease progression or unacceptable toxicity, up to 2 years (yrs)/35 cycles. Disease assessments were performed every 9 wks through wk 54 then every 12 wks thereafter. Pts were followed for survival and subsequent anti-cancer therapy. **Results:** As of 11 October 2019, 34 pts were enrolled and evaluable for efficacy analyses. The median age of this population was 61.5 yrs (range: 37–77); 85% were male; 53% received ≥1 prior line of therapy in the metastatic setting. ORR was 26% (95% CI: 12.9, 44.4; n = 9 with 4 complete and 5 partial responses); disease control rate was 68% (95% CI: 49.5, 82.6; n = 23). Among pts with PD-L1 IHC status by 22C3 pharmDx assay (n = 24; 71%), the majority of pts with a response or stable disease (SD) had PD-L1 CPS status < 20 (11 of 15 pts including 1 SD pt with CPS < 1). Median PFS was 5.6 months (95% CI: 3.9, 6,2). Median OS was not reached at time of analysis (95% CI: 8.2, NR); 6-month OS rate was 84% (95% CI: 66, 93). Treatment-related adverse events were reported in 66% of pts; the majority of events were Grades 1 or 2 with < 10% of pts experiencing ≥ Grade 3 events. **Conclusions:** This updated analysis with a more mature dataset shows promising clinical activity that supports further randomized investigation of GSK609 in combination with PE with an OS endpoint in HNSCC. Clinical trial information: NCT02723955. Research Sponsor: Study is funded by GlaxoSmithKline and in collaboration with Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

A prospective phase II open-label randomized controlled trial to compare mandibular preservation in upfront surgery to neoadjuvant chemotherapy followed by surgery in operable oral cavity cancer. *First Author: D. Chaukar, TMH, Mumbai, India*

Background: The study objective was to evaluate the non-Inferiority of survival and ability to preserve mandible with the use of neoadjuvant chemotherapy (NACT) in locally advanced oral cancers compared to upfront surgery alone without compromising survival. **Methods:** This study was a randomized, single centre, non-inferiority trial. Eligibility criteria included treatment naïve histologically confirmed cancer of the oral cavity; cancers requiring segmental resection for paramandibular disease without clinicoradiological evidence of bone erosion, clinical T2, T3 and T4, any N, M0 as per TNM (AJCC) 7th edition, age at least 18 years; and written informed consent. The patients were randomly assigned (1:1) to receive either upfront surgery followed by adjuvant treatment (Standard arm-SA) or receive two cycles of three drugs NACT (Docetaxel, Cisplatin, 5-Flurouracil) at three weekly interval (Intervention arm-IA). Depending on the response after two cycles, the patient would either receive an additional third cycle or undergo surgery followed by adjuvant treatment as decided by the tumour board. The primary endpoint was mandible preservation rate at 30% in the experimental arm. The secondary end points being Loco regional control and treatment related toxicity. **Results:** Between September 2010 and April 2013, 68 patients were enrolled and randomized to SA (34 patients) and IA (34 patients) with a median follow-up of 3.6 years (IQR 0.95- 7.05 years). Majority of the patients were T4 (n = 40, 58.8%) In the IA 28 patients had partial response (n = 28,82.4%), with a mandible preservation (Marginal Mandibulectomy) rate of 48% (n = 16/34). There were no close or positive margins in the IA. All patients received adjuvant treatment. The number of recurrences was similar in both the arms. All patients in the IA developed toxicities with the majority developing Grade III-IV toxicities (Grade III: 14, 41.2%, Grade IV: 11, 32.4%) (p = 0.739). The disease free survival (DFS) (p = 0.715, HR 0.911[0.516-1.607]) and overall survival (OS) (p = 0.747, HR 0.899 [0.510-1.587]) were similar in both the arms. **Conclusions:** NACT seems to be a feasible option for mandibular preservation with acceptable toxicities in a select group of patients without compromising survival. However this needs to be tested in a larger phase III randomized trial. Clinical trial information: CTRI/2015/11/006396. Research Sponsor: Tata Memorial Centre Intramural Funds.

6519 Poster Discussion Session; Displayed in Poster Session (Board #180), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

A multicenter phase II trial of the combination cisplatin/ docetaxel/ durvalumab/tremelimumab as single-cycle induction treatment in locally advanced HNSCC (CheckRad-CD8 trial). *First Author: Markus Hecht, Department of Radiation Oncology, Universitatsklinikum Erlangen, Friedrich-Alexander-Universitat Erlangen-Nürnberg, Erlangen, Germany*

Background: PD-1/PD-L1 inhibitors are efficient in head and neck squamous cell cancer (HNSCC). Combination with anti-CTLA4 agents may enhance anti-tumor activity compared to anti-PD-1/PD-L1 monotherapy in different tumor types. In the CheckRad-CD8 trial the typical induction treatment consisting of Cisplatin/Docetaxel was combined with Durvalumab/Tremelimumab. Patients with pathological complete response (pCR) in the re-biopsy after induction treatment or at least 20% increase of intratumoral CD8 density in the re-biopsy compared to baseline entered radioimmunotherapy with concomitant Durvalumab/Tremelimumab. **Methods:** In this prospective multicenter phase II trial, patients with HNSCC stage III-IVB received a single cycle of Cisplatin 30mg/m² d1-3, Docetaxel 75mg/m² d1, Durvalumab 1500mg fix dose d5 and Tremelimumab 75mg fix dose d5. Objectives of this interim analysis were to quantify the effect of the induction treatment on intratumoral CD8 density and the pCR rate and to generate safety data. **Results:** Between Sep 2018 and Dec 2019, 57 patients were enrolled. Median age was 59 years, 22 patients (37%) were current smokers, 27 patients (47%) had oropharyngeal tumors (52% p16 positive). The median pre-treatment intratumoral CD8 density was 335 CD8+ cells/mm². After induction treatment 27 patients (47%) had a pCR in the re-biopsy and further 25 patients (44%) had a relevant increase of intratumoral CD8+ cells (median increase by factor 3.0). Response according to RECIST criteria was CR in 1 (2%), PR in 19 (33%) and SD in 20 patients (35%) (17 patients not evaluable). Adverse events (AE) grade 3-4 appeared in 39 patients (68%) and mainly consisted of leucopenia (43%) and infections (28%). 6 patients (11%) developed grade 3-4 immune-related AEs. In multivariable analysis the intratumoral CD8 density was the only independently significant predictor of pCR (odds ratio 1.0013 per cell/mm², 95%-CI 1.00023-1.0023, p=0.017). 42 patients (74%) continued with Durvalumab/Tremelimumab concomitant to radiotherapy. **Conclusions:** Single cycle induction treatment with Cisplatin/Docetaxel/Durvalumab/Tremelimumab is feasible and achieves a high pCR rate. CD8 density may have a predictive role for further treatment planning in locally advanced HNSCC. Clinical trial information: NCT03426657. Research Sponsor: Astra Zeneca.

GEM20110714: Final overall survival results of the phase III study of first-line gemcitabine plus cisplatin versus fluorouracil plus cisplatin in recurrent or metastatic nasopharyngeal carcinoma. *First Author: Shaodong Hong, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: GEM20110714, the first randomized, phase III study (NCT01528618) of systemic chemotherapy in recurrent or metastatic (R/M) nasopharyngeal carcinoma (NPC), reported significant reduction of disease progression with gemcitabine plus cisplatin (GP) versus fluorouracil plus cisplatin (FP; hazard ratio [HR], 0.55; 95% CI, 0·44–0·68; P < .001). This study establishes GP as the standard-of-care for first-line treatment of R/M NPC. We present the final overall survival (OS) analysis here. **Methods:** In this multicenter, open-label study conducted in China, patients who had an Eastern Cooperative Oncology Group performance status of 0 or 1 and R/M NPC were randomly assigned (1:1) to receive up to six cycles of either GP or FP once every 3 weeks. The primary endpoint was PFS, which has been previously reported; OS was a secondary endpoint. The final OS analysis was conducted with the data cutoff date of December 17, 2019. **Results:** After a median follow-up time of 64.4 months (95% CI, 61.1-67.6), 148 (81.8%) and 165 (91.2%) deaths occurred in the GP and FP arms, respectively. The estimated hazard ratio for OS was 0.723 (95% CI, 0.578 to 0.904; two-sided P = .004). The median OS was 22.1 months with GP versus 18.6 months with FP. The OS probabilities at 1, 3, and 5 years were 79.9% vs. 71.8%, 31.0% vs. 20.4%, and 18.5% vs. 7.6%, respectively. Un-predefined subgroup analyses based on baseline characteristics were consistent with the primary OS analysis. Postdiscontinuation systemic therapy use was similar: GP, 52%; FP, 57%. No new safety signals emerged. **Conclusions:** In patients with R/M NPC, GP is the first regimen to show significant improvement in OS in a phase III randomized study compared with a traditional chemotherapy regimen (i.e. FP). GP should be considered the standard treatment option for these patients. Clinical trial information: NCT01528618. Research Sponsor: None.

Development and validation of a gene expression-based signature predicting efficacy of induction chemotherapy in locoregionally advanced nasopharyngeal carcinoma: A multicenter cohort study. *First Author: Yuan Lei, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Induction chemotherapy (IC) followed by concurrent chemoradiotherapy is the mainstay treatment for patients with locoregionally advanced nasopharyngeal carcinoma (LA-NPC). However, some patients obtain little benefit and experience unnecessary toxicities from IC. We intended to develop a gene expression signature that can identify patients who will benefit from IC. **Methods:** We screened chemoresistance-related genes by comparing gene expression profiles of patients with short-term tumor response or non-response to IC (n = 95) using microarray analysis. Chemoresistance-related genes were quantified by digital expression profiling in a training cohort (n = 342) to obtain a gene signature. We then validated this gene signature in the clinical trial cohort (n = 187) and an external independent cohort (n = 240). **Results:** We identified 43 chemoresistance-related genes associated with the short-term tumor response to IC. In the training cohort, a 6-gene signature was developed that was highly accurate at predicting the short-term tumor response to IC (area under the curve [AUC] 0.87, sensitivity = 87.5%, specificity = 75.6%). We then apply the 6-gene signature to classify patients into the benefit group and the no-benefit group. In the benefit group, patients could benefit from IC in terms of failure-free survival (hazard ratio [HR] 0.54 [95% confidence interval 0.34-0.87]; p = 0.01), while patients in the no-benefit group could not (HR 1.25 [95%CI 0.62-2.51]; p = 0.53). In the clinical trial cohort, the developed 6-gene signature was also highly accurate at predicting the response to IC (AUC = 0.82; sensitivity = 87.5%; specificity = 71.8%). Additionally, IC conferred failure-free survival benefits only on patients in the benefit group (HR 0.37 [95%CI 0.18-0.75], p = 0.004) and not on those in the no-benefit group (HR 0.70 [95%CI 0.27-1.82]; p = 0.46). In the external independent cohort, similar results were observed. **Conclusions:** The 6-gene signature can help select patients who will benefit from IC and thus lay a foundation for a more individualized therapeutic strategy for LA-NPC patients. Network-meta-analysis of chemotherapy in nasopharyngeal carcinoma (MAC-NPC): An update on 8,221 patients. *First Author: Claire Petit, Gustave Roussy, Villejuif, France*

Background: Based on an individual patient data (IPD) network meta-analysis (NMA) of 20 randomized trials and 5,144 patients (pts), the MAC-NPC collaborative group has shown that the addition of adjuvant chemotherapy (AC) to chemo-radiotherapy (CRT) achieved the highest survival benefit in nasopharyngeal carcinoma (NPC; Ribassin-Majed JCO 2017). Here, we updated the meta-analysis with the addition of 8 trials. **Methods:** Trials of Radiotherapy (RT) with or without chemotherapy (CT) in patients with non-metastatic NPC were identified and updated IPD obtained. Both Western and Chinese medical literatures were searched. Overall Survival (OS) was the main endpoint. Fixed and random-effects frequentist NMA models were applied, network heterogeneity and consistency were evaluated. P-score was used to rank the treatments. R software - netmeta package was used to perform the analyses. Treatments were grouped in the following categories: RT alone (RT), induction chemotherapy followed by RT (IC-RT), induction chemotherapy without taxanes followed by concomitant chemoradiotherapy (ICtax(-)-CRT), induction chemotherapy with taxanes followed by concomitant chemoradiotherapy (ICtax(+)-CRT), concomitant chemoradiotherapy (CRT), concomitant chemoradiotherapy followed by adjuvant chemotherapy (CRT-AC) and RT followed by adjuvant chemotherapy (RT-AC). **Results:** Overall 28 trials and 8,214 pts were included. Median follow-up was 7.2 years. There was no heterogeneity in the NMA. There was inconsistency in the main analysis, which disappeared after the exclusion of 2 outlier trials. ICtax(+)-CRT ranked the best treatment for OS with a P-Score of 91%. Hazard ratio [HR, 95% Confidence Interval] for ICtax(+)-CRT was 0.75 [0.59-0.96] compared to CRT and 0.92 [0.69-1.24] compared to CRT-AC (second best treatment in raking with a P-Score of 85%; see league table below). When the 2 types of IC were merged, CRT-AC ranked the first followed by IC-CRT with P-Scores of 93% and 86% respectively, with a HR of 0.97 [0.84-1.14] for CRT-AC vs. IC-CRT. **Conclusions:** This IPD NMA of the treatment of locally advanced NPC demonstrates that the addition of IC or AC to CRT improves disease control probability and survival over CRT alone. Data on progression-free survival, locoregional and distant control will be presented at the meeting. Research Sponsor: french LNCC, PHRC.

6524 Poster Session (Board #185), Fri, 8:00 AM-11:00 AM

Phase II study of consolidative intensity-modulated radiation therapy following first-line palliative systemic chemotherapy for de novo previously untreated metastatic (M1) nasopharyngeal carcinoma. *First Author: Victor Ho-Fun Lee, Department of Clinical Oncology, Queen Mary Hospital, The University of Hong Kong, Hong Kong, Hong Kong*

Background: The prognosis of de novo previously untreated metastatic (M1) nasopharyngeal carcinoma (NPC) at diagnosis is poor, and the role of consolidative intensity-modulated radiation therapy (IMRT) to the primary tumor and the neck following first-line palliative chemotherapy remains unknown. We report a phase II study of consolidative IMRT after first-line chemotherapy in previously untreated M1 NPC. **Methods:** Consolidative IMRT was given in prospectively recruited patients whose previously untreated M1 NPC did not progress after 6 cycles of first-line chemotherapy with gemcitabine and cisplatin. The primary study objective was overall survival (OS). Secondary objectives included progression-free survival (PFS), local relapse-free survival (LRFS), regional relapse-free survival (RRFS), response and toxicity. **Results:** Sixty-nine consecutive patients were enrolled. Sixty-four (92.8%) patients received first-line chemotherapy, of which 8 (12.5%) developed progressive disease and another 8 (12.5%) did not receive IMRT despite non-progression to first-line chemotherapy. The remaining 48 patients whose disease controlled after chemotherapy received IMRT, including 18 (37.5%) who received concurrent chemoradiation. OS was significantly better in those who received IMRT (35.1 *versus* 14.2 months; $P < 0.001$), after a median follow-up duration of 3.40 years (range 0.43 years to 12.14 years). PFS, LRFS, and RRFS were also significantly longer in those who received IMRT. Multivariable analyses revealed that IMRT was the only prognostic factor of all survival endpoints. Grade 3 adverse events were observed in 10 (20.8%) patients, mainly mucositis, dysphagia and desquamation. **Conclusions:** Consolidative IMRT was associated with an OS benefit and favorable tolerability among previously untreated M1 NPC patients who had non-progressive disease following first-line chemotherapy. These results support the rationale to further investigate IMRT as part of the initial treatment in this setting. Clinical trial information: NCT02476669. 6526 Poster Session (Board #187), Fri, 8:00 AM-11:00 AM

Association between calcitonin and efficacy of anlotinib in medullary thyroid carcinoma: An analysis based on the ALTER01031 trial. *First Author: Ming Gao, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China*

Background: Calcitonin (Ct) is the most important biomarker for medullary thyroid carcinoma (MTC). In a randomized, placebo-controlled phase IIb trial (ALTER01031, NCT02586350) for MTC, anlotinib exhibited a strong capability not only in PFS prolongation but also in decreasing Ct level. This subanalysis explored the relationship between Ct level and anlotinib efficacy in this trial. **Methods:** Serum Ct of patients (pts) were tested at baseline and on week 6 (after 2 treatment cycles). Correlation between changes in Ct level and changes in target lesion diameters was explored. The influence of baseline Ct level on median PFS for anlotinib treated pts was estimated. Finally, pts in anlotinib arm were divided into two subgroups based on the percentage decline of Ct levels ($>$ 50% vs. $\leq$50%) at week 6. Median PFS (mPFS), median OS (mOS) and objective response rate (ORR) of two groups were compared. **Results:** 86 of 91 enrolled pts (58 in anlotinib arm and 28 in placebo arm) were recorded their serum Ct levels at baseline and no significant difference was observed between two arms (7990.0 ng/L vs. 10891.5 ng/L, $P = 0.192$). After 2 treatment cycles, the Ct level decreased to 4597.5 ng/L in anlotinib arm (n = 50) while increased slightly in placebo arm (12640.0 ng/L, n = 24, $P = 0.006$). For 49 pts in anlotinib arm who had complete assessments at baseline and week 6, roughly linear relationship was observed between Ct levels (X-axis) and target lesion diameters (Y-axis) in percent changes from baseline to week 6 ($y = 0.175x - 0.049$; $r = 0.352$, $P = 0.016$, excluding 3 outliers). Pts with less baseline Ct level ($\leq$ median value vs. $>$ median value) did not show more PFS benefit (17.7 vs. 22.4 months, $P = 0.802$). However, after 2 treatment cycles, a trend of better survival and higher response was observed in pts with high percentage decline of Ct level ($>$ 50%, n = 25) than those with low percentage decline ($\leq$50%, n =25) although without statistical difference (data presented in the table below). **Conclusions:** In ALTER01031, anlotinib showed a strong capability in rapidly decreasing serum Ct. Lower baseline Ct level does not mean better prognosis while a rapid Ct decrease may predict improved survival and treatment response to MTC pts received anlotinib. Clinical trial information: NCT02586350. Research Sponsor: None.

6527 Poster Session (Board #188), Fri, 8:00 AM-11:00 AM

Influence of Eastern Cooperative Oncology Group performance status (ECOG PS), tumor size and age on patient outcomes after anlotinib treatment: A subgroup analysis based on ALTER01031 trial for medullary thyroid carcinoma (MTC). *First Author: Ming Gao, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China*

Background: Anlotinib is a newly developed TKI achieved a nearly 2-fold PFS prolongation in a randomized, placebo-controlled phase 2b trial (NCT02586350) for MTC, the results of which were firstly published in 2019 ASCO annual meeting. This subanalysis examined the influence of baseline demographic (ECOG PS score, age) and tumor size on efficacy in this study. **Methods:** Kaplan-Meier method was applied to estimate the median PFS (mPFS) for subgroups of patients (pts) received anlotinib or placebo based on ECOG PS score (0 vs. 1), median tumor lesion diameter ($<$ 67 vs. $\geq$67mm) and age ($<$ 55 vs. $\geq$55 years old). **Results:** 91 eligible pts were randomly assigned in a 2:1 ratio to receive anlotinib or placebo. The numbers of pts in each subgroup were summarized in the table below. In placebo arm, mPFS did not differ significantly between pts with ECOG PS 0 and 1 (11.3 vs. 11.1months; HR = 0.895 [95% CI 0.347, 2.312], P = 0.821) or between pts with tumor lesion diameter $<$ 67mm and $\geq$ 67mm (7.0 vs. 11.1 months; HR = 1.168 [95% CI 0.463, 2.945], P = 0.737). Conversely, pts in anlotinib arm with ECOG PS 0 obtained more PFS benefits (34.6 vs. 14.0 months; HR = 0.331 [95% CI 0.163, 0.671], P = 0.002). Similarly, anlotinib treated pts with tumor lesion diameters $<$ 67mm achieved a longer mPFS (Not reached vs. 14.0 months, HR = 0.567 [95% CI 0.280, 1.147], P = 0.111). Consistent with that has been verified in differentiated thyroid cancer, high age predicted poor prognosis as mPFS were 14.3 months and 6.8 months in pts $<$ 55 and $\geq$ 55 years old respectively in placebo arm (HR = 0.322 [95% CI 0.116, 0.893], P = 0.007).). Anlotinib treatment exhibited PFS improvement to pts in both age groups but higher PFS prolongation was observed in pts $<$ 55 years old (22.4 vs. 14.0 months; HR = 0.720 [95% CI 0.321, 1.614], P = 0.381). **Conclusions:** This analysis showed that for pts in placebo arm, PFS was similar regardless of functional status (ECOG PS) or tumor size while older pts had higher progression risk. Treatment with anlotinib exhibited greater PFS benefits for pts with better functional status (ECOG PS = 0), younger age or lower tumor burden. These results indicated that it is reasonable to start anlotinib treatment at a relative earlier disease stage before the worsen of ECOG PS, increase of tumor size or ageing. Clinical trial information: NCT02586350. Research Sponsor: None.

Number of pts	ECOG PS (0/1)	Tumor lesion diameter ($<$ 67/$\geq$ 67 mm)	age ($<$ 55/ $\geq$ 55)
Placebo	10/19	12/17	18/11
Anlotinib	25/37	34/28	38/24

6529 Poster Session (Board #190), Fri, 8:00 AM-11:00 AM

A phase II study on the efficacy and toxicity of cabozantinib in recurrent/metastatic salivary gland cancer patients. *First Author: Wim van Boxtel, Radboud University Medical Center, Nijmegen, Netherlands*

A phase II study on the efficacy and toxicity of cabozantinib in recurrent/metastatic salivary gland cancer patients. **Background:** Because c-MET and VEGFR are often overexpressed in salivary gland cancer (SGC), this study evaluated the efficacy and safety of cabozantinib in recurrent/metastatic (R/M) SGC pts. **Methods:** A single center, single arm, phase II study was conducted. Immunohistochemical c-MET positive (H-score $\geq$10) R/M SGC pts were included in 3 cohorts: adenoid cystic carcinoma (ACC), salivary duct carcinoma (SDC), and other SGCs. Objective growth or complaints due to the disease were required before inclusion in the ACC and other SGC cohort. No prior systemic treatments were required. Pts started 60 mg cabozantinib tablets OD. Primary endpoint was the objective response rate (ORR). A Simon two-stage design was used. In case of $\geq$1 objective response in the first 9 pts/cohort, 8 additional pts would be included in the cohort. **Results:** In total 25 pts were included from Sep. 2018 until premature closure due to severe toxicity in Nov. 2019. Median age was 56 years (range 49-72), prior treatments included: primary tumor resection (n=19), radiotherapy $\geq$50Gy (n=24), systemic therapy (n=10; adjuvant in 2 pts, palliative in 8 pts). Six pts had grade 3 (n=4), grade 4 (n=1), or grade 5 (n=1) wound/fistula complications, occurring at a median of 7.2 mths on cabozantinib (range 2.1-12.8). This resulted in a severe wound complication rate of 32% in 19 pts on treatment for $\geq$2 mths. Remarkably, 4 out of 6 pts developed this complication in the area exposed to high-dose Rx; 2/4 had a pre-existing fistula in this area. Median interval between Rx and start of cabozantinib was 71.3 mths (range 10.6-94.7). Other grade $\geq$3 adverse events in $>$1 pt were: hypertension (5 pts), diarrhoea (2 pts) and dehydration (2 pts). Current median follow-up is 6.8 mths. The ORR was 6% (1/17 pts) in the ACC cohort, 20% (1/5 pts) in the SDC cohort, and 0% (0/3 pts) in other SGC pts; median PFS is 12.6 mths (95% CI 6.8 – 18.4 mths), 9.0 mths (insufficient events for 95% CI), and 6.9 mths (95% CI 0 – 15.2 mths), respectively. Median OS is not reached in any cohort. **Conclusions:** This phase II study on cabozantinib in R/M SGC pts demonstrated severe wound and fistula complications in 32% of pts on treatment for $\geq$2 mths, mostly (4/6 pts) within the radiotherapy field. Because of this toxicity the study was closed prematurely. Furthermore, cabozantinib showed minimal clinical activity in SGC pts. Research funding: Ipsen Pharmaceuticals Clinical trial information: NCT03729297. Research Sponsor: Ipsen Pharmaceuticals.

6530 Poster Session (Board #191), Fri, 8:00 AM-11:00 AM

Pembrolizumab (P) or P + chemotherapy (C) versus EXTREME (E) as first-line (1L) therapy for recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC): analysis of KEYNOTE-048 by disease state. *First Author: Danny Rischin, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: In the phase 3 KEYNOTE-048 trial (NCT02358031) in R/M HNSCC (N = 882), 1L P vs E showed superior OS in PD-L1 CPS $\geq$20 and CPS $\geq$1 populations, noninferior OS in the total population, no PFS benefit, and favorable safety; 1L P+C vs E showed superior OS in CPS $\geq$20, CPS $\geq$1, and total populations, no PFS benefit, and comparable safety. Results of P or P+C vs E in incurable recurrent only, metastatic only, and R/M subgroups are shown. The metastatic only and R/M subgroups were combined and classified as metastatic. **Methods:** Patients with incurable recurrent (local and/or regional node recurrent disease) or metastatic HNSCC were randomly assigned 1:1:1 to P, P+C, or E. OS and PFS were estimated using the Kaplan-Meier method. Hazard ratios and 95% CIs were based on a Cox regression model with Efron s method of tie handling with treatment as a covariate stratified by ECOG performance status, HPV status, and PD-L1 status. Data cutoff: Feb 25, 2019. **Results:** In the incurable recurrent only subgroup (n = 252), median OS was 11.5 vs 12.1 mo (P vs E) and 13.0 vs 11.1 mo (P+C vs E). In the metastatic subgroup (n = 620), median OS was 11.4 vs 9.7 mo (P vs E) and 13.0 vs 10.1 mo (P+C vs E). Median follow-up, OS, and PFS are shown in Table. Treatment-related adverse events (TRAE) in the incurable recurrent only subgroup: 49.4% (P), 94.7% (P+C), and 97.8% (E); grade 3-5 TRAEs rates: 16.0%, 78.7%, and 73.3%, respectively. TRAE rates in the metastatic subgroup: 61.6% (P), 96.4% (P+C), and 96.4% (E); grade 3-5 TRAEs rates: 17.6%, 69.5%, and 67.0%, respectively. **Conclusions:** P and P+C vs E were efficacious in the metastatic subgroup; in the relatively smaller subgroup of patients with incurable recurrent only HNSCC, the effect was less pronounced. Consistent with the total study population and regardless of disease state, the safety profile was favorable with P vs E and comparable with P+C vs E. These data further support use of 1L P or P+C in patients with R/M HNSCC. Clinical trial information: NCT02358031. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Disease State	Treatment	Median follow-up, mo	Median OS, mo	HR (95% CI) for OS	Median PFS, mo	HR (95% CI) for PFS
Incurable recurrent only	P (n = 82) vs E (n = 94)	11.5 vs 12.1	11.5 vs 12.1	1.09 (0.79-1.51)	2.6 vs 6.3	1.81 (1.32-2.49)
Incurable recurrent only	P+C (n = 76) vs E (n = 88)	13.0 vs 11.1	13.0 vs 11.1	0.92 (0.66-1.28)	4.8 vs 6.2	1.22 (0.88-1.70)

6531 Poster Session (Board #192), Fri, 8:00 AM-11:00 AM

Initial analyses of a phase I/II trial of durvalumab (D) plus tremelimumab (T) and stereotactic body radiotherapy (SBRT) for oligometastatic head and neck carcinoma. *First Author: Houda Bahig, Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada*

Background: PD-1/PD-L1 +/- CTLA-4 blockade in head-and-neck carcinoma (HNSCC) has shown signs of clinical activity. SBRT aims to reduce tumor burden and perhaps be immune-stimulatory. This analysis seeks to assess the safety and efficacy signal of the triple treatment combination (TTC) consisting of SBRT sandwiched between cycles of D (αPD-L1) and T (αCTLA-4) in oligometastatic (2-10) HNSCC. **Methods:** This is a single arm multi-institutional phase I/II trial (NCT03283605). D (1500 mg) and T (75 mg) were given for 4 monthly cycles, followed by monthly D. SBRT to 2-5 lesions was administered during cycle 2. The median prescribed and maximum SBRT doses were 40 Gy (range:18-50) and 49 Gy (range:28-61), respectively, given in 3-5 fractions. Global health status was derived from EORTC QLQ C30 questionnaires. **Results:** At data cut-off (Dec 31, 2019), 20 patients were recruited, of which 16 had a study treatment and were analyzed. Table describes the patient characteristics. There were 1 CTCAE V5.0 Grade 2 and 1 Grade 3 (both GI) serious adverse event (SAE) attributable to D and T. Two patients had unrelated SAEs (1 Grade 3-hypercalcemia and 1 Grade 5-GI). The Grade 5 SAE was a gastric hemorrhage that occurred the night of the first D + T infusion. There was no Grade 3+ AE secondary to SBRT. Thus, SBRT did not add to the 2/16 patients who had D + T related SAEs. Global health status scores did not differ statistically between baseline (75) and cycle 3 (73). Of the 14 patients that received SBRT, 7 patients had RECIST target lesions untreated by SBRT. The best responses for these 7 patients were: 1 CR, 3 PR, and 3 SD. When SBRT treated lesions are included and analyzed per RECIST (n = 14), there were 9 PR, 3 SD and 2 PD. The estimated median progression free survival was 7.2 months. **Conclusions:** The first 16 evaluable patients demonstrated tolerable profiles to the TTC (D + T + SBRT) for the treatment of oligometastatic ($\leq$10 lesions) HNSCC. Best response rates were encouraging and could be due to the addition of SBRT during immunotherapy that served to either stimulate the immune system or annihilate slow responding or immunotherapy resistant lesions. Smaller overall tumor burden and 7/16 patients being treated in first line could also have contributed to better results. Clinical trial information: NCT03283605. Research Sponsor: AstraZeneca.

HANNA: Real-world outcomes from an observational study with nivolumab in patients with recurrent or metastatic squamous cell carcinoma of the head and neck in Germany. *First Author: Andreas Dietz, Universitaetsklinikum Leipzig, Leipzig, Germany*

Background: Nivolumab has demonstrated efficacy in clinical trials of recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN). As only limited real-world data are available, we describe the use of nivolumab and its outcomes in routine clinical practice. **Methods:** HANNA is a prospective, observational study of patients with R/M SCCHN treated with nivolumab in 56 hospitals and practices in Germany. In total, 385 patients will be followed for $\leq$ 5 years from treatment initiation until death, withdrawal of consent, loss of follow-up/record, or end of study. The primary objective is overall survival (OS). Secondary objectives include baseline characteristics, safety profiles, and quality of life (QOL) assessment. **Results:** By November 2019, data from 311 patients were available. Median follow-up was 3.5 months. Baseline characteristics were male, 81.7%; median age, 63 years; history of smoking, 73.3%; Eastern Cooperative Oncology Group performance status (ECOG PS) 0/1, 60.8%; ECOG PS 2/3, 29.6%. Location of primary tumor was oropharynx, 38.3%; hypopharynx, 20.9%; oral cavity, 22.8%; larynx, 11.6%; others, 6.4%. 55.6% of R/M SCCHN patients progressed $\leq$ 6 months after platinum-based therapy, whereas 43.4% were platinum-sensitive (progressed $>$ 6 months after platinum-based therapy). Nivolumab was received by 25.1% of patients as first therapy after platinum-based chemo- or radiochemotherapy, by 62.1% as second therapy, and by 12.9% as later line therapy. Median treatment duration was 4.6 months. OS at 1 year was 43.3%. 1-year OS for patients with ECOG PS 0 was 75.9%; ECOG PS 1, 41.2%; and ECOG PS 2, 27.3%. Platinum-sensitive patients had higher 1-year OS probability (51.6%). Drug-related adverse events (grade 1/2) and serious adverse events (grade 3/4) were observed in 28.9% and 10.0% of patients, respectively. Interim QOL data (per FACT-H&N and EQ-5D questionnaire) indicated a tendency toward stabilization or slight improvement. We will present an update of the data with longer follow-up (data cut March 2020). **Conclusions:** HANNA represents one of the largest real-world datasets for nivolumab in R/M SCCHN and comprises a more diverse set of patients than the phase 3 CheckMate 141 trial, including patients with higher ECOG PS, age, and platinum sensitivity. Outcomes from HANNA show that the improved OS, safety, and QOL seen with nivolumab in the real-world setting are consistent with the outcomes from CheckMate 141. Clinical trial information: NCT03114163. Research Sponsor: Bristol-Myers Squibb.

6533 Poster Session (Board #194), Fri, 8:00 AM-11:00 AM

Selection of patients for surveillance imaging after radiotherapy for squamous cell carcinoma of oral cavity and oropharynx. *First Author: Johnathan Zeng, Cleveland Clinic, Cleveland, OH*

Background: NCCN guidelines do not recommend routine surveillance imaging for distant failure (DF) after definitive treatment of head & neck squamous cell carcinoma (SCC). We hypothesized that there exists a subset of patients with sufficiently high enough risk for DF to benefit from surveillance imaging. This study attempts to define high risk cohorts of oropharynx (OP) and oral cavity (OC) patients. **Methods:** A retrospective review was conducted of patients with SCC of the OP or OC at a single tertiary care institution from 1994-2019. Patients were staged according to AJCC 7th edition and included in this study if they completed definitive-intent treatment and received 60 Gray or higher of radiotherapy (RT). Local, regional, and distant failure were estimated with cumulative incidence. Univariable & multivariable risk factors for DF were identified with Fine & Gray competing risk regression. Significant variables were compiled to calculate a risk score. **Results:** 863 patients were included (676 OP/187 OC). OC patients were 60.4% male, median age 61, with median follow up of 77.5 months. Smoking status was 27.3% current, 44.4% former, 28.3% never, with 30 median pack years. Disease was 57.3% T1-2, 42.7% T3-4, 55.6% N0-2a, 44.4% N2b-3. 94.1% had surgery & 34.3% had concurrent systemic therapy. OP patients were 87.9% male, median age 58, 96.3% HPV+, with median follow up of 60.8 months. Smoking status was 20.9% current, 44.5% former, 34.6% never, with 20 median pack years. Disease was 67.9% T1-2, 32.1% T3-4, 29.9% N0-2a, 70.1% N2b-3. 11.5% had surgery & 87.3% had concurrent systemic therapy. Specifically, 52.2% of OP patients received concurrent cisplatin, 10.6% concurrent cetuximab, and 24.5% other systemic therapies. 11.7% of patients experienced DF, of which 77% failed in the lung. Within the OC cohort, nodal stage 2b or higher was the only predictive factor (HR 3.26, $p < 0.001$), conferring a 3 year risk of DF of 34% vs 10%. Within the OP cohort, a high risk cohort of 87 patients (12.9%) was identified with a 3 year incidence DF of 22%, compared to 10% or less in lower risk cohorts. This high risk cohort consisted of active smokers treated with definitive RT and either concurrent cisplatin or no concurrent therapy, with at least T3 and N2b disease, as well as any patients treated with definitive RT and concurrent cetuximab. **Conclusions:** We identified groups of OC & OP patients with greater than 20% risk of developing DF at 3 years, the majority of which occurred in the lung. Surveillance imaging of the chest should be considered for patients meeting these criteria. Research Sponsor: None.

Distinct transcriptional profiles in plasma exosomes associated with recurrence of nasopharyngeal carcinoma patients with standard treatment. *First Author: Yongjiang Li, West China Hospital, West China Medical School, Sichuan University, Chengdu, China*

Background: Nasopharyngeal carcinoma (NPC) is endemic with a high prevalence in Southern China, Asia,cetuximab and North Africa. Exosomes are small vesicles containing a wide range of functional proteins, mRNA and miRNA. In the progression of NPC, the tumor cells constantly release exosomes into the surrounding environment and also into the circulating blood. The aim of this study was to explore the association between RNA expression in plasma exosomes and prognosis of NPC patients after standard treatment. **Methods:** In this retrospective study, a total of 25 eligible NPC patients were included: 12 patients in the recurrence (R) subgroup and 13 patients in the no recurrence (NR) subgroup. RNA was extracted from the exosomes of plasma specimens which were collected at West China Hospital, Sichuan University. Gene expression profiles were conducted by using the RNA-sequencing platform. The DESeq2 package was used to analyze the differentially expressed genes (DEGs) between R and NR subgroups. The gene set variance analysis (GSVA) was performed to explore C5 gene sets enrichment related to the recurrence after standard treatment. **Results:** We observed 332 DEGs between R and NR subgroups, which include 125 up-regulated and 207 down-regulated genes (R vs. NR,|log2fold change|$>$1, $p$$<$0.05). Moreover, hierarchical clustering analysis of the 332 DEGs revealed that all samples clustered into two subgroups, with cluster 1 containing 82% (9/11) recurrence patients and cluster 2 containing 79% (11/14) no recurrence patients. Further, univariate Cox regression analysis showed that 293 out of 332 DEGs were significantly correlated with DFS ($p$$<$0.05), such as TRAM1, CAPN1, SAT1 and ACTB. GSVA and Log Rank test of survival data demonstrated that a total of 824 pathways/biological processes were significantly different between R andNR subgroups ($p$$<$0.05). Specifically, the top 9 pathways/biological processes, such lipoxygenase pathway, rough endoplasmic reticulum membrane and low density lipoprotein particle clearance, was mainly enriched in the NR subgroup (p $<$0.001). **Conclusions:** Profiling of plasma exosomes RNA in NPC patients reveals distinctive gene expression pattern between patients with or without recurrence. Further functional analysis revealed that top enriched 9 pathways/biological processes may correlate with a favorable prognosis and are worth investigating. Moreover, for the prognosis of patients with NPC, RNA expression of plasma exosomes may be a potentially valuable research object. Dendritic cell therapy with CD137L-DC-EBV-VAX in locally recurrent or metastatic nasopharyngeal carcinoma (NPC). *First Author: Robert John Walsh, Department of Haematology-Oncology, National University Cancer Institute, National University Health System, Singapore, Singapore*

Background: Epstein-Barr virus (EBV) is associated with non-keratinising (NK) NPC, a disease prevalent in Southeast Asia, and provides a potential target for dendritic cell (DC) vaccine therapy. CD137 ligand (CD137L) expressed on antigen presenting cells costimulates CD137 expressing T cells upon receptor/ligand interaction. CD137L signalling differentiates monocytes to CD137L-DC, a novel type of DC, which are more potent than classical DC in stimulating autologous T cells. Here, we explore the safety and efficacy of autologous CD137L-DC pulsed with EBV peptides spanning Epstein Barr nuclear antigen 1, latent membrane protein 1 (LMP1) and LMP2 (CD137L-DC-EBV-VAX) in patients with locally recurrent or metastatic NPC. **Methods:** In this single centre, phase I study, eligible patients (pts) with locally recurrent or metastatic NK-NPC and clinical benefit (CB) from their prior treatment (stable disease [SD], partial [PR] or complete response[CR]), underwent apheresis to isolate monocytes which were differentiated to CD137L-DC through CD137L agonist exposure. CD137L-DC were pulsed with EBV antigens during maturation to obtain CD137L-DC-EBV-VAX which was administered intradermally every 2 weeks (w) for up to 7 injections following site preconditioning with Tetanus and Diphtheria vaccine. **Results:** 14 pts were enrolled of which 2 progressed rapidly and did not begin treatment. Mean age was 58 years. Median lines of prior treatment for metastatic NPC was 1 (range 1-6), the most common being cisplatin and gemcitabine. 9 pts received 7 vaccine doses (range 2-7) with a mean administered cell count of 23.9x10^6. CB was seen in 5 cases (42%) with 1 PR and 4 SD beyond 1 year. Median progression free survival (mPFS) was 26w (95% CI, 23-43). The lowest PFS (8w) was in a pt with 6 prior lines of treatment including a checkpoint inhibitor. Mean pretreatment neutrophil: lymphocyte ratio (NLR) was 3.4 and a value of less than 3 was associated with prolonged mPFS (42 *vs* 14w, p = 0.01). Enzyme linked immune absorbent spot (ELISPOT) analysis in 5 pts with CB showed a rise in interferon-γ secreting peripheral T cells prior to the 3rd vaccine versus baseline. Treatment was well tolerated with only 4 cases of grade 1 related adverse events reported, most commonly injection site reaction (3pts). **Conclusions:** CD137L-DC-EBV-VAX is safe and exhibits promising efficacy when administered following CB from chemotherapy. A rise in activated peripheral blood mononuclear cells after 2 vaccinations in selected patients showing benefit suggests immunological correlates with efficacy. Clinical trial information: NCT03282617. Research Sponsor: National Medical Research Council (Singapore) - NMRC/BnB/0018c/2015.

Cisplatin every three weeks versus weekly cisplatin or carboplatin with definitive radiotherapy for squamous cell carcinoma of the head and neck is associated with improved overall survival in a representative national population. *First Author: Michael Gerard McCusker, University of Maryland Medical Center, Baltimore, MD*

Background: For patients with primary untreated locally advanced head and neck squamous cell carcinoma (PULA-HNSCC), high dose once every 3 weeks cisplatin (HDC; 100 mg/m^2) added to curative radiotherapy (RT) prolongs survival, but is associated with severe toxicities. Concurrent chemoradiation (CRT) with low dose weekly cisplatin (LDC; 30-40 mg/m^2), carboplatin (C), or RT alone is often substituted for HDC. We estimated and compared overall survival (OS) and acquired toxicities among Medicare beneficiaries treated with CRT using HDC, LDC, C, or RT. **Methods:** Patients diagnosed from 2004-2011 with PULA-HNSCC (stages III-IVB AJCC 6th and 7th editions) of the oropharynx (OPC), hypopharynx (HP), or larynx (L) who received definitive RT or CRT were identified using the linked SEER-Medicare database. An analytic cohort of patients receiving CRT with HDC, LDC, or C was constructed using well-established eligibility criteria. OS was estimated and compared between patients grouped by treatment received utilizing a multivariable stratified propensity scores weighted Cox regression model, including demographic and disease characteristics. Toxicities were compared using exact common odds-ratio and Fisher's tests. **Results:** We identified 1,335 patients that received RT: OPC (n = 731), HP (n = 174), or L (n = 430). Out of those, patients were treated with HDC (n = 264), LDC (n = 259), C (n = 353), or RT alone (n = 459). Median OS (years) was 5.61 (95% CI = 4.58-7.69) for HDC, 3.7 (95% CI = 3.1-4.79) for LDC, 3.1 (95% CI = 2.48-3.86) for C, and 1.36 (95% CI = 1.19-1.58) for RT, respectively. OS was significantly greater for HDC than for LDC (HR = 1.35, 95% CI = 1.06-1.72, p= 0.02), C (HR = 1.41, 95% CI = 1.12-1.76, p= 0.003), or RT (HR = 2.1, 95% CI = 1.68-2.61, p= $<$ 0.001). Treatment with HDC compared to LDC was not associated with increased prevalence of dysphagia or neutropenia. HDC was associated with hearing loss when assessed at 9-12 months post-diagnosis (p =0.03). **Conclusions:** In SEER-Medicare beneficiaries with PULA-HNSCC of the OPC, HP, or L, OS was significantly better for HDC than LDC when accounting for baseline clinical and demographic characteristics and propensity score weights. Toxicities were similar between regimens, except for an increased incidence of the late acute toxicity of hearing loss in HDC. A regimen of HDC improves OS, but needs to be carefully assessed against increased toxicity risk, with hearing loss in particular. Research Sponsor: None.

6537 Poster Session (Board #198), Fri, 8:00 AM-11:00 AM

Association of autoimmunity with survival in patients with recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) treated with immune checkpoint inhibitors (ICIs). *First Author: Panagiota Economopoulou, Attikon University Hospital, Athens, Greece*

Background: ICIs are associated with immune-related adverse events (irAEs) that occur as a consequence of enhanced immune response due to T-cell activation. The objective of this observational cohort study was to investigate the association between irAEs and disease outcome in pts with R/M HNSCC. **Methods:** 110 pts treated with ICIs were reviewed. Overall survival (OS) was calculated from the date of initiation of ICI to the date of death. To overcome guarantee-time bias, we calculated post-irAEs survival from the date of first irAE presentation in patients who developed irAEs or from the date of ICI initiation in pts without irAEs. **Results:** Primary site was the oral cavity (N = 51), oropharynx (N = 20), larynx (N = 29), hypopharynx (N = 1), paranasal sinuses (N = 5) and nasopharynx (N = 4). 41 (37.3%) had metastatic and 69 (62.7%) recurrent disease. 32 pts (29.1%) developed irAEs, with more common thyroiditis (N = 15, 13.6%). Of 100 pts with evaluable disease, 14 (14%) responded. 6/31 (19.4%) with irAEs vs. 8/69 (11.6%) without irAEs responded to ICI (p = 0.354). After a median follow-up of 16.4 months, 69 pts died. Median OS was 10 mo (95%CI, 6.7-13.4), 10 mo (95%CI, 5.6-14.5) for pts with recurrent and 10 mo (95%CI, 7.7-12.3) for pts with metastatic HNSCC (p = 0.966). Median OS was 17.9 mo (95%CI, 7.9-27.9) for pts with irAEs and 6.6 mo (95%CI, 3.3-9.9) for pts without irAEs (p = 0.001). Median post-irAEs survival was 16.3 (95%CI, 7.1-25.5) for pts with irAEs vs. 6.6 mo (95%CI, 3.3-9.9) for pts without irAEs (p = 0.020). Responders to ICI did not differ in median post-irAEs survival irrespective of whether they developed irAEs (p = 0.561), while among non-responders, those who developed irAEs had significantly longer median post-irAEs survival compared to those who did not (10 vs. 6 mo, respectively, p = 0.044). Multiviariate Cox proportional hazard models showed that independent favorable prognostic factors for post-irAEs survival were the development of irAEs (HR 0.54, 95%CI 0.30-0.97, p = 0.039) and response to ICI (HR 0.16, 95%CI 0.05-0.50, p = 0.002). **Conclusions:** The development of irAEs is a strong predictor of improved survival in patients with advanced HNSCC treated with ICIs.
