Background: The current standard treatment for unresectable recurrent/metastatic (R/M) nasopharyngeal carcinoma (NPC) is cytotoxic chemotherapy but prognosis remains poor. Recent phase I-II trials of anti-PD-1 therapy (aPD-1) have demonstrated promising activity in R/M NPC, but the published experience is primarily limited to Epstein-Barr virus (EBV) positive tumors in the Asian population. Here we report our three institutional real-world experience with aPD-1 in patients (pts) with R/M NPC. **Methods:** A retrospective analysis was conducted after IRB approval at the Massachusetts General, Johns Hopkins, and University California San Francisco Hospitals. Demographic and clinical data was collected on pts with R/M NPC who received aPD-1 at the participating institutions. Objective response rate (ORR) was the primary outcome of interest and progression free survival (PFS) and overall survival were secondary outcomes. Univariate and multivariate analyses were conducted to assess association between clinicopathologic factors and outcomes, using logistic regression models. **Results:** A total of 36 pts were identified: 20 pts were treated with pembrolizumab and 16 with nivolumab. Median age was 50 (15-74). Twenty-nine (81%) were male. Twenty pts (56%) were Asian. Twenty-nine pts (81%) had EBV positive disease. Nine (25%) had aPD-1 as first-line therapy (1L). Molecular profiling results were available in 16 pts: TP53 mutation was the most common alteration (25%) and was limited to EBV negative tumors. Median total mutational burden (TMB) was 3/Mb (1-28). Median PD-L1 expression was 10% (0-90). Median follow up was 13.9 months (mos). Objective response was evaluable in all 36 pts: 9 pts achieved objective response (ORR 25.0%, 95% CI 12.1-42.2) with 2 complete responses: EBV positive vs. negative (27.6% vs. 14.2%, P=0.472), Asian vs. non-Asian (25% vs. 25%, P=1.000), and 1L vs. >1L (33.3% vs. 22.2%, P=0.511). Thirteen pts had stable disease (disease control rate 61.1%). Responses were seen in both TMB high (28/Mb) and low (1/Mb) tumors and no association with PD-L1 expression was observed. One-year survival rate was 81.3%. EBV positive pts had a trend towards better survival (84.8 vs. 66.7, P=0.640). Median PFS was 5.5 mos and not different between EBV positive vs. negative pts (5.6 vs. 4.0 mos, P=0.919). **Conclusions:** Our multi-institutional real-world experience with checkpoint inhibitor therapy in R/M NPC confirms that a similar degree of activity is seen as reported in the phase I-II experience in diverse races, but efficacy seems more prominent in EBV positive disease. Research Sponsor: None.

6539 Poster Session (Board #200), Fri, 8:00 AM-11:00 AM

Efficacy and tolerance of carboplatin-cetuximab in patients with metastatic or recurrent head and neck squamous cell carcinoma unfit for extreme regimen. *First Author: Charlotte Le Roy, Tenon Hospital, Paris, France*

Background: Head and neck squamous cell carcinoma (HNSCC) is the fourth cause of death by cancer in France. For metastatic patients, the standard first line treatment is the EXTREME regimen. However, a lot of these patients have a poor performance status (PS) and/or several comorbidities making them unfit for this regimen. We have treated them with carboplatin and cetuximab (simplified EXTREME regimen) since 2007. The aim of this study is to assess the efficacy and tolerance of this regimen in this frail population. **Methods:** We retrospectively reviewed the medical charts of all patients treated with simplified EXTREME regimen for recurrent or metastatic HNSCC in three French academic hospitals between 2007 and 2017. The primary endpoint was overall survival (OS) and secondary endpoints were progression free survival (PFS), overall response rate (ORR), identification of prognostic factors, and toxicity. **Results:** 103 patients were included with a median age of 63 y.o., 60% had a PS 0-1 and 40% a PS 2-3. With a median follow-up of 30.2 months, median OS was 7.2 months and median PFS 3.7 months. ORR was 39% and 24% of patients had disease stabilization. On univariate analysis, a PS of 2 or more was significantly associated with a worse OS (median OS 10.1 months if PS 0-1 versus 4.6 months if PS 2-3; HR = 1.68; 95%CI = 1.11-2.57; p = 0.01). Acute grade 3-4 hematologic and non-hematologic toxicity rates were 25.2% and 27.2%, respectively, with 11.8% of thrombopenia, 9.7% of neutropenia, 10% of skin toxicity, and 12.6% of asthenia. Patients with grade 1 or more skin toxicity had a higher ORR (HR = 3.44; 95%CI = 1.16-10.23; p = 0.03) and a prolonged OS (HR = 0.37; 95%CI = 0.23-0.58; p $<$ 0.0001) and PFS (HR0.29; 95%CI = 0.19-0.47; p $<$ 0.0001). During treatment, 29% of patients had a pain decrease, 13.5% a gain of weight, and 17.2% an improvement in PS. **Conclusions:** This is the largest cohort of patients treated with simplified EXTREME for HNSCC. Simplified EXTREME was well tolerated in this frail population with a high ORR. Patients with a good PS had prolonged survival. Interestingly, skin toxicity of any grade was significantly correlated with treatment efficacy. Research Sponsor: Merck Serono.

6540 Poster Session (Board #201), Fri, 8:00 AM-11:00 AM

Final results of the multicenter, open-label, randomized phase II trial PAZOTHYR evaluating continuous versus intermittent administration of pazopanib in radio-iodine-refractory thyroid cancers (NCT01813136). *First Author: Christelle De La Fouchardiere, Leon Berard Cancer Centre, Lyon, France*

Background: Multikinase inhibitors (MKI) targeting angiogenesis, including pazopanib (P), have shown efficacy in progressive radioiodine refractory thyroid cancers (RAIR-TC) but are accompanied by adverse effects, leading to dose adjustments/interruptions. We aimed to investigate the efficacy and tolerance of a discontinuous scheme of pazopanib administration in this situation. **Methods:** This randomized phase II study enrolled RAIR-TC patients (pts) in first or second-line of MKI with documented disease progression within 12 months (m). After a 6-m pazopanib continuous induction phase, pts with stable disease (SD) or tumor response were randomly assigned in a 1:1 ratio to receive continuous pazopanib (CP) or intermittent pazopanib (IP) until progression and restart. They were stratified by best tumor response [stable disease vs. objective response] and prior MKI treatment [yes vs. no]). Primary endpoint was time to treatment failure (TTF) defined as time between randomization and permanent discontinuation of pazopanib (either for disease progression or intolerance); secondary endpoints included overall response rate (ORR), progression-free survival (PFS) and safety. **Results:** 168 pts (66.5 years median age; 51.8% female) were included and 100 pts randomized (CP: 50, IP: 50). The median number of metastatic sites was 2.0 (1-7) and 50 pts (29.8%) were pretreated with MKI. With a median follow-up of 31.3 m, we did not show any statistically significant difference in the TTF, 80% (66.0-88.7%)] of the pts being under P at 6 m after randomization in the IP arm *versus* 78% (63.8-87.2%) in the CP arm. Median TTF was 14.7 m 95% CI [9.3; 17.4] and 11.9 m 95% CI [7.5; 15.6] respectively (HR 0.79 [0.49-1.27]). The best response with P was 35.6% (95% CI [28.2; 43.6]) and the disease control rate was 89.4% 95% CI [83.5; 93.7]. Median time to progression under P was not statistically different between 2 arms (5.7m 95% CI [4.8;7.8] in the IP arm vs. 9.2m 95% CI [7.3;11.1] in the CP arm (HR 1.36 [0.88; 2.12]). 36/100 pts (36%) experienced pazopanib-related grade 3/4 AEs (CP: 17; IP: 19) mainly represented by gastrointestinal disorders, hypertension, cardiac disorders and asthenia. Five pazopanib-related deaths were reported (CP:1;IP: 4). **Conclusions:** The intermittent administration of pazopanib study did not significantly demonstrate superiority in efficacy or tolerance over continuous treatment. Continuous administration of MKI remains the standard in RAIR-TC. Clinical trial information: NCT01813136. Research Sponsor: PHRC11-089.

6541 Poster Session (Board #202), Fri, 8:00 AM-11:00 AM

A phase I/Ib study of lenvatinib and cetuximab in patients with recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). *First Author: Lara Dunn, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite overexpression of EGFR in HNSCC, cetuximab monotherapy has limited benefit. Fibroblast growth factor receptor (FGFR) signaling is a known resistance mechanism to EGFR inhibition. Lenvatinib is a multi-targeted receptor tyrosine kinase inhibitor (RTKI) and has unique activity against FGFR 1,2,3, and 4. We are evaluating inhibition of EGFR and RTKs including FGFR through the combination of cetuximab and lenvatinib in patients (pts) with R/M HNSCC. **Methods:** In this phase I/Ib, single-institution study, pts with measurable disease per RECIST v1.1 that is incurable with surgery and radiation are eligible regardless of prior cetuximab therapy. The dose de-escalation phase included pts with HNSCC and cutaneous squamous cell carcinoma (cSCC) treated with standard cetuximab dosing and lenvatinib in 3 potential dose levels (DL): (0) 24mg, (-1) 20mg, (-2) 14mg oral daily in a standard 3+3 design. The primary objective was to determine the MTD of lenvatinib in combination with cetuximab. The expansion phase included an additional 5 pts with HNSCC treated at the MTD. Exploratory endpoints include ORR and PFS in HNSCC pts treated at the MTD. **Results:** 12 evaluable pts were treated on the dose de-escalation phase. There were no DLTs on DL 0; however, 3/6 pts were removed immediately following the 28-day DLT period due to toxicity that included extensive thrombotic events and athlerosclerotic disease. On DL -1, 0/6 pts (5 HNSCC/1 cSCC) had a DLT establishing lenvatinib 20mg daily as the MTD. 7 pts were enrolled onto the expansion phase; 4 are currently evaluable for response and 2 are unevaluable because of withdrawal due to a cetuximab reaction and required surgery. Of the 9 evaluable HNSCC pts treated with lenvatinib 20mg daily, 6 pts had a PR with a 67% ORR. For the 8 pts who have completed treatment, the median PFS is 3.6 months (range 1.6-10.4). Grade 3 AEs regardless of attribution included hypertension (3), oral mucositis (3) and oral cavity fistula (1). The most common AEs were acneiform rash (7), fatigue (6), and hypertension/hypothyroidism/oral mucositis (5 each). **Conclusions:** The MTD of lenvatinib 20mg daily with cetuximab appears to be active in R/M HSNCC with an impressive preliminary ORR, warranting further evaluation of the efficacy of this combination. Clinical trial information: NCT03524326. Research Sponsor: Eisai Pharmaceuticals.

6542 Poster Session (Board #203), Fri, 8:00 AM-11:00 AM

Clinical response and biomarker analysis of POLARIS-02 a phase II study of toripalimab, a humanized IgG4 mAb against programmed death-1 (PD-1) in patients with metastatic nasopharyngeal carcinoma. *First Author: Fenghua Wang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Metastatic nasopharyngeal cancer (mNPC) patients progressed after standard therapy have limited treatment options. This study is to evaluate the clinical efficacy and safety of toripalimab in mNPC patients refractory to standard chemotherapy treatment (Clinical trial ID: NCT02915432). **Methods:** Patients receive 3 mg/kg toripalimab Q2W via IV infusion until disease progression, unacceptable toxicity, or voluntary withdrawal. Clinical response is assessed every 8 weeks according to RECIST v1.1. Tumor PD-L1 expression, plasma EBV titer and other biomarkers will be evaluated for correlation with clinical response. **Results:** From Dec 2016 to Feb 2019, 190 mNPC patients were enrolled from 17 participating centers in China. The median age was 46 years with 83% male. Patients were heavily pretreated with a median of 2 lines of prior systemic treatments. By the cutoff date of Jan 17, 2020, 97% patients experienced treatment related adverse events (TRAE). Most common TRAE included anemia, hypothyroidism, AST increased, proteinuria and fever. Grade 3+ TRAE occurred in 28% patients. Among 190 patients assessed by Independent Review Committee per RECIST v1.1, 6 CR, 33 PR and 40 SD were observed for an ORR of 20.5% and a DCR of 41.6%. The median DOR was 12.9 months. The median PFS and median OS were 1.9 months and 18.6 months respectively. PD-L1+ patients (n=48) had higher ORR than PD-L1- patients (n=134), 27.1% versus 19.4%. By tumor histology, ORR was higher in keratinizing NPC (n=8) than non-keratinizing NPC (n=168), 62.5% versus 19.0%. 144 patients had valid plasma EBV titer measured every 28 days during the study. An average drop of 101-fold plasma EBV titer from baseline was observed in patients with objective responses. Patients with 2-fold+ drop in plasma EBV titer on day 28 (n=60) went on to have 48.3% ORR and 76.7% DCR, whereas patients with less than 2-fold drop (n=88) had 5.7% ORR and 25.0% DCR. 14 responding patients who later developed progressive disease had at least 2-fold+ increase of plasma EBV tier 3-months (median) before radiographic identification of disease progression. **Conclusions:** Toripalimab demonstrated encouraging clinical activity with a manageable safety profile in mNPC patients refractory to standard chemotherapy. Patients with 2-fold+ drops in plasma EBV titer on day 28 from baseline had favorable clinical response of 48.3% ORR, which might be used as a predictive biomarker. Clinical trial information: NCT02915432. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd.

6543 Poster Session (Board #204), Fri, 8:00 AM-11:00 AM

Phase I dose escalation of stereotactic body radiation therapy and concurrent cisplatin for re-irradiation of unresectable, recurrent head and neck squamous cell carcinoma. *First Author: Michelle Echevarria, Department of Radiation Oncology, Moffitt Cancer Center and Research Institute, University of South Florida, Tampa, FL*

Background: For patients with unresectable, previously radiated, locoregionally recurrent head and neck cancer, stereotactic body radiation therapy (SBRT) has become an attractive option. The use of high daily doses of radiotherapy may overcome the inherent radioresistance of these recurrent cancers. Given the resistant and advanced nature of many of these cancers, the addition of chemotherapy to radiotherapy is typically recommended as a radiosensitizer. We therefore performed a phase I clinical trial in order to establish a maximum tolerated dose of SBRT with concurrent chemotherapy in locoregionally recurrent head and neck cancer. **Methods:** Major inclusion criteria were recurrence of previous squamous cell carcinoma of the head and neck in patients who had previously undergone radiotherapy to doses $\geq$ 45 Gy to the area of recurrence, $\geq$ 6 months prior to enrollment, and who were medically unfit for surgery, deemed unresectable, or refused surgery. Patients were treated with radiation therapy every other day for five fractions at three dose levels; 30 Gy, 35 Gy, and 40 Gy. Cisplatin was given prior to every SBRT fraction at a dose of 15 mg/m2. Patients were monitored for safety and tolerability for any grade 4 or greater toxicity (per CTCAE v4.0) that occurred within 3 months from the start of SBRT. Primary end point was maximum tolerated dose (MTD). **Results:** Twenty patients were enrolled and of those 17 patients were evaluable for the primary endpoint. Nine patients had a primary tumor in the oropharynx, four patients in the oral cavity, three in the neck, one in the larynx, and one simultaneously in the larynx and neck. Of the three patients that were not evaluable two withdrew consent, and one patient in the 30 Gy dose level died of unknown causes two weeks following completion of treatment. Due to safety concerns the 30 Gy dose level was expanded an additional three patients, and no further dose limiting toxicities (DLTs) were observed. At the 35 Gy and 40 Gy dose level there were no reported grade 4 or 5 adverse events (per CTCAE v4.0). There were 5 (27%) reported grade 3 toxicities and 12 (66%) grade 2 toxicities. **Conclusions:** This phase I study demonstrates that 40 Gy SBRT with concurrent cisplatin at a dose of 15mg/m2 is feasible, safe, and well tolerated. Patients continue to be followed for secondary outcomes of local control and overall survival. Clinical trial information: NCT02158234. Research Sponsor: H. Lee Moffitt Cancer Center Department of Radiation Oncology.

6544 Poster Session (Board #205), Fri, 8:00 AM-11:00 AM

INDUCE-1: Report on safety run-in cohorts combining Inducible T-cell co-stimulatory receptor (ICOS) agonist GSK3359609 (GSK609) with platinum+5-FU chemotherapy (5-FU/plat), with or without pembrolizumab (PE), for the treatment of advanced solid tumors. *First Author: Erminia Massarelli, City of Hope Helford Clinical Research Hospital, Duarte, CA*

Background: The KEYNOTE-048 study (Burtness, at al. *Lancet* 2019;394: 1915–28) led to approval of PE in combination with 5-FU/plat for first-line (1L) treatment of head and neck squamous cell carcinoma (HNSCC). The Phase I INDUCE-1 study (NCT02723955) has shown that GSK609±PE has a manageable safety profile in patients (pts) with advanced solid tumors (Hansen, at al. *Annals of Oncology* 2018;29[suppl_8]:viii404) and that GSK609 combined with PE has anti-tumor activity in pts with anti-PD-1/L1-naïve HNSCC (Rischin, et al. *Annals of Oncol* 2019;30[Supplement_5]:v454–5). To evaluate the safety of GSK609±PE in combination with 5-FU/plat, we initiated additional safety cohorts. **Methods:** Pts eligible for GSK609+5-FU/plat had a diagnosis of advanced selected solid tumors and ≤5 prior lines of systemic therapy. Pts eligible for GSK609+PE+5-FU/plat had a diagnosis of recurrent or metastatic 1L HNSCC deemed incurable by local therapies. 5-FU/plat was administered every 3 weeks (Q3W) for 4-6 cycles (Burtness, at al. *Lancet* 2019;394:1915–28); GSK609 24 or 80 mg ±PE 200 mg were administered Q3W for up to 2 years/35 cycles or until disease progression or unacceptable toxicity. **Results:** Twenty-nine pts were enrolled in the 5-FU/plat safety cohorts: 10 pts in the GSK609+5-FU/plat cohort and 19 pts in the GSK609+PE+5-FU/plat cohort. With GSK609+5-FU/plat, 9/10 (90%) pts experienced ≥ 1 adverse event (AE). Of 32 AEs of any grade, 9 were Grade ≥3 and 3 were serious AEs (SAEs). Two of the 3 SAEs were related to study treatment (oral mucositis and febrile pancytopenia). With GSK609+PE+5-FU/plat, 18/19 (94.7%) pts experienced ≥ 1 AE. Of 119 AEs of any grade, 24 were Grade ≥3 and 15 were SAEs. Of the 15 SAEs, 11 were related to study treatment (febrile neutropenia [n=4], colitis [n=2], diarrhea [n=1], vomiting [n=1], acute kidney injury [n=1], cardiac chest pain [n=1] and lung infection [n=1]). For all cohorts, no Grade 5 AEs were observed. For 10 pts evaluable for confirmed best overall response in all cohorts, 2 pts had partial response, 6 pts had stable disease and 2 pts were nonevaluable. No difference in GSK609 exposure was observed relative to GSK609 monotherapy. **Conclusions:** The safety profile of GSK609 in combination with 5-FU/plat±PE is manageable. Most AEs were Grades 1 or 2 and consistent with PE and chemotherapy toxicities. Continued follow-up to investigate long-term safety and efficacy of this combination is warranted. Clinical trial information: NCT02723955. Research Sponsor: Study is funded by GlaxoSmithKline and in collaboration with Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

6545 Poster Session (Board #206), Fri, 8:00 AM-11:00 AM

Radiomic response evaluation of recurrent or metastatic head and neck squamous cell cancer (R/M HNSCC) patients receiving pembrolizumab on KEYNOTE-012 study. *First Author: Kirsty Taylor, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Immunotherapy has become a standard of care in the treatment of R/M HNSCC, however only a subset of patients respond, highlighting the need for predictive and prognostic biomarkers. Radiomics is a non-invasive method to quantitatively analyze tumors through conventional imaging. **Methods:** The pre-treatment and first-on-treatment (after 8 weeks) computed tomography (CT) scans from 132 R/M HNSCC patients treated with single-agent Pembrolizumab (10mg/kg Q2W or 200mg Q3W IV) on the KEYNOTE-012 study were analyzed. Identified target lesions, per RECIST 1.1, were manually contoured, and radiomic features from the tumor and peritumoral region (3 mm expansion of the tumor) were extracted using PyRadiomics. All combinations of image filters and feature classes, not including shape descriptors of peritumoral region, were extracted. Feature space dimensionality was reduced by clustering features (hierarchical clustering using Pearson-based distance and complete linkage) and selecting the medoid of each cluster. Correlation with lesion-level response (LLR) at first-on-treatment CT and overall response (OR) was evaluated using concordance index (CI) with Benjamini-Hochberg multiple testing correction. **Results:** A total of 406 lesions were included (45 head & neck (HN), 207 lung, 57 liver, 86 lymph nodes (LN), 11 other). 3562 features were extracted from pre-treatment scans (2246 tumor, 1316 peritumor). Considering all lesion sites collectively, 27 of 110 feature clusters were significantly correlated with LLR (false discovery rate (FDR) < 0.05) but not with best overall RECIST response per patient on study. However, when grouped by organ, a number of feature cluster medoids were significantly associated (FDR < 0.05) with LLR (HN: 1, lung: 28, liver: 8, LN: 1) and OR (liver: 18). Feature clusters predictive of LLR and OR included descriptors of both tumor-specific and tumor/peritumoral gray-level intensity and texture (e.g. 74% tumor and 26% peritumoral features in clusters significantly associated with OR in liver). **Conclusions:** Tumor and peritumoral radiomic features at baseline correlate with LLR and OR to immunotherapy in R/M HNSCC. Despite significant heterogeneity in lesion site, both global and site-specific significant feature clusters could be identified. Research Sponsor: Merck.

6546 Poster Session (Board #207), Fri, 8:00 AM-11:00 AM

The impact of tumor hypoxia on the clinical efficacy of anti-PD-1 mAb treatment in recurrent/metastatic HNSCC patients (R/M). *First Author: Dan Paul Zandberg, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Anti-PD-1 mAbs have changed the landscape of R/M HNSCC treatment, but physical, immunologic, and metabolic barriers present in the tumor microenvironment are likely drivers of low response rates. Hypoxia is a well-established feature of the tumor microenvironment and may act as a barrier to T cell infiltration and function. We evaluated the effect of hypoxia on the efficacy of anti-PD-1 mAb treatment in R/M HNSCC patients. **Methods:** We conducted a retrospective analysis of R/M patients treated with anti-PD-1 mAb that had consented to the UPMC Hillman tissue banking protocol (HCC 99-069). Pre-treatment archival FFPE samples were analyzed via immunofluorescent imaging for number of CD8+ T cells (CD8), Tregs, and the percent area (% CAIX) and mean intensity (Int) of carbonic anhydrase IX, a well-described marker of hypoxia. Tissue sections stained with PanCK, CAIX, CD8, Foxp3, and DAPI were imaged with an Olympus IX 83 microscope. ImageJ software and custom software plugins were used to determine %CAIX, Int, CD8, and Treg. PD-L1 by IHC was reported as a combined positive score (CPS) defining positive as CPS $>$ 1. We compared non-responders (NR) i.e. PD to responders (R) i.e. PR or SD, and analyzed OS, PFS. All data were analyzed using GraphPad Prism software. Two-tailed unpaired t test was used when comparing 2 groups, 1-way ANOVA was used for multiple comparisons, and log-rank test was used for survival analysis. **Results:** The 36 patients included were 69% male, median age 59, 58% smokers. 61% were platinum failure. Primary site included 39% OC, 22% OPC (38% HPV positive), 17% Larynx, 17% other, 5% hypopharynx. Low %CAIX/Int, high CD8, and high CD8/Treg were all significantly associated with R. Patients with low %CAIX/Int (12 month OS Low: 75% vs. Mid: 17% vs. High:8%, p = 0.02) and high CD8/Treg had a significant increase in OS. Only high CD8 was associated with significantly higher PFS. Low %CAIX alone showed a non-significant trend towards increased R and no difference in PFS/OS. There was no difference in CD8, CD8/Treg, PD-L1 and Treg between %CAIX/Int groups. **Conclusions:** To our knowledge this is the first evaluation of tumor hypoxia as a predictive biomarker in anti-PD-1 mAb treated R/M HNSCC patients. Lower hypoxia by %CAIX/Int was associated with significantly increased response and OS. While further analysis in a larger dataset is needed to confirm, the lack of significant difference in CD8, Treg, PD-L1, and CD8/Treg between %CAIX/Int groups (Low, Mid, High) suggests that hypoxia may be an independent predictive marker. Research Sponsor: U.S. National Institutes of Health.

6548 Poster Session (Board #209), Fri, 8:00 AM-11:00 AM

Molecular biomarkers to identify patients (pts) who may benefit from durvalumab (D; anti-PD-L1) ± tremelimumab (T; anti-CTLA-4) in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) from HAWK and CONDOR studies. *First Author: Weimin Li, Astrazeneca, Gaithersburg, MD*

Background: Baseline tumor and germline biomarkers in R/M HNSCC were analyzed for predictive potential in pts benefitting from D or D+T. **Methods:** In HAWK (NCT02207530), 112 pts (PD-L1 tumor cells [TC]≥25%) received D (10 mg/kg Q2W for ≤12 m); in CONDOR (NCT02319044), 67 pts (PD-L1 TC $<$ 25%) received D (10 mg/kg Q2W for ≤12 m), 133 pts received D+T (D 20 mg/kg Q4W, T 1 mg/kg Q4W for ≤12 m), and 67 pts received T (10 mg/kg Q4W [7 doses] then Q12W [2 doses] for ≤12 m) VENTANA PD-L1 (SP263) Assay determined PD-L1 status. Paired FFPE archival tumor and PBMC samples (as germline control) in the HAWK and CONDOR trials were evaluated by whole exome sequencing (WES). Tumor mutation burden (TMB) was number of somatic mutations/megabase. HLA class I types were obtained via WES of PBMCs (CONDOR only). HPV and neutrophil-to-lymphocyte ratio (NLR) were tested locally in CONDOR. Wilcoxon, log-rank tests, and COX-PH models were used. Pooled D & D+T data were analyzed unless noted. **Results:** 153 pts had paired evaluable FFPE tumor and PBMC samples (HAWK, n = 48; CONDOR, n = 105). TMB distributions were similar between studies (P= 0.43). TMB correlated with smoking (P= 0.02) but not HPV (P= 0.24), NLR (P= 0.66), or PD-L1 status (P= 0.43). Overall, high TMB (≥upper tertile) trended with longer OS vs low TMB in all evaluable pts (N = 153; 9.0 vs 5.6 m; HR = 0.70; 95% CI = 0.48-1.01); P= 0.06). In HAWK, there was no association of TMB with OS. In CONDOR, pts (D and D+T arms) with high TMB vs low had significantly longer OS (N = 76; 16.3 vs 5.3 m; HR = 0.53; 95% CI = 0.31-0.92). TMB and OS association was further assessed by increasing TMB cutoffs. Improved HRs trended with higher cutoffs; cutoffs ≥upper quartile significantly linked to OS.TMB was not associated with PFS or ORR. Pts with low PD-L1 and low TMB had worse OS compared to pts with high PD-L1 or high TMB. Pts with high NLR (≥median) and low TMB had significantly worse OS than pts with low NLR and high TMB (HR = 2.63, P< 0.001). Analysis of germline HLA alleles revealed significantly poorer survival for carriers of the HLA-B*15:01 allele (9.4%) (HLA-B variant status did not affect TMB and OS association in CONDOR). Germline HLA heterozygosity did not impact OS. Pts with mutations in *ATM* (5%), a DNA damage repair gene, also trended with prolonged OS. **Conclusions:** TMB is a possible predictive biomarker of IO HNSCC therapy. Combined analysis of NLR and TMB may provide additional PD-L1 data in assessing pts most likely to have long-term benefit. Clinical trial information: NCT002207530, NCT02319044. Research Sponsor: AstraZeneca.

6549 Poster Session (Board #210), Fri, 8:00 AM-11:00 AM

Overall survival modeling and association with serum biomarkers in durvalumab-treated patients with head and neck cancer. *First Author: Vadryn Pierre, Astrazeneca, Gaithersburg, MD*

Background: Optimal patient selection for immunotherapy remains a challenge as most patients fail to respond. We aim to assess baseline factors for association with long-term survival from durvalumab treatment in patients with recurrent/metastatic head and neck squamous cell carcinoma (HNSCC)[1,2]. **Methods:** Pooled longitudinal tumor size, survival, and dropout data from four trials (1108: NCT01693562, CONDOR: NCT02319044, HAWK: NCT02207530, and EAGLE: NCT02369874) involving 467 HNSCC patients were used to develop tumor size-driven hazard models. A panel of 66 serum protein biomarkers at baseline and 4 relevant clinical markers from 346 out of 413 patients treated with durvalumab (all studies except 1108) were initially screened to select a pool of 21 candidate covariates. The criteria for dimensionality reduction comprised correlation strength between biomarkers and pharmacological hypotheses pertaining to a prior analysis[3] (inflammation, immunomodulation, tumor burden and angiogenesis). **Results:** The final tumor model highlighted that high tumor burden, elevated LDH and neutrophil-lymphocyte ratio were associated with faster tumor growth while patients with lower baseline tumor burden had an increase in net tumor shrinkage. For overall survival, the model suggested that high levels of immunomodulators (IL23, Osteocalcin), low inflammation (IL6, NLR), low tumor burden, and low angiogenesis factors (von Willebrand factor (vWF), plasminogen activator inhibitor-1 (PAI-1)) were associated with survival benefits for patients treated with durvalumab. Specifically, these patients had baseline serum IL23 $>$ 2.1 pg/mL and Osteocalcin $>$ 32 pg/mL or serum PAI-1 $<$ 229 pg/mL and serum IL6 $<$ 5.4 pg/mL which corresponded to a hazard ratio estimate (HR and 95%CI) of 0.36 (0.27- 0.47), logrank p-value: $2.3x10^{-14}$. The median (n, 95%CI) overall survival time for the patients with favorable biomarker profile was 14.6 months (n = 129, 11.2-21.4) vs. 4.4 months (n = 217, 3.6-5.3). **Conclusions:** Our results corroborate the prior hypothesis highlighting the prognostic value of inflammation, disease burden, tumor angiogenesis, and immunomodulatory factors on the clinical outcomes of HNSCC patients treated with durvalumab[3]. Collectively, we identified a serum biomarker profile of HNSCC patients with median survival times exceeding 1 year which may potentially be used for patient enrichment following further validation in prospective studies. 6551 Poster Session (Board #212), Fri, 8:00 AM-11:00 AM

CD3 and CD20 immune cell densities in primary tumors, lymph node metastasis, and recurrent disease samples of head and neck squamous cell carcinoma. *First Author: Simon Laban, Department of Otolaryngology - Head and Neck Surgery, University Hospital Ulm, Universität Ulm, Ulm, Germany*

Background: Immune cell (IC) infiltrates in primary tumors (PT) have been identified as prognostic markers in head and neck squamous cell carcinoma (HNSCC). IC densities may differ among PT, lymph node metastasis (LNM) and recurrent disease (RD) and by primary disease site (oral cavity- OC, oropharynx- OP, hypopharynx- HP, larynx- L). Here, we compare CD3 and CD20 IC densities in PT, LNM and RD in paired samples from different disease sites and determine the prognostic impact of IC infiltrates. **Methods:** Tissue microarrays with 425 PT, 198 LNM and 46 RD samples--each in triplicate--were stained immunohistochemically for CD3 and CD20 in the same slide. Immune cell densities per mm^2 were determined using a digital image analysis software (QuPath). Individual means were calculated from triplicates of each sample. IC infiltrates from different sample types (PT, LNM, RD) and primary tumor sites were compared using Kruskal-Wallis and Mann-Whitney-U tests. Paired samples were compared using Wilcoxon signed rank test. IC densities were classified as CD3 high/low and CD20 high/low for each primary tumor site using the individual median as a cut-off. Overall survival (OS) was calculated using the Kaplan-Meier method. P-values for each hypothesis were corrected using a false discovery rate of 5%. **Results:** CD3 and CD20 IC densities differed significantly by sample type (both $p<0.0001$) and primary site (CD3: p=0.012, CD20: p=0.0017). CD3 and CD20 densities were significantly lower in PT compared to LNM or in RD compared to PT and LNM. Paired samples (n=172) revealed a significantly higher CD3 and CD20 density (both $p<0.0005$) in LNM compared to PT, but no significant differences between PT and RD (n=28, $p>0.05$). CD3 densities were significantly higher than CD20 densities in all sample types. $CD3_{high}$ patients had the best prognosis in all sites except for OC ($q<0.05$) independent of CD20 status. In OC, CD3 density was not prognostic, but $CD3_{low}/CD20_{high}$ patients had the worst OS compared to $CD3_{low}/CD20_{low}$ and $CD3_{high}/CD20_{high}$ or even $CD3_{high}/CD20_{low}$ patients (p=0.018) who had the best prognosis. **Conclusions:** IC densities of CD3 and CD20 vary by sample type and primary site. Except for OC, in all sites the prognostic impact is determined by $CD3_{high}$, whereas in OSCC only the combination of CD3 and CD20 IC densities achieves a good prognostic value. Interestingly, $CD3_{low}/CD20_{high}$ patients have the worst overall survival in OC patients. Further work is needed to understand the interaction of B- and T cell infiltrates in the tumor, especially in OC. Research Sponsor: Clinician Scientist Program, Other Foundation.

6552 Poster Session (Board #213), Fri, 8:00 AM-11:00 AM

Correlation of tumor mutational burden (TMB) with CDKN2A and TP53 mutation in HPV-negative head and neck squamous cell carcinoma (HNSCC). *First Author: Barbara Burtness, Yale School of Medicine and Yale Cancer Center, New Haven, CT*

Background: The tumor suppressors *TP53* and *CDKN2A* are commonly mutated or lost in HNSCC, impairing G1 checkpoints. This reduces ability to repair DNA damage arising from hypoxia, replication stress, and mutagen exposure, thus increasing TMB, a potential predictive biomarker for immunotherapy benefit. *TP53* mutations can be classified as loss-of-function (LOF) with or without dominant negative (DNE) activity, gain-of-function (GOF) and benign. We investigated whether specific categories of *TP53* mutation were associated with increased TMB, and whether these cooperated with *CDKN2A* mutation to elevate TMB. **Methods:** We analyzed 1010 HPV- HNSCC tumor samples (246 female) profiled with a 592-gene panel by Caris Life Sciences from 2015 to 2019. Predominant subsites were oral cavity (285), oropharynx (225) and larynx (153). TMB reflected all somatic nonsynonymous missense mutations detected. We report mean TMB per megabase (MB). Pathogenicity of *TP53* and *CDKN2A* mutations was determined according to American College of Medical Genetics (ACMG) guidelines. We also used four alternative methods of characterizing *TP53* mutations based on analysis of protein structure, public databases (IARC, ClinVar, InterVar), and publications (PMID: 25108461 and others) assessing structure-function relations. **Results:** 60% of cases had *TP53* mutations ($TP53^{mut}$) designated pathogenic by ACMG guidelines. Estimates of frequency of LOF/DNE mutations ranged from 30-42.8% of cases among the alternative classification methods. Damaging *CDKN2A* mutations were present in 20%. Average TMB per MB varied from 8.2/8.6 (females/males) in oral cavity cancers to 26.5/27.7 (females/males) in cancer of the lip. Mean TMB was typically higher in the presence of damaging LOF/DNE *TP53* mutations or *CDKN2A* mutations, but not *TP53* GOF mutations. Based on ACMG, for tumors with *TP53* and *CDKN2A* wild type (WT) TMB was 8.03, for those with $CDKN2A^{mut}$ only 9.82, for $TP53^{mut}$ only 10.56, and $TP53^{mut}/CDKN2A^{mut}$ 17.6 ($p < 0.001$). For disruptive $TP53^{mut}$ (Poeta algorithm), mean TMB for WT/WT was 8.67, for $TP53^{mut}$ 11.31, $CDKN2A^{mut}$ 17.9 and $TP53^{mut}/CDKN2A^{mut}$ 15.83 ($p < 0.001$). **Conclusions:** Mutation of *TP53* and/or *CDKN2A* is associated with increased mean TMB relative to WT; mean TMB was highest for tumors bearing damaging mutations in both genes. GOF *TP53* mutation was not clearly associated with increased TMB. As TMB is evaluated as a predictive biomarker in the immunotherapy of HNSCC, specific *TP53/CDKN2A* mutational status should also be evaluated. Research Sponsor: Caris Life Sciences.

6553 Poster Session (Board #214), Fri, 8:00 AM-11:00 AM

Prognostic role of pre-treatment magnetic resonance imaging (MRI) radiomic analysis in patients with squamous cell carcinoma of the head and neck (SCCHN). *First Author: Salvatore Alfieri, Head and Neck Cancer Medical Oncology 3 Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Emerging data suggest that radiomics can be used to predict outcomes in SCCHN. At present, only few data are available for pre-treatment MRI. **Methods:** Study population was retrieved from an ongoing multicenter, randomized, prospective trial (NCT02262221, HETeCo) evaluating health and economic outcomes of two different follow-up (FUP) strategies (intensive vs non-intensive) in effectively cured stage III-IV (VIII TNM ed.) SCCHN. We selected only patients with both pre- and post-contrast enhancement T1 and T2-weighted baseline MRI (b-MRI) and at least 2 years (2y) of FUP. A radiomic model was developed to identify high risk (HR) and low risk (LR) of disease recurrence. Radiomic features (RF) were extracted from the primary tumor in the b-MRI. The best RF combination was selected by Least Absolute Shrinkage and Selection Operator (LASSO). Ten-fold cross-validation was used to compute sensitivity, specificity and area under the curve (AUC) of the classifier. Kaplan-Meier (KM) curves were estimated for HR and LR, for both overall survival (OS) and disease-free survival (DFS) and log rank test was performed. Three years (3y)-DFS and OS were also estimated for the two groups. The radiomic risk class was used as a new variable in a multivariate Cox model including well established prognostic factors in SCCHN (TNM stage, subsite and HPV). **Results:** Out of 155 enrolled HETeCO patients, 98 baseline imaging were retrieved of which 57 b-MRI. Of these, 51 met the eligibility criteria (25 in intensive and 26 in non-intensive arm). Baseline patients' characteristics were: median age 66 yr (38-86); sex (M 42; F 9); median smoking history: 30 packs/y (1-100); 25 oral cavity (49%), 18 oropharynx (35%, 14 HPV+), 6 larynx (12%), 2 hypopharynx (4%). At a median FUP of 42 months (25-64), 45 (88%) patients are still alive. The recurrence rate was 20% (10/51, of which 2 distant). In total, 1608 RF were extracted. The sensitivity, specificity and AUC of the classifier were 90%, 76%, and 80%, respectively. The radiomic risk class was found to be an independent prognostic factor for both DFS and OS (p=0.01 and p=0.046, respectively). KM curves for DFS and OS were significantly different between HR and LR groups (p=0.002 and p=0.04, respectively). In HR vs LR, 3-y DFS and OS were: 78% [61-100%] vs 97% [90-100%], and 88% [75-100%] vs 96% [88-100%], respectively. **Conclusions:** Radiomics of pre-treatment MRI can predict outcomes in SCCHN. External validation of this preliminary radiomics-based model is currently ongoing. Research Sponsor: BRI (Bando Ricerca Istituzionale) 2018. D/17/1SA (statement n. 511 on December, 21th, 2.

6554 Poster Session (Board #215), Fri, 8:00 AM-11:00 AM

HPV ctDNA analysis in unresectable recurrent/metastatic oropharyngeal cancer. *First Author: Catherine T Haring, University of Michigan Department of Otolaryngology-Head and Neck Surgery, Ann Arbor, MI*

Background: There is an increasing incidence of human papillomavirus associated (HPV+) oropharyngeal cancer (OPC). While HPV + portents improved prognosis, survival for patients with unresectable recurrent/metastatic (R/M) OPC remains poor. Extant data suggest that HPV ctDNA levels correlate with disease burden and treatment outcomes in patients with HPV + OPC in the primary setting but scant data exists in the metastatic setting. Objective: To develop a highly precise droplet digital (ddPCR) assay for quantification of plasma HPV ctDNA and to evaluate whether HPV ctDNA predicts treatment response in patients with HPV+ R/M OPC. **Methods:** Patients with HPV + R/M OPC starting systemic therapy were enrolled in a biorepository in which blood was collected prior to each cycle of therapy. PCR probes were created for the most common high-risk HPV subtypes, 16 and 18. HPV ctDNA was extracted from plasma and quantified with ddPCR. Percent change in HPV ctDNA was calculated after 1 and 2 cycles of treatment. Treatment response was assessed per standard of care or study protocol after 2-3 cycles of treatment. ROC curve analyses were performed. **Results:** A precise ddPCR assay was developed to identify plasma HPV ctDNA in 10 patients who underwent 16 distinct treatment courses. On ROC curve analysis, percent change in HPV ctDNA after 2 cycles of treatment was predictive of radiographic response (AUC 0.82, p = 0.03). The optimal cutoff point to optimize sensitive and specificity was identified as 30% change in HPV ctDNA (Table). Changes in HPV ctDNA after 1 cycle of treatment were also predictive of radiographic response (AUC 0.82, p = 0.05). **Conclusions:** Changes in HPV ctDNA may be predictive of treatment response in patients with R/M HPV + OPC. Furthermore, HPV ctDNA predicts response earlier than conventional imaging. While validation is needed, this assay shows promise in identifying poor responders who can be directed early towards clinical trials or alternative therapies. Research Sponsor: Internally funded by University of Michigan.

	Stable Disease or Partial Response	Disease Progression	
< 30% increase in HPV ctDNA	6	1	PPV 85.7% (95% CI 48-98%)
≥30% increase in HPV ctDNA	1	8	NPV 88.9% (95% CI 56-98%)
	Sensitivity 85.7% (95% CI 42-100%)	Specificity 88.9% (95% CI 52-100%)	

6556 Poster Session (Board #217), Fri, 8:00 AM-11:00 AM

Molecular correlates of response to preoperative olaparib alone or with cisplatin or with durvalumab in head and neck squamous cell carcinoma (HNSCC): A Hellenic Cooperative Oncology Group study. *First Author: Amanda Psyrri, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

Background: Poly(ADP-ribose) polymerase (PARP) inhibitors drive increased DNA damage and tumor cell death, particularly in tumors with existing defects in DNA repair. Furthermore,they promote immune priming, through a range of molecular mechanisms. Foremost, among candidate intracellular pathways is STING (stimulator of interferon genes), an innate immune response activated by cytosolic DNA (perhaps a consequence of DNA damage) that can lead to enhanced interferon (IFN) production. PARP inhibitor-induced DNA damage also leads to adaptive upregulation of programmed death ligand 1 (PD-L1) expression. To this end, there is increasing rationale for testing PARP inhibitors alone or in combination with chemotherapy or PD1 checkpoint inhibitors in HNSCC. **Methods:** 39 patients were enrolled in OPHELIA phase II trial in which pts were randomized 3: 3:3:1 to Cisplatin (C) 60 mg/m2 on d1 followed by Olaparib (O) 75mg d 1-5 (Arm A), O 300 mg bid for 21-28 days (Arm B), no treatment (ARM C) orD 1500 mg on d1 followed by O 600 mg daily for 21-28 days (Arm D). Response was defined as tumor reduction noted on exam, imaging or pathology. Pretreatment biopsies were subjected to 310 gene OncoDNA NGS panel. Double Stranded Brakes/Repair (DSB/R) was measured by evaluating phosphorylation of histone H2AX by immunochistochemistry (IHC). In addition, IHC for PD-L1 (CPS) and STING was performed in paired pre- and post-treatment biopsies. **Results:** 17/36 pts in (O) treatment arms (6/11 evaluable pts Arm A, 9/11 evaluable pts Arm B, 2/11evaluable\ pts arm D) developed a response. One patient in D+O arm developed path CR. Low γH2AX staining at pretreatment biopsies was associated with progression (p=0.029). Higher PD-L1 expression (CPS≥1) was associated with disease progression (p=0.014). CPS PD-L1 was upregulated following (O) treatment. STING expression was not significantly upregulated post treatment in (O) treatment arms. Alterations in genes that have been previously reported to be associated with (O) sensitivity, namely DNA damage Response/Repair (DDR) genes and genes involved in chromatin remodeling (*CHK2, KMT2D, KMT2C, ARID2 and AJUBA*), were identified in responders. **Conclusions:** This window study demonstrated promising signs of activity of (O) in HNSCC, particularly in tumors with high expression of γH2AX and alterations in DDR or chromatin remodeling genes. Clinical trial information: NCT02882308. Research Sponsor: Preoperative Administration of Olaparib With Cisplatin or With Durvalumab or Alone or no Tratment in Patients Who Are Candidates for Surgery of Carcinoma of the Head and Neck. (OPHELIA).

6557 Poster Session (Board #218), Fri, 8:00 AM-11:00 AM

Exome scale liquid biopsy characterization of putative neoantigens and genomic biomarkers pre- and post anti-PD-1 therapy in squamous cell carcinoma of the head and neck. *First Author: Charles Abbott, Personalis Inc, Menlo Park, CA*

Background: The reduced scope, and number of genes profiled by typical liquid biopsy panels can result in missed biomarkers including neoantigens, which may change with treatment, as well as potentially undetected resistance mechanisms and pathways beyond the scope of targets typically captured by panels. To address these limitations, we used a whole-exome scale liquid biopsy monitoring platform, NeXT Liquid Biopsy, to analyze head and neck squamous cell carcinoma (HNSCC) patients that have received anti-PD1 therapy. Presently, we sought to (1) monitor neoantigen changes in cfDNA as a complement to tumor biopsy-derived neoantigens, (2) compare the impact of tumor escape mechanisms, including HLA-LOH, on neoantigens identified in tissue and cfDNA and (3) to identify novel biological signatures that combine information from both solid tumor and liquid biopsies. **Methods:** Pre- and post-intervention matched normal, tumor and plasma samples were collected from a cohort of 12 patients with HNSCC. Following baseline sample collection all patients received a single dose of nivolumab, followed by resection approximately one month later when feasible, or a second biopsy where resection was impractical. Solid tumor and matched normal samples were profiled using ImmunoID NeXT, an augmented exome/transcriptome platform and analysis pipeline. Exome-scale somatic variants were identified in cfDNA from plasma samples using the NeXT Liquid Biopsy platform. Data from these two platforms were compared with corresponding clinical findings. **Results:** Concordant somatic events were detected between plasma and tumor at pre- and post-treatment timepoints. Neoantigens predicted to arise from these somatic events were reduced in solid tumor post-treatment, but increased in cfDNA, when compared to pre-treatment timepoints. HLA LOH was identified in a number of subjects, likely resulting in reduced neoepitope presentation in those cases. Immune cell infiltration increased in the tumor following treatment, with no changes to the $CD8^+$/Treg cell ratio, suggesting consistent immunoregulation. **Conclusions:** Exome-wide neoantigen burden was reliably predicted from cfDNA, providing additional insight complementing data from solid tumor. Analyzing HLA LOH, and neoantigen burden from both solid and liquid biopsies together over the course of treatment creates a more comprehensive profile of therapeutic response and resistance mechanisms in HNSCC patients missed with typical liquid biopsy panels. Research Sponsor: Personalis, Inc.

6558 Poster Session (Board #219), Fri, 8:00 AM-11:00 AM

Association of radiation treatment failure in head and neck cancer with differential immune infiltrate. *First Author: Mohamed Abdelhakiem, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Previously we have shown that PD-L1 expression is associated with treatment failure in Head and Neck Cancer (HNSCC) treated with radiation. We have further evaluated the effect of pre-treatment immune infiltrate on treatment failure following radiation. **Methods:** A total of 75 patients with HPV negative HNSCC treated with surgery and post-operative radiation were included in this study. Pre-treatment tumors were examined via RNA-Sequencing utilizing an Illumina platform. These data were then subjected to immune profiling utilizing publicly available software (xCell) to infer relative enrichment of immune cell infiltrate per sample. Each immune cell type detected at any level in at least 15 tumors was then evaluated for effect on loco-regional recurrence using Cox-regression analysis. Clinical variables included in this analysis include tumor stage, nodal stage and treatment site. Survival analysis was performed utilizing the method of Kaplan Meier, with log rank statistics used to test for significant comparisons. **Results:** The majority of HNSCCs analyzed in this study were from the oral cavity (65.3%), followed by the larynx and hypopharynx (28%) and oropharynx (6.7%). The total median dose of radiation delivered was 60 Gy (range: 36-79.2) and median follow up in living patients was 80.5 months (range: 7-190). On univariate analysis, no measured clinical variable was significantly associated with loco-regional recurrence (LRR). Similar to our previous studies in other HNSCC cohorts treated with radiation, PD-L1 expression was negatively associated with LRR (p = 0.005). Additionally, multiple immune cell infiltrates were negatively associated with LRR including: Th2 helper cells (p = 0.007), CD8+ central memory T cells (p = 0.02), immature dendritic cells (p = 0.037), CD4+ memory T cells (p = 0.043). In a multivariate model including these immune cell subsets, Th2 helper cells, CD8+ central memory T cells and immature dendritic cells remained significantly negatively associated with LRR following radiation. **Conclusions:** This analysis demonstrates the importance of pre-treatment immune infiltrate on outcomes in HNSCC and points to potential avenues to explore to augment response to radiation. Research Sponsor: NIH.

Computerized features of spatial interplay of tumor-infiltrating lymphocytes predict disease recurrence in p16+ oropharyngeal squamous cell carcinoma: A multisite validation study. *First Author: Germán Corredor, Case Western Reserve University, Cleveland, OH*

Background: While overall, patients with p16+ oropharyngeal squamous cell carcinoma (OPSCC) have a favorable prognosis, subsets of patients experience disease recurrence (DR) and death despite aggressive multimodality treatment. Aside from routine staging criteria, there are no biomarkers of tumor behavior routinely employed in OPSCC to identify patients at higher risk of DR. In this study we sought to evaluate whether the interplay between tumor-infiltrating lymphocytes (TILs) & cancer cells, in both stromal and epithelial compartments from digitized H&E-stained slides, can predict DR in OPSCC patients. **Methods:** OPSCC resected specimens from 354 patients (66 with DR) were retrospectively collected from 3 different sites. 107 (16 DR) patients from site 1 formed the training set and 247 (50 DR) patients from sites 2 & 3 formed the independent validation cohort. Computerized algorithms automatically identified 4 types of nuclei (TILs & non-TILs in both stromal & epithelial regions), defined clusters for each nuclei type based on cell proximity, and used network graph concepts to capture measurements relating to the arrangement of these clusters. The top 10 features determined by a statistical selection method (LASSO) were used to train a Cox regression model that assigns a risk of DR to each patient on the training set. The median risk score was used as threshold for stratifying patients on the validation set into low and high-risk of DR. Survival analysis was used to evaluate the stratification given by the trained model. **Results:** Patients identified by the TIL interplay model as high risk for DR had statistically worse disease specific survival. Univariate analysis yielded an HR=2.49 (95% CI: 1.22-5.07, p=0.04) for site 2 and HR=3.62 (95% CI: 1.39-9.43, p=0.03) for site 3. Multivariate analysis controlling the effect of different clinical variables is shown in the attached table. **Conclusions:** We introduce a prognostic model based on the automated quantification of the interplay between tumor microenvironment cells that is able to help distinguish OPSCC patients with higher DR risk from those who will experience longer disease-free survival. Research Sponsor: U.S. National Institutes of Health.

6560 Poster Session (Board #221), Fri, 8:00 AM-11:00 AM

Prognostic value of radiological extranodal extension detected by computed tomography for predicting outcomes in head and neck squamous cell cancer patients treated with radical chemoradiotherapy. *First Author: Abhishek Mahajan, Tata Memorial Centre, Mumbai, India*

Background: As per the AJCC 8th edition ENE/ECS is the most important predictor for N staging of HNSCC and is one of the key predictor of outcomes. Because ENE/ECS is based on pathological findings after surgery and it is difficult to predict outcomes for locally advanced squamous head and neck cancer (LASHNC) treated radically with CCRT. We hypothesized that ENE assessed by CT imaging (rENE) may directly correlate with outcomes in LASHNC treated radically with CCRT. **Methods:** This open-label, investigator-initiated, phase 3, randomized trial was conducted from 2012 to 2018. Adult patients with LASHNC who were fit for radical chemoradiation were randomized 1:1 to receive either radical radiotherapy (66-70 grays) with concurrent weekly cisplatin (30 mg/m^2) (CRT) or the same schedule of CRT with weekly nimotuzumab (200 mg) (NCRT). 536 patients were accrued,182 were excluded due to non-availability DICOM CT scan, 354 patients were analysed for rENE (based on 6 criterion for metastasis and 3 for rENE). Near equal distribution of patients was achieved in CRT arm (170 patients) and NCRT arm (184 patients). There were 181 (51.1%) oropharynx and 173(48.9%) larynx and hypopharynx patients. We evaluated association of radiological ENE and clinical outcomes.The endpoints were disease-free survival (DFS), duration of locoregional control (LRC), and overall survival (OS). **Results:** There were 244(68.9%) patients with radiologically metastatic nodes, out of which 140(57.3%) had rENE. There was no significant association between rENE and CRT (p value 0.3) or NCRT (p value 0.412). The median follow-up was 33.0 months (95%CI 30.7-35.2 months). Complete response was achieved in 204 (57.6%) cases, PR/SD in 126(35.6%) cases and PD in 24(6.8%) cases. rENE positive patients had poor overall 3-year survival (46.7%), poor DFS (48.8%) and LRC (39.9%) than rENE negative cases (63.6%, 87%, 60.4%). rENE positive cases had 1.71 times increase chances of incomplete response than rENE negative cases. Overall stage, clinical positive node, response, rENE and site were the only significant factors for predicting OS, DFS and LRC. **Conclusions:** In conclusion, pre-treatment rENE can be regarded as an independent prognostic factor for survival (OS, DFS, LRC) in patients with LASHNC treated radically with CCRT. Pre-treatment rENE is not only associated with CCRT response but is also associated with poor prognosis and hence rENE, as an imaging biomarker, can stratify responder's vs non-responders. Clinical trial information: CTRI/2014/09/004980. Research Sponsor: This study was funded by Biocon Ltd, Science and Engineering Research Board grant EMR/2015/001591, and by the Tata Memorial Center Research Administration Council.

6561 Poster Session (Board #222), Fri, 8:00 AM-11:00 AM

Immune functional portraits of head and neck cancer using next generation sequencing. *First Author: Susan Raju Paul, Massachusetts General Hospital, Boston, MA*

Background: The addition of biomarkers as companion diagnostics and Next Generation Sequencing (NGS) have dramatically increased therapeutic efficacy and have aided precision medicine development. The unique genomic profile and tumor microenvironment (TME) composition of each patient can be ascertained through NGS. Using TCGA and Geo datasets, we characterized head and neck cancers (HNC) according to the cellular and functional state of their TME and conducted a pilot validation study using prospectively collected HNC tumors. **Methods:** To stratify the TME of HNC tumors into molecular functional portraits, we analyzed the sequencing data of 1,486 HNC tumor samples and 143 controls (normal, oral leukoplakia) from TCGA and GEO data sets. For the prospective pilot study, resected tissue from oropharyngeal carcinomas independent of HPV status were processed for whole exome (WES) and RNA-seq (n = 6; HPV-positive = 1). **Results:** To characterize the cellular composition and functional state of HNC tumors and their TMEs, we created 26 separate molecular signatures related to functional processes such as immune checkpoint inhibition, immune infiltration, immunosuppression, and stromal activities represented by angiogenesis and mesenchymal stromal cells. Unsupervised clustering of these signatures delineated tumors into 4 types: immune infiltration with increased stromal signatures (type A), immune infiltration with decreased stromal signatures (type B), no immune infiltration with increased stromal signature (type C), and no immune infiltration and decreased stromal signatures (type D). Most HPV-positive tumors were type B (p = 1e-27) and associated with increased survival compared to the HPV-negative tumors (types C and D; p = 3e-05). Type B HPV-positive tumors had reduced *FAT1* and *TP53* mutations, whereas type B HPV-negative tumors had increased *caspase 8* mutations/loss. In the validation cohort, actionable mutations were found in *PI3KCA* and *TSC2* in types A and B HPV-negative tumors. Moreover, while the HPV-positive tumor was classified as type C, we identified a *caspase 8* homozygous deletion and absence of *FAT1* and *TP53* mutations, supporting the TCGA and GEO analysis. **Conclusions:** Exome and transcriptome analyses with cellular deconvolution from bulk RNA-seq enrich tumor characterization by including major TME components, providing a comprehensive biomarker profile for precision therapy and clinical decision making. Our prospective analysis identified TME parameters comparable with the large datasets and revealed targetable genomic alterations. Research Sponsor: None.

Detection of somatic mutations in saliva of patients with oral cavity squamous cell carcinoma. *First Author: Evgeny Izumchenko, University of Chicago, Chicago, IL*

Background: Oral cavity squamous cell carcinoma (OCSCC) frequently presents as clinically advanced disease with poor prognosis. When diagnosed at early stages, survival rates approach 80%, underscoring the need for validated, cost-effective detection methods. OCSCC is driven by the serial acquisition of genetic alterations. Tumor-defining somatic mutations are attractive biomarkers and hence their presence in saliva may be associated with malignancy as shown in a few proof-of-concept studies, including our previous work. Based on this premise, we present a low-cost, accurate, next generation sequencing (NGS) test with high clinical utility aimed at detecting mutations in the saliva for early diagnosis and potential screening of OCSCC. **Methods:** We have designed a custom NGS panel that covers exons of 7 most frequently mutated genes in OSCC. This minimal gene set derived from the analysis from 3 public datasets, predicted incidence of at least one somatic aberration in 89% of patients. We recruited 91 treatment-naïve OCSCC patients and profiled DNA from tissue and matched pre-operative saliva using this test. We also tested DNA from 12 subjects with premalignant lesions with high-grade oral dysplasia and matched saliva. **Results:** Using stringent variant calling criteria, at least one somatic variant was detected in 88 (96%) of the 91 primary tumors. 90.9% of the matched saliva were concordant, with only a minor decrease in early stage disease. Tumor-specific mutations (≥5% AF) in driver genes were detected in 10 (83.3%) dysplastic lesions, suggesting that driving clonal events may occur early in disease development. Interestingly, in 3 matched saliva of the dysplastic samples, the same mutations were detected. To ensure a variant is not a false positive call, we performed a vigorous multistep analytical validation of this saliva-based test: (i) independent re-sequencing of 24 saliva confirmed 94% reproducibility; (ii) no functionally relevant variants were detected in saliva from 12 of 13 healthy subjects without history of tobacco and alcohol usage; (iii) reproducibility, sensitivity, and specificity were confirmed using a positive control with 7 loci at 0.25% AF across 8 independent saliva sequencing runs and a certified negative control and was found to be on par with droplet digital PCR. **Conclusions:** These data highlight the feasibility of saliva-based testing for early diagnosis of OCSCC and premalignant lesions. 6563 Poster Session (Board #224), Fri, 8:00 AM-11:00 AM

18 FDG PET/CT prediction of treatment outcomes in patients with p16-positive, non-smoking associated, locoregionally advanced oropharyngeal cancer (LA-OPC) receiving deintensified therapy: Results from NRG-HN002. *First Author: Rathan M Subramaniam, 290 Great King Street, Dunedin, New Zealand*

Background: To determine the negative predictive value (NPV) of 12-14 week post-treatment PET/CT for 2-year progression-free survival (PFS) and 2-year locoregional control (LRC) in NRG-HN002, which is a two-arm phase II trial for patients with low-risk, non-smoking associated p16-positive LA-OPC randomized in a 1:1 ratio to reduced-dose IMRT with or without cisplatin. **Methods:** PET/CT scans were reviewed both centrally and locally by participating institutions. Tumor response evaluations for primary site, right neck, and left neck were carried out using a 5-point ordinal scale ('Hopkins Criteria'). Overall scores were then assigned as 'Negative,' Positive,' or 'Indeterminate.' Patients who had a 'Negative' score for all three evaluation sites were given an overall score of 'Negative.' The endpoints were NPV for LRC and PFS at 2 years testing NPV $\leq$ 90% vs $>$ 90% (1-sided alpha 0.10 and 76% power). **Results:** There were 316 patients enrolled, of whom 306 were randomized and eligible. Of these, 131 (42.8%) patients consented to a post-therapy PET/CT, and 117 (89.3%) patients were eligible for PET/CT analysis. The median time from end of treatment to PET/CT scan was 94 days (range 52-139). The rates of 2-yr PFS and LRC in the analysis subgroup were 91.3% and 93.8%, respectively. Based on central review, post-treatment scans were negative for residual tumor for 115 patients (98.3%) and positive for 2 patients (1.7%). The NPV for 2-year LRC was 94.5% (90% lower confidence bound [LCB] 90.6%; p = 0.07). NPV for 2-year PFS was 92.0% (90% LCB 87.7%; p = 0.30). Similar NPV results were obtained based on analysis of local reviews. **Conclusion:** Within the context of deintensification with reduced-dose radiation, the NPV of a 12-14 week post-therapy PET/CT for 2-year LRC is statistically $>$ 90%, similar to that reported for patients receiving standard chemoradiation. However, in this study, there was not enough evidence to conclude that the NPV of a 12-14 week post-therapy PET/CT for 2-year PFS is $>$ 90%. Computational discovery of non-mutational tumor-restricted antigens reveals evidence of immunoediting in head and neck squamous cell carcinoma. *First Author: Jan Ole Kemnade, Baylor College of Medicine, Houston, TX*

Background: We previously identified 107 expression-based tumor antigens (EbTAgs) defined as genes with negligible expression in healthy tissue and overexpression in cancer. EbTAgs present novel targets for the adaptive anti-tumor immune response and exhibit evidence of immunoediting in highly immune infiltrated oral cavity tumors. To detail the landscape of EbTAgs in head and neck squamous cell carcinoma (HNSC) and further elucidate EbTAg immunoediting, we compared the expression EbTAgs in the context of tumor immune infiltration among four HNSCC subtypes: oral cavity (OC), HPV+ oropharyngeal (HPV+OP), HPV- oropharyngeal (HPV-OP), and laryngeal/hypopharyngeal (LH). **Methods:** Upper quartile FPKM gene expression values of all protein coding genes were calculated for all HNSC samples using RNAseq data from The Cancer Genome Atlas (TCGA). TCGA HNSC tumors were divided into subtypes and analyzed for EbTAg expression. Individual tumor sample immune infiltrate was determined using unsupervised clustering of 14 immune cell signature ssGSEA scores for the HNSC dataset as a whole and for each subtype. **Results:** LH tumors expressed significantly more EbTAgs than other subtypes (p=0.0014), specifically HPV+OP (p=0.0008, Tukey's test). Immune clustering analysis showed that LH tumors were significantly more likely to be in the low than the high immune cluster whereas the reverse was true for HPV+OP tumors ($p<0.0001$). Hypothesizing that EbTAg expression was a function of tumor immune infiltration rather than HNSC subtype, we compared EbTAg expression between tumors in low and high immune clusters of the entire HNSC dataset as well as of each HNSC subtype. Significantly more EbTAgs were expressed in low immune tumors compared to high immune tumors of the HNSC dataset ($p<0.0001$). Similarly, significantly more EbTAgs were expressed in low immune tumors compared to high immune tumors of the OC, OP-all tumors, and HPV+OP datasets (p=0.0003, $p<0.0001$, p=0.0006) with a trend of more EbTAgs in the immune low versus high tumors in the HPV-OP and LH datasets (p=0.12, p=0.095). **Conclusions:** EbTAg expression in TCGA HNSC samples correlates with tumor immune infiltration resulting in lower expression under greater immunological pressure. These results reinforce the hypothesis that EbTAgs undergo immunoediting and are immunologically relevant. Exploration of EbTAgs as antigenic targets of modular vaccines or adoptive T-cell therapy as well as biomarkers of immune checkpoint inhibition therapy response is warranted. 6565 Poster Session (Board #226), Fri, 8:00 AM-11:00 AM

Does sinonasal cancer survival differ based on human papillomavirus status? *First Author: Shreya Pusapadi Ramkumar, Saint Louis University School of Medicine, St. Louis, MO*

Background: The sinonasal tract is a lesser known "hot spot" for the human papillomavirus (HPV), compared with the oropharynx. Additionally, unlike the oropharynx, the role of HPV tumor status in the survival and overall prognosis of the sinonasal tract and other non-oropharyngeal head and neck cancer sites remains inconclusive. Understanding differences in survival based on HPV status could be useful clinically, as it has been for HPV-positive oropharyngeal disease. This study examined whether there are survival differences in sinonasal cancer based on HPV status. **Methods:** This study included adult sinonasal cancer cases diagnosed between 2010 and 2015 in the National Cancer Database. A multivariable Cox proportional hazards model estimated the association between sinonasal cancer HPV status (HPV-positive, HPV-negative) and all-cause mortality while controlling for covariates (sex, age, race/ethnicity, insurance status, urban/rural, county-level household income, county-level percentage without high school diploma, comorbidity score, stage, histology, facility type, and treatment). A second multivariable proportional hazards model stratified HPV-positive tumor status by high-risk HPV (16, 18, 26, 31, 33, 35, 36, 45, 51, 52, 53, 56, 58, 59, 66, 67, 68, 69, 70, 73, 82, and 85) vs. low-risk HPV (6, 11, 32, 34, 40, 42, 44, 54, 61, 62, 64, 71, 72, 74, 81, 83, 84, 87, and 89) and compared their all-cause mortality to HPV-negative patients. **Results:** There were 1,750 sinonasal cancer patients included in this study, and 484 (27.7%) had HPV-positive disease. Among patients with HPV-positive disease, 75.6% had high-risk types. Mortality risk among all HPV-positive patients combined was 23% lower than HPV-negative patients (aHR = 0.77; 95% CI 0.64, 0.93). After stratifying by high-risk vs. low-risk HPV, high-risk HPV positive patients had 30% lower mortality risk than HPV-negative patients (aHR = 0.70; 95% CI 0.57, 0.88) while risk of mortality did not significantly differ between low-risk HPV-positive patients and HPV-negative sinonasal cancer patients. **Conclusions:** Sinonasal cancer shows differential survival based on HPV status, and sinonasal cancer patients positive for high-risk HPV had a significantly greater survival advantage than low-risk strains and those with HPV negative disease. HPV status might yet play a role in prognostication of sinonasal cancer, if future studies confirm these findings. Research Sponsor: None.

Combination of tumor multinucleation and spatial arrangement of tumor-infiltrating lymphocytes to predict overall survival in oropharyngeal squamous cell carcinoma: A multisite study. *First Author: Can Koyuncu, Case Western Reserve University, Cleveland, OH*

Background: Oropharyngeal squamous cell carcinoma patients can have major morbidity from current treatment regimens, necessitating accurate identification of patients with aggressive versus indolent tumors. In this study, we sought to evaluate whether the combination of computer extracted features of tumor cell multinucleation (MN) and spatial interplay of tumor-infiltrating lymphocytes (TILs) is prognostic of overall survival (OS) in OPSCC patients. **Methods:** OPSCC specimens from 688 patients were retrospectively collected from 3 different sites. 141 patients from site 1 formed the training set (D1) and 322 patients from site 2 and 225 patients from site 3 formed the independent validation cohort (D2, n = 547). A machine learning (ML) model was employed to automatically calculate a Multi-nucleation risk index (MNI), which is the ratio of the number of MN to the number of epithelial cells, to each patient. A separate ML model was also used to capture measurements related to the interplay between TILs and tumor cells (SpaTIL), which were then used to compute a risk score using a Cox regression model. The median value of both the MNIs and the SpaTIL risk scores in D2 were used to identify patients as either low- or high-risk. A definitive label was assigned to each patient by combining the class labels obtained from the MNI and SpaTIL models using a logical AND operation. **Results:** In D2, the patients with high-risk scores had statistically significantly worse survival in univariate analysis. The univariate analysis yielded an HR = 1.91 (95% CI: 1.25-2.93, p = 0.0027) for D. Multivariate analysis controlling the effect of different clinical variables is shown in the table. **Conclusions:** We presented a computational pathology approach to prognosticate disease outcome in OPSCC by combining features relating to density of multinucleation and spatial arrangement of TILs and validated the approach on a large multi-site dataset. With additional validation the approach could potentially help identify OPSCC patients who could benefit from de-escalation of therapy. Research Sponsor: U.S. National Institutes of Health.

Machine learning guided adjuvant treatment of head and neck cancer. *First Author: Frederick Howard, Section of Hematology/Oncology, Department of Medicine, University of Chicago, Chicago, IL*

Background: A combined analysis of the EORTC 22931 and RTOG 95-01 trials confirmed that patients (pts) with head and neck squamous cell carcinoma (HNSCC) and positive margins or extracapsular extension (ECE) benefit from adjuvant chemoradiotherapy (CRT), but the best treatment of pts with other risk factors is unclear. We hypothesized that deep learning models could identify the margin/ECE negative pts who benefit from CRT. **Methods:** We abstracted pts from the NCDB diagnosed from 2004-2016 with resected HNSCC who received radiotherapy (RT). We reserved 20% of pts for validation and used the remaining 80% for feature selection and model training. Features were chosen based on independent significance in a Cox proportional hazards model, and included demographics, tumor stage, site, grade, RT dose, and receipt of chemotherapy. HPV status was included, and imputed when unknown. We generated survival predictions with DeepSurv (DS), random survival forest (RSF), and neural network multitask (NNM) models. We consider CRT to be recommended by a model if predicted survival is longer with CRT than RT. We calculated the median overall survival (mOS) difference and hazard ratio (HR) for receipt of treatment in line with model recommendations. This was repeated with inverse probability of treatment weighting (IPTW) to account for confounding. As a comparator, we used the intermediate risk factors in the EORTC (T3-4 except T3N0 larynx, N2-3, LVI, deep nodes with oral / oropharynx cancer) and RTOG (2 involved nodes) trials as decision rules. **Results:** 36,831 pts from the NCDB met the inclusion criteria. 92% had T3-4 or node positive disease, and 40% received CRT. RTOG, EORTC, DS, NNM, and RSF models recommend CRT for 32%, 74%, 63%, 61%, and 35% of pts. The concordance index in the validation set was 0.696, 0.692, and 0.699 for DS, NNM, and RSF. Treatment according to model recommendations in the validation cohort was associated with a mOS benefit of 18.4 months (7.6 to 29.3, 95% CI) for DS, 20.5 months (8.8 to 32.2, 95% CI) for NNM, and 5.8 months (-6.6 to 18.3, 95% CI) for RSF. Similar results were seen with IPTW. **Conclusions:** Machine learning models can predict benefit from CRT in margin/ECE negative pts, and outperform treatment according to EORTC or RTOG inclusion criteria in this cohort. External validation of these models is warranted. Research Sponsor: None.

	HR (95% CI)	p-value	HR, IPTW (95% CI)	p-value
RTOG	0.94 (0.87 – 1.01)	0.10	0.84 (0.70 – 1.00)	0.06

Association of sarcopenia with higher toxicity and poor prognosis in nasopharyngeal carcinoma. *First Author: Xin Hua, SunYat-sen University Cancer Center, Guangzhou, China*

Background: Given the growing evidence that sarcopenia is associated with toxicity and survival in various cancers, we investigated its significance in patients with nasopharyngeal carcinoma (NPC) receiving concurrent chemoradiotherapy (CCRT). **Methods:** In this retrospective analysis, we studied 862 NPC patients who had received CCRT between 2010 and 2014. Sarcopenia was determined using routine pre-radiotherapy computed tomography (CT) simulation scans at the third cervical (C3) vertebral level. Receiver-operating characteristic (ROC) curve analyses were used to determine the optimal cutoff values. Propensity score matching (PSM) was applied to develop comparable cohorts of patients with or without sarcopenia. **Results:** A total of 862 patients were included as the primary cohort, and 308 patients were matched and regarded as the matched cohort. In the primary cohort, the five-year overall survival (OS), locoregional recurrence-free survival (LRFS), and distant metastasis-free survival (DMFS) rates for the sarcopenia group vs. non-sarcopenia group were 78.2% vs. 93.6% ($P < 0.001$), 89.4% vs. 87.9% ($P = 0.918$), and 82.5% vs. 89.0% ($P = 0.007$), respectively. Univariate and multivariate survival analyses revealed that sarcopenia was an independent predictor of OS ($P < 0.001$ and $P < 0.001$) and DMFS ($P = 0.009$, $P = 0.034$). Patients with sarcopenia experienced significantly higher rates of treatment-related toxicities compared with patients without sarcopenia ($P = 0.032$). In addition, patients with sarcopenia also experienced significantly worse treatment response than those without sarcopenia ($P = 0.004$). Similar results were found in a PSM cohort. **Conclusions:** The current findings support that sarcopenia is a promising indicator for predicting clinical outcomes in NPC patients receiving CCRT. A simple and rapid analysis on CT simulation images can provide information about the therapeutic toxicity and survival prognosis, consequently guiding personalized multi-modality interventions during CCRT. 6569 Poster Session (Board #230), Fri, 8:00 AM-11:00 AM

SNOW: Sitravatinib and nivolumab in oral cavity cancer (OCC) window of opportunity study. *First Author: Marc Oliva Bernal, Catalan Institute of Oncology (ICO), Barcelona, Spain*

Background: Sitravatinib (receptor TKI against TYRO3, AXL, MERTK and VEGF family of receptors) is predicted to increase M1-type tumor-associated macrophages (TAMs) and decrease MDSCs in the tumor microenvironment. SNOW is a window-of-opportunity study evaluating the immunogenic and antitumor effects of preoperative sitravatinib and nivolumab in patients (pts) with OCC. Early results demonstrated the combination was safe and active (Oliva et al, SITC 2019). Biomarker analyses and updated results are presented. **Methods:** Pts with untreated T2-4a, N0-2 or T1>1cm-N2 OCC are eligible. All pts receive oral sitravatinib 120mg daily from day (D) 1 up to 48h pre-surgery and 1 dose of Nivolumab 240mg on D15. Surgery planned between D23-D30. Standard of care adjuvant radiotherapy given based on clinical stage. Tumor pictures, fresh tumor biopsies, blood samples taken at baseline, D15 and pre-surgery. Tumor flow cytometry and multiplex immunofluorescence staining performed on all biopsies to study changes in immune-cell populations. Tumor whole-exome sequencing (WES) performed on baseline biopsies. **Results:** As of Jan 31st 2020, 10 out of 12 planned pts were enrolled. Study treatment was well-tolerated: only 1 pt had grade (G) >3 toxicity (hypertension) and 1 pt required surgery delay due to G2 thrombocytopenia. None had intraoperative complications. 1 pt had wound infection and tracheostomy bleeding 11 days post-surgery, possibly-related to study drugs. All pts had tumor reduction, 9/10 had pathological downstaging, including 1 complete response (Table). All had clear margins with no extranodal extension; none required adjuvant chemotherapy. All pts are alive with no recurrence (median follow-up= 69 weeks). Lower % of MDSCs and increased % of M1-TAMs and M1:M2 ratio trend was seen at D15 and pre-surgery, with stronger effect in major responders. Best responders (Pts S1-S2) had higher % of PD-L1+ TAMs at baseline. Tumor WES revealed an HRAS G12D mutation in pt S2 and a BLM mutation (DNA repair) in pt S6 (no downstaging). **Conclusions:** Pharmacodynamic analyses support the antitumor and immune effects of sitravatinib and nivolumab in OCC. Immune pathological response assessment and transcriptomics are on-going. Clinical trial information: NCT03575598. Research Sponsor: Tumor Immunotherapy Program, Princess Margaret Cancer Centre, Pharmaceutical/Biotech Company.

Phase I trial of hafnium oxide nanoparticles activated by radiotherapy in cisplatin-ineligible locally advanced HNSCC patients. *First Author: Christophe Le Tourneau, Institut Curie, Saint-Cloud, France*

Background: The standard of care non-surgical approach for locally advanced head and neck squamous cell carcinoma (LA HNSCC) patients (pts) is concurrent chemoradiation with high dose cisplatin or cetuximab in case of contra-indication. Older age is a contra-indication to cisplatin, and cetuximab might not improve survival in older pts. It is therefore urgently needed to develop new treatment options for elderly pts with LA HNSCC. NBTXR3 are hafnium oxide nanoparticles that can enhance the efficacy of radiotherapy (RT) by increasing locally the deposited dose. In this phase I clinical trial we aimed to evaluate the feasibility and safety of NBTXR3 administered as intratumoral (IT) injection prior to RT in LA HNSCC elderly pts. **Methods:** Pts with stage III-IV LA HNSCC of the oropharynx or oral cavity ineligible for platinum-based chemoradiation received a single IT injection of NBTXR3 into a selected primary tumor and intensity modulated RT (IMRT; 70 Gy/35 fractions/7 weeks) [NCT01946867]. A 3+3 dose escalation design, tested NBTXR3 dose levels equivalent to 5, 10, 15, and 22% of baseline tumor volume, followed by a dose expansion at the Recommended Phase II Dose (RP2D). Primary endpoints included RP2D determination, and early dose limiting toxicities (DLT). NBTXR3 intratumoral bioavailability and anti-tumor activity (RECIST 1.1) were also evaluated. **Results:** Enrollment was completed at all dose escalation levels: 5% (3 pts), 10% (3 pts), 15% (5 pts), and 22% (8 pts). No early DLT or SAE related to NBTXR3 or injection were observed. The median follow-up from NBTXR3 administration is 7.6 months. One AE (Grade 1) related to NBTXR3 and four AEs (Grade 1-2) related to the injection were observed. RT-related toxicity was as expected with IMRT. CT-scan assessment showed a good dispersion of NBTXR3 throughout the injected tumor and not in surrounding healthy tissues. The RP2D was determined to be 22%. Preliminary efficacy was evaluated in pts who received the intended dose of NBTXR3 and RT. A complete response of the injected lesion was observed in 9/13 (69%) evaluable pts at doses ≥10% (2 unconfirmed) and an overall complete response in 5/13 (38%) evaluable pts at doses ≥10%. Preliminary safety and efficacy data of the dose expansion cohort at the RP2D will also be presented. **Conclusions:** NBTXR3 activated by RT was well tolerated at all tested doses and demonstrated promising preliminary anti-tumor activity. Recruitment is ongoing in the dose expansion cohort. These results demonstrate that further testing of NBTXR3 in this population is warranted. Clinical trial information: NCT01946867. Research Sponsor: Nanobiotix, SA.

6574 Poster Session (Board #235), Fri, 8:00 AM-11:00 AM

DURTRERAD: A phase II open-label study evaluating feasibility and efficacy of durvalumab (D) and durvalumab and tremelimumab (DT) in combination with radiotherapy (RT) in non-resectable locally advanced HPV-negative HNSCC—Results of the preplanned feasibility interim analysis. *First Author: Konrad Friedrich Klinghammer, Charite Comprehensive Cancer Center, Berlin, Germany*

Background: DURTRERAD is a randomized phase II study evaluating feasibility and efficacy of durvalumab (anti-PD-L1) vs. durvalumab and tremelimumab (anti-CTLA-4) in combination with radiotherapy as primary treatment for locally advanced HPV negative HNSCC**.** (NCT03624231). Concurrent chemo-RT with a platinum-based regimen is considered the standard treatment, although efficacy and long-term toxicity are not satisfactory. Combining immunotherapy with RT might result in improved efficacy with limited long-term toxicity. **Methods:** The phase II study planned to enroll 120 pts, 60 pts (1:1) in each treatment arm. Treatment with DT (1500mg/75 mg, arm DT),or D (1500mg, arm D) both in combination with RT (70Gy) was considered to be feasible if less than 10% of the patients treated will discontinue treatment due to on-treatment toxicities. A first interim analysis for feasibility and efficacy was planned after randomisation of 20 patients. **Results:** So far 23 patients have been screened, 16 patients have been randomised and started their allocated treatment, 10 in arm D and 6 in arm DT. Of 10 patients in arm D 1 patient stopped infusional treatment due to immune related toxicity. Out of 6 patients in the DT arm, however, 5 patients stopped treatment due to treatment related AEs, 2 pts due to immune related toxicity with one Grade 5 AE. Three patients stopped due to non-immune related AE. The grade 5 AE prompted the interim analysis, which revealed non-feasibility as well as safety-issues of the DT+radiotherapy combination . As a result, the DT arm was prematurely terminated. **Conclusions:** Even though in the recurrent/metastatic setting DT was not associated with increased toxicity, DT in combination with RT was not feasible in our poor prognostic, vulnerable patient cohort of advanced HPV negative unresectable HNSCC, warranting early disclosure of these results. No increase in toxicity was observed in the D monotherapy arm, and the trial continued with D monotherapy in combination with RT. Clinical trial information: NCT03624231. Research Sponsor: AstraZeneca.

Dose and volume de-escalation for HPV-associated oropharyngeal cancer: Long-term follow-up of the OPTIMA trial. *First Author: Ari Rosenberg, University of Chicago, Chicago, IL*

Background: Human papilloma virus (HPV) associated oropharyngeal cancer is associated with a favorable prognosis, but standard multimodality treatment is associated with substantial treatment related toxicity. A de-escalation treatment paradigm that optimizes oncologic outcomes while reducing toxicity is needed. We sought to further expound on our published OPTIMA data with long-term follow-up and additional pts subsequently treated using the OPTIMA treatment paradigm. **Methods:** Long-term follow-up of our institutional de-escalation OPTIMA trial (NCT02258659) and retrospective review of additional patients treated subsequently per OPTIMA outline was performed. Pts were classified as low-risk (LR) ($\leq$T3, $\leq$N2B, $\leq$10PYH) or high-risk (HR) (T4, $\geq$N2c, $>$ 10PYH). Pts received induction chemotherapy (IC) of 3 cycles of dose dense carboplatin and nab-paclitaxel (OPTIMA) or paclitaxel (subsequently treated). LR with $\geq$50% response received low-dose radiotherapy (RT) to 50 Gy. LR with 30-50% response or HR with $\geq$50% response received intermediate-dose chemoradiotherapy (CRT) to 45Gy. All others received full-dose CRT to 75Gy. **Results:** 108 pts consented and 107 were treated (61 on study; 46 subsequently) from October 2014 through November 2019. 1 pt transferred care post-enrollment. Median follow-up was 36 months (interquartile range 17-45). Median age was 63 years (range 33-84) and 95% were male. 47% were LR and 53% were HR. $\geq$50% tumor shrinkage occurred in 78/107 (73%) of pts overall, and 37/51 (73%) among LR; 41/56 (73%) among HR. 82% of pts received de-escalated (C)RT. Overall, 94% of pts were alive at last follow-up (98% LR; 89% HR). 3 pts (2 HR and 1 LR) developed disease recurrence (2.7%), with 2 local recurrences and 1 distant recurrence. Likelihood of G-tube placement was 3% in low-dose RT, 35% in intermediate-dose CRT, and 84% in full-dose CRT. **Conclusions:** IC followed by risk-adapted dose and volume de-escalated treatment for HPV+ oropharyngeal cancer demonstrates excellent oncologic and functional outcomes with long-term follow-up. 6576 Poster Session (Board #237), Fri, 8:00 AM-11:00 AM

Single-cell multiplexed proteomics to identify novel polyfunctional CD8+ T cell signatures induced by nivolumab in head and neck cancer patients after salvage surgery. *First Author: Shuchi Gulati, University of Cincinnati Medical Center, Cincinnati, OH*

Background: Immune checkpoint inhibitors (ICIs) are FDA approved for use in head and neck squamous cell cancer (HNSCC), however, only ~20% patients achieve a response. Identification of biomarkers of response or toxicity remains a challenge. Polyfunctional T-cells, or T-cells producing multiple cytokines, have been recognized as contributors to durable immunity against various cancers. However, their role has not been studied prospectively in HNSCC patients receiving ICIs. To look for an early predictor of response, we used single-cell functional proteomic profiling (IsoPlexis) on blood samples pre- and post- first dose of nivolumab (nivo) in patients on our phase-II study of locally recurrent HNSCC (NCT03355560). **Methods:** HNSCC patients who failed definitive radiation +/-chemotherapy and were subsequently treated with curative intent salvage resection were enrolled to receive 6 months of nivo beginning 4 to 11 weeks after surgery. Blood samples were collected before and after the first dose of nivo. Peripheral blood mononuclear cells were isolated, enriched for CD8+ T cells and using the 32-plex IsoCode technology, single-cell cytokine signals were captured and polyfunctional strength of CD8+ T cells was evaluated across four groups (effector, stimulatory, regulatory, inflammatory). A comparison analysis was performed between pre- and post- nivo treatment and between patients who relapsed (non-responders) vs those who did not (responders). **Results:** Thirty-three of 39 planned patients have been enrolled, of which 28 are evaluable and 5/28 (18%) developed recurrence. Median age is 68 years (range 51-85), 9/28 (32%) patients are female, 26/28 (93%) are white, disease sites include oropharyngeal 6/28 (21%), oral cavity 11/28 (39%) and larynx 11/28 (39%). Samples were evaluated at a median follow up of 5.9 months from enrollment. Single-cell analysis demonstrated a strong upregulation of polyfunctional human CD8+ T cell subsets in responders. Polyfunctional Strength Index (PSI) was enhanced in CD8+ T cells across the responders' samples, composed largely of effector cytokines (granzyme-β, IFN-γ, MIP-1α, perforin, TNF-α). **Conclusions:** Single-cell functional proteomic analysis revealed significantly upregulated polyfunctional profiles and an increase in effector cytokines in patients who responded to nivo. This data provides important insights into PD-1 inhibitor triggered T-cell activity and may be used to predict response to ICIs in HNSCC patients using a blood test. Clinical trial information: NCT03355560. Research Sponsor: BMS.

6577 Poster Session (Board #238), Fri, 8:00 AM-11:00 AM

Nivolumab (Nivo) and ipilimumab (Ipi) in combination with radiotherapy (RT) in high-risk patients (pts) with locally advanced squamous cell carcinoma of the head and neck (LA SCCHN). *First Author: Jennifer Maria Johnson, Thomas Jefferson University, Department of Medical Oncology, Philadelphia, PA*

Background: Immune checkpoint inhibitors (ICI) are the standard of care in recurrent/metastatic SCCHN but their role in the curative therapy setting with RT is under study. We evaluated the novel approach of combining Nivo, a PD-1 inhibitor, and Ipi, a CTLA-4 inhibitor, in lieu of chemotherapy, with concurrent RT in pts with high-risk LA SCCHN. **Methods:** We enrolled newly diagnosed, chemotherapy eligible pts with AJCC 7th edition stage IVA-IVB SCCHN of the oral cavity, oropharynx (OP), hypopharynx, and larynx. HPV+ OP were T4, N2c or N3 OP. Nivo (3 mg/kg every 2 weeks IV x 17 doses) and Ipi (1 mg/kg every 6 weeks x 6 doses) were administered starting 2 weeks prior to the start of RT. RT was prescribed to a dose of 70 Gy delivered in 2 Gy/fraction/day using VMAT. The primary objective was safety of combination ICI with RT. Secondary objectives included 1-year progression-free survival (PFS), overall survival, and correlative studies. **Results:** 24 pts were enrolled; median age of 60 (range 48-77); 20 were male; 16 oropharynx (14 HPV+), 2 hypopharynx, and 6 larynx; AJCC 7th edition stage IVA (23), IVB (1). Grade 3 acute in-field adverse events (AEs) occurred in 17/24 (71%) of patients during concurrent ICI-RT (9 mucositis, 6 dysphagia, 5 dermatitis, 4 odynophagia, 1 dysphonia); there were no grade 4/5 AEs during ICI-RT. During ICI maintenance 5 pts developed in-field ulcerations at the primary site detected at an average of 3 months post RT; 1 of them died of bleeding due to erosion into the carotid artery with no evidence of active cancer; 4 additional pts developed in-field necrosis. 7 pts discontinued ICI treatment at $>$ 3 months post-RT: 1 due to immune AE, 5 due to in-field ulcerations, 1 due to persistent mucositis without ulceration. 4 pts (17%) had grade 3 immune AEs: 1 elevation of lipase, 1 colitis, and 2 rash. There were no grade 4/5 immune AEs. The median follow-up is 16 months (range, 6.3-30.6). 21 of 24 pts (87.5%) are alive with no evidence of disease progression. 2 pts recurred at distant sites: 1 had a solitary lung lesion at 11 months and was treated with RT; 1 in mediastinal lymph nodes at 9 months and was treated with chemo-RT. Locoregional control remains at 100%. **Conclusions:** RT plus dual ICI combination was feasible and resulted in no locoregional relapses so far in 24 high-risk LA SCCHN pts. Longer follow-up is needed to fully assess PFS and locoregional control as well as post-treatment in-field ulceration/necrosis that may be attributed to the potent radiosensitizing effect of dual PD-1 and CTLA-4 blockade. Clinical trial information: NCT03162731. Research Sponsor: Bristol Myers Squibb.

6578 Poster Session (Board #239), Fri, 8:00 AM-11:00 AM

Prospective, longitudinal digital activity monitoring before and after treatment of low-risk oropharyngeal squamous cell carcinoma: A feasibility study. *First Author: Gary Brandon Gunn, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Given the expected excellent prognosis of low-risk oropharyngeal squamous cell carcinoma (OPSCC), consideration of long-term toxicity and functional outcomes has become increasingly important. Activity monitors (e.g. FITBIT) are imperfect but have been shown to have reasonable validity in healthy adults. Here we aimed to test the feasibility of using medical grade longitudinal digital activity monitoring to better define objective functional outcomes after treatment of low-risk OPSCC. **Methods:** This prospective, observational parallel cohort study included patients with previously untreated stage I-III (AJCC 7) OPSCC eligible for standard of care single-modality treatment with either Intensity-Modulated Proton Therapy (IMPT) or TransOral Robotic Surgery (TORS). Objective Actigraph accelerometer data (Actigraph, Pensacola, FL) were collected continuously for 1 week at baseline, 3, 6 and 12 months after treatment along with subjective patient-reported outcome (PRO) measures. **Results:** Forty-four patients (34M, 10F) enrolled with median age 59 years (range: 42-78). Baseline, 3 and 6 month activity data were available for 40 patients (91%): 16 IMPT and 24 TORS. There was a significant decrease in mean percent of day performing moderate to vigorous physical activity (MVPA) (-0.78, 0.021) mean number of steps/minute (-1.1, $p = 0.035$), and mean kcals/day (-115.9, $p < 0.001$) from baseline to 3 months after treatment for the overall cohort. A significant decrease in mean kcals/day (-82.2, $p = 0.004$) persisted for the overall cohort at 6 months with no significant difference between groups. **Conclusions:** Longitudinal digital activity monitoring is feasible before and after treatment of low-risk OPSCC. This approach may offer objective functional endpoints for future de-escalation trials. Similar short-term decreases in objective activity measurements were observed after IMPT and TORS. Long-term (12 month) activity data and correlations to subjective PRO measures will be available at the time of presentation. Clinical trial information: 02663583. Research Sponsor: Philanthropy, U.S. National Institutes of Health.

6579 Poster Session (Board #240), Fri, 8:00 AM-11:00 AM

Risk of chronic opioid use after radiation for head and neck cancer: A systematic review and meta-analysis. *First Author: Sondos Zayed, Department of Radiation Oncology, London Health Sciences Centre, London, ON, Canada*

Background: Opioid overuse is a major international public health concern. The prevalence and risk factors for chronic opioid use (COU) in radiation-induced head and neck pain are poorly understood. The aim of this study was to estimate the rates of COU and to identify risk factors for COU in head and neck cancer (HNC) patients undergoing curative-intent radiotherapy (RT) or chemoradiotherapy (CRT). **Methods:** We performed a systematic review and meta-analysis based on the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines, using the PubMed (Medline), EMBASE, and Cochrane library databases, queried from dates of inception until present. COU was defined as persistent opioid use ≥3 months after treatment completion. Studies in the English language that reported on COU in HNC patients who received RT/CRT were included. Meta-analyses were performed using random effects models. Heterogeneity was assessed using the I^2 value. **Results:** A total of 134 studies were identified, with 7 retrospective studies (reporting on 1841 patients) meeting inclusion criteria. Median age was 59.4 years (range 56.0-62.0) with 1343 (72.9%) men and 498 (27.1%) women. Primary tumour locations included oropharynx (891, 48.4%), oral cavity (533, 29.0%), larynx (93, 5.1%), hypopharynx (32, 1.7%), and nasopharynx (29, 1.6%). 846 (46.0%) patients had stage I/II disease and 926 (50.3%) had stage III-IV disease. 301 (16.3%) patients had RT alone, 738 (40.1%) received CRT, and 594 (32.3%) underwent surgery followed by adjuvant RT/CRT. The proportion of HNC patients who received radiotherapy and developed COU was 40.7% at 3 months (95% CI 22.6%-61.7%, $I^2 = 97.1\%$), 15.5% at 6 months (95% CI 7.3%-29.7%, $I^2 = 94.3\%$) and 7.0% at 1 year. There were significant differences in COU based on primary tumor sites ($P < 0.0001$), with the highest rate (46.6%) in oropharyngeal malignancies. Other factors associated with COU included history of psychiatric disorder (61.7%), former/current alcohol abuse (53.9%), and start of opioids prior to radiation treatment (51.6%). There was no significant difference in the proportion of COU by gender ($P = 0.683$), disease stage (I/II vs III/IV; $P = 0.443$), or treatment received (RT, CRT, or adjuvant RT/CRT; $P = 0.711$). **Conclusions:** A significant proportion of patients who undergo radiotherapy for head and neck cancer suffer from COU. High-risk factors for COU include an oropharyngeal primary tumour, history of psychiatric disorder, former/current alcohol abuse, and pre-treatment opioid use. New strategies to mitigate opioid use are needed. Research Sponsor: None.

6580 Poster Session (Board #241), Fri, 8:00 AM-11:00 AM

Upfront DPYD genotyping and toxicity associated with fluoropyrimidine-based concurrent chemoradiotherapy for oropharyngeal carcinomas. *First Author: Antoine Desilets, CHUM, Montreal, QC, Canada*

Background: The combination of carboplatin and 5-fluorouracil (5-FU) is effective when used concurrently with radiotherapy for locoregionally advanced oropharyngeal carcinomas (Calais et al. 1999). DPYD polymorphisms can be associated with an increased risk of severe toxicity to fluoropyrimidines (Deenen et al. 2016). Upfront screening for the DPYD*2A allele is available in the province of Québec, Canada since March 2017. This study aimed to determine the effect of upfront genotyping on grade ≥3 toxicities. **Methods:** The studied population included all consecutive cases of oropharyngeal carcinomas treated with 5-FU based chemoradiotherapy one year before and after the implementation of upfront DPYD*2A genotyping. All patients were treated at the Centre Hospitalier de l'Université de Montréal (CHUM) between March 2016 and April 2018. Clinical data were extracted from chart review. Extended screening for 3 supplemental at-risk DPYD variants was also retrospectively performed in August 2019. **Results:** 181 patients were included in the analysis (87 patients before and 94 patients after DPYD*2A screening implementation). 91% of patients (n = 86) were prospectively genotyped for the DPYD*2A allele. Of those screened, 2% (n = 2/87) demonstrated a heterozygous DPYD*2A mutation. Those two patients received cisplatin-based treatment and thus avoided 5-FU toxicities. Extended genotyping of DPYD*2A-negative patients later allowed for the retrospective identification of 6 additional patients with alternative DPYD variants (two c.2846A > T and four c.1236G > A allele mutations). **Conclusions:** The DPYD*2A, c.2846A > T and c.1236G > A polymorphisms are associated with an increased risk of G3-4 toxicity to 5-FU, as well as higher hospitalization rates. Upfront DPYD genotyping can identify patients in whom fluoropyrimidine-related toxicity should be avoided. This represents an interesting addition in terms of pharmacovigilance. Research Sponsor: None.

Adverse events of interest are summarized in the table below.

	Pre-DPYD*2A screening	Post-DPYD*2A screening	*p*	DPYD-mut (non-DPYD*2A) (n = 6)	DPYD WT (n = 78)	*p*
Grade ≥3 toxicity	71%	62%	0.18	100%	60%	0.046
Mucositis	54%	47%		100%	44%	
Dysphagia	39%	26%		66%	23%	
Radiation-induced dermatitis	15%	14%		0%	14%	
Neutropenia	8%	9%		17%	9%	
Hospitalization	29%	21%		33%	23%	
Enteral feeding	41%	30%		50%	32%	

6582 Poster Session (Board #243), Fri, 8:00 AM-11:00 AM

A novel multiple-catheter implantation method for advanced head and neck cancer. *First Author: Masatoshi Ohmae, Rinku General Medical Center, Izumisano, Japan*

Background: We previously developed a super-selective intra-arterial chemotherapy (iaCT) approach for head and neck cancer (HNC), by which, an intra-arterial catheter is retrogradely inserted via either the superficial temporal artery (STA) or occipital artery (OA) and connected to a subcutaneous reservoir. As a result, since this approach overcomes the need for frequent fluoroscopy sessions, the infusion frequency can be increased and the therapeutic effectiveness improved. However, since the anticancer effect is limited to the region supplied by the selected blood vessel, it is often difficult to control an advanced HNC by single-catheter iaCT. Subsequently, a novel multiple-catheter implantation method (MCIM) for super-selective iaCT has been developed using, both, the STA and OA. **Methods:** A total of 21 patients with stage III or IV HNC were enrolled in this study and treated via MCIM for iaCT between 2009 and 2017. The catheters were super-selectively placed in the tumor-feeding arteries after having entered the STA or OA. The first catheter was introduced into one of the target branches. Next, a second catheter was introduced into another target branch. If a third catheter was required, the procedure was repeated. The extra-arterial portions of the catheters were subcutaneously connected to an implanted juxta-mastoidal infusion reservoir. **Results:** The response rate was 100%; particularly, 20 cases of complete response and 1 of partial response were confirmed. Although the partial responder underwent salvage surgery and two complete responders ultimately died (due to either delayed recurrence or brain metastases), the other 18 patients have been living cancer-free for 2-9 years. **Conclusions:** The MCIM method allows to expand the infusion region while maintaining the main advantages of super-selective iaCT. As a consequence, due to the lack of need for patient confinement in the catheter room and for frequent fluoroscopy sessions, patients' mental and physical distress, medical expenses, and treatment time are all ultimately reduced. Research Sponsor: None.

6583 Poster Session (Board #244), Fri, 8:00 AM-11:00 AM

Neoadjuvant nivolumab (N) plus weekly carboplatin (C) and paclitaxel (P) in resectable locally advanced head and neck cancer. *First Author: Ralph Zinner, University of Kentucky, Department of Medical Oncology, Lexington, KY*

Background: Despite multimodality standard therapy, patients (pts) with resectable locally advanced squamous cell carcinoma of the head and neck (LA SCCHN) are at high risk for recurrence. Pts with pathologic complete response (pCR) or major pathologic response (MPR) to neoadjuvant chemotherapy have improved overall survival. PD-1 checkpoint inhibitors are approved in combination with platinum-based chemotherapy in the 1st-line treatment of recurrent/metastatic SCCHN. We hypothesize the addition of N to wkly carboplatin C and P will increase the pCR rate at the primary site compared to historical controls. **Methods:** This is an investigator-initiated trial for pts with newly diagnosed (AJCC 8^{th}) stage III-IV HPV- (oral cavity (OC), oropharynx (OP), hypopharynx (HP), and larynx (L) or stage II-III HPV+ OP SCCHN without distant metastasis who are surgical candidates. Neoadjuvant chemo starting d1 is C AUC 2 IV wkly x 6 plus P 100 mg/m2 IV wkly x 6 plus N 240 mg IV q 2 wks x 3 with surgery on wk 8. The primary endpoint is pCR at the primary site. To estimate pathologic response, the resected pathology specimens are cut >1 section/cm. Using the Aperio Digital scanning system, slides are imaged, and then annotated by at least 2 pathologists for viable tumor vs. treatment effect with areas automatically calculated to yield the percentage of viable tumor. Our primary endpoint will be reached if 11/37 planned pts have a pCR at the primary site. **Results:** From 11/17-12/19, 27 pts received the study regimen and had surgery (1/27 had an unknown primary; thus, inevaluable for the primary endpoint). Of 27 pts, median age was 59 (46-83), women 31%, HPV+ 15%, OC 73%, OP 19%, HP 7%, L 4%; stage III 33%, stage IVA 67%. Gd 3 toxicities were in 37% pts; 1 pt febrile neutropenia, 3pts anemia, 1pt diarrhea, 1pt cellulitis and 1pt rash. Four pts had gd 3-4 neutropenia. Dose reductions were in 2 pts, and 4 pts had 1 wkly dose dropped. All 27 pts went to surgery, none with PD by CT; all with negative margins. One pt died with rapid recurrence; no other recurrences (median f/u 13 mos). Our primary endpoint was met; 11/26 (42%) pts (excluding pt with unknown primary) had a pCR at the primary site. 9/23 (39%) HPV- pts, had a pCR. MPR or pCR was 18/26 (69%) and in HPV- pts, 15/23 (65%). 2/11 pts had microscopic residual disease in 1 LN each. **Conclusions:** The combination of N and wkly PC was well tolerated. The primary endpoint of pCR at the primary site in > 11/37 pts was met with the 27^{th} pt. Accrual continues. Exploratory outcomes assessing markers of immune bias in tumor tissue and plasma are in process. Clinical trial information: NCT03342911. Research Sponsor: Bristol-Myers Squibb.

6584 Poster Session (Board #245), Fri, 8:00 AM-11:00 AM

***RAS*-mutated sporadic medullary thyroid cancer: A single-center experience.** *First Author: Spandana Brown, Houston Methodist Hospital, Houston, TX*

Background: Activating *RAS* mutations are recognized as important drivers in sporadic medullary thyroid cancer (sMTC), with a reported prevalence between 0-43%. However, few studies have looked at correlations between *RAS*-mutated sMTC and clinicopathologic features. **Methods:** Patients with sMTC diagnosed between 1992 – 2019 with NGS testing for *RET* and *RAS* mutations seen at a tertiary cancer center were retrospectively evaluated. The objective was to analyze demographic and clinical features among patients with *RAS*-mutated sMTC and to evaluate associations between these features and overall survival (OS). Analyses were performed to correlate patient demographics and pathologic staging with treatment characteristics, disease course, and OS. **Results:** We identified 42 patients (50% female) with *RAS*-mutated sMTC out of 218 pts with sMTC. Median age at diagnosis was 50 years (range 24-78 years). 26 (62%) patients had stage IV disease at time of diagnosis. 28 (67%) of patients had *HRAS* mutations and 14 (33%) had *KRAS* mutations. *HRAS Q61R* was the most common *HRAS* mutation type (n = 19, 45%). Median follow-up time was 64 months (range 23-274 months) during which 11 (26%) patients died. The median OS was 16.2 years, with 5- and 10- year OS of 88% and 73% respectively. Of the 20 (48%) patients who received systemic therapy, 79% had stage IV disease and tended to be older (median age 54). Median time from diagnosis to initiation of systemic therapy was 33 months. Factors associated with worse OS included distant metastases at diagnosis, shorter time interval between diagnosis and treatment, and Ctn/CEA doubling times < 6 months. *HRAS Q61R* mutations were associated with a better prognosis, with 100% 10-year OS compared with 10-year OS of 39% and 51% (p = 0.02) for other *HRAS* and *KRAS* mutations respectively. **Conclusions:** At a tertiary cancer center, patients with *RAS*-mutated sMTC had a 10-year OS rate of 73%, with significantly worse OS in patients with *HRAS/KRAS* mutations other than *HRAS Q61R*. In comparison, prior studies have reported 10-year OS rates between ~71-90% in sMTC and 10-year OS rates as low as 56% for more aggressive *RET M918T* sMTC mutations. The findings here are consistent with other studies that have suggested patients with *RAS*-mutated sMTC are at intermediate risk for aggressive disease, though there are limited data on OS rates in *RAS* or RAS-/RET- sMTC. Future research comparing outcomes between various *RAS* mutations and in comparison to *RET+* and RAS-/RET- patients is needed, especially as systemic therapy use in *RAS*-mutated sMTC evolves. Research Sponsor: None.

6585 Poster Session (Board #246), Fri, 8:00 AM-11:00 AM

ELLA01-1: A study to determine the utility of TP53 mutations as a prognostic biomarker in adenoid cystic carcinoma. *First Author: Robert Metcalf, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: TP53 mutations are reported in 5% of patients with adenoid cystic carcinoma (ACC). Whilst TP53 mutations are associated with adverse clinical outcomes across multiple tumour types, their prognostic significance in ACC is unknown. We sought to determine the utility of TP53 mutations as a prognostic biomarker in a prospective cohort of ACC patients. **Methods:** From April 2017 to September 2019, 146 patients with ACC were prospectively recruited to an ethically approved study. DNA was extracted from archival FFPE samples and underwent targeted next generation sequencing (Qiagen GeneRead DNAseq Targeted Panel V2 n = 134; Foundation Medicine; n = 12). Clinical, pathological and outcome data were collected on all patients and Kaplan-Meier survival analysis was performed to test for survival differences between TP53 mutated and wild-type ACC. **Results:** 146 ACC patients (mean age 48 years, range 16-79) underwent DNA extraction and next generation sequencing for TP53 mutations. The primary site was major salivary gland in 47% and minor salivary gland in 48% (other 5%). Analysis was successful in 122/146 patients (84%). Recurrent or metastatic disease was present in 94% (115/122) at study entry. TP53 alterations were identified in 9% (11/122), most frequently within the DNA binding domain (9/11). Non-pulmonary visceral metastases were seen more frequently in TP53 wild-type than in TP53 mutated ACC (44% vs. 10%; p = 0.042), and other clinical parameters were balanced between groups. During follow-up from diagnosis (median follow up 6.6 years), death occurred in 45% of patients with TP53 mutation and in 23% with TP53 wild-type ACC (p = ns). In TP53 mutated ACC, median overall survival was significantly shorter (5.3 vs. 16.3 years), and 10-year survival rate significantly lower (42% vs. 82%) than TP53 wild-type ACC (log-rank p = 0.013). **Conclusions:** In this cohort of patients with ACC, TP53 mutations were seen with a higher frequency than previously reported. This may be explained by the high frequency of recurrent or metastatic disease at study entry. TP53 mutation was associated with a statistically significant reduction in overall survival in patients with recurrent and metastatic ACC. These findings suggest that stratifying by TP53 status may be of clinical value to inform follow-up strategy in addition to established clinical, pathological and genomic biomarkers. Research Sponsor: The Christie Charity, University of Manchester, Syncona Foundation, Infrastructure Industry Foundation.

6586 Poster Session (Board #247), Fri, 8:00 AM-11:00 AM

Recurrent or metastatic salivary gland tumor (MSGT) patients treated with selinexor, a first in class selective exportin-1 (XPO1) inhibitor. *First Author: Eoghan Ruadh Malone, Princess Margaret Hospital, Toronto, ON, Canada*

Background: MSGT are rare with limited systemic treatments. This single institution, prospective study in recurrent or metastatic (RM) MSGT involved 2 phases: genomic profiling followed by treatment with either genomically-matched or unmatched therapy. Here we present the results of the unmatched arm for patients (pts) treated with S an oral selective inhibitor of XPO1 that leads to activation of tumor suppressor proteins and retention of oncoprotein mRNAs in the cell nucleus, inducing cancer cell apoptosis. **Methods:** Patients (pts) with RM-MSGT had archived paraffin embedded tumor samples profiled with targeted next generation sequencing, immunohistochemistry for androgen receptor (AR) and fluorescent in-situ hybridization for HER-2 and ALK. If no actionable mutations were identified or if no matched agents were available, pts with progressive disease could receive S (60mg given twice weekly Q28 days). The study had a simon-2 stage design; 1 partial response in the first 18 pts treated with S, would trigger an additional 7pts to receive S in stage 2. **Results:** Between July 2014 and April 2019 85 pts were enrolled on study: 73 had sequencing which identified 41 with no actionable mutations and 32 with actionable mutations. 18 pts (10F/8M, median age 61 years [40-79]) were treated with S and included adenoid cystic (n = 8), salivary duct (n = 4), acinic cell (n = 2) and other subtypes (n = 4). Of these 18, 4 pts had actionable aberrations: AR amplification (n = 2), mutations in SMARCB1 (n = 1) and CDKN2A (n = 1). 13pts were treatment naïve, 3pts and 2pts received 1 and 2 or more lines of treatment respectively prior to enrollment: androgen deprivation therapy (n = 2), chemotherapy (n = 3), early phase clinical trials (n = 3). The median number of cycles of S received were 3 (range: 1-19). The best response by RECIST was SD in 13pts (72%) (SD > 6 months (range: 6-18 months) in 5pts (28%); tumor reduction measured in 7pts (39%)), no PRs, PD in 3pts (17%), and 2pts (11%) were not evaluable for response due to insufficient duration of treatment coming off early due to toxicity. The median PFS (95% CI) was 7.6 (3.5-NA) months and the median OS (95% CI) was 15.4 (7.3-NA) months. The most common drug-related toxicities were grade 1-2 fatigue 14pts (78%), nausea 13pts (72%) and dysguesia 10pts (56%). 5 (28%) pts had a dose reduction and 6 (33%) in total had a dose interruption due to toxicity. **Conclusions:** Single agent antitumor activity was limited and the side effect profile was tolerable. No specific genomic aberration was associated with response to S. Clinical trial information: NCT02069730. Research Sponsor: Karyopharm.

6587 Poster Session (Board #248), Fri, 8:00 AM-11:00 AM

Radioiodine (RAI) in combination with durvalumab for recurrent/metastatic thyroid cancers. *First Author: Bharat Burman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune checkpoint blockade (ICB) has limited efficacy for radioiodine-refractory thyroid cancer. The high incidence of autoimmune thyroid disease and ICB-induced hypothyroidism suggests that loss of T cell tolerance to thyroid protein epitopes is common and can be activated by ICB to induce immune responses. We hypothesize that RAI can enhance presentation of thyroid protein immunogens and putative neoantigens in thyroid cancers to amplify the effectiveness of ICB. We studied the safety and efficacy of RAI plus the anti-PD-L1 agent durvalumab (durva) in recurrent/metastatic (R/M) patients (pts). **Methods:** Pts. had at least one RAI-avid tumor on the most recent RAI scan or one tumor on FDG PET with an SUVmax < 10. RECIST measurable disease was required. Any number of prior therapies was allowed. Pts were treated with durva 1500 mg IV every 4 weeks with recombinant human TSH (rhTSH)-stimulated RAI (100 mCi) administered in Cycle 1. Treatment beyond progression was allowed. The primary objective was to assess safety. Durva related dose limiting toxicities (DLTs) were monitored for 6 weeks after the first dose. Since no durva DLTs were observed in the first 6 pts, per protocol rules the trial accrued 11 pts total. Secondary objectives were assessing best overall response (BOR) per RECIST and progression-free survival (PFS). **Results:** 11 pts (7 female) were enrolled. Eight had prior drug therapy. No DLTs or $>$ Grade 3 durva related adverse events (AEs) were observed. The most common non-laboratory AEs (regardless of attribution) were cough (7), hypertension (7), pain (6), edema (5), and fatigue/nausea/diarrhea/arthralgia/dry skin/dyspnea/edema (4 each). As of 2/6/20, 2 had partial response, 7 stable disease, and 2 progression of disease as BOR. Six pts had tumor regression. Four pts received treatment for $>$ 6 months. Six are still on treatment. Analyses of research biopsies (bxs) (8 had pre-treatment bxs, 6 had an additional on-treatment bx) will be presented. **Conclusions:** Durva plus RAI is safe and well tolerated. The preliminary efficacy signal in this small cohort is promising. Understanding how RAI plus PD-L1 targeting impacts the tumor immune microenvironment may guide how RAI should be evaluated in future ICB trials. Clinical trial information: NCT03215095. Research Sponsor: AstraZeneca, U.S. National Institutes of Health.

6588 Poster Session (Board #249), Fri, 8:00 AM-11:00 AM

Effect of ARMS-qPCR on detection sensitivity of earlier diagnosis of papillary thyroid cancers with worse prognosis determined by BRAF V600E and TERT promoter mutation coexisting. *First Author: Peng-cheng Yu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Co-existing of *BRAF* V600E and *TERT* promoter C228T/C250T mutation has been extensively related to prognosis in thyroid cancer. Our study aimed to establish a more sensitive method for mutation detection and explore the correlation more in-depth. **Methods:** *BRAF* and *TERT* promoter mutation status of 250 papillary thyroid cancer was detected by both Amplification Refractory Mutation System quantitative PCR (ARMS-qPCR) and Sanger sequencing to compare the sensitivity. The associations between the mutation status and the clinicopathological features were analyzed. **Results:** ARMS-qPCR displayed higher sensitivity than Sanger (*BRAF* V600E: 75.2% vs. 52.4%, $p< 0.001$; *TERT* promoter C228T/C250T: 12.0% vs. 3.6%, $p= 0.001$; Co-mutation (9.6% vs. 3.2%, $p= 0.005$). Both methods indicated that patients with *BRAF* V600E and *TERT* promoter co-mutation were higher in age at diagnosis (ARMS-qPCR: 51.0 ± 14.2 vs. 40.2 ± 12.6, $p<0.001$; Sanger: 64.3 ± 7.1 vs. 40.5 ± 12.6, $p <0.001$), and the recurrence rate (16.7% vs. 3.1%, $p= 0.014$; 50.0% vs. 2.9%, $p< 0.001$), besides, the co-mutation group were related to more advanced TNM stage ($p< 0.001$; $p< 0.001$) and higher MACIS score (5.1 ± 1.5 vs. 4.2 ± 0.7, $p= 0.006$; 6.6 ± 1.1 vs. 4.2 ± 0.8, $p< 0.001$). In addition, compared with the co-mutation results of Sanger, it seems that ARMS-qPCR has identified an earlier stage of group, which were younger (43.3 ± 10.1 vs. 66.4 ± 6.1, $p< 0.001$), and with smaller tumor (1.8 ± 1.5 vs. 4.0 ± 1.3, $p= 0.002$), as well as lower recurrence rate (0.0% vs. 50%, $p= 0.007$). Besides, the newly identified group were lower in MACIS score (4.2 ± 0.8 vs. 6.9 ± 0.7, $p= 0.002$) and with lower TNM stage ($p= 0.001$). **Conclusions:** Patients with *BRAF* V600E and *TERT* promoter C228T/C250T co-mutation have a worse prognosis. Using ARMS-qPCR, the more sensitive method could identify earlier stages of patients with a potentially worse prognosis. Research Sponsor: National Science Foundation of China.

TPS6589 Poster Session (Board #250), Fri, 8:00 AM-11:00 AM

Phase III LEAP-010 study: first-line pembrolizumab with or without lenvatinib in recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). *First Author: Lillian L. Siu, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The PD-1 inhibitor pembrolizumab is currently approved as first-line monotherapy for patients with R/M HNSCC whose tumors express PD-L1 combined positive score (CPS) $\geq$1. In a phase 1b/2 trial (NCT02501096) of pembrolizumab plus lenvatinib (multikinase inhibitor of VEGFR 1-3, FGFR 1-4, PDGFRa, RET, and KIT) in solid tumors, the combination demonstrated promising antitumor activity and a manageable safety profile in patients with HNSCC. LEAP-010 (NCT04199104) is a randomized, double-blind, placebo-controlled, phase 3 study that will evaluate the efficacy and safety of first-line pembrolizumab with or without lenvatinib in patients with PD-L1–positive R/M HNSCC. **Methods:** Key eligibility criteria include histologically confirmed R/M HNSCC incurable by local therapies, PD-L1–positive tumor (CPS $\geq$1) as determined by central laboratory, measurable disease as assessed by blinded independent central review (BICR) per RECIST v1.1, and ECOG performance status (PS) 0 or 1. Patients will be randomly assigned 1:1 to pembrolizumab plus lenvatinib or pembrolizumab plus placebo. Randomization will be stratified by PD-L1 status defined by tumor proportion score ($<$ 50% vs $\geq$50%), human papillomavirus status for oropharynx cancer (positive vs negative), and ECOG PS (0 or 1). Patients will receive intravenous pembrolizumab 200 mg every 3 weeks for 35 cycles (~2 years) and oral lenvatinib 20 mg or placebo once daily; patients may continue to receive lenvatinib or placebo after pembrolizumab treatment is complete. Treatment will continue until BICR-verified disease progression or unacceptable toxicity. Pembrolizumab retreatment (second course) for 17 additional cycles will be allowed for eligible patients who stop pembrolizumab and subsequently experience BICR-verified disease progression. These patients could have stopped treatment with stable disease, partial response, or complete response or after 35 cycles of pembrolizumab for reasons other than disease progression or toxicity. Tumor imaging assessment will be performed at week 6, then every 6 weeks until 1 year, and thereafter every 9 weeks. Primary end points are objective response rate and progression-free survival, assessed by BICR per RECIST v1.1, and overall survival. Secondary end points are duration of response and safety and tolerability. Recruitment is ongoing; planned enrollment is ~500 patients. Clinical trial information: NCT04199104. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA; and Eisai Inc., Woodcliff Lake, NJ, USA.

TPS6590 Poster Session (Board #251), Fri, 8:00 AM-11:00 AM

Single-arm study of bimiralisib in head and neck squamous cell carcinoma (HNSCC) patients (pts) harboring *NOTCH1* loss of function (LOF) mutations. *First Author: Faye M. Johnson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Effective targeted therapies are needed for HNSCC that is lethal despite recent advances with immunotherapy. A major challenge to personalize treatment is that most genomic alterations are in tumor suppressors, including *NOTCH1* that is mutated in ~20% of HNSCC. We recently published that HNSCC cell lines harboring *NOTCH1* LOF mutations undergo cell death *in vivo* and *in vitro* following PI3K inhibition, in contrast to *PIK3CA* mutant cell lines that merely undergo cell cycle arrest when exposed to the same drugs. Based on these results we initiated a novel genomic biomarker-driven phase II clinical trial treating *NOTCH1* mutant HNSCC pts with the dual PI3K/mTOR inhibitor bimiralisib (PQR309). **Methods:** The primary objective is to determine the objective response rate (ORR) of recurrent/metastatic HNSCC harboring *NOTCH1* LOF mutations to bimiralisib. Pts who have already received standard platinum chemotherapy and immunotherapy will receive bimiralisib orally twice per wk unless progression or intolerable toxicity occurs. Tumors will be evaluated using RECIST q 6 wks. A Simon's optimal two-stage design is used. To have 80% power to detect an ORR of 30%, (one-sided $\alpha = 0.05$, $\beta = 0.20$) 10 pts will be enrolled in the first stage. If $\leq$1 pts respond, the trial will be closed for futility. If $\geq$2 pts have an OR, the study will enroll an additional 19 pts in the second stage. The null hypothesis (ORR $\leq$ 10%) will be rejected if $\geq$ 6 in 29 pts have an OR. Seven pts have enrolled. The algorithm for determining *NOTCH1* mutation function is based on the patterns of mutations in HNSCC vs. leukemia where mutations are activating. It may be difficult to determine whether *NOTCH1* mutations are homo- or heterozygous due to normal cell contamination. Therefore, levels of activated NOTCH1 in pretreatment tumors may be assessed by IHC with an antibody against activated NOTCH1 (NICD). In parallel with the trial, to further confirm *NOTCH1* LOF, we can use site-directed mutagenesis to re-create *NOTCH1* mutations from trial pts that will then be introduced into NOTCH1-null cell lines to assay for NICD and growth inhibition with culture on NOTCH1 ligand. All pts will have serial collection of blood for pharmacokinetics and for ctDNA to examine clonal evolution associated with acquired resistance. Samples with high *NOTCH1* mutation ctDNA VAF will be analyzed by WES and compared with pretreatment tissue. In the second stage, IHC and WES may be performed on pre- and post- treatment (day 15 and progression) tissue to examine pharmacodynamics and mechanisms of resistance. Clinical trial information: NCT03740100. Research Sponsor: PIQUR.

TPS6591 **Poster Session (Board #252), Fri, 8:00 AM-11:00 AM**

INDUCE-3: A randomized, double-blind study of GSK3359609 (GSK609), an inducible T-cell co-stimulatory (ICOS) agonist antibody, plus pembrolizumab (PE) versus placebo (PL) plus PE for first-line treatment of PD-L1-positive recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). *First Author: Aaron Richard Hansen, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Pembrolizumab as part of first-line treatment for patients (pts) with R/M HNSCC has improved survival. However, in order to further improve outcomes in this population investigation of rational combinations targeting different mechanisms that cancers exploit to evade the immune system is required. ICOS, a member of the CD28/B7 immunoglobulin receptor superfamily, provides a co-stimulatory signal augmenting T-cell proliferation, cytokine production, cytotoxic function and survival. GSK609 is a humanized IgG4 antibody selected for its potent agonist activity and non-depleting properties. The rationale for targeting ICOS with GSK609 plus PD-1 blockade with PE is supported by preclinical and clinical evidence (Rischin, et al. *Annals of Oncol* 2019;30[Supplement_5]: v454–5). INDUCE-3 trial (NCT04128696) will explore if the addition of GSK609 to PE improves outcomes of pts with R/M HNSCC. **Methods:** INDUCE-3 uses a 2-in-1 adaptive design that has the option to seamlessly expand from an initial Phase 2 to a Phase 3 study. Pts (n = 600) will be stratified by PD-L1 status and HPV status (oropharynx only) then randomly assigned in a 1:1 ratio to receive GSK609 plus PE or PL plus PE, every 3 weeks until progression, unacceptable toxicity, or up to 35 cycles. GSK609 plus PE will be assessed for superiority versus PL plus PE in overall survival (OS) and progression-free survival (PFS) per RECISTv1.1 as dual primary endpoints; secondary endpoints include PFS per immune-based RECIST; milestone OS; safety and tolerability; time to deterioration in patient-reported physical function and pain. Efficacy and patient-reported outcome endpoints will be assessed in the PD-L1 combined positive score (CPS) $\geq$1 and $\geq$20 populations. Key eligibility criteria are aged $\geq$18 years; locally incurable R/M HNSCC of the oral cavity, oropharynx, hypopharynx, or larynx; no prior systemic therapy in the R/M setting; PD-L1 CPS $\geq$1 by central testing; measurable disease per RECIST v1.1 and ECOG PS 0/1. Recruitment is ongoing in countries across the globe. Funding: Study is funded by GlaxoSmithKline and in collaboration with Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA. Clinical trial information: NCT04128696. Research Sponsor: GSK.

TPS6592 **Poster Session (Board #253), Fri, 8:00 AM-11:00 AM**

CCTG HN.10: A phase II single-arm trial of elective volume adjusted de-escalation radiotherapy (EVADER) in patients with low-risk HPV-related oropharyngeal squamous cell carcinoma (NCT03822897). *First Author: Scott Victor Bratman, Department of Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Treatment for HPV positive(+) oropharyngeal squamous cell carcinoma (OSCC) is highly effective but associated with significant short and long term treatment related morbidity. We hypothesize that decreasing the regions of elective nodal irradiation (ENI) in the neck will lead to less toxicity and better quality of life/functional outcomes while maintaining high disease control rates in patients with favourable prognosis HPV+ OSCC. **Methods:** HN.10 is a Canadian Cancer Trials Group phase II trial with a primary objective to evaluate the efficacy of primary definitive radiotherapy (RT) or chemoradiotherapy (CRT) utilizing volume reduced ENI as measured by 2-year event-free survival (EFS) in patients with low-risk HPV+ OPSCC. Secondary objectives include to evaluate overall survival, local control, regional control, locoregional control, out-of-field regional control, distant metastasis free survival, early and late toxicities of treatment, subjective swallowing functions, quality of life, utilization of healthcare resources, work productivity, and prognostic biomarkers. An imaging and biospecimen bank will be compiled as part of trial conduct. Key eligibility criteria include: pathologically proven diagnosis of HPV+ OPSCC; HPV association determined locally by either p16 immunohistochemistry or direct detection of HPV DNA sequences (e.g. by PCR or in situ hybridization) performed on a core needle or surgical biopsy specimen of the primary tumour or involved cervical lymph node; clinical stage T1-3 N0-1 M0 (UICC/AJCC 8th Ed.); fit for radiotherapy +/-chemoradiotherapy. Statistical Design: The primary endpoint is 2-year EFS. Assuming 2-year EFS to be 91% (Ha) for low-risk HPV-related OPSCC with standard treatment, and that the experimental treatment will be considered as ineffective if the 2-year EFS is $\leq$ 85% (H0), with one-sided alpha of 0.1, a sample size of 100 patients will have 80% power to detect a 6% difference of 2-year EFS. With 3 years of accrual and 2 years of follow-up, the total duration of this study will be 5 years. A total of 304.7 person-years of follow-up is needed for the final analysis. The null hypothesis (H0) will be rejected when the observed survival rate is 88.85% or higher (i.e. if there are 18 or fewer EFS events observed). Conduct to Date: Study activation February 20, 2019. Enrollment as of January 29 2020: 23. Clinical trial information: NCT03822897. Research Sponsor: CIHR Project Scheme.

TPS6593 **Poster Session (Board #254), Fri, 8:00 AM-11:00 AM**

The AIM-HN and SEQ-HN study: A pivotal study evaluating the efficacy of tipifarnib in patients with head and neck squamous cell carcinoma (HNSCC) with *hras* mutations (AIM-HN) and the impact of *hras* mutations on response to first line systemic therapies for HNSCC (SEQ-HN). *First Author: Robert I. Haddad, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: *HRAS* mutations define a unique molecular subset of ~ 5% of HNSCC. Evidence suggests that these tumors respond poorly to standard systemic therapy but the impact of *HRAS* missense mutations on clinical outcomes has not been formally characterized. Tipifarnib is a potent and selective inhibitor of farnesyltransferase, a critical enzyme for *HRAS* activity. Phase 2 Proof of concept for tipifarnib in *HRAS* mutant HNSCC was recently achieved in study KO-TIP-001 (NCT02383927, Ho et. al. ESMO 2018). **Methods:** The AIM-HN and SEQ-HN Study (KO-TIP-007, NCT03719690) is an ongoing international, multicenter, open-label, 2 cohort (AIM-HN and SEQ-HN), pivotal trial designed to determine the Overall Response Rate (ORR) of tipifarnib in patients (pts) with *HRAS* mutant HNSCC (AIM-HN). SEQ-HN will retrospectively investigate how the ORR to first line treatment compares between the accrued *HRAS* mutant pts to matched-case control *HRAS* wild type (wt) HNSCC pts. Information on subsequent lines of therapy for *HRAS* mutant and wt pts will also be collected. AIM-HN will enroll at least 59 pts (oral cavity, pharynx, larynx, sinonasal, nasopharyngeal, or unknown primary) who are refractory or have relapsed from at least one prior line of systemic platinum-based therapy and have measurable disease by RECIST 1.1. AIM-HN pts must have tumors with $>$35% *HRAS* mutant variant allele frequency (VAF) or $>$20% VAF if serum albumin is $>$3.5 g/l. AIM-HN pts will receive treatment with tipifarnib at 600 mg bid on days 1-7 and 14-21 of 28-day cycles. Using Simon's Two-Stage Minimax design, if true ORR is $>$ 30%, the study will have 80% power to detect ORR $>$ 15% at 0.025 significance level. Both interim (after first 31 pts) and final analysis, 2-sided 95% CI on ORR, will be performed on the modified intent to treat population. The SEQ-HN observational cohort will enroll ~225 control pts who will receive standard of care treatment. A subset of SEQ-HN pts will be matched to the *HRAS* mutant AIM-HN pts according to defined patient characteristics and compared for responses to therapy. Clinical trial information: NCT02383927. Research Sponsor: Kura Oncology.

TPS6594 **Poster Session (Board #255), Fri, 8:00 AM-11:00 AM**

Randomized, phase II study of ficlatuzumab with or without cetuximab in patients with pan-refractory, recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). *First Author: Julie E. Bauman, University of Arizona Cancer Center, Tucson, AZ*

Background: Patients with pan-refractory R/M HNSCC, with clinical resistance to cytotoxic therapy, anti-EGFR molecular targeting, and immunotherapy, have poor survival. An established tumor-intrinsic resistance mechanism to cetuximab, an anti-EGFR IgG1 monoclonal antibody (mAb), is activation of the hepatocyte growth factor (HGF)/cMet pathway, which converges with the EGFR network at both the PI3K/Akt and MAPK nodes allowing for reciprocal compensation. Moreover, over-expression of HGF in the tumor microenvironment is immunosuppressive. Convergent data suggest that HGF/cMet pathway inhibition concurrent with EGFR blockade may overcome cetuximab resistance. We previously reported a Phase I study of ficlatuzumab, a humanized anti-HGF IgG1 mAb, with cetuximab in cetuximab-resistant R/M HNSCC. The combination showed promising safety, overall response rate (ORR) and progression-free survival (PFS). Preliminary biomarker analyses showed that high circulating cMet was associated with poor PFS whereas serum Veristrat, a proteomic classifier associated with worse prognosis in the setting of anti-EGFR monotherapy, was not. An increase in total peripheral T cells, particularly the $CD8^+$ subset, was associated with treatment response while progression was associated with expansion of a unique myeloid population. We designed a follow-on randomized phase II trial evaluating ficlatuzumab with or without cetuximab in pan-refractory, R/M HNSCC with signaling and immune correlatives. **Methods:** This is a multicenter phase II trial with a randomized, non-comparative, two-arm design (ficlatuzumab 20 mg/kg with or without cetuximab 500 mg/m^2 every 2 weeks) in patients with pan-refractory R/M HNSCC. Key eligibility criteria include: R/M HNSCC; cetuximab resistance (progression during or within 6 months of cetuximab-radiation or palliative cetuximab); platinum resistance; prior exposure to anti-PD1 mAb; ECOG 0-1; consent to baseline research biopsy. The primary objective is to evaluate the efficacy of each arm as measured by PFS. To test the hypothesis that either regimen improves historical PFS from 2 to 3.33 months requires 66 eligible patients. Key secondary endpoints are ORR and survival. Mechanistic biomarkers include tumor HGF/cMet pathway activation, tumor and peripheral immune profiles, soluble cMet, and serum Veristrat. Thirty-five of 66 subjects have enrolled at 6 centers. A Bayesian continuous monitoring rule for futility has not been triggered for either arm. Clinical trial information: NCT03422536. Research Sponsor: Aveo.

TPS6595 Poster Session (Board #256), Fri, 8:00 AM-11:00 AM

Window-of-opportunity trial of nivolumab with or without the IDO inhibitor BMS-986205 in patients with resectable squamous cell carcinoma of the head and neck (SCCHN). *First Author: Adam Luginbuhl, Thomas Jefferson University, Department of Otolaryngology, Philadelphia, PA*

Background: Indoleamine 2,3-dioxygenase (IDO1) catabolizes tryptophan to kynurenine and is highly expressed in multiple malignancies including SCCHN. Elevated IDO1 activity may contribute to an immunosuppressive tumor microenvironment and compromise therapeutic responses to immune checkpoint therapy. We designed a window-of-opportunity trial to test whether the IDO inhibitor BMS-986305 improves treatment responses and T cell function in SCCHN patients treated with nivolumab. **Methods:** Patients with previously untreated, resectable, pathologically confirmed SCCHN are eligible. Primaries of the oral cavity, oropharynx, larynx, hypopharynx, or nasal cavity/paranasal sinuses must be AJCC 8th edition stage II or higher (M0). Stage I oropharyngeal cancers with lymphadenopathy are also eligible. Patients are randomized 3:1 to receive either A) nivolumab 480 mg IV x 1 plus BMS-986205 100 mg PO daily starting a week prior to nivolumab and continuing for 4 more weeks (total of 5 weeks) or B) nivolumab 480 mg IV alone for 4 weeks. At the 5th week of treatment patients are assessed for response with physical exam and repeat CT scans for tumor volumes: if there is greater than 10% reduction in volume of either primary tumor or lymph node metastases, patients will be considered responders and receive another cycle of their originally assigned treatment, i.e. nivolumab 480 mg IV for a second dose +/- BMS-986205 100 mg PO daily for an additional 4 weeks followed by surgery in week 9. If tumor volume is stable or progression is noted in either the primary site or lymph nodes, patients are considered non-responders followed by definitive surgery in week 5 (i.e. after only one cycle of treatment). The primary endpoint of this study is the response rate after cycle 1 (using the criteria defined above). The projected sample size is 48 patients (36 in arm A and 12 in arm B). Secondary endpoints include safety, pathologic treatment effect and metabolic and molecular correlates of treatment in the tumor microenvironment. Clinical trial information: NCT03854032. Research Sponsor: Bristol Myers Squibb.

TPS6596 Poster Session (Board #257), Fri, 8:00 AM-11:00 AM

ROMAN: Reduction in oral mucositis with avasopasem manganese (GC4419)–Phase III trial in patients receiving chemoradiotherapy for locally advanced, nonmetastatic head and neck cancer. *First Author: Jon Holmlund, Galera Therapeutics, Malvern, PA*

Background: Approximately 70% of patients receiving intensity-modulated radiotherapy (IMRT) plus cisplatin for locally advanced head and neck cancer (HNC) develop SOM, defined as WHO Grade 3 or 4, which limits patients' ability to eat solids (Gr 3) or liquids (Gr 4, requiring enteral nutrition). An RT-induced burst of superoxide initiates oral mucositis (OM) development. GC4419, a superoxide dismutase mimetic, interrupts this process by converting superoxide to H2O2. It showed promising reduction of SOM in a published open-label Phase 1b/2a trial (IJROBP 1 Feb 2018). In a subsequent randomized, double-blind placebo-controlled trial in 223 patients receiving IMRT/cisplatin for HNC (ASCO 2018), 90 mg of GC4419 administered M-F prior to IMRT demonstrated statistically significant reduction in SOM duration (p=0.024, median 1.5 days @ 90 mg vs. 19 days placebo) and meaningful reductions @ 90 mg in SOM incidence (43% vs. 65%) and severity (incidence of Grade 4, 16% vs. 30%). The safety results were acceptable and consistent with the known toxicities of IMRT/cisplatin. **Methods:** 335 patients at multiple centers in the U.S. and Canada with locally-advanced, nonmetastatic head and neck cancer (oral cavity/oropharyngeal) receiving 70 Gy IMRT (>50 Gy to > 2 oral sites) plus cisplatin (40 mg/m2 qwk x 6-7, or 100 mg/m2 q3wk x 3) are being randomized (double-blinded) 3:2 to 90 mg of GC4419 or placebo, M-F before each RT fraction. Enrollment is stratified by cisplatin schedule and treatment setting (definitive vs. post-op). OM by the WHO scale will be assessed twice weekly during RT & weekly for 2 weeks post RT. The primary efficacy endpoint is incidence of SOM through the end of IMRT. Secondary efficacy endpoints include severity (incidence of Grade 4 OM through the end of IMRT), & days of SOM (days from first to last SOM for all patients, with patients never developing SOM having 0 days of SOM by definition). Days of SOM for the subset developing SOM will be analyzed descriptively. Patients will be followed for one year post IMRT for tumor progression/recurrence and for two years for survival. Clinical trial information: NCT03689712. Research Sponsor: Galera Therapeutics, Inc.

TPS6597 Poster Session (Board #258), Fri, 8:00 AM-11:00 AM

A phase II open-label, multicenter, study to evaluate the efficacy and safety of rivoceranib in subjects with recurrent or metastatic adenoid cystic carcinoma. *First Author: Hyunseok Kang, University of California, San Francisco, San Francisco, CA*

Background: Adenoid cystic carcinoma (ACC) is a rare salivary gland malignancy, also found in other secretory gland sites (tracheobronchial tree, esophagus, breast, lungs, prostate, uterine cervix and vulva). Initial disease is typically treated with surgical resection and radiation, but recurrent or metastatic disease remain to be a significant challenge. There is no standard systemic therapy option for advanced ACC, although recent studies with tyrosine kinase inhibitors have shown moderate objective response and disease stabilization rates. Rivoceranib (also known as apatinib) is a potent selective inhibitor of VEGFR-2 and has been evaluated in a single arm phase II study of 59 recurrent or metastatic ACC patients in China and has demonstrated an (ORR) of 47.1% and disease control rate of 98.1. **Methods:** This is a phase II, open-label, multicenter[HGJ3], single arm clinical trial of oral rivoceranib (700 mg daily) in patients with recurrent or metastatic ACC of any anatomic site, not amenable to curative surgery or radiotherapy to confirm activity of rivoceranib. Subjects must have at least one evaluable lesion by RECIST v1.1 and have evidence of disease progression within the 6 months prior to study entry. Fifty-five subjects will be enrolled at 7 US sites and 4 South Korean sites. The primary endpoint is ORR assessed by investigators with a target ORR of 25% to detect a difference of 15% from the historical ORR of 10% at 1-year (this achieves 80% power with a 5% significance level). Secondary endpoints include overall survival, disease control rate, progression free survival at 6, 12 and 24 months and time to progression. Exploratory objectives include correlation between ORR and the presence of MYB/MYB-L1 fusion, pharmacokinetics evaluation, and patient-reported quality of life assessments by FACT-G. This study is open and enrolling at the time of submission. References: 1. Tchekmedyian V, Sherman EJ, Dunn L, et al. 7000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

The oncology hospital at home: Health care utilization outcomes from the huntsman at home trial. *First Author: Kathi Mooney, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Unplanned hospitalizations and emergency department (ED) visits are common during cancer care. Providing acute hospital level care at home may add value by decreasing hospital and ED use. We conducted the first evaluation of an oncology Hospital-at-Home program, Huntsman at Home (H@H). **Methods:** The Huntsman Cancer Institute began H@H services in 2018 and accepts referral of cancer patients for acute-medical or post-surgical care at home. Patients are admitted who require continued acute level medical care after hospitalization or have emergent unstable symptoms related to treatment or disease progression that would otherwise require ED evaluation or hospitalization. Prospectively, patients referred to H@H from 8/2018 through 10/2019 were compared to a usual care comparison group (UC) drawn concurrently from patients living within the Salt Lake City metropolitan area who qualified for admission to H@H, but lived outside the service zip codes. Probability of H@H enrollment propensity scores were constructed via random forest from patient descriptors and health care utilization at admission. We used an intent-to-treat approach for analysis. Primary outcomes were hospitalizations, length of stay (LOS), ED visits and cumulative charges over 30 and 90 days post admission to either group. Comparisons were made by generalized linear models, stratified by tertiles of H@H vs. UC propensity score. **Results:** 367 patients, 169 H@H and 198 UC, were evaluated. The average age was 62 yrs, 85% were Caucasian, and 77% had stage IV cancer. Propensity score distributions were overlapping, demonstrating group comparability. A variety of cancers were represented; the most common being colon, gynecologic, prostate and lung cancers. Compared to UC, H@H patients were more likely to be female (61% vs 43%) and during the month prior to admission, showed a trend towards longer LOS if hospitalized (6.7 vs 5.5 days). During the first 30 days after admission, propensity stratified comparisons showed H@H patients with lower hospital LOS (mean reduction 1.19 days, p=0.022), 56% lower odds of unplanned hospitalizations (OR 0.44, p=0.001), 45% lower odds of ED visits (OR 0.55, p=0.037) and 50% lower cumulative charges (mean ratio 0.50, $p<0.001$) compared to UC. Results over 90 days were similarly robust. **Conclusions:** In the first reported trial of an adult oncology Hospital at Home program, there was strong evidence for reduced hospitalizations, ED visits, and cost. Oncology Hospital at Home programs show promise for increased patient-centered care while simultaneously improving value. Research Sponsor: Cambia Foundation.

7001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A multicenter study comparing granulocyte-colony stimulating factors to antibiotics for primary prophylaxis of taxotere/cyclophosphamide-induced febrile neutropenia in patients with early-stage breast cancer. *First Author: Mark J. Clemons, Cancer Research Group, Ottawa Hospital Research Institute, Ottawa, ON, Canada*

Background: Docetaxel-cyclophosphamide (TC) adjuvant chemotherapy is commonly used in patients with early stage breast cancer (EBC). Due to the risk of febrile neutropenia (FN) with TC, primary prophylaxis with either ciprofloxacin (cipro) or granulocyte-colony stimulating factors (G-CSF) is recommended. Despite significant differences in costs (7-120 $US/course [cipro] vs. 2100-7000 $US/dose [G-CSF]) and toxicity profiles, optimal primary FN prophylaxis is unknown. We performed a pragmatic randomised trial comparing the superiority of G-CSF to cipro. **Methods:** EBC patients receiving TC chemo were randomized to receive cipro or G-CSF as primary FN prophylaxis. The primary outcome is a composite of either treatment-related hospitalisations or FN. Secondary outcomes included: chemo dose reductions, delays, discontinuations and incidence of *C. difficile* infections. Primary analysis was performed with the intention to treat (ITT) population. **Results:** 455 eligible patients were randomized to cipro (227) or G-CSF (228). 37/227 (16.3%) patients on cipro had a hospitalization, compared with 25/228 (11.0%) on G-CSF (Fisher's exact test p-value=0.10). Relative risk (RR) of hospitalization for patients on G-CSF:0.68, 95%CI=0.42 to 1.09. Patients on cipro were statistically significantly more likely to be hospitalized for FN (30/227, 13.2%) vs 9/228 (4.0%) patients on G-CSF($p<0.001$). RR of developing FN and being hospitalized for patients on G-CSF: 0.44, 95%CI=0.26 to 0.76. There was no significant difference between groups for chemo dose reductions, delays, and *C. difficile* rates. Twenty patients on cipro (8.8%) and 9 on G-CSF (3.9%) discontinued chemo early (p=0.036). RR of discontinuing chemo: 0.43, 95% CI=0.19 to 0.96. **Conclusion:** G-CSF was superior to cipro at reducing FN. While a trend towards reduced hospitalizations was also observed with G-CSF, it did not attain statistical significance. However, as 18 patients would need to be treated with G-CSF to prevent one hospitalization compared to cipro, this would suggest a cost of over $100000 $US to prevent a hospitalization. A formal cost-effectiveness analysis will be performed. Clinical trial information: NCT02173262, NCT02816112. Research Sponsor: Canadian Institute of Health Research - Strategy for Patient Oriented Research Grant, Cancer Care Ontario Clinical Programs and Quality Initiatives grant.

7002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase III randomized controlled trial of eRAPID (electronic patient self-Reporting of Adverse-events: Patient Information and advice)—An eHealth intervention during chemotherapy. *First Author: Galina Velikova, Leeds Institute of Medical Research at St James's, University of Leeds, Leeds, United Kingdom*

Background: Routine monitoring of patients' symptoms can improve symptom management, quality of life (QOL) and survival. eRAPID is an online system for patients to report symptoms, uniquely providing automated severity-dependent advice (self-management or alerts for hospital contact). We evaluated eRAPID impact on patient experiences & clinical care. **Methods:** A prospective randomized two-arm parallel group trial (1:1 allocation Usual Care (UC): UC+eRAPID). Eligible patients started chemotherapy for colorectal, breast & gynecological cancers at Leeds Cancer Centre. In eRAPID arm, patients completed weekly online symptoms for 18 weeks. Primary outcome: QOL/symptom control (FACT-PWB Physical Wellbeing Scale) at 18 weeks. Secondary outcomes: process of care (admissions/ chemotherapy delivery), patient self-efficacy (Lorig Self-Efficacy Scale) & global QOL (EQ5D).Mixed effects repeated measures models were employed. **Results:** During Jan 2015-June 2018, we screened 1484 patients; 508/690 eligible patients (73.6%) consented & were randomized (256 eRAPID:252 UC). No statistically significant effect of eRAPID on FACT-PWB score was found at 18 weeks (difference in means 0.20 95% CI -0.81, 1.20; p = 0.699). There was a positive impactat 6 & 12 weeks (1.08, 95% CI 0.12, 2.05; p = 0.028 & 1.01, 95% CI 0.05, 1.98; p = 0.039).In responder analysis lower proportion of eRAPID patients had clinically meaningful deterioration 47.5% at 12 weeks vs 56.3% UC. Pre-planned subgroup analysis found no effect in metastatic disease, but better FACT-PWB in non-metastatic/adjuvant group at 6 & 12 weeks (1.45, 95% CI 0.32, 2.58; p = 0.011 & 1.13; 95% CI 0.07, 2.19; p = 0.036). eRAPID patients reported better self-efficacy (p = 0.007) & QOL EQ5D-VAS at 12 (p = 0.030) & 18 weeks (p = 0.010). There were no differences for admissions/chemotherapy delivery. 3314 online reports were completed, median per patient 14.0 (range 0-117). Emergency alerts were activated in 29/3314 cases (0.9%), self-management advice 2714/3314 (81.9%). Post-hoc analysesshowed high patient adherence was associated with clinicians' use of the data, high baseline FACT-PWB & older age. High adherence patients had better FACT-PWB scores at 12 weeks. **Conclusions:** Online symptom monitoring with immediate advice improved symptom control early during adjuvant chemotherapy (6 &12 weeks), helping patient education & self-efficacy. The results support its utility as an improved model for patient care during adjuvant chemotherapy. Clinical trial information: ISRCTN88520246. Research Sponsor: National Institute for Health Research.

7004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Early discontinuation to adjuvant endocrine therapy in the ECOG-ACRIN TAILORx Trial. *First Author: Betina Yanez, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: The TAILORx study demonstrated women with an intermediate Oncotype DX score receive the same benefit with endocrine therapy (ET) compared to chemoendocrine therapy (CET). However, early discontinuation of adjuvant ET is problematic among breast cancer survivors, with previous studies suggesting that up to 50% of women do not adhere to the full 5 years of recommended ET treatment. The aim of this study was to identify patient-level risk factors associated with early discontinuation of ET in the TAILORx study. **Methods:** TAILORx was coordinated by the ECOG-ACRIN Cancer Research Group. Participants were a subgroup of 954 women who completed additional measures on health-related quality of life (HRQoL) including endocrine symptoms (ES) physical well-being (PWB) and social well-being (SWB) prior to initiating ET, which categorized into three groups by tertile for analysis. All participants were diagnosed with hormone-receptor–positive, human epidermal growth factor receptor 2–negative, axillary node–negative breast cancer who started ET within a year of study entry. Early discontinuation of ET, defined as discontinuation less than 4 years from initiation for reasons other than death or recurrence, was assessed by clinician report. Rate of discontinuation was calculated using Kaplan-Meier estimates, and Cox-proportional hazards joint models were used to analyze the association between rates of adherence to ET with patient-level factors. **Results:** In a joint model, receipt of CET therapy (vs receipt of ET only; HR = .59, 95% CI .38-.94, p = .02) and age above 40 (versus age < = 40; HR = .30, 95% CI .14-.66, p = .003) were associated with a lower probability of early discontinuation of ET. Adjusted for these factors, a history of depression compared to no history of depression (HR 1.82, 95% CI 1.19-2.77, p = 0.005), worse ES compared to better ES (HR 1.70, 95% CI 1.06-2.74, p = 0.03), worse PWB compared to better PWB (HR 2.12, 95% CI 1.30-3.45,p = 0.003), and worse SWB compared to better SWB (HR 1.94, 95% CI 1.20-3.13, p = 0.007) were individually and significantly associated with a higher probability of early discontinuation of ET, although none reached statistical significance when all were included in a joint model. **Conclusions:** Younger women are at risk for early discontinuation and modifiable characteristics such as HRQoL and history of depression are potential risk factors for early discontinuation of ET. These results support systematic screening for HRQoL and depressive symptoms to identify women at risk for discontinuation of ET. Clinical trial information: NCT00310180. Research Sponsor: U.S. National Institutes of Health.

7005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

U.S. trends and racial/ethnic disparities in opioid access among patients with poor prognosis cancer at the end of life (EOL). *First Author: Andrea Catherine Enzinger, Dana-Farber Cancer Institute, Boston, MA*

Background: Heightened US opioid regulations may limit advanced cancer patients' access to effective pain management, particularly for racial/ethnic minority and other vulnerable populations. We examined trends in opioid access, disparities in access, and pain-related emergency department (ED) visits among cancer patients near end of life (EOL). **Methods:** Using a 20% random sample of Medicare FFS beneficiaries, we identified 243,124 patients with poor prognosis cancers who died between 2007-2016. We examined trends in outpatient opioid prescription fills and pain-related ED visits near EOL (30 days prior to death or hospice enrollment), for the overall cohort and by race (white, black, other). Per-capita opioid supply by state was obtained from the federal Drug Enforcement Agency ARCOS database. Geographic fixed-effects models examined predictors of opioid use near EOL, opioid dose in morphine milligram equivalents (MMEs), and pain-related ED visits, adjusted for patient demographic and clinical characteristics, state, opioid supply, and year. **Results:** From 2007-2016 the proportion of patients with poor prognosis cancers filling an opioid prescription near EOL fell from 41.7% to 35.7%, with greater decrements among blacks (39.3% to 29.8%) than whites (42.2% to 36.5%) and other races (38.2% to 32.4%). The proportion of patients receiving long-acting opioids near EOL fell from 17% to 12% overall (15% to 9% among blacks). Among patients receiving EOL opioids, the median daily dose fell from 40MMEs (IQR 16.5-98.0) to 30MMEs (IQR 15.0–78.8). In adjusted analyses, blacks were less likely than whites to receive EOL opioids (AOR 0.85; 95% CI, 0.80 to 0.91) and on average received 10MMEs less per day (b -9.9; 95% CI -15.7 to -4.2). Patients of other race were also less likely to receive EOL opioids (AOR 0.92; 95% CI, 0.85-0.95), although their dose did not differ significantly from whites. Rates of pain-related ED visits near EOL increased from 13.2% to 18.8% over the study period. In adjusted analyses, blacks were more likely than whites to have pain-related ED visits (AOR 1.29, 95% CI, 1.16-1.37) near death, as were those of other races (AOR 1.30; 95% CI, 1.17-1.37). **Conclusions:** While lawmakers have sought to mitigate the impact of opioid regulations upon cancer patients, access to EOL opioids have decreased substantially over time with concomitant increases in pain-related ED visits. There are significant racial/ethnic disparities in opioid access, with blacks receiving fewer opioids at lower doses and having more ED-based care for pain near EOL. Research Sponsor: U.S. National Institutes of Health.

7006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Relationships among skeletal muscle, symptom burden, health care use, and survival in hospitalized patients with advanced cancer. *First Author: Chinenye C. Azoba, Massachusetts General Hospital, Boston, MA*

Background: Loss of skeletal muscle mass (quantity) is common in patients with advanced cancer, but little is known about muscle density (quality). Hospitalized patients with advanced cancer are a highly symptomatic population at risk for the adverse effects of muscle loss. Thus, we sought to describe associations between muscle mass and density, symptom burden, health care use, and survival in these patients. **Methods:** We prospectively enrolled hospitalized patients with advanced cancer from 9/2014-4/2017. Upon admission, patients reported their physical (Edmonton Symptom Assessment System [ESAS]) and psychological (Patient Health Questionnaire 4 [PHQ4]) symptoms. We used computed tomography (CT) scans performed per routine care ≤45 days prior to enrollment to evaluate muscle mass and density at the level of the third lumbar vertebral body. We categorized patients as sarcopenic using validated sex specific cutoffs. We used regression models to examine associations between muscle mass and density and patients' symptom burden, health care use, and survival. **Results:** Of 1,121 patients enrolled, 677 had evaluable CT scan data (mean age = 62.86±12.95 years; 51.1% female). The most common cancer types were gastrointestinal (36.8%) and lung (16.7%) cancer. Most met criteria for sarcopenia (64.0%). Older age and female sex were associated with lower muscle mass (age: B = -0.16, $p < .01$; female: B = -6.89, $p < .01$) and density (age: B = -0.33, $p < 0.01$; female: B = -1.66, p = .01), while higher BMI was associated with higher muscle mass (B = 0.58, $p < .01$) and lower muscle density (B = -0.61, $p < .01$). Higher muscle mass was significantly associated with improved survival (HR = 0.97, $p < .01$), but not with symptom burden or health care use. Higher muscle density was significantly associated with lower ESAS physical (B = -0.17, p = .02), ESAS total (B = -0.29, $p < .01$), PHQ4 depression (B = -0.03, $p < .01$) and PHQ4 anxiety (B = -0.03, $p < .01$) symptoms. Higher muscle density was also associated with decreased hospital length of stay (B = -0.07, $p < .01$), risk of readmission or death in 90 days (OR = 0.97, $p < .01$), and improved survival (HR = 0.97, $p < .01$). **Conclusions:** Most hospitalized patients with advanced cancer have muscle loss consistent with sarcopenia. We found that muscle mass (quantity) correlated with survival, whereas muscle density (quality) was associated with patients' symptoms, health care use, and survival. These findings underscore the added importance of assessing muscle quality when seeking to address the adverse effects of muscle loss in oncology. Research Sponsor: Massachusetts General Hospital Cancer Center.

7007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Associations between psoas muscle area (PMA) and density (PMD) with phase I oncology clinical trial outcomes. *First Author: Pritish Iyer, Fox Chase Cancer Center, Philadelphia, PA*

Background: Malnutrition and cancer cachexia can lead to loss of muscle mass (sarcopenia) and are associated with poor outcomes. Muscle status can be evaluated by computed tomography (CT)-based radiographic measures, specifically at the L3 vertebrae where the psoas and other core muscles reside. We previously found that baseline malnutrition was associated with worse phase 1 clinical trial outcomes including increased toxicity and reduced survival (Jain et al. Oncologist, 2019). We sought to evaluate the relationship between muscle status and phase 1 trial outcomes. **Methods:** CT-based psoas muscle area (PMA) and psoas muscle density (PMD) were evaluated in 83 patients who enrolled in a phase 1 trial. We localized the L3 vertebral body on axial imaging and manually outlined the psoas muscle to calculate PMA (standardized to height) and PMD. Two reviewers independently conducted the analyses. We stratified patients by having a PMA or PMD above or below the group's median. We evaluated for associations between PMA/PMD and the following clinical trial outcomes: rates of grade ≥ 3 toxicity, frequency of dose reductions/interruptions, hospitalizations, tumor response, duration on study (DOS), and overall survival (OS). We also evaluated for correlations between PMA/PMD and a validated measure of nutritional status, the PG-SGA. Chi-square analysis was used to determine statistical significance between groups. Kaplan-Meier curves were used to compare DOS and OS. **Results:** 83 patients were included (38 male, 45 female), with a median age of 60 (range 28-85). The most common cancer type was gastrointestinal (33%). Mean PMA was 2.89 cm^2/m^2 (range 1.41-5.72) and mean PMD 37.77 Hounsfield units (range 13.27-56.18). PMA above the median was associated with a reduced risk of grade ≥ 3 toxicity (32.5% vs 67.4%, p = 0.001). There was no association between PMD and grade ≥ 3 toxicity, or between PMA/PMD and other phase 1 trial outcomes. There was a significant correlation between nutritional status and PMA (r = -0.278, p = 0.01) but not PMD. **Conclusions:** PMA and PMD are readily available CT-based measures of muscle status. In oncology phase 1 clinical trial participants, lower baseline PMA was associated with a two-fold increased risk of grade ≥ 3 toxicity. Baseline PMA was moderately correlated with nutritional status which was previously shown to be associated with poor trial outcomes. More research is necessary to further understand the specific mechanisms by which nutritional status and muscle mass may influence toxicity risk in this population. Research Sponsor: None.

7008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Benefits of an early mobility program for hospitalized cancer patients: A pilot study. *First Author: Cardinale B. Smith, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Cancer patients are often hospitalized with complications from cancer and cancer treatment. Many experience a decline in physical functioning which likely contributes to increased length of stay (LOS) and excess days, increased readmissions and decreased patient experience. We aimed to determine whether a mobility program project would improve quality of care and decrease healthcare utilization. **Methods:** We implemented a mobility aide program on an oncology unit in a large academic medical center between April 2, 2019 to December 31, 2019. The program consisted of nursing evaluation using the Activity Measure for Postacute Care (AMPAC), an ordinal scale ranging from bed rest to ambulating ≥250 feet, was used to quantify mobility. Plan of care was determined in a multidisciplinary manner with physical therapy (PT), nursing and a mobility aide, a medical assistant with enhanced rehabilitation training. Patients were then mobilized two times per day seven days a week. Using descriptive statistics we evaluated the programs impact on excess days, readmissions, changes in mobility and patient experience as measured by Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) during this time period compared to the 6 month interval prior to implementation. **Results:** During the study interval, 988 patients were admitted and received the mobility program. There was a 6% reduction in excess days (p = 0.04). Similarly, readmission rates decreased from 25% to 19% (p = 0.03). Overall 76% of patients wither maintained or improved their mobility score. During this time period HCAHPS scores (willingness to recommend hospital) increased from 63% at baseline to 91% (p = 0.01). **Conclusions:** Use of this mobility program resulted in a significant decrease in healthcare utilization and improvement in patient experience. This demonstrates that non-PT professionals can mobilize hospitalized cancer patients decreasing the burden of PT and nursing resources. Future work will evaluate the sustainability of the program and evaluate association with healthcare costs. Research Sponsor: None.

Survival outcomes among older adults (OA) receiving second-line therapy for metastatic CRC (mCRC): 5,289 patients (pts) from the ARCAD Clinical Trials Program. *First Author: Nadine Jackson McCleary, Dana-Farber Cancer Institute, Boston, MA*

Background: Survival outcomes of 2nd line mCRC therapy for OA are poorly understood. We evaluated the rates and survival outcomes of 2nd line therapy among OA age 70+ compared to younger adults (YA) age < 70 following progression on 1st line clinical trials. **Methods:** Associations between clinical characteristics of pts with available treatment data after progression on 10 of 23 1st line ARCAD trials, time to initial progression (TTiP) and 2nd line therapy were evaluated. Time to progression (TTP) and overall survival (OS) were compared between OA and YA enrolled on 2nd line trials by Cox regression, adjusting for age, sex, ECOG PS, number of metastatic sites, presence of metastasis in lung/liver/peritoneum. **Results:** Sixteen percent of 1st line ARCAD trial participants were age 70+ (n = 870). Data for 2nd line therapy was available for 60.6% pts (3206/5289). Each additional decade of life was associated with 11% lower odds of receiving 2nd line therapy in multivariate analysis (p = 0.0117). OA participating in 2nd line trials (7.9% age 75+ of 7921) experience similar TTP and OS to YA (mTTP: 5.1 vs. 5.2mos; mOS 11.6 vs 12.4mos, respectively). **Conclusions:** We did not observe a statistical difference in survival outcomes by age following 2nd line mCRC therapy. Further study is needed to examine unmeasured comorbidity and use of geriatric assessment to select OA likely to benefit from 2nd line therapy. Research Sponsor: NIH/NCI Gastrointestinal SPORE Dana-Farber/Harvard Cancer Center.

Multivariate analysis of survival outcomes for mCRC OA vs. YA following initial progression.

Cumulative incidence of financial hardship in metastatic colorectal cancer patients: Primary endpoint results for SWOG S1417CD. *First Author: Veena Shankaran, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Despite evidence that rising cancer care costs are contributing to "financial toxicity" in cancer pts, no studies, to our knowledge, have prospectively assessed the financial impact of cancer diagnosis (dx) using both self-reported and objective financial measures. S1417CD, led by the SWOG Cancer Research Network and conducted in the NCI Community Oncology Research Program (NCORP), was the first national prospective cohort study to evaluate time-to-first evidence of major financial hardship (MFH) in pts with newly diagnosed mCRC. We present results of the primary endpoint analysis. **Methods:** Pts age ≥ 18 within 120 days of mCRC dx receiving systemic treatment completed surveys every 3 months (mo) for 12 mo. MFH was defined as ≥ 1 occurrence of self-reported increase in debt, new loans, selling home, refinancing home, or ≥ 20% income decline during the 12 mo study period. Cumulative incidence (CI) of MFH was estimated to account for competing risk of death. Additional endpoints, not reported here, included quality of life, caregiver strain, and changes in credit status over 12 mo. **Results:** In total, 380 pts (median age 59.9) across 126 clinic sites were enrolled, with 377 eligible and evaluable for the primary endpoint (reached 12 mo assessment, death, or MFH endpoint); complete data were available for 92% of pts as of Jan 23, 2020. Most pts were white (78%), male (61%), and insured (98%), with annual income ≤ $50,000 (56%). Cumulative incidence of MFH at 12 mo was 71.5% (95% CI: 65.9%-76.3%), with 24.6%, 52.4%, and 61.8% at 3, 6, and 9 mo. The dominant components of MFH were new debt (12-mo CI, 56.7%) and >20% decline in income (26.7%); 104 (41%) pts reported ≥ 2 elements of MFH. In a secondary analysis excluding new debt, 12 mo cumulative incidence of MFH was 42.9% (95% CI: 37.2%-48.5%), with 10.3%, 24.4%, and 31.9% at 3, 6, and 9 mo. **Conclusions:** In a national sample of mCRC pts on systemic tx, financial hardship, most commonly in the form of increased debt, accumulates progressively over time. Nearly 3 out of 4 pts experiencing MFH at 12 mo despite access to health insurance coverage. These findings underscore the need for clinic and policy solutions such as early financial navigation and elimination of cost sharing to protect pts from financial devastation as they continue with tx. Clinical trial information: NCI-2015-01885. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology, Other Foundation, U.S. National Institutes of Health.

Cumulative incidence of MFH in mCRC.

	3 mo	6 mo	9 mo	12 mo

Reassessing the net health benefit (NHB) of FDA approved cancer drugs with evolution of evidence using the American Society of Clinical Oncology Value Framework (ASCO-VF). *First Author: Seanthel Delos Santos, Sunnybrook Research Institute, Toronto, ON, Canada*

Background: Regulatory approval of oncology drugs are often based on data presented in the primary publication of clinical trials (CT). However, clinically relevant data, such as long-term overall survival (OS) and quality of life (QOL), are often reported in subsequent publications. Therefore, this study aimed to evaluate the ASCO-VF NHB at the time of drug approval and over time as further evidence is published. **Methods:** All FDA approved oncology drug indications from 01/06-12/16 were reviewed to identify CTs that were scorable using the ASCO-VF version 2. Subsequent publications of included CTs relevant for scoring were identified from Web of Science with a follow-up time of 3 years from approval. Using ASCO-defined threshold scores of ≤40 for low benefit and ≥45 for substantial benefit, changes in classification of benefit were assessed at 3-years post-FDA approval. **Results:** We identified 57 FDA approved indications (40.4% OS, 59.6% progression-free survival (PFS) as primary endpoints) with scorable ASCO-VF CTs. Among those 57 indications, 36.8% at the time of FDA approval demonstrated substantial benefit, 10.5% demonstrated intermediate benefit, and 52.6% demonstrated low benefit. We then identified 96 subsequent publications relevant to scoring within 3-years of FDA approval, consisting of primary endpoint updates (29.2%; 14.6% OS, 12.5% PFS), secondary endpoint updates (44.8%; 16.7% OS, 7.3% PFS), new reporting of secondary endpoint (4.2% OS), safety updates (28.1%), and QOL reporting (43.8%). Upon reassessment of the NHB in subsequent publications, there was an overall change from initial classification of benefit in 36.8% of trials (17.5% became substantial, 8.8% became low, and 10.5% became intermediate). Changes in scores were mainly the result of an updated hazard ratio (35.1%), change in scoring endpoints from PFS to OS as per ASCO-VF endpoint hierarchy (8.8%), toxicity updates (57.9%), new tail of the curve bonus (12.3%), palliation bonus (14.0%), or QOL bonus (22.8%). Overall, at reassessment at 3 years post-FDA approval, 42.1% were substantial, 10.5% were intermediate, and 47.3% were low benefit. **Conclusions:** Only a modest proportion of FDA approved drugs have demonstrated substantial NHB at time of approval. As further evidence was published, a substantial proportion of indications have a change in classification of NHB, resulting in a small increase in the overall proportion of indications being deemed to have substantial benefit at 3 years post-approval. Saving the best to the last: Can we wait for second-line? *First Author: Renana Barak, Institute of Oncology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: A common perception of some oncologists is that the vast majority of their patients with metastatic disease will receive 2nd line treatment upon progression. Therefore, "saving" good treatment options for the future may be acceptable. We aimed to examine whether this perception correlates with real-life. **Methods:** Using an oncology electronic database, consisting of >27,000 patients treated at our institution, we selected consecutive patients with metastatic or locally advanced lung, colon, pancreatic, bile duct and gastric cancers who started standard 1st line, consisting of at least doublet therapy. We then assessed the correlation between proceeding to 2nd line therapy and demographic and clinical variables, including age, gender, initial BMI, hemoglobin, WBC, creatinine, glucose, calcium, as well as survival. **Results:** A total of 553 patients met the inclusion criteria. Their median age was 66 and 317 were men. Their diagnoses were colon (197), lung (129), pancreas (101), bile duct (71) and gastric (55) cancers. Only 59% received at least one course of 2nd line treatment (61.9% colon, 65.1% lung, 66.3% pancreas, 35.2% bile duct and 54.5% gastric). Probability of reaching 2nd line treatment was associated with disease site (P=0.0002) as well as with age, with patients who received 2nd line being 2.5 years younger compared to those who did not (65 vs. 67.5 years, P=0.008). No other factor, including gender, BMI or standard laboratory values at presentation could predict chances of proceeding to 2nd line, for either the whole group or by primary cancer origin. Survival of patients not starting 2nd line was also significantly shorter across all tumor types. **Conclusions:** These real-life data indicate that only 60% of patients starting standard doublet or triplet treatment for advanced cancers will commence 2nd line therapy; and this cannot be reliably predicted in advance using standard clinical and laboratory characteristics. Our data challenge the practice of saving good treatment options for subsequent lines, and call for the development of tools enabling prediction of response and tolerance to treatment, pursuing for better patient selection and patient-tailored therapy. Going off pathway: Problem or good care? *First Author: Stephen B. Edge, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Clinical oncology pathways (COP) provide decision support and benchmarking against national standards. Some organizations provide financial incentives for using COP-recommended treatment (on pathway: OnP). Treatment (Rx) other than COP recommended Rx (off pathway: OffP) is appropriate for some cases. There are limited data on the appropriateness of OffP Rx. This study examines rates and reasons for OffP Rx in one cancer center. **Methods:** All systemic Rx decisions entered in the ClinicalPath COP from 10/1/18 - 9/30/19 were classified as OnP (including Rx on a clinical trial) or OffP and as adjuvant/neoadjuvant therapy (ADJ) or for metastatic cancer (MET). Oncologists must provide free text reasons for OffP Rx. Records of all OffP care were reviewed by a senior nurse-led team and physician to verify and classify OffP reasons. Cases without clear documentation were referred to the treating oncologist and/or multidisciplinary team for review. Justified OffP reasons (R1-6) were classified as: R1. Documented drug toxicity and/or treatment-limiting co-morbidity; R2. Prior treatment precluding pathway Rx; R3. New drug indication or molecular targeted therapy not in COP; R4. Continuation of Rx started prior to referral; R5. Other clearly documented and reviewed provider or multidisciplinary team rationale; and R6. Patient preference. **Results:** There were 2,997 COP treatment decisions for 2,389 patients. The OnP rate was higher for ADJ than for MET Rx (87% vs. 78%). Non-justified OffP care accounted for 1% of cases. 69% of OffP Rx was because of known drug toxicity, co-morbidity limiting therapy, prior therapy precluding COP choice, and new drug indications (Table). **Conclusions:** COPs provide decision support and practice benchmarking. Lower OnP rates for MET Rx likely reflect the nuances of Rx for advanced cancer. Most OffP care was justified and appropriate. Financial incentives that focus on the percentage of COP OnP care could paradoxically harm the quality of care, especially given the high percentage of OffP decisions for reasons of drug toxicity, co-morbidity and new drug indications. Research Sponsor: None.

Impact of utilization management policy on uptake of hypofractionated radiation in early-stage breast cancer. *First Author: Winnie Chi, Healthcore, Inc, Wilmington, DE*

Background: While hypofractionated radiation (HFR) after breast-conserving surgery is a cost-effective, patient-centered treatment in early-stage breast cancer (ESBC), less than 40% of eligible women received it in 2013. In 2016, a large commercial payer implemented a utilization management policy to encourage HFR for eligible women through denying reimbursement for extended-course radiation. We assessed the impact of the policy on HFR use and associated spending. **Methods:** We conducted a retrospective, adjusted difference-in-differences analysis using administrative claims of women continuously enrolled in 14 geographically diverse commercial health plans covering 6.9% of US adult women. The study population included women aged 18 or older with ESBC who were eligible for HFR according to 2011 guidelines from the American Society for Radiation Oncology. Women who received mastectomy, brachytherapy, or < 11 or > 40 external beam fractions were excluded. We compared HFR use and associated spending between women in fully-insured and Medicare Advantage (fully-insured) plans for whom the policy applied vs. self-insured or Medicare supplemental insurance (self-insured) plans for whom the policy did not apply. We adjusted for age, comorbidity, region, Medicare enrollment, and prior chemotherapy. **Results:** Among 10,540 eligible women, 3,619 (34%) were in fully insured plans and thus subject to the policy. There were no meaningful differences in mean age (63.8 vs. 65.0), Charlson comorbidity index (3.0 vs. 3.2), or practice setting between the fully-insured and self-insured groups. The policy was associated with an increase in HFR (4.2 adjusted percentage point difference-in-difference [ppd], 95% CI 0.0 to 8.4, p = 0.051) and a non-significant decrease in radiotherapy-associated expenditures (-$2,275, p = 0.09). Spillover analyses revealed significantly higher uptake of HFR among self-insured patients who were indirectly exposed to the policy through seeing the providers who also treated fulled insured women (8.5 adjusted ppd, 95% CI 3.6 to 13.5, p = 0.001), compared to those who were not exposed. **Conclusions:** A payer's utilization management policy was associated with direct and spillover increases in HFR use, even after accounting for a strong secular trend towards increased hypofractionation use. However, policymakers must balance the impact of this and similar policies against their additional administrative costs. Research Sponsor: None.

Effect of mammography screening frequency on false-positive biopsy rates and detection of local recurrence among breast cancer survivors. *First Author: Julia E McGuinness, Columbia University Irving Medical Center, New York, NY*

Background: Current guidelines recommend that women with a history of early-stage breast cancer treated with breast-conserving therapy (BCT) continue screening mammography after treatment. One strategy is semi-annual ipsilateral mammography for the first 3 years after diagnosis, when risk of local recurrence is highest. However, a potential harm of more frequent screening is false-positive breast biopsy. We examined the association between screening frequency and rates of false-positive biopsy and local recurrence among breast cancer survivors. **Methods:** We conducted a retrospective cohort study at Columbia University Irving Medical Center (CUIMC) in New York, NY, of women diagnosed with stage 0-III breast cancer from 2007 to 2017, who were treated with BCT and had at least 2 screening mammograms at CUIMC within the first 3 years after diagnosis. Demographic and clinical information were collected from the electronic health record. Frequency of mammography screening was defined as the median interval between two consecutive mammograms (every 6 months vs. yearly). False-positive biopsy and local recurrence were identified by review of breast pathology reports. A false-positive biopsy was defined as a breast biopsy without evidence of invasive or non-invasive cancer. Descriptive statistics and logistic regression models were conducted to examine relationships between covariates and either false-positive biopsy or local recurrence. **Results:** In our study cohort (n = 1404), the median age at breast cancer diagnosis was 61 years (range, 24-94), including 45% white, 14% black, 32% Hispanic, and 8% Asian. Eighty percent of women had screening mammography of the ipsilateral breast every 6 months during the first 3 years after diagnosis. Comparing women who screened every 6 months vs. yearly, there was no difference in local recurrence rates (4.0% vs. 4.1%), including screen-detected and invasive recurrences, but a higher rate of false-positive biopsy (13.5% vs. 7.5%). In multivariable analysis, women who screened every 6 months had about a 2-fold increased risk of having a false-positive biopsy (OR 1.93; 95% CI 1.17-3.19); no other factors were significantly associated with false-positive biopsy. **Conclusions:** We observed that women with early-stage breast cancer treated with BCT who underwent more frequent screening mammography had more false-positive breast biopsies, but no difference in local recurrence rates. Future studies are needed to determine optimal screening strategies for breast cancer survivors. Research Sponsor: U.S. National Institutes of Health.

The potential cost-effectiveness of a risk-based pancreatic cancer screening strategy in new-onset diabetes. *First Author: Naomi RM Schwartz, University of Washington, Seattle, WA*

Background: There are no established methods for pancreatic cancer (PC) screening, but the National Cancer Institute and the Pancreatic Cancer Action Network (PanCAN) are investigating risk-based screening strategies in new-onset diabetes (NOD)—a group with elevated PC risk. Preliminary estimates of the cost-effectiveness of these strategies can provide insights about potential value and inform supplemental data collection. Using data from the Enriching New-Onset Diabetes for Pancreatic Cancer (ENDPAC) risk model validation study, we assessed the potential value of CT screening for PC in those determined to be at elevated PC risk, as is being done in a planned PanCAN Early Detection Initiative (EDI) trial. **Methods:** We created an integrated decision tree and Markov state-transition model to assess the cost-effectiveness of screening those age ≥50 and with NOD for PC using CT imaging vs. no screening. PC prevalence, sensitivity, and specificity were derived from the ENDPAC validation study. PC stage distribution in the no screening strategy and PC survival were derived from SEER. Background mortality for diabetics, screening and cancer care expenditure, and health state utilities were derived from the literature. The base case assumed 40% of screen-detected PC cases were resectable, and a threshold analysis explored the fraction required for screening to be <$100,000 per QALY gained. Life years (LYs), quality-adjusted life years (QALYs), and costs were tracked over a lifetime horizon and discounted at 3% per year. Results are presented in 2019 USD, and we took a U.S. payer perspective. **Results:** In the base case, screening resulted in 0.0055 more LYs, 0.0045 more QALYs, and $305 in additional expenditure for a cost per QALY gained of $68,059 (Table). Among PC cases, screening resulted in 0.67 more LYs, 0.55 more QALYs, and $22,691 in additional expenditure. In probabilistic analyses, screening resulted in a cost per QALY gained of <$50,000 and <$100,000 in 34% and 99% of simulations, respectively. In the threshold analysis, >25% of screen-detected cases needed to be resectable for the cost per QALY gained with screening to be <$100,000. **Conclusions:** We found that risk-based pancreatic cancer screening in NOD is likely to be cost-effective in the U.S. if even a modest fraction (>25%) of screen-detected cases are resectable. Future studies should reassess the value of this intervention once PanCAN EDI data become available. Research Sponsor: Pancreatic Cancer Action Network (PanCAN) Grant.

Strategy	QALYs	Cost	Cost per QALY
Screening	14.711	$65407	
No Screening	14.706	$65102	
Difference	0.0045	$305	$68059

Composite grading algorithm for National Cancer Institute's PRO-CTCAE. *First Author: Amylou C. Dueck, Mayo Clinic, Scottsdale, AZ*

Background: Standard reporting of symptomatic adverse events (AEs) in oncology relies on clinicians to rate patient (pt) experience using CTCAE; each symptom is represented by a single graded item. To capture direct pt experience, NCI developed PRO-CTCAE to supplement CTCAE. In PRO-CTCAE, the pt answers up to 3 questions per AE about a symptom's frequency, severity and interference with daily activities. To align PRO-CTCAE with CTCAE, we developed an algorithm for mapping sets of questions for an AE to a single composite numerical grade. **Methods:** We used a 5-step process. (1) All 187 possible PRO-CTCAE score permutations were presented to clinical investigators to subjectively map permutations to single numerical grades (range 0-3). (2) Permutations with < 75% agreement were presented to investigator committees at a National Clinical Trials Network meeting to gain majority consensus via anonymous voting. (3) The resulting algorithm was refined via graphical and tabular approaches to assure directional consistency. (4) Validity, reliability and sensitivity were assessed in a national study dataset. (5) Accuracy for delineating AEs between study arms was measured in 2 phase III clinical trials (Alliance for Clinical Trials in Oncology A091105 and Exelixis COMET-2). **Results:** (1) 12/187 score permutations had < 75% initial agreement. (2) Majority consensus was reached for all permutations. (3) 5 mappings were adjusted to assure directional consistency. (4) Composite grades for 46/59 (78%) AEs were higher in pts with ECOG performance status 2-4 vs 0-1 (median effect size 0.23 [range -0.49-0.73]; 32/59 effect size ≥0.2; 25/59 $p< 0.05$), similar to when conducting analysis on individual unmapped items. The test-retest reliability for 24 selected composite grades ranged from 0.57-0.96 (median intraclass correlation coefficient [ICC] 0.77) with 18/24 (75%) grades having ICC ≥0.7. Median (range) standardized response means in pts reporting worsening, no change, and improvement were 0.20 (0.03-0.34), -0.06 (-0.20-0.03) and -0.12 (-0.32-0.06). (5) Pattern, directionality and statistical significance of between-arm differences in both trials were preserved with composite grades as compared to individual unmapped items. **Conclusions:** A composite grading algorithm for PRO-CTCAE was rigorously developed and validated. PRO-CTCAE composite grades may be useful in analyses to provide a single metric for each pt-reported AE for trial and real-world reporting. Predictive survival ability of patient-reported in comparison to physician-reported performance status in solid malignancies. *First Author: Abdulla Al-Rashdan, Tom Baker Cancer Centre, Calgary, AB, Canada*

Background: Performance status (PS) is an important prognostic tool in cancer management that is mainly generated by physicians. In oncology, the Eastern Cooperative Oncology Group (ECOG) measure is commonly used. Patient-reported functional status (PRFS) is an emerging method that allows patients to provide an estimate of their function; however, there is limited information about its prognostic significance in solid tumors. We explored the prognostic value of PRFS in comparison to ECOG on survival. **Methods:** 13,045 newly diagnosed cancer patients in Ontario, Canada, who had information from both PRFS and ECOG on the same day of an outpatient visit between March 2013 and March 2018 were included. The dataset were randomly divided into 60% training (n = 7,827) and 40% validation (n = 5,218) cohorts. Covariates were similar at baseline for both training and validation datasets. Survival was estimated by modeling clinical characteristics with PRFS, with ECOG, and alone. **Results:** PRFS and ECOG scores were statistically significant predictors of overall survival. Both higher PRFS and ECOG scores tended to be associated with inferior survival, hazard ratio (HR) = 1.71 (P < .0001), and HR = 1.90 (P < .0001) respectively. Models that included either PRFS or ECOG scores outperformed the model with baseline clinical characteristics only. C statistics were 0.836, 0.839, and 0.811 respectively. **Conclusions:** Patient-reported functional status adds to survival modeling and is equally predictive as the ECOG scale at various stages of solid malignancies. PRFS may be used instead of ECOG in clinical or research setting for survival estimation. Research Sponsor: Study done by Cancer Care Ontario that is funded by Government of Ontario.

Subjective cognition in chimeric antigen receptor T-cell therapy recipients. *First Author: Anna Barata, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy can lead to durable responses in chemorefractory patients with hematologic malignancies. CAR-T, however, can be associated with neurotoxicity. There is a significant body of literature describing patient-reported concerns with cognition in hematopoietic cell transplant (HCT) recipients, a similar treatment group. However, little is known about subjective cognition in CAR-T patients. This study examined changes in subjective cognition over time in CAR-T recipients and compared their outcomes with allogeneic HCT recipients. **Methods:** At baseline and 90 days after infusion, participants completed the Everyday Cognition Questionnaire (ECog). The ECog provides scores for total cognition, memory, language, visuospatial abilities, planning, organization, divided attention, and satisfaction with cognition. Comparison data from allogeneic HCT recipients came from a previous observational study. Linear mixed models compared changes in subjective cognition between recipients of CAR-T and allogeneic HCT over time. Models were adjusted by age, marital status, education, and Karnofsky performance status. **Results:** Participants were 111 CAR-T recipients (mean age 60 years, 37% female) and 190 allogeneic HCT recipients (mean age 53, 42% female). Linear mixed models indicated CAR-T recipients' subjective cognition didn't change within the 90 days after infusion (p's > .05). At baseline, there were no group differences between CAR-T and allogeneic HCT recipients in subjective cognition (p's > 0.05). Over time, however, subjective cognition between groups differed. Specifically, CAR-T recipients reported stable subjective cognition whereas allogeneic HCT recipients reported worsening total subjective cognition (p = 0.04), memory (p = 0.02), visuospatial abilities (p = 0.01), planning (p = 0.01), and divided attention (p = 0.01). At follow-up, CAR-T recipients reported better total subjective cognition (p < 0.01), memory (p < 0.01), language (p = 0.01), visuospatial abilities (p < 0.01), planning (p < 0.01), and divided attention (p < 0.01) than allogeneic HCT recipients. **Conclusions:** Despite the neurotoxicity associated with CAR-T, patients can expect to perceive similar subjective cognition at day 90 compared to baseline. Future studies should also evaluate objective cognition in CAR-T recipients. Research Sponsor: U.S. National Institutes of Health, 2017 Moffitt Team Science Award.

Global perspectives on clinical cancer research: A comparison of randomized controlled trial (RCT) design and outcomes across high income and low-middle income countries. *First Author: Connor Wells, Queen's University, Kingston, ON, Canada*

Background: Cancer clinical trials have become increasingly international in scope. There are limited data regarding trial variation based on the economic status of the country in which they are conducted. Here we describe trial characteristics, design, and results of all RCTs published globally during 2014-2017. **Methods:** A structured literature search was designed using PUBMED to identify all RCTs evaluating anti-cancer therapies published during 2014-2017. Data captured included authorship, participants, study characteristics, design, and results. RCTs were classified based on the World Bank country-level economic classification of the first author [low-middle/upper-middle income countries (LMIC) and high-income countries (HIC)]. Among superiority RCTs that met the primary endpoint (i.e. statistically "positive"), we calculated the ESMO-MCBS to identify trials with substantial clinical benefit (MCBS scores 4/5 or A/B). Outcomes were compared with Chi Square or Fisher's Exact tests. **Results:** The study cohort included 694 RCTs; 636 (92%) were led by HIC and 58 (8%) were led by LMIC. Compared to LMIC, RCTs in HICs were more likely to be funded by industry [73% vs 41%, $p<0.001$] and more likely to test novel systemic therapies [87% vs 78%, p=0.027]. LMIC studies were typically smaller (median N=220 vs N=474 participants, $p<0.001$) and more likely to meet their primary endpoints [66% vs 44%, p=0.002]. In "positive" superiority trials, the effect size was larger in LMICs compared to HICs (median HR 0.62 vs HR 0.84, $p<0.001$). The proportion of trials identifying treatments with substantial clinical benefit (ESMO MCBS 4/5/A/B) was 45% (LMIC) and 31% (HIC, p=0.291). Studies from LMIC were published in journals with lower impact factors (IF) (median IF 7 vs 21, $p<0.001$); a publication bias persisted when adjusted for whether a trial was positive or negative: median IF LMIC negative trial=5 vs HIC negative trial=18 ($p<0.001$); median IF LMIC positive trial=9 vs HIC positive trial= 26 ($p<0.001$). **Conclusions:** Only a small minority of oncology RCTs are led by investigators in LMIC; these trials are less likely to be funded by industry and more likely to meet their primary endpoint. "Positive" RCTs from LMIC identify therapies with a substantially larger effect size than HIC. These data identify a substantial publication bias against RCTs conducted in LMIC. Videos improve patient understanding of misunderstood chemotherapy terms in a rural population. *First Author: Eli Rowe Abernethy, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Rural communities can have low health literacy, which impacts the adequacy of informed consent, adherence to treatment, and outcomes. We had previously created and tested educational videos about basic chemotherapy terminology for use in an underserved population at our inner-city hospital. This study aimed to determine if these videos increased understanding of these terms in rural communities. **Methods:** Through patient and provider interviews in an underserved urban setting, 20 basic cancer treatment terms were identified as frequently misunderstood. As a pilot, 6 of these terms were explained in short, animated one-minute videos using VideoScribe (Sparkol).To determine if these videos improved understanding in the rural setting, 50 rural patients, specified as patients living in a county ranked 4-9 on the USDA Rural Urban Continuum Code (RUCC) scale, were asked to define each term before and after viewing the video. All answers were audiotaped and double coded for correctness of definition pre and post video screening, using the video definition as the correct definition. Before video and after video correct definition rates were calculated, along with 95% exact binomial confidence intervals using the Clopper-Pearson method. The videos for all 20 terms can be viewed on CancerQuest (https://www.cancerquest.org/media-center/videos/cancer-treatment-terms). **Results:** Participants were mostly white (79%), female (52%), resided in the more rural counties RUCC ranked 6-9 (62%), had < a high school degree (56%) and had a family income of <$40K (59%). **Conclusions:** Improving health literacy is a critical component in improving care. Our study establishes that a simple and easily disseminated intervention can significantly increase patient understanding of basic chemotherapy terminology in a rural setting. Research Sponsor: U.S. National Institutes of Health, Research reported in this publication was supported in part by the Biostatistics and Bioinformatics Shared resource of Winship Cancer Institute of Emory University and NIH/NCI under award number P30CA138292. The content is solely the responsibility of the.

The percentages of patients who provided correct definitions pre and post video intervention.

Term	Before – Rate (95% CI)	After – Rate (95% CI)	McNemar p-value
Cancer	32% (20% – 47%)	76% (62% – 87%)	<0.001
Chemotherapy	52% (37% – 66%)	84% (71% – 93%)	<0.001
Palliative chemotherapy	10% (3% – 22%)	76% (62% – 87%)	<0.001
Curative treatment	35% (22% – 50%)	76% (62% – 87%)	<0.001
Blood count	55% (40% – 69%)	90% (78% – 97%)	<0.001
Risk of infection	54% (39% – 68%)	82% (69% – 91%)	<0.001

7023 Poster Session (Board #295), Fri, 8:00 AM-11:00 AM

Project facilitate: A review of the FDA oncology center of excellence expanded access pilot program. *First Author: Natasha L Kormanik, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Expanded Access (EA), also known as "compassionate use," is a regulatory pathway in which a patient with an immediate life-threatening condition or disease can gain access to an investigational product for treatment when no satisfactory therapy is available. Oncology practices may lack the regulatory experience or administrative support to use EA. In response, FDA OCE launched Project Facilitate (PF), a call center to assist oncology healthcare providers requesting EA. An analysis of single-patient investigational new drugs (IND) was performed to assess the first 10 months of PF compared to the period prior to its launch. **Methods:** Preliminary data was extracted from the FDA's central database that yielded 719 single-patient INDs between May 31-November 30, 2018 & 2019 in the Office of Oncologic Diseases (OOD). Data collected included IND receipt date, acknowledgment date, application status, drug name, underlying malignancy of patient, address of requesting physician, withdrawal date, and patient demographics. A manual review of INDs was performed to assess for actual processing dates and to capture demographics not captured by the database. A total of 28 INDs were excluded due to duplications, cancellation by Sponsor prior to issuance of FDA decision, or coding errors in the database. Industry denial explanations were reported by the provider by emails. **Results:** Data from 692 INDs were analyzed and 692 (100%) were granted safe to proceed. The median processing time was 1.5 days (mean = 2) in 2018 and 0.5 day (mean = 0.5) in 2019. Our findings indicate that the volume of oncology EA requests increased by 76 (19%) in 2019 vs 2018. A total of 207 unique drugs were requested. Malignancies most frequently involved included: Acute myeloid leukemia (n = 84, 8.3%), soft tissue sarcoma (n = 77, 7.6%), and non-small cell lung cancer (n = 60, 5.9%). States with the highest requests included: California (n = 82, 11.8%), New York (n = 81, 11.7%), and Massachusetts (n = 42, 6.1%). A majority of requests were from major academic centers (77%). All denied requests (N = 9) by industry were due to company's decision to not provide products outside of a clinical trial. **Conclusions:** The positive trends in decreased processing times and increased number of requests are consistent with OCE's mission to improve efficiency of the EA program and ensure equitable access to all oncology patients. Research Sponsor: None.

Breast and cervical cancer screening disparities among transgender patients. *First Author: Oluwadamilola Temilade Oladeru, Harvard Radiation Oncology Program, Boston, MA*

Background: Over a million Americans identify themselves as transgender and this population is growing. Transgender status was a pre-existing condition prior to the Affordable Care Act (ACA), and transgender individuals faced unique disparities in gender-specific cancer screening in part due to discrimination in health insurance coverage. Modern literature for transgender adults' adherence to cancer screening is limited. To fill this knowledge gap, we conducted a cross sectional study to investigate transgender individuals' self-reported adherence to cancer screening and access to primary care compared to cisgender individuals. **Methods:** The Behavioral Risk Factor Surveillance System database was queried for transgender (either male-to-female [MTF] or female-to-male [FTM]) and cisgender adults from 2014-2016 and 2018. Primary endpoints were adherence to breast and cervical cancer screening guidelines and access to primary health care. Those with prior hysterectomy, breast and cervical cancer were excluded. Multivariable logistic regression was performed to evaluate the association of transgender status with cancer screening and healthcare access, after adjusting for demographic characteristics and survey weights. **Results:** A total of 219,665 and 206,446 participants were eligible for breast and cervical cancer screening, respectively. Of those, 614 (0.28%) and 587 (0.29%) transgender participants were eligible for each cancer screening type, respectively, representing a weighted estimate of nearly 200,000 transgender participants total. When compared to cisgender counterparts, transgender participants were less likely to adhere to breast cancer screening (FTM: OR 0.47, $p < 0.001$; MTF: OR 0.04, $p < 0.001$) and to have received any breast cancer screening (FTM: OR 0.32, $p < 0.001$; MTF: OR 0.02, $p < 0.001$). Similarly, FTM participants were less likely to adhere to cervical cancer screening (OR 0.42, $p < 0.001$) and to have received any cervical cancer screening (OR 0.26, $p < 0.001$). In addition, transgender participants were more likely to have no primary care physician (FTM: OR 0.79, $p < 0.001$; MTF: OR 0.58, $p < 0.001$) and to be unable to see a physician when needed within the past year due to medical cost (FTM: OR 1.44, $p < 0.001$; MTF: OR 1.36, $p < 0.001$). **Conclusions:** Despite the implementation of the ACA, limited primary care access and poor adherence to breast and cervical cancer screening are evident for transgender populations. Further research efforts to improve the utilization of preventive cancer services are needed for this underserved population. Research Sponsor: None.

7025 Poster Session (Board #297), Fri, 8:00 AM-11:00 AM

Racial disparities in immune-related adverse events (irAE) of immune checkpoint inhibitors (ICPi) and association with survival based on clinical and biochemical responses. *First Author: Monica Peravali, MedStar Washington Hospital Center, Washington, DC*

Background: ICPi cause various irAE with thyroid dysfunction as a commonly reported abnormality. There is increasing evidence showing positive association with development of irAE and survival. However, prior trials with ICPi had underrepresentation of minorities with <5% African Americans (AA). **Methods:** We retrospectively reviewed patients (pts) with stage IV solid malignancies treated with PD1/PDL1 blockers between 1/2013-12/2018 across MedStar Georgetown Cancer Institute facilities. Pts treated with CTLA-4 inhibitors were excluded. Progression free survival (PFS) and overall survival (OS) were primary endpoints and were calculated using Kaplan-Meier methods and Wilcoxon rank sum test for comparison. **Results:** 293 pts met eligibility criteria. 91 pts (31%) had any grade irAE; most common AE were endocrine (40.7%) specifically TSH elevation, dermatological (23.1%) and rheumatologic (18.7%). Proportion of irAE was significantly higher in Caucasians versus AA (60.4% vs 30.8%), in pts with low PDL1, lower LDH, older age, and those who had more treatment cycles with ICPi. Rate of progression was lower in pts with irAE (30.8% vs 46.0%, p-0.0140). Median PFS (5.8 vs 3.0 months (mo), p- 0.0204) and OS (17.1 vs 7.2 mo, p value- <0.0001) were higher with irAE. Statistically significant difference in OS (17.1 vs 8.6 mo, p- 0.0002) but not in PFS (5.8 vs 3.3 mo, p: 0.0545) was noted with endocrine irAE. No differences in survival were observed among other commonly reported irAE. Differences in survival among subgroups of pts with irAE are detailed in table. **Conclusions:** Development of irAE positively correlated with improved PFS and OS as reported in previous studies. To our knowledge, this is the first study observing differences in OS favoring endocrine AE and Caucasian race. These factors may be potential surrogate markers of prognosis pending replication of these results in large-scale studies. Research Sponsor: None.

Health insurance status and cancer stage at diagnosis and survival in the United States. *First Author: Jingxuan Zhao, American Cancer Society, Atlanta, GA*

Background: While previous studies demonstrated associations between Medicaid coverage or no health insurance with both advanced stage at cancer diagnosis and worse survival, access to health care in the U.S. has changed substantially in the past decade. This study examined associations of health insurance status with stage at diagnosis and survival among 17 common cancers using recent national data. **Methods:** We identified 1,427,532 cancer patients aged 18-64 years newly diagnosed with 17 common cancers from the 2010-2013 National Cancer Database. Multivariable logistic regression models were used to examine the distribution of stage at diagnosis by health insurance status (private, Medicare, Medicaid, dual Medicare/Medicaid, and uninsured) overall and for each cancer site. Cox models compared stage-specific survival by health insurance for each site. **Results:** Compared to privately insured patients, Medicaid and uninsured patients were significantly more likely to be diagnosed with advanced-stage cancer (III/IV) for all the 17 cancers combined (adjusted odds ratio [AOR]: 2.27, 95% confidence interval [95CI]: 2.24-2.29; AOR: 2.39, 95CI: 2.36-2.42, respectively) and for all included cancer sites separately. Medicare and Medicare-Medicaid patients were also more likely to be diagnosed at advanced-stage for all the 17 cancers combined, but results varied by cancer site. Compared to the privately insured patients, worse survival was observed for patients with all other insurance types and uninsured at each stage for all the 17 cancers combined and most cancer sites. For example, among patients diagnosed at stage I, adjusted mortality hazard ratios for Medicare, Medicaid, Medicare-Medicaid, and uninsured patients were 1.72 (95CI: 1.70-1.75), 1.73 (95CI: 1.71-1.76), 2.07 (95CI: 2.02-2.17) and 1.56 (95CI: 1.53-1.58), respectively, compared with privately-insured patients. **Conclusions:** Patients with non-private insurance were more likely to be diagnosed with cancer at advanced stage and have worse survival. Improving access to health insurance with adequate coverage is crucial for receiving appropriate cancer screening, diagnosis, and quality care. Research Sponsor: None.

7027 Poster Session (Board #299), Fri, 8:00 AM-11:00 AM

Effect of shorter time to treatment on survival in rural patients with breast cancer. *First Author: Suneel Deepak Kamath, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Rural cancer care in the United States has unique challenges from variable access to care. This study examined differences in time to first treatment (TTT), a potential surrogate for access, and predictors of overall survival (OS) between rural and non-rural patients with breast cancer. **Methods:** Women with stage I-III breast cancer from 2004-2012 in the National Cancer Database of Commission on Cancer (CoC)-accredited facilities were included and categorized as rural and non-rural. Differences in demographic, disease and treatment characteristics, socioeconomic factors and TTT (< 4 weeks, 4-8 weeks and > 8 weeks) between rural and non-rural patients were assessed by Chi-square test. The effect of age, insurance status, cancer center type, community median income, community % no high school, and TTT on OS were assessed using univariate and multivariate Cox models. **Results:** The study included 1,205,031 patients, 18,417 (2%) of whom were rural. Compared to non-rural patients, rural patients were more likely to be age > 65, Caucasian, receive care at non-academic centers, have government insurance, have lower income and less education ($p < 0.0001$ for all). Significant demographic and socioeconomic differences are shown in Table. Rural patients had shorter mean TTT (3.72 vs. 4.35 weeks, $p < 0.0001$). More rural patients had TTT < 4 weeks (67% vs. 57%) and < 8 weeks (94% vs. 90%), $p < 0.0001$ for both. Shorter TTT (both < 4 weeks vs. 8 weeks and 4-8 weeks vs. > 8 weeks) was associated with improved OS (HR: 0.84, 95% CI: 0.82-0.86, $p < 0.0001$ and HR: 0.82, 95% CI: 0.81-0.83, $p < 0.0001$, respectively). After adjusting for demographic, socioeconomic, disease stage and treatment factors, rural status was associated with significantly better OS compared to non-rural status (HR: 0.92, 95% CI: 0.89-0.96, $p < 0.0001$). **Conclusions:** Despite several adverse socioeconomic factors, rural patients with breast cancer with access to CoC-accredited facilities had significantly shorter TTT and better OS compared to non-rural patients. These data suggest improving TTT can mitigate disparities in rural cancer care. It is unclear whether our data apply to non-CoC-accredited facilities in rural United States. Research Sponsor: None.

Characteristic	Rural	Non-Rural	P value

7028 Poster Session (Board #300), Fri, 8:00 AM-11:00 AM

Geographic and demographic disparities in breast cancer outcomes: A population-based study. *First Author: Rohit Gosain, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Breast cancer (BC) is one of the leading causes of cancer-related mortality worldwide, with over 2 million new cases diagnosed each year. Area of residence has been shown to affect survival, but its impact on BC is unknown. The purpose of this study is to address the potential disparities in BC outcomes between the urban area (UA) and rural area (RA). **Methods:** We obtained data based on BC patients' (pts) area of residence; UA vs RA, using the Surveillance, Epidemiology, and End Results (SEER) database treated from 1975-2016. Different socio-demographic variables and tumor characteristics (cts) from both groups were analyzed. Disease specific survival (DSS) and overall survival (OS) were analyzed by Kaplan-Meier methods. Multivariable analyses were conducted using Cox regression models. **Results:** A total of 99,339 and 872,742 pts were analyzed from RA and UA respectively. Pt cts, including age, sex, marital status, insurance status were similar across both RA and UA. There were a higher number of Black and Hispanic pts in the UA compared to RA. A total of 264,191 pts had receptor subtype data available. A slightly higher percentage of triple negative BC (TNBC) pts was seen in the RA compared to UA (13.5% v 12.7%) whereas UA had a higher percentage of HER2+ BC (18% v 17.3%). There were 95.4% early/locally advanced (stage I-III) and 4.6% metastatic pts. UA pts had significantly improved DSS and OS regardless of stage, grade or other tumor cts compared to RA pts. When stratified by receptor subtype, UA had significantly improved DSS and OS in hormone positive (HR+) (OS HR of 0.86; DSS HR of 0.87; $p < 0.05$) and HER2+ pts (OS HR of 0.87; DSS HR of 0.83; $p < 0.05$). However, there were no significant differences seen between UA and RA pts with TNBC. **Conclusions:** To our knowledge, this is the first study to report BC outcomes based on geographic disparities. Interestingly, HR+ and HER2+ UA pts had better outcomes than RA pts, whereas TNBC pts had similar survival regardless of residence area. Perhaps this disparity is partly due to the longer duration of treatment needed with hormonal therapy in the adjuvant setting making compliance an important factor to take into account in RA pts, in addition to complicated decision making with upcoming data in HER2 + cancer in the early stage setting. Access to healthcare, differences in surgical and systemic approaches of pt care, management of treatment-related toxicities and environmental factors are all potential factors that may affect outcomes in BC pts. Based on the above data, further studies are needed to further evaluate and reduce such disparities. Research Sponsor: None.

7029 Poster Session (Board #301), Fri, 8:00 AM-11:00 AM

Socioeconomic disparities in *MGMT* promoter methylation testing for glioblastoma patients. *First Author: Bryan Iorgulescu, Dana-Farber Cancer Institute, Boston, MA*

Background: *MGMT* promoter methylation holds important prognostic and predictive implications for glioblastoma (GBM) patients. Herein we evaluate whether any barriers faced *MGMT* testing. **Methods:** Adults with newly-diagnosed GBMs were identified from the U.S. National Cancer Database (2010-2016). Patient socioeconomic, tumor, and cancer program features were evaluated for association with *MGMT* testing by multivariable logistic regression. **Results:** Of 12,380 GBM patients, only 57% had *MGMT* testing–a rate that increased to 74% by 2016. Testing was independent of patients' sex or race/ethnicity (all $p > 0.05$); and was largely independent of GBM histology, size, and location. Older patients were less likely to receive testing (54% of ≥70-years-olds vs 62% of those in their 40s, $p = 0.01$). Insurance status was an independent predictor of testing: only 43% of uninsured patients had testing, vs 61% of privately-insured or 55% of Medicare patients ($p \leq 0.01$). The uninsured rate dropped from 3.6% in 2010 to 2.5% in 2016 and was associated with Medicaid expansion under the Affordable Care Act. Patients from non-expansion states had the lowest rates of testing (55%), vs patients from expansion states (58%, $p < 0.001$). Additionally, household incomes were independently associated with testing: only 50% of patients living in the poorest quartile of households had testing vs 61% in the richest quartile ($p = 0.001$). Diagnosing hospital type was also an independent predictor of testing: patients diagnosed at academic/NCI-designated cancer programs were most likely to have testing (65%), vs only 45% of community and 44% of comprehensive community cancer program patients were provided testing (all $p < 0.001$). By 2016, testing rates had improved in all program types–particularly at comprehensive community (67%) and academic (80%) programs, but lagged at community programs (56%, $p < 0.001$). Patients without *MGMT* testing received less chemotherapy (mOR = 0.66, $p < 0.001$) and were associated with worse overall survival (mHR = 1.08, $p = 0.002$). **Conclusions:** Newly-diagnosed GBM patients in the U.S. who were uninsured, from the poorest quartile of households, or diagnosed at community cancer programs faced significant barriers to receiving *MGMT* testing. Medicaid expansion under the ACA was associated with reduced uninsurance, increased Medicaid insurance, and improved rates of testing. Reduced testing rates were associated with less chemotherapy and worse OS. Together our results indicate that substantial socioeconomic and care setting disparities exist in *MGMT* testing for GBM patients. Research Sponsor: None.

7030 Poster Session (Board #302), Fri, 8:00 AM-11:00 AM

Association between Medicaid expansion status and metastatic disease at diagnosis in patients with melanoma. *First Author: Jesus C. Fabregas, Harvard TH Chan School of Public Health, Boston, MA*

Background: The Affordable Care Act (ACA) expanded Medicaid coverage in 2010. It is unknown what impact the ACA expansion has had on a timely diagnosis for patients with melanoma. We hypothesize Medicaid ACA expansion has decreased the odds of being diagnosed with Stage IV melanoma. **Methods:** The National Cancer Database was queried. Analysis was restricted to patients diagnosed (dx'd) in or after 2010. Stage IV dx was the outcome variable. Predictors were dx'd at an already expanded ACA state (ES) or not (NES). Covariates were age, race, sex, education status, income, rural setting, and Charlson comorbidity index. Univariate and Multivariate analyses were performed using logistic regression (table). The outcome model was adjusted using a generated Propensity Score as a continuous variable. An interaction term was used to evaluate for effect modification of ES on the association between race and Stage IV. **Results:** 219,475 patients diagnosed in 2010 or later were included. Median age was 62 years. By Univariate analysis, NES, age >= 65, black race, male sex, lower educational and income level, rural area, and a higher Charlson score were significantly associated with increased odds of being dx'd with Stage IV melanoma (all $p < 0.001$). By Multivariate Analysis, these associations persisted except for rural area and age. After adjusting for propensity score, ES patients were 9% less likely to be diagnosed with Stage IV melanoma as compared with NES patients (OR = 0.91 $p < 0.001$; 95% CI 0.867 – 0.959). ACA expansion status was an effect modifier on the association between race and late diagnosis ($p = 0.004$ for interaction term). For NES patients, black race had 3.26 odds ($p < 0.001$ 95% CI 2.56 – 4.18) of being diagnosed with Stage IV as compared with white patients. The odds dropped to 1.76 (p 0.004; 95% CI 1.20 – 2.57) for ES patients. **Conclusions:** ES patients were less likely to be diagnosed with Stage IV melanoma as compared to NES patients. Medicaid expansion decreased the likelihood for black patients to be diagnosed with Stage IV as compared with whites. This suggests Medicaid expansion improves access to care and earlier diagnosis of melanoma and decreases racial gaps. Research Sponsor: None.

Disparities by race, socioeconomic status, and insurance type in the receipt of NCCN guideline concordant care for select cancer types in California. *First Author: Kiran Clair, University of California Irvine Medical Center, Orange, CA*

Background: There are a limited number of studies that have evaluated the association between National Comprehensive Cancer Network (NCCN) guideline adherence and survival across different cancers. We aim to assess the relationship between race/ethnicity, socioeconomic status (SES), insurance type and the receipt of NCCN guideline concordant cancer care and survival. **Methods:** This is a retrospective population-based cohort study of patients with 7 types of invasive cancer using the California Cancer Registry. Adherence with NCCN guidelines was defined by appropriate surgical, radiation, and chemo- or hormonal therapies. Multivariate logistic regression was used to evaluate the relationship between the patient, insurance type, tumor, and guideline adherence. Disease-specific survival analysis was performed using multivariate proportional hazards model. **Results:** A total of 543,198 patients were identified with invasive cancer between 2004-2017 (cases by disease type: breast 189,311, prostate 156,502, colon 80,102, liver 25,857, gastric 22,066, ovary 22,551, and cervix 16,691). The proportion of patients receiving NCCN guideline-concordant care varied by disease type. Non-concordant guideline treatment was associated with increased disease-specific mortality across all cancer types: breast (HR 1.28, 95%CI 1.23-1.33), prostate (HR 1.31, 95%CI 1.22-1.41), colon (HR 1.73, 95%CI 1.67-1.78), liver (HR 2.52, 95%CI 2.42-2.63), gastric (HR 2.38, 2.28-2.49), ovary (HR 1.32, 95%CI 1.26-1.38), and cervical cancer (HR 1.17, 95%CI 1.08-1.26). In multivariate models, compared to White, black patients were less likely to receive guideline concordant care for breast (OR 0.88, 95%CI 0.84-0.92), prostate (OR 0.90, 95%CI 0.86-0.93), colon (OR 0.85, 95%CI 0.79-0.92), and ovarian cancer (OR 0.71, 95%CI 0.62-0.82). Compared to Managed care insurance patients, Medicaid payer status was also associated with lower guideline concordant care for breast (OR 0.81, 95%CI 0.78-0.84), prostate (OR 0.91, 95%CI 0.86-0.97), colon (OR 0.70, 95%CI 0.65-0.75), gastric (OR 0.69, 95%CI 0.63-0.75), and liver cancer (OR 0.66, 95%CI 0.61-0.72). **Conclusions:** Less than half of cancer patients received NCCN guideline concordant care. There was an incremental relationship observed between SES and the likelihood of receiving guideline concordant care. Patients receiving non-guideline concordant care had worse disease-specific survival. Research Sponsor: None.

7032 Poster Session (Board #304), Fri, 8:00 AM-11:00 AM

The impact of census-tract socioeconomic status on survival in stage III colon cancer. *First Author: Amina Dhahri, University of Maryland Capital Regional Health, Cheverly, MD*

Background: Socioeconomic status (SES) has been associated with worse outcomes in stage III colon cancer. However, these studies have used large geographic areas (zip codes or counties) as a proxy for SES which may bias results. To overcome this challenge, we used a national database with census-tract level SES to assess the impact on cancer-specific (CSS) and overall survival (OS). **Methods:** Using the SEER Census-Tract Dataset from 2004-2015, we identified 8th edition AJCC stage III colon adenocarcinoma patients who underwent curative-intent surgery and initiated adjuvant chemotherapy. The predictor variable was census-tract level SES, consisting of 7 variables such as income, housing, and education. SES was analyzed as quartiles. Statistical analysis included chi square tests for association and Kaplan-Meier and Cox regression for survival analysis. **Results:** We identified 27,222 patients who met inclusion criteria. Lower SES was associated with younger age, Black or Hispanic race/ethnicity, Medicaid or uninsured status, higher T stage, <12 lymph nodes examined and lower grade tumors. Median CSS was not reached; the 25th percentile CSS time was 54 months for the lowest SES (LSES) quartile and 80 months for the highest (HSES). Median OS was 113 months for LSES and not reached for HSES. The 5-year CSS rate was 72.4% for the LSES quartile compared to 78.9% in the HSES ($p<0.001$). The 5-year OS rate was 66.5% for LSES and 74.6% in the HSES ($p<0.001$). After adjusting for potential confounders (age, sex, race, insurance, pathologic T and N stage and grade), LSES was associated with increased cancer-specific death relative to the HSES (HR 1.22; 95% CI [1.114-1.327]) **Conclusions:** This is the first study to evaluate CSS and OS in a national cohort of stage III colon cancer patients using a granular, standardized measure of SES. Despite receipt of guideline-based treatment, low SES remained a predictor of increased cancer-specific mortality. These data suggest that investigating treatment barriers beyond adjuvant therapy is needed to address colon cancer survival disparities. Research Sponsor: None.

Relative hazard of death: multivariable cox proportional regression for cancer-specific survival for stage III colon cancer

	Hazard Ratio	95% Confidence Interval		p-value
Highest SES (80th Percentile)	1.000	-	-	-
Higher SES (60th percentile)	1.178	1.087	1.277	<0.001
Middle SES (40th Percentile)	1.170	1.079	1.269	<0.001
Lower SES (20th Percentile)	1.181	1.088	1.283	<0.001
Lowest SES (0th Percentile)	1.212	1.111	1.322	<0.001

7033 Poster Session (Board #305), Fri, 8:00 AM-11:00 AM

A randomized controlled trial of a self-administered, online decision-aid ("Navya Patient Preference Tool") to reduce decisional conflict in women with early breast cancer. *First Author: Shalaka P Joshi, Tata Memorial Centre, Mumbai, India*

Background: Shared decision making to confront choices with clinical equipoise, has been the privilege of those patients with access to time intensive consults with oncologists. We conducted a randomized controlled trial for breast cancer patients to use an online, self-administered, out-of-the-medical-encounter decision aid (DA) to choose between breast conserving surgery (BCS) and mastectomy. **Methods:** Navya Patient Preference Tool (Navya PPT) is a multilingual DA based on adaptive conjoint analysis of tradeoffs between cost, adverse effects of radiation, and breast conservation. Prior analysis established high internal reliability and external validity of the Navya PPT. Eligible cT1/2, cN0 breast cancer patients planned for surgery were block randomized, in 1:1:1 ratio, to receive the research questionnaire (RQ) to measure decisional conflict on choice of surgery (control, arm 1), Navya PPT followed by RQ (experimental, arm 2) or Navya PPT followed by RQ administered with key male family member (experimental, arm 3). Groups were stratified with respect to age, socio-economic status (SES) and educational level. The study was powered to detect a decrease in Decisional Conflict Index (DCI) by 0.25 (β-0.8, two sided α- 0.01). **Results:** Between June 2017 and December 2019, 247/255 patients were randomized to arm 1 (83), arm 2 (84), and arm 3 (80). Median age was 48 years (IQR 23-76), and median pT size was .5 cm (0.5-6 cm). 59% of patients were middle or lower SES and 46.2% had $\leq$ 12th grade education. DCI was significantly reduced in arm 2 as compared with arm 1 (1.34 vs. 1.65, Cohen's d 0.49 ($\pm$ 0.31) $p<0.05$) as well as in arm 3 as compared with arm 1 (1.30 vs. 1.65, Cohen's d 0.54 ($\pm$ 0.31) $p<0.05$). 80% ($\pm$ 6%) of patients underwent surgery of choice as determined by Navya PPT. BCS rate was similar in all three arms (85.2, 88.9 and 86.5% respectively (p=0.779). **Conclusions:** Online, self-administered, adaptive DAs used out of the medical encounter can reduce decisional conflict and increase access to shared decision making for every patient; especially in practices with low doctor to patient ratios. Clinical trial information: IEC/0116/1619/001. Research Sponsor: Intramural Institutional Funding.

7035 Poster Session (Board #307), Fri, 8:00 AM-11:00 AM

Impact of the affordable care act and early Medicaid expansion on head and neck cancer mortality in the United States. *First Author: Nosayaba Osazuwa-Peters, Saint Louis University School of Medicine, St. Louis, MO*

Background: Medicaid expansion has been associated with increased access to care and earlier stage at diagnosis among patients with head and neck cancer (HNC). However, it is unclear whether Medicaid expansion has impacted HNC mortality rates. We examined the associations between early Medicaid expansions (2010-2011) with mortality rates for HNC in the United States. **Methods:** Data were obtained from the Surveillance, Epidemiology, and End Results (SEER) program. SEER*Stat was utilized to obtain mortality rates for early expansion (CA, CT, DC, MN, NJ, and WA) and non-early expansion states (all others) in the year ranges as available in SEER: 2005-2007 (pre-expansion) and 2012-2016 (post-expansion). Deaths in 2008-2011 were excluded as a phase-in/washout period. Difference-in-differences analyses were utilized to compare mortality rates pre- and post-early expansion in early expansion vs. non-early expansion states. The parallel trends assumption was tested comparing changes in HNC mortality rates between early expansion and non-early expansion states from 2002-2004 to 2005-2007 and from 2005-2007 to 2008-2011. **Results:** There were 6882 and 35459 deaths due to HNC in early expansion and non-early expansion states, respectively. HNC mortality rates (deaths per 100,000) decreased from 2005-2007 to 2012-2016 in both early expansion (2.17 to 1.85, difference = -0.32, 95% CI = -0.42 to -0.22) and non-expansion states (2.59 to 2.43, difference = -0.16, 95% CI = -0.22 to -0.11). Relative to non-expansion states, there was a reduction of 0.16 deaths per 100,000 (95% CI = 0.05 to 0.27, p = 0.007) after early Medicaid expansion in expansion states. However, in parallel trends testing, there was no difference in the change in mortality rates between early expansion and non-expansion states from 2002-2011 ($p > 0.37$). **Conclusions:** In this quasi-experimental analysis, there was an association between early Medicaid expansion with decreased HNC mortality. Thus, Medicaid expansion might help decrease disparities associated with access to care among HNC survivors. As longer-term data emerges, additional follow-up will be necessary to understand the mechanisms that underlie the HNC mortality benefits seen in early Medicaid expansion. Research Sponsor: None.

7037 Poster Session (Board #309), Fri, 8:00 AM-11:00 AM

Feasibility of switching to S-1 after other fluoropyrimidine-related cardiotoxicity during chemotherapy for solid tumors. *First Author: Pia J. Osterlund, Tampere University and Central Hospital, Tampere, Finland*

Background: Fluoropyrimidines (FP) are the cornerstone of chemotherapy in many solid tumors and linked to cardiotoxicity (CarTx) in about 5% (Polk, Cancer Treat Rev 2013), often leading to FP discontinuation. CarTx may be less common with S-1 and successful switch from other FP has been reported (Kwakman, EJC 2017). **Methods:** This 6-country, 12-center, cohort study included patients with solid tumors (ICD10 C15-C21, C24-25, C50, C80) who experienced FP-related CarTx. Primary endpoint was recurrent (R) CarTx during S-1 therapy after switch from any other FP. **Results:** CarTx during capecitabine (n = 124), continuous (n = 13) or bolus 5-fluorouracil (n = 4) was reported for 141 patients who switched to S-1 therapy. CarTx was chest pain including vasospasm without cardiac findings (55%), acute coronary syndrome or myocardial infarction (32%), atrial fibrillation (4%), heart failure/cardiomyopathy (4%), tachy-/bradycardia (3%), and/or other (15%). CarTx was grade 3-4 in 55%, appeared on cycle 1-2 in 89%, and at median 4 days (range 0-466) from FP initiation (Table). Causality was judged related in 26%, probable in 60%, and possible in 14%. Action with FP causing CarTx was permanent discontinuation in 91%. Treatment intent was curative in 70%. Cumulative incidence of RCarTx with S-1 was 3.5% ($CI_{95\%}$, 1.2-8.4%) and median time to R-CarTx was 11 (range 6-195) days. Four (out of 141) had grade 1 and one grade 2 R-CarTx. Three were judged possibly related to S-1 and 2 not related. S-1 was discontinued in one patient and continued in 4 (for 63-252 days) without action (n = 2), with dose reduction (n = 1), or delay (n = 1). There were no differences in demographic or risk factors regarding R-CarTx on S-1 (Table). **Conclusions:** FP-related CarTx is often severe, occurs early, and leads to permanent FP discontinuation. Switching to S-1-based therapy is safe, with, at the most, grade 1-2 R-CarTx in only 3.5%, and rarely leads to treatment discontinuation (0.7%), allowing patients to continue on an FP-based regimen. Clinical trial information: NCT04260269. Research Sponsor: None.

7038 Poster Session (Board #310), Fri, 8:00 AM-11:00 AM

Patient-reported health literacy and numeracy among new patients seeking consultation at a comprehensive cancer center. *First Author: Nadine Jackson McCleary, Dana-Farber Cancer Institute, Boston, MA*

Background: Health literacy and numeracy are essential for patients to make informed cancer treatment decisions. Oncologists do not typically evaluate literacy and numeracy and vary in their ability to adapt health discussions to meet patients' needs. Systematic ascertainment of literacy and numeracy may provide oncologists with useful information to help guide initial oncology consultations. **Methods:** We deploy an electronic new patient intake questionnaire (NPIQ) that includes health literacy and numeracy, basic demographics and cancer risk screening. Patients are considered to have limited health literacy and/or numeracy if they respond with either "somewhat", "a little bit" or "not at all" to a single question: "How confident are you filling out medical forms?" or "How confident are you in understanding medical statistics?" respectively. **Results:** Between January 2018 and August 2019, 8418 (24.6%) of patients presenting for a new patient consultation responded to the NPIQ. Among respondents with non-missing data, limited health literacy was reported by 19.4% respondents with 13.9% reporting "not at all" and 33.1% reporting "not at all" or only "a little bit" of confidence completing medical forms. Limited health numeracy was reported by 33.2% respondents with 9.1% reporting "not at all". Nearly 20% of respondents reported both limited health literacy and numeracy. Patients reporting lack of confidence completing medical forms or understanding medical statistics were older (20.3%, 30.7% ³ 70 years old), male (20.2%, 30.1%), and non-white (21.3%, 32.1%). **Conclusions:** A substantial proportion of cancer patients report lack of confidence in their ability to complete medical forms or understand medical statistics, potentially limiting the ability to actively engage in shared decision-making. Prospective identification of these social determinants of health prior to consultations may provide oncologists with information necessary to tailor health discussions and to provide materials that promote understanding and informed decision-making. Research Sponsor: None.

Association of medical comorbidities and cardiovascular disease with toxicity and survival in patients receiving checkpoint inhibitor immunotherapy. *First Author: Andrew Johns, Dept. of Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Checkpoint inhibitor immunotherapy (IO) is widely used to treat advanced cancer in pts. with medical comorbidities (MC), but the effect of MC on outcomes is poorly understood. **Methods:** We performed a single institution retrospective cohort study of pts. who received IO from 2011-2018. Immune-related adverse events (irAEs) were graded by Common Terminology for Adverse Events criteria, v4.0. MC were abstracted by query of ICD-10 codes corresponding to diagnoses in the Charlson Comorbidity Index (CCI) at any time prior to IO start. Modified CCI scores excluding points for cancer were calculated for each pt. Bivariate analysis with chi-squared statistics was used to describe characteristics and MC of pts. with vs. without irAEs. Overall survival (OS) was estimated by the Kaplan-Meier method (from start of first-line IO) and compared using the log-rank test. The association of CCI score and individual MC with irAEs and OS was tested with regression models adjusted for pt. characteristics. **Results:** Among 671 pts. with advanced cancer (39.6% melanoma; 21.8% non-small cell lung) treated with IO, median age 65 (IQR 55-74) years, the most common MC were COPD (24%) and diabetes (20%). 33.8% of pts. had CCI score ≥2. Neither CCI score nor any specific MC were associated with any grade or ≥G3 irAEs ($P > 0.05$). Increasing CCI score was significantly associated with decreased OS ($P = 0.002$). CHF (13.9 vs. 8.1 months, $P = 0.008$) and previous MI (14.2 vs. 10.1 months, $P = 0.009$) were associated with decreased median OS but did not remain significant in the regression model. Among pts. without cardiovascular disease (CVD), pts. with ≥G3 irAEs had longer OS than pts. with no ≥G3 irAEs ($P < 0.001$). This OS benefit for ≥G3 irAEs was not seen in pts. with CVD ($P = 0.94$). See table for adjusted HR. **Conclusions:** Risk for irAEs does not appear to be impacted by MC. Pts. with MC have shorter OS, but no specific MC are associated with OS after adjustment for pt. characteristics. OS is significantly increased among pts. without CVD who experience ≥G3 irAEs. CVD may be an important predictor of OS in pts. with irAEs and should be evaluated in patients receiving IO. Research Sponsor: REDCap project and The Ohio State University Center for Clinical and Translational Science grant support (National Center for Advancing Translational Sciences, Grant UL1TR002733); OSU K12 Training Grant for Clinical Faculty Investigators #5K12 CA133250-09.

7040 Poster Session (Board #312), Fri, 8:00 AM-11:00 AM

Morbidity, mortality and healthcare use among siblings of children with cancer: A population-based study. *First Author: Aditi Desai, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Siblings of children with cancer are at increased risk of adverse mental health outcomes; impact of the childhood cancer experience on these siblings' physical health is unclear. We characterized the long-term risk of adverse physical health outcomes and healthcare use among siblings of children with cancer. **Methods:** Pediatric cancer patients in Ontario diagnosed between 1988 and 2016 were linked to their biological siblings to form the siblings/case cohort. Cases were matched to population controls based on sex, age, and residence area. Index date for cases was the date of their brother's or sister's cancer diagnosis (controls had the same index date as cases). After individual linkage to health services data, we compared several outcomes between these two groups: 1) physical health conditions (e.g. cancer, hypertension, injuries, death); 2) acute healthcare use (hospitalization, emergency department [ED] visits), and; 3) preventative healthcare use (periodic health checkups, influenza vaccinations). Predictors of outcomes, including demographics and characteristics of the cancer-affected child, were examined in cases. Cox proportional hazards, recurrent event, or logistic regression models were used as appropriate. **Results:** We identified 8,529 cases and 30,364 matched controls [median age at index: 6 years, interquartile range (IQR) 0-10; median follow-up time: 9 years, IQR 5-15]. Compared to controls, cases had increased risk of hypertension [hazard ratio (HR) 1.8; 95% confidence interval (95CI) 1.1-2.9; $p = 0.01$]. They also had higher rates of ED visits [rate ratio 1.1; 95CI 1.1-1.2; $p < 0.001$] and increased risk of hospitalization [HR 1.1; 95CI 1.1-1.2; $p < 0.001$]. Cases were more likely to undergo periodic health checkups [odds ratio (OR) 1.1; 95CI 1.0-1.1; $p = 0.01$] and influenza vaccinations [OR 1.5; 95CI 1.4-1.6; $p < 0.001$]. In multivariable analysis restricted to cases, rurality and bereavement, among other predictors, were associated with increased use of acute healthcare. **Conclusions:** Increased risk of hypertension and hospitalization in cases suggests that these siblings are experiencing poorer physical health compared to their peers. Increased rates of ED visits and preventive healthcare suggests parental anxiety surrounding these siblings' health. Siblings at highest risk of adverse outcomes could be identified through demographic characteristics, among others. Siblings would benefit from targeted surveillance and further investigation to elucidate underlying mechanisms influencing their health. Research Sponsor: Canadian Institutes of Health Research.

Breast cancer patients' insurance status correlates with their adherence to endocrine therapy: Analysis of ECOG-ACRIN TAILORx trial. *First Author: Gelareh Sadigh, Emory University, School of Medicine, Atlanta, GA*

Background: Cancer patients spend substantial amounts on their healthcare services, and are at high risk for financial toxicity, a patient-reported outcome shown to be associated with care non-adherence. Even with insurance, cancer patients often face unpredictable or unmanageable costs. In women with breast cancer enrolled in TAILORx trial, we investigated the association between study entry insurance status and adherence to endocrine therapy (ET). **Methods:** Women with hormone-receptor–positive, human epidermal growth factor receptor 2–negative, axillary node–negative breast cancer enrolled in TAILORx clinical trial who started ET within a year of study entry were included. Early discontinuation was defined as stopping ET within 4 years of start for reasons other than distant recurrence or death, and the rate was calculated using Kaplan-Meier estimates. Cox proportional hazards model was used to analyze association between the patients' insurance status at study entry and early discontinuation of ET incorporating patients' treatment, age, race and Recurrence Score in the model. **Results:** A total of 9,475 patients were included (mean age: 55.6; 84% white; 9% Hispanic). A total of 58.0% had private insurance, while 11.7% had Medicare; 5.8% had Medicaid; 0.98% had military/VA insurance; 3.8% were self-pay, and 19.1% were patient recruited from international sites. The rates of 4-year early discontinuation were highest among self-pay (18.7%) and Medicaid patients (18%) and lowest among patients with military/VA insurance (8.6%) and international sites (9.8%). In multivariable analysis, compared to private insurance patients with Medicaid (HR 1.6; 95% CI 1.3-2.0) and self-pay (HR 1.6; 95% CI 1.3-2.1) had higher probability of discontinuing ET within 4 years of start and those at international sites had lower probability of early discontinuation (HR 0.8; 95% CI 0.7-0.9) (All p values < 0.05). **Conclusions:** Patients' insurance status plays an important role in adherence to ET with uninsured and underinsured having a high rate of treatment non-adherence. Early identification of patients at risk and enrollment in insurance optimization programs may improve adherence to therapy. Clinical trial information: NCT00310180. National estimates of substance use, substance use disorders, and treatment among adolescent and young adult cancer survivors. *First Author: Xu Ji, Department of Pediatrics, Emory University and Aflac Cancer and Blood Disorders Center of Children's Healthcare of Atlanta, Atlanta, GA*

Background: Adolescent and young adult (AYA) survivors of cancer are at an elevated risk of early-life morbidity and mortality due to the disease trajectory and treatment. Engagement in risk behaviors, including substance use, can exacerbate survivors' vulnerabilities and place them at further risk for adverse health outcomes. This study provides national estimates of the prevalence of substance use and misuse, substance abuse or dependence (i.e., substance use disorders [SUD]), and receipt of treatment for SUD among AYA cancer survivors. **Methods:** We used 2015-2018 National Survey of Drug Use and Health data to identify a nationally-representative AYA sample (aged 12-34 years). Outcomes included past-year alcohol use, marijuana use, other illicit drug use, misuse of any prescription psychotherapeutic drugs (including opioid analgesics, stimulants, sedatives, or tranquilizers), and misuse of prescription opioid analgesics. Outcomes also assessed past-year SUD in aforementioned drug classes. Among those with SUD, we evaluated past-year receipt of SUD treatment. Multiple logistic regressions were estimated to compare outcomes between 846 AYAs who reported a cancer history and 142,870 AYAs who did not, adjusting for sociodemographic and need-related characteristics. **Results:** In bivariate analyses, AYAs with a cancer history were *more* likely than noncancer peers to use alcohol (78.6% vs. 63.4%; $p< 0.001$) and illicit drugs other than marijuana (11.2% vs. 7.8%; $p= 0.02$), misuse any prescription psychotherapeutic drugs (16.9% vs. 10.6%; $p< 0.001$) and prescription opioid analgesics (12.0% vs. 5.9%; $p< 0.001$), and have an illicit drug (other than marijuana) SUD (3.7% vs. 1.3%; $p< 0.01$) in the past year. In regression analyses, differences in past-year misuse of any prescription psychotherapeutic drug and prescription opioid analgesics persisted ($p= 0.02$, $p< 0.01$, respectively). Among AYAs with SUD, those with a cancer history were *more* likely than noncancer peers to receive SUD treatment (21.0% vs. 8.1%; $p= 0.01$) in the past year; this difference persisted in regression analyses ($p= 0.03$). **Conclusions:** AYAs with a cancer history had an elevated risk for misusing prescription psychotherapeutic medications, which was driven by misuse of prescription opioids; yet, only one in five AYAs with a cancer history and SUD received treatment. Our findings underscore the need for future interventions designed to reduce substance use and misuse and improve access to SUD treatment in AYA cancer survivors. Research Sponsor: None.

Concurrent and sequential chemoradiation therapy are associated with improved survival among unresected stage III non-small cell lung cancer patients in the United States. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: Concurrent chemoradiation therapy (cCRT) has been shown to improve survival outcomes among inoperable stage III non-small cell lung cancer (NSCLC) patients compared to sequential CRT (sCRT) and single-modality therapy in clinical trials. However, many "real world" patients do not receive CRT, and less is known about the survival benefits of concurrent CRT vs other treatment modalities in pragmatic, non-clinical trial settings. **Methods:** We used the National Cancer Database (2004-2011) to identify unresected stage III NSCLC patients (ages 18-79 years) with Charlson comorbidity score ≤ 1 and 5-year follow up through the end of 2016. cCRT was defined as the initiations of chemotherapy (CT) and radiation therapy (RT) that were ≤ 14 days (n = 30,290) apart, whereas sCRT was defined as $>$ 14 days apart (total n = 10,596). The remaining three treatment groups included CT only (n = 11,216), RT only (n = 7,772), and neither CT/RT during first course treatment (n = 10,694). Cox proportional hazard model was used to examine the 5-year survival by treatment modalities, controlling for patient demographics, comorbidity score, health insurance, facility type, area-level social deprivation index (SDI, a composite measure for area-level socio-economic status), driving time to the treatment facility, diagnosis year, and region. Adjusted hazard ratios (HR), and medium survivals were generated by treatment modalities. **Results:** Among 70,568 unresected stage III NSCLC patients, 61,487 (87.1%) patients died within the 5-year follow-up period. In adjusted analyses, cCRT and sCRT had similar survival (median survivals: 15.3 months), whereas other treatment modalities were associated with worse survival compared to cCRT: CT only (median survival: 10.8 months; HR [95%CI]: 1.46 [1.43-1.50]), RT only (median survival: 6.7 months; HR [95%CI]: 1.93[1.88-1.99]), and no treatment (median survival: 3.2 months; HR [95%CI]: 2.64 [2.58-2.71]), all $p < 0.001$. Higher comorbidity score (Charlson score 1 vs 0, HR [95%CI]: 1.18 [1.16-1.21]), non-private insurance (Medicaid: 1.16 [1.12-1.20]; Medicare: 1.10 [1.08-1.13]; uninsured: 1.21 [1.16-1.26]) were all associated with worse survival (all $p < 0.001$). **Conclusions:** Concurrent CRT and sequential CRT have similar survival outcomes among unresected stage III NSCLC patients with minimum comorbidities, however, single modality and no therapy are associated with much poorer survival among "real world" patients, and should be avoided unless clinically appropriate. Research Sponsor: AstraZeneca.

7044 Poster Session (Board #316), Fri, 8:00 AM-11:00 AM

Nurse, oncologist, and patient impressions of electronic symptom monitoring via patient-reported outcomes in community oncology practices: Qualitative results from the U.S. national PRO-TECT trial (AFT-39, NCT03249090). *First Author: Ethan M. Basch, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: There is growing interest to implement electronic patient-reported outcomes in oncology practices for symptom monitoring. It is not well known what nurse, physician, and patient impressions of benefits, acceptability, and challenges are in routine care use. **Methods:** PRO-TECT is an ongoing U.S. national trial including 26 community oncology practices across 15 states that implemented PRO symptom monitoring [NCT03249090]. Patients complete weekly PROs between visits, nurses receive alerts for severe/worsening symptoms, and oncologists review PROs at office visits. Interviews were conducted with 147 stakeholders including nurses (N = 46), oncologists (N = 27), data managers (N = 15), and patients (N = 59). Each stakeholder group had different interview guides with overlapping topics to explore experiences with the PRO system. Interviews lasted 15-60 minutes, were digitally recorded, transcribed, and entered into a qualitative analysis software program. A codebook was developed from the research questions, interview guides, and discussions with the project team. Standardized coding methods were applied, with transcripts double coded for thematic analysis. Feedback surveys were also completed by nurses (N = 57), oncologists (N = 38), and patients (N = 435). **Results:** Key benefits perceived across stakeholder groups included increased patient self-awareness of symptoms; improved direct communication of patients with care teams; more open and honest conveying of symptom experiences; ability to track symptoms over time; and increased involvement of patients in their own care. Most stakeholders felt PRO symptom monitoring had a positive impact on quality of care delivery, and believed benefits of PROs outweighed necessary staff efforts. Challenges included additional work by nurses to review and respond to alerts, staff turnover requiring retraining, and limited time of oncologists. In the survey, 39/56 (70%) nurses felt the PRO system improved quality of care; 27/33 (82%) oncologists noted PROs were useful for team discussions and care delivery; and 320/434 (74%) patients agreed that weekly PRO reporting improved discussions with their care team. **Conclusions:** Clinicians and patients perceived weekly PRO symptom monitoring between visits to be valuable despite added staff effort. Results of additional analyses are forthcoming. Clinical trial information: NCT03249090. Research Sponsor: Patient-Centered Outcomes Research Institute.

7046 Poster Session (Board #318), Fri, 8:00 AM-11:00 AM

Neoadjuvant treatment with chemotherapy or chemoradiation in stage III non-small cell lung cancer: Analysis of the National Cancer Database. *First Author: Sindhu Janarthanam Malapati, Van Elslander Cancer Center-Ascension St John Hospital, Detroit, MI*

Background: Use of neoadjuvant chemotherapy (Neo-chemo) improves survival in locally advanced NSCLC. However, data regarding the benefit of adding radiation (Neo-CRT) is limited. Meta-analyses suggest that the use of Neo-CRT could lead to significant tumor downstaging but with increase in therapy-related mortality. **Methods:** Patients with resected stage III NSCLC were identified from the NCDB between 2010 and 2015. Patients were divided into two groups based on the type of neoadjuvant therapy received (Neo-chemo vs. Neo-CRT). Surgical and survival outcomes were compared. Kaplan-Meier method and log-rank test were used for survival analysis. **Results:** Of the 136,942 patients with stage III NSCLC, 15,804 patients had definitive surgery. Mean age was higher for those who received Neo-chemo (63.8 vs. 61.8 years, $p<0.0001$). Median overall survival (OS) for Neo-CRT was 49.8 months and for Neo-chemo was 53.6 months. After adjusting for treatment facility, age, gender, race, comorbidity index, insurance status, T and N stage, there was a 12% reduction in mortality with use of Neo-chemo compared to Neo-CRT (p=0.03, 95% confidence interval 0.78-0.98). 3 years OS for Neo-CRT and Neo-chemo was 51.1 and 54.3%, respectively. The 30-day operative mortality rate was slightly higher in the Neo-chemo group (4.6 vs. 3.2%, p=0.004) but 90-day mortality rates were similar (7.41% vs. 6.83%, p=0.37). Length of hospital stay for primary tumor resection was shorter for the Neo-chemo group (5 vs. 6 days, $p<0.0001$); however, there was no significant difference in 30-day readmission rates between the two groups (91.53% vs. 94.01%, p=0.09). **Conclusions:** In this study, neoadjuvant chemotherapy resulted in 12% lower mortality compared to neoadjuvant chemoradiation despite the notable increase in the rate of complete pathologic tumor and nodal response achieved with the addition of neoadjuvant radiation. There was no difference in R0 resection rates, postoperative mortality or readmissions between the two groups. Research Sponsor: None.

	Neo-CRT (%) N=3,022	Neo-chemo N=1,069	HR for death (Neo-chemo compared to Neo-CRT)	p-value for HR

7047 Poster Session (Board #319), Fri, 8:00 AM-11:00 AM

Inclusion of economic outcomes in NCI grants: A portfolio analysis. *First Author: Michael T. Halpern, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: While new interventions have improved cancer screening, treatment, and survivorship, the costs and other economic impacts of interventions may affect their uptake and availability. It is unknown what proportion of recently-funded National Cancer Institute (NCI) grants include economic outcomes. **Methods:** We used the NIH Query/View/Report (QVR) System to determine the number of competitive grants funded by NCI 2015-2020 that included economic outcomes. Grants were identified using the NIH Research, Condition, and Disease Categorization (RCDC) category "Cost Effectiveness Research"; 19 RCDC terms/concepts related to economic analyses; and 18 economic phrases searched for in grant titles, abstracts, and specific aims. The specific aims and abstracts of all grants meeting any of these search criteria were reviewed by an NCI scientist to ensure the presence of economic study outcomes. **Results:** Among over 13,700 competitive grants awarded by NCI 2015-2020, the search identified 149 grants; following abstract/specific aims review, 102 of these grants (0.74% of all grants) included an economic outcome. Most (69 of 102, 67.6%) included cost-effectiveness analysis; 24 included other cost analyses, 7 assessed financial hardship or similar outcomes, and 2 focused on developing economic methods. Among RCDC terms, more than half (53) listed modeling (9 listing Cancer Intervention and Surveillance Modeling Network), 24 randomized controlled trials, 15 QALYs, 11 implementation science, 3 willingness to pay. The most common cancer sites listed were breast (28), lung (23), cervical (19), and colorectal (17) cancer. Almost half (48) mentioned screening and 24 cancer prevention. Risk factors listed included 28 for smoking, 18 HPV, 8 HIV, 8 physical activity, 6 obesity, 4 nutrition. Ten listed treatment efficacy, 6 chemotherapy, 4 radiation therapy, 3 hormone therapy, and 1 chemo-radiation. "Treatment as usual" was listed by 16, symptom management 4, and telehealth 4. Survivors were listed for 15, caregivers 3, health disparity 18, rural 15, young adult 4. The majority of grant mechanisms were R01 (76, 74.5%); 3 were R21/R03, 4 other R mechanisms, 7 K awards, 6 U grants, 6 P, F, or L grants. **Conclusions:** While this search may not have identified all funded NCI grants over the past 5 years involving economic analyses, we found that less than 1% included economic outcomes. Recommendations to assist NCI in supporting health economics research focused on cancer across the entire care spectrum should be considered. Research Sponsor: None.

7048 Poster Session (Board #320), Fri, 8:00 AM-11:00 AM

Long-term financial outcomes and quality of life in partners of colorectal cancer survivors. *First Author: Christine M Veenstra, University of Michigan, Ann Arbor, MI*

Background: Many patients with colorectal cancer face financial toxicity, but little is known about financial outcomes among their partners. Moreover, virtually nothing is known about associations between partners' quality of life and their financial outcomes. **Methods:** In 2019 we surveyed patients who, in 2014-18, underwent resection of Stage III colorectal cancer and were seen at a community oncology practice, an academic cancer center, or reported to Georgia SEER (current RR 46%). Patients gave a separate survey to their partner. 254 partners (68% RR) completed surveys. Partners were asked about financial impacts of the patient's cancer. Partners' quality of life (QOL) was measured with the PROMIS global health scale. Multivariable regression analyses of 3 partner-reported outcomes (1. Perception that their financial status is worse off, 2. Substantial worry about finances, 3. Debt related to patients' cancer) were generated to assess associations between each outcome and key partner and patient variables, and associations between partners' QOL and financial outcomes. **Results:** Among partners, 55% were $<$ age 65, 64% female, 86% white, and 27% had $<$ high school education. 61% were employed at time of patient's diagnosis; 38% of those missed 7-30 days work and 13% missed $>$ 1 month work due to the patient's cancer. 66% patients were employed at diagnosis. Among those, 34% were no longer working at the time of survey. In 14% dyads only the patient was working at diagnosis and among those, 50% were no longer working at the time of survey. 32% partners reported their financial status is worse off, 36% reported substantial worry about finances, and 28% reported current debt, all due to the patient's cancer. After adjustment for partner and patient variables, partners of patients further out from diagnosis and partners of patients who were working at diagnosis were more likely to report substantial worry. Partners $<$ age 50, with $<$high school education, with $>$1 comorbid condition, and partners of patients who were working at diagnosis were more likely to report debt (all $p < 0.05$). Endorsing each of the 3 financial outcomes was associated with lower QOL among partners, after adjustment for partner and patient variables (all $p < 0.01$). **Conclusions:** Nearly 1/3 of partners of survivors of colorectal cancer reported long-term adverse financial outcomes due to the patient's cancer. Partners of patients working at the time of diagnosis were more likely to report substantial worry and debt, perhaps because many patients who were working at diagnosis are no longer working in the survivorship period. 7049 Poster Session (Board #321), Fri, 8:00 AM-11:00 AM

Comparative effectiveness of proton versus photon chemoradiotherapy for patients with private insurance. *First Author: Brian Christopher Baumann, Washington University in St. Louis, St. Louis, MO*

Background: Proton therapy may increase the tolerability/efficacy of concurrent chemoradiotherapy (CRT) but is controversial & generally not covered by private insurers. There is little data on the comparative effectiveness (CE) of proton vs photon CRT among private insurance pts to guide payers on proton coverage policies. **Methods:** We conducted a CE study of adult non-metastatic cancer pts with private insurance treated with curative-intent proton vs photon CRT from 2011-2016 at Penn. The choice of radiation modality was heavily influenced by the insurer's proton coverage policy. Data on adverse events (AEs) & survival were gathered prospectively using standardized templates. Primary endpoint was 90-day AEs associated with unplanned hospitalizations (CTCAEv4 grade $\geq$3 AEs). Secondary endpoints included 90-day grade $\geq$2 AEs, decline in ECOG performance status (PS) during treatment, disease-free survival (DFS) & overall survival (OS). Modified Poisson regression models with inverse propensity score weighting were used for adverse event outcomes. Weighted Cox proportional hazards models were used for survival outcomes. Propensity scores were estimated using an ensemble machine-learning approach. $P<0.01$ was significant. **Results:** 920 pts were included (178 proton/742 photon), with H&N(25 proton/296 photon); CNS(44/128); lung(41/120); upper GI(34/78) & lower GI/GYN(34/120). Median age was 57. Race, comorbidity score, BMI, baseline AEs & baseline PS were similar ($p>0.05$ for all). 11.2% of proton pts had grade $\geq$3 AE's vs 26.8% of photon pts. On propensity score weighted-analyses, proton CRT was associated with significantly lower relative risk (RR) of 90-day grade $\geq$3 AEs (RR 0.51, 95%CI 0.32-0.81, $p<0.01$). 90-day grade $\geq$2 AE's (RR 0.91, 95%CI 0.83-0.99, p=0.03); decline in PS (RR 0.85, 95%CI 0.70-1.04, p=0.11); DFS (HR 0.64, 95%CI 0.27-1.52, p=0.31) & OS (HR 0.53, 95%CI 0.18-1.52, p=0.24) favored protons. Sensitivity analysis showed that a substantial imbalance in an unmeasured confounder would be needed to alter the significance of the primary outcome. Proton accepting insurance status was not associated with a difference in 90-day grade $\geq$3 AE's (RR 1.02, 95%CI 0.95-1.10, p=0.54) for pts treated with photon CRT (608 with non-proton accepting insurance & 134 with proton-accepting insurance). **Conclusions:** In adults with private insurance, proton CRT was associated with significantly reduced acute grade $\geq$3 AE's with similar DFS & OS. Proton-accepting insurance status was not associated with better health outcomes when adjusting for RT modality. Research Sponsor: None.

7050 Poster Session (Board #322), Fri, 8:00 AM-11:00 AM

Prior authorization process improvement for pain medications in an oncology unit: Timely initiation of test claim request form. *First Author: Susy Varghese, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Oncology patients with extensive metastatic disease and advanced-stage cancer frequently require controlled medications for pain managements. Insurers require Prior Authorization (PA) for high-cost specialty medications including: Hydromorphone, Oxycodone, Oxymorphone, Fentanyl, Nucynta, Lyrica and Lidocaine patch. Failure to obtain PA may delay patient hospital discharge and attainment of discharge medications, increase patient medication costs, increase hospital readmissions and emergency visits, and exacerbate clinical complications. In order to avoid delays, providers must submit a Claim Request (CR) to initiate the PA process. PA usually takes 48-72 hours after the CR is submitted; therefore, timely CR submission in anticipation of discharge is imperative. Baseline rates for initiating CR in a timely manner was 15%. A quality improvement project was conducted to increase provider-initiated CRs for prescribed pain medications requiring PA and to demonstrate a sustainable process, anchored by development of new policy. **Methods:** The project revised the provider-initiated CR process by implementing the following interventions: The Electronic Medical Record (EHR) was modified to create a 'quick link' to facilitate CR form submissions. The link was made available to providers via their dashboard for easy access to the CR form.The medication reconciliation process was revised to require nurses to send reminders to providers for any of the seven discharge medications requiring CR submission for PA. A new component was incorporated into the discharge planning process by discussing PA and CR during interdisciplinary rounds. Providers and nurses were educated about the revised process. **Results:** Rates for timely CR submission were collected from the EHR biweekly for 3 months post-intervention. Post-intervention, 77% of timely CR claims increased from baseline of 15% to 87%. Due to the timely initiation of CR, some medications were deemed not to require PA, and the percentage of PA requirement reduced from 95% to 55%. In addition, up to 16% of patients had money refunded as a result of timely CR submission. **Conclusions:** The new process was effective for ensuring an efficient and effective process for patients who require high-cost controlled medications for pain management, reducing waste and providing a quality experience for the patient. As a result of the project, the new process has become policy and is now being used on other units in the institution for additional medications that requires CR and PA. Research Sponsor: None.

7051 Poster Session (Board #323), Fri, 8:00 AM-11:00 AM

Rates of adherence to bone health guidelines for women with breast cancer treated with anti-estrogen therapy. *First Author: Leighton Andrew Elliott, Geisinger Medical Center, Danville, PA*

Background: Long-term use of aromatase inhibitor (AI) therapy has been shown to decrease bone mineral density (BMD) and is associated with at least twice the fracture risk when compared to an age-matched healthy population. AI's are a common treatment in hormone receptor-positive breast cancer for post-menopausal women. Similarly, tamoxifen has been shown to decrease BMD in premenopausal women. As a result, the National Comprehensive Cancer Network (NCCN) recommends BMD screening for women being treated with anti-estrogen therapy (AET), typically via Dual-energy X-ray absorptiometry (DEXA) scan. Previous studies have shown poor adherence to BMD screening with AI therapy, but no known study has evaluated compliance with tamoxifen therapy. **Methods:** We evaluated a retrospective cohort (December 2015 – July 2019) of all women with a breast cancer diagnosis initiating AET using data from the electronic health records of patients throughout a rural integrated health system. We assessed non-adherence to baseline and annual BMD screening using descriptive statistics along with preliminary data regarding fractures associated with AET therapy. **Results:** A total of 3,693 health records of women with a breast cancer diagnosis and documented prescription for AET were evaluated. In the year before AET initiation, 16% of women received BMD screening. Overall, 1,189 women treated with AET had a DEXA scan ordered at any point after drug initiation: 37% for AI's and 12% for tamoxifen. Of those treated with AI, 84% had no DEXA ordered within 12 months of starting drug after a minimum of 9 months of continuous use; this value was 96% for tamoxifen use. Patients complied with the ordered DEXA scan within the first year 81% of the time. Repeat DEXA scans were ordered 34% of the time, and patient compliance decreased to 55%. There was no significant difference in the number of patient comorbidities between patients who did and did not have a DEXA scan ordered. After starting an AI, 131 fractures were documented; 44% occurred within the first year following starting drug treatment with an average of 5 months from drug start to diagnosis. **Conclusions:** A significant proportion of breast cancer patients treated with AET did not receive guideline-recommended BMD screening. These findings should raise awareness of the importance of BMD screening by responsible providers, including oncologists, primary care physicians, care managers and insurance companies in order to decrease avoidable morbidity. Research Sponsor: None.

7052 Poster Session (Board #324), Fri, 8:00 AM-11:00 AM

Factors associated with change in the magnitude of clinical benefit of anti-cancer drugs in the post-marketing period. *First Author: Aida Bujosa Rodríguez, Hospital de Sant Pau, Barcelona, Spain*

Background: Initial drug approval is often based on surrogate endpoints. Definitive outcomes like Overall Survival (OS) or Quality of life (QoL) may not be available. Here, we evaluate changes in the magnitude of clinical benefit using the American Society of Clinical Oncology Value Framework (ASCO-VF) and European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS) comparing the time of approval to the most recent available data for cancer drugs approved by the US Food and Drug Administration (FDA) between 2006 and 2015. **Methods:** We examined data on trials supporting FDA accelerated (AA) and regular (RA) cancer drug approvals between January 2006 and December 2015. We performed a systematic search of Pubmed and ClinicalTrials.gov to identify updated OS and/or QoL data, with follow up through April 2019. For AA drugs we analysed initial and confirmatory trials as follow-up. ASCO-VF and ESMO-MCBS grades were applied for trials at approval and after marketing. We explored variables associated with improved clinical benefit scores using multivariable logistic regression. **Results:** We identified 102 trials supporting the approval of 59 drugs for 96 solid tumour indications. Of these indications, 22 (23%) were granted AA and 21 (95%) were converted to RA. At time of approval, 38% of trials showed improved OS and 17% improved QoL. Substantial clinical benefit was observed in 26% of initial approval trials using ESMO-MCSB and in 34% using ASCO-VF. After a median post-marketing period of 3.3 years, updated results changed substantial clinical benefit in 20 trials with ESMO-MCBS (19 upgrades, 1 downgrade) and in 23 trials using ASCO-VF (19 upgrades, 4 downgrades). For 25% of trials no updated information was found. In the palliative setting, multivariable analysis showed association between improved ASCO-VF scores and initial approvals based on single-arm trials (OR 9.21, 95%CI 1.36-62.29, P=0.023), drugs with companion diagnostics (OR 4.95, 95%CI 1.01-24.22, *P*=0.049) and second or later lines (OR 7.80, 95%CI 1.35-45.02, *P*=0.022) while for ESMO-MCBS, drugs with companion diagnostics (OR 6.86, 95% CI 1.82-25.86, *P*=0.004) and immunotherapy drugs (OR 6.42, 95%CI 1.27-32.59, *P*=0.025) were associated with greater clinical benefit. **Conclusions:** Drugs with companion diagnostic tests, immunotherapy as well as approved based on single-arm trials were associated with increased clinical benefit after marketing approval. For a quarter of trials there were no updated data in the post-marketing period. Research Sponsor: None.

7053 Poster Session (Board #325), Fri, 8:00 AM-11:00 AM

Implementing routine patient-reported outcome collection in a large, academic health system. *First Author: Nishant Shah, University of Pennsylvania, Philadelphia, PA*

Background: Patients' symptoms and side effects have traditionally been assessed by clinicians. There is increasing evidence that patient self-reported symptom severity often differs from clinician assessment, and that collecting patient-reported outcomes (PRO) can improve communication, symptom management, and even survival. However, the implementation of routine PRO collection across a large healthcare system poses operational and informatics challenges. **Methods:** Using native electronic health record (EHR) functionality, we implemented a standardized PRO questionnaire across a large academic cancer center and associated community-based practices. The questionnaire is based on the Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE) developed by the National Cancer Institute. It assesses eleven common side effects of cancer care and is available for completion from home via the EHR patient portal or in clinic via tablet PC. Implementation was stepwise, beginning with a disease-specific patient population in the main academic cancer center and expanding over two years to include all cancer types, three specialties (radiation oncology, hematology/oncology, gynecologic oncology), and multiple satellite practice locations. **Results:** PRO collection was initiated for patients with gastrointestinal malignancies in two clinic locations at the main cancer center in 12/2017. During the first 3 months of implementation (12/2017-2/2018), questionnaires were completed for 1838 (56.3%) of 3267 eligible patient visits. Work with practice managers and staff to refine operational workflows led to improvement to a 75.6% capture rate for the period 3/2018 – 5/2018. From 6/2018 through 6/2019, the program was expanded to all multidisciplinary clinics in the main cancer center, as well as eight satellite practices. Aggregate capture rates from 7/2018 through 12/2019 have shown sustained performance, with 101,082 (76.7%) of 131,720 eligible visits captured. Of twelve total clinics participating, eleven have sustained capture rates above 70%, and nine capture over 80% of eligible visits. Questionnaires were completed through the online patient portal 12.1% of the time, with the remainder completed in clinic via tablet PC. **Conclusions:** Routine PRO collection as standard-of-care is possible across a variety of practice environments in a large, complex health system, with sustained capture of approximately three-fourths of eligible visits. Most patients prefer to complete the questionnaire in clinic. Research Sponsor: None.

7054 Poster Session (Board #326), Fri, 8:00 AM-11:00 AM

NSCLC: Integrating the "Yale model shared decision-making solution" into the practice setting. *First Author: Kerin B. Adelson, Yale University, New Haven, CT*

Background: Lung cancer patients are faced with treatment choices that involve complex decisions that can be preference-sensitive. In 2017 the National Quality Forum initiated a "Call to Action" to integrate shared decision-making (SDM) processes into practice in which clinicians and patients work together to make healthcare decisions that align with what matters most to patients. Projects In Knowledge, @Point of Care, Dartmouth and Yale collaborated to develop a pilot educational initiative to address and improve patient-centered care and SDM processes in the institutional cancer-care setting. **Methods:** Training materials co-developed for the Yale NSCLC team members (oncologists, nurses/NPs, social worker) address SDM, *Checkpoint Inhibitor Therapy in NSCLC,* and clinician-patient role play methods for implementing SDM in treatment discussions/decisions. Qualitative interview and observational methods were used to assess improved SDM performance by the multidisciplinary Yale NSCLC team by comparing baseline pre-intervention to post-intervention interviews and rating observed performance on case study role-play scenarios. Following the training and assessments, a focus group that included all team members was conducted to assess the acceptability, feasibility, and repeatability of the program and to inform future education. **Results:** Training empowered all Yale NSCLC team members to show pre- to post-education improvement in SDM (34% to 88%). Areas of greatest improvement: 1) providing reasonable treatment options to patients (+58%); 2) determining decision style preference – to what extent a patient wants to participate in the treatment decision process with their clinician (+76%); 3) determining patients' risk tolerance regarding treatments that may be more efficacious but may have more side effects (+77); and 4) determining patients' goals/preferences (+88%). **Conclusions:** Educational training improved SDM skills by all Yale NSCLC team members, which can lead to improved clinician-patient decision-making and patient-centric care. The training process also facilitated team building and encouraged ongoing participation in SDM. Research Sponsor: Genentech.

7055 Poster Session (Board #327), Fri, 8:00 AM-11:00 AM

Hyponatremia could be an important prognostic factor for oncology patients: Result of a retrospective study. *First Author: Prantik Das, Derby Teaching Hospitals NHS Trust, Derby, United Kingdom*

Background: Hyponatraemia is the most common electrolyte disorder encountered in clinical practice. Hyponatraemia in hospitalized people is associated with an increased morbidity, mortality and longer hospital stay compared with people with normal serum sodium concentrations. It is a negative prognostic indicator for survival in oncology patients. Incidence of hyponatremia in malignancy is largely underestimated. **Methods:** Retrospective analysis of patients admitted to oncology ward in our institution between August to September 2018 was conducted. Patients were identified from admission register and data were analysed from electronic medical records. Primary aim was to evaluate the incidence of hyponatraemia in oncology in-patients and impact on survival. Data were also analysed for patients demography, cancer types, grade of hyponatremia and treatment approach. **Results:** 119 patients were admitted to oncology ward during study period. Out of them 38% were identified to be Hyponatraemic and 51 % patients were male. Lung cancer was the predominant cancer type followed by breast, upper GI and ovarian respectively. Of hyponatraemic patients, 63% were asymptomatic, among symptomatic patients vomiting, confusion and headaches are common. According to severity, 42% patients had grade 1, 40% grade 2 and 18% grade 3 hyponatraemia respectively. When it comes to status of hydration, 62.2% were noted to be euvolaemic, 6.66% were hypervolaemic and 15.5% were hypovolaemic and the hydration status of the rest of 15.5% were not known. Considering mortality, 53% patients died within 30 days of diagnosis of hyponatremia compared to 17% deaths among non-hyponatraemic patients. Median survival of patients with grade 3, 2 and 1 hyponatremia were 29, 35 and 62 days respectively. Out of 45 patients 14 (31.1%) had acute onset hyponatraemia and they had considerably poorer survival compared to their chronic hyponatraemic counterparts. 80% of acute hyponatraemic patients have died within 30 days of diagnosis, compared to 140 days for chronic hyponatraemics with similar death rate. Out of 48% non-hyponatraemic patients who died within next 6 months, 31% developed hyponatraemia at some point before their death and amongst them, 5.7% had severe, 8.5% had moderate and 17% had mild hyponatraemia respectively. **Conclusions:** Our study indicated that hyponatremia is poor prognostic factor among oncology patients, with mortality being significantly higher when the grade is higher and when acute in onset. Identifying and early intervention could improve patient outcome. Research Sponsor: None.

7056 Poster Session (Board #328), Fri, 8:00 AM-11:00 AM

Improving the delivery of team-based survivorship care after primary breast cancer treatment through a multi-level intervention. *First Author: Lauren P. Wallner, University of Michigan Medical School, Ann Arbor, MI*

Background: The delivery of team-based survivorship care after primary cancer treatment remains challenging, in part due to a lack of effective interventions. We developed a multi-level intervention for breast cancer patients and their primary care and medical oncology providers to improve the delivery of team-based survivorship care called ConnectedCancerCare (CCC). CCC includes a patient-facing, personalized mobile website, and tailored feedback letters to providers. **Methods:** We conducted a pilot randomized controlled trial in a breast oncology clinic to establish the feasibility and acceptability of CCC. Women within one year of completing primary treatment for stages 0-II breast cancer were randomized to CCC (intervention) or a static online survivorship care plan (control). Participants completed online surveys at baseline and 3 months, ascertaining their knowledge about PCP roles in their survivorship care, their communication with their PCP about team-based care, and whether they scheduled a follow-up visit with their PCP. Multiple measures of acceptability were collected among women in the intervention arm (n = 28). Qualitative interviews were conducted at the completion of the study with 5 PCPs, 6 oncology providers, and 10 intervention patients to identify barriers and facilitators to implementing CCC. **Results:** Among 160 eligible women invited to participate, 66 women completed the baseline survey and were randomized (41% participation rate), and 54 completed the 3-month follow-up survey (83% response rate). Women in the intervention arm found the content of the CCC website to be highly acceptable, with 82% reporting it was easy to use, and 86% reporting they would recommend it to other patients. A greater proportion of women randomized to CCC (vs. control) reported scheduling a PCP follow-up visit (64% vs. 42%) and communicating with their PCP about provider roles (67% vs. 18%). Women in the CCC arm also reported higher mean knowledge scores regarding team-based cancer care (3.7 vs. 3.4). Providers noted challenges to implementing CCC, including integration into electronic medical records, and supporting sustained engagement with CCC over time. **Conclusions:** Our findings suggest deploying CCC in medical oncology practices is feasible, and the intervention content is acceptable among breast cancer patients. CCC shows promise for improving understanding and communication about provider roles in survivorship care, and facilitating patients to follow up with their PCP early in the survivorship period. Clinical trial information: NCT03618017. Research Sponsor: U.S. National Institutes of Health, University of Michigan Rogel Cancer Center.

7057 Poster Session (Board #329), Fri, 8:00 AM-11:00 AM

A personalized prediction model for hospital readmission risk for cancer patients. *First Author: Jacob Tyler Shreve, Cleveland Clinic, Cleveland, OH*

Background: Cancer patients (pts) are at high risk of unplanned hospital readmissions. Predicting which cancer patients are at higher risk of readmission would improve post-discharge follow-up/navigation, decrease cost, and improve pt outcomes. **Methods:** We conducted a retrospective cohort study of non-surgical cancer pts hospitalized at our center between 12/2014 to 7/2018. A machine learning algorithm was trained on 348 medical, sociodemographic and cancer-specific variables with a total of 1,801,944 data points. The cohort was randomly divided into training (80%) and validation (20%) subsets. Prediction performance was measured by area under the receiver operator characteristic curve (AUC). **Results:** A total of 5,178 hospitalizations were included, of which 45.1% were women, and 27.6% experienced an unplanned readmission within 30 days. The most frequently represented cancers were hematologic malignancies (30.5%), followed by GI (18.1%), lung (13.7%), and GU (10.9%). Significant variables that impacted the algorithm decision are ranked from the most to the least important, including: days from last admission; planned index chemotherapy admission; number of vascular access lines, drains, and airways in use; length of stay; cancer diagnosis; total ED visits in past 6 months; age; discharge lab values (sodium, albumin, alkaline phosphatase, bilirubin, platelets); number of prior admissions; and discharge disposition. The AUC for the validation subset was 0.80. To ease the translation of this model into the clinic, we developed a web application whereby users can supply the aforementioned variables to the model and receive a personalized prediction that highlights those variables most affecting a subject's readmission risk status: www.Cancer-Readmission.com. **Conclusions:** A cancer-specific readmission risk model with high AUC for 30-days unplanned readmission has been developed. The model is embedded in a freely available web application that provides personalized, patient-specific predictions. Programs that integrate this model can identify cancer patients with a greater risk for unplanned hospital readmission, thus providing a personalized approach to prevent future unplanned readmissions. 7059 Poster Session (Board #331), Fri, 8:00 AM-11:00 AM

The effect of cardiovascular disease on the association between immune-related adverse events and overall survival. *First Author: Ohad Oren, Mayo Clinic, Rochester, MN*

Background: Preliminary data suggests that immune-related adverse events (irAEs) are associated with lower all-cause mortality, presumably due to improved anti-tumor responses. Investigations of large cohorts are needed to establish better understanding of that association. **Methods:** We reviewed the Mayo Clinic database for all patients who received an immune checkpoint inhibitor (ICI). The primary outcome was all-cause mortality. Descriptive and uni-variate analyses were generated. **Results:** Between March, 2010 and July, 2019, 3,326 patients received an ICI. The most common irAEs were colitis (287, 8.6%), pneumonitis (238, 7.2%) and hepatitis (227, 6.9%). A total of 933 (28.1%) patients developed at least 1 irAE and 176 (5.3%) patients experienced 2 or more irAEs. Survival analysis demonstrated an association between the number of irAEs and all-cause mortality (log-rank, $P < 0.0001$), a relationship which was maintained for the 3 most common cancer types (lung, melanoma, renal) and for the individual ICI agents. In patients with lung cancer, colitis ($P = 0.04$) but not pneumonitis ($P = 0.83$) was associated with improved overall survival. No association between irEA and all-cause mortality was demonstrated in patients with history of stroke (log-rank, $P = 0.12$), peripheral artery disease (PAD) (log-rank, $P = 0.68$) and obesity (log-rank, $P = 0.18$). In an analysis of pre-ICI body-mass index (BMI), an association between irAE and lower overall mortality was shown in patients with BMI < 30 (log-rank, $P < 0.001$) and not in those with higher BMIs (log-rank, $P = 0.09$). The presence of stroke, PAD and obesity were associated with higher all-cause mortality in a survival analysis ($P < 0.001$). The irAE-mortality association was not modulated by the presence hypertension (log-rank, $P < 0.0001$), diabetes mellitus (log-rank, $P < 0.0001$), or heart failure (log-rank, $P = 0.006$). **Conclusions:** The development of any irAE is associated with higher overall survival. The presence of numerous cardiovascular disease states neutralizes that association, likely a result of competing causes of mortality although interaction with immune or inflammatory pathways is possible. In addition, pneumonitis is not associated with better overall survival in patients with lung cancer presumably due to compromise of already-tenuous respiratory status. Research Sponsor: Research funds of mentor.

7060 Poster Session (Board #332), Fri, 8:00 AM-11:00 AM

The association of fitness and body mass index (BMI) on all-cause mortality in cancer survivors: The Henry Ford Exercise Testing Project (The FIT Project). *First Author: Catherine Handy Marshall, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: The obesity paradox –i.e. inverse associations between body mass index (BMI) and mortality – has been reported in patients with cancer, heart failure, and diabetes. However, the influence of cardiorespiratory fitness (CRF) on this relationship is not well established. This study assesses the association of BMI and CRF with all-cause mortality among cancer patients. **Methods:** The Henry Ford (HF) FIT Project is a retrospective cohort study of 69,885 consecutive patients who underwent physician-referred exercise stress testing from 1991 through 2009. Cancer diagnosis was identified through linkage to the HF tumor registry. We included patients 40-70 years old, with BMI recorded, at time of exercise test, with a history of cancer > 6 months prior. BMI was categorized as normal (18.5-24.9kg/m^2), overweight (25-29.9kg/m^2), or obese (> = 30kg/m2). All-cause mortality was obtained from the National Death Index. Because of a significant interaction between BMI and cancer type, patients with breast or prostate cancer were excluded. Multivariable adjusted Cox proportional hazard models were used to evaluate the association of CRF andBMI with all-cause mortality; adjusted for age at exercise test, sex, diabetes, smoking, cancer stage, and time from cancer diagnosis to exercise test. **Results:** Included were 676 patients with a mean age of 58 years (SD 7.5), 51% female, 70% White, 25% Black, with a median of 4.8 years from diagnosis to exercise test and median follow up time of 10.3 years. Among patients achieving < 10 METs, those who are overweight and obese had a lower risk of mortality HR 0.47 (95% CI 0.25,0.86) and HR 0.44 (95% CI 0.26, 0.74, respectively), compared to those with normal BMI. Among patients with METs > = 10, those who were overweight had the lowest risk of all-cause mortality (HR 0.23, 95% CI 0.09-0.62) compared to normal weight, while no statistically significant different risk of mortality was observed when comparing those who are obese to normal weight (HR 0.37, 95% CI 0.13-1.06). In an analysis combining BMI and fitness groups (four categories), those with BMI > = 25 and METs > = 10 had the lowest risk of all-cause mortality (Table). **Conclusions:** In non-breast/non-prostate cancer patients, increased BMI is associated with improved overall survival in those with METs < 10, while a U-shaped relationship between BMI and all-cause mortality exists among those with METs > = 10. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology, Other Government Agency, U.S. National Institutes of Health.

7061 Poster Session (Board #333), Fri, 8:00 AM-11:00 AM

Global oncology authorship and access patterns. *First Author: Maria Teresa Bourlon, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

Background: Global Oncology is a movement to improve equitable access to cancer control and care, recognizing challenges due to economic and social factors between high, middle, and low-income countries (HIC, MIC, LIC). Access to local, regional, and global cancer data and analysis is a major driver for building a global oncology community. The JCO Global Oncology (JCO GO) online open access journal was established in 2015 with the mission to be the voice of research relevant to populations with limited resources. To assess its goals of encouraging global interaction and increasing MIC and LIC engagement, we analyzed authorship and accessing data. **Methods:** Logged views of articles published in 2018 were identified by DOI, using Google Analytics during the period 01/01/2018 to 06/30/2019. The country of origin of all authors and the location of downloads were classified according to the 218 economies listed in The World Bank Data (WBC) of 2019. **Results:** 132 articles were published in JCO GO in 2018 with 88152 views, from which the accessing nation was identified for 99%. Views originated from 180 countries: 35% HIC, 51% MIC, and 14% LIC. The most common accessing countries were: USA (37%), India (14%), United Kingdom (3%), Brazil (3%), and Ethiopia (3%). Corresponding authors came from 34 nations: 60% HIC, 32% MIC, and 8% LIC. The most common economies involved in any authorship were: USA (47%), India (10%), Brazil (5%), Mexico (4%), and Nigeria (3%). Reader origin did not differ according to corresponding author WBC. Article authorship was exclusively from one economic category in 49%: 23% HIC 16% MIC, 2% LIC. For 59% of articles, authorship came from mixed economies: 42% HIC + MIC, 11% HIC + LIC, 0% MIC + LIC, 6% HIC + MIC + LIC. **Conclusions:** JCO GO 's reach extends to over 80% of the world´s economies. The majority of articles have authors from mixed WBC countries. Areas identified to address are: low level of LIC corresponding authorship; few papers from authors across all economies; no papers from only LMICs authors; low percentage of views by LIC. This information provides focus for global oncology authorities to target interventions to reduce the academic segregation of LICs, such as global oncology funding opportunities, mentorship and policies to encourage interactions and develop MIC and LIC leaders. 7062 Poster Session (Board #334), Fri, 8:00 AM-11:00 AM

iStopCancer: A database of 6,016 low pass whole genome sequencing of minimal invasive samples from 21 cancer types of Chinese population. *First Author: Min Yuan, Shanghai Tenth People's Hospital, Shanghai, China*

Background: Cancer is a group of genetic diseases that result from changes in the genome of cells in the body, leading them to grow uncontrollably. Recent researches suggest Chromosome instability (CIN), which is defined as an increased rate of chromosome gains and losses, manifests as cell-to-cell karyotypic heterogeneity and drives cancer initiation and evolution. **Methods:** In the past two years, we initiated iStopCancer project, and characterized 4515 'best available' minimal-invasive samples from cancer patients and 1501 plasma samples from non-tumor diseases by using low-pass whole genome sequencing. DNA from 'best available' minimal-invasive samples, including peripheral plasma, urines, pancreatic juice, bile and effusions were analyzed by low coverage whole genome sequencing followed by the UCAD Bioinformatics workflow to characterize the CINs. In total, 32T bp nucleotide (coverage =1.7X for each sample) were collected. All the data can be visualized on website: http://www.istopcancer.net/pgweb/cn/istopcancer.jsp. **Results:** 3748(83%) of tumors present detectable CIN (CIN score>1000) in minimal-invasive samples. The missed cancer patients were majorly from patients with either tumor size less than 2cm or less-aggressive cancers, including thyroid cancer, low-grade urothelial carcinoma, lung cancer in-situ, et al. Of the 1501 non-tumor individuals, 30(2.0%) present detectable CIN (|Z|>=3) at the time of sample collection, 24(80.0%) was diagnosed as tumor patient in 3-6 months follow-up. There were 9 (0.59%) of non-cancer individuals without detectable CIN were also reported as tumor patients during 6-month following up. In summary, the positive and negative prediction value is 80.0% and 99.4% respectively. The false alarms were majorly from patients with EBV activations, which indicates virus may interference chromosome stability and drove virus-associated carcinogenesis. For the patient with repeated detections, plasma cfDNA CIN dynamics predicted clinical responses and disease recurrences. Quick clearance of plasma cfDNA CIN in 2-3 weeks was found in 153 (83.6%) patients. Meanwhile, no quick clearance was found in majority of SDs/PDs (73/88=83.0%). Furthermore, cfDNA CIN predicts clinical response 2-8 weeks ahead of traditional biomarkers (CEA, CA15-3, CA199, AFP et al). **Conclusions:** Large-scale low coverage whole genome sequencing data provides useful information for cancer detection and managements. Research Sponsor: None.

7063 Poster Session (Board #335), Fri, 8:00 AM-11:00 AM

Linking insurance claims across time to characterize treatment, monitoring, and end-of-life care in metastatic breast cancer. *First Author: Jennifer Lee Caswell-Jin, Stanford University, Stanford, CA*

Background: Treatment and monitoring options for metastatic breast cancer (MBC) are increasing, but little is known about patterns or predictors of their use. Insurance claims are potentially informative, but tracking patient care timelines using episodic claims data has been cumbersome. **Methods:** We used an advanced cohort engine, implementing a temporal query language, to link IBM Marketscan claims over time for > 125 million US individuals from 2007-2014. To select the most common MBC subtype (ER+, HER2-), our criteria were: ≥2 MBC ICD codes, ≥1 year of follow-up, and ≥1 CPT or medication code for endocrine therapy and 0 for HER2-targeted therapy. We defined aggressive MBC as ≥1 ICD code for visceral or central nervous system metastasis < 1 year after the first MBC code. Geographic area was defined by 9 Census-Bureau designated regions. End-of-record was used as a surrogate for death in a Cox regression. We used multivariate logistic regression to determine correlation of factors, including disease aggressiveness and geography, with treatment, monitoring, and end-of-life events. **Results:** 7,335 women met criteria for ER+, HER2- MBC, with median age 59. Nearly half (46%) had aggressive disease, which correlated with shorter survival (hazard ratio (HR) 1.5 [1.4-1.6], P < 0.001). Treatment: first-line was endocrine therapy for 64% versus chemotherapy for 36%. Monitoring: 79% were imaged mostly by CT versus 21% by PET-CT, with median between-scan interval of 81 days; 63% received CA 15-3 serum tumor markers. End-of-life: 10% had a hospice code, of whom 19% had an ICU stay and 34% chemotherapy in the prior 3 months. Correlates of care: Disease aggressiveness correlated with first-line chemotherapy (odds ratio (OR) 2.0 [1.8-2.2], P < 0.001), PET/CT (OR 1.6 [1.4-1.8], P < 0.001), more frequent scans (OR 2.3 [2.1-2.6], P < 0.001), and chemotherapy < 3 months pre-hospice (OR 1.2 [1.1-1.4], P < 0.001), but not with CA 15-3 monitoring or ICU stay. Disease aggressiveness did not vary by region ($\chi 2$ P = 0.8), but region was significantly associated with treatment, monitoring, and end-of-life care (P < 0.001). **Conclusions:** Approximately two-thirds of ER+, HER2- MBC patients receive first-line endocrine therapy and are monitored with CA 15-3 serum tumor markers; 10% had evidence of hospice use, a likely underestimate due to differential follow-up. MBC care patterns vary by geography while disease aggressiveness does not, suggesting that care is not optimally tailored to individuals. These insights from claims data can inform quality improvement for MBC care. Research Sponsor: Breast Cancer Research Foundation, Other Foundation.

7064 Poster Session (Board #336), Fri, 8:00 AM-11:00 AM

Vital status ascertainment in cancerlinq discovery (CLQD): Improvement in mortality capture with a supplemental data source. *First Author: Danielle Potter, American Society of Clinical Oncology, Alexandria, VA*

Background: Overall survival (OS) is the gold standard outcome in clinical cancer research but many clinical trials cannot assess long-term OS. Real-world data sources can be used to calculate long-term OS, but only if vital status is accurately captured. **Methods:** The primary goal was to assess concordance of death dates from CLQD and an external source, and the effect of incorporation of external death data on estimates of OS. CLQD obtains electronic medical record (EMR) data from participating US oncology sites. Underreporting of vital status is a common problem with EMR data; we investigated the value of including death data from a commercially available database, obituarydata.com (OBD) into CLQD. OBD pulls death data from published obituaries across the US. A matching algorithm is used to match patients in CLQD and OBD. OBD death data from breast, lung, ovarian, and pancreatic cancer patients diagnosed between 2010–2018 supplemented the CLQD in this study. OS was calculated using Kaplan-Meier estimation; Pearson correlation was used for comparing time to death. **Results:** The addition of OBD modestly changes OS estimates (see Table). Among a subset of patients with death dates in both CQLD and OBD, dates were highly correlated for breast (r = 0.98), lung (r = 0.93), ovarian (r = 0.99), and pancreatic (r = 0.88) cancers. When date differences existed, they were ≤10 days for > 95% of the patients. These results suggest death dates are reliable in CLQD EMRs. OS curves were as expected, with OS decreasing by stage and age at diagnosis. **Conclusions:** Incorporating OBD modestly improves OS estimates and shows that when death data is present in CLQD, it is reliable. Future enhancements will focus on improving sensitivity of mortality ascertainment with external data linkages, without compromising specificity. Research Sponsor: AstraZeneca.

OS (95% CI) for CLQD EMR alone and with OBD supplemental dates.

Real-world outcomes of immune-related adverse events in 2,125 patients managed with immunotherapy: A United Kingdom multicenter series. *First Author: Anna Claire Olsson-Brown, Clatterbridge Cancer Centre, Liverpool, United Kingdom*

Background: Immune-related adverse events (irAE) are a recognised complication of immune checkpoint inhibitor (ICI) therapy. Previous characterisation of irAEs has been limited to clinical trial or registry populations and small case series. Here we present a multi-centre, granular, real-world analysis of the prevalence and outcomes of irAEs experienced by patients managed within a single comprehensive public health service. **Methods:** A multi-centre retrospective analysis of 2125 consecutive patients treated with ICIs was undertaken across 12 centres. All patients were managed within the UK National Health Service outside of a trial setting between June 2016 and September 2018. Patients received either ICI monotherapy (MT) or combination therapy (CT). Data were collected using a standardised, pre-piloted, collection tool. IrAEs ≥ grade 2 or endocrinopathies of any grade were considered clinically significant and recorded as per the Common Terminology Criteria for Adverse Events (V5) (CTCAE). Descriptive statistics were employed using Stata v15 (College Station, TX). **Results:** Patients received αPD-1 (1757; 82%), combination αPD-1/αCTLA-4 (285, 13%), αCTLA-4 (51; 2%) and αPD-L1 (31; 1%) immunotherapy for malignant melanoma (961), non-small cell lung cancer (788) or renal cell carcinoma (335). The median age was 66 (MT) and 57 (CT). Clinically significant irAEs occurred in 732 (34%) individuals; 28% (524) on MT and 73% (208) on CT. Colitis (206,10%), thyroiditis (194, 9%), hepatitis (142, 7%) and dermatitis (126, 6%) were most commonly observed. Grade 1 endocrinopathies occurred in 20% (173) of cases. Grade 2 irAEs occurred in 43% (359), grade 3 31% (269) and grade 4 6% (51). The were 3 (0.4%) cases of grade 5 irAE; pneumonitis (2) and hepatitis, all following αPD-1 MT. 93% (680) required corticosteroids with 64% (490) requiring systemic corticosteroids and 11% (80) steroid sparing immunosuppression. 16% (336) of patients had pre-existing autoimmune disease of whom 40% (136) experienced irAEs. IrAEs led to admission in 42% (308) of cases, accounting for 2996 bed days. Length of stay was 7 days (1-67; IQR 4-13). Higher dependency care was required in 0.7% (15) of cases. Colitis (35%, 107) and hepatitis (25%, 77) accounted for the most admissions. Pneumonitis accounted for 3% (66) of irAEs but 12% of admissions. **Conclusions:** One third of patients experienced a clinically-significant irAE resulting in significant morbidity and admission burden highlighting the need for effective management strategies to optimise patient outcomes. Research Sponsor: None.

7066 Poster Session (Board #338), Fri, 8:00 AM-11:00 AM

Perioperative chemotherapy versus adjuvant chemoradiation in resectable gastric cancer: A national cancer database analysis. *First Author: Sindhu Janarthanam Malapati, Van Elslander Cancer Center-Ascension St John Hospital, Detroit, MI*

Background: In patients with resectable gastric cancer, the use of either perioperative chemotherapy (POC) or adjuvant chemoradiotherapy (CRT) are acceptable treatment options in addition to surgical resection. Both approaches improved overall survival (OS) compared to surgery alone. Randomized controlled trials comparing these two modalities are lacking. This study uses real-world data to compare the clinical outcomes of these two approaches. **Methods:** We identified gastric cancer patients in the NCDB who had definitive surgery between years 2004 and 2015. They were divided into two cohorts: POC and adjuvant CRT. We compared the OS and surgical outcomes in both groups. Kaplan-Meier method and multivariable Cox regression model were used to estimate survival. **Results:** Of 75,654 patients who underwent definitive surgical resection, 1,920 had POC and 9,161 had adjuvant CRT. Median OS was 56 months with POC and 38.5 months with CRT. After adjusting for age, gender, race, insurance status, comorbidity index, and treatment facility, patients who received POC had an 18% reduction in all-cause mortality compared to those who received adjuvant CRT ($p < 0.0001$, 95% confidence interval 0.74- 0.88). Although, 30- and 90-day mortality was slightly higher with POC compared to CRT (0.047 vs. 0.03%, $p<0.0001$ and 1.46 vs. 0.45%, $p<0.0001$ for 30 and 90 day mortality, respectively). Length of hospital stay for primary tumor resection was similar between the two groups; but the 30 day readmission rate after surgery was higher with CRT compared to POC (12.74 vs. 8.33%, $p<0.0001$). **Conclusions:** Among patients undergoing definitive surgical resection for gastric cancer, our study shows an association between the use of POC (vs. adjuvant CRT) and improvement in OS. In the POC cohort, while there was a slight increase in postoperative mortality, this was surpassed by the benefit derived from use of POC, resulting in net improvement of survival. These interesting observations warrant confirmation in randomized clinical trials. Research Sponsor: None.

	CRT (%) N=9,161	POC(%) N=1,920	HR for mortality (POC compared to CRT)	p-value for HR
Node positive	1,936 (21.8)	870 (46.1)	0.72	<0.0001

Effectiveness of adjuvant FOLFOX versus 5FU for colon cancer treatment in community oncology practice using a hybrid study approach. *First Author: Jennifer Leigh Lund, Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Treatment effects may differ between trials and community settings, in part due to underrepresentation of certain patient subgroups in trials. We used a hybrid approach combining clinical trial and real-world data to compare the effectiveness of adjuvant FOLFOX vs 5FU for stage II-III colon cancer in community oncology practice. **Methods:** We used Multicenter International Study of Oxaliplatin/5FU-LV in the Adjuvant Treatment of Colon Cancer (MOSAIC) combined with patients who met trial eligibility criteria within US Oncology from 1/1/2008-5/31/2019. In the combined data, we used logistic regression to estimate the probability of trial enrollment as a function of age, sex, substage, body mass index (BMI), and performance status. We estimated inverse odds of sampling weights and weighted MOSAIC participants to reflect three US Oncology populations: 1) patients meeting trial eligibility, 2) stage III patients, and 3) stage III patients initiating FOLFOX. Within the weighted trial populations, we estimated mortality hazard ratios (HRs) and bootstrapped 95% confidence intervals (CIs) comparing FOLFOX with 5FU. **Results:** There were 2246 MOSAIC participants and 9335 US Oncology patients. MOSAIC participants were younger, had more stage II cancer, lower BMI, and worse performance status compared with US Oncology patients. After weighting MOSAIC participants to reflect the US Oncology populations, the HRs were attenuated (Table) compared with the original MOSAIC estimate (HR = 0.84; 0.71,1.00). **Conclusions:** When differences between trial and clinical populations exist and response to therapy varies across subgroups, treatment efficacy can differ from clinical effectiveness. Compared with trial results, we found that effectiveness of FOLFOX versus 5FU was attenuated in community oncology practice. Research Sponsor: Patient-Centered Outcomes Research Institute.

Effectiveness of FOLFOX vs 5FU on mortality in MOSAIC and three US Oncology populations.

Population	Trial Arm	6-Year Mortality	HR (95% CI)
Trial eligible US Oncology patients	5FU	19.3%	1.0
	FOLFOX	20.0%	1.05 (0.80,1.33)
Stage III US Oncology patients	5FU	24.0%	1.0
	FOLFOX	24.8%	0.97 (0.73,1.31)
Stage III US Oncology patients on FOLFOX	5FU	24.5%	1.0
	FOLFOX	24.4%	0.93 (0.71,1.25)

The economic impact of cancer-related premature mortality in Brazil: A human capital approach analysis. *First Author: Marianna De Camargo Cancela, Division of Population Research, Brazilian National Cancer Institute, Rio De Janeiro, Brazil*

Background: One method of calculating indirect costs of cancer is the analysis of productivity loss. Using the human capital approach, we estimate how much cancer-related premature mortality indirectly impacts the economy. Given the diverse causes of cancer death and sociodemographic profiles in Brazil, we estimated lost productivity due to cancer by regions, providing evidence for local decision-makers. **Methods:** Data of all cancers deaths among working-age people (15-64 years for men and 15-60 for women) occurring in 2016 were extracted from the National Mortality System, by region, sex and age-group. Data on life expectancy, workforce participation, unemployment and wages were extracted from the Brazilian National Institute of Geographics and Statistics. Loss of productivity was calculated as the value of time between death and potential retirement age. **Results:** In total 536,827 (men) and 407,737 (women) years of potential productive life (YPPLL) were lost in 2016, corresponding to US$ 6,196,682,092 (PPP) for Brazil. The profile of YPPLL by cancer type varied by region. In the affluent South and Southeast regions, the cancers with higher impact in men were lung (12.4% and 9.9% of total YPPLL) and colorectal (9.6% and 10.4% of total YPPLL) while in the less affluent North and Northeast, stomach cancer was responsible for 17% and 12% of YPPLL, respectively. Among women, breast cancer had the highest impact in all regions (21.7%-26.2%), excepting the North, where cervical cancer was responsible for 31.3% of the YPPLL. Nationally, individual YPPLL was higher for testicular cancer in males (31.3 years) and Hodgkin's disease in females (20.2). In the North and the Northeast, despite lower mortality rates, the economic impact of productivity loss was higher, representing 0.23 and 0.29% of the regional GDP. **Conclusions:** Our results show the indirect economic impact of premature cancer mortality in Brazil, at a total cost of US$ 6,196,682,092 in 2016, representing 0.2% of the entire country's GDP. The regional patterns highlight the need for adaption of public policies, typical from a country in transition, with the impact of lifestyle and infection-related cancers simultaneously and differently affecting economically the regions. Differences in real-world (RW) non-small cell lung cancer (NSCLC) treatment patterns among people living with HIV/AIDS (PLWHA) compared to those without HIV/AIDS (PWoHA). *First Author: Andrew J. Klink, Cardinal Health, Dublin, OH*

Background: NSCLC is the most common non-AIDS-defining cancer in PLWHA with an estimated prevalence 2-5 times that of PWoHA. Guidelines now support treatment of NSCLC among PLWHA to follow those for PWoHA. However, PLWHA have been often excluded from cancer clinical trials that test novel agents including immunotherapy (IO). This study aimed to assess differences in systemic therapy patterns for advanced NSCLC among PLWHA and PWoHA in the RW. **Methods:** Adult patients with ≥2 claims for NSCLC between 1/1/13-12/31/18 (earliest claim = index date), ≥3 months data pre/post index date, and no evidence of clinical trial participation, pregnancy or other malignancy prior to index date were identified from Symphony Health longitudinal prescription and medical claims. Patient characteristics and treatment patterns were summarized by descriptive statistics and comparisons by HIV status made on univariate analyses. Times to discontinuation were estimated by Kaplan-Meier method and compared by log-rank tests. **Results:** There were 60,278 NSCLC PWoHA who received systemic therapy. Of 1,344 PLWHA with NSCLC, 239 (18%) received systemic therapy. PLWHA differed significantly from PWoHA: median age at diagnosis (58 v 68 years), male preponderance (66% v 47%), payer mix (Medicare 26% v 42%; Medicaid 21% v 7%), Charlson Comorbidity Score (median 6 v 1), depression (13% v 5%) and liver disease (8% v 2%), respectively (all $P< 0.01$). Differences in common systemic therapies among PLWHA v PWoHA include use of first line (1L) carboplatin + paclitaxel (28% v 19%; $P< 0.01$), 1L erlotinib (6% v 11%, $P= 0.02$) and 2L gemcitabine (10% v 4%, $P< 0.01$). IOs were used in 1L among 43 (18%) and 7,149 (12%) of PLWHA v PWoHA, respectively ($P< 0.01$). RW surrogates for PFS: median duration of 1L therapy was shorter among PLWHA (1.8 v 2.3 months, $P< 0.01$); median times from 1L initiation to 2L were similar (5.4 v 4.9 months; $P= 0.48$). Similar proportion of patients continued onto 2L (32% and 30%) and 3L (10% and 9%) among PLWHA and PWoHA, respectively (all $P> 0.05$). Total time from diagnosis to last follow-up (RW surrogate for overall survival) was 12.8 v 15.5 months in PLWHA and PWoHA ($P= 0.07$). **Conclusions:** PLWHA are younger at diagnosis of NSCLC and have higher comorbidity. Important differences in regimen selection and IO utilization exist across PLWHA and PWoHA. PLWHA have shorter 1L than PWoHA. Given higher risk and younger age at diagnosis, additional research is needed to establish screening and treatment guidelines for NSCLC in PLWHA. Research Sponsor: Cardinal Health.

7071 Poster Session (Board #343), Fri, 8:00 AM-11:00 AM

The correlation between clinical benefit and financial cost of cancer drugs. *First Author: Aaron Philip Mitchell, Memorial Sloan Kettering Cancer Center, New York City, NY*

Background: The cost of many cancer drugs is very high, but it is unclear if these costs are associated with commensurate improvement in outcomes. We aimed to assess the association between the cost of cancer treatments and their clinical benefit, using the NCCN Evidence Blocks value assessment framework. **Methods:** The NCCN Evidence Blocks include 4 measures of clinical benefit: Efficacy, Safety, Quality of Evidence, and Consistency of Evidence. The NCCN assigns scores on each measure ranging from 1 (least favorable) to 5 (most favorable). We obtained the NCCN Evidence Blocks scores as of December 31, 2018 for all recommended cancer treatments for the 30 most prevalent cancers in the US. For each treatment, we calculated total treatment costs (including drugs, administration fees, and supportive care medications) using Medicare reimbursement rates. We categorized treatments as either "time-limited" or "time-unlimited" according to whether their costs are best reflected as per full treatment course (often, adjuvant/neoadjuvant treatments) (time-limited) or per month of therapy (often, treatments for advanced disease) (time-unlimited). We used generalized estimating equations, with clustering within treatment indications, to estimate the association between Evidence Blocks scores and treatment costs, modeling the expected change in cost associated with a one-unit increase in the score on an Evidence Blocks measure. **Results:** There were 541 time-unlimited and 845 time-limited treatments. Among time-unlimited treatments, monthly treatment cost ranged from $4 to $64,630. Monthly treatment cost was positively associated with Efficacy ($3,036, 95%CI: $1,782, $4,289) and Quality of Evidence ($1,509, 95%CI: $171, $2,847) but negatively associated with Safety (-$1,470, 95%CI: -$2,790, -$151) and Consistency of Evidence (-$2,003, 95%CI -$3,420, -$586). Among time-limited treatments, cost per course of therapy ranged from $0 to $775,559, and no measure was significantly associated with cost. Evidence Blocks scores accounted for little of the variation in treatment cost (linear model R-squared = 0.10 for time-unlimited, and < 0.01 for time-unlimited). **Conclusions:** The association between NCCN Evidence Blocks measures and treatment cost was inconsistent, and accounted for little of the cost variation among treatments for the same indication. The clinical benefit of cancer treatments does not appear to be a primary determinant of treatment cost, suggesting that current pricing models may be inadequate to incentivize the development and utilization of high-value treatments. 7072 Poster Session (Board #344), Fri, 8:00 AM-11:00 AM

Breast density notification with adjunctive digital breast tomosynthesis (DBT): A cost-effectiveness analysis. *First Author: Jason Semprini, Uni-University of Iowa, College of Public Health, Department of Health Management and Policy, Iowa City, IA*

Background: Dense breasts increase a woman's risk of developing cancer while also raising the likelihood of a missed diagnosis from traditional mammography screening. Digital Breast Tomosynthesis (DBT) has been shown to identify positive breast cancer more accurately in women with dense breasts, but no study has estimated the cost-effectiveness of this screening mode under a notification requirement. **Methods:** Taking the perspective of a healthcare system, we estimated the incremental cost-effectiveness ratio (ICER) of providing DBT as an alternative to mammography for 40-year old women. Model parameters reflecting risk of breast cancer, detection rates, and costs were estimated from recent meta analyses, Tufts' CEA registry, and Medicare Fee Schedules. We used probabilistic Markov Models to estimate the ICER under uncertainty, and a time-variant model in which breast density and cancer risk change over time. Additionally, a heterogeneity analysis included all women between the ages of 40-65, while also using 1st and 2nd degree family history to calculate cancer risk. **Results:** In the probabilistic model, adjunctive DBT has a cost differential of $12,203, with an increase of 0.0382 quality-adjusted life years (ICER = $319,491/QALY) compared to mammography. This result was most sensitive to the probability of a missed diagnosis for women with dense breasts. At a willing-ness to pay of $50,000, adjunctive DBT had a 57% chance of being more costly and less effective than standard mammography. Conversely, DBT only had a 20% chance of being cost-effective and a 9.9% chance of being less costly and more effective. The time-variant model reported an ICER of $174,218, but adjunctive DBT became even more cost-effective after expanding the population and including family history of cancer (ICER_All Ages = $157,146; ICER_FamHist = $153,388). **Conclusions:** Breast density notification laws which provide additional screening via DBT are not cost-effective at a willingness to pay of $50,000. Policymakers, however, should note that many modern cancer therapeutics also exceed this threshold. As an adjunctive screening technique, DBT would result in fewer deaths and increase quality of life, but the effect is minimal and carries a high cost. Including breast density within greater risk stratification protocols, however, may prove highly cost-effective, especially for older women with a family history of cancer. Research Sponsor: None.

7073 Poster Session (Board #345), Fri, 8:00 AM-11:00 AM

A randomized controlled trial (RCT) testing a mobile application (app) to identify cancer treatment-related financial assistance. *First Author: Aaron Tarnasky, Duke University School of Medicine, Durham, NC*

Background: Insured cancer patients face high treatment-related, out-of-pocket costs. While philanthropic- and pharmaceutical-sponsored financial assistance programs exist, patients are often unaware of them. We developed "Bridge", a patient-facing app that identified financial assistance programs for which a patient might be eligible based on treatment, disease, insurance, and financial characteristics. We hypothesized that patients in the Bridge study arm would be more likely than controls to apply for and receive financial assistance. **Methods:** We enrolled patients at a single institution from January 2018-March 2019. Patients were receiving treatment for any cancer, had a life expectancy of ≥6 months, and self-reported out-of-pocket costs. We randomized patients 1:1 to intervention (Bridge) vs. control (financial assistance educational websites). We assessed subjective financial distress with the validated COST measure. Outcomes included application for and receipt of financial assistance. Data on outcomes was collected from the medical record, institutional pharmacy database, and Bridge. We compared patient characteristics between study arms using chi-square and Mann-Whitney-Wilcoxon tests. We used an unadjusted logistic regression model to compare differences in outcomes. **Results:** We randomized 200 patients and found no significant differences between arms in baseline characteristics (Table). At 6 months from enrollment, patients in the Bridge arm were more likely than controls to apply for financial assistance [35% Bridge vs. 10% control, OR 3.53, 95% CI 1.69-7.34, $p < 0.01$]. Bridge patients were also more likely than controls to receive financial assistance (30% Bridge vs. 9% control, OR 3.39, 95%CI 1.78-6.46, $p < 0.01$). **Conclusions:** Among patients with treatment-related out-of-pocket costs, those who interacted with a financial assistance app were significantly more likely to apply for and receive treatment-related financial assistance. Research Sponsor: U.S. National Institutes of Health.

Baseline	Control (n = 100)	Bridge (n = 100)	Total (n = 200)
Median age, years	59	56	57
Female gender	59%	49%	54%
White race	67%	74%	71%
Stage IV/metastatic	48%	57%	53%
Educated past high school	80%	69%	75%
Median income	$55,000 (n = 83) (IQR $35,000-$100,000)	$66,000 (n = 83) (IQR $40,000-$120,000)	$62,000 (n = 166) (IQR $36,000-$100,000)
Private insurance	69%	72%	71%
Median monthly out-of-pocket cost	$775 (n = 93) (IQR $280-$2421)	$1,100 (n = 93) (IQR $413-$2195)	$928 (n = 186) (IQR $330-$2421)
Median financial distress score	24	23 (n = 99)	23 (n = 199)

7074 Poster Session (Board #346), Fri, 8:00 AM-11:00 AM

Venous thromboembolism prophylaxis in ambulatory cancer patients initiating chemotherapy: A cost-effectiveness analysis. *First Author: Emma Ryan, Duke University School of Medicine, Durham, NC*

Background: Venous thromboembolism (VTE) is a major cause of morbidity and mortality among cancer patients. The Apixaban for the Prevention of Venous Thromboembolism in High-Risk Ambulatory Cancer Patients (AVERT) randomized controlled trial concluded that apixaban is a safe and effective option for VTE prophylaxis in high-risk ambulatory cancer patients initiating a new chemotherapy regimen. We performed a cost-effectiveness analysis from a health system perspective to determine if apixaban is a feasible prophylactic strategy for this population. **Methods:** A decision model was created from a third party payer perspective with a time horizon of 6 months, based on the treatment arms of the AVERT trial: (1) apixaban 2.5 mg twice daily for 6 months during active chemotherapy versus (2) placebo. Rates of VTE (4.2% apixaban vs 10.2% placebo), major bleeding (3.5% vs 1.8%) and clinically relevant nonmajor bleeding (CRNMB) (7.3% vs 5.5%) were modeled from the results of the AVERT trial. Cost estimates for treatments and events were obtained from wholesale drug costs, previously published studies and Medicare reimbursement data, and adjusted for inflation to 2018 dollars. Quality adjusted life years were calculated based on previously published utility values for the health states of advanced cancer, DVT, PE, and major bleeding events. An exploratory analysis was performed comparing prophylactic aspirin to no prophylaxis assuming a VTE rate of 7.2%, major bleeding rate of 3.5%, and CRNMB rate of 7.3%, based on the conservative assumptions that while aspirin may not be as effective at preventing VTE, the rate of clinically significant bleeding events would be similar or greater than that of apixaban. **Results:** In the base case model, apixaban is more costly and more effective than placebo (ICER = $5,013,190/QALY), and the cost per VTE prevented in the apixaban arm is $33,000. In one-way sensitivity analysis, if the cost of apixaban were reduced by 40% from $3,197 to $1,250 for a 6 month course, this could potentially be a cost-effective prophylaxis strategy with an ICER less than $100,000/QALY. In the alternative analysis, aspirin dominates placebo as it is both more effective and less expensive, and remains cost-effective even when the rate of clinically recognized bleeding with aspirin exceeds 15%. **Conclusions:** Further investigation into less costly prophylactic options such as generic direct oral anticoagulants (once available) and aspirin is warranted prior to broader implementation of a VTE prophylaxis strategy in this population. Research Sponsor: None.

7075 Poster Session (Board #347), Fri, 8:00 AM-11:00 AM

Cost-effectiveness of genomic profiling in veterans with metastatic lung adenocarcinoma. *First Author: Pradeep Poonnen, Duke University Health System/Durham VA Medical Center, Durham, NC*

Background: Tumor profiling identifies patients who are eligible for targeted anticancer therapies. Common tumor profiling approaches include targeted gene panel testing (TGPT), which tests for common mutations in select genes, and multigene panel sequencing (MGPS), which tests for a broad range of mutations in a comprehensive set of genes. Our objective was to determine the lifetime cost-effectiveness of MGPS and TGPT compared to no tumor profiling for Veterans with metastatic lung adenocarcinoma from the Veterans Health Administration's (VHA) perspective. **Methods:** A decision analytic model was developed to simulate outcomes for a closed cohort of hypothetical Veterans with metastatic lung adenocarcinoma considering anticancer therapy. OncoKB genes with levels of evidence 1 and 2 for guiding therapy were included. Three profiling strategies were studied: TGPT (*ALK, EGFR, ROS1*), MGPS (*ALK, BRAF, EGFR, HER2, MET, NTRK1, NTRK2, NTRK3, RET, ROS1*), and no tumor profiling. We assumed 95% of patients with actionable mutations received targeted therapies. Non-targeted therapy options included chemotherapy and/or immunotherapy, and no anticancer therapy. Model inputs were derived from randomized trials (progression-free survival), VHA and Medicare (drug costs), published studies (non-drug cancer-related management costs, health care utilities), and VHA National Precision Oncology Program and cBioPortal for Cancer Genomics databases (mutation prevalence). Costs (2019 US$) and quality-adjusted life years (QALYs) were discounted at 3%/year. Base-case scenario, one-way sensitivity analyses, and probabilistic sensitivity analyses (PSA) using 1,000 Monte Carlo simulations were completed. **Results:** Base-case results and corresponding 95% credible intervals from the PSA indicated the cost/QALY gained was $309,399 ($280,371-$343,161) for TGPT and $324,707 ($296,086-$359,778) for MGPS compared to no tumor profiling. Of the 3 strategies, MGPS resulted in the highest number of QALYs. One-way sensitivity analyses revealed the cost/QALY estimates were most impacted by changes in health state utility on a targeted therapy (quality of life), costs of alectinib, and non-drug cancer-related costs in patients receiving targeted therapy. Compared to no tumor profiling, cost-effectiveness ratios for both profiling approaches surpassed the $150,000/QALY threshold in 100% of PSA simulations. **Conclusions:** Tumor profiling (TGPT or MGPS) can optimize anticancer therapy selection in patients with metastatic lung adenocarcinoma and improve quality-adjusted survival, but compared to no tumor profiling, is not cost-effective. Research Sponsor: None.

7076 Poster Session (Board #348), Fri, 8:00 AM-11:00 AM

Three versus six months of adjuvant chemotherapy for colorectal cancer: A multi-country cost-effectiveness and budget impact analysis. *First Author: Catherine Hanna, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom*

Background: The international Short Course Oncology Treatment (SCOT) trial demonstrated non-inferiority and significantly less toxicity of 3 versus 6 months of adjuvant chemotherapy for patients with colorectal cancer (CRC). This study assesses the value of shorter treatment and the economic implications of implementing the findings from the perspective of the countries that participated in the SCOT trial. **Methods:** Individual patient level data (n=6055) from the SCOT trial was used in a fully-pooled, cost utility analysis for the six participating countries. The incremental net monetary benefit (INMB) per patient was calculated using a willingness to pay threshold of one Gross Domestic Product per capita for each country. Responses to a clinician questionnaire (n=265 across 21 countries collected in April 2019) were used to estimate extent of practice change. The budget impact over 5 years of using shorter treatment was calculated, using 2019 and US dollars (USD) as the base year and currency, respectively. **Results:** Cost drivers for differences between the SCOT trial arms were reduced chemotherapy costs and fewer hospitalisations in the first treatment year. The INMB per patient of using shorter treatment and subsequent monetary impact on healthcare provider budgets resulting from implementation are shown in Table. This is a cost saving treatment strategy in all countries. The budget impact over 5 years amounts to savings of nearly half a billion USD. **Conclusions:** The economic burden of CRC treatment globally exceeds $39 billion per annum. Understanding the costs and consequences of widespread clinical practice change is important for optimal budget planning. This study has widened the transferability of results from a phase III cancer trial, showing shorter treatment is cost-effective from a multi-country perspective. The vast savings could provide benefit elsewhere within a limited healthcare budget, and justify the investment in conducting the SCOT trial. Research Sponsor: CRUK.

	Australia	Denmark	New Zealand	Spain	Sweden	United Kingdom
INMB	$14 966	$15 578	$12 266	$11 147	$13 868	$14 738
Budget impact ($ million) (55% practice change stage III, 20% practice change stage II)	-$55	-$18	-$8	-$156	-$27	-$208

7077 Poster Session (Board #349), Fri, 8:00 AM-11:00 AM

Total cost of lung cancer care associated with broad panel versus narrow panel sequencing. *First Author: Rogelio Alberto Brito, CVS Health, Woonsocket, RI*

Background: Many lung cancer patients are diagnosed late with advanced or metastatic disease. Targeted therapies can improve quality of life and increase the chances of progression-free survival versus conventional treatments. An understanding that there may be more than one driver mutation associated with a specific lung tumor is crucial for the timing and delivery of the most effective line of therapy. Broad panel sequencing (BPS) minimizes tissue use and enables personalized treatment that decreases the use of ineffective agents and unwarranted side effects, in addition to opening pathways to early clinical trials. However, many payors do not reimburse for BPS. The objective of this study was to determine if BPS leads to lower total cost of care versus narrow panel sequencing (NPS). **Methods:** We identified new lung cancer patients who completed BPS (Current Procedural Terminology (CPT) code 81455, 51+ genomic test) or NPS (CPT code 81445, 5-50 genomic test) using medical claims from January 1, 2018, to March 31, 2019. We defined total cost of care as allowed costs paid for medical and pharmacy claims across a six-month time period from the first gene sequencing panel. We also compared the allowed costs of BPS and NPS. A Student's t-test was used to compare differences and results are presented as mean +/- standard deviation. **Results:** From January 2018 to March 2019, we identified 45 patients who underwent BPS sequencing and 399 patients who underwent NPS. The average BPS cost was $1,977 +/- $2,713 versus the average NPS lab cost $719 +/- $1,087, $p < 0.0001$. The average 6-month per member per month (PMPM) total cost was $11,535 +/- $9,168 among those who underwent BPS compared to $20,039 +/-19,642 in those who underwent NPS. This difference of $8,504 was statistically significant, $p = 0.0022$. **Conclusions:** BPS has been shown to optimize treatments in patients with lung cancer. These initial results of claims suggest that while lung cancer patients undergoing BPS have higher total sequencing costs than those undergoing NPS, BPS significantly reduces overall total cost of lung cancer care. Identifying the broader genomic landscape of a patient's tumor earlier will empower oncology providers and lung cancer patients with information to make timely, precise treatment decisions that are ultimately more cost effective. Research Sponsor: CVS Health.

Hospitalization for complications due to systemic therapy in the United States. *First Author: Muni Rubens, Miami Cancer Institute Baptist Health South Florida, Miami, FL*

Background: Management of complications of systemic therapy for cancer involves significant healthcare burden for both patients and healthcare system. Aim of this study is to estimate trends as well as burden associated with these hospitalizations, using a nationally representative data. **Methods:** National Inpatient Sample data during 2005-2016 was used to identify complications of systemic therapy using ICD-9 and ICD-10 external cause of injury codes. Primary outcome was hospitalization rate while secondary outcomes were cost and in-hospital mortality related to these complications. **Results:** There were 443,222,223 hospitalizations recorded during the study period, of which 2,419,722 were due to complications of systemic therapy. The average annual percentage change of these hospitalizations was 8.1%, compared to -0.5% for general hospitalizations. The 3 most common causes for hospitalization were anemia (12.8%), neutropenia (10.8%), and sepsis (7.8%). During the study period, hospitalization rates had highest relative increases for sepsis (1.9 fold) and acute kidney injury (1.6 fold) and highest relative decrease for dehydration (0.21 fold) and fever of unknown origin (0.35 fold). Complications responsible for highest costs per hospitalization were sepsis ($16,834), acute kidney injury ($13,172), and pneumonia ($13,040). Leading causes of in-hospital mortality associated with systemic therapy were sepsis (15.8%), pneumonia (7.6%), and acute kidney injury (7.0%). **Conclusions:** During 2005-2016, hospitalization rates for systemic therapy complications increased by an annual rate of 8.1%, with anemia, neutropenia, and sepsis as the most common complications requiring hospitalization. Initiatives such as rule OP-35 by the Centers for Medicare and Medicaid Service, improving access and providing coordinated care, early identification and management of symptoms, and expanding urgent care access could decrease these hospitalizations and the burden on healthcare. Research Sponsor: None.

Number of hospitalizations, mortality, and cost for top 8 complications of systemic therapy.

Diagnosis	Number of hospitalizations (%)	Mortality %	Total Charges in Billions USD
Anemia	309,724 (12.8%)	2.8%	12,024
Neutropenia	261,330 (10.8%)	1.6%	9,091
Sepsis	188,738 (7.8%)	15.8%	16,834
Pneumonia	106,468 (4.4%)	7.6%	13,040
Acute kidney injury	87,110 (3.6%)	7.0%	13,172
Nausea with vomiting	77,431 (3.2%)	0.70%	6,059
Dehydration	72,592 (3.0%)	2.8%	6,351
Urinary tract infection	31,459 (1.3%)	1.5%	8460

7079 Poster Session (Board #351), Fri, 8:00 AM-11:00 AM

A cost analysis of managing cancer-related pain among hospitalized US cancer patients. *First Author: Olatunji B. Alese, Winship Cancer Institute, Atlanta, GA*

Background: Pain is a common symptom of cancer, affecting patients' function and quality of life. It is also a common cause of hospitalization for cancer patients. The aim of this study was to evaluate the cost of in-hospital pain management among US cancer patients. **Methods:** A retrospective analysis of data from all US hospitals that contributed to the National Inpatient Sample for 2011-2015 was conducted. All cancer patients admitted for pain management were included in the analysis. Main outcomes were factors significantly associated with hospital length of stay, total charge per hospital stay, and in-hospital mortality. Weighted chi-square test was used for categorical covariates and univariate analysis was performed using a logistic model. **Results:** 122,776 patient discharges were identified. Mean age was 59.3 years and 52.3% were female. 65.9% stayed in the hospital for longer than 72 hours, with a median total hospital charge of $48,156. Conversely, the median total hospital charge for those spending less than 72 hours on admission was $15,966. Median total charge per hospital stay was similar among insured and uninsured/self-pay patients ($32,879 vs. $32,323; p=0.013), but higher in patients without metastatic disease ($33,315 vs. $29,369; $p<0.001$). It was also higher in those with the highest income quartile when compared with lowest income patients ($38,223 vs. $30,047; $p<0.001$). Co-morbid medical illnesses were more prevalent in those with longer hospital stay (15 vs. 12; $p<0.001$) and the overall in-hospital mortality rate was 8.2%. There was no significant difference in median total hospital charges between those who died in, or those discharged from the hospital ($33,746 vs. $32,795; $p<0.001$). On multivariate analyses, gender, race, insurance status, diagnosis of metastatic cancer, age, number of co-morbid medical illnesses, year of diagnosis, and median income were significant predictors of length of stay. Race, insurance payor, metastatic cancer, age, and number of co-morbid medical illnesses were significant predictors of total hospital charges, after adjusting for other covariates. **Conclusions:** In-patient pain management of cancer patients is associated with significant health care costs. Optimization of outpatient pain management strategies could significantly lower the cost of care for cancer. Research Sponsor: None.

7080 Poster Session (Board #352), Fri, 8:00 AM-11:00 AM

Patient-reported benefit from proposed interventions to reduce financial hardship during cancer treatment. *First Author: Emeline Aviki, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Awareness of cancer patients' financial toxicity (FT) has increased substantially over the past decade; however, interventions to minimize financial burden remain underdeveloped and understudied. This survey-based study explores patient beliefs on which potential mitigating strategies could improve their financial hardship during cancer treatment. **Methods:** Interviewer-administered surveys were conducted with consecutive patients in an outpatient, urban, private academic Gynecologic Cancer clinic waiting room for 2 weeks in August 2019. The survey items included patient demographics, disease characteristics, the Comprehensive Score for Financial Toxicity (COST) tool (validated measure of FT with score 0-44; lower scores indicate worse FT), assessment of cost-coping strategies, and patient-reported anticipated benefit from described potential interventions (items that were feasible and relevant to implement in clinic). **Results:** Of 101 patients who initiated the survey, 87 (86%) completed it and were included in this analysis. The median age was 66 (range, 32-87). Thirty-eight patients (44%) had ovarian, 29 (33%) uterine, 5 (6%) cervical, and 15 (17%) an "other" gynecologic cancer. The median COST score was 32 (range, 6-44). Twenty-nine patients (33%) had COST scores $\leq$25 and 16 (18%) had COST scores $\leq$18. The most frequent cost-coping strategy reported was reducing leisure activities (n = 36, 41%) and using savings to pay for medical bills (n = 34, 39%). Six patients (7%) reported not taking a prescribed medication in the past 12 months due to the inability to pay and 0 reported skipping a recommended imaging study. When it came to interventions patients anticipated would improve their current financial hardships, 34 (39%) indicated access to transportation assistance to and from appointments, 31 (36%) said "knowing up front how much I'm going to have to pay for my healthcare", 29 (33%) indicated "minimizing wait time associated with appointments, which keeps me away from work", and 22 (25%) indicated "access to free food during/around appointments and treatments". Only 26 (30%) noted they were not experiencing financial hardship. **Conclusions:** For an outpatient population of gynecologic cancer patients, several focused, feasible interventions could be implemented to potentially decrease patient FT. Our study can help health care providers in the design of interventions to create meaningful improvements in patient financial burden. Next steps should assess the impact of targeted interventions on patient outcomes. Research Sponsor: National Cancer Institute P30 CA008748, Other Government Agency, New York Community Trust.

7081 Poster Session (Board #353), Fri, 8:00 AM-11:00 AM

Health plan expenditures young adults with newly-diagnosed Hodgkin lymphoma (HL) by care at NCI-designated comprehensive cancer centers (CCC) vs. other treatment sites (non-CCC). *First Author: Julie Anna Wolfson, City of Hope, Duarte, CA*

Background: Patients diagnosed with HL between 22-39y have worse outcomes than younger patients ($\leq$21y); we previously reported that treatment at a CCC mitigates these disparities [Wolfson, Leukemia 2017]. While there is general consensus that CCC care is expensive, expenditures for managing young adults with HL in CCC vs. non-CCC are not known. **Methods:** Cancer-related expenditures were examined in HL patients diagnosed between 2001-2014 at age 22-39y and treated at CCC and non-CCC sites using commercial insurance claims data (OptumLabs Data Warehouse). Multivariable generalized linear models with log link modeled average monthly health plan paid expenditures, adjusting for sociodemographics, stage, adverse events, pre-existing comorbidities, and diagnostic era. **Results:** Of the 1501 HL patients, 33% (n = 489) were treated at a CCC. Patients treated at CCC vs. non-CCC did not differ with respect to race, sex, income, diagnostic era or comorbidities ($p\geq0.3$). Mean duration of enrollment was longer in CCC than non-CCC (25 vs. 23 mos; $p < 0.001$) patients. *During the first year after HL diagnosis*, total average monthly expenditures were higher in CCC ($9,111) than non-CCC ($7,834, p = 0.001), including those related to inpatient (CCC: $1,790 vs. non-CCC: $1,011; p = 0.001) and outpatient (CCC: $6,971 vs. non-CCC: $6,487; p = 0.001) expenditures. The higher CCC expenditures were associated with higher monthly rates of inpatient admissions (IRR = 1.3, p = 0.001) and outpatient visits (IRR = 1.1, p = 0.02) at CCC. Rates of chemotherapy-related inpatient admissions were higher (IRR = 2.3, p = 0.001) in CCC than non-CCC patients, while outpatient chemotherapy visit rates were lower (IRR = 0.9, p = 0.001) in CCC. *During Years 2-3*, total average monthly expenditures were higher in CCC ($19,259) than non-CCC ($4,145, p = 0.002) patients. Outpatient expenditures were higher in CCC ($10,164) vs. non-CCC ($2,901, p = 0.001), with higher monthly outpatient visit rates (IRR = 1.7, p = 0.001) at CCC. **Conclusions:** Inpatient and outpatient cancer-related expenditures in young adults with HL were higher at CCC than non-CCCs. Higher outpatient expenditures at CCC were associated with only higher monthly visit rates. Higher inpatient expenditures were in the setting of higher admission rates, including those related to chemotherapy. Additional work is necessary to understand whether these higher expenditures at CCC are related to supportive care and/or differences in facility structure and billing practices. 7082 Poster Session (Board #354), Fri, 8:00 AM-11:00 AM

Patient-reported out-of-pocket costs and financial toxicity during early-phase oncology clinical trials. *First Author: Ryan Huey, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clinical trials are an important therapeutic option for cancer patients (pts). Although financial burden in cancer treatment is well-documented, the financial burden associated with clinical trials is not well understood, especially for pts with lower income. **Methods:** We conducted a survey regarding economic burden and financial toxicity in cancer pts who had been on Phase I clinical trials for ≥1 month. Financial Toxicity Score (FTS) was assessed using the validated COmprehensive Score for Financial Toxicity (COST) survey (scale 0-44, lower scores indicate worse toxicity). Pts also reported monthly out-of-pocket (OOP) medical and non-medical expenses. We applied multivariable logistic regression to analyze risk of financial toxicity, and unanticipated expenses. **Results:** Early-phase clinical trial pts (N = 213, median age = 59y; 59% female; 74% White, 45% w/ annual income ≤$60K; 50% lived > 300 miles from the clinic; 40% required air travel; 37% had Medicare, 54% had employer sponsored insurance) had a median FTS of 20, with interquartile range of 12. Median monthly OOP costs for non-medical expenses was $1075, and for medical expenses was $475. Median total monthly OOP costs was $1750. 55% and 64% of pts reported that actual medical and non-medical expenses were higher than expected, respectively. Worse financial toxicity (≤ median FTS) in pts was associated with yearly household income < $60K (OR: 2.7, P = 0.008), having medical costs higher than expected (OR: 3.2, P = 0.024), participation on ≥1 Phase I clinical trial prior to their current trial (OR: 2.2, P = 0.028), and living > 100 miles away from the clinical trials hospital (OR: 2.3, P = 0.043). However, 34% of pts who lived > 100 miles away received partial/full reimbursement of clinical trial-related travel costs from study sponsor/other/insurance. Racial/ethnic minority (OR: 2.6, P = 0.008) and pts who were unemployed or not working outside the home (OR: 2.4, P = 0.023) were more likely to report that actual medical costs were much higher than expected. 53% of pts used savings and 18% retirement accounts to pay for treatment. **Conclusions:** Among cancer pts participating on clinical trials, economic burden is high, and most of pts' OOP costs were on non-medical expenses. Financial toxicity is disproportionally higher in pts with lower income. OOP costs can be substantial and are often unexpected for pts. Furthermore, prior participation in ≥1 Phase I clinical trial and living far away from the clinical trials hospital seem to increase risk of financial toxicity. Research Sponsor: Institutional Funds, Conquer Cancer Foundation of the American Society of Clinical Oncology.

7083 Poster Session (Board #355), Fri, 8:00 AM-11:00 AM

Financial burden of discarded weight-based cancer drugs to payers and patients in private insurance market. *First Author: Ya-Chen T. Shih, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Studies assessing wastage of discarded weight (WT)-based cancer drugs (can-RX) derived their estimates from Medicare Average Sales Prices + 6% mark-up. With higher mark-ups, financial impact of discarded can-RX can be much higher in private insurance market. In addition, no study has examined the financial burden for patients(pts) even though they are subject to out-of-pocket payment (OOP) of the discarded RX. This study fills in these important knowledge gaps. **Methods:** We obtained the list of WT-based can-RX from the 2017 Centers for Medicare and Medicaid Services Part B Discarded Drug Units Report and gathered information on package size and recommended dose from IBM Micromedex. We identified pts who received WT-based can-RX from 2017 MarketScan data and linked to MarketScan Health Risk Assessment to obtain WT and height for a subset of pts. For each claim, we derived the recommended dose based on pt's RX and his/her WT or body surface area (calculated from WT and height) and estimated the % of discarded dose. We quantified OOP as the sum of deductible, copayment, and coinsurance, and classified pts' insurance by their enrollment to high-deductible (HD) plans. For claim-level analysis, we applied beta regression (for fractional outcomes) to determine factors associated with % discarded while accounting for within pts correlations. Covariates were age group (grp) (< 50, 50-59, > = 60), WT grp (< 150, 150-199, > = 200lb), HD plan (yes/no), region, cancer type, and can-RX. For pt-level analysis, we calculated the amount payers and pts spent on all and discarded can-RX in 2017 and compared OOP b/t pts in HD and non-HD plans. **Results:** Of 27,883 claims of WT-based can-RX, the median discarded % was 0.10 (mean 0.19, SD = 0.21). In addition to can-RX and cancer type, significantly higher discarded % was found in the lowest WT grp (0.03, P < 0.001, vs. WT > = 200lb) and significantly lower % was found in the middle age grp (-0.01, P = 0.02 vs. age < 50). Of 1963 pts, 778 (40%) had HD plans. Payments by payers (NETPAY) and pts (OOP) for total and discarded can-RX and the comparison b/t HD and non-HD plans are shown in Table. **Conclusions:** Payers incurred substantial financial burden from discarded can-RX. While OOP costs were modest for most privately insured pts, 5.3% of pts (~8% in HD plans) paid > $400 for discarded RX. Research Sponsor: U.S. National Institutes of Health.

	Total	HD	non-HD	P value
Total				
median NETPAY	$12620	$13185	$12240	.7
mean OOP*	517	700	397	< .01
Discarded				
median NETPAY	1839	2087	1737	.1
mean OOP*	73	98	57	< .01
OOP: 90th percentile	218	331	177	< .01
OOP: 90th percentile	407	509	302	< .01
OOP > = $400	5.3%	7.7%	3.6%	< .01

* median OOP = 0

Cost implications of clinical trial (CT) participation in metastatic non-small cell lung cancer (NSCLC). *First Author: Cristina Merkhofer, University of Washington, Seattle, WA*

Background: To assess the value of CTs in advanced NSCLC from the payer perspective, we compared insurance-related total direct medical costs for NSCLC patients who enrolled in CTs vs. those who did not. **Methods:** After linking electronic health records with tumor registry and claims data, we identified 101 patients with metastatic NSCLC diagnosed between 1/1/2007 and 12/31/2015 and treated at the Seattle Cancer Care Alliance. Eligibility criteria included 60-day minimum survival, claims for ≥ 1 anti-cancer drug within 180 days of diagnosis and insurance enrollment for the first 12 months after diagnosis. We abstracted patient sociodemographic, disease and treatment data, and obtained death dates from the Washington State Cancer Registry, censoring patients alive on 3/7/2019.We used the Kaplan-Meier sample-average (KMSA) estimator with bootstrapped 95% confidence intervals to describe direct medical costs and compared costs in CT enrollees vs. non-enrollees by applying a generalized linear model (Gamma distribution, log link) adjusted for confounding covariates. **Results:** Of 101 patients, 39 (39%) enrolled in CTs. Compared with non-enrollees, CT enrollees were younger (mean age 61.6 vs. 66.5 years), female (67% vs. 47%), Asian (18% vs. 11%), never smokers (41% vs.32%), had commercial insurance (44% vs. 35%), resided in metropolitan areas (90% vs. 79%) and had a higher median income ($81,149 vs. $76,844). Table shows KMSA estimates of total direct medical costs and adjusted mean lifetime total direct medical costs by CT participation. After adjusting for sex, smoking status, residence, income, insurance payer, ECOG and mutation status, CT enrollment was associated with an increase in lifetime total direct medical costs compared with no enrollment (adjusted cost ratio=1.39; 95% CI: 1.01, 1.90; p=0.043). **Conclusions:** CT participation is associated with increased total direct medical costs in patients with metastatic NSCLC. Our results may inform partnerships between trial sponsors, oncology centers and payers to sustain treatment innovation through CTs. Research Sponsor: Seattle Cancer Care Alliance Thoracic Oncology Research Donation Funds.

Total direct medical costs by CT participation.

Time after diagnosis	Non-CT participant KMSA estimates (95% CI)	CT participant KMSA estimates (95% CI)
0-12 months	$97,441 ($87,920, $105,823)	$113,425 ($103,243, $123,657)
> 12 months	$79,215 ($73,127, $84,931)	$175,685 ($162,688, $188,450)
	Non-CT participant adjusted mean total direct medical costs (95% CI)	**CT participant adjusted mean total direct medical costs (95% CI)**
Lifetime	$223,433 ($178,479, $268,387)	$309,629 ($231,891, $387,367)

7085 Poster Session (Board #357), Fri, 8:00 AM-11:00 AM

Cost-effectiveness analysis of stereotactic ablative radiotherapy in patients with oligometastatic cancer. *First Author: Abhishek Kumar, UC San Diego Health System, La Jolla, CA*

Background: The SABR-COMET randomized clinical trial found that stereotactic ablative radiotherapy (SABR) improved outcomes among cancer patients with oligometastatic disease. Yet, the cost of SABR along with the large number of patients with oligometastatic disease raises the important question of value. This study sought to evaluate the cost-effectiveness of SABR compared to standard therapy among cancer patients with oligometastatic disease. **Methods:** We constructed a Markov model to simulate treatment with stereotactic ablative radiotherapy or standard therapy among patients with oligometastatic cancers. The model derived transition probabilities from clinical trial data to estimate risks of toxicity, disease progression and survival. Healthcare costs and health utilities were estimated from the literature. Cost-effectiveness was estimated with an incremental cost-effectiveness ratio (ICER) defined as dollars per quality-adjusted life year (QALY), with an ICER less than $100,000/QALY considered cost-effective. One-way and probabilistic sensitivity analyses were used to examine model uncertainty. **Results:** The addition of SABR increased total costs by $54,279 and improved effectiveness by 1.20 QALYs compared with standard therapy, leading to an ICER of $45,162/QALY. The model was sensitive to assumptions about tumor progression, though the model was not sensitive to assumptions about survival or cost of treatment. The cost of SABR would need to increase approximately six-fold from $12,241 to $78,151 before SABR becomes cost-ineffective. Probabilistic sensitivity analyses demonstrated that SABR was the cost-effective treatment option 97.2% of the time. **Conclusions:** The addition of SABR increased costs and improved quality adjusted survival, overall leading to a cost-effective treatment strategy for patients with oligometastatic cancer. Research Sponsor: U.S. National Institutes of Health.

TPS7086 Poster Session (Board #358), Fri, 8:00 AM-11:00 AM

Open-label, randomized, multicenter, phase IV trial comparing parenteral nutrition using multi-chamber bags (Eurotubes) versus traditional 2/3-chamber bags in subjects with metastatic or locally advanced inoperable cancer requiring parenteral nutrition: The PEKANNUSS trial of the AIO. *First Author: Georg Martin Haag, Department of Medical Oncology, National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany*

Background: Approximately 50% of all cancer subjects suffer from cancer anorexia-cachexia syndrome accompanied by an inadequate food intake and predicting mortality, poor therapeutic response, diminished functional capacity, and reduced QoL. Especially in the advanced stages, parenteral nutrition (PN) is often required and accompanied by an increased risk of blood stream infections associated with increased mortality and other serious medical conditions such as sepsis. Furthermore, the switch from oral food intake to PN changes the patient's everyday life leading to reduced autonomy and flexibility (e.g. due to dependency on home nursing services). This study aims at evaluating the incidence of catheter-related infections (CRI) and the frequency of self-administered parenteral nutrition at home (HPN) in patients receiving standard PN via A) traditional two- or three-chamber bags (often requiring addition of vitamins and/or medications by home care service) or B). the multi-chamber bags Eurotubes (minimizing additional supplements and enabling self-administration by patients at home). In addition, one group of patients will receive low glucose HPN via Eurotubes to investigate a possible benefit on clinical outcome. **Methods:** This is an open-label, randomized, multicenter, investigator-initiated, phase IV trial. Overall, 350 patients with inoperable metastatic or locally advanced solid tumors who have an indication for parenteral nutrition will be enrolled. Patients will be randomized 1:1:1 ratio to Arm A (Standard PN using Eurotubes) or Arm B (Standard PN using 2/3-chamber bags), or to Arm A-1 (low glucose using Eurotubes). Patients will be assessed (physical exam, ECOG, weight, QoL, lab tests, AEs, HPN documentation) every 4 weeks during the 12 months HPN treatment period. Co-primary endpoints are incidence of CRI and patient autonomy (rate of self-administered PN at home). Secondary endpoints comprise weight change, change in albumin and CRP levels, overall survival, QoL, and safety. Recruitment has just started; first patient in was on February 5th, 2020. Clinical trial information: NCT04105777. Research Sponsor: Eurozyto Holding GmbH.

TPS7087 Poster Session (Board #359), Fri, 8:00 AM-11:00 AM

Head-to-head comparison of the non-G-CSF small molecule single agent (SA) plinabulin with SA pegfilgrastim for the prevention of docetaxel chemotherapy (chemo)-induced neutropenia (CIN) in the protective-1 trial. *First Author: Douglas W. Blayney, Stanford University, Stanford, CA*

Background: Plinabulin (Plin) is a small molecule with anti-cancer activity and CIN effects. The Phase (Ph) 2 clinical trial NPI-2358-101 (NCT00630110) evaluated Plin at 20 or 30 mg/m2 on Day (D) 1 and D8) plus D1 Docetaxel (Doc) 75 mg/m2 combination versus D1 Doc alone in patients (pts) with non-small cell lung cancer(NSCLC). In a large ($>$ 70%) subset of pts with a measurable lung lesion in the lung (per RECIST 1.1) receiving 30 mg/m2 Plin + Doc (n = 38), mOS was 4.6 months longer vs Doc alone (n = 38) (Mohanlal ASCO-SITC 2018). An unexpected post-hoc finding was a CIN benefit with adding at 20 or 30 mg/m2 Plin to Doc: 33% of pts in the Doc arm had grade 4 neutropenia, whereas in the Plin +Doc group 4% of pts ($P < 0.0003$) (Blayney ASH 2018). Plin boost the number the number of hematopoietic/progenitor cells in bone marrow. We subsequently initiated two global Ph3 programs with Plin: 1. A Ph 3 trial confirming its anticancer activity in NSCLC (study BPI-2358-103; NCT02504489; this trial is ongoing) and 2. An evaluation of Plin for CIN prevention through studies BPI-2358-105 (NCT03102606; PROTECTIVE-1), and study 106 (NCT03294577; PROTECTIVE-2). We previously reported from the Ph 2 portion of study 105, that SA Plin and Pegfigrastim (Peg) had comparable protection against CIN induced by Doc, however in contrast to Peg, Plin did not cause bone pain or thrombocytopenia (Blayney IASLC 2018, ESMO 2018). Plin is given by 30 min IV infusion on the same day of Chemo, 30 min after Chemo. The Ph3 portion of Study 105 in ongoing. **Methods:** In the Ph 3 portion of PROTECTIVE-1, pts with NSCLC, HRPC or BC are randomized (1:1) to either Plin 40 mg (over 30 minutes on D1; n = 75) or Peg 6mg (on D2, n = 75), and the primary endpoint is Duration of Severe Neutropenia (DSN). Plin 20 mg/m2 is similar to a 40 mg fixed dose. Absolute neutrophil counts (ANC) is determined on D 0, 1,2,3,6,8,9,10, 15 in Cycle 1 The trial aims to demonstrate non-inferiority of Plin vs Peg. Non-inferiority will be declared if the non-inferiority margin (NIM) of 0.65 day will be met, which NIM is more conservative than the 1 day NIM, typically employed for G-CSG biosimilar trials. Pts should have at least 1 risk factor as per NCCN guidelines.The trial is double-blinded to enable reliable PRO, Bone Pain and QoL assessments through validated questionnaires (EQ-5D-5L; EORTC QLQ-C30; Wang Baker Faces Pain Rating Scale). Following an Interim Analysis, the trial will continue without modifications. Clinical trial information: NCT03102606. Research Sponsor: BeyondSpring Pharmaceuticals Inc.

TPS7088 Poster Session (Board #360), Fri, 8:00 AM-11:00 AM

The FLEX real-world data platform explores new gene expression profiles and investigator-initiated protocols in early stage breast cancer. *First Author: Nina D'Abreo, NYU Winthrop Hospital, Mineola, NY*

Background: Genomic expression profiles have enabled the classification of breast cancers into molecular sub-types and provide prognostic information about the metastatic potential of the tumor, both of which have implications for the personalized treatment of breast cancer beyond clinical and pathological features. However, to precisely stratify tumors into actionable subgroups, full genome expression data should be combined with comprehensive clinical information. The FLEX Registry aims to aggregate a large, real-world dataset, which will enable discovery of novel genomic profiles, particularly for patient subsets that are underrepresented in traditional clinical trials and will contribute to improved precision in the management of breast cancer. **Methods:** The FLEX Registry (NCT03053193) is a multicenter, prospective, observational trial for patients with Stage I, II, and III breast cancer. Patients with stage I-III breast cancer who receive the 70-gene signature risk of recurrence test, with or without the 80-gene signature molecular sub-typing test, on a primary tumor are eligible for enrollment. The primary objective of FLEX is to create a large scale, population-based registry that links complete clinical data with full genome expression data to elucidate new prognostic and/or predictive gene associations in a real-world setting. The FLEX Registry employs a shared study infrastructure to develop and investigate hypotheses for targeted subset analyses and/or clinical trials based on full genome expression data. The adaptable protocol is designed to be amended with the inclusion of targeted sub-studies. Patients enrolled in the initial study are eligible for inclusion in sub-studies for which they meet all eligibility criteria and additional consent is not required. Data will be collected on patients from diagnosis through 10 years of follow-up and any necessary additional clinical data will be collected as specified in the appendix protocols. Target enrollment is a minimum of 10,000 patients; $>$4,000 patients have enrolled since April 2017 at more than 80 sites, including seven National Cancer Institute-designated comprehensive cancer centers. The FLEX collaborative platform enables participating investigators the opportunity to author their own sub-study protocols, as approved by the FLEX Steering Committee. Fifteen sub-studies have been approved for investigation within the FLEX Registry. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Iinc.

7500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase Ib/II study of the IDH1-mutant inhibitor ivosidenib with the BCL2 inhibitor venetoclax +/- azacitidine in IDH1-mutated hematologic malignancies. *First Author: Curtis Andrew Lachowiez, M.D. Anderson Cancer Center, Houston, TX*

Background: Mutations in the isocitrate dehydrogenase-1 gene (*IDH1*) result in myeloid differentiation arrest and accumulation of the oncometabolite 2-hydroxyglutarate (2-HG), promoting leukemogenesis. We report a primary safety and efficacy analysis of the IDH1 inhibitor ivosidenib (IVO; 500 mg PO daily D15-continous) combined with venetoclax (VEN; D1-14 per 28-day cycle), with and without azacitidine (AZA; 75mg/m^2 D1-7). **Methods:** Eligible patients age ≥18 with *IDH1* mutated myeloid malignancies (high-risk MDS and AML) enrolled into one of three successive cohorts (Cohort 1: IVO+VEN 400 mg, Cohort 2: IVO+VEN 800 mg, Cohort 3: IVO+VEN 400 mg+AZA). Primary endpoints include safety and tolerability and overall response rate (ORR) by revised IWG criteria. Key secondary endpoints include survival endpoints and PK correlates. **Results:** 19 patients (median age 68) enrolled, 17 with AML: 9 relapsed/refractory AML (R/R; median 1 prior line of therapy), 5 treatment naïve AML, and 3 HMA-failure MDS with secondary AML. Two patients had high-risk MDS. ELN risk was favorable, intermediate, and adverse risk in 37%, 15%, and 47%. Co-mutations included *NPM1* (37%), chromatin-spliceosome (32%), methylation (16%), and RAS pathway (21%). Adverse events of special interest included IDH differentiation syndrome (n=4, grade > 3 in 1) and tumor lysis syndrome (TLS; n=2), including one grade 3 TLS event in a *NPM1*$^+$ patient (successfully managed without hemodialysis). In evaluable patients (n=18), composite complete remission (CRc: CR+CR$_i$+CR$_h$) rates were 78% overall (treatment naive: 100%, R/R: 75%), and 67%, 100%, and 67% by cohort (median time to best response: 2 months). 7 (50%) patients achieving CRc were also MRD negative by flow cytometry. 1 patient had HI without CR/CR$_i$ and 1 had a MLFS. 9 (50%) patients remain on study, 3 (17%) proceeded to SCT in CR, 2 were non-responders, and 5 (22%) experienced progressive disease following CR$_c$ occurring after a median of 3 months. After a median follow up of 3.5 months, median OS was not reached in treatment naïve patients, and 9.7 months in R/R patients. **Conclusions:** IVO+VEN +AZA therapy is well tolerated and highly effective for patients with *IDH1* mutated AML. Follow up and accrual is ongoing to better define duration and biomarkers of response. Clinical trial information: NCT03471260. Research Sponsor: Agios, AbbVie, Other Foundation.

7501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Effect of enasidenib (ENA) plus azacitidine (AZA) on complete remission and overall response versus AZA monotherapy in mutant-*IDH2* (*mIDH2*) newly diagnosed acute myeloid leukemia (ND-AML). *First Author: Courtney Denton Dinardo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ENA and AZA each induce overall response rates (ORR) of ~30% and complete remission (CR) rates of ~20% in ND-AML. *In vitro*, combining ENA + AZA enhances cell differentiation. We report results of the phase II portion of an open-label, randomized phase I/II study of ENA + AZA (E+A) vs. AZA monotherapy (A) in patients (pts) with m*IDH2* ND-AML (NCT02677922). **Methods:** Pts age ≥ 18 years ineligible for intensive chemotherapy, with ECOG PS ≤ 2 and intermediate- or poor-risk cytogenetics, were randomized 2:1 to E+A or A in 28-day (d) cycles. All pts received SC AZA 75 mg/m^2/d x 7 d/cycle; pts randomized to E+A also received ENA 100 mg QD. The primary endpoint was ORR (CR, CR with incomplete recovery, partial remission, morphologic leukemia-free state). Other endpoints include duration of response (DOR), overall and event-free survival (OS, EFS), safety, and m*IDH2* VAF. **Results:** 101 pts received E+A (n = 68) or A (n = 33). Median age was 75 years (5785); most pts (83%) had intermediate-risk cytogenetics. 21 pts in the E+A arm and 1 in the A arm were ongoing at data cutoff (Aug 2019). Most common reason for discontinuation was disease progression (E+A 31%, A 52%). Median number Tx cycles was 10 (126) in the E+A arm and 6 (128) in the A arm. 7 pts (21%) in the A arm received subsequent Tx with ENA. ORR, CR rate and DOR were significantly improved with E+A *vs.* A (Table). Median OS was 22 mo in both arms (HR 0.99 [95%CI 0.52, 1.87]; $P = 0.97$). Median EFS was 17.2 and 10.8 mo in the E+A and A arms, respectively (HR 0.59 [95%CI 0.30, 1.17]; $P = 0.13$). Maximal m*IDH2* VAF change from BL was 83.4% with E+A *vs.* 17.7% with A ($P < 0.01$). No baseline co-mutation predicted primary resistance. Common Tx-related grade 34 AEs in the E+A arm were thrombocytopenia (37%), neutropenia (35%), anemia (19%), and febrile neutropenia (15%); these occurred in 19%, 22%, 22%, and 16% in the A arm. Grade 34 infections occurred in 18% of E+A pts and 31% of A pts. IDH differentiation syndrome occurred in 12 pts (18%) in the E+A arm. 5 E+A pts (7%) and 1 A pt (3%) died in the first 60 d. **Conclusions:** Combining ENA + AZA resulted in significantly improved response rates and durations, and was generally well-tolerated in older patients with m*IDH2* ND-AML. The impact of subsequent Tx on OS/EFS and new translational data will be presented at the meeting. Clinical trial information: NCT02677922. Research Sponsor: BMS.

7502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Interim analysis (IA) of OPTIC: A dose-ranging study of three ponatinib (PON) starting doses. *First Author: Jorge E. Cortes, Georgia Cancer Center, Augusta, GA*

Background: In PACE (NCT01207440) heavily pretreated patients (pts) with chronic-phase CML (CP-CML) had deep, lasting responses to PON; long-term follow-up showed increasing rates of arterial occlusive events (AOEs). We present IA results from OPTIC (NCT02467270), evaluating the association between PON exposure, efficacy, and safety, and response-based dose reduction in pts with CP-CML. **Methods:** This ongoing, multicenter, randomized phase 2 trial enrolled pts with CP-CML resistant or intolerant to ≥2 TKIs or with a T315I mutation to receive PON at a starting dose of 45 mg (cohort A), 30 mg (B), and 15 mg (C) qd. Doses were reduced to 15 mg qd on achievement of ≤1% BCR-ABL1^{IS} in A/B. Primary endpoint: 12 mo ≤1% BCR-ABL1^{IS}; secondary endpoints include cytogenetic and molecular response and AOE, VTE, and TEAE rates. Results are descriptive at this IA and will be inferential by adjusting multiplicity across 3 cohorts at final analysis. **Results:** 283 pts were randomized (A/B/C: n = 94/95/94); median age 48 y (18–81 y). 26% had hypertension history; 2/43/55% received 1/2/≥3 TKIs; 40% had ≥1 baseline (BL) mutations, with 23% T315I. At IA data cutoff (20 Jul 2019), 162 pts (57%; n = 57/51/54) remained on study treatment. Among 282 pts in the safety population, median duration of exposure was ≈1 y (A/B/C, 12.9/11.2/11.0 mo). At 12 mo, 39% (95% CI, 27.6, 50.6), 27% (17.6, 39.1), and 26% (16.5, 38.6) in A, B, and C, respectively, achieved ≤1% BCR-ABL1^{IS}. Additional efficacy in Table. Dose reductions due to efficacy (A/B): 35/21%. Most common TEAEs (any grade/≥3): thrombocytopenia 39/27%, neutropenia 25/17%. AOEs/serious AOEs were reported by (A, B, C) 5%/2%, 4%/3%, and 1%/0%. Dose reductions due to TEAEs: (A/B/C): 44/31/28%; discontinuations due to TEAEs: 18/15/14%. There were 4 (1.4%) on-study deaths; A, sudden death, n = 2; C, pneumonia, n = 2; no deaths were due to AOEs. Clinical trial information: NCT01207440. **Conclusions:** OPTIC IA shows a trend toward dose-dependent efficacy and safety and may provide a refined understanding of the PON benefit:risk profile and its relation to dose. Data from longer follow-up may support an alternate dosing regimen for pts with CP-CML. Research Sponsor: ARIAD Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Month 12 BCR-ABL1^{IS},[a] n (%)	45 mg n = 75	30 mg n = 73	15 mg n = 68
≤10%	38 (50.7)	31 (42.5)	30 (44.1)
≤1%	29 (38.7)	20 (27.4)	18 (26.5)
≤0.1% (MMR)	11 (14.7)	13 (17.8)	13 (19.1)

MMR, major molecular response.
[a]Includes all pts who are randomized and with measurable BCR-ABL1^{IS} at BL. Those still on treatment who have not reached 12 mo were excluded. As the primary endpoint was ≤1% BCR-ABL1^{IS} at 12 mo, pts who were already ≤1% BCR-ABL1^{IS} at BL (n = 3 pts; A, 2; C, 1) were not considered responders.

7503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Development and validation of a pediatric disease risk index for allogeneic hematopoietic cell transplantation. *First Author: Muna Qayed, Emory University, Atlanta, GA*

Background: Characteristics such as disease, disease status and cytogenetic abnormalities impact relapse and survival after transplantation for acute myeloid (AML) and acute lymphoblastic (ALL) leukemia. In adults, these attributes were used to derive the disease risk index for survival. Thus, the current analysis sought to develop and validate a pediatric disease risk index (p-DRI). **Methods:** Eligible were patients aged <18 years with AML (n=1135) and ALL (n=1228) transplanted between 2008 and 2017 in the United States. Separate analyses were performed for AML and ALL. Patients were randomly assigned (1:1) to a training and validation cohort. Cox proportional hazards model with stepwise selection was used to select significant variables (2-sided p<0.05). The primary outcome was leukemia-free survival (LFS; relapse or death were events). Based on the magnitude of log(HR), a weighted score was assigned to each characteristic that met the level of significance and risk groups were created. **Results:** Four risk groups were identified for AML and three risk groups for ALL (Table). The 5-year probabilities of LFS for AML were 81% (68-91), 56% (51-61), 44% (39-49) and 21% (15-28) for good, intermediate, high and very high-risk groups, respectively. The 5-year probabilities of LFS for ALL were 68% (63-72), 50% (45-54) and 15% (3-34) for good, intermediate, high risk groups, respectively. **Conclusions:** This validated p-DRI successfully stratified children with AML and ALL for prognostication undergoing allogeneic transplantation. Research Sponsor: U.S. National Institutes of Health.

Post-traumatic stress symptoms in hematopoietic stem cell transplant (HCT) recipients. *First Author: Sarah Griffith, Massachusetts General Hospital, Boston, MA*

Background: Patients admitted for HCT, an intensive and potentially curative therapy for hematologic malignancies, experience a prolonged, isolating hospitalization and endure substantial physical and psychological symptom burden. However, data are limited regarding long-term post-traumatic stress (PTSD) in HCT survivors and its risk factors. **Methods:** We conducted a secondary analysis examining longitudinal data from 250 patients who underwent autologous and allogenic HCT. We used the Post-Traumatic Stress Checklist (PTSD-CL) to assess for PTSD symptoms at six months post-HCT. We used the Functional Assessment of Cancer Therapy—Bone Marrow Transplant (FACT-BMT), and the Hospital Anxiety and Depression Scale to assess quality of life (QOL), depression, and anxiety symptoms at the time of admission for HCT, at week-2 during hospitalization, and at six months post-HCT. We used multivariate regression models to assess factors associated with PTSD symptoms, modeling QOL, depression, and anxiety symptoms separately given their collinearity. **Results:** The mean age was 56.3 (SD = 13.3). The rate of clinically significant PTSD symptoms at six months post-HCT was 18.9% and these patients experienced hypervigilance (92.3%), avoidance (92.3%), and intrusion (76.9%) symptoms. Among patients without clinically significant PTSD symptoms, 24.5% and 13.7% had clinically significant hypervigilance and avoidance symptoms, respectively. Lower QOL at time of HCT admission (B = -0.04, P = 0.004), and being single (B = -3.35, P = 0.027) were associated with higher PTSD symptoms at six months post-HCT. Higher anxiety at time of HCT admission (B = 1.34, P $<$ 0.001), change in anxiety during HCT hospitalization (B = 0.59, P = 0.006), and being single (B = -3.50, P = 0.017), were associated with higher PTSD symptoms at six months. In a separate model, younger age (B = -0.13, P = 0.017), being single (B = -3.58, P = 0.018), and higher baseline depression symptoms were also associated with higher PTSD symptoms at six months (B = 0.97, P $<$ 0.001). **Conclusions:** Approximately one fifth of patients undergoing HCT experienced clinically significant PTSD symptoms at six months post-transplant. Patients' baseline QOL and psychological symptoms emerged as important predictors of their risk for PTSD at six months post-HCT. Thus, interventions to prevent and treat PTSD symptoms in HCT recipients are clearly warranted. Research Sponsor: Lymphoma and Leukemia Society.

7506 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Phase II study of pevonedistat (P) + azacitidine (A) versus A in patients (pts) with higher-risk myelodysplastic syndromes (MDS)/chronic myelomonocytic leukemia (CMML), or low-blast acute myelogenous leukemia (LB AML) (NCT02610777). *First Author: Lionel Ades, Hôpital Saint-Louis, Paris, France*

Background: P, the first and only small-molecule inhibitor of the NEDD8-activating enzyme, disrupts proteasomal degradation of select proteins and has shown promising clinical activity and good tolerability in combination with A in AML. **Methods:** 120 pts with higher-risk (Revised International Prognostic Scoring System risk $>$ 3) MDS/CMML or LB AML naïve to hypomethylating agents were randomized 1:1 to receive P 20 mg/m^2 intravenously (IV) on days (d) 1, 3, 5 + A 75 mg/m^2 (IV/subcutaneously) on d 1–5, 8, 9 (n = 58), or A alone (n = 62), in 28-d cycles until unacceptable toxicity, relapse, transformation to AML, or progression. The primary endpoint was overall survival (OS), although the study was underpowered for OS. **Results:** Baseline characteristics were generally balanced between arms. Pts received a median of 13.0 vs 8.5 cycles of P+A vs A. Median OS in the intent-to-treat (ITT) population with P+A vs A (n = 120) was 21.8 vs 19.0 mos (hazard ratio [HR] 0.80; 95% CI 0.51–1.26; *P* = .334; median follow-up 21.4 vs 19.0 mos). Subanalyses showed median OS with P+A vs A in higher-risk MDS (n = 67) of 23.9 vs 19.1 mos (HR 0.70; 95% CI 0.39–1.27; *P* = .240) and in LB AML (n = 36) of 23.6 vs 16.0 mos; HR 0.49; 95% CI 0.22–1.11; *P* = .081). Event-free survival (EFS – time from randomization to death/transformation to AML) with P+A vs A trended longer in the ITT population (median 21.0 vs 16.6 mos; HR 0.65; 95% CI 0.41–1.02; *P* = .060) and was significantly longer in higher-risk MDS (median 20.2 vs 14.8 mos; HR 0.54; 95% CI 0.29–1.00; *P* = .045). In response-evaluable pts, overall response rate was 71% (n = 39/55; 46% complete remission [CR] + CR with incomplete blood count recovery [CRi], 5% partial response [PR], 20% hematologic improvement [HI]) with P+A vs 60% (n = 32/53; 38% CR+CRi, 8% PR, 15% HI) with A. In higher-risk MDS, CR rate was 52% vs 27% (*P* = .050) with P+A vs A. Median A dose intensity was 97% vs 98% with P+A vs A. Rates of grade ≥3 adverse events were 90% vs 87% with P+A vs A; the most common were 31% vs 27% neutropenia, 26% vs 29% febrile neutropenia, 19% vs 27% anemia, and 19% vs 23% thrombocytopenia. On-study deaths occurred in 9% of P+A pts and 16% of A pts. **Conclusions:** P+A had a comparable safety profile to A alone, did not increase myelosuppression, and maintained A dose intensity. Although not statistically significant, P+A increased OS, EFS, and response rates vs A, particularly in pts with higher-risk MDS. Further evaluation of P+A vs A is ongoing in a randomized phase. Clinical trial information: NCT02610777. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

7507 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Tolerability and efficacy of the first-in-class anti-CD47 antibody magrolimab combined with azacitidine in MDS and AML patients: Phase Ib results. *First Author: David Andrew Sallman, Moffitt Cancer Center, Tampa, FL*

Background: Magrolimab (Hu5F9-G4) is an antibody blocking CD47, a macrophage immune checkpoint and don't eat me signal on cancers. It induces tumor phagocytosis and eliminates leukemia stem cells. Azacitidine (AZA) synergizes with magrolimab by inducing eat me signals on leukemic cells, enhancing phagocytosis. We report Ph1b data including a potential MDS registration cohort. **Methods:** Magrolimab+AZA was given to untreated intermediate to very high risk IPSS-R MDS and intensive chemo unfit AML patients. A magrolimab priming/intrapatient dose escalation regimen (1-30 mg/kg QW, Q2W Cycle 3+) was used. AZA was dosed 75mg/m^2 days 1-7. Efficacy was assessed by IWG 2006 (MDS) and ELN 2017 (AML) criteria. **Results:** 68 patients (39 MDS, 29 AML) with a median age of 72 were treated with magrolimab+AZA. 19% were intermediate cytogenetic risk with 68% poor risk (13% unknown). 27% were *TP53* mutant. The combo was well-tolerated with safety similar to AZA alone. Common treatment-related AEs were anemia (38%), fatigue (21%), neutropenia (19%), thrombocytopenia (18%) and infusion reaction (16%). Treatment-related febrile neutropenia was 1.5%. Only 1 patient (1.5%) discontinued due to an AE. In RBC transfusion dependent patients, 58% of MDS and 64% of AML patients became transfusion independent. 30/33 (91%) efficacy evaluable MDS patients had an objective response (42% CR, 24% marrow CR (4/8 also with HI), 3% PR, 21% HI alone, 9% SD). MDS patient responses deepened on study, with a 56% CR rate in patients with ≥ 6 mo follow-up. In AML, 16/25 (64%) responded (40% CR, 16% CRi, 4% PR, 4% MFLS, 32% SD, 4% PD). In 12 *TP53* mutant AML patients, 75% had a CR+CRi (42% CR, 33% CRi, 17% SD, 8% PD). Cytogenetic CR was seen in 35% and 50% of responding MDS and AML patients. 22% of MDS and 50% of AML patients with CR/CRi/marrow CR were MRD negative by flow cytometry. Median duration of response is not reached in either MDS or AML, including *TP53* mutant AML, with a median follow-up of 5.8, 8.8 and 9.4 mos, respectively (range: 1.9 – 16.8 mos). 91% of MDS and 100% of AML responding patients are in response at 6 mos. The 6 mo overall survival estimate is 100% in MDS and 91% in TP53 mutant AML patients. **Conclusions:** Magrolimab is a macrophage targeting immunotherapy that with AZA is well tolerated with durable efficacy in MDS, AML, particularly *TP53* mutant, a poor prognostic group. A potential registration single arm MDS cohort is ongoing (NCT03248479). ENHANCE, a randomized Ph3 MDS trial is planned. Additional patients/analyses will be reported. Funded by Forty Seven and CIRM. Clinical trial information: NCT03248479. Research Sponsor: Forty Seven, Inc., Other Government Agency

7508 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Updated results from phase I dose-escalation study of AMG 330, a bispecific T-cell engager molecule, in patients with relapsed/refractory acute myeloid leukemia (R/R AML). *First Author: Farhad Ravandi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In this open label phase 1 dose escalation study, safety, tolerability, pharmacokinetics, pharmacodynamics and preliminary efficacy of AMG 330 were evaluated in patients (pts) with R/R AML (NCT#02520427). **Methods:** AMG 330 was evaluated as a continuous IV (cIV) infusion using a 3+3 design. Response was assessed per revised IWG criteria. Each cycle (2–4 weeks duration) was followed by an infusion-free interval. Eligible pts were ≥18 y/o with $>$ 5% blasts in bone marrow and ≥1 line/s of prior therapy. **Results:** As of December 10, 2019, 55 pts (median age, 58.0 [18.0–80.0] years) were enrolled in 16 cohorts. AMG 330 was administered on 4 schedules (0–3 dose steps) prior to the target dose (TD, 0.5–720 μg/day). Dose steps were implemented in the dose schedule design based on the adverse event (AE) profile. Across all schedules, 55 (100%) pts reported treatment-emergent AEs (any grade). AMG 330–related AEs reported in 49/55 (89%) pts included cytokine release syndrome (CRS; 67%; ≥ grade 3 in 13%), (60%) and nausea (20%) as the most frequent AEs. CRS was reversible and occurred in a dose/schedule-dependent manner mostly within the first 24 hours of administration of triggering AMG 330 dose. The frequency and severity of CRS correlated with the dose level and leukemic burden at baseline. AMG 330 exhibited dose-dependent increase in steady state exposures over the studied dose range with clinical PK profile consistent with cIV administration. Eight of 42 evaluable pts responded: 3 complete remissions (CR; including 1 CR with negative measurable residual disease reported after data snapshot), 4 CR with incomplete hematologic recovery, and 1 morphologic leukemia free state. Seven responders who achieved CR/CRi received a TD equal or above the minimal efficacious dose of 120 μg/day. Among analyzed CR/CRi responders, 4/6 (67%) had adverse cytogenetic risk profile, 3/6 (50%) had ≥4 lines of prior therapy and all had relapsed disease. Responders had higher AMG 330 exposures and 3 responders treated with ≥600 μg/day TD remain in CR/CRi: 1 patient for $>$ 5 months after cycle 1, 1 patient bridged to hematopoietic stem cell transplant after cycle 4 and 1 patient is in cycle 3. Preliminary response assessment showed a correlation with lower tumor burden at baseline with a trend towards higher CD8+ lymphocyte count and E:T ratio. **Conclusions:** AMG 330 dosed up to 720 μg/day provided early evidence of acceptable safety profile, drug tolerability and anti-leukemic activity, and supports further dose escalation. Clinical trial information: NCT02520427. Research Sponsor: Amgen Inc.

7509 Poster Discussion Session; Displayed in Poster Session (Board #282), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Glasdegib (GLAS) plus low-dose cytarabine (LDAC) in AML or MDS: BRIGHT AML 1003 final report and four-year overall survival (OS) follow-up. *First Author: Michael Heuser, Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany*

Background: In newly diagnosed AML or high-risk MDS, primary analysis of the randomized phase 2 BRIGHT AML 1003 trial (data cutoff Jan 2017) showed superior OS for GLAS+LDAC vs LDAC alone. The trial then continued to predefined completion 4 years from randomization of all patients (pts), reached in Mar 2019 and presented herein. **Methods:** Pts with newly diagnosed AML or high-risk MDS and unsuitable for intensive chemotherapy were randomized 2:1 to GLAS+LDAC (n=88) or LDAC alone (n=44). For these groups, median (range) treatment duration was 83 (3-1575) and 47 (6-239) days; median follow-up for survival 47.6 and 48.1 months; 4 (4.5%) and 1 pt (2.3%) completed ≥4 years' follow-up. **Results:** Consistent with the primary findings (OS HR 0.51; 80% CI 0.39, 0.67 p=0.0004), GLAS+LDAC prolonged OS vs LDAC alone (table). Results were consistent in AML pts and cytogenetic risk/disease history subgroups (table), as were analyses by pt characteristics and baseline risk factors (not shown). Survival probability was 39.5% vs 9.5% at 1 year and 18.0% vs 2.4% at 2 years. GLAS+LDAC induced higher complete remission (CR) rates overall (16/88 vs 1/44; RR 8.12, 95% CI 1.05, 62.78, p=0.010) and across subgroups. Notably, fewer pts discontinued GLAS+LDAC due to AEs (38.1% and 46.3%) and there was no increased sepsis or bleeding vs LDAC alone despite longer glasdegib treatment. With GLAS+LDAC, SMO-inhibitor-associated AEs included dysgeusia (25.0%), muscle spasms (22.6%) and alopecia (10.7%), with only 1 pt discontinuing due to dysgeusia. **Conclusions:** Consistent with primary analyses, GLAS+LDAC continued to have an acceptable safety profile and improved OS vs LDAC alone. HRs were consistent across cytogenetic risk subgroups and support use of GLAS+LDAC in de novo and secondary AML. Clinical trial information: NCT01546038. Research Sponsor: Pfizer.

Five-year final results of a phase III study of CPX-351 versus 7+3 in older adults with newly diagnosed high-risk/secondary AML. *First Author: Jeffrey E. Lancet, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: CPX-351 (Vyxeos; daunorubicin and cytarabine liposome for injection), a dual-drug liposomal encapsulation of cytarabine [C] and daunorubicin [D], is approved by the FDA and EMA for the treatment of adults with newly diagnosed therapy-related AML or AML with myelodysplasia-related changes. Primary analysis of the pivotal phase 3 study (NCT01696084) that formed the basis for these approvals evaluated patients (pts) aged 60-75 y with newly diagnosed high-risk/secondary AML and found that CPX-351 significantly improved median overall survival (OS) vs conventional 7+3, with a comparable safety profile. Here, we report the prospectively planned final 5-y follow-up results from this phase 3 study. **Methods:** Pts were randomized 1:1 to receive ≤2 induction cycles of CPX-351 (100 units/m^2 [C 100 mg/m^2 + D 44 mg/m^2] as a 90-min infusion on Days 1, 3, 5 [2nd induction: Days 1, 3]) or 7+3 (C 100 mg/m^2/d continuously for 7 d + D 60 mg/m^2 on Days 1-3 [2nd induction: 5+2]). Pts achieving complete remission (CR) or CR with incomplete platelet or neutrophil recovery could receive up to 2 consolidation cycles. Pts could receive a hematopoietic cell transplant (HCT) at the physician's discretion. Pts were followed until death or up to 5 y following randomization. **Results:** In total, 309 pts were randomized to CPX-351 (n = 153) or 7+3 (n = 156). The survival rate at 5 y was higher for CPX-351 vs 7+3 (18% vs 8%; Table). Among pts who died, the most common primary cause of death was progressive leukemia in both arms (CPX-351: 56%; 7+3: 53%). After a median follow-up of 60.65 mo, improved median OS with CPX-351 vs 7+3 was maintained: 9.33 vs 5.95 mo; Kaplan-Meier (KM) OS curves plateaued at ~30 mo. HCT was received by 53 (35%) vs 39 (25%) pts after CPX-351 vs 7+3; among these pts, the survival rate at 5 y was higher for CPX-351 vs 7+3 (52% vs 23%), and median OS landmarked from the HCT date was not reached for CPX-351 vs 10.25 mo for 7+3 (Table). **Conclusions:** After 5 y of follow-up, improved OS was maintained in this phase 3 study, supporting that CPX-351 has the ability to produce or contribute to long-term remission and survival in older pts with newly diagnosed high-risk/secondary AML. Clinical trial information: NCT01696084. Research Sponsor: Jazz Pharmaceuticals.

A phase III study of venetoclax plus low-dose cytarabine in previously untreated older patients with acute myeloid leukemia (VIALE-C): A six-month update. *First Author: Andrew H. Wei, The Alfred Hospital and Monash Universtiy, Melbourne, VIC, Australia*

Background: VIALE-C was designed to compare the safety and efficacy of the BCL-2 inhibitor venetoclax (VEN) or placebo (PBO) plus low-dose cytarabine (LDAC) in previously untreated patient (pts) with acute myeloid leukemia (AML; ≥75 yr or ≥18 yr with comorbidities precluding intensive chemotherapy). The primary overall survival (OS) analysis showed a clinically meaningful improvement with VEN+LDAC, although the primary endpoint was not met. Herein, we present a 6-mo update after primary analysis, with a focus on OS. **Methods:** This double-blind, PBO-controlled phase 3 study (NCT03069352) randomized pts 2:1 to VEN (600 mg orally QD, days [d]1–28) with 4-d ramp-up in first cycle or PBO in 28-d cycles, plus LDAC (20 mg/m^2 subcutaneously QD, d1–10). The primary endpoint was OS; secondary endpoints included response, transfusion independence (TI; red blood cells [RBC] or platelets), and event-free survival (EFS). OS and EFS were analyzed by the Kaplan-Meier method and compared between arms using the log-rank test stratified by AML status (de novo vs secondary) and age (18 to < 74 vs ≥75). The planned sample size was 210 pts (n = 140, VEN; n = 70, PBO) to detect a hazard ratio (HR) of 0.545 in OS with 2-sided alpha of 5% and power of 90%. **Results:** As of 15 Aug 2019, 211 pts were randomized (n = 143, VEN; n = 68, PBO); median age: 76 yr in both arms (range: 36–93); secondary AML: 38% (88% post-MDS/CMML); prior hypomethylating agent: 20%. With a median follow-up of 17.5 mo (range: 0.1–23.5), median OS was 8.4 mo vs 4.1 mo in the VEN+LDAC and PBO+LDAC arms (HR 0.70; 95% CI 0.50–0.99; *P*= .04), representing a 30% reduction in the risk of death. Complete remission (CR)/CRi and CR/CRh (CR with partial hematologic recovery) rates were both 48% for the VEN+LDAC arm, and 13% and 15%, respectively, for PBO+LDAC. RBC/platelets TI rates were 43%/49% vs 19%/32% for VEN+LDAC and PBO+LDAC. Median EFS was 4.9 mo vs 2.1 mo in the VEN+LDAC and PBO+LDAC arms (HR 0.61; 95% CI 0.44–0.84; *P*= .003). Grade ≥3 adverse events (AEs [> 30%]; VEN+LDAC/PBO+LDAC) included neutropenia (49%/18%), thrombocytopenia (45%/38%), and febrile neutropenia (32%/29%); serious AEs (> 10%) were febrile neutropenia (17%/18%) and pneumonia (14%/10%); tumor lysis syndrome occurred in 5.6%/0%. **Conclusions:** VEN+LDAC demonstrates a clinically meaningful improvement in OS compared with PBO+LDAC, with a tolerable and manageable safety profile. These data support VEN+LDAC as a frontline treatment option for older pts with AML, as well as those considered unfit for intensive chemotherapy. Clinical trial information: NCT03069352. Inotuzumab ozogamicin (INO) plus bosutinib (BOS) in R/R PH+ ALL or CML in lymphoid blast phase (CML LBP). *First Author: Nitin Jain, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pts with R/R Ph+ ALL and CML LBP have poor outcomes. INO is an anti-CD22 antibody drug conjugate approved for R/R ALL. BOS is a 2nd generation BCR-ABL TKI approved for CML. **Methods:** This was a phase I/II study of INO + BOS for R/R Ph+ ALL and CML LBP. Primary objective was to determine safety and the maximum tolerated dose (MTD) of the combination. Secondary objective was to assess efficacy. Pts with T315I mutation were excluded. Pts needed to have adequate organ function (Cr ≤2 gm/dL, total bilirubin ≤2 mg/dL, ALT & AST ≤3xULN). BOS was dosed once daily starting on cycle 1 day 1, and 3 dose levels were evaluated (300, 400, 500 mg) in a standard 3+3 design. INO was given IV weekly during cycle 1 (0.8 mg/m^2 day 1; 0.5 mg/m^2 day 8; 0.5 mg/m^2 day 15). In responding pts, INO was subsequently administered at 1 mg/m^2 once every 4 weeks for a total of 6 cycles. **Results:** Between June 2015 and December 2019 we enrolled 18 R/R pts (16 Ph+ ALL, 2 CML LBP). The median age was 62 yrs (range 19-74), median no. of prior therapies was 1 (range 1-5) and 9 pts had ABL kinase domain mutations at screening. There were no early deaths (<30 days). 3 pts were treated at BOS dose level 1; 6 pts at dose level 2; 9 pts at dose level 3. 1 pt had a DLT at dose level 2 - G3 skin rash, and 2 pts had a DLT at dose level 3 - both G3 skin rash. First 3 pts at dose level 3 did not receive ≥80% BOS doses during cycle 1 due to issues unrelated to adverse events (AE). As 2/6 DLT evaluable pts at dose level 3 had DLTs thus exceeding the MTD, the dose level 2 was identified as the MTD. Most frequent AE were diarrhea in 50%, rash in 50%, and nausea in 39%. Grade 3 AEs were rash (3), reversible ALT elevation (1) and hyponatremia (1). No pts had veno-occlusive disease. Pts have received a median of 3 cycles (range 1-8) with a median of 1 cycle to response (range 1-2). Responses are shown in Table. Median time to response was 1 months (mo, range 0.8-2.1), median time to negative MRD by flow cytometry (FCM) was 6.9 mo (range 3.4-18) and median time to complete molecular response (CMR) was 9.1 mo (range 3.4-18). After a median follow-up of 32 mo, the median overall survival was 15.4 mo and median event-free survival censored at stem-cell transplantation (SCT) was 6.1 mo. 6 pts underwent SCT, 8 pts relapsed, 10 pts are alive and 2 pts continue therapy. **Conclusions:** INO + BOS was well tolerated and showed promising activity in R/R Ph+ ALL and CML LBP. Clinical trial information: NCT02311998. Research Sponsor: U.S. National Institutes of Health.

Responses with INO + BOS in R/R Ph+ ALL and CML LBP.

Response	n/N (%)
Overall response rate	15/18 (83)

Escalated dosing schedules of CC-486 for patients experiencing first acute myeloid leukemia (AML) relapse: Results from the phase III QUAZAR AML-001 maintenance trial. *First Author: Hartmut Dohner, Universitätsklinikum Ulm, Ulm, Germany*

Background: A goal of AML maintenance therapy is to decrease the risk of relapse by suppressing growth of residual leukemic cells post-induction. CC-486 is an oral hypomethylating agent that allows for extended dosing schedules (>7 days [d]/28d cycle) to sustain therapeutic activity. In the QUAZAR AML-001 trial (NCT01757535), CC-486 maintenance treatment (Tx) significantly prolonged overall (OS) and relapse-free survival vs. placebo (PBO) in pts with AML in first remission following induction chemotherapy (IC), who were not candidates for hematopoietic stem cell transplant (HSCT). Pts initially received CC-486 or PBO for 14d/cycle, but pts who relapsed with 5–15% blasts could receive escalated 21d/cycle dosing. We review outcomes of pts who received 21d dosing in QUAZAR AML-001. **Methods:** Pts were aged ≥ 55 years, with intermediate- or poor-risk cytogenetics and ECOG PS ≤ 3, and had achieved first CR/CRi after IC ± consolidation. Within 4 mo of CR/CRi, pts were randomized 1:1 to CC-486 300 mg or PBO QD on d 1–14 of 28d Tx cycles. CR/CRi status was assessed every 3 cycles. Pts relapsing with 5%–15% blasts in blood or bone marrow could receive study drug for 21d/cycle at the investigator's discretion. Tx could continue until > 15% blasts, unacceptable toxicity, or HSCT. **Results:** 91 patients (CC-486, 51/238 [21%]; PBO, 40/234 [17%]) were assigned to ≥ 1 21d/cycle dosing schedule. Median time to dose escalation was 9.2 mo (range 1.0-52.7) for CC-486 and 6.0 mo (0.5-19.3) for PBO. Median number of 21d dosing cycles was 2.0 (range 1-45) in the CC-486 arm and 2.0 (1-16) in the PBO arm; 43% and 18% of pts, respectively, received > 3 cycles of 21d dosing. Among 78 evaluable pts, 10/43 (23%) CC-486 pts and 4/35 (11%) PBO pts regained CR/CRi (central review) during dose escalation. Median OS from randomization was 22.8 mo *vs.* 14.6 mo with CC-486 *vs.* PBO, respectively (HR 0.66 [95%CI 0.42, 1.0]; $P = 0.073$), and 1-year survival rates were 80.4% *vs.* 59.5% (+20.9% [95%CI 2.1%, 39.7%]). The most common AEs with first onset during 21d dosing were febrile neutropenia (CC-486 24%, PBO 3%), thrombocytopenia (22%, 23%), anemia (22%, 20%), and neutropenia (20%, 10%). **Conclusions:** Escalated 21d CC-486 dosing was well tolerated and resulted in prolongation of OS and restoration of remission in approximately one-fourth of pts. Hematologic AEs first reported during escalated dosing in both Tx arms may be due in part to disease relapse. A 21d dosing schedule should be considered for pts receiving CC-486 who experience relapse with 5–15% blasts. Clinical trial information: NCT01757535. Research Sponsor: BMS.

Long-term survivors and gilteritinib safety beyond one year in *FLT3*-mutated R/R AML: ADMIRAL trial follow-up. *First Author: Alexander E. Perl, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: The phase 3 ADMIRAL trial showed that gilteritinib was superior to salvage chemotherapy (SC; median overall survival [OS]: 9.3 vs 5.6 mo, respectively) in $FLT3^{mut+}$ R/R AML patients (pts; Perl, et al. *N Engl J Med.* 2019). This follow up (FU) of the ADMIRAL trial assessed long-term (LT) survivors and gilteritinib safety beyond 1 year. **Methods:** A data cut was performed 1 year after the primary analysis. Response outcomes in LT survivors (OS ≥18 mo) in the gilteritinib arm, and safety during and after 12 mo of gilteritinib therapy were assessed. **Results:** At 1 year after the primary analysis, median FU for OS was 29.2 mo. Median OS remained longer with gilteritinib (9.3 mo) than with SC (5.6 mo; HR=0.679 [95% CI: 0.527, 0.875], nominal *P*=0.0026); 18-mo OS rates were 27% and 15%, respectively (Table). Of 49 censored pts in the gilteritinib arm, 20 continued treatment; 13 of these 20 pts underwent transplantation (HSCT) and received gilteritinib post-HSCT. Median gilteritinib exposure was 4.1 mo (IQR, 2.1-8.2) and median average dose was 120 mg/day (range, 43.8-192.3); 12% (n=30/246) of pts had ≥18 mo and 7% (n=17/246) had ≥24 mo of drug exposure. A total of 63 gilteritinib-treated pts had OS ≥18 mo (median exposure, 17.6 mo [IQR, 3.1-25.7 mo]). A high proportion of these LT survivors achieved remission pre-HSCT (Table); median durations of complete remission (CR) or CR with partial hematologic recovery (CRh) have not been reached. After a median of 3.5 mo, 35 of 63 (56%) LT survivors underwent HSCT; 25 of these 35 pts (71%) received post-HSCT gilteritinib therapy. Of 28 pts who did not undergo HSCT, 15 (54%) received gilteritinib for ≥18 mo. Most common grade ≥3 adverse events (AEs) during the first 12 mo of gilteritinib therapy were febrile neutropenia (45%), anemia (40%), and thrombocytopenia (23%); rates of these grade ≥3 AEs decreased to 8%, 10%, and 0, respectively, after 12 mo of treatment. Most common fatal AEs during the first 12 mo of gilteritinib therapy were AML (11%), infections (11%), and cardiac disorders (3%); after 12 mo of treatment, rates of these fatal AEs were 6%, 8%, and 2%, respectively. **Conclusions:** Results from this ADMIRAL trial FU suggest LT survival in pts receiving gilteritinib is related to ongoing remission, subsequent HSCT, or post-HSCT gilteritinib therapy. The safety profile of gilteritinib beyond 1 year was stable. Clinical trial information: NCT02421939. Research Sponsor: Astellas Pharma, Inc.

Type of prior genotoxic insult determines the genomic characteristics of therapy-related acute myeloid leukemia. *First Author: Michael Ozga, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Therapy-related AML (tAML) is a long-term complication of cytotoxic cancer therapy. It is characterized by adverse genetics and inferior survival outcomes when compared to de novo AML. A proposed mechanism in tAML pathogenesis includes treatment-induced selection of clones harboring pre-existing mutations (i.e. clonal hematopoiesis, CH). We hypothesize that genotoxic therapies used to treat prior malignancy drive leukemogenesis through different mechanisms leading to unique clonal compositions. **Methods:** AML patients (pts) treated at The Ohio State University between 2015-2018 were included. Genetic profiling was performed using Miseq Illumina platform with a 49-gene targeted sequencing panel at our clinical laboratory. **Results:** We studied 337 AML pts (Table), of whom 53% had smoking history. Mutations involving *ASXL1* were more common in smokers vs non-smokers (14% vs 5.8%, p= .001), while *JAK2* mutations were more common in non-smokers (8% vs 1.2%, p= .003). Regarding specific genotoxic therapies and mutations in tAML, we investigated common CH-associated mutations including *DNMT3A*, *TET2*, and *ASXL1* (DTA mutations). In tAML pts, those exposed to radiotherapy experienced a higher frequency of DTA (52% vs 27%, p= .05), *NPM1* (21% vs 0%, p= .002), and *SRSF2* (15% vs 0%, p= .01) mutations, and conversely, a lower incidence of *TP53* mutations (21% vs 46%, p= .04). Pts with history of cytotoxic chemotherapy had a lower incidence of DTA mutations, including those who received platinum agents (8% vs 49%, p= .005) and taxanes (7% vs 52%, p< .001), but had a higher incidence of *TP53* mutations (75% vs 25%, p< .001 for platinum; 53% vs 25%, p= .04 for taxanes). Similarly, alkylators and anthracyclines were associated with lower incidence of *DNMT3A* (0% vs 20%, p= .009) and *ASXL1* (0% vs 12.5%, p= .04) mutations. **Conclusions:** Different genotoxic agents demonstrate unique effects in leukemia development. Our data suggest that CH clones with DTA mutations may be enriched with smoking and radiotherapy, while cytotoxic chemotherapy may confer a higher incidence of *TP53* mutations. Given the adverse prognosis of *TP53* mutated AML, identification of pre-existing CH clones might influence treatment selection in solid tumor pts receiving anticancer therapy. Evolving risk of therapy-related myelodysplastic syndromes and acute myeloid leukemia (tMDS/AML) following modern cancer therapies. *First Author: Abhay Singh, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Data describing risks of tMDS/AML after targeted and immunotherapy (IO) agents are lacking. Melanoma (Mel) and renal cell carcinoma (RCC) are considered chemotherapy insensitive and have been treated with IO (interferon and interleukin) since the 1990s. In 2004, use of tyrosine kinase inhibitors (TKIs) began in non-small cell lung cancer (NSCLC) and expanded to RCC in 2005 and Mel trials in 2011. Checkpoint inhibitor (CPI) use began in 2011 for Mel, 2012 for NSCLC in trials and later for RCC. For multiple myeloma (MM), use of lenalidomide has been increasing since 2007. All these modern therapies have well described immunomodulatory functions. **Methods:** Using 17 population-based SEER cancer registries, we studied 565,149 patients diagnosed from 2000-2015 with Mel, RCC, NSCLC, or MM who survived ≥1 year and assessed risk of tMDS/AML across periods P1 (2000-2005), P2 (2006-2010) and P3 (2011-2015). Censoring occurred at 5 years of follow up to limit bias and assess risk alteration across approval and utilization periods of these modern therapies. **Results:** tMDS/AML risk was significantly elevated after RCC in P1 [standardized incidence ratio *(SIR): 1.61*, possibly from chemo exposure that was still prevalent to some extent in P1 period] and a downtrend noted in P2 *(SIR: 1.11)* and P3 *(SIR: 0.60)*. tMDS/AML risk after Mel showed similar downtrend, not statistically significant. In contrast, risk for tMDS/AML after MM increased across all periods (*SIRs 4.51 > 5.05 > 5.23*), and risk after NSCLC increased from P1 to P2 but decreased thereafter, pattern most pronounced in stage I-III NSCLC (*1.64 > 3.15 > 1.92*). **Conclusions:** Periods when TKI and CPI use became standard in Mel and RCC, we observed a decrease in tMDS/AML risk. Similar decrease in the most recent period for stage I-III NSCLC was observed, possibly due to progression of these earlier staged cancers resulting in receipt of TKIs and CPI for stage IV disease. tMDS/AML risk after MM increased contradicting the decline in risk previously reported in the literature. Discordance may be due to survival bias as MM patients are now living longer (SEER 5-yr survival in '00 was 35% and 53% in '15) with more time to develop tMDS/AML. Overall, aside from better efficacy and/or tolerability of modern therapies, another observed benefit was lower tMDS/AML risk. This risk was lower than general population in Mel/RCC, suggesting a possible protective effect of these therapies. SIR tables/graphs with updated SEER data (available 04/2020) with follow up through 2018 will be presented. Research Sponsor: None.

Clonal hematopoiesis in the bone marrow and blood of healthy volunteers. *First Author: Pierre Hirsch, Sorbonne Université, UMRS 938, APHP, Hôpital Saint-Antoine, Paris, France*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) has been described in blood samples from large series of patients. Its prevalence and consequences remain questioned because sequencing methods vary and because most studies were performed in cohorts of individuals suffering from non-hematological diseases (solid cancers, diabetes, cardiovascular or psychiatric diseases). CHIP has been described as a risk factor for blood cancer. However, the diagnosis of most blood cancers relies on morphologic and genetic examination of the bone marrow, and clonal hematopoiesis has never been evaluated in bone marrow samples from healthy individuals. Hence, it is not clear whether the current definition of CHIP is clinically relevant. To address this issue, we studied clonal hematopoiesis in paired peripheral blood and bone marrow samples from an unprecedented cohort of rigorously selected healthy volunteers. **Methods:** Here, we investigated the frequency of clonal hematopoiesis in 82 paired bone marrow and blood samples from carefully selected healthy adult volunteers (HEALTHOX clinical trial, ClinicalTrials.gov Identifier: NCT02789839). This study was approved by the ethics committees (CPP Tours and AFSSAPS identifier ID-RCB: 2011-A00262-39; CPP Ile-de-France III: 2753). Forty-one genes known to be mutated in myeloid malignancies were sequenced with a 1% threshold of detection. All variants were checked using IGV software v2.3. Statistical analyses were performed using Mann-Whitney, chi-squared, Fisher's exact, Wilcoxon matched-pairs tests or Spearman correlation using GraphPad Prism 6. **Results:** In bone marrow samples, clones were found in almost 40 % of healthy volunteers over 50 years-old (yo). The most frequent mutations were found in *DNMT3A* (48%) and *TET2* (28%) and the other mutations were found in *ASXL1* (8%), *JAK2* (8%), *RAD21* (4%) and *SRSF2* (4%) with one individual carrying three variants. Blood parameters and bone marrow smears were normal with the exception of two individuals with mild macrocytosis or thrombocytosis. Clonal hematopoiesis cases differed from others by age (62.8 vs. 38.6 years, $P < .0001$) and platelet count (294 vs. 241 G/L, $P < .0208$). **Conclusions:** These results confirm that clonal hematopoiesis is a very common condition in healthy adults over 50 years old. Consequently, the detection of driver myeloid mutations should be interpreted with caution in the absence of cytologic abnormalities in the blood and/or in the bone marrow. Research Sponsor: INCa - Institut National du Cancer, Paris, France.

Longer-term RBC transfusion reduction in the phase III MEDALIST study of luspatercept in patients (pts) with lower-risk MDS with ring sideroblasts (RS). *First Author: Rami S. Komrokji, Moffitt Cancer Center, Tampa, FL*

Background: MEDALIST (NCT02631070) is a randomized, placebo (PBO)-controlled, phase 3 trial evaluating the efficacy and safety of luspatercept, a first-in-class erythroid maturation agent, in pts with anemia due to lower-risk MDS (LR-MDS) with RS (Fenaux & Platzbecker et al. *NEJM.* 2020;382:140-51). **Methods:** Pts were aged ≥ 18 years; had IPSS-R-defined Very low-, Low-, or Intermediate-risk MDS with RS; were refractory, intolerant, or unlikely to respond to ESAs; and required RBC transfusions (≥ 2 units/8 weeks in the 16 weeks prior to randomization). 229 pts were randomized 2:1 to luspatercept (1.0 mg/kg, titration to 1.75 mg/kg) or PBO subcutaneously every 3 weeks. This analysis evaluates long-term transfusion burden reduction with luspatercept in all pts in the MEDALIST trial. **Results:** As of July 1, 2019, 77/153 (50.3%) and 11/76 (14.5%) pts in the luspatercept and PBO arms, respectively, achieved ≥ 50% RBC transfusion burden reduction for ≥ 24 weeks ($P <$ 0.0001). The median longest single response episode was 131.6 weeks with luspatercept, and not estimable with PBO due to pts stopping treatment. In Weeks 9–24, mean change from baseline in RBC units transfused was −3.0 (95% CI −3.9, −2.1) vs +0.4 (95% CI −0.6, 1.4) in the luspatercept vs PBO arms. In Weeks 33–48, mean change in RBC units transfused in the luspatercept arm was −4.9 (95% CI −5.9, −3.9). In Weeks 1–24, mean number of transfusion visits was 5.9 vs 9.5 in the luspatercept vs PBO arms. Risk of recurrent transfusion visits in Weeks 1–24 for luspatercept vs PBO was 0.699 (95% CI 0.597, 0.819; $P <$ 0.0001). Mean number (least squares [LS] mean) of RBC units transfused/48 weeks during Weeks 1–48 was 22.89 (23.28) vs 35.98 (35.20) in luspatercept vs PBO arms (LS mean difference −11.92 [95% CI −15.55, −8.28]; $P <$ 0.0001). The mean number (LS mean) of RBC transfusion events over 48 weeks was 12.95 (13.14) vs 19.54 (19.15) in the luspatercept vs PBO arms (LS mean difference −6.00 [95% CI −8.16, −3.85]; $P <$ 0.0001). LS mean change from baseline in serum ferritin was −2.7 μg/L vs +226.5 μg/L in luspatercept vs PBO (LS mean difference −229.1 μg/L; $P =$ 0.0024) in Weeks 9–24; and −72.0 μg/L vs +247.4 μg/L in Weeks 33–48 (LS mean difference −319.5 μg/L; $P =$ 0.0294). In Weeks 1–24, 38/127 (29.9%) vs 5/65 (7.7%) pts ($P =$ 0.0005) achieved major HI-E response per IWG 2018 criteria in luspatercept vs PBO arms, respectively. **Conclusions:** Luspatercept demonstrated clinical efficacy in pts with LR-MDS with RS and was associated with significant reductions in RBC transfusions (≥ 50%) and serum ferritin. Clinical trial information: NCT02631070. Research Sponsor: Bristol-Myers Squibb in collaboration with Acceleron Pharma.

Ten-day decitabine with venetoclax (DEC10-VEN) in AML and high-risk (HR) MDS. *First Author: Abhishek Maiti, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: VEN-based low intensity regimens have shown promise in older pts with newly diagnosed (ND) AML. We hypothesized that adding VEN to 10-day (d) DEC may improve outcomes in AML and HR MDS. **Methods:** Pts received VEN 400 mg daily or equivalent with DEC 20 mg/m^2 for 10d every 4-8 weeks for induction and DEC 5d with VEN for consolidation after CR/CRi. If cycle 1 day 21 bone marrow showed ≤5% blasts, VEN was held to enable count recovery. VEN duration could be further reduced for myelosuppression. FLT3 and IDH inhibitors were allowed for applicable pts. All pts received tumor lysis syndrome (TLS) prophylaxis. Primary objective was overall response rate (ORR). Secondary objectives were safety and overall survival (OS). Data cut-off date was February 6, 2020. **Results:** Between January 2018 and December 2019 we enrolled 184 pts with ND AML (>60 yrs), untreated secondary AML (sAML), treated sAML, relapsed/refractory (R/R) AML and HR MDS (Table). 58% pts were ≥70 yrs, 30% pts had ECOG PS ≥2, 67% pts had ELN adverse risk AML. Previously treated pts (n=96) had received a median of 1 prior therapy (range 1-8) including HMA (62), intensive chemotherapy (49) and stem cell transplantation (SCT, 27). 30d mortality was 3.3% and 60d mortality was 7.6%. 30d mortality in ND AML was 1.4%. Most common G3/4 adverse events were infections with G3/4 neutropenia (46%), febrile neutropenia (28%), infections with ANC ≥1x10^9/L (6%) and TLS (3%). Outcomes are shown in Table. 25 pts (14%) proceeded to SCT including treatment naive AML (ND+ untreated sAML, 12), previously treated AML (treated sAML + R/R, 11) and HR MDS (2). 100d post-SCT mortality was 4%. Median OS in treatment naïve AML pts undergoing SCT was not reached (1yr OS 100%) and for previously treated AML pts was 22.1 months (mo). After a median follow up of 15 mos, 25% PTS continue therapy. Additional analyses by molecular subgroups will be presented. **Conclusions:** DEC10-VEN is safe and highly effective in ND AML and can serve as an effective bridge to SCT in previously treated pts. Trial continues to accrue (NCT03404193). Clinical trial information: NCT03404193. Research Sponsor: U.S. National Institutes of Health.

Outcomes with DEC10-VEN in AML and MDS.

Outcome	ND AML N=70	Untreated sAML N=15	Treated sAML N=28	R/R AML N=55	R/R MDS N=13
	n (%) / median [range]				
ORR	62 (89)	12 (80)	17 (61)	34 (62)	8 (62)
CR + CRi or mCR	60 (86)	10 (67)	11 (39)	23 (42)	3 (23)
MRD negative (flow cytometry)	35/52 (67)	4/10 (40)	7/15 (47)	14/26 (57)	0/1 (0)
No. of cycles to response	1 [1-8]	1 [1-2]	1 [1-3]	2 [1-4]	2 [1-7]
Median OS, mos	18.1	7.8	6.0	7.8	8.9

3 more pts with untreated HR MDS achieved marrow CR (mCR) ongoing for a median of 5 mo
ORR = CR+CRi+MLFS+PR for AML and CR+mCR+PR+stable disease for MDS per IWG criteria

A fork in the road: A mixed methods study exploring why older adults with acute myeloid leukemia choose different treatment paths. *First Author: Thomas William LeBlanc, Duke University Medical Center, Durham, NC*

Background: Current treatment options for acute myeloid leukemia (AML) are diverse, including intensive chemotherapy (IC), low intensity therapy, best supportive care (BSC), and hospice care. Despite continued development of new therapies, recent data suggest that approximately 60% of older US patients remain untreated, but reasons for this are not well understood. By gathering insights from physicians, patients, and their family members, this study aims to better understand the factors that influence treatment decisions for adults with AML. **Methods:** Physicians in the US (n=4), UK (n=3) and Canada (n=3), and 15 US AML patient-family member dyads took part in one-on-one, 60-minute semi-structured interviews. Each participant rated a series of factors on a scale from 0 (not at all important) to 3 (very important) to determine their importance in treatment decision-making. Among the 15 adults with AML (>65 years, not taking IC) interviewed thus far, 13 had not received any treatment. Additional interviews are scheduled in the UK and Canada with patients having varied treatment experiences (data will be available for presentation). **Results:** To date, findings highlight the key role perceptions of side effects and patient health play in treatment decision making. A fear of treatment side effects was the primary reason patients (n=9/13) opted not to receive treatment. For the 2/15 study patients who had received treatment, side effects were considered the worst part of their treatment experience. Physicians also stated patients on BSC would be more willing to take low intensity treatments if risks (e.g., side effects) were minimized. Patients (n=11/15), their family members (n=11/15), and physicians (n=10/10) agreed that patients' health (including age and comorbidities) influenced if treatment was pursued. Additionally, US physicians suggested that some patients have little desire to pursue treatment, with patients' perception of low intensity therapy having poor efficacy and proximity of care influencing their choice for BSC or hospice care. Further analysis will explore other factors influencing patients' treatment decisions and differences among patients who receive treatment versus those who do not. **Conclusions:** The treatment decision-making process for older adults with AML is complex and multifactorial. Understanding factors that influence treatment decisions is important if drug developers and prescribers are to ensure the availability of therapies that better align with individual patients' needs. Research Sponsor: Pfizer.

7521 Poster Session (Board #294), Fri, 8:00 AM-11:00 AM

Ivosidenib (IVO) prior to hematopoietic cell transplant for patients with *IDH1*-mutant relapsed or refractory acute myeloid leukemia (R/R AML). *First Author: Courtney Denton Dinardo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Allogeneic hematopoietic cell transplantation (HCT) provides a potentially curative option for patients (pts) with R/R AML. Disease status at the time of transplant is a major determinant of long-term prognosis, with pts typically receiving salvage chemotherapy prior to HCT to induce a remission. However, older and/or heavily pre-treated pts frequently cannot tolerate intensive chemotherapy (IC) or do not obtain adequate disease control to permit an HCT. IVO is an oral, potent, targeted inhibitor of mutant IDH1 (mIDH1) approved for the treatment of adults with newly diagnosed AML ≥75 y of age or ineligible for IC, and those with R/R AML. We assessed HCT outcomes in pts with m*IDH1* R/R AML who proceeded to HCT after treatment with IVO in a phase I study (NCT02074839). **Methods:** Baseline characteristics, clinical response (including CR, CRi/CRp, MLFS), and overall survival (OS) for the subgroup of pts with m*IDH1* R/R AML who received IVO 500 mg QD, responded to treatment and then underwent HCT are reported. m*IDH1* variant allele frequency (VAF) from bone marrow mononuclear cells was assessed using BEAMing digital PCR (0.02–0.04% VAF detection limit). **Results:** Among 179 pts with R/R AML treated with IVO, 18 proceeded to HCT: median age, 61.5 y (range 36–68); 56% male; 16.7% had secondary AML; 27.8% had ≥3 prior regimens; 11.1% had a prior HCT. The median duration of IVO treatment prior to HCT was 3.9 mo (range 2.1–15.2). The last reported response prior to HCT was 50.0% CR. Six- and 12-mo post-HCT survival rates were 77.8% and 50.0%; median relapse-free survival post HCT was 7.3 mo (range 2.6–NE). Median OS from start of IVO was 16.8 mo (95% CI 9.2, NE) for HCT pts vs 9.0 mo (95% CI 7.1, 10.2) in the entire study cohort; median follow-up time, 33.2 mo (range 3.2–41.9). Eight HCT pts were censored for OS: 5 are in remission, 2 relapsed and are in survival follow-up, and 1 was lost to follow-up. Median OS was not estimable (95% CI 9.1, NE) for the 12 HCT pts who achieved CR after IVO therapy and was 20.5 mo (95% CI 16.4, NE) for the 31 CR pts who did not undergo HCT. m*IDH1* was undetectable in 1/18 (6%) pts; 4/18 (22%) pts had reduction below 1% VAF in ≥1 at the last assessment prior to HCT. **Conclusions:** IVO monotherapy is a putative treatment option to induce remissions prior to HCT for m*IDH1* R/R AML pts who are not considered candidates for intensive salvage therapy. Post-transplant survival rates are encouraging and warrant further investigation of IVO monotherapy or combination salvage therapies prior to HCT. Clinical trial information: NCT02074839. Research Sponsor: Agios Pharmaceuticals, Inc.

Activity of decitabine as maintenance therapy in core binding factor acute myeloid leukemia. *First Author: Mahran Shoukier, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Real-time quantitative (RTPCR) based minimal residual disease (MRD) monitoring provides prognostic information in core binding factor acute myeloid leukemia (CBF-AML). Earlier we reported on the activity of decitabine (DAC) as maintenance therapy in a smaller cohort of patients with CBF AML. **Methods:** We have summarized the results in patients (pts) with CBF who received DAC maintenance for persistent RTPCR positivity or because of inability to complete all planned consolidation in a fludarabine, GCSF, cytarabine (FLAG) based regimen. The planned number of DAC cycles was 12 but could be adjusted at the discretion of the treating physician based on RTPCR response. Serial RTPCR was obtained approximately every 2-3 months. **Results:** Thirty-four pts with CBF-AML [t(8;21)=14 and inv(16)=20] received DAC as maintenance. Eighteen pts (53%) completed a full course (7 cycles) of FLAG based regimen before DAC for persistent PCR positivity (group 1). Sixteen pts (47%) were switched to DAC as they did not complete planned consolidation (group 2). In group 2, 9 pts (56%) had negative PCR (group 2A) and 7 pts (46%) had positive PCR (group 2B) prior to starting DAC. Patient characteristics are summarized in table. The median follow up was 59.2 [15.4-107.2] and 32.47 [8.5-86.3] months for group 1 and 2, respectively. In Group 1 and group 2A only 1 patient each had relapse, while 5 pts (72%) from group 2B had relapse. All the patients in group 2B with relapse were at suboptimal RTPCR response (>0.1%). **Conclusions:** Our study shows DAC is an effective maintenance for CBF-AML pts who have persistent PCR positively after FLAG based induction consolidation and those unable to tolerate a full course, but have negative PCR. However patients with high levels of MRD persistence should be considered for stem cell transplant. Research Sponsor: None.

Comparative study of therapy-related (tALL) and de novo adult acute lymphoblastic leukemia (dnALL): Contemporary Mayo Clinic ALL cohort. *First Author: Zaid Abdel Rahman, Mayo Clinic, Jacksonville, FL*

Background: tALL is a recently appreciated but poorly defined clinical entity. We define tALL as any prior exposure to cytotoxic chemotherapy and/or radiation for another malignancy, and we report a comparative analysis of characteristics, cytogenetics and outcomes for this subset among a modern unselected ALL cohort from the Mayo Clinic Cancer Center (MCCC). **Methods:** We performed a systematic search in the 3-site MCCC registry and included all patients (pts) diagnosed and received at least 1 cycle of ALL-directed therapy and/or underwent allogeneic transplantation (AlloHCT) between 2008-2018. Comparisons of characteristics between tALL and dnALL were made using a Wilcoxon rank sum test (continuous variables) and Fisher's exact test (categorical variables). Time-to-event variables were compared using unadjusted Cox proportional hazards regression models. **Results:** 431 ALL pts were identified during the study period, including n = 69 (16%) classified as tALL. Median follow-up from diagnosis was 2.3 years (range 0-18 years). The most common prior malignancies among tALL pts were Breast (24.6%), Lymphoma (15.9%), Myeloid (15.9%), GU/GYN (14.5%) and Myeloma (11.6%). In comparison to dnALL, pts with tALL were significantly older (63.2 vs 45.2 years, $P < 0.001$), more often female (65.2% vs 39.8%, $P < 0.001$), less frequently Hispanic (3.5% vs 13.1%, $P = 0.042$); more often of B-lineage (92.8% vs 81.8%, $P = 0.022$). On review of cytogenetics, tALL pts more often had hypodiploidy/near triploidy (Ho/Tr) (21.7% vs 4.1%, $P < 0.001$), more often had monosomal (MDS-like) (33.3% vs 12.4%, $P = 0.0047$) and complex karyotype (38% vs 17.3%, $P = 0.0069$). Importantly, incidence of BCR/ABL-positive (Ph+) ALL was not significantly different. Latency period between exposure to prior cancer therapy and development of tALL was significantly longer for Ph+ compared to Ph-negative ALL (median 9 vs. 4 years, $P = 0.007$). Patients with tALL had a 3-year OS after diagnosis of 37% [vs 59.7% for dnALL (HR death 1.86, 95% CI 1.31-2.65, $P < 0.001$)]. However, the two groups did not differ significantly regarding occurrence of AlloHCT (HR = 0.91, 95% CI 0.63-1.31, $P = 0.61$) or post-AlloHCT survival (HR = 1.29, 95% CI 0.75-2.23, $P = 0.35$). **Conclusions:** Therapy-related ALL represents an important & unique clinical entity with poor prognosis & adverse cytogenetic features. Ph+ tALL has a longer latency and similar frequency in both tALL and dnALL. AlloHCT appears to be an appropriate treatment strategy, possibly abrogating the poor prognosis of tALL. Research Sponsor: None.

7524 Poster Session (Board #297), Fri, 8:00 AM-11:00 AM

Clinicopathologic and molecular profile of Philadelphia like ALL in Hispanic population of Central Valley California. *First Author: Hugo Akabane, UCSF Fresno, Clovis, CA*

Background: Philadelphia-like Acute B-ALL(PHL) are Ph negative B-ALL(PHN) with molecular signatures that mirrors Ph + B ALL. Studies have shown worse prognosis in this subtype of leukemias, but few have reported outcomes with incorporation of novel agents. Our study seeks to describe clinical and molecular profile of a single center experience. **Methods:** This is a retrospective study of patients treated for PHL in community referral center in central valley of California from 1/2009 to 12/2019. Of the initial 71 patients, 34 met the inclusion and exclusion criteria. 16 of the 34 patients who had Next Generation Sequencing (NGS) by Foundation Medicine (14) or NeoGenomics (2). Data for 34 PHN and 8 with PHL patients were analyzed. **Results:** There are no differences in mean ages (36.7 x 36) and gender between the PHN and PHL subgroup. There is over representation of Hispanics in both groups (63% x 65%) with slightly male predominance in PHL group (62%). This ratio is slightly higher than reported by 2010 census of 46%. The BMI 38.4(27.5-48.4) vs. 29.1(26.6-39.1), mean WBC (71 vs. 58), bone marrow CD20+ by flow cytometry (90% vs. 63%) and abnormal cytogenetics (50% vs.15%) are all higher in PHL compared to PHN group. The prevalence rate of PHL signature in 16 tested patients is 8(50%). CRLF2 like subtype accounted for 6/8(75%), with 1 each of ABL-like and JAK-Stat subtype. All patients harbored multiple other mutational abnormalities in addition to those associated with Ph-like genetic signatures (Table). The median number of mutations was 4.55(3-7). The distribution of the 20 other mutation is as shown in table. 6 patients had morphological remission after induction chemotherapy of HyperCVAD (37%) and CALGB 10403 (25%) with measurable MRD in 5 of the patients. 7 patients were exposed to novel therapy; Blinatumomab; 2nd line (6 patients), Cart T cell; 3rd line (2 patients), Inotuzumab; 3rd line (3 patients) and ASCT; (3 Patients post second- or third-line remission). 2 patients died at the time of data cut off, 1 from infection and other from refractory leukemia. **Conclusions:** Our data shows high incidence of PHL signatures in the cohort. The mutational heterogeneity between and within patients, may represent sub-clonal population vs. passenger and hence poor clinical outcomes. Research Sponsor: None.

Distribution of 20 mutations in 8 patients with PHL signatures.

Effect of early blood counts on overall survival (OS) following glasdegib + LDAC in newly diagnosed AML: BRIGHT AML 1003 post hoc analysis. *First Author: Eunice S. Wang, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Addition of glasdegib (GLAS) to LDAC approximately doubled OS without significant worsening of myelosuppression-related complications, ostensibly by targeting leukemic stem cells dependent on the hedgehog pathway, which is not involved in normal adult hematopoiesis. We assessed potential association of early blood counts and OS. **Methods:** In BRIGHT AML 1003, patients (pts) with newly diagnosed AML were randomized to GLAS + LDAC (n = 78) or LDAC alone (n = 38). GLAS was given once daily continuously and LDAC on days 1–10 of a 28-day cycle. We evaluated peripheral blood counts measured early in the study (cycle 2 day 1 [C2D1]), approximately 1 month before the first bone marrow assessments. OS was compared for GLAS+LDAC vs LDAC alone subgroups meeting thresholds of absolute neutrophil count (ANC; ≥1000 or 500/μL), hemoglobin (Hb; ≥10 or 9 g/dL) or platelets (≥100,000 or 50,000/μL). Data cut-off was Apr 2019. **Results:** Among all pts regardless of baseline values, achievement of ANC, Hb and platelet thresholds at C2D1 was associated with improved OS with GLAS+LDAC (table, left side). Notably, in pts who did not meet ANC, Hb or platelet thresholds (table, right side), OS benefit with GLAS+LDAC was also observed (table, all p≤0.05). Among pts below threshold at baseline, C2D1 recovery of platelets ≥50,000 or 100,000 and Hb ≥9 or 10 was associated with improved OS (not shown). Clinical trial information: NCT01546038. **Conclusions:** In pts with newly diagnosed AML, improved OS was associated with various blood count thresholds after 1 cycle of GLAS+LDAC vs LDAC alone. In pts with baseline measurements below threshold, recovery of specific thresholds was associated with improved OS. These exploratory results are consistent with the hematopoiesis-sparing mechanism of GLAS, and merit further evaluation. Research Sponsor: Pfizer.

7526 Poster Session (Board #299), Fri, 8:00 AM-11:00 AM

Glasdegib in combination with azacitidine (AZA) in patients (pts) with untreated higher-risk myelodysplastic syndromes (MDS), acute myeloid leukemia (AML) and chronic myelomonocytic leukemia (CMML): Effects on marrow recovery and transfusion independence. *First Author: Amer Methqal Zeidan, Yale University School of Medicine and Yale Cancer Center, New Haven, CT*

Background: Glasdegib, an oral inhibitor of the Hedgehog signaling pathway, is approved in the USA in combination with low-dose cytarabine to treat pts with newly diagnosed AML unable to receive intensive chemotherapy due to comorbidities or age (≥75 years). Glasdegib + AZA showed promising remission rates and overall survival with a generally well-tolerated and manageable safety profile in an analysis of BRIGHT MDS & AML 1012 in pts with MDS, AML and CMML. Here we evaluate early hematopoietic recovery and transfusion independence with glasdegib + AZA in this ongoing Phase Ib study. **Methods:** Untreated pts with MDS, AML and CMML ineligible for intensive chemotherapy received glasdegib (100 mg QD) + AZA (75 mg/m^2/D on D1–7 q28D). Data cutoff: Sept 11, 2019. **Results:** Among pts with MDS (n=30; including 3 with CMML), median duration of treatment was 5.0 months (range, 0.4–15.5). Recovery of absolute neutrophil count (ANC), hemoglobin (Hb) and platelets at 2 thresholds started in cycle (Cyc) 1 (Table). Early platelet recovery correlated with response to treatment; 54% (7/13) of pts with platelets ≥100,000/μL at Cyc 2, D1 achieved complete or partial remission vs 0% (0/13) of pts with <100,000/μL, *P*=0.002. Start of Cyc 2 was delayed due to AEs in 8% (2/26) of pts. 54% (7/13) of evaluable pts transfusion dependent at baseline (BL) became transfusion independent. Among pts with AML (n=30), median duration of treatment was 5.0 months (range, 0.3–14.9). ANC, Hb and platelet recoveries started in Cyc 1 (Table). 9% (2/23) of pts had Cyc 2 dose delays due to AEs. 64% (9/14) of evaluable pts transfusion dependent at BL became transfusion independent. Clinical trial information: NCT02367456. **Conclusions:** Glasdegib + AZA shows promising rates of survival with early marrow recovery in the up-front treatment of pts with MDS, AML and CMML ineligible for intensive chemotherapy. The association between early hematopoietic recovery and efficacy in the MDS cohort merits further study. Research Sponsor: Pfizer.

7527 Poster Session (Board #300), Fri, 8:00 AM-11:00 AM

Health-related quality of life (HRQoL) in patients with untreated higher-risk myelodysplastic syndromes (MDS), acute myeloid leukemia (AML), and chronic myelomonocytic leukemia (CMML) receiving glasdegib + azacitidine (AZA). *First Author: Eunice S. Wang, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Glasdegib + AZA showed promising remission rates and overall survival in an analysis of BRIGHT MDS & AML 1012 in patients (pts) with MDS, AML and CMML. Here we assess the impact of glasdegib + AZA on HRQoL in this ongoing Phase Ib study. **Methods:** Untreated pts with MDS, AML and CMML ineligible for intensive chemotherapy received glasdegib (100 mg QD) + AZA (75 mg/m^2/D on D1–7 q28D). Pt-reported outcomes (PRO) that characterize HRQoL were measured using the MD Anderson Symptom Inventory (MDASI)-AML/MDS, Pt Global Impression of Severity (PGI-S), and Pt Global Impression of Change (PGIC) tools. PRO were assessed at baseline (BL; except the PGIC), D7 and D15 of cycle (Cyc) 1, D1 of each subsequent Cyc and at end of treatment. Data cutoff: Sept 11, 2019. **Results:** For the MDS (n=30, including 3 with CMML) and AML (n=30) cohorts, median (range) number of Cyc started was 5 (1–14) and 5 (1–15), respectively. HRQoL over time, as determined by MDASI-AML/MDS, is shown in the Table, with mean scores indicating low symptom burden over time. For the PGI-S, both cohorts showed similar trends in pt's impression of current leukemia symptoms remaining constant over time (i.e. absent to mild). For the PGIC, pt's impression of change of leukemia symptoms since starting study medication remained constant over time (i.e. no to minimal change) for the MDS cohort and showed improvement in the AML cohort (i.e. minimal change to much improved). **Conclusions:** Glasdegib + AZA is a promising first-line treatment option that does not negatively impact the HRQoL of pts with MDS, AML and CMML ineligible for intensive chemotherapy. Clinical trial information: NCT02367456. Research Sponsor: Pfizer.

7528 Poster Session (Board #301), Fri, 8:00 AM-11:00 AM

Stability of rare TP53 co-mutations in AML patients. *First Author: Kenneth Joel Bloom, Clarient Diagnostic Services, Inc., Aliso Viejo, CA*

Background: Acute Myeloid Leukemia (AML) is a devastating disease with poor overall survival. Access to precision medicines, is revolutionizing AML care and is driving an increase in Next Generation Sequencing (NGS) utilization to determine the genomic profile of patients with AML. Advanced analysis into the interplay between mutational status for multiple genes is granting access to new targeted and precision medicine treatment options with improved outcomes. **Methods:** Rate of NGS adoption and TP53 mutation status were determined for a cohort of 984 AML patients tested by NGS from the Diaceutics Diagnostic Index between 2017 and 2019. Mutation rate of other genes on the same NGS panel used to determine if TP53 status was determined and compared using the z-score test for two population proportions. The stability of TP53 and co-mutation status at time of diagnosis and relapse/refractory was also analyzed. **Results:** We have seen a 2-fold increase in the average routine clinical practice uptake of NGS in a representative real-world patient cohort (Q3 2017, n = 144; Q3 2019, n = 290). In a cohort of 984 AML patients tested by NGS 151 (15.3%) had a TP53 mutation (Exon 4-9). Of those that had a TP53 mutation, significant negative associations were observed with mutations in seven other genes (ASXL1 p = 0.00308, CEBPA p = 0.0027, FLT3 p < 0.00001, IDH1 p = 0.04338, NRAS p = 0.0012, RUNX1 p = 0.01878 and TET2 p = 0.0251). There were no statistically significant differences in TP53 mutation and other gene mutation rates between diagnosis and relapse/refractory timepoints. **Conclusions:** This data suggests that TP53 and other gene co-mutants may act in similar activation pathways resulting in rare detection. One possibility is that double mutants result in synthetic lethality leading to a low clonal population. Second, when co-mutated clones escape immune surveillance and regulation, it results in particularly aggressive leukemias with lower overall survival. The stability of TP53 and co-mutation is relatively stable, which has implications for testing algorithms and clinical utility as a marker of MRD. Although a clinical trial may be difficult due to low numbers of patients, a TP53 antagonist and targeted therapy may be a valuable treatment option in rare cases where co-mutation does exist. Research Sponsor: Diaceutics (data analytics and implementation service provider in diagnostic commercialization).

Post-remission clonal hematopoiesis; Practical implications for measurable residual disease assessment in acute myeloid leukemia (AML). *First Author: Sanam Loghavi, Department of Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clonal Hematopoiesis may persist following complete remission (CR) in patients with acute myeloid leukemia (AML) but does not necessarily indicate residual AML and may represent persistence of pre-leukemic stem cells. Post-remission CH identified by NGS has not been systemically studied in parallel with measurable residual disease (MRD) detection by flow cytometric immunophenotyping (FCI). **Methods:** We studied bone marrow sample from AML patients at baseline and CR by targeted deep NGS of 295 genes (median 403x depth) and compared the results to FCI. Measurable residual disease (MRD) detection by FCI was performed by comparing the phenotype at CR to baseline and by detection of leukemia associated immunophenotype (LAIP) and derivation from normal (DFN) (sensitivity: 0.1%). Post-CR CH was defined as presence of mutations originally detected in AML with variant allele frequency > 2.5%. FCI results were categorized into 4 groups: a) AML MRD negative by LAIP or DFN b) AML MRD+ (similar to baseline) c) AML MRD+ (different from baseline), d) Negative for AML MRD, but aberrant phenotype suggestive of pre-leukemic cells. We correlated FCI and NGS results. **Results:** 101 patients were included in the study. 45 (45%) had persistent post-CR clonal hematopoiesis; 23 (51%) had phenotypic alterations detected by FCI including AML MRD+ in 18 (40%) and pre-leukemic cells in 5 (10%). Among patient with no detectable mutations by NGS (n = 56; 55%), 14 (25%) had FCI aberrancies including AML MRD+ in 4 (7%) and pre-leukemic cells in 10 (18%). CH was significantly more common in samples with residual phenotypic aberrancies detected by FCI (p = 0.004). There was no significant correlation between FCI group d and persistent CH (p = 0.4). Persistent *ASXL1* (p = 0.024, OR = 7.2) and *RUNX1* (p = 0.016; OR = 17.3) mutations were significantly associated with FCI abnormalities. The correlation coefficient between FCI abnormalities and *RUNX1* mutations inferred from a Bayesian network structure was 0.66. **Conclusions:** NGS and FCI are complementary in evaluating post treatment disease status in AML. Post CR-CH is associated with phenotypic abnormalities that either represent residual AML or pre-leukemic cells. The latter may not have the same prognostic implications as AML MRD; however, the association with outcome needs to be elucidated. Single cell DNA sequencing technologies may be helpful in more accurately deciphering the association of individual gene mutations and their contribution to phenotypic aberrations. 7530 Poster Session (Board #303), Fri, 8:00 AM-11:00 AM

CC-486 is safe and well-tolerated as maintenance therapy in elderly patients (≥75 years) with acute myeloid leukemia (AML) in first remission following induction chemotherapy: Results from the phase III QUAZAR AML-001 trial. *First Author: Farhad Ravandi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: About 40-50% of older patients (pts) with AML attain complete remission (CR) with induction chemotherapy (IC) but relapse is common.Effective, well-tolerated maintenance treatment (Tx) is needed for older pts in remission who are not eligible for hematopoietic stem cell transplant (HSCT). CC-486 is an oral hypomethylating agent that allows for extended dosing schedules (>7 days [d]/cycle) to sustain therapeutic activity. In the phase III placebo (PBO)-controlled QUAZAR AML-001 trial (NCT01757535), CC-486 maintenance therapy in pts with AML in first remission following IC produced significant improvements in overall and relapse-free survival. Here we report safety and tolerability findings among pt subgroups defined by age at study entry. **Methods:** Eligible pts were ≥ 55 yrs of age, with *de novo* or secondary AML, intermediate or poor risk cytogenetics, and ECOG PS ≤ 3; had achieved first CR or CRi after IC ± consolidation; and were not candidates for HSCT. Within 4 mo of CR/CRi, pts were randomized 1:1 to CC-486 300 mg or PBO QD on d 114 of repeated 28d Tx cycles. Safety was assessed across 3 age subgroups (≥ 55 to < 65, ≥ 65 to < 75, and ≥ 75 yrs) in pts who received ≥ 1 dose of study drug. Adverse events (AEs) were coded using MedDRA v. 22.0 and graded by NCI-CTCAE v. 4.0. **Results:** 469 pts (>99% of all enrolled pts) were evaluable for safety (CC-486 n = 236; PBO n = 233). Median age was 68 yrs (range 55-86). Age distribution was similar between the two Tx arms (Table). Between Tx arms, AE rates within each age stratum were similar to rates in the overall study population. The most common AEs (any grade) with CC-486 were GI events, which were more frequent than in the PBO arm across age groups. Within the CC-486 arm, AE rates were generally consistent across age groups, except for constipation, which was > 20% more frequent in pts aged ≥ 75 yrs, and thrombocytopenia, which was ≥ 20% less frequent in this group (Table). Overall, 13% and 4% of pts in the CC-486 and PBO groups discontinued Tx due to AEs. **Conclusions:** In QUAZAR AML-001, CC-486 was generally well tolerated in all age groups, including elderly pts aged ≥ 75 yrs. Clinical trial information: NCT01757535. Research Sponsor: BMS.

Table. Common AEs (> 20% of all pts; any grade) by pt age category

	CC-486			PBO

7531 Poster Session (Board #304), Fri, 8:00 AM-11:00 AM

Timing of response to venetoclax combination treatment in older patients with acute myeloid leukemia. *First Author: Brian Andrew Jonas, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Venetoclax (Ven) has synergistic activity with hypomethylating agents (eg, azacitidine [Aza] or decitabine [Dec]) or low-dose cytarabine (LDAC). These Ven-based combinations have demonstrated rapid median response times. This analysis describes the rapidity and likelihood of response to Ven treatments, and its associated characteristics, in older patients with newly diagnosed acute myeloid leukemia (AML). **Methods:** Included are data from two open-label trials of Ven, at label recommended doses, in combination with Aza, Dec (NCT02203773; phase 1b), or low-dose cytarabine (NCT02287233; phase 1/2) in newly diagnosed patients with AML. Patients were classified based on CR/CRi timing: within 2 cycles of therapy, after 2 cycles, or never achieving CR/CRi. Within each group, baseline and post-baseline characteristics were evaluated to determine impact on response timing. The percentage of patients in each category and duration of response (DOR) in each category were also evaluated. **Results:** Data cutoff was August 2018. Of 197 patients, 42% (n = 83) had CR/CRi in ≤2 cycles, 22% (n = 44) had CR/CRi in > 2 cycles, and 36% (n = 70) did not achieve CR/CRi. Median DOR was 21.2 mos. (95% CI 14.1-NR) for ≤2 cycle responders and 8.1 mos. (95% CI 5.3-14.9) for > 2 cycle responders. Baseline characteristics are shown in the Table. Patients with baseline *IDH1/2* mutation were more likely to have CR/CRi in ≤2 cycles, while those with secondary AML and no response by the end of cycle 2 were more likely to never achieve CR/CRi. Of the patients who achieved CR/CRi after 2 cycles of therapy, 43% (19/44) achieved MLFS within the first two cycles. Of those who never achieved CR/CRi, 17% (12/70) of patients achieved MLFS within 2 cycles. In depth regression analyses of factors predictive of response, including analysis of biomarkers, will be available upon presentation. **Conclusions:** Over 1/3rd of patients that achieved CR/CRi on Ven combination therapy within these two studies required more than 2 cycles of treatment. Therefore, prior to discontinuing therapy for nonresponders, it is critical to assess key predictive patient characteristics. Clinical trial information: NCT02203773 and NCT02287233. Research Sponsor: AbbVie and Genentech.

7532 Poster Session (Board #305), Fri, 8:00 AM-11:00 AM

FACT physical wellbeing to independently predict overall survival in patients with acute myeloid leukemia. *First Author: John Peipert, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Patient-reported outcomes (PROs) predict overall survival (OS) in solid cancer populations, but little evidence exists around the prognostic value of PROs in patients with hematologic malignancies. We investigated whether scales from the Functional Assessment of Cancer Therapy – Leukemia (FACT-Leu) predicted OS beyond established prognostic factors. **Methods:** Data were from 317 AML patients unfit for intensive therapy from a clinical trial comparing Dacogen (decitabine) plus Talacotuzumab versus Dacogen (decitabine) alone (AML2002; NCT02472145). We used ridge-penalized Cox models to determine whether baseline (1st cycle) FACT-Leu scales predicted OS. FACT-Leu scales significant in these models and factors from a validated prognostic model, the AML composite model (AML-CL; covariates listed in Table), were entered into Cox proportional hazard models. Lastly, model selection procedures were run with 1000 bootstrapped samples using all variables. The inclusion frequency of each FACT-Leu scale in the final models was examined to evaluate prognostic value for OS (i.e., higher the % of inclusion, higher importance of the variable). **Results:** In the ridge-penalized Cox models, the Physical Wellbeing Scale (PWB), Trial Outcome Index (TOI), and FACT-Leu Total scales were significant predictors of OS. After adjusting for the AML-CL factors, an important difference (2 pts) in PWB score was associated with a 9% decline in OS. (Table) Model validity was evidenced as the PWB scale appeared in a large majority of selected models (90%-97%), while the TOI (45%-73%) and FACT-Leu Total (41%-71%) appeared less often. **Conclusions:** FACT-Leu scales, especially the PWB, were significant prognostic factors for OS among AML patients not suitable for intensive therapy. These results may indicate PROs' value as stratification factors in trials with AML patients and underscore the need to more systematically collect PRO data in routine care practice with AML patients. Clinical trial information: NCT02472145. Research Sponsor: None.

FACT-Leu Scales	Hazard Ratio (95%)	p-value
PWB per 2 point change	0.91 (0.86-0.97)	0.002
TOI per 4 point change	0.96 (0.93-0.99)	0.03
FACT-Leu Total Score per 5 point change	0.96 (0.92-0.99)	0.02

Separate models for each FACT-Leu scale.
Each adjusted for AML-CL factors: arrhythmia, cardiac comorbidity, IBD, diabetes, cerebrovascular disease, psychiatric disturbance, obesity, infection, rheumatologic comorbidity, peptic ulcer, renal comorbidity, prior solid tumor, heart valve disease, pulmonary comorbidity, hepatic comorbidity, cytogenetic/molecular risk, LDH level, and age.

7533 Poster Session (Board #306), Fri, 8:00 AM-11:00 AM

Health-related quality of life (HRQoL) in the phase III QUAZAR-AML-001 trial of CC-486 as maintenance therapy for patients with acute myeloid leukemia (AML) in first remission following induction chemotherapy (IC). *First Author: Gail J. Roboz, Weill Cornell Medical College and New York Presbyterian Hospital, New York, NY*

Background: Effective AML maintenance treatment (Tx) should decrease the risk of relapse and prolong survival without compromising HRQoL. In the placebo (PBO)-controlled phase III QUAZAR AML-001 trial (NCT01757535), CC-486, an oral hypomethylating agent, provided significant improvements in overall (OS) and relapse-free survival (RFS) in patients (pts) with AML in first remission following IC. Here we present pt-reported HRQoL outcomes from that study. **Methods:** Eligible pts were ≥ 55 yrs of age with intermediate- or poor-risk cytogenetics and ECOG PS ≤ 3, and in CR/CRi after IC ± consolidation. Pts were randomized 1:1 to CC-486 300 mg or PBO QD on days (d) 1–14 of 28d Tx cycles. HRQoL was assessed by FACIT-Fatigue scale and EQ-5D-3L health utility index, completed on d1 of each cycle and at end of Tx (EOT). Endpoints include Tx differences in mean changes from baseline (BL), and proportions of pts with clinically meaningful change from BL (improvement, no change, deterioration). Evaluable pts had an HRQoL assessment at BL and ≥ 1 post-BL visit. Stratified ANCOVA models included Tx and BL scores as covariates. **Results:** In all, 225/238 pts (95%) in the CC-486 arm were evaluable for FACIT-Fatigue and EQ-5D-3L, and 219/234 pts (94%) in the PBO arm were evaluable for FACIT-Fatigue and 217 (93%) for EQ-5D-3L. Pt characteristics were comparable between Tx arms. Most pts (61%) were 65-74 yrs of age. Median number of CC-486 Tx cycles was 12 and PBO cycles was 7. Compliance rates were > 95% at BL and remained high (> 85%) at all post-BL visits except for EOT. At BL, pts in both Tx arms had comparable low levels of fatigue and generally good HRQoL relative to an age-matched general population. There were no meaningful differences between CC-486 and PBO in mean changes from BL in FACIT-Fatigue or EQ-5D-3L scores at any post-BL visit. There was no statistically significant difference between Tx arms in proportion of pts with a clinically meaningful deterioration in FACIT-Fatigue score at any post-BL visit except at cycle 29 (likely due to chance; no adjustment made for multiple testing), or in EQ-5D-3L at any visit. Median time to deterioration was not significantly different between CC-486 and PBO on the FACIT-Fatigue scale (41 vs 44 weeks, respectively; $P = 0.70$) or the EQ-5D-3L (200 vs 164 weeks; $P = 0.63$). **Conclusions:** HRQoL and low levels of fatigue were preserved with CC-486 maintenance Tx. CC-486 significantly improved OS and RFS while maintaining HRQoL comparable to PBO. Clinical trial information: NCT01757535. Research Sponsor: BMS.

7534 Poster Session (Board #307), Fri, 8:00 AM-11:00 AM

Molecular dissection of normal karyotype acute myeloid leukemia. *First Author: Jacob Tyler Shreve, Indiana University School of Medicine, Indianapolis, IN*

Background: Conventional cytogenetics remain one of the most important prognostic factors in acute myeloid leukemia (AML), though 50-60% of patients (pts) have normal karyotype (NK), conventionally classified as intermediate-risk, and have very heterogeneous outcomes. A fraction of mutations such as *NPM1*, *FLT3-ITD,* and *CEBPa* can improve risk stratification for some pts but underestimate the molecular complexity and interactions between these genes and others. **Methods:** Genomic and clinical data of 2,793 primary AML (pAML) pts were analyzed. A panel of 35 genes that are commonly mutated in AML and myeloid malignancies and have shown to impact OS was included. Correlation of each mutation with others and their impact on OS were evaluated. OS was calculated from the date of diagnosis to date of death or last follow-up. **Results:** Of 2,793 pts with pAML, 1,352 (48%) had NK and were included in the final analysis. The median age was 55 years (range, 18-93). The median number of mutations/sample was 3 (range, 0-7). The most commonly mutated genes were: *NPM1* (49%), *DNMT3A* (37%), *FLT3-ITD* (24%), *CEBPa* (19%), *TET2* (17%), *IDH2* (17%), and *RUNX1* (15%). In univariate Cox regression analysis, mutations in *NPM1* (HR 0.81, p =0.008), and *CEBPa* (single mutant, HR 0.8, double mutant, HR 0.69, $p< 0.001$, respectively) were associated with longer OS, while mutations in *DNMT3a* (HR 1.26, p =0.003), *FLT3-ITD* (HR 1.49, $p<$ 0.001), *TET2* (HR 1.26, p =0.02), *RUNX1* (HR 1.36, p =0.003), *SRSF2* (HR 1.58, p <0.001), *IDH1* (HR 1.29, p <0.001), and *ASXL1* (HR 1.89, p <0.001) were associated with shorter OS. A total of 67% of pts had *NPM1, DNMT3A,* and *FLT3-ITD* mutated alone or in combination with each other. The median OS for pts with $NMP1^{Mut}/DNMT3A^{WT}/FLT3\text{-}ITD^{WT}$ was 99.1 months(m), $NMP1^{Mut}/DNMT3A^{Mut}/FLT3\text{-}ITD^{WT}$ 54.8m, $NMP1^{Mut}/DNMT3A^{WT}/FLT3\text{-}ITD^{Mut}$ 42.3m, $NMP1^{Mut}/DNMT3A^{Mut}/FLT3\text{-}ITD^{Mut}$ 13.4m, $NMP1^{WT}/DNMT3A^{Mut}/FLT3\text{-}ITD^{Mut}$ 13.1m, and $NMP1^{WT}/DNMT3A^{WT}/FLT3\text{-}ITD^{WT}$ (triple negative) 32.7m. The median OS for pts with 0-2 mutations/sample was 59.3m, compared to 34.1m for pts with 3-4 mutations, and 16.1m for pts with > 5 mutations ($p<$ 0.001). **Conclusions:** We propose a simplified and robust approach to risk stratify AML pts with NK based on the mutational status of *NPM1*, *DNMT3A*, *FLT3-ITD* (alone or in combination with each other), *CEBPa*, and the number of mutations/sample. Research Sponsor: None.

7535 Poster Session (Board #308), Fri, 8:00 AM-11:00 AM

Relation between measurable residual disease and morphologic relapse in AML. *First Author: Lauren Shih, University of Washington, Seattle, WA*

Background: Measurable residual disease (MRD) in AML portends a poor prognosis. The outcomes and treatments of MRD after an initial MRD negative complete remission (MRD- CR) are unclear. **Methods:** We retrospectively identified 432 patients ≥ 18 years of age treated for AML or high grade myeloid neoplasm (10-19% blasts in blood and/or marrow) at University of Washington/Seattle Cancer Care Alliance from 2008-2017 who achieved MRD- CR after initial treatment. Next disease recurrence was recorded, with patients either developing MRD (< 5% blasts via multiparameter flow cytometry; n = 44) or developing morphologic relapse (≥5% blasts; n = 100). The remaining patients remained in MRD- CR (n = 288, median follow up time 3.7 years). A landmark analysis at one year was performed to compare overall survival (OS). **Results:** Patients who developed MRD tended to be older (p = 0.009), but baseline characteristics were otherwise similar. Therapies for MRD included allogeneic transplant, low intensity chemotherapy, and high intensity chemotherapy; no significant associations were found between type MRD directed therapy and survival. Landmark OS at 1 year after MRD- CR was significantly different for patients without relapse at 1 year compared to those with MRD or morphologic relapse (median OS was 8.5 years for no relapse, 2.2 years for MRD, and 1.0 years for morphologic relapse). A multivariable Cox regression model among patients alive at 1 year showed patients without relapse had significantly improved OS compared to those with morphologic relapse [HR 0.18 (95% CI 0.1-0.31)]. Although there was a trend towards improved OS, we did not identify a significant difference between patients with MRD relapse compared to morphologic relapse [HR 0.54 (95% CI 0.27-1.11)]. There were no significant differences in patient characteristics for patients with MRD vs morphologic relapse matched by time of relapse (days 30-90, 90-150, 150-210). **Conclusions:** Following MRD- CR, development of either MRD or morphologic relapse were both associated with decreased OS. Notably, no significant differences in terms of survival were seen between patients who presented with MRD as opposed to morphologic relapse. No clear predictors were identified for MRD vs morphologic relapse. In this cohort, development of MRD carried a poor OS prognosis, similar to the prognosis of developing morphologic relapse. Future clinical trials should focus on MRD directed therapies, as no consensus exists about optimal treatment of MRD. Research Sponsor: None.

7536 Poster Session (Board #309), Fri, 8:00 AM-11:00 AM

Characterization of clinical pharmacokinetics and exposure-response relationships of AMG 330, a bispecific CD33 T-cell engager antibody construct, in patients with relapsed/refractory AML. *First Author: Suresh K Agarwal, Amgen Inc., South San Francisco, CA*

Background: AMG 330 binds both CD33 and CD3 and redirects T cells toward $CD33^+$ cells leading to T-cell–mediated cytotoxicity against AML blasts. An ongoing open label phase I dose-escalation study (NCT02520427) has shown preliminary activity and acceptable safety in relapsed or refractory (R/R) acute myeloid leukemia (AML) patients (pts) (Ravandi et al. ASH 2018). Pharmacokinetics and exposure-response (E-R) relationships of AMG 330 were characterized in this trial. **Methods:** A continuous IV infusion of AMG 330 was evaluated at escalating target doses (range from 0.5 to 720 μg/day) using a 3+3 design with pts receiving step dose/s prior to reaching target doses of ≥ 30 μg/day. Population pharmacokinetics (popPK) using non-linear mixed effects modeling and E-R analyses were conducted to characterize relationships between AMG 330 exposure (steady-state concentration [Css]) at target dose, the baseline tumor burden, clinical response per revised IWG criteria and incidence of cytokine release syndrome (CRS). **Results:** As of Dec 10, 2019, 55 patients (males, 56.4%; median age, 58.0 [18.0–80.0] years) were enrolled in 16 cohorts. AMG 330 PK was best described by a one-compartment linear PK model. Dose dependent increases were observed in AMG 330 Css exposures. Responders typically showed higher AMG 330 Css than non-responders. Preliminary exploratory analysis indicated that higher AMG 330 exposures, lower baseline leukemic burden in bone marrow and CD33+ AML cells in peripheral blood, and higher baseline Effector:Target cell ratio may be associated with clinical response. Additionally, a positive relationship was observed for AMG 330 exposures and baseline leukemic burden ($p < 0.05$) with probability of CRS occurrence and severity. Based on the model, at a baseline leukemic burden of 20%, a 240 μg/day target dose is predicted to result in a 28% and 4% probability of developing CRS of grade ≥ 2 and ≥ 3, respectively. **Conclusions:** Clinical pharmacokinetic profile and E-R relationships of AMG 330 were characterized to identify optimal AMG 330 dosing regimens that minimize the risk for CRS in ongoing and planned clinical investigations. Clinical trial information: NCT02520427. Research Sponsor: Amgen Inc.

7537 Poster Session (Board #310), Fri, 8:00 AM-11:00 AM

Outcomes in older patients with high-risk/secondary AML who achieved remission with CPX-351 versus 7+3 but did not undergo transplant: Phase 3 exploratory analysis. *First Author: Tara L. Lin, University of Kansas Medical Center, Kansas City, KS*

Background: CPX-351 (Vyxeos; daunorubicin [D] and cytarabine [C] liposome for injection) is approved by the FDA and EMA for the treatment of adults with newly diagnosed therapy-related AML or AML with myelodysplasia-related changes. In a phase 3 study (NCT01696084) in patients (pts) aged 60-75 y with newly diagnosed high-risk/secondary AML, CPX-351 demonstrated significantly longer overall survival (OS) and higher rates of remission and hematopoietic cell transplant (HCT) vs conventional 7+3, with a comparable safety profile. To better understand the impact of treatment on outcomes in pts who did not undergo HCT, this exploratory analysis evaluated outcomes in the subgroup who achieved complete remission (CR) or CR with incomplete neutrophil or platelet recovery (CRi) with CPX-351 vs 7+3 but did not undergo HCT. **Methods:** Pts were randomized 1:1 to receive ≤2 induction cycles of CPX-351 (100 units/m^2 [C 100 mg/m^2 + D 44 mg/m^2] as a 90-min infusion on Days 1, 3, 5 [2nd induction: Days 1, 3]) or 7+3 (C 100 mg/m^2/d continuously for 7 d + D 60 mg/m^2 on Days 1-3 [2nd induction: 5+2]). Pts achieving CR or CRi could receive up to 2 consolidation cycles. Pts could receive HCT at the physician s discretion. **Results:** CR+CRi was achieved by 73/153 (48%) pts with CPX-351 vs 52/156 (33%) with 7+3; of these pts, 33/73 (45%) vs 28/52 (54%) did not subsequently undergo HCT. The baseline characteristics of these pts were generally balanced between arms; however, the CPX-351 arm had more male pts vs 7+3 (64% vs 43%) and pts with ECOG PS of 1 (82% vs 54%), and fewer pts with antecedent MDS and HMA exposure (21% vs 39%). Median OS was longer with CPX-351 vs 7+3 (14.72 vs 7.59 mo; HR = 0.57 [95% CI: 0.31-1.03]; Table). There was no early mortality by Day 60 in either arm (see Table for additional data). **Conclusions:** CPX-351 improved median OS vs 7+3 in pts who achieved CR+CRi but did not undergo HCT, suggesting a treatment benefit with CPX-351 even among pts who do not undergo HCT. The CPX-351 safety profile in this subgroup was consistent with the overall study population and known profile of 7+3. Clinical trial information: NCT01696084. Research Sponsor: Jazz Pharmaceuticals.

STAG2-mutated AML patients: ASXL1 cohesin binding motif status and mutation landscape. *First Author: Frank J Scarpa, NeoGenomics Laboratories, Aliso Viejo, CA*

Background: *ASXL1* and the cohesin complex (*STAG2*, *RAD21*, *SMC1A*, and *SMC3*) are commonly mutated chromatin regulators with significant clinical implications in AML. The ASXL1-cohesin interactome regulates gene expression through chromatin accessibility via *ASXL1*'s cohesin binding motif (CBM). *ASXL1* variants are most commonly located in the ASXM1 domain and onwards, and characteristically lead to loss of the PHD domain. Gain-of-functions in truncated *ASXL1* are suggested to increase catalytic activity of *BAP1,* which binds the ASXH domain at AA 351, and to gain an interaction with *BRD4,* which binds somewhere between the ASXN and ASXH domains, to drive H3K4Me3 and H2AK119Ub. **Methods:** 2463 suspected AML patient bone marrow, peripheral blood, or FFPE tissue samples were evaluated using an all exon amplicon-based 27 gene NGS panel. Patients with a VAF <10% in *ASXL1* were excluded to avoid reporting artifacts, particularly in variant c. 1934dup. Statistics were performed using Fisher's exact test. **Results:** Mutations in *STAG2*-mutated patients were enriched for sAML, as evidenced by the higher number of mutations in *ASXL1, SRSF2,* and *BCOR* (associated with sAML) compared to *NPM1, DNMT3A,* and *PTPN11* (pAML). *STAG2* mutations were found in 173 samples representing 93.5% of cohesin mutations. Of all *ASXL1* mutations (VAF 10.1– 54.5%; median 32.2%) 4.0% occurred in the CBM. While 23.5% of samples with mutations outside *ASXL1* CBM had concomitant mutations in *STAG2*, none of the 18 samples with CBM mutations (VAF 11.3 – 51.7%; median 42.5%) had any cohesin gene mutation (P = 0.0174). The proportion of *BCOR* (27.8% vs 9.2%; P = 0.024) and *CEBPA* (27.8% vs 8.2%; p = 0.016) mutated patients in the CBM+ group was significantly higher than the CBM- group. *JAK2* (16.7% vs 5.4%), *KRAS* (22.2% vs 13.6%), *EZH2* (22.2% vs 13.6%), and *RUNX1* (38.9% vs 27.7%) mutations were also higher though not significantly in this group. Mutations throughout all of *ASXL1*, the 13 amino acids after the CBM, and hotspot variants all had *STAG2* mutations at a frequency of 20.9-44.4%, further suggesting mutual exclusivity. **Conclusions:** STAG2 mutations and mutations in the CBM were mutually exclusive events and harbored different co-mutation frequencies. In compromised ASXL1 CBM cases, *BCOR* and *CEBPA* transcriptional regulators are significantly more mutated, but in cases of ASXL1 mutation outside the CBM, cohesin mutations are preferred, suggesting alternative chromatin accessibility mechanisms driving leukemogenesis. This observation has not been previously reported in the literature to our knowledge. Research Sponsor: None.

7539 Poster Session (Board #312), Fri, 8:00 AM-11:00 AM

Venetoclax (Ven) added to intensive chemo with cladribine, idarubicin, and AraC (CLIA) achieves high rates of durable complete remission with low rates of measurable residual disease (MRD) in pts with newly diagnosed acute myeloid leukemia (AML). *First Author: Tapan M. Kadia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ven is a BCL2 inhibitor that is approved in combination with lower intensity therapy for pts with newly diagnosed AML who are ineligible for intensive chemo. We previously reported the safety and efficacy of cladribine and araC with idarubicin in young and fit pts with AML. Here, we studied the combination of ven with the intensive CLIA regimen in newly diagnosed AML. **Methods:** Pts < 65 yrs with newly diagnosed FLT3-wildtype AML were enrolled. Induction was cladribine 5 mg/m^2 IV on D 1-5, followed by ara-C 1.5 g/m^2 IV on D 1-5, idarubicin 10 mg/m^2 IV D 1-3, and ven at an effective dose of 400mg PO on D2-8. There was no ramp up for ven and dose modifications for CYP3A4 inhibitors were made. Consolidation consisted of up to 5 more cycles of CLIA+Ven. All pts underwent baseline next generation sequencing and MRD testing by multiparameter flow cytometry at the time of response. **Results:** 18 pts are enrolled, with a median age of 50 yrs (range, 18-64). Baseline pt characteristics are in Table. 16 pts were evaluable for response and 2 are too early. 14 of 16 pts (88%) achieved a remission, including 10 (63%) complete remission (CR) and 4 (25%) CR with incomplete count recovery (CRi). The median time to response was 1 cycle and the median number of cycles given was 2 (1-5). 10 of the 14 responders (71%) had undetectable MRD at the time of remission. Both nonresponding pts had a complex karyotype and 1 had a TP53 mutation. With a median follow up of 4.5 months (0.2 – 11.2), none of the responding pts have relapsed. 8 of the 14 responders (57%) have received allogeneic stem cell transplant. The median survival has not been reached; the 6-month OS and RFS are 90% and 100%, respectively. Treatment was well tolerated, with 0% 4-week mortality. The median days to ANC ≥ 1 and Platelets ≥ 100 were 30 (19-49) and 26 (18-39), respectively. Tumor lysis syndrome was not seen. The most common adverse events were neutropenic fever, pneumonia, nausea, and liver transaminitis. **Conclusions:** The addition of ven to CLIA was safe and effective in newly diagnosed pts with AML. The combination was not associated with early mortality or prolonged myelosuppression, but did result in high rates of durable MRD negative remissions. Clinical trial information: NCT02115295. Research Sponsor: Internal Departmental Funds.

Characteristics	N = 18 Pts Median [Range] or N (%)

7540 Poster Session (Board #313), Fri, 8:00 AM-11:00 AM

Meta-analysis of case-control studies to examine the relationship between occupational pesticide exposure and risk of acute myeloid leukemia. *First Author: Nicolas Vallet, Tours University Hospital and ERL7001 LNOX, EA 3549, Tours, France*

Background: Occupational pesticide exposure (OPE) is associated with the risk of developing lymphoid malignancies, but less information is available on large cohorts about the risk of occurrence of acute myeloid leukemia (AML). To answer this question, we performed a meta-analysis including relevant adult case-control studies which reported OPE. **Methods:** Following PRISMA and MOOSE guidelines, two investigators performed a systematic search in PubMed and Cochrane databases for case-control studies evaluating the association between OPE and AML between 1946 and August 28, 2018. In order to identify the maximum number of studies, keywords related to demographical, pesticides and chemicals data exposures were used. Studies reporting AML diagnosis based only on death certificates, controls from cancer databases and pediatric cases (<15 years-old) were not included. Statistical analyses were performed with R software and the 'mefafor' package. **Results:** Fifteen studies which included 4,068 AML patients and 250,975 control subjects were included. Using a random effects model, the overall analysis showed a significant adverse association between OPE and AML with OR=1.49 (95%CI: 1.10-2.01), and a significant heterogeneity between studies (I^2=0.73, p<0.001). The robustness was checked after sequential exclusion of one study at a time which did not influence the overall OR estimate. A publication bias underestimating the OR was suggested by an asymmetrical funnel plot. Using trim-and-fill method, hypothetical missing studies were added studies in order to adjust the OR (OR=1.76 [95%CI: 1.30-2.38]. A stratified analysis showed that the association was significant in Asian populations (OR=1.74; 95%CI: 1.32-2.30) and upon exposure to insecticides (OR=1.45; 95%CI: 1.16-1.81), yet partly influenced by other factors, since most of the studies reported unadjusted results (n=8, 53%). Data on biological characteristics were unavailable to stratify patients according to AML molecular or cytogenetic characteristics. **Conclusions:** From this new extensive review and analysis, it clearly appears that AML should be considered as occupational illness in patients with demonstrated OPE. Further studies will have to focus on the biological effects of individual and pesticides cocktails in order to determine the pathogenesis mechanisms involved in leukemogenesis, and to improve individual protection. Research Sponsor: None.

7541 Poster Session (Board #314), Fri, 8:00 AM-11:00 AM

Antibacterial antibiotic exposures and cytomegalovirus reactivation after allogeneic hematopoietic stem cell transplantation. *First Author: Shijia Zhang, Division of Hematology, Oncology, and Transplantation, University of Minnesota, Minneapolis, MN*

Background: Cytomegalovirus seropositive (CMV+) recipients of CMV seronegative (CMV-) hematopoietic cell allografts are at the highest risk for CMV reactivation. Inspired by the recently described effect of antibiotic (abx)-induced dysbiosis on antiviral immunity, we retrospectively evaluated whether antibacterial abx exposures influence the risk of CMV reactivation after CMV- to CMV+ cord blood (CB) or matched sibling donor (MSD) transplantation, the serologic setting with highest risk of CMV reactivation. **Methods:** We identified 213 eligible patients (pts; 146 CB, 67 MSD, mean age 50, range 18-73). Exposures to fluoroquinolones (FQN), 3rd or higher generation cephalosporins (CPN3+), intravenous vancomycin (Vanc), piperacillin-tazobactam (Pip-Tazo), carbapenems, and metronidazole/clindamycin (Metro/Clinda) from day (D) -7 to D +14 (binary variables) or until CMV reactivation (or D +100, whichever occurred first; time-varying variables) were included in multivariable Fine-Gray regression models with competing risk for non-CMV death to estimate the risk of CMV reactivation by D +100. Other pre-defined covariates were ATG use during conditioning, anti-CMV abx exposure for other viruses, and acute GVHD. **Results:** 91% of pts received FQN, 67% CPN3+, 56% Vanc, 21% Pip-Tazo, 22% carbapenems, and 28% Metro/Clinda until D +14. These numbers increased to 94%, 81%, 76%, 31%, 38%, and 39% by D +100 (or CMV reactivation), respectively. 83 pts (39%: 66 CB, 17 MSD) had CMV reactivation by D +100. Vanc exposure by D +14 almost doubled the risk of CMV reactivation (HR 1.96, 95%CI 1.11-3.46, $P = 0.02$). With abx exposures up to D +100 modeled as time-varying covariates, Vanc exposure predicted a higher risk for CMV reactivation (HR 1.86, 95%CI 0.99-3.52, $P = 0.06$). The table below summarizes the results, excluding non-abx covariates for brevity. **Conclusions:** Our results suggest that vancomycin-sensitive bacteria may protect against CMV reactivation. Identifying the specific taxa and their location (intestinal vs. extraintestinal) requires more research. Microbiota considerations and abx exposure patterns can help personalize CMV prophylaxis. Research Sponsor: None.

Antibiotic	HR (95%CI), D +14, binary	P	HR (95%CI), D +100, time-varying	P

Incidence of graft versus host disease in peri transplant hospitalization after *clostridium difficile* infection. *First Author: Drew Carl Drennan Murray, Division of Hematology and Medical Oncology, James Graham Brown Cancer Center, University of Louisville, Louisville, KY*

Background: Hyperacute graft versus host disease (GVHD) after allogenic stem cell transplantation (SCT) has adverse outcomes with increased rates of chronic GVHD and relapse. GVHD risks include mismatched related or matched unrelated donors, myeloablative conditioning, heavy pretreatment, and donor-recipient sex mismatch. *Clostridium difficile* infection (CDI) is a leading cause of diarrhea in immunocompromised patients. Proposed microbiome effect on immunity and GVHD in allogenic SCT recipients prompts concern of microbiome modulation from CDI and antibiotics inciting GVDH. **Methods:** National Inpatient Sample database 2014 for hospitalizations with allogeneic SCT in patients ≥18yo. Characteristics (age, sex, race, insurance, graft source, hospital type, region, comorbidities) were compared for hospitalizations with and without CDI. Primary outcome was the difference in the incidence of GVHD during the transplant hospitalization between the 2 groups. Other outcomes were mortality, length of stay and hospital charges. Chi-square, t-test, and multivariate logistic regression utilized. **Results:** Of 6210 patients with allogenic SCT, 745 (12%) had CDI during the transplant hospitalization. In transplanted patients without CDI the average age was 55yo, 43.9% female, 69.5% Caucasian (C), 7.1% African American (AA), 8.6% Hispanic (H), 32.1% had Medicare/Medicaid, 61.8% private insurance, 5.7% uninsured, 44.7% had hypertension, 13.7% had diabetes, graft source was 84.3% PBSC (peripheral blood stem cells), 11.3% bone marrow, and 4.4% cord blood. CDI group the average age was 52.5yo, 45.3% female, 73% C, 4.7% AA, 8.1% H, 25.7% had Medicare/Medicaid, 66.2% private insurance, 8.1% uninsured, 41.9% had hypertension, 10.1% had diabetes, graft source was 83.8% PBSC, 10.8% bone marrow, and 5.4% cord blood. 25.7% of patients with CDI developed GVHD during that hospitalization while 14.2% of patients without CDI developed GVHD during the hospital stay (OR 2.1, $p < 0.001$ multivariate analysis). GVHD during the hospitalization had no difference in length of stay ($p = 0.32$), total cost of stay ($p = 0.50$) or same hospitalization mortality ($p = 0.94$). **Conclusions:** Allogeneic SCT patients with CDI develop GVHD on the same hospitalization at significantly higher rates than patients without CDI. This is true after controlling for age, sex, race, insurance, comorbidities, graft source, hospital location, and type of institution. Despite known associations of early evidence of GVHD on relapse, overall mortality was not different between the two groups. Research Sponsor: None.

7543 Poster Session (Board #316), Fri, 8:00 AM-11:00 AM

Etanercept with extracorporeal photopheresis (ECP) for steroid-refractory acute graft versus host disease following allogeneic hematopoietic stem cell transplantation. *First Author: Sunny R K Singh, Henry Ford Health System, Detroit, MI*

Background: Acute graft versus host disease (aGVHD) is a well-described complication of allogeneic stem cell transplantation (allo-SCT). Complete response to steroids is achieved in 40-50% of cases, with steroid refractory GVHD requiring second line therapy. Currently, there is no accepted standard of care in this setting. In our study, we assessed the safety and efficacy of etanercept with ECP for steroid refractory aGVHD in a single center tertiary care hospital. **Methods:** Thirty adult patients who underwent peripheral blood allo-SCT and developed steroid-refractory aGVHD between January 2010 - July 2019 were retrospectively analyzed. Patients were planned to receive etanercept 25 mg subcutaneously twice weekly for at least 4 weeks. Safety was assessed by estimating infection related mortality. For efficacy, we analyzed the change in grade of aGVHD using the Wilcoxon signed-rank test. **Results:** Median age at the time of allo-SCT was 57.6 years and the most common indication for transplant was Myelodysplastic syndrome. Median time from allo-SCT to steroid initiation was 39.5 days (range 14-183 days). Median time from steroid initiation to etanercept was 6 days, with 7.5 median number of etanercept doses received. A total of 25 patients (83.3%) received ECP. As depicted in the table, there was a significant improvement in severity of aGVHD after etanercept therapy compared to that before its initiation. Overall response rate was 83.3%, while overall mortality was 86.7%. Median overall survival for responders was 306 days (range 59-2005 days) and for non-responders was 181 days (range 89-261 days). Death attributed to infection alone occurred in 28% (n=7), infection along with GVHD in 28% (n=7) and infection with relapsed disease in 1 patient. Active infection within 6 months of transplant occurred in 93.3% patients. **Conclusions:** The use of Etanercept with ECP resulted in improvement of steroid refractory aGVHD following allo-SCT, with responses noted in the majority of patients. High rates of infection related mortality were also noted and remain a cause of concern. Research Sponsor: None.

Response at Day 56 for aGVHD (from initiation of steroids)	Complete Response	Partial Response	No Response	Progression
Skin	3 (30%)	4 (40%)	3 (30%)	
Gut	3 (20%)	10 (66.7%)		2 (13.3%)
Liver	3 (42.9%)	2 (28.6%)		2 (28.6%)
aGvHD Severity	**Before Etanercept**	**After Etanercept**	**Z-score (for change in severity)**	**p - value**
Absent		7 (26.9%)	-2.9	0.003
Grade I	2 (6.7%)	3 (11.5%)

Incidence of large granular lymphocytosis (LGL) in patients with late cytopenias after allogeneic blood or marrow transplantation (AlloBMT). *First Author: Marcus Messmer, Johns Hopkins University, Baltimore, MD*

Background: LGL - often called LGL leukemia - is a clonal disorder of T or NK cells often associated with cytopenias, autoimmunity, splenomegaly, and B symptoms. There are a limited number of studies of benign LGL expansion after alloBMT, some suggesting an association with improved transplant-related outcomes. In contrast, clinically significant LGL leukemia after alloBMT is only described in case reports. **Methods:** We cross referenced all patients receiving an alloBMT at Johns Hopkins since 2010 with patients who were evaluated for LGL expansion by peripheral blood (PB) flow cytometry (FC) since 2012. **Results:** There were 1930 alloBMTs from 1/1/10 to 7/1/19. PB FC for suspected LGL was sent on 153 unique patients after alloBMT, usually in the setting of cytopenias (97%). Median age was 59. 69 (45%) had LGL expansion (LGL+) at a median 194 days after alloBMT. Among LGL+, 53 (77%) had an absolute neutrophil count (ANC) < 1500. The majority of the alloBMTs were non-myeloablative (NMA) (97%), related (88%), and haploidentical (89%), consistent with our center's characteristics. Graft vs host disease (GVHD) prophylaxis was post-transplant cyclophosphamide (PTCy), mycophenolate mofetil, and tacrolimus or sirolimus. 64 (93%) cases were T cell LGL (T-LGL) and 5 were NK cell. Of those with T-LGL, 43 were assessed for T cell receptor clonality. 21% were clonal, 53% oligoclonal, 5% polyclonal, and 21% indeterminate. There were no significant demographic or transplant-related differences between LGL+ and LGL- in our 153 patient cohort. LGL+ were more likely to have had CMV viremia (75% vs 26%, $p < 0.0001$), but not acute or chronic GVHD. LGL+ had higher lymphocyte counts (1520/cu mm vs 495, $p < 0.0001$) and a trend toward more neutropenia (77% vs 63%, $p = 0.07$). There were no differences in overall survival, relapse, or non-relapse mortality. 29 (42%) of LGL+ received immunosuppressive therapy (IST) for cytopenias. First line treatment was corticosteroids for 24 (83%). 65% had normalization of ANC with first line treatment, compared to improvements in anemia in 15% and thrombocytopenia in 36%. 34% of those treated required ≥2 lines of treatment. **Conclusions:** In contrast to prior studies, where LGL after alloBMT was asymptomatic and associated with improved transplant outcomes, we identified a high rate of LGL with cytopenias and no improvement in transplant outcomes. Neutropenia was common in LGL+ and usually improved with IST. Research Sponsor: None.

7545 Poster Session (Board #318), Fri, 8:00 AM-11:00 AM

Toxicities after high dose post-transplant cyclophosphamide in haploidentical donor transplants: Risk factors and impact on survival. *First Author: Dipenkumar Modi, Karmanos Cancer Institute/Wayne State University, Detroit, MI*

Background: Post-transplant cyclophosphamide (pCY) when given at 50mg/kg on day +3 and +4 in haploidentical donor transplants (HIDT) leads to considerable morbidity. Information on its toxicity and impact on outcomes is limited. **Methods:** We analyzed 91 patients (pt) undergoing HIDT with pCY to estimate incidence and risk factors of mucositis, hemorrhagic cystitis, renal and cardiac toxicities during the first 6 months after transplant and its impact on overall survival (OS). We compared these complications with 91 pt who were matched for age, disease, disease status at transplant, conditioning regimen and received 8/8 HLA-matched transplants without pCY (non-pCY cohort). **Results:** Fourteen pt (15%) in non-pCY and 28 (31%) in pCY experienced hypoxia requiring oxygen ($p = 0.03$). Ten pt (11%) in non-pCY and 21 (23%) in pCY developed clinically significant hypotension ($p = 0.05$). Day +100 cumulative incidence rate (CIR) of mucositis was 59.3% for non-pCY and 84.6% for pCY ($p < 0.001$). Seven pt (13%) in non-pCY cohort and 39 (51%) in pCY developed grade 3-4 mucositis ($p < 0.001$). Two pt (2%) in non-pCY and 22 (24%) in pCY developed gross hematuria ($p = 0.05$). Day +180 CIR of hemorrhagic cystitis was 13.2% for non-pCY and 29.7% for pCY ($p = 0.005$). Hemorrhagic cystitis did not have an adverse impact on non-relapse mortality (NRM) and OS. Day +180 CIR of renal toxicities was 17.6% for non-pCY and 28.6% for pCY ($p = 0.10$). The CIR of cardiac toxicities at day +180 was 9.9% for non-pCY and 14.3% for pCY ($p = 0.34$). Congestive heart failure (59%) and atrial fibrillation (36%) were the most common cardio-toxicities. One-year NRM was 38.5% in pt developing cardio-toxicity in the pCY cohort compared to no cardio-toxicity (15.3% in non-pCY and 18.3% in pCY, $p = 0.004$). OS was inferior in pt with cardio-toxicity in non-pCY (HR 5.49, $p < 0.001$) and pCY (HR 2.3, $p = 0.03$) compared to pt without cardio-toxicity. In multivariable analysis, pCY was associated with an increased risk of mucositis (HR 1.48, $p = 0.03$), and hemorrhagic cystitis (HR 2.67, $p = 0.004$). The number of infused CD34 cells was associated an increased risk of cardiac toxicity (HR 1.13, $p = 0.005$). pCY was not associated with higher cardiac complications, and no impact of the number of infused CD34 cells, conditioning regimen and prior transplant was observed on hemorrhagic cystitis and mucositis. **Conclusions:** pCY was associated with significant morbidity compared to HLA-matched non-pCY cohort. Although cardio-toxicities were similar between both groups, it was associated with worse survival. Research Sponsor: None.

7546 Poster Session (Board #319), Fri, 8:00 AM-11:00 AM

Grade III-IV cytokine release syndrome is associated with inferior survival in patients undergoing haploidentical donor stem cell transplants. *First Author: Omar Albanyan, Karmanos Cancer Institute/Wayne State University, Detroit, MI*

Background: Haploidentical transplant (HIDT) with post-transplant cyclophosphamide (pCY) is being increasingly used because of the universal availability of donor and rapid graft acquisition time. Cytokine release syndrome (CRS) is one of the commonly occurring complications in this population. The information on the impact of CRS on the post-HIDT outcomes is limited. **Methods:** We retrospectively evaluated 91 patients who underwent HIDT between June 2012 and June 2019 for the onset and severity of CRS. CRS was graded per ASTCT guidelines. The primary objective was to compare RFS (relapse-free survival), NRM (non-relapse mortality), OS (overall survival) and GVHD in patients with no CRS, CRS grade 1-2 and 3-4. **Results:** All received peripheral blood stem cells and pCY/tacrolimus/mycophenolate as GVHD prophylaxis. Fifty-six (62%) received reduced intensity and 35 (38%) received full intensity conditioning regimen. Ten (10.9%) had no CRS, 74 (81.3%) developed grade 1-2 CRS and seven (7.7%) experienced grade 3-4 CRS. Median time to onset of CRS was one day post-transplant. The most common symptoms were fever (87%), fatigue (30%), nausea/vomiting (24%), rigors (24%), diarrhea (20%) and rash (11%). Fifteen (20%) with grade 1-2 and six (85%) with grade 3-4 CRS received tocilizumab. Day +100 cumulative incidence of grade III-IV acute GVHD for no CRS, grade 1-2 and grade 3-4 CRS was 0%, 2.7%, and 14.3%, respectively ($P = 0.36$). One-year cumulative incidence of chronic GVHD for no CRS, grade 1-2 and grade 3-4 CRS was 30%, 31.9% and 14.3%, respectively ($P = 0.70$). One-year NRM for no CRS, grade 1-2 and grade 3-4 CRS was 30%, 16.5%, and 57.1%, respectively ($P = 0.002$). One-year RFS for no CRS, grade 1-2 and grade 3-4 CRS was 48%, 63.4% and 28.6%, respectively ($p = 0.03$). OS at 1-year for no CRS, grade 1-2 and grade 3-4 CRS was 60%, 73.9%, and 28.6%, respectively ($P = 0.008$). Multivariable analysis revealed that grade 3-4 CRS was associated with significantly higher NRM (HR 5.54, $P = 0.002$), worse RFS (HR 3.41, $P = 0.011$) and worse OS (HR 4.91, $P = 0.001$). Conditioning regimen, degree of HLA match and disease risk index did not affect post-transplant outcomes and were not predictors for developing CRS. **Conclusions:** Our study showed that grade 3-4 CRS was associated with inferior post-transplant outcomes. However, no impact on acute or chronic GVHD was noted. Therefore, early recognition and prompt management of CRS may help improve outcomes. Research Sponsor: None.

7547 Poster Session (Board #320), Fri, 8:00 AM-11:00 AM

Pre-transplant molecular minimal residual disease (MMRD) is associated with inferior outcomes in patients with acute myeloid leukemia undergoing allogeneic stem cell transplantation. *First Author: Muhammad Husnain, University of Miami/Sylvester Cancer Center, Miami, FL*

Background: Allogeneic Stem Cell Transplant (alloSCT) continues to be the optimal consolidation strategy for many patients with AML; cytogenetic and molecular abnormalities are known predictors of post-transplant outcomes. There is increasing evidence that Molecular Minimal Residual Disease (MMRD) following induction has important prognostic implications and its value in the prediction of post-transplant relapse continues to be elucidated. We aim to evaluate the impact of genetics and pre-transplant MMRD on clinical outcomes following alloSCT. **Methods:** We retrospectively evaluated eighty-nine patients, ≥18 years with a diagnosis of AML in complete morphologic remission (i.e. < 5% BM blasts by morphologic assessment) who received alloSCT between 01/2012-05/2018 at the University of Miami and for whom cytogenetic and comprehensive molecular data was available prior to transplantation. Patients were stratified into favorable, intermediate and poor-risk categories based on 2017 ELN criteria. MMRD was defined as persistent leukemia-specific mutations prior to transplantation (i.e. NPM1, FLT3, CEBPA, IDH1-2, RUNX1 and TP53). Persistence of DTA mutations (DNMT3A, TET2 and ASXL1) was not considered MMRD, patients with unavailable cytogenetic/molecular data at diagnosis were excluded. **Results:** Seventy-four (83%) patients were transplanted in CR1, myeloablative conditioning was used in 72% of patients. Two-year OS and LFS were 69.4% and 78.2%, respectively. Stratification by ELN criteria resulted in prognostic separation for patients transplanted in CR1: 2-year OS for favorable (87%), intermediate (68%) and adverse risk (51%) patients ($p = 0.0417$). The presence of MMRD was the strongest predictor of post-transplant outcomes for the whole cohort with 2-year OS and LFS of 29.4% and 37.1% (HR 5.45 [95%CI 2.43-12.3] $p = 0.0001$; HR 12.4 [95%CI: 3.76 to 39.8] $p = 0.0001$); respectively. Subgroup analysis confirmed that MMRD was associated with significantly inferior LFS for IM/favorable and adverse risk patients (HR: 6.76 [95% CI 1.12 to 40.9], $p = 0.038$). **Conclusions:** Pre-transplant MMRD was the most important prognostic factor for relapse and survival in our cohort of AML patients undergoing alloSCT. Correlation of MMRD with other transplant variables such as conditioning intensity, MRD status by MFC and the impact of pre-emptive/therapeutic strategies in high-risk patients continues to be explored. Research Sponsor: None.

Discontinuation of tyrosine kinase inhibitor (TKI) therapy in chronic myeloid leukemia in chronic phase (CML-CP) in US clinical practice after guideline updates. *First Author: Ehab L. Atallah, Hematologic Malignancies, Medical College of Wisconsin, Milwaukee, WI*

Background: NCCN CML practice guidelines were updated in 11/2016 and in 9/2019 to include considerations for discontinuation of TKI therapy in patients (pts) with CML-CP. This study characterized TKI discontinuation practices in the US after these updates and drew parallels with a similar study conducted prior to these guideline updates (Ritchie et al. *Leuk Lymphoma.* 2019). **Methods:** Pt charts of adult CML-CP pts with TKI discontinuation (1/2017-12/2018) outside a clinical trial after achieving an adequate response were abstracted (11/2019-12/2019) via an online case report form by US oncologists/hematologists. Physicians' assessment of adequate response (TKI duration, molecular response [MR], MR duration) and relapse were described. **Results:** 61 physicians (academic: 43%; community-based practices: 57%) contributed 153 pt charts. Most physicians were from large practices (57%), had > 10 years (y) experience since completing subspecialty training (59%), and treated a median of 30 CML pts in the last 2y; 56% did not have access to precise molecular response monitoring for BCR-ABL of ≥4.5 log when attempting TKI discontinuation. Pts with TKI discontinuation had mean age 56 years, were mostly male (60%), white (69%), and had TKI discontinued in first-line (96%). Most common reasons for TKI discontinuation were pt request (54%) and adverse events (18%), besides achieving an adequate response. Physicians' assessment of adequate response for TKI discontinuation are reported in the Table. 21% of pts (academic: 12%; community: 30%) relapsed after TKI discontinuation (treatment-free remission [TFR] failure; 66% relapsed within 1y). **Conclusions:** Although NCCN CML practice guidelines provide guidance for discontinuation of TKI therapy, there remains heterogeneity in US practice and TKI discontinuation is predominantly attempted in first-line (similar to Ritchie et al. 2019). TKI discontinuation is being practiced without adequate sensitive tools mandated by practice guidelines to monitor response. Broader application of practice guidelines for optimal TKI therapy discontinuation in CML-CP pts is needed, particularly in community-based practices, to improve long-term TFR rates. Research Sponsor: Novartis Pharmaceutical Corporation.

Bosutinib (BOS) for chronic phase (CP) chronic myeloid leukemia (CML) after imatinib (IMA) failure: ≥8-y update of a phase I/II study. *First Author: Tim H. Brümmendorf, Universitätsklinikum RWTH Aachen, Aachen, Germany*

Background: BOS is approved for newly diagnosed CP CML and CML resistant/intolerant to prior therapy. In a phase I/II study, BOS showed durable efficacy and manageable toxicity in patients (pts) with CP CML after IMA failure. We report an ≥8-y update of this phase I/II and ongoing extension study. **Methods:** Pts with CP CML resistant/intolerant to IMA (CP2L) or IMA + dasatinib and/or nilotinib (CP3L) or with accelerated/blast phase (AP/BP) CML or Philadelphia chromosome+ acute lymphoblastic leukemia with prior tyrosine kinase inhibitor (TKI) therapy (ADV) received BOS starting at 500 mg/d. **Results:** 54/284 (19%) CP2L pts were still on BOS after ≥9 y and 8/119 (7%) CP3L and 5/167 (3%) ADV pts after ≥8 y; 61 CP2L pts discontinued BOS since y 5 and 21 CP3L and 12 ADV pts since y 4. Overall, the most common reason for discontinuation was disease progression/lack of efficacy in CP2L (27%), CP3L (42%) and ADV (50%) pts; last dose before discontinuation was ≥500 mg/d in 59 (21%), 28 (24%) and 46 (28%) pts, respectively. In CP2L pts, median (range) of follow-up was 54 (1–155) mo, treatment duration 26 (<1–155) mo and dose intensity 438 (87–599) mg/d; responses were durable (Table) and overall survival (OS) at 9 y was 74% vs 84% at 5 y. OS at 8 y was 69% in CP3L, 54% in AP CML and 23% in BP CML pts vs 78%, 59% and 23% at 4 y. 55 CP2L, 29 CP3L and 98 ADV pts died on study (10, 3 and 2 since the 4/5-y reports); 15, 5 and 3 had on-treatment transformations to AP/BP. Most common new treatment-emergent adverse events since y 5 in CP2L pts were pleural effusion (n=13), arthralgia (n=12) and increased blood creatinine (n=11). **Conclusions:** After ≥8 y, BOS continued to show durable efficacy and no new safety signals in pts with CP CML on long-term treatment, providing further support for BOS use after prior TKIs. Clinical trial information: NCT00261846 and NCT01903733. Research Sponsor: Pfizer Inc.

An independent review of arterial occlusive events (AOEs) in the ponatinib (PON) phase II PACE trial (NCT01207440) in patients (pts) with Ph+ leukemia. *First Author: James L Januzzi, Massachusetts General Hospital, Boston, MA*

Background: The final 5-year analysis of the PACE trial, which evaluated use of PON in pts with refractory chronic myeloid leukemia (CML) and Ph+ acute lymphoblastic leukemia, identified a 25% incidence of AOEs (Cortes, *Blood* 2018) from a search utilizing > 400 preferred terms (PTs) defined by MedDRA and related to vascular ischemia or thrombosis. We performed a retrospective review using an independent Endpoint Adjudication Committee (EAC) to better understand clinically relevant AOE rates in PACE. **Methods:** The EAC consisted of 3 cardiologists, 1 hematologist, and 1 neurologist to review AOEs (identified using > 500 terms) in PACE using American College of Cardiology/American Heart Association (ACC/AHA) definitions for major adverse cardiovascular events (MACE), and to review pt profiles including event, severity, concomitant medication, and hospitalization data. These results were compared with MedDRA PT search results. The EAC was blind to dose, dose modification, and investigator causality opinion. **Results:** The PACE review included 449 heavily pretreated pts with Ph+ leukemia (median age, 59 y; 47% female; 93% ≥2 tyrosine kinase inhibitors). With median follow-up 37.3 mo in all pts, AOEs were identified by MedDRA PT search in 25% of pts and EAC-verified in 17% (Table). In each category listed in the table, the EAC verification identified fewer AOEs and serious AOEs. Serious AOEs were identified by MedDRA PT search in 20% of pts and EAC-verified in 16%. Events that were not associated with a cardiovascular etiology or failed to meet the MACE definition set forth by the ACC/AHA were determined by the EAC not to be an AOE. **Conclusions:** The independent EAC review showed a lower rate of clinically relevant AOEs than was reported in PACE, suggesting an earlier possible overestimation that may not accurately reflect the risk of AOEs with PON. The ongoing PON dose-ranging OPTIC study will further evaluate the PON risk:benefit profile. Clinical trial information: NCT01207440. Research Sponsor: ARIAD Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Bosutinib in patients with chronic phase chronic myeloid leukemia intolerant to prior tyrosine kinase inhibitors: Analyses from the BYOND study. *First Author: Susanne Saussele, University Hospital Mannheim, Heidelberg University, Mannheim, Germany*

Background: Bosutinib (BOS) is approved for patients (pts) with Philadelphia chromosome (Ph)+ chronic myeloid leukemia (CML) resistant/intolerant to prior therapy and in newly diagnosed pts in chronic phase (CP). **Methods:** The ongoing phase 4 BYOND study is further evaluating efficacy and safety of BOS (starting dose 500 mg/d) for CML resistant/intolerant to prior tyrosine kinase inhibitors (TKIs). We report findings in pts intolerant to all prior TKIs. Data are reported ≥1 y after the last enrolled pt (~85% TKI-intolerant pts had ≥2 y follow-up). **Results:** Of 163 pts who received BOS, 156 had Ph+ CP CML. 73 pts entered the study due to intolerance; 29, 26 and 18 had 1 (CP2L), 2 (CP3L) and 3 (CP4L) prior TKIs, respectively. After a median follow-up of 30.4 mo, median treatment duration across all 3 cohorts (CP2L, CP3L, CP4L, respectively) was 25.3 mo (29.2, 24.6, 17.6) and median dose intensity was 292.0 mg/d (304.5, 284.8, 272.1). Across CP CML cohorts (CP2L, CP3L, CP4L, respectively), 84.9% of patients (82.8%, 88.5%, 83.3%) had ≥1 dose reduction and 83.6% (79.3%, 84.6%, 88.9%) had ≥1 dose interruption due to adverse events (AEs). At the data cutoff, 53.4% (CP2L 65.5%, CP3L 42.3%, CP4L 50.0%) were still receiving BOS. The most common reason for discontinuation was AEs (28.8%). The most common (> 40%) treatment-emergent AEs (TEAEs) were diarrhea (87.7%) and nausea (43.8%). Grade 3/4 TEAEs in > 10% of pts were diarrhea (16.4%), increased alanine aminotransferase (19.2%) and increased lipase (12.3%). Most pts with a valid baseline assessment achieved major molecular responses (MMR) across therapy lines (Table). Deaths occurred in 4 pts (CP2L 1, CP3L 3, CP4L 0); none were related to BOS or CML. Overall survival rate (95% CI) at 2 y in TKI-intolerant pts was 97.2% (89.2–99.3); rates were 96.4% (77.2–99.5), 96.0% (74.8–99.4) and 100% (100–100) in CP2L, CP3L and CP4L pts, respectively. **Conclusions:** A long duration of treatment and high response rate were observed in TKI-intolerant pts treated with BOS. Despite being intolerant to all prior therapies, ≥50% of pts in the overall intolerant cohort remained on BOS treatment at the data cutoff and > 80% achieved/maintained MMR. These results further support BOS use in pts with Ph+ CP CML and intolerance to all prior TKIs. Clinical trial information: NCT02228382. Research Sponsor: Pfizer Inc.

Cumulative response, n/N (%)	CP2L	CP3L	CP4L	Total
MMR	26/29 (89.7)	22/26 (84.6)	12/18 (66.7)	60/73 (82.2)
Excluding pts with baseline MMR	10/11 (90.9)	9/11 (81.8)	6/9 (66.7)	25/31 (80.6)

7552 Poster Session (Board #325), Fri, 8:00 AM-11:00 AM

Myelodysplastic syndrome survival and secondary AML trends in the United States. *First Author: Wade T. Swenson, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND*

Background: Myelodysplastic syndrome (MDS) is a rare heterogeneous group of hematologic stem cell disorders. The most recent FDA therapies approved for the treatment of MDS were decitabine (May 2006), lenalidomide (June 2005), and azacitidine (November 2004). This analysis utilized a population-based cancer registry to identify changes in survival rates and secondary AML rates among patients with MDS. **Methods:** SEER 18 regions database (November 2017 submission) was accessed to obtain data on survival and secondary malignancies using SEER*Stat 8.3.6. ICD-O-3 codes were used to identify patients with refractory anemia (RA), refractory anemia with ringed sideroblasts, refractory anemia with excess blasts, refractory anemia with excess blasts in transformation, refractory cytopenia with multilineage dysplasia, MDS with 5q deletion, therapy-related MDS, and MDS, not otherwise specified. An observed survival analysis was conducted using a cohort diagnosed between 2001 and 2004 and another diagnosed between 2009 and 2012. Secondary AML risk was calculated using multiple primary - standardized incidence ratios (MP-SIR) to obtain observed/expected (O/E) ratio. **Results:** Three-year observed survival rates for patients diagnosed between 2001 and 2004 was 53.2% (50.4%, 55.9%) and was 61.2% (57.9%, 64.3%) for patients diagnosed between 2009 and 2012. There was no observed survival difference among other MDS subtypes. O/E ratio for development of AML among patients with RA was 2.77 (0.57, 8.11) for patients diagnosed between 2001 and 2004, and 49.49 (33.39, 70.65) for patients diagnosed between 2009 and 2012. **Conclusions:** Survival among patients diagnosed with RA has improved in recent years, whereas survival among other subtypes of MDS has not changed. Secondary AML rates have increased among RA patients identified in the population-based cancer registry. Research Sponsor: None.

7553 Poster Session (Board #326), Fri, 8:00 AM-11:00 AM

Molecular diagnostic testing patterns in patients (pts) with myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) in the Connect MDS/AML Registry. *First Author: Tracy George, University of Utah and ARUP Laboratories, Salt Lake City, UT*

Background: MDS and AML diagnosis requires an integrated approach including morphologic, cytogenetic and molecular testing. The WHO classification criteria for MDS and AML diagnosis were updated in 2016; however, the impact on clinical practice is unclear. We investigated molecular testing patterns for pts with MDS or AML treated in academic (AC) or community/government (CO/GOV)-based centers in the Connect MDS/AML Registry. **Methods:** The Connect MDS/AML Disease Registry (NCT01688011) is a large ongoing, US, multicenter, prospective observational cohort study of pts with MDS (aged ≥ 18 yrs) or AML (aged ≥ 55 yrs). Patient data were collected for this analysis upon enrollment from 12 Dec 2013 to 13 Dec 2019, the analysis cut-off. Differences in molecular testing between MDS and AML pts were evaluated and logistic regression used to assess factors associated with increased molecular testing. **Results:** As of 13 Dec 2019, 800 MDS pts and 626 AML pts were enrolled; median age was 74 vs 71 yrs, 66.3% vs 61.5% were male, and 73.5% vs 60.2% were insured by Medicare/Medicaid. A greater proportion of AML pts (77.5%) had molecular testing vs MDS pts (29.1%). Of 380 MDS pts enrolled before 2017 (< 2017), 16.8% had molecular testing, increasing to 40.2% in 420 MDS pts enrolled from 2017 onward (≥ 2017). Of 289 AML pts enrolled < 2017, 68.9% had molecular testing, increasing to 84.9% in 337 AML pts enrolled ≥ 2017. Mean number of mutations tested increased between < 2017 and ≥ 2017 from 6.9 to 12.7 in MDS pts and from 6.1 to 10.4 in AML pts. Of the 11 mutations most frequently tested ≥ 2017 in MDS and AML pts, 0% and 36%, respectively, have FDA-approved targeted therapies. Gene mutations tested differed between MDS and AML pts; *ASXL1* was most frequently tested in MDS pts (68.2%) and *FLT3-ITD* in AML pts (89.7%). Testing rates increased between < 2017 and ≥ 2017 for *ASXL1* from 48.4% to 75.7% in MDS pts and for *FLT3-ITD* from 84.4% to 93.4% in AML pts. Factors associated with increased testing were age < 75 (vs ≥ 75) yrs, ELN score ≥ 2 (vs 1) and enrollment at AC site (vs CO/GOV) (all $P < 0.01$) in AML pts and age < 80 (vs ≥ 80 yrs; $P < 0.01$), AC site (vs CO/GOV; $P < 0.01$), and geographic region outside the Midwest ($P = 0.015$) in MDS pts. **Conclusions:** While molecular testing rates have increased since the publication of the WHO 2016 criteria, molecular testing rates for MDS pts remain lower than those for AML pts in real-world clinical practice. Elderly pts and pts enrolled in CO/GOV sites were found to have lower rates of molecular testing in both MDS and AML patient cohorts. Research Sponsor: Bristol-Myers Squibb.

7554 Poster Session (Board #327), Fri, 8:00 AM-11:00 AM

Clinical benefit of luspatercept in patients (pts) with lower-risk MDS (LR-MDS) and high transfusion burden in the phase III MEDALIST study. *First Author: Amer Methqal Zeidan, Department of Internal Medicine, Yale School of Medicine and Yale Cancer Center, Yale University, New Haven, CT*

Background: Anemic pts with LR-MDS and high baseline RBC transfusion burden (HTB) have very few treatment options and constitute a pt population with significant clinical unmet need. In this secondary analysis of the MEDALIST trial (NCT02631070), we sought to evaluate the clinical benefit of luspatercept in this pt population. **Methods:** MEDALIST is a randomized, placebo (PBO)-controlled, phase 3 study evaluating the efficacy and safety of luspatercept in pts with anemia due to LR-MDS with ring sideroblasts (RS) (Fenaux & Platzbecker et al. *NEJM.* 2020;382:140-51). Pts were aged ≥ 18 years; had IPSS-R-defined Very low-, Low-, or Intermediate-risk MDS with RS; were refractory, intolerant, or unlikely to respond to erythropoiesis-stimulating agents (serum erythropoietin > 200 U/L); and had anemia requiring regular RBC transfusions (≥ 2 units/8 weeks in the 16 weeks prior to randomization). 229 pts were randomized 2:1 to luspatercept (starting dose 1.0 mg/kg; titration up to 1.75 mg/kg allowed) or PBO subcutaneously every 3 weeks. HTB was defined as ≥ 6 RBC units transfused/8 weeks. **Results:** 153 pts were randomized to luspatercept and 76 to PBO. As of July 1, 2019, 23/66 (34.8%) and 12/66 (18.2%) HTB pts receiving luspatercept achieved a ≥ 50% and ≥ 75% reduction from baseline in RBC transfusion burden over ≥ 24 weeks, respectively, vs 3/33 (9.1%; $P = 0.0063$) and 1/33 (3.0%; $P = 0.0363$) pts receiving PBO. 6/66 (9.1%) luspatercept-treated HTB pts and 1/33 (3.0%) PBO-treated HTB pt achieved RBC-transfusion independence (TI) ≥ 8 weeks in Weeks 1–24 ($P = 0.2699$). The median (range) time to achieve RBC-TI with luspatercept was 50.0 days (1.0–100.0) and median (range) duration of RBC-TI in the luspatercept arm was 42.6 weeks (8.4–81.1). Mean number of transfusion events in Weeks 1–24 was 9.2 in the luspatercept arm vs 12.4 in the PBO arm (hazard ratio [95% confidence interval] 0.794 [0.660–0.956]). 65/66 (98.5%) luspatercept- and 29/33 (87.9%) PBO-treated HTB pts reported ≥ 1 treatment-emergent adverse event (TEAE); 11/66 (16.7%) and 3/33 (9.1%) pts, respectively, reported ≥ 1 TEAE leading to discontinuation. 28/66 (42.4%) luspatercept- and 15/33 (45.5%) PBO-treated pts reported ≥ 1 serious AE. Incidence of grade 3–4 TEAEs in HTB pts was similar between arms (53.0% luspatercept vs 54.5% PBO). **Conclusions:** Luspatercept treatment resulted in clinically significant reductions in transfusion burden and reduced number of transfusion events in HTB pts with LR-MDS with RS, with an acceptable safety profile consistent with the overall population. Clinical trial information: NCT02631070. Research Sponsor: Bristol-Myers Squibb in collaboration with Acceleron Pharma.

7555 Poster Session (Board #328), Fri, 8:00 AM-11:00 AM

Disparities in receipt of complete diagnostic evaluation to confirm myelodysplastic syndromes. *First Author: Sudipto Mukherjee, Leukemia Program, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

Background: A complete diagnostic evaluation (CDE), including bone marrow (BM) biopsy, cytogenic testing, FISH panel, and/or flow cytometry, is widely accepted as a prerequisite for histopathologic confirmation of MDS. Earlier reports have raised concerns regarding accuracy of MDS diagnosis in population registries that do not require confirmatory tests for disease reporting. We queried Medicare files to analyze the extent of use of, and factors associated with CDE for diagnosing MDS. **Methods:** The study population included Medicare patients with at least one inpatient or two outpatient claims for MDS within a 12-month period during the years 2012 and 2013. Variables included age, sex, race, morphologic MDS categories, cytopenias (isolated or any combination), transfusion burden, comorbididities, as well as county-level characteristics (income, educational attainment, rurality, and availability of internal medicine subspecialists). Classification and regression tree (CART) and multivariable logistic regression analysis were used to identify combinations of factors associated with receipt of CDE. **Results:** Our study population included 45,067 MDS patients, of whom only 68.6% received CDE that included BM biopsy and/or chromosomal studies. The percent of patients undergoing CDE was significantly lower among those 85 years of age or older (56.1%); women (63.7%); Blacks (64.2%); patients with isolated anemia (60.3%); and those who were transfusion independent ($p < 0.001$ for all comparisons). On the other hand, CDE was significantly higher among patients with the category of MDS with excess blasts (89.4%); those presenting with pancytopenia (92.2%); and those with high transfusion burden (80%). There was little variation by comorbidity burden, county level characteristics, or availability of subspecialists. In CART analysis, 80% of patients presenting with any two or more cytopenias received CDE. In multivariable analysis, advanced age, female sex, Black race, higher comorbidity burden and availability of subspecialists were associated with a lower likelihood to receive CDE, while patients with MDS with excess blasts, and with any > 2 cytopenias were more likely to receive CDE ($P < .0001$). **Conclusions:** Nearly one third (31%) of MDS patients in the Medicare database lack CDE especially BM biopsy. Disparities in CDE can be corrected through proper physician education and stringent registry reporting to avoid such high diagnostic inaccuracies, leading to potential missed treatment opportunities. Research Sponsor: Celgene Corporation.

7556 Poster Session (Board #329), Fri, 8:00 AM-11:00 AM

Phase II study of lower-dose pracinostat plus azacitidine safety and efficacy in patients with high/very high-risk myelodysplastic syndromes. *First Author: Ehab L. Atallah, Hematologic Malignancies, Medical College of Wisconsin, Milwaukee, WI*

Background: Hypomethylating agents (HMA), such as azacitidine (AZA), are the standard of care for patients (pts) with higher-risk myelodysplastic syndromes (MDS). However, overall response rate (ORR=CR+PR) with HMA alone is approximately 30%, with a 2-year overall survival (OS) rate of 50.8%. Preclinical studies show that pracinostat (PRAN), an oral histone deacetylase inhibitor, synergizes with HMA. A study in pts with untreated IPSS intermediate-2/high-risk MDS receiving 60 mg PRAN plus AZA resulted in early discontinuations, mainly due to adverse events (AE), potentially leading to diminished clinical benefit. This follow-up phase II study evaluates a lower dose of PRAN (25% reduction) in combination with AZA in order to reduce toxicity, decrease early discontinuations, and improve outcomes. An interim analysis showed low discontinuation rate and promising efficacy, allowing trial expansion. Herein, we report preliminary safety and efficacy in the overall population. **Methods:** Open-label, II-stage, phase II trial (NCT03151304) in pts (≥18 years) naive to HMA therapy and with IPSS-R of high/very high-risk MDS. Planned enrollment was 60 pts. Pts received 45 mg PRAN 3 days/week for 3 consecutive weeks plus standard AZA dose for 7 days of each 28-day cycle. Primary objectives were to define the safety/tolerability of the combination and to assess the ORR (CR+PR). OS was a secondary endpoint. **Results:** Sixty-four pts were enrolled and received ≥1 dose of treatment. Most pts were male (67%), median age was 68 years (range 47–89), and the proportion of pts with high/very high-risk MDS was similar. After 17.6 months' median follow-up, 31% of pts remain on treatment; 69% of pts discontinued treatment due to stem cell transplant (25%), disease progression (17%), AEs (11%), consent withdrawal (3%), pt noncompliance (3%), death (3%), lost to follow-up (2%), and other (5%). Most common nonhematologic AEs were constipation (55%), nausea (52%), fatigue (45%), decreased appetite (39%), peripheral edema (36%), diarrhea, and dyspnea (31% each). Frequent hematologic AEs were decreased neutrophil count (50%), anemia (39%), decreased platelet count (38%), febrile neutropenia (36%), and thrombocytopenia (30%). ORR was 33% (95% CI 22-46), with 33% achieving CR; 34% of pts had marrow CR. Median OS was 23.5 months (95% CI 16.4-nc), with an estimated 1-year OS of 77%. **Conclusions:** In pts with high/very high-risk MDS, a lower dose of pracinostat in combination with AZA demonstrated a tolerable safety profile and promising efficacy. Clinical trial information: NCT03151304. Research Sponsor: Helsinn Healthcare SA and MEI Pharma, Inc.

7557 Poster Session (Board #330), Fri, 8:00 AM-11:00 AM

Expression of CD47 and CALR in myeloproliferative neoplasms and myelodysplastic syndrome: Potential new therapeutical targets. *First Author: Ciro Roberto Rinaldi, University of Lincoln, Lincoln, United Kingdom*

Background: Myelodysplastic neoplasms (MPN) and myelodysplastic syndrome (MDS) are myeloid malignancies tendency to evolve into acute myeloid leukaemia. We investigate the expression and cellular localisation of pro-phagocytic CALR and anti-phagocytic CD47 in untreated and treated patients with essential thrombocythemia (ET), polycythemia vera (PV) myelofibrosis (MF), and in MDS patients in comparison with healthy controls. **Methods:** Mononuclear cells were collected by Ficoll separation, from peripheral blood of 27 MPN (8 PV, 16 ET, 3 MF); 14 MPN patients received cyto-reductive therapies (Hydroxyurea, Anagrelide or Ruxolitinib); 10 MDS patients and 4 controls. Cells were fractionised into 4 compartments: membrane, cytoplasm, cytosol and nucleus. Proteins were extracted using TRIzol, with CALR and CD47 protein expression analysed by western blotting. **Results:** CD47 showed higher expression of its overall protein on MPN cell membranes when compared with CALR (22% vs 13.9%). We observed a significant reduction of CALR expression in all MPN subtypes when patients were treated with cyto-reductive agents (ET- untreated 43.3% vs treated 2%, PV- 3.6% vs 2.2%, ET- 21% vs 11%). Interestingly we have observed a significant increase in CD47 cell membrane expression after treatment in MF and PV (CD47 in MF- untreated 11.8% vs treated 34.3%, PV-11.4% vs 35.9%). In MDS cells CD47 is overexpressed compared with controls (CD47- 11.31 vs 2.2 fold, respectively) and it mainly located to the membrane. Interestingly the degree of CD47 expression correlated to patients IPSS-R, increasing from low risk to high risk (low – 15.7%, intermediate 1 – 41.3%, intermediate 2 – 53.9% and high – 67.6%). CALR expression is also reduced in MDS cells comparing with controls when split by IPSS-R risk score (low – 9%, intermediate 1 – 11.9%, intermediate 2 – 17%, high – 17.9% Vs control - 29.1%). **Conclusions:** CD47, but not CALR, is overexpressed on the membrane of patients with MPN and MDS. In MDS, we observed a progressive increase in CD47 expression as the MDS evolve in accordance to the IPSS-R risk score. In MPN patients we observed a significant difference in CD47 expression across different MPN subtypes. The use of anti-CD47 antibodies could represent a new strategy to enhance the pro-phagocytic signal via increasing the CALR expression, and in combination with standard cyto-reduction therapy, might represent a new therapeutical strategy in both MPN and MDS. Research Sponsor: Celgene.

7558 Poster Session (Board #331), Fri, 8:00 AM-11:00 AM

Comparative analysis of characteristics, survival trends, and associated malignancies of B-cell and T-cell prolymphocytic leukemia: A surveillance, epidemiology, and end results (SEER) based study1998 to 2016. *First Author: Doaa Attia, Alexandria University, Alexandria, Egypt*

Background: Prolymphocytic leukemia (PLL) compromises two subsets; B-cell and T-cell, accounting for less than 2% of mature lymphocytic leukemia. Both of them are rare lymphoid neoplasms with a very aggressive clinical course and poor prognosis. **Methods:** We used SEER program dataset between 1998 and 2016. We divided the patients into 2 groups: B-PLL and T-PLL and identified them using 'ICD-O-3 histology recode: 9833/3 and 9834/3 respectively. We used SPSS software (version 26, IBM, NY, USA) to calculate overall survival using Kaplan-Meier methods and compare the survival between the two subtypes using the log-rank test. We also used multivariable covariate-adjust cox models to determine the impact of age, sex, race, cause of death, and associated primary malignancies on survival in both types. **Results:** A retrospective cohort study of 783 patients (295 B-PLL and 488 T-PLL) with overall survival rate of 22.5% (30.2% B-PLL and 18% T-PLL). The overall median survival for PLL was 16 months (95 CI, 13.745-18.255). The median survival of B-PLL (25 months, 95%CI, 15.733-34.267) was much better than T-PLL (14 months, 95%CI, 11.922-16.078). The mean age was 68.7 ± 15.3. Patient age was an independent factor in determining the survival and inversely associated with survival time in both types ($p < 0.0001$). The survival rate was worst) among age groups older than 79, between 70-79 years (8.9%, 18.9%) respectively. Although white male patients were more affected in both types, neither sex nor race significantly affected survival (P 0.554, 0.062 respectively). 64.7% of PLL patients died due to cancer. Patients with cancer-related death had significantly shorter survival time in both T-PLL group (HR = 0.351, 95% CI 0.241-0.512) and B-PLL group (HR = 0.682, 95% CI 0.491-0.945). We also found that 24.4% of B-PLL and 19% of T-PLL patients have another associated primary malignancy. Among hematological malignancies, non-hodgkin lymphoma was the commonest. Although associated solid tumors were less common, Prostate cancer and breast cancer were the commonest for both types and lung/bronchus malignancies were more associated with T-PLL. **Conclusions:** T-PLL subtype has worse prognosis. Age is the most important independent predictor of survival in both types. Although most of affected patients were white males, race and gender have no impact on survival. Non-hodgkin lymphoma is the commonest primary associated malignancy followed by breast and prostate cancer in both types. Research Sponsor: None.

7559 Poster Session (Board #332), Fri, 8:00 AM-11:00 AM

Chronic myelomonocytic leukemia genomic signature correlates with the degree of bone marrow fibrosis: A single-institutional retrospective study. *First Author: Feras Ally, City of Hope National Medical Center, Duarte, CA*

Background: Chronic myelomonocytic leukemia (CMML) has features of both a myeloproliferative neoplasm and a myelodysplastic syndrome. The median overall survival (OS) in most series is 20-40 months. CMML is a relatively rare entity, and there is limited understanding of prognostic molecular markers. CMML associated with bone marrow fibrosis grade 1, appear to have shorter progression free survival. In this study we investigated the correlation of mutations with bone marrow reticulin fibrosis in patients with CMML. **Methods:** We investigated a cohort of 41 consecutive patients diagnosed with CMML 0, 1, 2, and CMML-AML from 2014 to 2019 at our institute. The median age of 41 patients was 68 years (range, 34-82). 27% were females and 73% were males. This cohort consists of 8 (20%) patients with CMML0, 19 (46%) with CMML1, 8 (20%) with CMML2 and 6 (15%) with CMML-AML. Genomic DNA was extracted from the bone marrow aspirates and targeted mutation NGS libraries were prepared from 200 ng of genomic DNA using the SureSelect target enrichment system (Agilent Technologies Inc.). The gene panel consists of 73 genes focused on myeloid neoplasms. The data were curated on the basis of our molecular pathology and national databases. Additionally, clinical data and bone marrow (BM) reticulin fibrosis grades (n = 27 available) were retrieved from the patient's medical record. **Results:** The mutational profile frequency in our cohort showed that the most common mutations were *TET2* (31%), *ASXL1* (31%), and *SRSF2* (23%), with frequencies very similar to those reported in the literature. Of the 27 cases with an available reticulin stain, only low grade fibrosis (MF-0, n = 18. MF-1, n = 9) were identified in our cohort. The frequencies of mutations in *ASXL1*, *U2AF1*, *TP53*, *JAK2* and *RUNX1*, positively correlated with low grade fibrosis (MF-1). Additionally, patients with higher frequencies of *SRSF2*, *TET2*, and *SETBP1* mutations showed no fibrosis (MF-0). **Conclusions:** This study is the first to correlate the degree of fibrosis with the frequency of mutations in CMML. We found similar mutations spectrum reported in the literature in patients with CMML. The mutational profile associated with CMML cases appears to affect the degree of the bone marrow fibrosis at the time of diagnosis. Research Sponsor: None.

7560 Poster Session (Board #333), Fri, 8:00 AM-11:00 AM

Long-term outcome of 117 patients with Erdheim-Chester disease and mixed histiocytosis receiving targeted therapies (BRAF and MEK inhibitors): A monocentric experience. *First Author: Fleur Cohen-Aubart, Department of Internal Medicine and French reference Center for Rare Auto-immune and Systemic Diseases, Institut E3M, Assistance Publique-Hôpitaux de Paris (AP-HP), Pitié-Salpêtrière Hospital, & Université Pierre et Marie Curie, UPMC, Paris, France*

Background: Erdheim–Chester disease (ECD), an inflammatory myeloid neoplasm from the L group, is an histiocytosis associated with multisystem infiltration. Around 1500 cases have been reported worldwide since 1930. In 15% of cases, ECD is associated with another histiocytosis corresponding to mixed histiocytosis. Before 2004, 60% of patients died within 3 years after diagnosis. The targetable $BRAF^{V600E}$mutation is present in as much as 70% of all ECD cases. Targeted therapies (BRAF inhibitors in April 2012, followed by MEK inhibitors after 2015) have revolutionized the therapeutic options and prognosis of refractory ECD and mixed histiocytosis. **Methods:** This retrospective study was conducted between April 2012 and December 2019 on 117 ECD patients who received targeted therapies in the French National Referral Center for Histiocytosis at Pitié-Salpêtrière Hospital in Paris, France. 28 patients (pts) (24%) had a mixed histiocytosis. **Results:** 43 (36.7%) pts were female and 95/116 exploitable pts (81.9%) had a $BRAF^{V600E}$ mutation. 12 (10.3%) pts had a co-ocurring hemopathy (myeloproliferative neoplasm or myelodysplastic syndrom). Age at diagnosis was 57.2 yr (+/- 13.8). The main sites of involvement were: vascular ("coated aorta") in 85 pts (73%), heart in 83 pts (71%), xanthelasma in 30 pts (26%), central nervous system in 56 pts (48%) and peri-renal ("hairy kidney") in 84 pts (72%). 34 pts (29%) had previously received corticosteroids, and 63 pts (54%) interferon alpha regimen (mainly PEG interferon). 86 (74%) pts received the BRAF inhibitor vemurafenib, and 42 (36%) pts the MEK inhibitor cobimetinib (some patients receiving both). 25 pts died during follow-up. The median survival of patients with targeted therapies in december 2019 was undefined, whereas the patients with no targeted therapies had a median survival of 133 months (HR 0.64 (0.42-0.99); p = 0.04). Among the 117 pts, only 2 had a progression of VAF of mutations within genes frequently mutated in myeloid neoplasms. The most serious adverse events were cutaneous (squamous cell carcinoma, basocellular carcinoma, DRESS) and acute pancreatitis with BRAF inhibitors, whereas chorioretinitis and left ventricular dysfunction were seen with MEK inhibitors. None of the patients receiving targeted therapies progressed. **Conclusions:** Targeted therapies (BRAF and/or MEK inhibitors) were found dramatically efficacious in 117 patients with severe and refractory ECD and mixed histiocytosis, improving survival of patients. Research Sponsor: None.

TPS7561 **Poster Session (Board #334), Fri, 8:00 AM-11:00 AM**

A phase II study of BP1001 (liposomal Grb2 antisense oligonucleotide) in patients with hematologic malignancies. *First Author: Maro Ohanian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The growth factor receptor bound protein-2 (Grb2) is vital to oncogene signaling and tumor progression. BP1001 is a liposome-incorporated Grb2 antisense oligonucleotide that inhibits Grb2 expression. Grb2 inhibition suppresses cancer growth and survival. A Phase I/Ib single center study in patients with refractory/relapsed leukemias demonstrated the safety of BP1001 up to 90 mg/m^2 dose and the efficacy of BP1001 in combination with low dose cytarabine (LDAC) in refractory/relapsed acute myeloid leukemia (AML) patients (Ohanian, Lancet Haematol 2018). Based on pharmacokinetic (PK) considerations, the recommended Phase II dose was 60 mg/m^2. A phase II study was initiated to explore the clinical impact of BP1001 in combination with LDAC in untreated AML patients. Interim safety and efficacy of BP1001 + LDAC in untreated AML patients was presented at the 2018 Annual ASH Meeting. BP1001 was safely administered to 25 patients with untreated AML, who were considered unfit for standard chemotherapy. Efficacy data compared favorably to what has been reported with available options for unfit patients largely with secondary AML or adverse-risk AML. Since the Interim Data presentation, the study was amended to investigate BP1001 + decitabine combination and include myelodysplastic syndrome (MDS) patients. This is because BP1001 enhanced decitabine anti-leukemic effects in preclinical studies. **Methods:** This is a multi-center, open-label study with 2 parallel cohorts of BP1001 + decitabine treatment in untreated AML/high risk MDS patients and refractory/relapsed AML/high risk MDS patients who are considered by the investigator unsuitable for or refused intensive chemotherapy. BP1001 is given intravenously (IV) at 60 mg/m^2 twice weekly. Decitabine is given 20 mg/m^2 IV daily for 5 consecutive days. Each cycle is 28 days. Each cohort can enroll 19 patients, with a decision to stop or proceed to 54 patients. The primary objective of this study is to assess whether BP1001 + decitabine provides higher complete remission rates than decitabine alone (by historical comparison) in AML/high risk MDS patients. The secondary objectives of this study are to assess: Safety of BP1001 + decitabine; partial remissions and blast count reductions; overall survival, time to response and duration of response; minimal residual disease status in patients who achieve complete remission; and plasma PK profile of BP1001. The exploratory objective of this study is to evaluate the association of treatment response with cytogenetic and molecular characteristics. Clinical trial information: NCT02781883. Research Sponsor: Bio-Path Holdings, Inc.

TPS7562 **Poster Session (Board #335), Fri, 8:00 AM-11:00 AM**

A phase I clinical trial testing the safety of IL-21-expanded, off-the-shelf, natural killer cells for relapsed/refractory acute myeloid leukemia and myelodysplastic syndrome. *First Author: Sumithira Vasu, The Ohio State University, Columbus, OH*

Background: Allogeneic transplantation (Allo-HCT) demonstrates the enduring and potent role of the immune system in the control and eradication of acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). However, patients with relapsed, refractory (R/R) disease or comorbidities are not eligible for Allo-HCT. We sought to develop an allogeneic Natural killer (NK) cell-based immunotherapy approach to induce remission for these patients. The efficacy of haploidentical NK cells expanded ex vivo using a K562 feeder-cell line transfected with IL-21 and 41BBL has been established in R/R AML patients. However, haploidentical donor-derived NK cell manufacturing exceeds three weeks with the possibility of fulminant malignancy rendering patients ineligible for cellular therapy. To address this limitation we established a third-party NK cell bank derived from KIR and HLA-mismatched 'ideal' donors that allows scalable, affordable mass-production of large numbers of NK cells suitable for banking and immediate 'off-the-shelf' (OTS) administration to a broad population of recipients. **Methods:** This phase I study follows a 3+3 design to investigate the safety of mIL-21-expanded, third-party, OTS NK cells for treatment of R/R AML and MDS patients. Patients aged $\geq$18 or $\leq$80 years are enrolled into two cohorts: those $<$60 years and able to tolerate intensive chemo will receive Fludarabine 30mg/m^2/day (days -6 to -2) and Cytarabine 2g/m^2/day (days -6 to -2). Patients $>$60 years or $<$60 years and unable/unwilling to tolerate intensive chemo will receive Fludarabine 30mg/m^2/day (days -5 to -2) and Decitabine 20mg/m^2/day (days -6 to -2). All patients subsequently receive a total of 6 infusions of NK cells administered thrice weekly for two weeks (between days 0-21) and will be followed up to day 56 from first NK cell infusion. Three NK cell dose-levels: 1x10^7, 3x10^7 and 1x10^8 cells/kg/dose will be explored to determine maximum tolerated dose (MTD). 3-18 patients/cohort/dose may be enrolled for MTD determination plus an additional 10 patients/dose in an expansion phase (maximum 28/cohort = 56 total subjects). Primary objective is to determine safety and feasibility of NK cell infusions. Secondary objectives will explore rates of remission PFS, overall survival and measurable residual disease negativity, cell counts, infectious complications, and patients proceeding to transplant. Enrollment in dose level 1 has started. Clinical trial information: NCT04220684. Research Sponsor: None.

TPS7563 **Poster Session (Board #336), Fri, 8:00 AM-11:00 AM**

A phase I/II study of IMGN632, a novel CD123-targeting antibody-drug conjugate, in patients with relapsed/refractory acute myeloid leukemia, blastic plasmacytoid dendritic cell neoplasm, and other CD123-positive hematologic malignancies. *First Author: Naval Guastad Daver, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Overexpression of CD123 occurs in multiple hematological malignancies, including acute myeloid leukemia (AML), blastic plasmacytoid dendritic cell neoplasm (BPDCN), acute lymphoblastic leukemia (ALL) and others, thus making this antigen an attractive target for the development of new therapeutics. IMGN632 is a CD123-targeting antibody-drug conjugate (ADC) comprising a novel anti-CD123 antibody coupled, via a peptide linker, to a unique DNA-alkylating cytotoxic payload of the recently developed IGN (indolinobenzodiazepine pseudodimer) class. Preclinically, IMGN632 has demonstrated potent activity against AML, BPDCN and ALL models, with a wide therapeutic index in animal models, as well as a 150-fold differential cytotoxicity in AML patient samples compared to normal hematopoietic progenitors (PMIDs: 29661755, 30361418). Remarkable sensitivity of BPDCN patient derived xenografts to IMGN632 has been demonstrated (Blood 2018 132:3956). **Methods:** This Phase I/II study comprises a dose escalation phase designed to establish the recommended phase II dose (RP2D) for IMGN632, as well as dose expansion cohorts to further explore the safety and preliminary anti-leukemia activity of IMGN632. Expansion cohorts were designed to evaluate the following patient populations: adult patients with relapsed or refractory BPDCN or patients with untreated BPDCN who are inappropriate for available therapies, patients with relapsed or refractory AML, or with other CD123+ relapsed or refractory hematologic malignancies including ALL. Inclusion criteria include up to four prior lines of therapy which may include transplant. Patients with active central nervous system disease, history of veno-occlusive disease of the liver, or history of grade IV capillary leak syndrome or non-cardiac grade IV edema are ineligible. Expansion cohorts for unfit frontline and relapsed/refractory BPDCN, and relapsed/refractory ALL continue to enroll at the RP2D (0.045 mg/kg Q3W). Clinical trial information: NCT03386513. Research Sponsor: ImmunoGen, Inc.

TPS7564 **Poster Session (Board #337), Fri, 8:00 AM-11:00 AM**

A phase Ib/II study of the CD123-targeting antibody-drug conjugate IMGN632 as monotherapy or in combination with venetoclax and/or azacitidine for patients with CD123-positive acute myeloid leukemia. *First Author: Naval Guastad Daver, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Overexpression of CD123 is characteristic of a number of hematological malignancies, including acute myeloid leukemia (AML) and blastic plasmacytoid dendritic cell neoplasm (BPDCN). IMGN632 is a CD123-targeting antibody-drug conjugate (ADC) with a novel anti-CD123 antibody coupled to a unique DNA-alkylating payload of the recently developed IGN (indolinobenzodiazepine pseudodimer) class of payloads. In preclinical models of AML, IMGN632 exhibited potent anti-leukemia activity, with a wide therapeutic index. Confirming preclinical expectations, encouraging single-agent activity and favorable tolerability have emerged for IMGN632 in the ongoing Phase I trial in patients with CD123-positive AML (ASH 2019, NCT03386513). Preclinical data from AML xenograft models have demonstrated synergy in IMGN632 combinations with azacitidine and venetoclax (EHA 2019), supporting the exploration of these combinations in AML patients. **Methods:** This Phase Ib/II study is designed to determine the safety, tolerability, and preliminary anti-leukemia activity of IMGN632 when administered in combination with azacitidine and/or venetoclax to patients with relapsed and frontline CD123-positive AML, and the single-agent activity of IMGN632 in patients with minimal residual disease (MRD)-positive AML after frontline treatment. Study Design: Adult patients with CD123-positive relapsed or refractory AML, who are deemed appropriate for experimental therapy, are eligible to enroll as part of the dose escalation phase. Key exclusion criteria for all regimens include active central nervous system disease, and history of sinusoidal obstruction syndrome/venous occlusive disease of the liver. Three combination regimens are being evaluated: Regimen A, IMGN632 plus azacitidine (632+AZA); Regimen B, IMGN632 plus venetoclax (632+VEN); and Regimen C, IMGN632 plus azacitidine and venetoclax (632+AZA+VEN). For each regimen, a Phase Ib dose escalation cohort will determine the recommended Phase II dose (RP2D) of IMGN632 for the specific combination. This will be followed by a Phase II dose expansion stage to further characterize the safety profile and assess antileukemia activity in frontline or relapsed AML patients, depending on combination regimen. In addition, IMGN632 monotherapy is being explored in expansion cohorts of MRD-positive patients to assess conversion rate from MRD+ to MRD-, in fit and unfit AML subpopulations. Clinical trial information: NCT04086264. Research Sponsor: ImmunoGen, Inc.

TPS7565 Poster Session (Board #338), Fri, 8:00 AM-11:00 AM

CULMINATE: A phase II study of cusatuzumab + azacitidine in patients with newly diagnosed AML, ineligible for intensive chemotherapy. *First Author: Geralyn Carol Trudel, Janssen Research & Development, LLC, Raritan, NJ*

Background: AML, the most common acute leukemia in adults, is a heterogeneous malignancy characterized by uncontrolled clonal expansion of hematopoietic progenitor cells. Median diagnosis age is ~67 yrs. Despite current therapies prognosis is poor with 5-yr OS ~25% for patients (pts) ≥65 yrs. For pts unable to receive intensive chemotherapy, survival rates are worse, indicating a critical need to develop better treatments. CD70 is expressed on >95% of AML blasts harvested from newly diagnosed AML pts but not on normal hematopoietic stem cells nor most normal tissues. Cusatuzumab is a first-in-class, high-affinity anti-CD70 monoclonal antibody with multiple mechanisms of action, including Fc-mediated cytotoxicity with enhanced ADCC and inhibition of CD70/CD27 signaling, resulting in leukemia blast and stem cell cytotoxicity. As cusatuzumab and azacitidine target distinct pathways of myeloblast propagation, a combination may have a synergistic therapeutic effect and overcome treatment resistance. Initial data from a Phase I study (NCT03030612) with cusatuzumab (1–20 mg/kg) + standard dose azacitidine in AML pts ineligible for intensive chemotherapy showed no dose-limiting toxicity and a CR/CRi (CR with partial/incomplete hematologic recovery) in 10 of 12 pts (ASH 2019, Abs #234). This abstract describes a follow-on Phase II study (NCT04023526). **Methods:** CULMINATE is a 2-part study of cusatuzumab + azacitidine to determine the optimal dose of cusatuzumab (Table). Inclusion criteria: ≥18 yrs with *de novo* or secondary AML unfit for intensive therapy (≥75 or <75 yrs with a comorbidity [i.e. ≥1 of: ECOG 2, severe cardiac/pulmonary or moderate hepatic impairment]). In Part 1, pts are randomized 1:1 to cusatuzumab 10 or 20 mg/kg (IV, on Days 3 and 17 of each 28-day cycle) + azacitidine (75 mg/m^2 SC or IV on Days 1–7). Data will be reviewed after 15, 30 and 50 pts are enrolled into each arm to select the cusatuzumab dose for the Part 2 expansion cohort in which efficacy and safety will be further evaluated. Follow-up continues until death, loss to follow-up or study end. The primary objective is to determine CR rate. Secondary objectives include rate of CRi/CRh, rate of MRD-negativity, ORR, time to and duration of response, pharmacokinetics, immunogenicity, transfusion independence and safety. Enrollment began in Sept 2019 and is currently two-thirds complete. Clinical trial information: NCT04023526. Research Sponsor: Janssen R&D.

		Cusatuzumab dose + azacitidine 75 mg/m^2	
	No. of pts	10 mg/kg	20 mg/kg

TPS7566 Poster Session (Board #339), Fri, 8:00 AM-11:00 AM

Safety and efficacy of gemtuzumab ozogamicin and venetoclax in patients with relapsed or refractory CD33+ acute myeloid leukemia: A phase Ib study. *First Author: Saad Arain, UIC, Chicago, IL*

Background: AML is predominantly a disease of the elderly, yet outcomes remain dismal, especially for relapsed/refractory (R/R) AML patients (pts). Gemtuzumab Ozogamicin (GO) is a monoclonal antibody targeting CD33–commonly expressed on AML blasts, and, critically, AML stem cells (LSC)–that is linked to the cytotoxin calicheamicin. Recognized mechanisms of GO resistance include decreased (or aberrant) blast CD33 expression, upregulation of p-glycoprotein (re-exports calicheamicin), and decreased mitochondrial apoptosis. GO-induced apoptosis depends on pro-apoptotic Bax and Bak and is inhibited by overexpression of anti-apoptotic BCL-2 and BCL-XL. Venetoclax (VEN) is a BH3 mimetic, binding BCL-2, dislodging its binding to Bak/Bax, thus facilitating apoptosis. LSC uniquely overexpress BCL-2, however VEN resistance develops rapidly. Hypothesis: VEN targeting of BCL-2 proteins that protect LSC from GO-induced apoptosis will synergistically increase GO efficacy. Correlative studies include pre-treatment AML blast BH3 profiling and CD33 expression (& sequencing for isoforms), MRD measurement at post-therapy timepoints using digital drop PCR technology, and quality of life assessments (EORTC QLQ-C30, FACT-Fatigue). **Methods:** Single arm, open-label, multi-center (BTCRC), dose-escalation phase Ib study of combination of VEN and GO in R/R AML pts (18-75y), using a 3+3 design. Major eligibility: ECOG 0-2, adequate organ function, CD33+ in ≥ 20% AML blasts, ≤2 lines of prior therapy, no prior use of GO or VEN, no previous VOD, no BMT within 2 months, no CNS disease, and no history of HIV. Induction: 3-day VEN ramp-up to the target dose of 200 (cohort i), 400 (ii), or 600 (iii) mg daily x 28 d, with GO 3mg/m^2 infused d 1, 4, and 7. If CR/CRi achieved, pts proceed to BMT if applicable, otherwise, if in CR/CRi (provided ANC > 1000, plts 100K) or PR (regardless of counts), they are consolidated with VEN at the prescribed dose x 28d and GO 3mg/m^2 on days 1 and 4 (Cycle 2). If BMT not applicable, and then in CR/CRi or PR (as above), proceed to VEN alone as Maintenance in cycles 3+ until progression or toxicity. The primary endpoint is MTD of VEN with GO. Secondary endpoints include ORR, anti-leukemic activity, characterization of AEs, and estimates of RFS, EFS, and OS. This study is currently open and has to date enrolled 2 pts. Clinical trial information: NCT04070768. Research Sponsor: AbbVie, Pfizer.

TPS7567 Poster Session (Board #340), Fri, 8:00 AM-11:00 AM

Phase Ib study of CPX-351 lower-intensity therapy (LIT) plus venetoclax as first-line treatment for patients with AML who are unfit for intensive chemotherapy (IC). *First Author: Tara L. Lin, University of Kansas Medical Center, Kansas City, KS*

Background: CPX-351 (Vyxeos; daunorubicin and cytarabine liposome for injection) is approved by the FDA and EMA for the treatment of adults with newly diagnosed therapy-related AML or AML with myelodysplasia-related changes. In a phase 3 study in patients (pts) aged 60-75 y with newly diagnosed high-risk/secondary AML who were fit for IC, CPX-351 significantly improved median survival versus 7+3 cytarabine/daunorubicin and had a comparable safety profile. However, it may not be appropriate to administer CPX-351 at the label dosage in pts unfit for IC. Venetoclax, a BCL-2 inhibitor, has clinical efficacy in combination with low-dose cytarabine in AML pts unfit for IC, and preclinical data suggest a rationale for combining CPX-351 and venetoclax. This study thus evaluates CPX-351 LIT in combination with venetoclax in AML pts unfit for IC. **Methods:** This is an open-label, multicenter, 2-part, phase 1b study (NCT04038437) to determine the maximum tolerated dose (MTD) and evaluate the safety, efficacy, and pharmacokinetics of CPX-351 LIT plus venetoclax. Key eligibility criteria are shown in the Table. In the dose-escalation phase (3+3 design), up to 24 pts will receive CPX-351 (dose levels: 20, 40, 60, and 75 units/m^2) on Days 1 and 3 plus venetoclax 400 mg on Days 2-21 of each cycle to determine the MTD, with each dose escalation confirmed by a safety assessment committee. Pts who achieve complete or partial remission after 1 or 2 cycles may receive up to 4 similar cycles of CPX-351 plus venetoclax. In the expansion phase, an additional 20 pts will be treated at the MTD. All pts are assessed for response by morphology and minimal residual disease testing, and are monitored for safety (until 1 month after end of treatment) and survival (up to 1 year after start of treatment). The study is ongoing and actively enrolling pts. Clinical trial information: NCT04038437. Research Sponsor: Jazz Pharmaceuticals.

Key eligibility criteria.

- ≥18 y
- Histologically confirmed (per WHO criteria) newly diagnosed AML
- Considered unfit for IC
  - o ≥75 y
  - OR
  - o 18-74 y and ≥1 of the following criteria:
- ECOG PS 2-3
- History of congestive heart failure requiring treatment or LVEF ≤50%
- Diffusing capacity of the lung for carbon monoxide ≤65% or forced expiratory volume in 1 sec ≤65%
- Creatinine clearance ≥30 to < 45 mL/min
- Moderate hepatic impairment with total bilirubin > 1.5 to ≤3.0 × upper limit of normal
- Other comorbidity incompatible with conventional IC
- No CNS involvement
- No antecedent myeloproliferative neoplasms
- No favorable-risk cytogenetics (per NCCN guidelines)
- No prior AML treatment except hydroxyurea

TPS7568 Poster Session (Board #341), Fri, 8:00 AM-11:00 AM

A phase II/III study of JZP-458 in patients with acute lymphoblastic leukemia (ALL)/lymphoblastic lymphoma (LBL) who are hypersensitive to E. coli-derived asparaginases. *First Author: Luke Maese, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: L-asparaginase is an important component of ALL therapy and the inability to receive asparaginase secondary to hypersensitivity has been associated with poor patient (pt) outcomes. Alternative options for pts after hypersensitivity reactions are needed. JZP-458 is a recombinant *Erwinia* asparaginase produced using a novel *Pseudomonas fluorescens* expression platform that yields an enzyme with no immunologic cross-reactivity to *E. coli*derived asparaginases. In a phase 1 study, JZP-458 was well tolerated and maintained adequate (≥0.1 IU/mL) serum asparaginase activity (SAA), a surrogate marker for asparagine depletion, for up to 72 hrs in healthy adults. **Methods:** This is a pivotal, open-label, multicenter, dose confirmation, and pharmacokinetic (PK) study (NCT04145531) of JZP-458 in pts with ALL/LBL who develop hypersensitivity reactions to a long-acting *E. coli*derived asparaginase and have ≥1 course of asparaginase remaining in their treatment plan (Table); 6 doses of JZP-458 will be substituted for each remaining course. Treatment duration will depend on the number of asparaginase courses remaining in the treatment plan. The study has 2 sequential parts: Part A will determine the dose of intramuscular (IM) JZP-458 and confirm safety/efficacy; Part B will explore the dose/schedule of intravenous (IV) JZP-458. Blood samples will be collected to determine SAA levels and pts will be monitored for adverse events. Immunogenicity of JZP-458 will be assessed. Primary objectives are to determine (1) the efficacy of IM JZP-458 measured by the last 72-hr nadir SAA (NSAA) level (≥0.1 IU/mL) during the first treatment course, and (2) the safety/tolerability of IM JZP-458. Secondary objectives are to determine the efficacy (measured by the last 48-hr NSAA level [≥0.1 IU/mL] and the last 48- and 72-hr NSAA levels [≥0.4 IU/mL]), PK, and immunogenicity of IM JZP-458. Exploratory objectives include efficacy, safety, PK, and immunogenicity of IV JZP-458. The trial is active and enrolling. Clinical trial information: NCT04145531. Research Sponsor: Jazz Pharmaceuticals.

Eligibility criteria.

Pediatric and adult pts with ALL/LBL (excluding relapsed ALL/LBL)
≥1 course of *E. coli*derived asparaginase remaining in treatment plan
Full recovery from prior allergic reaction to long-acting *E. coli*derived asparaginase or silent inactivation with undetectable SAA levels (≤0.02 IU/mL), except for pts receiving < 10% *E. coli*derived asparaginase IV before the reaction
Adequate liver function
No prior exposure to asparaginase *Erwinia chrysanthemi* or JZP-458

8000 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Is autologous transplantation (autoHCT) in relapsed diffuse large B-cell lymphoma (DLBCL) patients achieving only a PET/CT positive partial remission (PR) appropriate in the CAR-T cell era? *First Author: Nirav Niranjan Shah, Medical College of Wisconsin, Milwaukee, WI*

Background: In relapsed, chemosensitive DLBCL patients (pts), autoHCT consolidation is a standard therapy option. With the approval of anti-CD19 CAR T-cells in 2017, relapsed DLBCL pts with residual PET/CT avid disease after salvage therapies are increasingly being offered CAR T-cells in lieu of autoHCT. According to Center for International Blood and Marrow Transplant Research (CIBMTR) data in 2018, the number of autoHCT for DLBCL in the U.S. decreased by ~45% from prior years, likely due to application of CAR T-cells for both chemorefractory DLBCL and chemosensitive DLBCL pts not achieving a complete remission. Using the CIBMTR database, we report outcomes of autoHCT in relapsed chemosensitive DLBCL pts achieving only a PET/CT+ PR prior to HCT. **Methods:** 249 relapsed DLBCL pts undergoing an autoHCT from 2003-13 with a PET/CT+ PR prior to transplant were identified. The study cohort was divided into two groups: (a) early chemo-immunotherapy failure (ECF) defined as pts with primary refractory disease (PRefD) or relapse within 12 months of diagnosis, (b) late chemoimmunotherapy failure (LCF) defined as pts relapsing ≥12 months. Primary outcome was overall survival (OS). Secondary outcomes included progression-free survival (PFS) and relapse. **Results:** 182 pts had ECF and 67 pts had LCF. The median age of ECF pts was 57 years versus (vs) 63 years for LCF ($p < 0.01$). ECF pts more frequently had stage III-IV at diagnosis (74% vs 54%, $p = < 0.01$). 79% of ECF pts had PRefD. The most common conditioning regimen was BEAM in both cohorts. The adjusted 5-year probabilities for PFS and OS (ECF vs LCF) was not different between the 2 cohorts: 41% vs 41% ($p = 0.93$) and 51% vs 63% ($p = 0.09$), respectively. Cumulative incidence of relapse at 5 years in similar order was 48% vs 57%, $p = 0.27$. On multivariate analysis compared to the LCF, pts with ECF had an increased risk of death (HR = 1.61, 95%CI 1.05-2.46, $p = 0.03$) but no increased risk in PFS or relapse. **Conclusions:** Using the CIBMTR registry, we report outcomes of relapsed DLBCL pts in a PR with residual PET/CT avid disease at time of autoHCT. While OS favored LCF pts, the adjusted 5-year PFS (41%) was comparable in both cohorts. This 5 year PFS is comparable to results reported in historical trials of auto-HCT for DLBCL. With no randomized data demonstrating superiority of CAR T-cell therapy in chemosensitive PR patients, these findings strongly support that autoHCT should remain the current standard of care for this patient population. Research Sponsor: None.

8001 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Phase I Alexander study of AUTO3, the first CD19/22 dual targeting CAR T cell therapy, with pembrolizumab in patients with relapsed/refractory (r/r) DLBCL. *First Author: Wendy Osborne, Newcastle, Newcastle, United Kingdom*

Background: CD19 directed CAR T cells are effective in patients with r/r DLBCL, however relapses due to CD19 loss or PDL1 upregulation are common. In this study, we evaluate the safety and efficacy of AUTO3, a CAR T targeting CD19/22 with limited duration of PD-1 blockade. **Methods:** We constructed a bicistronic retroviral vector encoding both an anti-CD19 (OX40 co-stim) and an anti-CD22 (41BB co-stim) CAR with humanized binders. The cell product was manufactured in a semi-automated and closed process using CliniMACS Prodigy. Patients (≥ 18 years) with r/r DLBCL (NOS) or transformed (tDLBCL); ECOG <2, adequate organ function are eligible. Lymphodepletion was Flu/Cy prior to AUTO3. Bridging therapy was allowed. The three dose levels explored are 50, 150, and 450 x 10^6 CAR T cells. Patients received AUTO3 alone, or with 3 doses of pembrolizumab (pem) 200 mg q 3 wks starting on D14 (regimen A), or with a single dose of pem 200 mg on D-1 (regimen B). The primary endpoint is frequency of DLTs and grade (G) 3-5 adverse events (AE) and secondary endpoints included ORR, CRR, and biomarkers. **Results:** As of Jan 21, 2020, 28 patients underwent leukapheresis, 27 successfully manufactured, 1 being manufactured, and 19 patients treated with AUTO3. The median age was 57 (28 - 71) and median number of prior therapies was 3 (2 - 10). 89% had refractory disease, 74% were DLBCL NOS, and 26% were tDLBCL. Dose escalation from 50 to 450 x 10^6 cells with pem regimen A and B have been completed without DLTs. G > 3 treatment emergent AEs that occurred > 15% were neutropenia (89%), thrombocytopenia (58%), anemia (47%), febrile neutropenia (16%), and hypophosphataemia (16%). Across all dose levels, there were 0% sCRS with primary infusion and 5% severe neurotoxicity (sNT) (1/19), which resolved. There were no cases of sCRS and no neurotoxicity of any grade at > 50 x 10^6 cells. Eighteen patients were evaluable for efficacy. Among the 11 treated at dose > 50 x 10^6, the ORR and CRR were 64% and 55%, and all CRs are ongoing (1-12 mth). Two out of 3 patients achieved CR at 450 x 10^6 cells on pem regimen B. Additional patients and longer follow up, as well as biomarkers, will be presented. **Conclusions:** AUTO3 at > 50 x 10^6 CAR T cells with pembrolizumab induces CRs without severe CRS or neurotoxicities of any grade. Clinical trial information: NCT03287817. Research Sponsor: Autolus Therapeutics.

8002 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

First-in-human data of ALLO-501 and ALLO-647 in relapsed/refractory large cell or follicular lymphoma (R/R LBCL/FL): ALPHA study. *First Author: Sattva Swarup Neelapu, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Allogeneic (off the shelf) chimeric antigen receptor (CAR) T cell therapy addresses the logistical challenges and variable product quality of autologous CAR T therapy. ALLO-501 is a genetically modified anti-CD19 CAR T cell product in which the *TCR alpha constant* gene is disrupted to reduce the risk of graft-versus-host disease (GvHD) and the *CD52* gene is disrupted to permit the use of ALLO-647, an anti-CD52 mAb, for selective and prolonged host lymphodepletion. **Methods:** This is an open-label, Phase 1 trial (NCT03939026) in adults with R/R LBCL/FL who have received ≥ 2 prior lines of therapy; prior anti-CD19 cell therapy is allowed. Patients (pts) receive fludarabine (flu) 90 mg/m^2, cyclophosphamide (cy) 900 mg/m^2, and ALLO-647 39 or 90 mg followed by ALLO-501 at 1 of 3 dose levels (DL) in a 3+3 design: 40, 120, and 360 × 10^6 CAR+ T cells. **Results:** As of 20 January 2020, 12 pts were enrolled: 9 received ALLO-501 at 3 DLs (4, 4 & 1 pts in DL1, DL2 and DL3 respectively), 1 pt discontinued due to kidney injury prior to lymphodepletion and 2 are starting treatment. Of the 9 treated pts aged 42 to 70 years: 5 had LBCL, 2 were female, 3 had primary refractory disease, and 3 had prior autologous stem cell transplants. The median number of prior lines of therapies was 3 (range 2 to 4). All treated pts received 39 mg of ALLO-647. No DLTs or GvHD have been observed to date. Most common Grade (Gr) ≥ 3 adverse events were neutropenia (55.6%), leukopenia (33.3%) and anemia (22.2%). Two pts (22.2%) developed cytokine release syndrome (1 Gr1 and 1 Gr2) that resolved within 72 hrs without steroids or tocilizumab. One pt developed Gr1 neurotoxicity that resolved without treatment. Infections included upper respiratory tract infection (Gr2), CMV (Gr3) and EBV viremia (Gr1), all reported in a single pt and resolved. One pt had a Gr2 infusion reaction to ALLO-647 which resolved with antihistamines. The overall response rate is 78% (95% exact CI: 40%, 97%): 3 complete and 4 partial responses. With a median follow up of 2.7 mos, 4 pts have ongoing responses and 3 pts progressed at 2, 4 and 6 mos. ALLO-501 cell expansion by qPCR was observed in 4 of 6 pts in varying degrees. **Conclusions:** These early data suggest that ALLO-501 and ALLO-647 have a manageable safety profile. ALLO-647 may be an effective and selective lymphodepleting agent with CD52 gene editing, and ALLO-501 shows evidence of clinical activity in pts with advanced NHL. Enrollment is ongoing, and updated safety, efficacy, PK/PD data will be presented including pts treated with increasing doses of ALLO-647. Clinical trial information: NCT03939026. Research Sponsor: Allogene Therapeutics.

8003 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Phase I study of the Bcl-2 inhibitor venetoclax with DA-EPOCH-R as initial therapy for aggressive B-cell lymphomas. *First Author: Sarah C. Rutherford, Weill Cornell Medicine, New York, NY*

Background: Dose-adjusted (DA) EPOCH-R is a frontline treatment for aggressive B-cell lymphomas. Bcl-2 is associated with chemoresistance due to BCL2 gene rearrangement or protein overexpression in lymphomas and is antagonized by BH3 mimetic venetoclax (ven). We conducted a phase I study combining ven with DA-EPOCH-R in aggressive B-cell lymphomas. **Methods:** This phase 1 study used Bayesian optimal interval design with dose expansion. Eligible patients (pts) were 18 years with newly diagnosed diffuse large B-cell (DLBCL), primary mediastinal, and high grade B-cell lymphoma (HGBCL) with double hit (DHL) or not otherwise specified (NOS). Ven was dosed at 400 mg (DL1), 600 mg (DL2), and 800 mg (DL3) daily for 10 days with 6 cycles of DA-EPOCH-R. A subsequent cohort received ven 600 mg daily for 5 days (DL2B). Toxicities were graded by CTCAE v4.0 and response assessed by Lugano criteria. Dose limiting toxicity (DLT) period was cycle 1 and primarily included grade (gr) ≥3 neutropenia on cycle 2 day 1, gr ≥4 febrile neutropenia/thrombocytopenia, and gr ≥3 nausea, vomiting, diarrhea despite supportive care. **Results:** 30 pts enrolled with median age 64 (24-79), and 50% female. Ann Arbor stage was III-IV in 23. IPI was high risk in > 50%. Diagnosis was DHL (15), DLBCL NOS (13), and HGBCL NOS (2). 18 had *MYC* and 14 had *BCL2* rearrangements. Bcl-2 was expressed ≥50% by IHC in 21/26 with data. There were no DLTs in DL1 (3 pts) or DL2 (9 pts). 1/6 had DLT in DL3 (gr 4 thrombocytopenia). Ven dose reductions occurred in subsequent cycles in 4 (2 in DL2; 2 in DL3). Of 18 in DL1-3, EPOCH was escalated above level 1 in 1 and de-escalated below level 1 in 7. Because of delays and ven dose reductions in DL2-3 due in part to cytopenias, infections and GI toxicities, we accrued DL2B. In DL2B, 0/12 pts had DLTs or ven dose reductions. EPOCH was escalated above level 1 in 4 and de-escalated below level 1 in 3. 1 died of sepsis during cycle 3. Most common gr 3-4 toxicities across all dose levels were cytopenias; febrile neutropenia occurred in 57%. Most common non-hematologic toxicities of all grades were hypocalcemia, nausea, diarrhea, hypokalemia and fatigue. ORR (N = 30) ITT was 97% with 27 (90%) complete and 2 (7%) partial responses; 1 was not evaluable. Follow up is ongoing. Of 15 DHL, ORR and CRR were 93% and 80%. **Conclusions:** We identified ven 600 mg for 5 days per cycle as RP2D with DA-EPOCH-R. DL2B was well tolerated and required no ven dose reductions. Further efficacy and safety is being evaluated in Alliance 51701, DA-EPOCH-R/R-CHOP in DH/double expressor lymphomas, using the dosing regimen defined by this study. Clinical trial information: NCT03036904. Research Sponsor: Genentech.

8004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A multicenter phase II study of venetoclax plus dose-adjusted R-EPOCH (VR-EPOCH) for Richter's syndrome. *First Author: Matthew Steven Davids, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: While therapeutic options for CLL have improved, patients (pts) who develop Richter's Syndrome (RS) still have a poor prognosis. Chemoimmunotherapy regimens such as R-EPOCH lead to CR in about 20% of RS pts, but PFS/OS is typically < 6 mo. The oral Bcl-2 inhibitor venetoclax (ven) had a 43% single agent response rate in RS. Here, we report the results of a phase 2 study of VR-EPOCH in RS. **Methods:** This is a single-arm, phase 2, IST of VR-EPOCH for RS (NCT03054896) at 3 US sites. CLL pts with biopsy-confirmed DLBCL were treated with R-EPOCH for 1 cycle, then after count recovery underwent accelerated inpatient ven daily ramp-up (20/50/100/200/400 mg), then ven + R-EPOCH for up to 5 more 21d cycles (ven 400 mg qd, d1-10 each cycle). Responders went to alloHCT or to continuous daily ven 400 mg maintenance. Response evaluation by Lugano criteria with PET/CT. **Results:** As of the data cut on 2/3/2020, the study is fully enrolled with 27 pts. Median age: 63 yrs (range 49-77). CLL features: 26% del(17p); 44% complex karyotype; 48% *IGHV* unmutated; 41% *TP53* and 15% *NOTCH1* mutation. Median prior CLL treatments: 2 (range 0-5, prior ibrutinib [n = 8], ven [n = 2], and PI3Ki [n = 2]) with 6 untreated CLL pts. Median # ven + R-EPOCH cycles: 4 (range 0-6). 5 pts had dose de-escalation of R-EPOCH, 1 pt had dose escalation. ≥Gr 3 heme tox: neutropenia (58%), anemia (50%), thrombocytopenia (50%). ≥Gr 3 non-heme tox in > 15% of pts: febrile neutropenia (38%) and hypophosphatemia (23% each). No pts had TLS with daily ven ramp-up. Infections: pneumonia (n = 4), sepsis during C1 of R-EPOCH prior to starting ven (n = 3), enterocolitis (n = 3), sinusitis (n = 2), and 1 pt each with influenza A and norovirus. 10 pts have died, including 7 due to disease progression (2 during C1 before ven), and 1 each due to sepsis, sudden death, and GVHD post-alloHCT. In ITT analysis, 16 responded (ORR 59%); 13/27 (48%) had CR as best response, all with undetectable bone marrow MRD for CLL. Six pts were not evaluable for efficacy of the combo (5 had toxicity in C1 and never started ven, 1 withdrew after C1). In the 21 pts who started combo therapy, the ORR was 76%, CR rate 62%. Only 1 pt with CR has progressed. The pt on longest ven maintenance is in CR 2 years post chemo. 8 pts went to alloHCT, with pts still in CR now up to 2.5 yrs post-alloHCT. With a median follow-up of 9.3 mo (range 0.6-30), median PFS and OS are both 16.3 mo. **Conclusions:** VR-EPOCH is active for RS. Expected toxicities from intensive chemoimmunotherapy and ven were seen, but daily ven ramp-up was feasible. The 48% CR rate and median PFS of 16.3 mo are favorable in the context of historical results. Clinical trial information: NCT03054896. Research Sponsor: Genentech, Other Foundation.

8005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

KEYNOTE-204: Randomized, open-label, phase III study of pembrolizumab (pembro) versus brentuximab vedotin (BV) in relapsed or refractory classic Hodgkin lymphoma (R/R cHL). *First Author: John Kuruvilla, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: PD-1 blockade via pembro monotherapy showed antitumor activity in R/R cHL. KEYNOTE-204 (NCT02684292) was a randomized, international, open-label, phase III study of pembro vs BV in R/R cHL. **Methods:** Patients (pts) were aged ≥18 y, were post−autologous stem cell transplant (auto-SCT) or ineligible for auto-SCT, and had measurable disease and ECOG PS 0 or 1. BV-naive and BV-exposed pts were eligible. Pts were randomized 1:1 to pembro 200 mg IV Q3W or BV 1.8 mg/kg IV Q3W and stratified by prior auto-SCT (yes vs no) and status after 1L therapy (primary refractory vs relapsed <12 mo vs relapsed ≥12 mo after end of 1L therapy). Primary end points: PFS by blinded independent central review (BICR) per International Working Group (IWG) criteria including clinical and imaging data after auto-SCT or allogeneic SCT (allo-SCT) and OS. Key secondary end points: PFS excluding clinical and imaging data after auto-SCT or allo-SCT (PFS-secondary), and ORR by BICR per IWG, PFS by investigator review per IWG, and safety. Exploratory end point: DOR by BICR per IWG. **Results:** 304 pts were randomized and 300 were treated (148, pembro; 152, BV); 256 discontinued. Median (range) follow-up: 24.7 (0.6-42.3) mo. 15 pts were BV exposed. Median (range) time on treatment was 305.0 (1-814) and 146.5 (1-794) days with pembro and BV, respectively. Statistically significant improvement was observed with pembro vs BV for primary PFS analysis (HR 0.65 [95% CI 0.48-0.88; P =0.00271]; median 13.2 vs 8.3 mo); 12-mo PFS rates were 53.9% vs 35.6%, respectively. Benefit was observed in all subgroups tested, including pts with no auto-SCT (HR=0.61), primary refractory disease (HR=0.52), prior BV (HR=0.34) and BV naive (HR=0.67). Significant improvement in PFS-secondary was observed with pembro vs BV (HR 0.62 [95% CI 0.46-0.85]; median 12.6 vs 8.2 mo). Per investigator assessment, PFS was longer with pembro vs BV (HR 0.49 [95% CI 0.36-0.67]; median 19.2 vs 8.2 mo). ORR was 65.6% for pembro and 54.2% for BV; CR rates were 24.5% and 24.2%, respectively. Median (range) DOR was 20.7 mo (0.0+ to 33.2+) for pembro and 13.8 mo (0.0+ to 33.9+) for BV. Grade 3-5 TRAEs: 19.6% of pts with pembro and 25.0% with BV. One death due to TRAE occurred with pembro (pneumonia). **Conclusions:** In pts with R/R cHL, pembro was superior to BV and demonstrated statistically significant and clinically meaningful improvement in PFS across all subgroups, with safety consistent with previous reports. Pembro monotherapy should be standard of care for this pt population with R/R/cHL. Clinical trial information: NCT02684292. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

8006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Initial results of a multicenter, investigator initiated study of MRD driven time limited therapy with zanubrutinib, obinutuzumab, and venetoclax. *First Author: Jacob Drobnyk Soumerai, Massachusetts General Hospital Cancer Center; Harvard Medical School, Boston, MA*

Background: Venetoclax (Ven)-Obinutuzumab (O) is approved for chronic lymphocytic leukemia (CLL) achieving frequent undetectable minimum residual disease (uMRD; Fischer NEJM 2019). Ven-Ibrutinib is synergistic with frequent uMRD but with grade >3 neutropenia in 33-48% patients (pts; Tam ASH 2019; Jain NEJM 2019). Zanubrutinib (B) is a highly specific BTK inhibitor that demonstrated 100% occupancy in lymphoid tissues, so may be preferred to combine with OVen. We hypothesize that treatment (tx) with BOVen using an MRD driven discontinuation strategy will achieve frequent uMRD and durable responses. **Methods:** In this multicenter, investigator initiated phase 2 trial (NCT03824483), eligible pts had previously untreated CLL requiring tx per iwCLL, ECOG PS <2, ANC >1, PLT >75 (ANC >0, PLT >20 if due to CLL). BOVen was administered in 28D cycles: B 160 mg PO BID starting D1; O 1000 mg IV D1 or split D1-2, 8, 15 of C1, D1 of C2-8; Ven ramp up initiated C3D1 (target 400 mg QD). Tx duration was determined by a prespecified uMRD endpoint (min 8 cycles). MRD was assessed in peripheral blood (PB; flow cytometry, sensitivity $>10^{-4}$) starting C7D1 then every 2 cycles. Once PB uMRD was determined and confirmed in bone marrow (BM), tx continued 2 additional cycles. Adverse events (AE) were assessed per CTCAE v5. Median (med) time to uMRD (primary endpoint) was estimated using the Kaplan-Meier method. **Results:** The study accrued 39 pts (3-10/19): med age 59 years (23-73), 3:1 male, CLL IPI >4 26/39 (67%), unmutated IGHV 28/39 (72%), 17p del/*TP53* mutated 4/39 (10%), all pts were evaluable for toxicity with 37 evaluable for efficacy. At a med follow up of 8 months (mo; 3-10), 25/37 (68%) pts achieved PB uMRD. Med time to PB uMRD is 6 mo (4-8+). Another 8/37 (22%) had PB MRD < 0.1%. Of 25 with PB uMRD, 19 had BM uMRD with 10/19 completing 2 additional cycles and discontinued; 3 had BM MRD (all <0.02%); 3 pending. The most common tx emergent AEs were neutropenia (49%), infusion related reaction (41%), bruising (39%), and diarrhea (39%). Grade ≥3 AEs in ≥5% pts were neutropenia (13%), thrombocytopenia (5%), rash (5%), and pneumonia (5%). Of 17 pts at high risk for TLS on C1D1, 2 cycles of BO reduced TLS risk to low/medium at Ven initiation in 15 (88%). No pts had laboratory/clinical TLS (Howard). **Conclusions:** BOVen is well tolerated and achieves rapid uMRD: currently 68% PB uMRD and 51% BM uMRD with limited follow up (to be updated on presentation). Ten (27%) have discontinued treatment thus far. The value of MRD directed treatment duration will be evaluated with continued follow up. Clinical trial information: NCT03824483. Research Sponsor: BeiGene; Genentech/Roche, Other Foundation, Lymphoma Research Fund (Andrew Zelenetz)).

8007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

ASPEN: Results of a phase III randomized trial of zanubrutinib versus ibrutinib for patients with Waldenström macroglobulinemia (WM). *First Author: Constantine S. Tam, Peter MacCallum Cancer Centre, Melbourne, St Vincent's Hospital, Fitzroy, University of Melbourne, Parkville and Royal Melbourne Hospital, Parkville, Victoria, Australia*

Background: Bruton tyrosine kinase (BTK) inhibition is an emerging standard of care for WM. ASPEN is a randomized phase 3 study comparing zanubrutinib (ZANU), a potent and selective BTK inhibitor, versus ibrutinib (IBR), a first generation BTK inhibitor, in WM patients. **Methods:** Patients with WM and *MYD88* mutation were randomly assigned 1:1 to receive ZANU (160 mg twice daily) or IBR (420 mg once daily). Patients without *MYD88* mutations were assigned to a separate cohort, received ZANU, and are reported separately. Randomization was stratified by CXCR4 mutational status and the number of lines of prior therapy (0 vs 1-3 vs >3). The primary end point was the proportion of patients achieving a complete response or very good partial response (CR+VGPR). Sample size was calculated to provide 81% power to detect a difference in CR+VGPR rate of 35% vs 15% in the subset of patients with relapsed or refractory (R/R) WM. Primary analysis was planned to occur at ~12 months after last patient enrolled. **Results:** In total, 201 patients were randomized from Jan 2017 to Jul 2018. The treatment groups were well balanced for important baseline factors, except in the ZANU arm there were more elderly patients (aged >75 years, 33.3% vs 22.2%) and more anemia (hemoglobin ≤110 g/L, 65.7% vs 53.5%). At a median follow-up of 19.4 months, the rate of CR+VGPR was 28.4% vs 19.2% with ZANU vs IBR, respectively (2-sided P=0.09). Rates of atrial fibrillation, contusion, diarrhea, edema peripheral, hemorrhage, muscle spasms, pneumonia, and adverse events (AEs) leading to discontinuation or death were lower with ZANU. The rate of neutropenia was higher with ZANU (Table); however, grade ≥ 3 infection rates were similar (17.8% vs 19.4%). **Conclusions:** ASPEN is the largest phase 3 trial of BTK inhibitors in WM and the first head-to-head comparison of BTK inhibitors in any disease. Although not statistically significant, ZANU was associated with a higher CR+VGPR response rate, and demonstrated clinically meaningful advantages in safety and tolerability compared to IBR. Clinical trial information: NCT03053440. Research Sponsor: BeiGene.

Assessment, %	ZANU (n=102)	IBR (n=99)
CR+VGPR Rate	28.4	19.2
12-mo PFS/OS – overall population	89.7/97.0	87.2/93.9
12-mo PFS/OS – R/R population (n=83 vs 81)	92.4/98.8	85.9/92.5
AEs ≥Grade 3 / Grade 5	58.4 /1.0	63.3/4.1
AEs leading to discontinuation	4.0	9.2
Atrial fibrillation/flutter	2.0	15.3
Hypertension	10.9	17.3
Major bleeding[a]	5.9	9.2
Neutropenia	29.7	13.3

PFS/OS, progression-free survival/overall survival.
[a]Includes grade ≥3 hemorrhage and central nervous system bleeding of any grade.

8008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Interim analysis of ZUMA-5: A phase II study of axicabtagene ciloleucel (axi-cel) in patients (pts) with relapsed/refractory indolent non-Hodgkin lymphoma (R/R iNHL). *First Author: Caron A. Jacobson, Dana-Farber Cancer Institute, Boston, MA*

Background: Advanced stage iNHL, including follicular lymphoma (FL) and marginal zone lymphoma (MZL), is considered incurable as most pts experience multiple relapses (Wang, et al. *Ther Adv Hematol*. 2017), highlighting a need for novel therapies. Here, we present interim results from ZUMA-5, a Phase 2, multicenter study of axi-cel, an autologous anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in pts with R/R iNHL. **Methods:** Adults with R/R FL (Grades 1-3a) or MZL (nodal or extranodal) after ≥ 2 lines of therapy (including an anti-CD20 monoclonal antibody [mAb] with an alkylating agent), and an ECOG of 0 – 1 were eligible. Pts were leukapheresed and received conditioning chemotherapy followed by axi-cel infusion at 2×10^6 CAR T cells/kg. The primary endpoint was objective response rate (ORR) by central review (Cheson, et al. *J Clin Oncol*. 2014). Secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety, and blood levels of cytokines and CAR T cells. **Results:** As of 8/20/19, 94 pts (80 FL; 14 MZL) received axi-cel with a median follow-up of 11.5 mo (range, 4.2 – 24.9). Median age was 63 y (range, 34 – 79), 47% of pts were male, 52% had stage IV disease, 51% had ≥ 3 FLIPI, and 59% had high tumor bulk (GELF). Pts had a median 3 prior lines of therapy, 66% progressed < 2 y after initial anti-CD20 mAb-containing therapy (POD24), and 73% were refractory to the last prior treatment. Of 87 pts evaluable for efficacy, ORR was 94% (79% complete response [CR] rate). Pts with FL (n = 80) had an ORR of 95% (80% CR rate). Pts with MZL (n = 7) had an ORR of 86% (71% CR rate). Overall, 68% of pts had ongoing responses as of the data cutoff. Updated data, including DOR, PFS, and OS with longer follow-up, will be included in the presentation. Of 94 pts evaluable for safety, 83% experienced Grade ≥ 3 adverse events (AEs), most commonly neutropenia (33%) and anemia (28%). Grade ≥ 3 cytokine release syndrome (CRS; per Lee et al, *Blood* 2014) and neurologic events (NEs; per CTCAE v4.03) occurred in 11% and 19% of pts, respectively. Median times to onset of CRS and NEs were 4 and 7 d, with median durations of 6 and 14.5 d. There were 2 Grade 5 AEs: multisystem organ failure in the context of CRS (related to axi-cel) and aortic dissection (unrelated to axi-cel). Median peak and $AUC_{0\text{-}28}$ CAR T cell levels were 44 cells/μL and 490 cells/μL × d, respectively. **Conclusions:** Axi-cel demonstrated significant and durable clinical benefit, with high rates of ORR and CR, and a manageable safety profile in pts with R/R iNHL. Clinical trial information: NCT03105336. Research Sponsor: Kite, a Gilead Company.

8009 Poster Discussion Session; Displayed in Poster Session (Board #342), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Epcoritamab (GEN3013; DuoBody-CD3×CD20) to induce complete response in patients with relapsed/refractory B-cell non-Hodgkin lymphoma (B-NHL): Complete dose escalation data and efficacy results from a phase I/II trial. *First Author: Martin Hutchings, Rigshospitalet, Copenhagen, Denmark*

Background: CD3×CD20 bispecific antibodies (bsAbs) have demonstrated promising results for the treatment of pts with R/R B-NHL. Epcoritamab is a novel subcutaneously administered bsAb with a favorable safety profile and encouraging preliminary anti-tumor activity at low doses in both aggressive and indolent B-NHL. Here we present updated safety and efficacy data from the ongoing trial (NCT03625037). **Methods:** Adults with R/R CD20+ B-NHL received a single SC injection of flat-dose epcoritamab in 28-day cycles (q1w: cycle 1–2; q2w: cycle 3–6; q4w thereafter) until disease progression or unacceptable toxicity. Primary objectives are determination of maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). Secondary objectives include anti-tumor activity. **Results:** As of 8 Jan 2020, 41 pts with median age of 66 (range: 21–82) were enrolled. Most pts had DLBCL/HGBCL (73%) or FL (20%) and received a median (range) of 3 (1–6) and 5 (2–18) prior lines of treatment. No DLTs were observed (median follow-up: 4.7 mo; range: 3.7– 5.6). MTD has not been reached. Most common TEAEs (>35%) were pyrexia (71%), fatigue (46%), and injection site reaction (39%; all Gr 1). AEs of special interest included cytokine release syndrome (59%; all Gr 1/2; all resolved) and cytokine release-related decreased CARTOX-10 score (n=1). There was no clinical tumor lysis syndrome or treatment-related deaths. Treatment is ongoing in 13 pts. Anti-tumor activity was observed at minimal efficacy threshold (based on PK modelling) for DLBCL/HGBCL and FL (Table). Complete dose escalation data and RP2D will be presented. **Conclusions:** SC epcoritamab continues to demonstrate a favorable safety profile across all doses with no ≥Gr 3 CRS and no DLTs. Dose escalation data show improved efficacy as doses reach above the modeled predicted exposure threshold, inducing CRs in heavily pretreated DLBCL pts. All pts achieving CRs remain in remission. Clinical trial information: NCT03625037. Research Sponsor: Genmab.

Durable responses to REGN1979, a human CD20 x CD3 bispecific antibody (bsAb), in patients (pts) with relapsed/refractory B-cell non-Hodgkin lymphoma (R/R B-NHL) including with or without (w/wo) prior chimeric antigen receptor T-cell therapy (CAR T). *First Author: Rajat Bannerji, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: REGN1979 is a human CD20 x CD3 IgG4 bsAb targeting CD20+ tumor cells via T cell-mediated cytotoxicity. We report extended follow-up of a global Phase 1 study (NCT02290951) of REGN1979 monotherapy in R/R B-NHL. **Methods:** Primary objectives were to assess safety, tolerability, and occurrence of dose limiting toxicities (DLTs) in R/R B-NHL pts after prior CD20 Ab therapy. REGN1979 (0.03–320 mg) dose regimen evolved over time to QW×12 with initial, intermediate, and step-up dosing in first weeks, followed by Q2W×12 (36 weeks total). **Results:** As of 1/7/2020, 116 pts with R/R B-NHL were enrolled; diffuse large B-cell lymphoma (DLBCL; 65), follicular lymphoma Gr 1–3a (FL; 31), mantle cell lymphoma (MCL; 11), marginal zone lymphoma (6), or other B-NHL (3). Pts had received a median (med) of 3 (range: 1–11) prior lines of therapy; 25 pts received prior CAR T (DLBCL: 21; FL: 2; MCL: 2). Med follow-up was 4.2 (0.4–25.4) months (mo). Most common treatment-emergent adverse events (TEAEs) were pyrexia (93 pts) and cytokine release syndrome (CRS; 70 pts). Gr 3/4 CRS occurred in 8 pts; all events were transient and no Gr 5 CRS was observed. No DLTs occurred during DE. Seven pts discontinued due to treatment-related AEs. Seventeen pts died during the study, 10 with progressive disease (PD), 6 due to TEAEs (5 related to treatment) and 1 due to fungal pneumonia unrelated to treatment. **Conclusions:** REGN1979 continues to show acceptable tolerability in pts with R/R B-NHL. FL pts had the longest follow up, KM estimate of med PFS was 11.4 mo. Durable responses can be >20 mo in pts with FL and >12 mo in pts with DLBCL w/wo CAR T failure. Enrollment into disease-specific registration intent expansion cohorts is ongoing. Clinical trial information: NCT02290951. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Prognostic impact of dose, duration, and timing of corticosteroid therapy in patients with large B-cell lymphoma treated with standard of care axicabtagene ciloleucel (Axi-cel). *First Author: Paolo Strati, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Corticosteroids are commonly used for management of severe toxicities associated with chimeric antigen receptor (CAR) T-cell therapy. However, it remains unclear whether the dose, duration, and timing of corticosteroid therapy may impact clinical efficacy of CAR T-cell therapy. **Methods:** This is a retrospective analysis of patients with relapsed or refractory LBCL treated with standard of care axi-cel at MD Anderson Cancer Center, Houston, Texas between 01/2018 and 05/2019 (data cut-off 12/21/2019). Progression-free survival (PFS) was defined as time from axi-cel infusion to progression/death or last follow-up, and the Breslow test was used for comparisons between subgroups. **Results:** One hundred patients with relapsed or refractory LBCL were included in the study, and 60 (60%) received corticosteroids for management of toxicities after axi-cel infusion. There was no significant difference in baseline tumor burden, disease stage or international prognostic index between the 2 groups. The median cumulative dexamethasone-equivalent dose was 186 mg (range, 8-1803 mg) and the median duration of corticosteroid treatment was 9 days (range 1-30); 45 (45%) patients started corticosteroid treatment between day 0 and 7, and 15 (15%) beyond day 7. After a median follow-up of 10 months (95% CI 8-10 months), median PFS was 8 months (95% CI, 3-13 months), and use of corticosteroids (any dose) showed a trend for association with shorter PFS (6 vs 9 months, p = 0.13). Use of high-dose corticosteroids (Quartiles (Q) 3-4, 195-1803 mg) significantly associated with shorter PFS (2 vs 9 months, p = 0.005). A trend for shorter PFS was observed among patients receiving corticosteroids for a prolonged time (Q3-Q4, 10-30 days) (5 vs 8 months, p = 0.12) and among patients starting corticosteroids within the first 7 days after axi-cel infusion (6 vs 11 months, p = 0.07). At most recent follow-up, 36 patients died, 28 of progression. Median overall survival has not been reached, and was significantly shorter among patients who received corticosteroids (13 vs not reached, p = 0.006). **Conclusions:** Early and prolonged use of high-dose corticosteroids is associated with early progression and death in patients with LBCL treated with axi-cel. Additional evaluation is needed to understand the mechanism underlying this association. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Retreatment (reTx) of patients (pts) with refractory large B-cell lymphoma with axicabtagene ciloleucel (axi-cel) in ZUMA-1. *First Author: Frederick Lundry Locke, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Axi-cel, an autologous anti-CD19 chimeric antigen receptor (CAR) T cell therapy, is approved in the US and EU for pts with relapsed/refractory large B cell lymphoma after ≥ 2 prior therapies. In the ZUMA-1 pivotal study (NCT02348216), the objective response rate (ORR) was 83% (58% complete response [CR] rate; Locke et al. *Lancet Oncol.* 2019). While axi-cel has demonstrated durable responses in a subset of pts, approximately half of all responders relapsed, and little is known on the viability of reTx with CAR T cell therapy. Here we report outcomes of pts retreated with axi-cel in ZUMA-1. **Methods:** Pts with progressive disease (PD) were eligible for reTx if there was no evidence of CD19 loss by local review, and if during 1st Tx they did not experience any dose-limiting toxicities, as defined in Phase 1, or comparable toxicities in Phase 2. Pts received the same regimen at reTx as at 1st Tx: 2×10^6 CAR T cells/kg after conditioning chemotherapy. **Results:** Thirteen pts in Cohorts 1 – 4 received axi-cel reTx. Prior to 1st Tx, most pts (69%) had an IPI score 3-4, 85% had disease stage 3-4, and the median number of prior regimens was 3 (range, 2 – 6). At first Tx, 6 pts achieved a CR, 6 achieved partial response (PR), and 1 pt had stable disease (SD) prior to PD. Median duration of first response was 96 days (range, 56 – 274). There was no Grade ≥ 3 cytokine release syndrome (CRS; 6 pts each had Grade 1 and 2). There were no Grade 4 or 5 neurologic events (NEs; 2 pts had Grade 1, 1 had Grade 2, and 7 had Grade 3). Upon reTx, 54% of pts achieved response (4 CR, 3 PR). Response to reTx was more common among pts who achieved CR at 1st Tx (83%; 4/6 CR, 1 PR, 1 SD) than in pts who achieved PR at 1st Tx (33%; 2/6 PR, 1 SD, 3 PD), and no response was observed in the pt with SD at 1st Tx. Median duration of response at reTx was 81 days (range, 1 – 225+). Response with reTx was longer than that with 1st Tx for 2 pts. One pt remains in response 255 days post-reTx. Comparable rates of CRS were observed with reTx as with 1st Tx. Compared with 1st Tx, fewer pts experienced NEs with reTx, and those that did occur were of lower grade: 23% (3 of 13 pts) had Grade 3; 23% (3 of 13 pts) had Grade 1, and 8% (1 of 13 pts) had Grade 2. Peak CAR T cell expansion was lower upon reTx vs 1st Tx (median, 4.3 vs 66.1 CAR gene-marked cells/μL blood). **Conclusions:** Based on this limited sample size, reTx with axi-cel may have clinical efficacy, although transient, in some pts, especially those who achieve CR with 1st Tx. CAR T cell expansion and severe CRS and NEs may be attenuated at reTx. Further studies with additional pts are needed to confirm these results. Clinical trial information: NCT02348216. Research Sponsor: Kite, a Gilead Company.

Nivolumab and brentuximab vedotin (BV)-based, response-adapted treatment in children, adolescents, and young adults (CAYA) with standard-risk relapsed/refractory classical Hodgkin lymphoma (R/R cHL): Primary analysis. *First Author: Peter D. Cole, Rutger's Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Outcomes for younger patients (pts) with R/R cHL are poor, particularly for those without complete metabolic response (CMR) before autologous transplant (auto-HCT). Nivolumab + BV has shown 67% CMR and a high 2-y PFS rate as first salvage in adults with R/R cHL. CheckMate 744 (NCT02927769) is an ongoing phase 2 study for CAYA with R/R cHL, evaluating a risk-stratified, response-adapted approach using nivolumab + BV and, for pts without CMR, BV + bendamustine. In the initial analysis of the standard-risk cohort (R2), the regimen was well tolerated with high CMR rates before consolidation with high-dose chemotherapy plus auto-HCT. We report data from the primary analysis. **Methods:** Pts were aged 5–30 y and had first-line treatment (tx) without auto-HCT. Risk stratification has been described previously (Harker-Murray, ASH 2018). Pts received 4 induction cycles of nivolumab + BV; pts without CMR by blinded independent central review (BICR) received BV + bendamustine intensification. Pts with CMR at any time could proceed to consolidation off study. Response was per Lugano 2014 criteria. Primary endpoint: CMR rate (Deauville ≤3) per BICR any time before consolidation. **Results:** At database lock, 44 pts were treated in R2 (median follow up: 20.9 mo); 43 received 4 induction cycles and 11 received intensification. Median age was 16 y (range 9–30); 24 (55%) pts had primary refractory cHL and 20 had relapsed cHL. CMR rates and ORR any time before consolidation and after induction are shown in Table. 1-y PFS rate by BICR was 91% (90% CI 77–96). During induction, 8 (18%) pts experienced grade (G) 3–4 tx-related adverse events (TRAEs); the most common any grade TRAEs were nausea and hypersensitivity (20% each). 1 TRAE led to discontinuation (G3 anaphylaxis). Most tx-related immune-mediated AEs were G1–2 (1 pt had 2 G3 infusion-related reactions). **Conclusions:** This risk-stratified, response-adapted approach offers a well-tolerated salvage strategy with high CMR rates and no new safety signals for CAYA with R/R cHL. Most pts avoided alkylator exposure prior to consolidation. Further follow up may confirm durability of disease control. Clinical trial information: NCT02927769. Research Sponsor: Bristol-Myers Squibb.

CMR and ORR per BICR and investigator (INV) in response-evaluable pts.

8014 Poster Discussion Session; Displayed in Poster Session (Board #347), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Phase II, multicenter trial of nivolumab (Nivo) and brentuximab vedotin (BV) in patients (Pts) with untreated Hodgkin lymphoma (HL) over the age of 60 years or unable to receive standard ABVD chemotherapy: Results of a study of Academic and Community Cancer Research United (ACCRU) RU051505I. *First Author: Bruce D. Cheson, Georgetown University Hospital, Washington, DC*

Background: HL is highly curable with > 90% of pts with limited and > 80% with advanced stage disease experiencing long-term disease-free survival. HL typically occurs in younger pts, yet 15-35% are > 60 yrs and experience a lower response rate, shorter survival, and greater toxicity. BV and checkpoint inhibitors have impressive activity in pts with relapsed and refractory HL. Thus, we initiated a phase II trial of BV-nivo in untreated pts with HL >60 yrs of age or considered unsuitable for standard ABVD therapy. **Methods:** Inclusion criteria: previously untreated pts with classical HL > 60 yrs or < 60 yrs but considered unsuitable for standard chemotherapy because of a cardiac ejection fraction of < 50%, diffusion capacity < 80%, or creatinine clearance > 30 but < 60 mL/min, or refused chemotherapy; ECOG PS 0-2, ANC >1500/mm^3, platelets > 100,000/mm^3, hemoglobin > 9 g/dl, bilirubin <1.5 x upper limits of normal (ULN), aspartate/alanine transaminases < 2.5 x ULN, amylase and/or lipase < 1.5 x ULN, and serum creatinine < 2.0 mg/dl. Pts received BV at 1.8 mg/kg (cap at 180 mg) and nivo 3 mg/kg every 21 days for 8 cycles. Response was assessed per the Lugano Classification. **Results:** The study accrued 46 pts between May 13, 2016-January 30, 2019. Median age of 71.5 yrs, 69.5% had ECOG PS 1 or 2; 64% stage III or IV; 39.1% with B symptoms; 4.3% were < 60 years. Median follow-up was 21.2 months (range 2.9, 38.5), and 35 pts (76.1%) completed all 8 cycles of therapy. At the interim analysis (1st 25 pts) ORR was 64% (52% mCR, 12% pMR) which was lower than the projected 80%. In all 46 pts, 45.7% achieved mCR and 15.2% mPR (ORR 60.9%); in evaluable pts, best ORR was 95% with 68% mCR. No clinical factors predicted response. Neither median duration of response nor median survival has been reached. Median PFS is 21.8 months (17.8, Not reached). 22 pts experienced 33 treatment delays, primarily due to BV. 22 pts experienced peripheral neuropathy (5 grade 3). Grade 4 toxicities included increased transaminases (n = 1), increased lipase and/or amylase (n = 2), pancreatitis (1). One pt died from cardiac arrest, possibly treatment-related. **Conclusions:** BV-nivo is active in untreated older HL pts with comorbidities. However, efficacy and response durability did not meet pre-specified criteria. Future trials based on these drugs, selecting pts most likely to benefit, may lead to a chemo-free approach for pts with HL. Clinical trial information: NCT02758717. Research Sponsor: Seattle Genetics, Bristol Myers Squibb.

8015 Poster Discussion Session; Displayed in Poster Session (Board #348), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Acalabrutinib (Acala) versus idelalisib plus rituximab (IdR) or bendamustine plus rituximab (BR) in relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL): ASCEND final results. *First Author: Paolo Ghia, Università Vita-Salute San Raffaele and IRCCS Ospedale San Raffaele, Milan, Italy*

Background: Acala is a next-generation, highly selective, covalent Bruton tyrosine kinase inhibitor approved for patients (pts) with CLL including those with R/R CLL. The efficacy and safety of acala alone vs IdR or BR were shown in R/R CLL pts in a preplanned interim analysis of ASCEND; final results are reported herein. **Methods:** In this randomized, multicenter, phase 3, open-label study (NCT02970318), R/R CLL pts were randomized 1:1 to receive oral (PO) acala 100 mg BID or investigator's (INV) choice of IdR (Id: 150 mg PO BID until progression or toxicity; R: 375 x1 then 500 mg/m^2 intravenously [IV] for 8 total infusions) or BR (B: 70 mg/m^2 IV and R: 375 x1 then 500 mg/m^2 IV for 6 total cycles) until progression or toxicity. Progression-free survival (PFS), overall survival (OS), overall response rate (ORR), and safety were assessed. **Results:** 310 pts (acala, n=155; IdR, n=119; BR, n=36) were enrolled (median age: 67 y; del(17p) 16%, del(11q) 27%, Rai stage 3/4 42%). At a median follow-up of 22.0 m, acala significantly prolonged INV-assessed PFS vs IdR/BR (median: not reached vs 16.8 m; hazard ratio: 0.27, P<0.0001); 18-m PFS rates were 82% for acala and 48% for IdR/BR. 18-m OS rate was 88% for both treatment regimens. ORR was 80% with acala vs 84% with IdR/BR (ORR + partial response with lymphocytosis: 92% vs 88%, respectively). Common adverse events (AEs) are listed in the Table. AEs led to drug discontinuation in 16% of acala, 56% of IdR, and 17% of BR pts. AEs of interest included atrial fibrillation (acala 6%, IdR/BR 3%), major hemorrhage (all grade; acala 3%, IdR/BR 3%), grade ≥3 infections (acala 20%, IdR/BR 25%), and second primary malignancies excluding non-melanoma skin cancer (acala 5%, IdR/BR 2%). **Conclusions:** Final ASCEND results with additional follow-up confirm earlier findings and support the favorable efficacy and safety of acala compared with standard-of-care regimens in R/R CLL pts. Clinical trial information: NCT02970318. Research Sponsor: Acerta Pharma, a member of the AstraZeneca group.

Tolerability and durable respones of the PI3Kδ inhibitor ME-401 administered on an intermittent schedule in relapsed/refractory (R/R) follicular lymphoma (FL) and other B-cell malignancies. *First Author: Andrew David Zelenetz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ME-401, a potent, selective, and structurally differentiated oral PI3kδ inhibitor was evaluated in a dose escalation/expansion Phase 1b study, and previously demonstrated a high objective response rate (ORR) in FL and chronic lymphocytic leukemia (CLL)/small lymphocytic leukemia (SLL) when given on a continuous (CS) or an intermittent schedule (IS). IS appeared to significantly reduce the incidence of immune-mediated adverse events of special interest (AESI) associated with PI3kδ inhibitors (diarrhea, rash, transaminase elevation, pneumonitis). We report maturing data from patients treated on the IS in this study. **Methods:** Eligible patients (pts) had FL, CLL/SLL, marginal zone lymphoma (MZL) and diffuse large B-cell lymphoma (DLBCL), at least 1 prior therapy, adequate bone marrow and organs function, ECOG status ≤2, and no prior PI3K therapy. IS dosing: ME-401 at 60 mg/day for two 28-day cycles, followed by 7 days of therapy every 28-day cycle until disease progression or intolerance. Pts received ME-401 monotherapy (n = 21) or a combination with rituximab (n = 36) given at 375 mg/m^2 for 8 doses in Cycles 1-6. **Results:** Total of 57 pts treated with IS: 35 FL, 10 CLL/SLL, 4 MZL, and 8 DLBCL with 38 (67%) currently still ongoing. Median age: 66 years (range 38-94) and median prior therapies: 2 (range 1-8). As of January 2020, median follow-up = 9.7 mo (range 0.6-25.4+). Grade 3 AESI reported in 7 pts: 2 diarrhea (3.5%), 2 colitis (3.5%), 1 rash (2%), 1 ALT increased (2%), and 1 pneumonitis (2%). No Grade 3 AESI reported beyond Cycle 3. Discontinuation for AE in 3 pts (5%). There were no discernable safety differences between the monotherapy and rituximab combination groups. ORR was 83% in FL (76% in monotherapy group, 88% in combination group) and 89 % in CLL/SLL (100%, 83%), with median duration of response not reached. Median PFS was not reached in all patients with FL and CLL (combined analysis of both single agent and with rituximab). ORR was 100% (4/4) in MZL and 25 % (2/8) in DLBCL (in combination group only). **Conclusions:** ME-401 administered on an IS was well-tolerated, with a low-rate of Grade 3 class-related AESI and achieved a high-rate of durable objective responses in R/R indolent B-cell malignancies. These results may differentiate ME-401 and support further evaluation as a single-agent and in combination regimens. An ongoing global trial is evaluating ME-401 by IS in pts with FL after failure of ≥2 prior therapies (NCT03768505). Clinical trial information: NCT02914938. Research Sponsor: MEI Pharma, Inc.

8017 Poster Discussion Session; Displayed in Poster Session (Board #350), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Results of a completed phase I study of LAM-002 (apilimod dimesylate), a first-in-class phosphatidylinositol-3-phosphate 5 kinase (PIKfyve) inhibitor, administered as monotherapy or with rituximab or atezolizumab to patients with previously treated follicular lymphoma or other B-cell cancers. *First Author: Catherine S. Magid Diefenbach, Perlmutter Cancer Center at NYU Langone Health, New York, NY*

Background: LAM-002 is a selective inhibitor of PIKfyve that disrupts lysosomal homeostasis, inducing cytotoxicity in B-cell lymphoma models as monotherapy or with anti-CD20 or anti-PDL1 antibodies (Gayle et al., Blood 2017;129(13):1768). **Methods:** In this study, patients received LAM-002 orally 2-3 times per day (BID or TID) in a 3+3 escalation. Additional patients received LAM-002 125 mg BID as monotherapy; with rituximab 375 mg/m^2 intravenously (IV) and or subcutaneously weekly (Q1W) x 4 → Q8W x 4; or atezolizumab 1200 mg IV Q3W until disease progression or unacceptable toxicity. Pharmacokinetics (PK) were assessed for 8 hours postdose on Days 1 and 8. Efficacy was evaluated Q6-12W. **Results:** The study enrolled 62 patients (M:F n = 32/30); median [range] age = 69 [46-89] years; with diagnoses (n) of diffuse large B-cell lymphoma (25), follicular lymphoma (19), marginal zone lymphoma (8), mantle cell lymphoma (5), or chronic lymphocytic leukemia (5) to receive LAM-002 alone (n) at 50 mg BID (3), 100 mg BID (8), 150 mg BID (8), 75 mg TID (4), or 125 mg BID (20); LAM-002/rituximab (12); or LAM-002/atezolizumab (7). During LAM-002 dose-ranging (50 mg BID → 100 mg BID → 150 mg BID → 75 mg TID → 125 mg BID) transient, reversible nausea and/or diarrhea occurred at 150 mg BID and 75 mg TID, resulting in a LAM-002 recommended Phase 2 dosing regimen (RP2DR) of 125 mg BID. Among 39 patients receiving LAM-002, 125 mg BID, alone or in combination for up to 22 cycles (1.9 years), adverse events were typically low-grade. LAM-002 PK showed rapid absorption, dose proportionality, minimal accumulation, and no substantive changes with rituximab or atezolizumab coadministration. In patients with follicular lymphoma and median [range] prior therapies = 3 [1-9] treated with the RP2DR, objective response rates were 2/7 (29%; 1 complete response [CR], 1 partial response [PR]) with LAM-002, 5/8 (63%; 1 CR, 4 PRs) with LAM-002/rituximab, and 2/2 (100%; 2 PRs) with LAM-002/atezolizumab. **Conclusions:** LAM-002, the first clinical PIKfyve inhibitor, is safe alone or with full-dose anti-CD20 or anti-PD-L1 inhibition. LAM-002 does not cause the myelosuppressive or immune adverse events associated with lenalidomide or PI3K inhibitors. Promising efficacy supports registration-directed Phase 2/3 testing of LAM-002 monotherapy and combination therapy for patients with previously treated follicular lymphoma. Clinical trial information: NCT02594384. Research Sponsor: AI Therapeutics, Inc.

Outcomes of GDPT (gemcitabine, cisplatin, prednisone,thalidomide) versus CHOP in newly diagnosed peripheral T-cell lymphoma patients. *First Author: Ling Li, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China*

Background: Peripheral T-cell lymphoma(PTCL) is highly heterogeneous invasive NHL.There is no consensus standard treatment for it now. So outcomes of GDPT versus CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) in treating newly diagnosed PTCL were compared. **Methods:** An open-label prospective clinical trial with 153 newly diagnosed PTCL patients conducted between January 2010 and December 2018 was designed. Patients were randomly assigned to the GDPT group (77 cases) and CHOP group (76 cases). Patients in each group were further divided into four subgroups: PTCL-NOS, ALCL, AITL, and an other types, in accordance with pathological patterns. Based on expression of RRM1, TOP2A, TUBB3 and ERCC1, patients were divided into groups with high and low gene expression levels. Clinical characteristics, side effects, efficacy, PFS and OS were compared. **Results:** There were no significant differences in the basic clinical features or side effects between the GDPT and CHOP groups. The ORR of the GDPT group was better than that of the CHOP group (66.3%vs. 50.0%, *P*= 0.042), as was the CR rate (42.9% vs. 27.6%, *P*= 0.049). Patients in the GDPT group had a longer PFS and OS than the CHOP group. The 4-year PFS and OS rates in the GDPT group were both superior to those in the CHOP group (63.6% vs. 53.0% for PFS, *P*= 0.035; 66.8% vs. 53.6% for OS, *P*= 0.039).In the GDPT group, the difference in CR between the four subgroups was statistically significant (P = 0.046).In the CHOP group, differences in both CR and ORR among the four subgroups were statistically significant (*P*= < 0.001 and *P*= 0.005, respectively).There were also statistically significant differences in CR between patients treated with CHOP and GDPT in the PTCL-NOS subgroup, AITL subgroup, and the other types subgroup(*P*= 0.015;*P*= 0.003;*P*= 0.005, respectively).The data also showed a significant difference in OS among the four subgroups within the GDPT group (*P*= 0.001).The OS of AITL was shorter than that of the other three subgroups. Four subgroups of CHOP showed a significant difference in PFS (*P*= 0.019). There was no statistical association between responses and the gene expression levels of RRM1, ERCC1, TUBB3 and TOP2A. **Conclusions:** The GDPT group had better response rates and prolonged the patients' PFS and OS. As a promising new regimen, GDPT is expected to become the first-line therapy for PTCL. New agents should be applied to patients who do not achieve good responses with previous treatment, such as those diagnosed with angioimmunoblastic T cell lymphoma. Clinical trial information: NCT01664975. Research Sponsor: the National Natural Science Foundation of China, Provincial Medical Science and Technology Research Project in Henan.

Lenalidomide plus R-GDP (R2-GDP) in relapsed/refractory diffuse large B-cell lymphoma: Final results of the R2-GDP-GOTEL trial. *First Author: Luis de la Cruz Merino, Clinical Oncology Department, Hospital Universitario Virgen Macarena, Seville, Spain*

Background: Lenalidomide is an immunomodulatory drug that could reverse rituximab refractoriness in lymphoma patients (pts). We conducted an open label multicenter phase 2 trial testing the efficacy and toxicity of a combination of lenalidomide and rituximab (R2) plus GDP schedule (R2-GDP) in Relapsed/Refractory Diffuse Large B Cell Lymphoma (R/R DLBCL) pts, not suitable for autologous stem cell transplant (ASCT). **Methods:** Patients with R/R DLBCL previously treated with at least 1 prior line of immunochemotherapy including rituximab, and not candidates for ASCT, were eligible. After a run-in phase period, treatment consisted of an induction phase with lenalidomide (LEN) 10 mg po d1-14, rituximab 375 mg/m2 iv d1, cisplatin 60 mg/m2 iv d1, gemcitabine 750 mg/m2 iv d1 and d8 and dexamethasone 20 mg d1-3, up to a maximum of 6 cycles. Pts without disease progression (DP) entered into a maintenance phase with LEN 10 mg, or last LEN dose received in the induction phase, d1-21 in cycles every 28 days. Primary endpoint was overall response rate (ORR) by investigator assessment. Secondary endpoints included disease free survival (DFS), event free survival (EFS), overall survival (OS), safety and response by cell of origin (COO), type of DLBCL (double-triple hit) and other microenvironment and genomic biomarkers. **Results:** 79 pts were enrolled between April 2015 and September 2018. Median age was 70 years (range 23-86), 48,7% women. 78 pts were considered for efficacy and safety in the intention to treat (ITT) analysis. With a median follow-up of 13 months at the time of cut-off (November 2019), ORRwas 59.0%, with 32.1% complete responses (CR) and 26.9% partial responses (PR). In the primary refractory population (n = 33), ORR was 45.5%, with 21.2% CR and 24.3% PR. There were no statistically significant differences in ORR with respect to COO. In Double-Hit R/R DLBCL (n = 16), ORR was 37.5% with 25% CR. Median OS was 12.0 months (6.9-17.0). Most common grade 3/4 (G3/4) adverse events were thrombocytopenia (60.2%), neutropenia (60.2%) and anemia (26.9%). Febrile neutropenia occurred in 14.1% pts. Most frequent non-hematologic G3/4 events were asthenia (19.2%), infection (15.3%) and renal insufficiency (6.4%). There were 4 toxic deaths related to the R2-GDP schedule. **Conclusions:** LEN with Rituximab and GDP (R2-GDP) is feasible and active in R/R DLBCL. Results in the primary refractory DLBCL population are particularly promising. Analysis of COO did not revealed differences in response rates. Immune biomarkers results will be showed at the meeting. Clinical trial information: EudraCT 2014-001620-29. Research Sponsor: CELGENE.

8020 Poster Discussion Session; Displayed in Poster Session (Board #353), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

RE-MIND study: A propensity score-based 1:1 matched comparison of tafasitamab + lenalidomide (L-MIND) versus lenalidomide monotherapy (real-world data) in transplant-ineligible patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL). *First Author: Grzegorz S. Nowakowski, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Patients with R/R DLBCL ineligible for autologous stem cell transplant (ASCT) have a poor prognosis. In these patients, tafasitamab (anti-CD19 antibody) plus lenalidomide (LEN) has shown encouraging results in the open-label, single-arm, phase II L-MIND study (n = 81; NCT02399085). To evaluate the contribution of tafasitamab to the activity of this doublet, we conducted a global, real-world study of patients treated with LEN monotherapy (RE-MIND; NCT04150328). Here we present the primary analysis of a 1:1 patient-level matched comparison between the L-MIND and RE-MIND cohorts. **Methods:** Patients treated with LEN monotherapy for R/R DLBCL were enrolled in the observational, retrospective RE-MIND cohort. As in L-MIND, patients had 1–3 prior systemic therapies, including ≥1 CD20-targeting regimen; were aged ≥18 years; and were not eligible for ASCT. A 1:1 estimated propensity score (ePS) matching methodology ensured balancing of nine pre-specified baseline covariates. The primary analysis set, Matched Analysis Set 25 (MAS25), included patients who received a LEN starting dose of 25 mg/day. The primary endpoint was investigator-assessed best objective response rate (ORR). Key secondary endpoints included overall survival (OS) and complete response (CR) rate. **Results:** 490 patients were enrolled in RE-MIND across 58 centers in the US and Europe, of which 140 fulfilled the ePS matching criteria. The MAS25 included 76 patients each from the two cohorts. Baseline characteristics between cohorts were comparable. The primary endpoint was met with a significantly better ORR of 67.1% (95% CI: 55.4–77.5) for the L-MIND cohort versus 34.2% (95% CI: 23.7–46.0) for the RE-MIND cohort (odds ratio 3.89; 95% CI: 1.90–8.14; $p < 0.0001$). The CR rate was 39.5% (95% CI: 28.4–51.4) in the L-MIND cohort and 13.2% (95% CI: 6.5–22.9) in the RE-MIND cohort. A significant difference in OS favored the L-MIND cohort (HR = 0.499; 95% CI: 0.317–0.785). ORR and CR outcomes in the RE-MIND cohort were similar to the published literature for LEN monotherapy in R/R DLBCL. **Conclusions:** Significantly better ORR, CR and OS indicate potential synergistic effects of the tafasitamab + LEN combination in ASCT-ineligible R/R DLBCL. ePS-based 1:1 matching allows robust estimation of the treatment effect of tafasitamab when added to LEN. RE-MIND demonstrates the utility of real-world data in interpreting non-randomized trials. Clinical trial information: NCT04150328. Research Sponsor: MorphoSys AG.

8021 Poster Session (Board #354), Fri, 8:00 AM-11:00 AM

Autologous stem cell transplantation for untreated transformed indolent B-cell lymphoma in first remission: An international, multicenter propensity matched study. *First Author: Collin K Chin, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Transformation of untreated indolent B-cell lymphoma (Tr-iNHL) is associated with poor outcomes. Current practices are extrapolated from prospective studies of *de novo* large B-cell lymphoma (DLBCL) or small retrospective studies. High dose chemotherapy (HDC) and autologous stem cell transplantation (ASCT) is used as consolidation in first remission (CR1) in some centers but the evidence-base is weak. **Methods:** CLL/SLL, MCL as primary diseases and non-DLBCL transformations were excluded. Propensity score analysis (PSM) using the "greedy match" algorithm was used to match the baseline covariates to adjust for potential selection bias. Landmark analysis was performed with time zero at 3 months after completion of front line chemotherapy (FLC). Kaplan-Meier method and the Cox proportional hazards model were was used for time-to-event analysis including progression-free survival (PFS) and overall survival (OS). **Results:** 319 transplant eligible patients (age <75, LVEF >45%, no severe lung disease, CR by PET or CT >3 months after FLC) who received >/= standard RCHOP intensity FLC were identified across three centers in Australia & US. 283 (89%) patients had follicular lymphoma, 30 (9%) marginal zone lymphoma, 6 (2%) other subtypes. 49 patients underwent HDC and ASCT in CR1, a matched cohort of 98 pts based on age, stage, HGBL-DH and ECOG PS at diagnosis was generated with a 1:2 ratio using PSM. After a median follow-up of 3.6 (min: 0.1, max: 18.3) years, ASCT was associated with significantly superior PFS on multivariable analysis (MVA) (HR 0.51, 0.27-0.98; P=0.043). Univariate analysis demonstrated a trend towards inferior OS in the ASCT cohort (HR 2.36; 0.87-6.42; P=0.092) with more deaths in the ASCT arm due to PD (8% *v* 4%). Of the 40 patients (41%) with relapsed disease in the non-ASCT cohort–15 patients underwent salvage HDC & ASCT with 7/15 (47%) ongoing CR; 10 patients underwent CAR-T therapy (5 relapse post ASCT, 4 refractory disease, 1 relapse post FLC) with 6/10 (60%) ongoing CR; 3 patients underwent allogeneic SCT (2 relapse post ASCT, 1 relapse post FLC) with 2/3 (67%) ongoing CR. **Conclusions:** Although ASCT in CR1 may improve initial duration of disease control in *de novo* Tr-iNHL, the impact on OS is less clear with effective salvage therapies in the CAR-T era. Research Sponsor: None.

8022 Poster Session (Board #355), Fri, 8:00 AM-11:00 AM

Effect of adding ublituximab to ibrutinib on PFS, ORR, and MRD negativity in previously treated high-risk chronic lymphocytic leukemia: Final results of the GENUINE phase III study. *First Author: Jeff P. Sharman, Willamette Valley Cancer Institute and US Oncology Research Center, Eugene, OR*

Background: The BTK inhibitor ibrutinib (IB) has advanced the treatment for patients (pts) with CLL, however, among pts with high-risk CLL, disease control with IB is less durable. Ublituximab (UTX) is a glycoengineered mAb with enhanced ADCC. The GENUINE study evaluated the addition of UTX to IB vs. IB alone in high-risk rel/ref CLL. With a median follow up now 3.5+ yrs, we present the final results. **Methods:** Eligible pts having rel/ref CLL with centrally confirmed del17p, del11q, and/or a TP53 mutation, were randomized 1:1 to IB (420 mg QD) alone or with UTX (900 mg on D1, 8, 15 of Cy 1, D1 of Cy 2-6, and Q3 Cy thereafter). No limit on # of prior Tx; prior IB excluded. Primary endpoint was overall response rate (ORR) by iwCLL 2008 (excludes PR-L); secondary endpoints were CR rate, peripheral blood MRD negativity (analyzed centrally), PFS, and safety. Response was by blinded independent review. **Results:** 117 pts were treated (59 in UTX + IB arm; 58 in IB arm). Med age was 66 yrs and med # of prior Tx was 1 (range 1-5) for each arm. Baseline features were relatively balanced including ECOG, gender, and med time since diagnosis (6+ yrs). 17p del was greater in the IB arm (50% vs 44%); bulky disease was greater in UTX + IB arm (47% vs 28%); IGHV-unmut was 83% for both arms. At data-cutoff of Sep 1, 2019, AEs were comparable between the arms, except infusion reactions (UTX + IB: All G 53% / G 3/4 3%) and neutropenia (All G 36% vs 21%, G 3/4 19% vs. 12%) which were higher for UTX + IB. At a med follow up of 42 mos, all efficacy endpoints were in favor of UTX + IB (see Table). **Conclusions:** In contrast to prior studies adding rituximab to IB, GENUINE is the first randomized trial to demonstrate a PFS benefit with the addition of an anti-CD20 to IB. Increasing depth of response (CR rate, MRD-neg) post first year of Tx supports maintenance therapy with UTX. Clinical trial information: NCT02301156. Research Sponsor: TG Therapeutics, Inc.

Efficacy	UTX + IB	Ibrutinib	p-value
ORR (CR/CRi, PR)	53 (90%)	40 (69%)	$p < 0.01$
CR/CRi	12 (20%)	3 (5%)	$p < 0.05$
ORR (CR/CRi, PR, PR-L)	55 (93%)	45 (77.5%)	$p < 0.05$
MRD-neg	27 (46%)	4 (7%)	$p < 0.0001$
PFS (All pts; N = 117)	Med NR (NE, NE) HR 0.455 (95%CI: 0.239 0.865)	Med 35.9 mos (17, NE)	p = 0.016
PFS (17p del and/or p53; N = 63)	Med NR (NE, NE) HR 0.253 (95%CI: 0.099 0.646)	Med 18.9 mos (11.4, NE)	p = 0.004
OS	HR 0.532 (95%CI: 0.241 1.174)		p = 0.118

PFS was superior for UTX + IB vs. IB alone, driven primarily by pts with del17p/p53mut. No meaningful difference in PFS was observed for pts with del11q. Among pts treated with UTX + IB, MRD-neg was associated with significant improvement in PFS. OS at 4 yrs was 82% vs. 70% for UTX + IB vs. IB alone.

8023 Poster Session (Board #356), Fri, 8:00 AM-11:00 AM

Comparison of efficacy and safety with obinutuzumab plus chemotherapy versus rituximab plus chemotherapy in patients with previously untreated follicular lymphoma: Updated results from the phase III Gallium Study. *First Author: William Townsend, Cancer Research UK and UCL Cancer Trials Centre, London, United Kingdom*

Background: Immunochemotherapy is standard of care for patients (pts) with previously untreated advanced stage follicular lymphoma (FL). Four-year data from the Phase III GALLIUM study (NCT01332968) have previously demonstrated an improvement in the primary endpoint of investigator-assessed progression-free survival (PFS) for obinutuzumab (GA101, G) plus chemotherapy (G-chemo) versus rituximab plus chemotherapy (R-chemo) (Townsend et al. ASH 2018). Here, we report efficacy and safety results from an updated analysis. **Methods:** Eligibility criteria: ≥18 years; advanced stage, previously untreated grade 1–3a FL; requiring treatment according to Groupe d'Etude des Lymphomes Folliculaires criteria. Pts were randomized 1:1 to receive G 1000mg IV (day [D] 1, 8 and 15 of Cycle 1; D1 of each subsequent cycle) or R 375mg/m^2 IV (D1 of each cycle) with CHOP, CVP, or bendamustine for 6 or 8 cycles. Responders received maintenance therapy with the same monoclonal antibody every 2 months for 2 years. **Results:** 1202 pts (median age 59 years) were enrolled (n = 601 per treatment arm). Median duration of follow-up was 76.5 months. Pts receiving G- vs R-chemo demonstrated improved PFS (5-year PFS: hazard ratio [HR] 0.76; 95% CI: 0.62–0.92; p = 0.0043; 70.5% [95% CI: 66.4–74.1] vs 63.2% [95% CI: 59.0–67.1]). There was no notable difference in 5-year overall survival (OS), with few events in either arm (HR 0.87; 95% CI: 0.62–1.22; p = 0.41; G-chemo: 90.2% [95% CI: 87.5–92.4]; R-chemo: 89.4% [95% CI: 86.6–91.6]). Time-to-next-treatment (TTNT) was greater in the G- vs R-chemo arm (5-year TTNT rate: HR 0.72; 95% CI: 0.57–0.90; p = 0.0039; 79.7% [95% CI: 76.1–82.7] vs 72.9% [95% CI: 69.1–76.4]). Incidence of grade 3–5 adverse events was 79.3% in the G-chemo arm and 71.2% in the R-chemo arm, and consistent with those reported in the primary analysis (Marcus et al. N Engl J Med 2017). **Conclusions:** These data further demonstrate the clinically meaningful and durable benefit of treatment with G-chemo relative to R-chemo in previously untreated FL pts. 8024 Poster Session (Board #357), Fri, 8:00 AM-11:00 AM

Acalabrutinib in treatment-naïve chronic lymphocytic leukemia: Mature results from phase II study demonstrating durable remissions and long-term tolerability. *First Author: John C. Byrd, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: The next-generation Bruton tyrosine kinase inhibitor acalabrutinib was approved in patients (pts) with treatment-naïve (TN) and relapsed/refractory chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) based on two complementary phase 3 studies, ELEVATE-TN and ASCEND. This report of ACE-CL-001 (NCT02029443), the first phase 2 study of acalabrutinib, provides the longest safety and efficacy follow-up to date in symptomatic TN CLL pts. **Methods:** Adults with TN CLL/SLL were eligible if they met iwCLL 2008 criteria for treatment, were inappropriate for/declined standard chemotherapy and had ECOG performance status 0–2. Pts received acalabrutinib 100 mg BID or 200 mg QD, later switching to 100 mg BID, until progressive disease (PD) or unacceptable toxicity. Primary endpoint was safety. Events of clinical interest (ECI) were based on combined AE terms for infections, bleeding events, hypertension, and second primary malignancies (SPM) excluding non-melanoma skin, and on a single AE term for atrial fibrillation. Additional endpoints included investigator-assessed overall response rate (ORR), duration of response (DOR), time to response (TTR), and event-free survival (EFS). **Results:** Ninety-nine pts (n = 62 100 mg BID; n = 37 200 mg QD), were treated [median age: 64 years, 47% Rai stage 3–4 disease, 10% del(17p), 62% unmutated IGHV]. At median follow-up of 53 months (range, 1–59), 85 (86%) pts remain on treatment; most discontinuations were due to AEs (n = 6) or PD (n = 3 [n = 1 Richter transformation]). Most common AEs (any grade) were diarrhea (52%), headache (45%), upper respiratory tract infection (44%), arthralgia (42%), and contusion (42%). All-grade and grade ≥3 ECIs included infection (84%, 15%), bleeding events (66%, 3%), and hypertension (22%, 11%). Atrial fibrillation (all grades) occurred in 5% of pts (incidence: 1% in years 1, 2, 4; 3% in year 3). SPMs excluding non-melanoma skin (all grades) occurred in 11%. Serious AEs were reported in 38% of pts; those in > 2 pts were pneumonia (n = 4) and sepsis (n = 3). ORR was 97% (7% complete response; 90% partial response). Median TTR was 3.7 months (range, 2–22). Response rates were similar across high-risk groups. Median DOR and median EFS were not reached; 48-month DOR rate was 97% (95% CI, 90%–99%), and 48-month EFS rate was 90% (95% CI, 82%–94%). **Conclusions:** Long-term data from ACE-CL-001 further support the favorable results with acalabrutinib in phase 3 studies and demonstrate durable responses with no new long-term safety issues. Clinical trial information: NCT02029443. Research Sponsor: Acerta Pharma, a member of the AstraZeneca group.

8025 Poster Session (Board #358), Fri, 8:00 AM-11:00 AM

First-line immunochemotherapy for follicular lymphoma in the GALLIUM study: Prognostic value of PET-CT status after long-term follow-up. *First Author: Tina Nielsen, F. Hoffmann-La Roche Ltd., Basel, Switzerland*

Background: The prognostic value of ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) response assessment following first-line immunochemotherapy for advanced-stage symptomatic follicular lymphoma (FL) was previously demonstrated for patients (pts) enrolled in the Phase III GALLIUM study (NCT01332968; Trotman et al. ICML 2017). Here, we evaluated the association between PET complete metabolic response (CMR) and survival after longer follow-up in this patient population. **Methods:** In the GALLIUM study, 1202 pts with previously untreated FL were randomized 1:1 to induction therapy of 1000mg obinutuzumab (G; Days 1, 8, 15 of Cycle 1 then Day 1 of subsequent cycles) or 375mg/m^2 rituximab (R; Day 1 of each cycle), in combination with chemotherapy (CHOP, CVP, or bendamustine) (Marcus et al. New Engl J Med 2017). PET-CT scans were mandatory, where available, at baseline and end-of-induction (EOI) for the first 170 pts enrolled, and optional thereafter. For this response analysis, the Lugano 2014 criteria were applied by an independent review committee (IRC) (Cheson et al. J Clin Oncol 2014). Associations between EOI PET complete metabolic response (PET-CMR) status and progression-free survival (PFS) and overall survival (OS) were evaluated, with hazard ratios (HR) stratified according to chemotherapy regimen and FL International Prognostic Index. **Results:** Of the 609 pts with a baseline PET scan, 595 (98%) had detectable lesions. Of these, 519 pts had an EOI PET evaluable by Lugano 2014 criteria. At EOI, per IRC assessment, 450/595 (76%) pts had achieved CMR. Pts with non-available scans were considered as non-responders and were excluded from the landmark (LM) analyses. Pts who died or progressed (CT-based progression assessment) before or at EOI were excluded from the PFS LM analysis; pts who died before EOI were excluded from the OS LM analysis. After a median follow-up of 76.5 months, EOI PET status was highly prognostic for both longer investigator-assessed PFS (non-CMR vs CMR: HR 3.40; 95% CI: 2.33–4.97; $p < 0.0001$) and longer OS (HR 3.34; 95% CI: 1.81–6.17; $p < 0.0001$). Six-year investigator-assessed PFS from EOI was 62.6% (95% CI: 57.0–67.6) for CMR pts compared with 23.4% (95% CI: 12.2–36.7) for non-CMR pts; the corresponding OS was 91.3% (95% CI: 88.1–93.6) vs 79.6% (95% CI: 68.0–87.4). **Conclusions:** With more than 6 years of follow-up, this analysis confirms that after first-line chemoimmunotherapy for FL, achieving CMR on PET-CT is an early and strong predictor of increased PFS and OS. Clinical trial information: NCT01332968. Research Sponsor: GALLIUM was sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of Judith Trotman, was provided by Aisling Lynch and Katie Smith of Gardiner-Caldwell Communications, and was funded by F. Hoffmann-La Roche Ltd.

8026 Poster Session (Board #359), Fri, 8:00 AM-11:00 AM

Cause of death in patients with newly diagnosed chronic lymphocytic leukemia (CLL) stratified by the CLL-International Prognostic Index (CLL-IPI). *First Author: Yucai Wang, Mayo Clinic, Rochester, MN*

Background: CLL progression and CLL-related complications (infections and second malignancies) were the leading cause of death (COD) in a prospective cohort of CLL patients (Strati, BJH 2017). The CLL-IPI integrates major clinical and molecular prognostic factors and stratifies patients into 4 risk groups with distinct prognosis. It is unknown if COD differs according to CLL-IPI risk group in patients with newly diagnosed CLL. **Methods:** Patients diagnosed with CLL between 1/2000-12/2019 and seen within 1 year of diagnosis were identified from the Mayo Clinic CLL database. Cumulative incidences of cause-specific death were analyzed using Gray's test, with deaths from different causes treated as competing events and deaths from unknown causes excluded. **Results:** 1276 patients were included in this study. The median age at diagnosis was 63 years (range 24-92), and 880 (69%) were male. Based on CLL-IPI score, 449 (35%) had low risk disease, 443 (35%) had intermediate risk disease, and 384 (30%) had high/very high risk disease. Median follow-up time for the study was 6 years; 286 deaths occurred. The COD was CLL progression in 99 (35%), infection in 16 (6%), second malignancy in 47 (16%), CLL-unrelated in 59 (21%), and unknown in 65 (23%) patients. The rates of death due to CLL progression were higher (17.3% at 5 years; 30.3% at 10 years) than the rates due to CLL-related complications (5.7% at 5 years; 12.9% at 10 years) or due to CLL-unrelated causes (8.6% at 5 years; 16.9% at 10 years) in the CLL-IPI high/very high risk group, but not the CLL-IPI low or intermediate risk group (Table). A higher CLL-IPI risk group was associated with a higher rate of death due to CLL progression ($P < 0.001$), as well as a higher rate of death due to CLL-related complications ($P = 0.013$), and CLL-unrelated causes ($P < 0.001$). **Conclusions:** Causes of death in newly diagnosed CLL patients differ according to their CLL-IPI risk group. In patients with high/very high risk CLL, improving CLL disease control with novel agents seems justified. In patients with low/intermediate risk CLL, there should be increased efforts to reverse immune dysfunction to reduce infections and second malignancies. Research Sponsor: None.

	Cumulative Incidence of Death (%)

8027 Poster Session (Board #360), Fri, 8:00 AM-11:00 AM

Fixed-duration venetoclax-obinutuzumab for previously untreated patients with chronic lymphocytic leukemia: Follow-up of efficacy and safety results from the multicenter, open-label, randomized, phase III CLL14 trial. *First Author: Othman Al-Sawaf, Department I of Internal Medicine and Center of Integrated Oncology Cologne-Bonn, German CLL Study Group, University of Cologne, Cologne, Germany*

Background: The CLL14 trial demonstrated significant improvement of progression-free survival (PFS) with fixed-duration venetoclax-obinutuzumab (VenG) as compared to chlorambucil-obinutuzumab (ClbG) in patients with previously untreated CLL and coexisting conditions. Here, we report follow-up data on safety and efficacy. **Methods:** Patients with previously untreated CLL and coexisting conditions were randomized 1:1 to receive 12 cycles of venetoclax with 6 cycles of obinutuzumab or 12 cycles of chlorambucil with 6 cycles of obinutuzumab. Primary endpoint was investigator-assessed progression-free survival. Key secondary endpoints were response rates, rates of minimal residual disease (measured every 6 months up to 5 years after last patient enrolment) and overall survival. Follow-up is ongoing but all patients are off study treatment. This trial was registered with ClinicalTrials.gov, number NCT02242942. **Results:** Of the 432 enrolled patients, 216 were randomly assigned to receive VenG and 216 to receive ClbG. After a median follow-up of 39.6 months (interquartile range 36.75 - 43.04), progression-free survival continued to be superior for VenG as compared to ClbG (median not reached vs 35.6 months; hazard ratio [HR] 0.31 [0.22-0.44], $p < 0.001$). At 3 years, the estimated progression-free survival rate was 81.9% in the VenG arm and 49.5% in the ClbG arm. This benefit was consistently observed across all clinical and biological risk groups, including patients with *TP53* mutation/deletion and unmutated IGHV status. Of note, PFS was also significantly longer for VenG treated patients with mutated IGHV status. Assessment of minimal residual disease 18 months after end of treatment showed that 47.2% of patients in the VenG arm had undetectable (u) uMRD ($< 10^{-4}$), 13% had low (L)-MRD ($\geq 10^{-4}$ and $< 10^{-2}$) and 7.9% high (H)-MRD ($\geq 10^{-2}$), compared to 7.4% uMRD, 17.1% L-MRD, 26.9% H-MRD in the ClbG arm. No difference has been observed (HR 1.027, 95% CI 0.602-1.753, p = 0.921) for overall survival; median overall survival has not been reached in either group. Second primary malignancies were reported in 36 (17%) patients in the VenG arm and 22 (10.3%) in the ClbG arm. No new safety signals were observed. **Conclusions:** The results suggest that the superior efficacy and deep remissions after fixed-duration VenG are maintained during extended follow-up, and show the long-term benefits of 12 cycles of VenG across all known risk categories. Clinical trial information: NCT02242942. Research Sponsor: F. Hoffmann–La Roche and AbbVie.

8028 Poster Session (Board #361), Fri, 8:00 AM-11:00 AM

Impact of premature venetoclax (Ven) discontinuation/interruption on outcomes in relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL): Phase III MURANO study results. *First Author: Anthony R. Mato, Center for CLL, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ven + rituximab (VenR) has a manageable safety profile and improves survival in patients (pts) with R/R CLL, but discontinuation/interruption is frequent. We present new data from the Phase III MURANO study on the impact of Ven early discontinuation/interruption on outcomes in pts with R/R CLL. **Methods:** Time-dependent Cox proportional hazards regression models, stratified by 17p deletion and risk status, evaluated the impact of Ven discontinuation/interruption on investigator-assessed PFS and OS. Analyses were performed retrospectively (without type-1 error control) in intent-to-treat pts with R/R CLL from the fixed-duration VenR arm of MURANO (NCT02005471; data cut-off: May 8, 2019). **Results:** 140/194 pts (72%) in the VenR arm completed 2 years of therapy. Early discontinuation occurred in 54/194 (28%) pts (adverse events [AEs]: 29, disease progression [PD]: 12, withdrawal: 5, physician decision: 3, death: 2, other: 2, non-compliance: 1). Median Ven durations for pts discontinuing due to AEs and PD: 11.3 (0.5–24.6) and 17.1 (4.6–25.1) months, respectively ($p = 0.08$). Inferior PFS was observed in pts who discontinued Ven early for any reason except PD or due to AEs, versus those who completed therapy (Table). Greater cumulative Ven exposure significantly reduced risk of a PFS/OS event (PFS: HR 0.93, 95% CI 0.88–0.99, $p = 0.0168$; OS: HR 0.85, 95% CI 0.79–0.92, $p < 0.0001$). Treatment interruption for AEs occurred in 134/194 (69%) pts, most commonly due to neutropenia (84/194; 43%), per protocol requirements. Median duration of interruption: 9 (1–93) days. Treatment interruption, regardless of duration, had no impact on PFS or OS (Table). 36 (19%) pts with interruptions later discontinued Ven. **Conclusions:** In MURANO, early Ven discontinuation was associated with suboptimal outcomes; Ven interruption was not. These data highlight the importance of effective control of toxicity to realize the full benefit of VenR treatment. Clinical trial information: NCT02005471. Research Sponsor: Genentech and AbbVie provided financial support for the study. Third-party medical writing assistance, under the direction of authors was provided by Rachel Dobb of Gardiner-Caldwell Communications, and was funded by F. Hoffmann-La Roche Ltd.

Impact of early Ven discontinuation/interruption on PFS and OS.

Brentuximab vedotin and bendamustine as first-line treatment of Hodgkin lymphoma in the elderly (HALO Trial). *First Author: Jean Marc Schiano de Colella, Institut Paoli-Calmettes, Marseille, France*

Background: Hodgkin Lymphoma (HL) treatment in the elderly is a challenge, as standard ABVD is able to cure no more than 60% of the patients (p.). Bendamustine (Be), and Brentuximab Vedotin (BV), are well-tolerated and effective drugs in relapsing HL, but only preliminary data exist in 1st line treatment of the elderly (Evens AM 2018). **Methods:** HALO is a prospective international multicenter open-label phase I/II study (NCT02467946) to assess the safety and efficacy of Be-BV in advanced-stage elderly HL p. Briefly, BV 1.2 mg/kg on D1, and Be 90 mg/m2 on D1-2 were administered Q3W for 6 cycles. The primary endpoint was the feasibility and the efficacy of Be-BV. **Results:** Between July 2015 and February 2019, 59/60 p. consecutive enrolled received at least 1 Be-BV cycle, and are valuable for primary endpoint. One p. was excluded because a histological review showing angioimmunoblastic T-Cell Lymphoma. The mean age was 70.32 (62-79), and M/F ratio 41/18. The Ann-Arbor stage was IIB in 12, III in 14 and IV in 33 patients, B-symptoms (y/n) 40/19. IPS was 0-2 in 19 and ≥ 3 in 40 p., P.S. (ECOG) was 0-1 in 53, 2 in 6 p., nonetheless most of them were frail, as ADL was ≥ 6 in 47 (79%) and IADL was ≥ 8 in 42 (71%) p. Most frequent co-morbidities were cardio-vascular disease (45) metabolism disorders (31) prostatic adenoma (11). 163 treatment-related adverse events (WHO 3-4) were recorded: neutropenia and lymphopenia, (134), infections (7), cutaneous reactions (5), liver toxicity (2). No case of grade > 2 peripheral neuropathy was recorded. Out of 59 p., 41 concluded and 18 interrupted the treatment for toxicity (8), progression (5), treatment failure (2), CMV reactivation (3). The latter was recorded in 17 p., 12/17 received valgancyclovir. 4 p. died with CMV viremia. After a mean follow-up of 20.6 (0.3-46.5) months, 37/59 (63%) were in CR, while 22 (37%) have progressed (5) or relapsed (17). The 2-y OS and PFS in ITT analysis were 83% (95% CI 71-96) and 54% (95% CI 41-72) and in PP 89% (95%CI 75-100) and 78% (95%CI 64-96), respectively. 22 p. had a PFS event: 5 progression (2 deaths), 17 relapse (8 deaths). 10 p. died for recurrent HL (5), sepsis (1), secondary malignancy (2), respiratory insufficiency (1) and unknown (1). **Conclusions:** The Be-BV combination, a novel anthracycline-free regiment for first line treatment of HL in elderly, proved effective in unselected, frail, poor-risk, HL p. aged more than 60 in daily hospital real life. The CMV reactivation is frequent and should be treated with preemptive antiviral therapy upon detection of CMV DNA in plasma. Clinical trial information: NCT02467946. Effect of antibiotic use prior to or concurrent with immune checkpoint inhibitors on outcomes in patients with Hodgkin lymphoma. *First Author: Steven R Hwang, Department of Internal Medicine, Mayo Clinic, Rochester, MN*

Background: There is growing interest in the identification of modifiable patient-specific factors that may predict response to immune checkpoint inhibitors (ICIs) in classical Hodgkin lymphoma (cHL). Recently, it has been proposed that antibiotic use could decrease the efficacy of ICIs in the treatment of advanced solid malignancies. The objective of our study is to assess whether antibiotic use prior to or concurrent with ICIs is associated with changes in outcomes in patients with cHL. **Methods:** Patients who received a PD-1 or CTLA-4 blocker for the treatment of cHL at Mayo Clinic Rochester between January 1, 2011 and October 20, 2018 were identified. We conducted a longitudinal retrospective chart review to identify those who received antibiotics within 30 or 90 days prior to initiation or concurrent with ICI therapy. Univariate cox regression analysis was used to assess for an association between antibiotic use and overall survival (OS) and progression-free survival (PFS) within these groups; a time-dependent variable was used for concurrent antibiotic use. **Results:** A total of sixty-two patients were identified (61% male, median age at ICI initiation 35 years [range: 19-87]). Median duration of follow up from ICI start was 38 months (range: 4-78). Twenty-one patients (34%) received antibiotics within 90 days of initiation of ICI, of which thirteen (21%) received antibiotics within 30 days. Thirty-five patients (57%) received antibiotics concurrently with ICI. Concurrent and prior antibiotic use within 90 days of ICI were both associated with inferior PFS (concurrent HR = 6.38 [95% CI 3.02-13.47]; 90-day HR = 2.21 [95% CI 1.10-4.47]) and OS (concurrent HR = 8.77 [95% CI 1.91-40.36]; 90-day HR = 2.96 [95% CI 1.09-8.04]). **Conclusions:** Antibiotic use is associated with inferior outcomes in patients with cHL treated with ICIs in this single institution cohort. This may reflect potential antibiotic effects on the gut microbiome (GMB) and immune system as has been suggested in prior studies. Further confirmatory studies and examination of potential confounding covariates are needed. Research Sponsor: U.S. National Institutes of Health.

8031 Poster Session (Board #364), Fri, 8:00 AM-11:00 AM

Outcome of elderly patients with classical Hodgkin lymphoma (HL) in British Columbia. *First Author: Phoebe Tsz Man Cheng, Department of Medicine, University of British Columbia, Vancouver, BC, Canada*

Background: Outcomes in elderly patients (pts) with Hodgkin lymphoma (HL) have traditionally been poor. We evaluated the survival of elderly pts (>60 years [y]) with classical HL in British Columbia (BC). **Methods:** All pts aged >60 y newly diagnosed with classical HL from 1961 to 2019 were identified in the BC Cancer Lymphoid Cancer Database. Limited stage was defined as non-bulky (<10 cm) stage 1A/1B or 2A (before 2000 1B = advanced stage), with the remainder considered advanced stage. **Results:** Following exclusions (HIV positive n=4, incomplete data n=21, prior or concurrent other lymphoproliferative disease n=67), 713 pts were identified. With a median follow up of 6.0 y (0.1 - 24.0 y) in living pts, there has been an improvement in 5 y DSS/OS (both p<.001) by decade comparison: 1960s (n=52) 25%/17%; 1970s (n=75) 38%/31%; 1980s (n=90) 51%/43%; 1990s (n=115) 53%/42%; 2000s (n=180) 66%/57%; 2010s (n=201) 63%/53%. To account for advances in diagnosis, staging, supportive care, and therapy in the modern era, we evaluated the outcome of pts diagnosed since 01/1995. A total of 368 pts were treated with curative intent (Table). Most pts received multi-agent chemotherapy (n=359, 98%: ABVD[like] n=351, alkylator-based n=7, CHOP n=1), 8 pts had radiotherapy (RT) alone, and 1 pt had surgery (primary CNS HL). The 5 y DSS, PFS, and OS were 74%, 57%, and 62%, respectively. Increasing age was associated with inferior outcomes (5 y DSS/PFS/OS): 61-70 y (81%/70%/74%), 71-80 y (69%/47%/52%), and >80 y (59%/27%/31%) (DSS p=.011; PFS p<.0001; OS p<.0001). Of 318 pts that received bleomycin, 60 (19%) developed pulmonary toxicity, including 22 cases that occurred after cycles 1 and 2. Overall, 24/368 pts (7%) died of acute treatment toxicity (pulmonary [bleomycin n=10, radiation n=1], infection n=10, cardiac n=3). There was no association between age and developing bleomycin (p=.80) or lethal treatment toxicities (p=.74). **Conclusions:** The outcome of elderly pts with HL has improved in recent decades. However, treatment related toxicity remains a concern and use of multi-agent chemotherapy, particularly bleomycin-containing regimens, should be undertaken with caution. Research Sponsor: None.

Clinical features of HL patients treated with curative intent in the modern era (1995 – present).

Frontline brentuximab vedotin as monotherapy or in combination for older Hodgkin lymphoma patients. *First Author: Christopher A. Yasenchak, Willamette Valley Cancer Institute and Research Center/US Oncology Research, Eugene, OR*

Background: Older patients with classical Hodgkin lymphoma (cHL) have poor outcomes relative to younger patients, often due to comorbidities and toxicities related to standard first-line (1L) chemotherapy (5-yr PFS: 30%–45% vs 75%–80%) (Evens 2008; Proctor 2009). Brentuximab vedotin (BV, ADCETRIS®), a CD30-directed antibody-drug conjugate, has robust activity in patients refractory to several lines of chemotherapy. **Methods:** This phase 2, open-label study, SGN35-015 (NCT01716806), evaluated efficacy and tolerability of BV alone or combined with single-agents in treatment-naive cHL patients ≥60 yr. The full-analysis set (FAS) includes all patients who received BV (1.8 mg/kg IV). Patients in Part A received BV monotherapy on Day 1 of every 3-week cycle (n = 26); Part B: BV+dacarbazine (DTIC; 375 mg/m^2; n = 19); Part C: BV+bendamustine (benda; 70 mg/m^2; n = 20); and Part D: BV+nivolumab (nivo; 3 mg/kg; n = 20). The efficacy evaluable (EE) set includes all patients who had at least 1 post-baseline response assessment (n = 25, 19, 17, 19). **Results:** Demographic characteristics were generally similar: median age 78, 69, 75, and 72 yr in Parts A, B, C, and D, respectively, and 62% of patients (range 45%–70%) reported impaired physical functioning at baseline. Most patients had disease stage III/IV (62%, 68%, 75%, 80%), were ECOG 0/1 (77%, 74%, 80%, 95%), and male (54%, 68%, 50%, 75%). Median time from diagnosis was 1.2 to 1.5 mo (FAS; 10 Jan 2019 data cutoff). ORR were high (92%, 100%, 100%, 95%) at a median follow-up of 59.4, 58.6, 51.3, and 19.4 mo in the EE data set. Median OS in the FAS set was 77.5 mo with monotherapy; 64.0, 46.9, and not reached in the combination parts. Treatment-related AE ≥ Grade 3 occurred in 50%, 37%, 70%, and 60% of patients; peripheral neuropathy (PN) was most common (35%, 26%, 20%, 35%). Treatment-related SAEs occurred in 12%, 11%, 40%, and 5% of patients. Part C enrollment (BV+benda) closed early due to multiple acute toxicities. There were no treatment-related deaths in any part of the study. The median treatment cycles per patient were 8.0, 12.0, 5.0, and 14.5. Treatment discontinuation due to related AEs occurred in 42%, 42%, 40%, and 30% of patients, most commonly due to PN (38%, 37%, 30%, 20%). **Conclusions:** Older patients with cHL and multiple comorbidities have very high response rates with BV as monotherapy or combined with other single agents and improved tolerability versus combination chemotherapy. Median overall survival exceeded 6 yr with BV monotherapy. BV+nivo or BV+DTIC appeared to be the most reasonable combination treatment options in this study. Clinical trial information: NCT01716806. Research Sponsor: Seattle Genetics.

8033 Poster Session (Board #366), Fri, 8:00 AM-11:00 AM

Gls-010, a novel anti-PD-1 mAb in Chinese patients with relapsed or refractory classical Hodgkin lymphoma: Preliminary impressive result of a phase II clinical trial. *First Author: Yuqin Song, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), the Department of Lymphoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: classical Hodgkin lymphoma (cHL) are characterized by genetic alterations at the 9p24·1 locus and PD-L1 ligand overexpression. GLS-010 is a novel fully human anti-PD-1 mAb and exhibited favorable result in previous Phase I study. This multi-center, single-arm Phase II clinical trial is aimed to further evaluate the safety and efficacy profile of GLS-010 in Chinese patients (pts) with relapsed or refractory cHL. **Methods:** All pts enrolled received GLS-010 240mg every 2 weeks until disease progression, death, unacceptable toxicity or withdraw from the study. The primary endpoint was objective response rate (ORR) by independent review committee (IRC) per Lugona 2014. Adverse events (AEs) were graded by NCI CTCAE v4.03. **Results:** 85 pts with relapsed or refractory cHL who had received at least 2 lines of prior systemic chemotherapies were enrolled and treated. As of August 2 2019, data cutoff, pts received a median of 8 treatment cycles (1 cycle include 2 injections), with 12 pts discontinued and 73 pts were still in treatment. At a median follow-up of 6.57 months, an ORR was reported in 78 of 85 patients (91.76%, 95%CI, 83.77-96.62), by an IRC assessment, including 30(35.3%) pts with a complete response (CR) and 48 pts (56.5%) with a partial response (PR). Median duration of response (DoR) and progression free survival (PFS) were not reached yet. Treatment-related adverse events (TRAEs) of any grade occurred in 77 (90.6%) of 85 patients, most of which were Grade 1-2.The most common TRAEs were fever (26/85, 30.6%), neutrophil count decreased (16/85, 18.82%), white blood cell count decreased (15/85, 17.65%). ≥ Grade 3 TRAEs occurred in 23 (27.06%) pts, most commonly, hepatic function abnormal (5/85, 5.88%), hyperuricaemia (4/85, 4.71%). **Conclusions:** GLS-010 showed impressive anti-tumor activity (ORR = 91.96%) and manageable safety profile in Chinese patients with relapsed or refractory cHL, which could be a new safe and effective treatment option in this setting. Clinical trial information: NCT03655483. Research Sponsor: Guangzhou Gloria Biosciences Co,. Ltd.

8034 Poster Session (Board #367), Fri, 8:00 AM-11:00 AM

Sintilimab for relapsed/refractory classical Hodgkin's lymphoma: Long-term follow-up on the multicenter, single-arm phase II ORIENT-1 study. *First Author: Hang Su, The Fifth Medical Center, Chinese PLA General Hospital, Beijing, China*

Background: Sintilimab, a programmed death-1 checkpoint inhibitor, has demonstrated efficacy in relapsed/refractory cHL after the primary analysis of the ORIENT-1 study. Here, we report the updated safety and efficacy profile after long-term follow-up. **Methods:** ORIENT-1 is a multicenter, single-arm, phase II study in China. Classical Hodgkin's lymphoma patients who had failed ≥2 lines of systemic therapy, including autologous hematopoietic stem cell transplantation (HSCT) were enrolled. Sintilimab, 200 mg IV was given every 3 weeks, until disease progression, death, unacceptable toxicity, or withdrawal from study. The primary endpoint objective response rate (ORR) by an independent radiological review committee (IRRC) per IWG 2007 has been reported before. The progression free survival (PFS) by IRRC follow-up data are reported herein. **Results:** 96 patients were treated. As of the data cutoff on 30 Sep, 2019, 57.3 % patients complete two-year treatment, with a median follow-up of 26.7 months. The median duration of treatment was 24.1 months (range: 0.7 to 24.8). Of 49 patients with progressive disease (PD) by investigator, 39/49 (79.6%) patients received treatment beyond PD, with a median treatment duration after PD of 8.0 months (range: 1.4 to 20.8). The median PFS was 18.6 months (95%CI: 14.4 to 22.3). Median overall survival has not been reached. Two-year OS rate was 96.3% (95%CI: 88.9% to 98.8%). The treatment-related adverse event (TRAE) was reported in 92/96 (95.8%) patients, most (71/96, 74.0%) of which were grade 1-2. The most common grade 3 or 4 TRAEs were pyrexia (3/96, 3.1%), lipase increased (3/96, 3.1%) and lymphocyte decreased (3/96, 3.1%). **Conclusions:** The results from long-term follow-up showed that, in addition to a high rate of response, sintilimab also demonstrated durable efficacy and favorable long-term safety profile. Considering the high rate (nearly 80%) of treatment beyond PD, IWG 2007 which was used to evaluate PFS may not be a suitable criteria for evaluating the efficacy of anti-PD-1 antibody in cHL. Further investigation and analysis are required. Clinical trial information: NCT03114683. Research Sponsor: Innovent Biologics, Inc., China National Major Project for New Drug Innovation (2017ZX09304015 and 2018ZX09301014009) and CAMS Innovation Fund for Medical Sciences (CIFMS) (2016-I2M-1-001)

8035 Poster Session (Board #368), Fri, 8:00 AM-11:00 AM

Mantle cell lymphoma: initial report from the North American Mantle Cell Lymphoma Consortium. *First Author: Kai Fu, University of Nebraska Medical Center, Omaha, NE*

Background: The goal of the North American Mantle Cell Lymphoma (MCL) Project is to evaluate the clinical, biological, and genomic markers that affect the outcome of patients with MCL. **Methods:** We have retrospectively studied the clinical and pathological features of 307/421 patients diagnosed with MCL between January 2000 to December 2012 from 23 institutions across North American. **Results:** The male to female ratio of MCL patients was 3.5:1, with a median age of 66 years (range: 24-106 years). Approximately 29% of patients (78/269) presented with B symptoms and 257 (257/307, 83.7%) patients had extranodal involvement at diagnosis. Median follow-up was 7.1 years (range, 0.03 to 16.6 years) with the five-year PFS and OS at 27.8%, and 54.4%, respectively. Univariate analysis revealed that the following factors were significantly associated with both inferior OS and PFS ($p< 0.05$): older age (≥60 years), presence of B symptoms, advanced Ann Arbor stage, elevated LDH, low platelets (≤100K/ml), blastoid/pleomorphic cytology, Ki67 proliferation ≥30%, circulating tumor cells, no transplantation (vs. transplantation), and allogeneic (vs. autologous) stem cell transplantation. In addition, large tumor size (maximal diameter > 3cm), high WBC ($> 10\times10^3$/ml), CD5 or CD23 positivity, and a complex karyotype were associated with inferior OS ($p< 0.05$). Multivariate Cox regression analysis showed age (≥ 60y; $p= 0.0028$, HR = 2.44, 95% CI: 1.36-4.38) and high LDH ($p= 0.0062$, HR = 2.19, 95% CI: 1.25-3.84) were the two factors predicting the clinical outcome. MIPI-c, a commonly used prognostic scoring system which includes Ki67, stratified the 100 MCL cases into four group with distinct clinical outcomes ($p< 0.001$). Using readily-available clinical and pathological variables, we developed a simple and robust scoring system, MIPI-P (pathology), which consisted of age (≥60 years), LDH (high), Ki67 index (≥30%), Ann Arbor stage (III/IV), and cytological type (blastoid/pleomorphic), each contributing one point. The MIPI-P system stratified 104 MCL cases into three distinct groups ($p< 0.001$). Median survival for the different groups were: low grade (0-1 points): 11.8 years; intermediate grade (2-3 points): 4.9 years; and high grade (4-5 points): 1.6 years. We further validated this system in an independent cohort of 33 MCL cases and confirmed that the modified MIPI-P provided robust prognostic predication ($p= 0.014$). **Conclusions:** The clinical and biologic characteristics of MCL can provide information assisting with the prognosis of patients with MCL. Research Sponsor: University of Nebraska Foundation.

8036 Poster Session (Board #369), Fri, 8:00 AM-11:00 AM

Clinical activity of cirmtuzumab, an anti-ROR1 antibody, in combination with ibrutinib: Interim results of a phase Ib/II study in mantle cell lymphoma (MCL) or chronic lymphocytic leukemia (CLL). *First Author: Hun Ju Lee, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ROR1 is an onco-embryonic tyrosine kinase receptor that is re-expressed at high levels on many hematologic and solid cancers but not on normal adult tissues. ROR1 binds Wnt5a, resulting in increased tumor growth and survival, cancer cell stemness and epithelial mesenchymal transition. Cirmtuzumab (Cirm) is a humanized monoclonal antibody designed to inhibit the tumor promoting activity of ROR1. In this study, we examined the safety and efficacy of Cirm in combination with ibrutinib (Ibr) in MCL or CLL. **Methods:** As of Jan 29, 2020, 12 pts with relapsed refractory (RR) MCL were enrolled into Part 1 Dose Escalation (DE). All MCL pts had stage 3/ 4 at original diagnosis, 25% had bulky tumor at study entry, 58% had intermediate/high risk MIPI scores and the majority (83%) had ≥ 2 prior regimens. 34 pts with CLL [12 treatment naïve (TN) and 22 RR pts] enrolled into Part 1 DE (n = 18) or Part 2 Expansion (n = 16). At least 79% of CLL pts were high risk as determined by unmutated IGHV, 17p/p53 loss, and/or del 11q. DE pts received Cirm IV q2wks x 3-5 doses then q4wks plus Ibr (starting D28). Following DE, Cirm 600mg IV q2wks x3 then q4wks plus Ibr (420mg/day CLL or 560mg/day MCL) was chosen for Expansion. **Results:** *Safety:* only grade 1/ 2 AEs were reported as possibly related to Cirm alone, whereas the safety profile attributed to Ibr or Ibr / Cirm was similar to published data, with no new or unexpected events. *Efficacy for MCL:* 83% ORR, 33% (4) CR, 50% (6) PR, 17% (2) SD**.** CRs were achieved at a median of 3.6 mos in heavily pretreated pts, including 2 with bulky disease > 5cm. Prior therapy of the 4 CR pts: 2 pts failed R-Ibr (7-10 mos) and R-hyperCVAD, 1 pt, auto-SCT and allo-SCT, 1 pt, auto-SCT and CAR-T. *Efficacy for CLL:* 88% ORR (92% TN, 86% RR), 3% (1) CR, 85% (22) PR/ (7) PR-L, 12% (4) SD. In addition, 3 PR pts with CLL met criteria for "Clinical CR, bone marrow biopsy not performed". The pt achieving a CR had RR disease with del 11q; this pt remains in remission > 6 mos after stopping all therapy. At a median follow-up of 9.9 mos, 100% of CLL pts are free of disease progression and > 82% remain on study. **Conclusions:** Cirm in combination with Ibr is a well-tolerated and active regimen for RR MCL and TN or RR CLL. In this evaluation of 46 pts, the ORR and PFS continue to improve with longer follow-up and additional pts, supporting continued investigation of this regimen in ROR1 expressing tumors. This study is ongoing and enrolling an Expansion arm for MCL pts and an open-label randomized Phase 2 in CLL pts comparing Ibr alone to Cirm /Ibr. Clinical trial information: NCT03088878. Research Sponsor: California Institute for Regenerative Medicine (CIRM) grant, Pharmaceutical/Biotech Company.

8037 Poster Session (Board #370), Fri, 8:00 AM-11:00 AM

Outpatient treatment with lisocabtagene maraleucel (liso-cel) across a variety of clinical sites from three ongoing clinical studies in relapsed/refractory (R/R) large B-cell lymphoma (LBCL). *First Author: Carlos R. Bachier, Sarah Cannon Blood Cancer Network, Nashville, TN*

Background: Currently approved CAR T cell therapies are generally administered as inpatient (inpt) treatment at university medical centers due to concerns about frequency, onset, severity, and management of AEs, including cytokine release syndrome (CRS) and neurologic events (NEs). We sought to characterize whether patients (pts) could be safely monitored in the outpatient (outpt) setting after receiving liso-cel, an investigational, CD19-directed CAR T cell product administered at equal target doses of CD8+ and CD4+ CAR+ T cells, across university and non-university sites in TRANSCEND NHL 001 (NCT02631044), OUTREACH (NCT03744676), and PILOT (NCT03483103). **Methods:** Eligible pts had R/R LBCL after systemic chemoimmunotherapy; moderately impaired organ function was allowed. For outpt infusion of liso-cel, pts were required to receive safety monitoring education, have a caregiver and stay within 1 h travel to site of care for 30 d post-treatment. All study sites had a multidisciplinary CAR T cell team and standard operating procedures for toxicity monitoring and management. **Results:** At data cutoff, 53 pts had received liso-cel on Study Day 1 and were monitored as outpts (university, n = 33; non-university, n = 20), including pts ≥65 y of age (n = 23) and with high tumor burden (SPD ≥50 cm^2; n = 16). Any grade CRS and NEs were reported in 18 (34%) and 14 pts (26%), respectively. Severe CRS and/or NEs occurred in only 2 pts (4%) and were reversible. Median (range) time to onset of CRS and NEs was 5 (2–9) and 8.5 (3–22) d, respectively. Tocilizumab and/or corticosteroids for treatment of CRS and/or NEs were required in 8 pts (15%). Overall, 30 pts (57%) required hospitalization post-treatment, with a median (range) time to hospitalization post-treatment of 5.5 (2–22) d; 9 pts (17%) were hospitalized Study Day 4 or earlier. Two pts required ICU-level care. There were no grade 5 treatment-emergent AEs. Safety in pts monitored as outpts was comparable across types of sites. Overall response rate was 81% (95% CI, 68–91). Safety and efficacy were consistent with data from inpts across the 3 studies (N = 270). **Conclusions:** Pts with R/R LBCL were successfully treated with liso-cel and monitored for CAR T cell-related toxicity in the outpt setting across different types of sites. Incidences of severe CRS, NEs, and early hospitalization were low; 43% of pts did not require hospitalization. A larger dataset will be presented, including comparisons of outpts vs inpts and sites of care. Clinical trial information: NCT02631044 (TRANSCEND NHL 001), NCT03744676 (OUTREACH), NCT03483103 (PILOT). Research Sponsor: Juno Therapeutics, a Bristol-Myers Squibb Company.

8038 Poster Session (Board #371), Fri, 8:00 AM-11:00 AM

Relevance of bone marrow biopsies for response assessment in NCTN follicular lymphoma clinical trials. *First Author: Sarah C. Rutherford, Weill Cornell Medicine, New York, NY*

Background: Bone marrow biopsies (BMB) are performed pre/post therapy to confirm complete response (CR) in patients (pts) with lymphoma on clinical trials. We evaluated 2 prior data sets and concluded that BMB impact response assessment in a minority of pts with follicular lymphoma (FL) (Rutherford BJH 2017; Rutherford ASH abstract 1605, 2018). We sought to establish if BMB add value in assessing response or identify distinct progression free (PFS) or overall survival (OS) outcomes in a large, multicenter, multi-trial cohort. **Methods:** Data were pooled from 7 trials of 580 pts with untreated FL conducted through the Alliance for Clinical Trials in Oncology and SWOG from 2002-2016. The proportion of pts with positive (+) baseline BMB, CR on imaging after treatment, and (+) repeat BMB was calculated using total pts enrolled as the denominator. We tested against the null hypothesis that the proportion was = 10%, the threshold below which BMB would be considered irrelevant for response assessment, versus (vs) the alternative hypothesis that this proportion was < 10%, using 1-sided exact binomial test. Response criteria were CT-based. Imaging was not used to assess BM involvement. Because confirmatory BMB were not completed in all indicated pts, landmark survival analyses compared PFS/ OS of pts with CR on imaging and negative (-) BMB vs pts with CR on imaging without repeat BMB. Pts with CR on imaging were categorized as having (-) repeat BMB or no repeat BMB within 60 days of first CR on imaging. PFS and OS were calculated from time of first CR and estimated using Kaplan-Meier and Cox models adjusting for age, sex, stage, Follicular Lymphoma International Prognostic Index (FLIPI) score, and treatment type (targeted vs chemotherapy plus targeted therapy), and stratified by treatment arm. **Results:** Median age was 55 with 51% male, 96% stage III-IV, and 88% grade I-II. FLIPI scores were 113 low, 265 intermediate, and 199 high risk. 67% received chemotherapy-based regimens. Baseline BMB was (+) in 321 (55%). Only 5/580 (0.8%) had (+) baseline BMB, CR on imaging, and subsequent (+) BMB (p < 0.0001). Of pts with CR on imaging, PFS and OS were not different among pts with (-) BMB vs pts without repeat BMB (PFS: HR = 1.08, 95%CI 0.61-1.93, p = 0.783; OS: HR = 0.52, 95%CI 0.20-1.40, p = 0.199). **Conclusions:** BMB requirements may discourage pt participation in trials and add pain, expense and time without providing necessary information. We recommend eliminating BMB for response assessment from FL clinical trials. Clinical trial information: NCT00553501, NCT01145495, NCT01190449, NCT01286272, NCT01829568, NCT00822120, and NCT00770224. 8039 Poster Session (Board #372), Fri, 8:00 AM-11:00 AM

Real-world outcomes of elderly patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) treated with chimeric antigen receptor T-cell (CAR-T) therapy. *First Author: Lindsey Fitzgerald, Huntsman Cancer Institute-University of Utah Health Care, Salt Lake City, UT*

Background: CAR-T has drastically improved outcomes for R/R DLBCL patients (pts). While CAR-T is now standard of care for the treatment of R/R DLBCL, little is known about its efficacy and toxicity in elderly pts. **Methods:** We conducted a multi-center retrospective analysis of pts age ≥ 70 years old with R/R DLBCL treated with either axicabtagene ciloleucel (axi-cel) or tisagenlecleucel (tisa-cel). Pt demographics, tumor characteristics, CAR-T data, survival and toxicity outcomes were collected at the time of T cell infusion and follow up. Comorbidities were measured using the cumulative illness rating score (CIRS) and hematopoietic cell transplantation-specific comorbidity index (HCT-CI). **Results:** A total of 77 pts were analyzed with a median age of 73 (range, 70-88); 30 (39%) pts were age ≥75. Most pts received axi-cel (n = 61, 79%). Unfavorable tumor characteristics included 27 (35%) pts with activated B-cell subtype and 12 (16%) with double/triple hit lymphomas. Median CIRS was 8 (range 0-25) and median HCT-CI was 2 (range 0-9) with significantly higher median CIRS and HCT-CI in pts age ≥75. With a median time to follow up of 5.2 months (m), median progression free survival (PFS) was 12m and median overall survival (OS) was 15.5m. There was no difference in PFS when comparing younger pts (age 70-74) to older pts (age ≥ 75), but median OS was significantly shorter for older pts (7.8m vs. not reached; hazard ratio [HR] 0.46, CI 0.21-0.98; p = 0.04). In a multivariate analysis (MVA) of PFS adjusting for baseline characteristics, HCT-CI > 2 (HR 0.23, CI 0.07-0.77; p = 0.02) and use of axi-cel (HR 0.07, CI 0.02-0.32; p = < 0.001) were associated with worse PFS. Grade 3/4 (Lee criteria) cytokine release syndrome (CRS) and CAR-related encephalopathy syndrome (CRES) were assessed in MVA adjusting for baseline characteristics. CRS was associated with CIRS ≥6 (odds ratio [OR] 3.92, CI 1.07-14.3; p = 0.002) and use of axi-cel (OR 44.9, CI 8.20-245.6; p = 0.006). CRES was associated with older age (OR 6.10, CI 1.86-20.0; p = 0.003), CIRS ≥6 (OR 3.92, CI 1.07-14.3; p = 0.04) and use of axi-cel (OR 44.9, CI 8.2-245.6; p = < 0.0001). **Conclusions:** Pts age ≥75 treated with CAR-T had worse OS, but comparable PFS as compared to younger pts. Validated frailty measurements (CIRS) predicted for increased CRS and CRES. Use of axi-cel was associated with worse PFS and increased toxicities in the elderly, but propensity matched scoring analysis will need to confirm this. Additional pts and longer follow up are required to validate these results. Research Sponsor: None.

8040 Poster Session (Board #373), Fri, 8:00 AM-11:00 AM

Lisocabtagene maraleucel (liso-cel) for treatment of second-line (2L) transplant noneligible (TNE) relapsed/refractory (R/R) aggressive large B-cell non-Hodgkin lymphoma (NHL): Updated results from the PILOT study. *First Author: Alison R. Sehgal, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Patients (pts) with aggressive large B-cell NHL who are R/R after first-line immunochemotherapy and not eligible for high-dose chemotherapy and HSCT have a poor prognosis and no established standard of care. The ongoing, open-label phase 2 PILOT study is the first to assess the safety and efficacy of liso-cel, an investigational, CD19-directed, defined composition, 4-1BB CAR T cell product infused at equal target doses of CD8+ and CD4+ CAR+ T cells, as 2L therapy in TNE pts (NCT03483103). **Methods:** Eligible pts had aggressive R/R diffuse large B-cell lymphoma NOS (de novo or transformed follicular lymphoma [FL]), high-grade B-cell lymphoma, or FL grade 3B with 1 line of prior therapy containing an anthracycline and anti-CD20 agent. Pts were deemed TNE by meeting ≥1 criteria: age ≥70 y, ECOG PS 2, or impaired organ function (DLCO ≤60% [but SaO_2 ≥92% and CTCAE ≤1 dyspnea], LVEF ≥40% to < 50%, creatinine clearance > 30 to < 60 mL/min, or AST/ALT > 2 to ≤5 × ULN). Liso-cel (100×10^6 CAR+ T cells) was administered 2–7 days after lymphodepletion (LD) with fludarabine/cyclophosphamide. The primary endpoint is ORR; key secondary endpoints are AEs and CR rate. **Results:** At data cutoff, 25 pts had LD followed by liso-cel infusion. Pt characteristics are summarized in the Table. Overall, 48% (n = 12) had high tumor burden and 48% were primary refractory. 18/25 (72%) pts had grade ≥3 treatment-emergent AEs, 40% of which were cytopenias. No grade 5 AEs occurred within the first 30 days after liso-cel. Five pts (20%) had cytokine release syndrome (CRS) and 3 (12%) had neurological events (NEs). No grade 3/4 CRS was observed; 2 pts (8%) had grade 3/4 NEs. Five pts (20%) received tocilizumab and/or dexamethasone for CRS/NEs. At a median follow-up of 3.5 mo, the ORR was 80% (95% CI, 59–93; n = 20); 48% of pts (n = 12) achieved CR. **Conclusions:** These interim data suggest that elderly and/or comorbid pts with R/R aggressive large B-cell NHL, who are not eligible for high-dose chemotherapy and HSCT, can receive 2L liso-cel with similar safety and efficacy to 3L+ pts as previously reported (Abramson, ASH 2019 #241). Updated data with longer follow-up will be presented. Clinical trial information: NCT03483103. Research Sponsor: Juno Therapeutics, a Bristol-Myers Squibb company.

8041 Poster Session (Board #374), Fri, 8:00 AM-11:00 AM

Role of radiotherapy and dose-densification of R-CHOP in primary mediastinal B-cell lymphoma: A subgroup analysis of the unfolder trial of the German Lymphoma Alliance (GLA). *First Author: Gerhard Held, Department Internal Medicine I, Westpfalzklinikum Kaiserslautern, Kaiserslautern, Germany*

Background: Primary mediastinal B-cell lymphoma (PMBCL) is a distinct entity of aggressive lymphoma, which typically presents in young patients (pts) with a bulky mediastinal mass. Therapy is based on R-CHOP or similar regimens, but the role of treatment intensification and consolidative radiotherapy (RT) is controversial, because data from randomized trials are rare. **Methods:** The UNFOLDER trial included 18-60 year-old pts (aaIPI = 0 with Bulk [≥7.5 cm] or aaIPI = 1) qualifying for radiotherapy to Bulk or extralymphatic involvement (E). Pts were randomized in a 2 x 2 factorial design to 6xR-CHOP-14 or 6x-R-CHOP-21 without RT or with RT (39.6 Gy) to Bulk and E. Primary endpoint was event-free survival (EFS), secondary endpoints were progression-free (PFS) and overall survival (OS). Response was evaluated by the Internat Standardized Response Criteria, Cheson 1999. **Results:** 131 PMBCLs were included with a median age of 34 years, 54% were female, 79% had elevated LDH > UNV and 24% had E. 82 pts (R-CHOP-21: 43; R-CHOP-14: 39) were assigned to RT and 49 (R-CHOP-21: 27, R-CHOP-14: 22) to no-RT. 96% (79/82) received RT per protocol and 5 pts in the no-RT arm received unplanned RT (4 after PR and 1 after CR/CRu). Response RT vs no-RT were CR/Cru 94% vs 84%, PR 2% vs 10%, PD 2% vs 4%. 3-year EFS was superior in pts assigned to RT (94% vs. 78%; p = 0.007), mostly due to events caused by initiation of RT (n = 5) in the no-RT arm. In an as treated analysis the difference between the RT and the no-RT arm was not significant (p = 0.136). Regarding PFS and OS no difference between the RT vs no-RT arm was detected (PFS: 95% (95% CI: 90-100) vs 90% (95% CI: 81-98), p = 0.253; OS: 98% (95% CI: 94-100) vs 96% (95% CI: 90-100), p = 0.636). Dose-densification of R-CHOP-21 by R-CHOP-14 did not improve EFS, PFS nor OS. Only 4 pts died. **Conclusions:** To our knowledge, this is the largest series of PMBCLs so far, which have been treated in a prospective, randomized trial in the rituximab era. The results reveal no differences between R-CHOP-14 vs R-CHOP-21. Pts assigned to RT had a superior EFS mostly due to a higher PR rate in the no-RT arm triggering RT, with no differences in PFS and OS. The results suggest a benefit of RT only for pts, who are responding to R-CHOP with PR. Testing RT in PET-positive residual tumors in a randomized trial can solve the question, while RT in PET-negative pts is studied in the ongoing randomized IELSG 37 trial. Our results indicate a very favorable 3-year OS of 96% in PMBCL pts treated with R-CHOP. Supported by Deutsche Krebshilfe, Amgen and Roche. Clinical trial information: NCT00278408. Research Sponsor: Deutsche Krebshilfe (German Cancer Aid), Pharmaceutical/Biotech Company.

8042 Poster Session (Board #375), Fri, 8:00 AM-11:00 AM

Myeloablative versus non-myeloablative consolidative chemotherapy for newly diagnosed primary central nervous system lymphoma: Results of induction therapy in Alliance 51101. *First Author: Tracy Batchelor, Brigham and Women's Hospital, Boston, MA*

Background: Optimal consolidative therapy for primary central nervous system lymphoma (PCNSL) is not defined. Avoidance of whole brain radiation may reduce risk of neurotoxicity. Non-radiation consolidative options include myeloablative chemotherapy followed by autologous stem cell transplantation (HDT/ASCT) or non-myeloablative chemotherapy. **Methods:** This is a randomized phase 2, National Clinical Trials Network study of induction methotrexate (MTX) (8 g/m^2days 1, 15), temozolomide (TMZ) (150-200 mg/m^2 D7-11), and rituximab (RTX) (C1 D3, 10, 17, 24 and C2 D3, 10) in four 28-day cycles followed by one cycle of cytarabine (ARA-C) (2 g/m^2 BID, D1, 2) (MTRA). Following induction, patients (pts) received consolidation with thiotepa (5 mg/kg BID, D -5, -4) plus carmustine (400 mg/m^2, day -6) and ASCT (Arm A) or one cycle of ARA-C (2 g/m^2 BID, D1-4) plus infusional etoposide (40 mg/kg over 96h) (Arm B). The primary endpoint was median progression-free survival (PFS), designed to compare consolidation regimens. This report describes the results of the 5 cycles of induction therapy. **Results:** 113 pts (median age 61 years, range 33-75) were randomized (Arm A: 57, Arm B: 56) across 27 centers. 108 eligible pts who received induction therapy were evaluated. 36 pts (33.3%) did not proceed to consolidation, mainly due to disease progression (17), pt withdrawal (8), or adverse events including death (6). Grade 3 or 4 febrile neutropenia occurred in 12 pts (11.1%) during induction. Dose modifications of MTX were required in 75% of pts and 63.3% of cycles, mainly due to renal adjustments. Dose delays of MTX were required in 52.8% of pts and 22.2% of cycles. Overall response rate (CR, CRu, PR) at the end of induction was 65.7% (95% CI, 56%, 74.6%). **Conclusions:** While MTRA is feasible and active a significant proportion of pts did not receive consolidation, supporting the need to develop more effective induction strategies. Clinical trial information: NCT01511562. Research Sponsor: U.S. National Institutes of Health.

8043 Poster Session (Board #376), Fri, 8:00 AM-11:00 AM

Outcomes of Burkitt lymphoma (BL) managed in academic (Acad) or community (Comm) centers: real-world evidence (RWE) from 30 US sites. *First Author: Adam J. Olszewski, Rhode Island Hospital-The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Prior analyses have suggested better overall survival (OS) of cancer patients (pts) treated in Acad rather than Comm hospitals, but these disparities may reflect different patient characteristics. We examined outcomes of pts with BL in a large RWE cohort from 30 US healthcare systems (Evens, *ASH* 2019) with a mix of Acad and affiliated Comm sites. **Methods:** We collected clinical data on adults with BL diagnosed in 2009-2018, individually assigned to Acad or Comm principal setting of care. We compared duration of chemotherapy (CTx, incl. standard CODOX-M/IVAC, hCVAD/MA, DA-EPOCH), rates of complete response (CR), progression-free survival (PFS), and OS adjusting for age, sex, HIV, performance status (PS), stage, LDH > 3x upper limit of normal (ULN), involvement of bone marrow or cerebrospinal fluid (CSF), reporting adjusted risk (RR) or hazard ratio (HR) with 95% CI. **Results:** Among 641 BL pts, 77 (12%) were managed in Comm setting. Comm pts had lower median age (45 vs 48 in Acad, *P*= .049), less frequent HIV (13% vs 23%, *P*= .039), less marrow (21% vs 36%, *P*= .009) or detected CSF involvement (8% vs 15%, *P*= .11), and less LDH > 3xULN (21% vs 41%, *P*= .013), with no significant differences in sex, PS, stage, hemoglobin, or receipt of CTx (97% vs 99%). Acad sites more often applied standard intensive CTx regimens (93% vs 85%, *P*= .03) and rituximab (92% vs 79%, *P*= .001), without significant difference in median time to CTx (*P*= .69) or treatment-related mortality (TRM, *P*= .16). Pts managed in Comm (vs Acad) sites were less likely to achieve CR (61% vs 75%, *P*= .03; RR = 0.79 [0.65-0.95]) and had worse 3-year PFS (46% vs 67%, log-rank *P*= .003; HR = 2.17 [1.51-3.14]) and OS (53% vs 72%, *P*= .006; HR = 2.20 [1.48-3.25]). There was no significant interaction with age, sex, HIV, PS, or CSF involvement. Excess mortality concentrated in the 1st year of follow-up. CR, PFS, and OS appeared similar between Acad and Comm settings for pts receiving hCVAD or DA-EPOCH, but outcomes were significantly worse in Comm setting for pts receiving CODOX-M/IVAC. Median number of cycles did not differ between Comm or Acad sites, but median duration of CODOX-M/IVAC delivery was significantly longer in Comm setting (113 vs 101 days, *P*= .023). **Conclusions:** In this large RWE analysis, superior outcomes of adults with BL in Acad setting were not explained by baseline patient characteristics or TRM. Differences in the use of standard CTx regimens, rituximab, duration of Ctx, and CR rates suggest need for further research on potential barriers to delivery of intensive CTx for BL in a broader Comm setting. Research Sponsor: None.

8044 Poster Session (Board #377), Fri, 8:00 AM-11:00 AM

Efficacy and safety of ABP 798 compared with rituximab: Results from the comparative clinical study in patients with non-Hodgkin's. *First Author: Dietger Niederwieser, University of Leipzig, Leipzig, Germany*

Background: ABP 798* is being developed as a biosimilar to rituximab, a CD20-directed cytolytic antibody. A randomized, double-blind, active-controlled study compared the efficacy, safety, and immunogenicity of ABP 798 with rituximab reference product (RP) in subjects with CD20-positive NHL; results of the final analysis are presented here. **Methods:** Adult subjects with grade 1, 2, or 3a follicular B-cell NHL and low tumor burden were randomized to receive intravenous ABP 798 or RP (375 mg/m^2) once weekly for 4 weeks, then at weeks 12 and 20. The primary endpoint was risk difference (RD) of overall response rate (ORR) by week 28. Secondary endpoints included RD of ORR at week 12, pharmacokinetics, pharmacodynamics, safety, and immunogenicity. **Results:** 254/256 randomized subjects were treated with at least one infusion of ABP 798 (n = 128) or RP (n = 126); ORR by week 28, based on independent central blinded assessment of the modified full analysis set, was comparable between the ABP 798 and RP groups (78% vs. 70%, respectively). The 2-sided 90% confidence interval of RD of ORR (-1.4%; 16.8%) was within the pre-specified margin (-15%; 35.5%) thereby establishing clinical equivalence between ABP 798 and RP. This result was supported by analyses of the secondary efficacy endpoint of RD of ORR at week 12. In the two groups, the geometric least squares means for serum concentrations over time (e.g., week 12, pre-dose: ABP 798, 21.89 vs. RP, 20.57; week 12 post-dose: ABP 798, 201.30 vs. RP, 203.52) and the extent of B-cell depletion from day 1 to day 8 (ABP 798, 98.3% vs. RP, 98.3%) were similar. Frequency, type, and severity of adverse events (AEs) were comparable between ABP 798 and RP groups; grade ≥3 AEs were reported in 10.9% and 10.3% of subjects and serious AEs in 3.9% and 4.0%, respectively. Most common AEs were headache, fatigue, and nausea; the most common AE of interest was infusion reactions. No new or unexpected safety signals were observed. Binding and neutralizing anti-drug antibodies were comparable between groups. **Conclusions:** Results of this study demonstrated clinical similarity between ABP 798 and rituximab RP in subjects with CD20-positive NHL. *At the time of this submission, ABP 798 had not been approved by the FDA or any relevant regulatory agency and the indications are yet undetermined. Please consult ABP 798's later approved label in the relevant country for information regarding the approved uses for ABP 798. Research Sponsor: Amgen.

8045 Poster Session (Board #378), Fri, 8:00 AM-11:00 AM

Treatment stratification in B-cell PTLD after solid organ transplantation (SOT) by international prognostic index (IPI) and response to rituximab: Interim results from the PTLD-2 trial. *First Author: Ralf Ulrich Trappe, Department of Hematology and Oncology, DIAKO Ev. Diakonie-Krankenhaus, Bremen, Germany*

Background: The PTLD-1 trials have established risk-stratified sequential treatment of B-cell PTLD. After rituximab induction, patients (pts) in complete remission (25 %) received rituximab consolidation, while all others received R-CHOP. The PTLD-2 trial tests modified risk-stratification including clinical risk factors. These are the results of the 2nd scheduled interim analysis (40/60 planned pts). **Methods:** The prospective, multicenter phase II PTLD-2 trial (NCT02042391) enrols treatment-naïve adult SOT recipients with CD20-positive PTLD. Key exclusion criteria are CNS involvement, ECOG > 2, pregnancy, and severe organ dysfunction or severe, active infection. Treatment consists of rituximab (1400 mg SC; first application 375 mg/m^2 IV) on days 1, 8, 15 and 22. After restaging, pts in CR as well as those in PR with ≤ 2 IPI risk factors at diagnosis (low-risk group) continue with four three-weekly courses of rituximab. Most other pts (high-risk group) receive 4 cycles of R-CHOP-21, while thoracic SOT recipients who progress under rituximab (very-high-risk group) receive six cycles of alternating R-CHOP-21 and R-DHAOx. The primary endpoint (event-free survival in the low-risk group) is not analyzed here. Secondary endpoints presented here are response and overall response (ORR) by computed tomography, overall survival (OS), time to progression (TTP) and treatment-related mortality (TRM) overall and by risk group. **Results:** 40 pts were recruited at 12 centers (2015 – 2019). 21/40 were kidney, 11 lung, 4 liver, 3 heart, and 1 liver/kidney transplant recipients. Median age was 54 years. 38/40 PTLD were monomorphic and 15/40 EBV-associated. 38 pts were evaluated for response at interim staging: 13 were allocated to the low-risk, 17 to the high-risk and 8 to the very-high-risk group. ORR was 28/30 (93 %, CR: 16/30 [53 %]). With a median follow-up of 1.9 years, the 1-year/3-year Kaplan-Meier (KM) estimates of TTP and OS in the intention-to-treat population (40 pts) were 85 %/80 % and 70 %/70 %, respectively. In the low-risk group, the 2-year KM estimate of OS was 100 %. The frequency of infections (all grades) was 50 %, and TRM occurred in 3/40 pts (8 %). **Conclusions:** One third of enrolled pts were treated in the low-risk group and the recruitment goal for evaluation of the primary endpoint will likely be reached. Interim efficacy and toxicity data with rituximab SC and modified risk-stratification are encouraging despite the inclusion of 35 % thoracic SOT recipients. Clinical trial information: NCT02042391. Research Sponsor: Roche.

MAGNIFY phase IIIb interim analysis of induction R^2 followed by maintenance in relapsed/refractory indolent NHL. *First Author: David Jacob Andorsky, Rocky Mountain Cancer Centers/The US Oncology Network, Boulder, CO*

Background: Patients (pts) with relapsed iNHL have limited standard treatment options. The immunomodulatory agent lenalidomide shows enhanced activity with rituximab (ie, R^2), which recently reported 39.4-mo median PFS in R/R iNHL pts (AUGMENT; *J Clin Oncol*. 2019;37:1188). **Methods:** MAGNIFY is a multicenter, phase IIIb trial in pts with R/R FL gr1-3a, MZL, or MCL (NCT01996865) exploring optimal lenalidomide duration. Lenalidomide 20 mg/d, d1-21/28 + rituximab 375 mg/m^2/wk c1 and then q8wk c3+ (R^2) are given for 12c followed by 1:1 randomization in pts with SD, PR, or CR to R^2 vs rituximab maintenance for 18 mo. Data presented here focus on induction R^2 in efficacy-evaluable FL and MZL pts (MCL not included) receiving ≥ 1 treatment with baseline/post-baseline assessments to analyze the primary end point of ORR by 1999 IWG criteria. **Results:** As of June 16, 2019, 393 pts (81% FL gr1-3a; 19% MZL) were enrolled with a median follow up of 23.7 mo (range, 0.6-57.8) for censored pts (n = 335). Median age was 66 y (range, 35-91), 83% had stage III/IV disease, with a median of 2 prior therapies (95% prior rituximab-containing). ORR was 69% with 40% CR/CRu (Table). Median DOR was 39.0 mo, and median PFS was 40.1 mo. 199 pts (51%) have completed 12c of R^2, and 188 (48%) have been randomized and entered maintenance. 139 pts (35%) prematurely discontinued both lenalidomide and rituximab, primarily due to AEs (n = 52, 13%) or PD (n = 45, 11%). Most common all-grade AEs were 48% fatigue, 43% neutropenia, 36% diarrhea, 31% nausea, and 30% constipation. Grade 3/4 AE neutropenia was 36% (9 pts [2%] had febrile neutropenia); all other grade 3/4 AEs occurred in < 7% of pts. **Conclusions:** R^2 is active with a tolerable safety profile in pts with R/R FL and MZL, including rituximab-refractory, double-refractory, and early relapse pts. Clinical trial information: NCT01996865. Research Sponsor: Bristol-Myers Squibb, Summit, NJ.

8047 Poster Session (Board #380), Fri, 8:00 AM-11:00 AM

Machine learning prediction of survival in diffuse large B-cell lymphoma based on gene-expression profiling. *First Author: Selin Merdan, Value Analytics Labs, Alpharetta, GA*

Background: The current clinical risk stratification of Diffuse Large B-cell Lymphoma (DLBCL) relies on the International Prognostic Index (IPI) comprising a limited number of clinical variables but is imperfect in the identification of high-risk disease. Our study aimed to: (1) develop a risk prediction model based on the genetic and clinical features; and (2) evaluate the model's biological implications in association with the estimated profiles of immune infiltration. **Methods:** Gene-expression profiling was performed on 718 patients with DLBCL for which RNA sequencing data and clinical covariates were available by Reddy et al (2017). Unsupervised and supervised machine learning methods were used to discover and identify the best set of survival-associated gene signatures for prediction. A multivariate model of survival from these signatures was constructed in the training set and validated in an independent test set. The compositions of the tumor-infiltrating immune cells were enumerated using CIBERSORT for deconvolution analysis. **Results:** A four gene-signature-based score was developed that separated patients into high- and low-risk groups with a significant difference in survival in the training, validation and complete cohorts ($p < 0.001$), independently of the IPI. The combination of the gene-expression-based score with the IPI improved the discrimination on the validation and complete sets. The area-under-the-curve at 2 and 5 years increased from 0.71 and 0.69 to 0.75 and 0.74 in the validation set, respectively. **Conclusions:** By analyzing the gene-expression data with a systematic approach, we developed and validated a risk prediction model that outperforms existing risk assessment methods. Our study, which integrated the profiles of immune infiltration with prognostic prediction, unraveled important associations that have the potential to identify patients who could benefit from the various therapeutic interventions, as well as highlighting possible targets for new drugs. 8048 Poster Session (Board #381), Fri, 8:00 AM-11:00 AM

Immunohistochemical characterization of anaplastic large cell lymphoma using tissue microarray. *First Author: Poorvi Kirit Desai, University of South Florida, Tampa, FL*

Background: Anaplastic Large Cell Lymphoma (ALCL) is a subtype of mature T-cell lymphoma comprised of systemic (ALK+ or ALK-) and primary cutaneous (PCALCL) forms. ALK+, usually associated with *NPM1-ALK* gene, has a favorable prognosis. PCALCL is usually indolent. Despite worse prognosis for ALK-, pts with *DUSP22* rearrangement have favorable outcomes similar to ALK+ while those with *p63* aberration have poor outcomes. We hypothesize that other genetic alterations in ALCL could aid in diagnosis and prognosis. We compared protein expression levels of selected signaling molecules (JAK1, STAT3, DUSP22, ERBB4/HER4, PRDM1/BLIMP1 and SOCS3) among the subtypes and correlated to outcomes. **Methods:** Of 50 pts with ALCL at Moffitt (MCC) from 2000-2019, 27 tissue samples (6 ALK+, 10 ALK-, 8 PCALCL, 3 controls) met eligibility criteria. Tissue microarrays (TMAs) were constructed from formalin-fixed, paraffin-embedded lymph node biopsies. Up to 3 replicate cores were taken from each block. Immunohistochemistry was performed with antibodies to the selected proteins. Stained TMA slides were scanned using the Aperio™ ScanScope XT2 to determine % positive biomarker stain within each core per established algorithm. Statistics: ANOVA was used to compared protein expression levels, with pairwise tests when significant. T-test compared PCALCL to systemic ALCL. Boxplots were created for differences in protein expression levels and time to event outcomes (OS and RFS) using Log rank test and Cox proportional hazards models. Kaplan-Meier curves were used for clinical time-to-event outcomes and quartiles of the protein expression levels. **Results:** The 3 subgroups had a significant difference in SOCS3 expression with mean and std respectively: 42.4% (0.153), 17.4% (0.089), and 21.0% (0.155), p = 0.008. Among all pairs, ALK+ and PCALCL groups were statistically different (P = 0.011). Patients with high BLIMP1 (≥28.5%) across 3 ALCL subgroups were associated with better median OS (not reached) in comparison to pts with lower expression (27.3 mos) (Log rank test p = 0.014, HR = 0.17, 95% CI 0.034-0.829). The same was seen for median RFS (81.1 vs. 12.5 mos). (Log rank test p = 0.009, HR 0.23, 95% CI 0.069-0.755). **Conclusions:** High BLIMP1 suggests favorable prognosis in ALCL and could potentially be a positive prognostic marker. High SOCS3 appears more prevalent in PCALCL than systemic and could aid in differential. Larger samples should be used to validate results. Secondary markers like Bcl-2 can be considered in the future to correlate expression levels to targeted treatments like venetoclax. Research Sponsor: University of South Florida Graduate Medical Education Grant ($7500).

8049 Poster Session (Board #382), Fri, 8:00 AM-11:00 AM

The Integration of PD1 blockade with epigenetic therapy is highly active and safe in heavily treated patients with T-cell lymphoma (PTCL) and cutaneous T-cell lymphoma (CTCL). *First Author: Enrica Marchi, Center for Lymphoid Malignancies, Columbia University Medical Center, New York, NY*

Background: Our group has demonstrated that combinations of epigenetic modifiers produce potent synergy in pre-clinical models of PTCL and induce the expression of cancer testis antigen, suggesting a role in the addition of the immune-checkpoint inhibitor, pembrolizumab. **Methods:** This is a phase 1b study of pembrolizumab combined with pralatrexate alone (Arm A), with pralatrexate + decitabine (Arm B), or decitabine alone (Arm C) in patients with relapsed and refractory PTCL and CTCL. A standard 3+3 dose-escalation is applied in the triplet Arm (Arm B) while in the doublet Arms (A and C) de-escalation is applied in case of toxicity. Pharmacokinetic and pharmacodynamic studies are ongoing. **Results:** We treated a total of 12 patients with 4 patients in each Arm. All patients that received at least one dose of drug were evaluable for toxicity. There was a dose limiting toxicity (DLT) in each arm including prolonged grade 3 thrombocytopenia (Arm A), febrile neutropenia (Arm B), grade 3 hyponatremia, and rash (Arm C). There were no treatment-related deaths. Six patients out of 12 were evaluable for response at the time of this analysis. One patient achieved a complete remission, 2 had partial remission, 1 had stable disease, and 2 experienced progression of disease. Interestingly, all of the responses were seen in the triple combination of pralatrexate, decitabine, and pembrolizumab. Table summarizes the patient characteristics, toxicities, and response rates. **Conclusions:** These preliminary clinical data suggest that the integration of pembrolizumab on an epigenetic backbone is safe and demonstrates encouraging responses in patient with PTCL and CTCL. Clinical trial information: 03240211. Research Sponsor: Merck.

Sintilimab for relapsed/refractory (r/r) extranodal NK/T cell lymphoma (ENKTL): Extended follow-up on the multicenter, single-arm phase II trail (ORIENT-4). *First Author: Jianyong Li, Jiangsu Province Hospital, Nanjing, China*

Background: Patients with r/r ENKTL have a poor prognosis after failing an asparaginase-based regimen. The overexpression of PD-L1 induced by EBV infection is a potential mechanism for ENKTL to avert immune surveillance. Sintilimab, a fully human anti-PD-1 monoclonal antibody, has demonstrated efficacy in r/r ENKTL after the primary analysis of the ORIENT-4 study. Here, we report the updated efficacy and safety results with extended follow-up. **Methods:** Patients with pathologically confirmed r/r ENKTL were enrolled. Sintilimab was given 200 mg IV Q3W, until PD, death, unacceptable toxicity, or withdrawal from the study. Treatment beyond PD is allowed. Tumor response evaluation was performed by both PET-CT and CT/MRI with contrast. The primary endpoint was objective response rate per Lugano 2014. Data cut-off date for this analysis was Jan 17, 2020. **Results:** A total of 28 patient were enrolled and treated. With a median follow-up of 26.9 months (range, 23.3 to 28.6), the median treatment duration was 24.15 months (range, 1.4 to 28.7). Of 20 patients with progressive disease (PD) by investigator per Lugano 2014 criteria, 19/20 (95%) patients received treatment beyond PD. The median OS has not been reached and 24-month OS rate was 78.6% (95% CI, 58.4% to 89.8%). ORR was 67.9% (95% CI, 47.6% to 84.1%), including 4 pts who experienced PD prior to having a response. DCR was 85.7%, including 5 pts who experienced PD before SD or response. Median duration of response was 4.1 months (range, 1.9 to 15.2+). After treatment, the mean EQ-5D-5L VAS Score (from 79.3 to 90.8), EQ-5D-5L Index Value (from 0.8 to 0.9) and EORTC QLQ-C30 (from 70.5 to 87.3) were all increased. The Treatment-related adverse events (TRAEs) of any grade occurred in 28 (100%) pts; grade 3 occurred in 11 (39.4%) pts, most commonly, decreased lymphocyte count (2 [7.1%]) and diabetes (2 [7.1%]); no grade 4-5 TRAE. **Conclusions:** In addition to an encourage response, sintilimab also demonstrated long-term clinical benefit, with 78.6% of 24-month OS rate, and favorable long-term safety profile after extended follow-up. Considering the high rate (95%) of treatment beyond PD, Lugano 2014 may not be a suitable criteria for evaluating the efficacy of anti-PD-1 antibody in r/r ENKTL. Clinical trial information: NCT03228836. Research Sponsor: Innovent Biologics, Inc.

8051 Poster Session (Board #384), Fri, 8:00 AM-11:00 AM

Three-year follow-up of treatment-naïve and previously treated patients with Waldenström macroglobulinemia (WM) receiving single-agent zanubrutinib. *First Author: Constantine S. Tam, Peter MacCallum Cancer Centre, Melbourne, St Vincent's Hospital, Fitzroy, University of Melbourne, Parkville and Royal Melbourne Hospital, Parkville, Victoria, Australia*

Background: Inhibitors of Bruton tyrosine kinase (BTK) have established therapeutic activity in patients with WM. Zanubrutinib, a potent and selective BTK inhibitor was evaluated in a phase 1/2 study in treatment-naïve (TN) and relapsed/refractory (R/R) patients with WM. **Methods:** Patients had TN or R/R WM and required treatment as per International Workshop on WM (IWWM) criteria. Treatment consisted of oral zanubrutinib at 160 mg twice daily (n = 50) or 320 mg once daily (n = 23) until disease progression or unacceptable toxicity. Efficacy endpoints included the proportion of patients achieving a complete response (CR) or very good partial response (VGPR) in accordance with IWWM-6 criteria. Efficacy analyses were conducted on the 73 patients evaluable (24 TN, 49 R/R). **Results:** Between September 2014 and August 2018, 77 patients with WM (24 TN and 53 R/R) began treatment with zanubrutinib (55% aged > 65 years; 21% aged > 75 years). At a median follow up of 32.7 months, 73% remain on treatment. Reasons for treatment discontinuation included adverse events (AE) in 13% (only one related), disease progression (10.4%), and other (3.9%). Results are presented for TN and R/R combined. The overall response rate was 96% and VGPR/CR rate was 45%. The rates of VGPR/CR increased over time; 22% at 6 mos, 33% at 12 months and 45% at 24 months. Three-year progression-free survival (PFS) was 81%, and overall survival (OS) was 85%. The most commonly reported AEs were upper respiratory tract infection (52%), contusion (33%, all grade 1) and cough (22%). AEs of interest include neutropenia (18.2%), major hemorrhage (4%), atrial fibrillation/flutter (5%), and grade 3 diarrhea (3%). **Conclusions:** Long-term follow up with continued zanubrutinib treatment demonstrated deep and durable responses in the majority of WM patients. The rates of VGPR/CR increased with prolonged therapy. Disease progression was uncommon. The safety profile of long-term zanubrutinib therapy in these patients was tolerable. Clinical trial information: NCT02343120. Research Sponsor: BeiGene.

Efficacy and safety outcomes.

8052 Poster Session (Board #385), Fri, 8:00 AM-11:00 AM

Prognostic relevance of CD4+ T-cells in the microenvironment of newly diagnosed follicular lymphoma (FL) patients is independent of the tumor gene expression profile. *First Author: Patrizia Mondello, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A significant proportion of patients with FL experience an early relapse and a subsequent poor outcome. While several prognostic indices have been developed, none were designed to predict early failure. Recently, we established that lack of intrafollicular CD4+ T-cell expression predicted risk of early failure, and integrating this microenvironment biomarker with the Follicular Lymphoma International Prognostic Index, termed BioFLIPI, further improved identification of FL patients at risk of early failure (*Blood* 2019; 134(suppl1):121). However, the microenvironment may be influenced by the genetic composition of tumor. We investigated whether the CD4 biomarker and BioFLIPI were impacted by genetic features of the tumor as assessed by a 23-gene expression prognostic score (*Lancet Oncol* 2018;19:549-61). **Methods:** Of the 186 cases with FL grade 1-3A treated with immunochemotherapy (IC) in our prior study, 152 had digital expression quantification of 23 selected genes (23-GEP score), which used RNA from formalin-fixed, paraffin-embedded samples. Event-free survival (EFS) was defined as time from diagnosis to progression, relapse, retreatment, or death. Early failure was defined as failing to achieve EFS at 24 months. Risk of early failure was estimated using odds ratios (ORs) and 95% confidence intervals from logistic regression models. We also used Cox regression to assess associations with continuous EFS and overall survival (OS). **Results:** 28% of patients failed to achieve EFS24. Lack of CD4+ intrafollicular expression (38% of patients, OR = 2.33, p = 0.024) and high risk 23-GEP score (26% of patients, OR = 3.52, p = 0.001) each predicted early failure, and in a multivariable model that included FLIPI, both CD4+ (OR = 2.26, p = 0.046) and 23-GEP score (OR = 2.26, p = 0.0.057) remained predictors. Similarly, BioFLIPI modeled as a continuous score (1-4, OR per one point increase = 2.31, $p < 0.001$) predicted early failure, and the association remained (OR = 2.14, $p < 0.001$) when the high risk 23-GEP score (OR = 2.79, p = 0.013) was included in the model. When stratified on 23-GEP score, BioFLIPI was a stronger predictor of early failure in low risk (74%, OR = 2.51, p = 0.002) relative to high risk (26%, OR = 1.55, p = 0.27) patients. Similar patterns were observed for EFS and OS. **Conclusions:** CD4+ T-cell infiltrate and tumor gene expression appear to be independently predictive of early failure in newly diagnosed FL patients treated with IC. Future studies should integrate and validate these measures. Research Sponsor: U.S. National Institutes of Health.

8053 Poster Session (Board #386), Fri, 8:00 AM-11:00 AM

Atezolizumab + obinutuzumab + venetoclax in patients with relapsed or refractory diffuse large B-cell Lymphomas (R/R DLBCL): Primary analysis of a phase II trial from LYSA. *First Author: Charles Herbaux, Centre Hospitalier Régional Universitaire de Lille, Institute of Hematolog-Tranfusion, Lille, France*

Background: R/R DLBCL treatment remains challenging. Atezolizumab (ATE) and obinutuzumab (OBI) are monoclonal antibodies acting respectively to inhibit T-lymphocyte exhaustion or by inducing lymphoma cells cytotoxicity, whereas venetoclax (VEN) is a small molecule inhibiting BCL-2. Combining tumor-targeted therapies with agents that enhance anti-tumor immunity represents an attractive treatment paradigm. This LYSA sponsored multicenter phase 2 trial (NCT03276468) evaluate the combination of ATE, OBI and VEN in R/R B lymphomas, we present here primary efficacy and safety data fromthe DLBCL cohort. **Methods:** Patients ≥18 years with biopsy-confirmed R/R DLBCL who failed at least one line of therapy were eligible. OBI was given IV at the dose of 1 g on day (D) 1, 8 and 15 of cycle (C) 1 and on D1 from C2 to C8 every 3 weeks. ATE was given IV, 1.2 g every 3 weeks, started at D2 of C1, then administered at D2 of each cycle for 24 cycles. VEN was given orally at 800 mg/D at full dose, started on D8C1 for 24 cycles. The primary endpoint wasthe Overall Metabolic Response Rate (OMRR) by Lugano criteria at the end of induction (EOI) after 8 cycles of ATE, OBI and VEN (M6) or at premature treatment discontinuation. **Results:** At the time of the primary analysis (03 Jan 2020), 58 pts were enrolled and the median follow-up was 9 months [6.9-11.8]. Baseline characteristics were: median age, 70 years; male, 53.4%; Ann Arbor Stage IV, 84.5%; aaIPI (≥2), 63.2%; > 2 prior lines of therapy, 83.6%; and refractory to last line of prior regimen, 63.6%. The OMRR at EOI was measured at 23.6% [14.58%-34.93%], including 18% of CMR. To date, these responses seem durable with only 3 reported relapses. According to the highest diameter mass, OMRR was 38.5% versus 10.3%, < 5cm and > 5cm respectively; P = 0,02. All three treatments were stopped in 78% of patients, mostly for progressive disease. At the time of analysis, a median of 4 cycles [1-8] has been administered. A total of 48 (84.2%) pts experienced grade 3–4 adverse event (AE) and 6 (10.5%) had an AE that led to discontinuation of any drug.AE of grade 3 or more reported in at least 20% of patients were neutropenia (33.3%) and lymphopenia (35.1%). Of note, a grade 3 autoimmune colitis and a grade 1 hypothyroidism were reported during induction. **Conclusions:** The ATE, OBI and VEN combinationappears to be well tolerated. The OMRR rate at EOI is comparable with currently available treatment options in this population, with durable responses. The OMRR seems better in patients with a low tumor burden. Clinical trial information: NCT03276468. Research Sponsor: Roche and AbbVie.

8054 Poster Session (Board #387), Fri, 8:00 AM-11:00 AM

Identification of predicted neoantigen vaccine candidates in follicular lymphoma patients. *First Author: Cody Ramirez, McDonnell Genome Institute, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Follicular lymphoma (FL) is incurable with conventional therapies and poorly responsive to immune checkpoint blockade. There is a need for new therapies without long-term complications of chemotherapy and with curative potential. We hypothesize that FL contains tumor-specific mutant antigens (TSMAs) that can be targeted by the immune system by vaccination. Recent reports have highlighted the potential for unique immunoglobulin peptides to elicit immune response in lymphomas. We utilized whole exome sequencing (WES) and RNA sequencing (RNA-Seq) of FL patient samples to infer HLA genotype, and predict TSMAs with the goal of designing a personalized cancer vaccine, supported by recent reports of this approach in solid cancers. **Methods:** DNA and RNA from 58 patients' FL biopsies underwent WES and RNA-Seq. pVACtools and MiXCR predicted potential somatic and B-cell clonotype neoantigens, which were filtered to identify high quality TSMAs. B-cell oligoclonality was determined by comparison to B-cell receptor (BCR) repertoire profiling of healthy individual lymph nodes. RNA-seq data allowed us to identify expressed TSMAs. Complementary *in silico* analysis based on mRNA-based peptide reconstruction and custom HLA affinity binding predictions were performed. **Results:** An average of 52 somatic mutations per patient (range: 2-172) were identified. At least one high quality TSMA was predicted for 57 of 58 patients. Five or more TSMA candidates were identified for 52 (90%) patients with a mean of 17 predicted peptides per patient (range: 0-45). 81% (813/1,004) of the total predicted TSMA peptides arose from missense mutations, 9% (94/1,004) from indels, and 10% (97/1,004) from BCR. 78% (45/58) of patients have both somatic and BCR vaccine candidates, while 21% (12/58) of patients had only somatic vaccine candidates. Predicted TSMAs were identified in multiple genes recurrently mutated in lymphoma (e.g., BCL2). There was a high prediction concordance with the orthogonal BostonGene Vaccine Module V1 pipeline. These pre-clinical results led to a first-in-human pilot trial of personalized TSMA vaccine combined with anti-PD-1 mAb for rel/ref FL patients (NCT03121677), with one response observed within 4 patients evaluable for response to date. **Conclusions:** TSMA peptides suitable for cancer vaccines were identified for most FL patients via next-generation sequencing, MiXCR and pVACtools. This pre-clinical study suggests that FL patients will be candidates for TSMA vaccine clinical trials and pilot clinical results provide proof of concept for this approach. Research Sponsor: Siteman Cancer Center, Other Foundation, The Jamie Erin Follicular Lymphoma Research Consortium.

8055 Poster Session (Board #388), Fri, 8:00 AM-11:00 AM

Multi-omics analysis of mantle cell lymphoma reveals an immune-cold tumor microenvironment associated with ibrutinib resistance. *First Author: Krystle Nomie, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Mantle cell lymphoma (MCL) is an aggressive and incurable B-cell lymphoma. Although the role of the MCL tumor microenvironment (TME) in survival and therapeutic response has been studied, greater knowledge regarding the tumor-immune interaction is needed to develop MCL immunotherapeutic strategies. **Methods:** Whole exome sequencing (WES; n = 41) and RNA-seq (n = 93) were performed on fresh peripheral blood, apheresis, or biopsy MCL patient primary samples. Joint WES and RNA-seq mutation calling, expression analysis were performed by BostonGene. **Results:** Both tumor and TME molecular signatures were characterized based on ibrutinib response. Concurrent analysis of MCL biopsy samples with an additional previously published cohort (n = 122; Scott et al., *JCO*, 2017) identified 4 MCL microenvironment signatures (Nomie et al., *Blood*, 2019) in which the ibrutinib-resistant MCL samples primarily belonged to the "stroma-enriched" subtype (29%; 6/8 resistant, non-immune with increased stromal signature and tumor-promoting cytokines), whereas most of the ibrutinib-sensitive samples were assigned to the "immune-hot" subtype (53%, 9/9 sensitive; anti-tumor infiltration, high immune and checkpoint molecule expression with low stromal expression, Chi-square test p-value = 0.001). *NOTCH1* gain-of-function mutations (25%, 3/12 resistant) in the PEST domain were found exclusively in the ibrutinib-resistant cohort associated with the microenvironment-depleted subtype. Frequent recurring inactivating mutations in the epigenetic modifier *KMT2D* (30%) were identified in MCL cells associated with the 'immune-suppressed" subtype ($p < 0.05$). Loss-of-function mutations in epigenetic modifiers have been tied to immune evasion. PD-L1 was significantly downregulated in the ibrutinib-resistant MCL tumors (p = 0.03), indicating that targeting the PD-L1 and PD-1 immune checkpoint axis may not be beneficial. **Conclusions:** Ibrutinib sensitivity and resistance were defined by immune-hot and immune-cold TME portraits, respectively, suggesting that the TME has a prominent role in mediating ibrutinib response. Ibrutinib has been suggested to activate the immune TME through its off target inhibition of interleukin 2–inducible T-cell kinase (ITK). The immune activation by ibrutinib suggests that anti-tumor activity of ibrutinib may be better harnessed by combining ibrutinib with immunotherapy. Research Sponsor: None.

8056 Poster Session (Board #389), Fri, 8:00 AM-11:00 AM

Phase Ib trial combining rapid determination of drug-drug interaction (DDI) followed by a dose finding period to assess safety and preliminary efficacy of fimepinostat plus venetoclax in patients with aggressive B-cell lymphoma. *First Author: Tycel Jovelle Phillips, University of Michigan, Ann Arbor, MI*

Background: Fimepinostat (F), a dual inhibitor of PI3K (α, β, δ) and HDACs type 1/2, causes suppression of MYC levels (Shulman *et al.*, 2017). A pooled analysis of diffuse large B-cell lymphoma (DLBCL) pts treated with F in two Ph 1/2 trials revealed an objective response rate in evaluable/ITT MYC-altered DLBCL pts of 29%/23%, respectively (Landsburg *et al.*, 2018). Based on compelling preclinical activity of F in combination with venetoclax (V) (a Bcl2 inhibitor), we initiated a Ph 1b/2 study of F + V in pts with relapsed or refractory (R/R) DLBCL or high-grade B-cell lymphoma (HGBL), with or without MYC alteration. V is metabolized primarily by CYP3A, and preclinical studies showed that F may inhibit CYP3A4 (IC_{50} of 13.58 and 0.28 μM for midazolam and testosterone, respectively), suggesting F could cause DDI with V. **Methods:** Cohorts of patients received increasing dose levels of F administered on a 5-days-on/2-days-off (5/2) schedule in combination with daily V in 21-day cycles (Cohort 1: F 30 mg QD 5/2 + V 400 mg QD; Cohort 2: F 60 mg QD, 5/2 + V 400 mg QD; Cohort 3: F 60 mg QD 5/2 + V 800 mg QD). A potential DDI was assessed during Cycle 0 (Table), where PK for V (10 mg) monotherapy was compared to that for V (10 mg) in the presence of F. Patient PK samples were collected, analyzed and reviewed in < 10 days to determine the final ramp-up dose level of V. **Results:** As of 1-Feb-2020, 16 pts have been enrolled in 2 dose cohorts. Intensive PK analysis of 13 pts showed only mild (≤ 2-fold) to no increase in V exposure in the presence of F. In Cohort 1 (n = 6), the mean AUC increased 1.6-fold, and mean C_{max} by 1.5-fold. In Cohort 2 (n = 7), no increase in mean AUC (0.9-fold) or C_{max} (1.0-fold) was observed. Accordingly, all pts ramped up V to 100% of the target dose (400 mg) upon entering Cycle 1; rapid escalation of V was well tolerated. DLT was observed in 1 pt (Grade 3 diarrhea) in Cohort 2. Overall, 75% of TEAEs have been mild or moderate (Grade 1/2), and most were of limited duration. 11 pts (69%) experienced SAEs; 4 pts (25%) had SAEs considered related to either F or V. **Conclusions:** Real-time PK evaluation showed that F had only a mild to no DDI with V. F + V is well tolerated at clinically active dose levels, and evaluation of higher dose-level cohorts was ongoing. Enrollment in Cohort 2 remains on-going. Clinical trial information: NCT01742988. Research Sponsor: Curis, Inc.

Cycle:	Cycle 0													Cycle 1
Day:	1	2-5	6-7	8	9-10	11-14	15	16	17	18	19 - End of PK Evaluation Period			1-2

8057 Poster Session (Board #390), Fri, 8:00 AM-11:00 AM

Haemophagocytic lymphohistiocytosis (HLH) in patients with large B-cell lymphoma treated with standard of care (SOC) axicabtagene ciloleucel (Axi-cel). *First Author: Sairah Ahmed, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: HLH is a rare but serious complication of chimeric antigen receptor (CAR) T cell therapy, characterized by severe immune activation, and immune mediated multi-organ failure. Diagnosis is difficult in the context of cytokine release syndrome (CRS) and optimal treatment and outcomes are unclear. **Methods:** Retrospective, descriptive analysis of patients with relapsed/refractory LBCL treated with SOC axi-cel at MD Anderson Cancer Center between 01/2018 - 10/2019 (data cut-off 12/21/2019). Progression-free survival (PFS) defined as time from axi-cel infusion to progression/death or last follow-up. Diagnosis of HLH per HLH-2004 and CART cell therapy toxicity guidelines (Neelapu, 2018) **Results:** One hundred and five patients with relapsed/refractory LBCL included, 6 diagnosed with HLH. No significant difference in baseline characteristics, disease stage, international prognostic index or inflammatory markers at baseline between groups, with exception of platelet count which was lower in HLH group 116 [37-129] versus 141 [9-391] (p = 0.07). Development of HLH was early after CART cell infusion at a median 11 days [7 – 78 days] with 3 patients having bone marrow hemophagocytosis; all 6 had abnormalities in liver function tests, fibrinogen, triglycerides, and at least 1 ferritin level > 10,000. CART toxicity in HLH cohort: 4 patients experienced grade 0-1 CRS, and 1 with grade 2 CRS while 3 HLH patients experienced grade 3-4 IEC-associated neurotoxicity syndrome (*ICANS*), and 2 patients had grade 0-1 ICANS. Five HLH patients treated with high dose steroids, and tocilizumab; anakinra administered in 2 patients. Four of 6 patients had resolution of HLH with treatment and didn't require escalation to HLH specific therapy however 1 patient was treated with steroids/etoposide. PFS and overall survival (OS) were significantly shorter in HLH group, PFS 1 months vs 8 months, respectively (p < 0.001) and median OS 2 months vs not reached, respectively (p = 0.001) follow up 10 months (95% CI 8-12 months). One patient died of acute respiratory failure, 2 patients died of HLH and multi-organ failure without progressive disease (PD). Of 3 remaining patients, all had radiographic PD at day 30, 2 of whom died of PD. **Conclusions:** HLH is likely an underreported complication of CART cell therapy, and patients with HLH have significantly worse outcomes. In this series the majority of patients died of PD, not the syndrome itself. More information is necessary to design treatment strategies that won't compromise CART outcomes. Research Sponsor: None.

8058 Poster Session (Board #391), Fri, 8:00 AM-11:00 AM

Safety and efficacy of TQ-B3525, a novel and selective oral PI3K α/δ inhibitor, in Chinese patients with advanced malignancies: A phase I dose-escalation and expansion trial. *First Author: Huaqing Wang, First People's Hospital of Tianjin, Tianjin, China*

Background: TQ-B3525 is a novel and selective oral PI3K α/δ inhibitor with activity 41 and 138 folds higher than Buparlisib against PI3K α and PI3K δ in pre-clinical research. This Phase I study (NCT03510767) assessed the safety, tolerability, pharmacokinetics and antitumor activity of TQ-B3525 in Chinese patients with advanced malignancies. **Methods:** Patients with relapsed or refractory (R/R) lymphoma who have experienced at least two prior systemic anti-cancer treatments, and advanced solid tumor who have failed standard anti-cancer treatment, were enrolled. TQ-B3525 was administered orally from 2mg, 5mg, 10mg, 20mg once daily (qd) to 10mg, 20mg twice daily (bid). DLT was observed in the first cycle (28 days) of dose-escalation phase. Dose-expansion phase started at the dose level which objective response occurs. **Results:** Between June 2018 and December 2019, a total of 40 patients were enrolled, Including 27 patients with R/R lymphoma and 13 patients with advanced solid tumor. Three DLTs (both grade 3 hyperglycemia) were observed: two in the 20mg bid dose cohort and one in the 10mg bid. The common AEs of all grades were hyperglycemia (65.0%), glycosylated hemoglobin increased (35.0%) and diarrhea (32.5%). Grade 3 or 4 treatment-related AEs occurred in 11 patients (27.5%), with the most common one also being hyperglycemia (10.0%). TQ-B3525 was rapidly absorbed (T_{max}: 1-2 h) and moderately eliminated ($T_{1/2}$: 10-12 h). At steady state, the geometric mean $AUC_{0\text{-}24}$ and C_{trough} of TQ-B3525 at 20mg qd were 1060.7 ± 198.6 h*ng/mL and 23.4 ± 9.5 ng/mL, which was above IC_{50} (4.2 ng/ml). 23 lymphoma patients were evaluable for clinical response per 2014 Lugano Classification. The overall response rate (ORR) was 60.9% (95% CI, 38.5-80.2). The ORR at ≥10mg qd was 70.0% (14/20, [95% CI, 49.9-90.1]). For R/R FL, the ORR was 72.7% (8/11, [95% CI, 46.4-99.1]). At data cut-off (2nd February, 2020), the median PFS for lymphoma was not reached (events rate: 33.3%). The longest duration of response at data cutoff was 11.8 months in a patient with FL. **Conclusions:** TQ-B3525 is well-tolerated in Chinese patients with advanced malignancies, and demonstrated high promising antitumor activity in R/R lymphoma patients. Recommended phase II dose was established at 20mg qd. A single-arm phase 2 trial of TQ-B3525 in patients with R/R FL is currently underway. Clinical trial information: NCT03510767. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

8059 Poster Session (Board #392), Fri, 8:00 AM-11:00 AM

The BCR repertoire comparison, lymphoma typing model and OS predicted model in 5 different pathological lymphomas: T-LBL/ALL, PTCL-NOS, B-MCL, B-FL, and DLBCL. *First Author: Wenhua Jiang, Second Hospital of Tianjin Medical University, Tianjin, China*

Background: Lymphatic system cancer is characterized by high heterogeneity in histology and clinical manifestations, B-cell antigen receptor (BCR) plays a vital role in anti-tumor immune responses. This study aimed to compare the BCR repertoire and identify some specific immune markers for different pathological lymphomas. **Methods:** 5 pathological types of non-Hodgkin's lymphoma (T-LBL/ALL, PTCL-NOS, B-MCL, B-FL, DLBCL) were collected, with reactive lymph node (RLN) hyperplasia as control. All patients were tested by high-throughput immunohistochemical sequencing (HTS-IR) to analyze the correlation between B-cell immunohistochemistry and clinical indicators, and constructed new strategy typing and overall survival (OS) predicted models for lymphomas. **Results:** The BCR repertoire had the highest diversity in RLN, followed by T-LBL/ALL, PTCL-NOS, DLBCL, B-MCL and B-FL. The diversity of BCR repertoire and similarity of B cell antigens were higher in B-MCL and B-FL patients. Similar to RLN, T-LBL/ALL and PTCL-NOS had broad and diverse V-J pairs, and rare in B-MCL, B-FL and DLBCL. RLN patients were with the highest average number of amino acids, followed by T-LBL/ALL, DLBCL, PTCL-NOS, B-MCL and B-FL. The expressed amino acid sequencing of ARDLIALDY, ARRPGSFDY, ARDIAGWGAVAGLLGRAYYGMDV, and ARDGPYGGNSVEYFQH were markedly different among 5 groups. Patients tended to recurrence expressed ASLDSSPSGFC, ARGMTTVTTAPNY, ARVPLYDDQNINDV and AGGVGGYDWGSYYFDY (P = 0.01605, 0.02869, and 0.01569), and prone to metastasis with expressions of ARVKEFYGILTGYDY, AHSIIGSSWYNWFDP and VRDGGWQSNNWLGFDV (P = 0.04259, 0.0450 and 0.0481). For all patients, 18 (7 negative, 11 positive) and 12 (10 negative, 2 positive) IGH V-J pairs were respectively associated with lymphoma recurrence and metastasis. The top 3 most significant pairs were IGHV7-4-1_IGHJ4, IGHV3-53_IGHJ5 and IGHV3-7_IGHJ5 bound up with recurrence (P = 0.0019, 0.0020 and 0.0021), and IGHV3-74_IGHJ1, IGHV1-69_IGHJ3 and IGHV1-2_IGHJ1 related to metastasis (P = 0.0022, 0.010 and 0.019). The accuracy of typing model in training and test sets was 78.125% (25/32) and 60% (6/10), respectively. The OS model can predict long (≥ 24 months) or short (< 24 months) OS. **Conclusions:** Our study identified new biomarkers, constructed novel lymphoma typing model and OS predicted model based on B cell repertoire. It provides a comprehensive understanding of immune response, and contributes to the diagnosis and prognosis of non-Hodgkin's lymphoma. Research Sponsor: National Natural Science Foundation of China.

8060 Poster Session (Board #393), Fri, 8:00 AM-11:00 AM

REFLECT real-world evidence (RWE) prospective study update: Efficacy and safety results of Sandoz biosimilar rituximab (SDZ-RTX) for the treatment of diffuse large B-cell lymphoma (DLBCL). *First Author: Manfred Welslau, Onkologische Schwerpunktpraxis am Klinikum, Onkologie Aschaffenburg, Aschaffenburg, Germany*

Background: SDZ-RTX (Rixathon) is approved in more than 20 countries and regions, including highly regulated markets e.g. Europe, Japan and Switzerland for all labeled indications of reference rituximab. REFLECT is the first prospective post-approval study to evaluate a rituximab biosimilar as a curative therapy in untreated pts with $CD20^+$ DLBCL. This interim analysis adds up efficacy and additional safety results on the previously presented data (Welslau et al, ASCO and EHA 2019). **Methods:** Adult patients (pts) were treated with SDZ-RTX and cyclophosphamide, doxorubicin, vincristine, prednisone (R-CHOP) according to the product label. The primary endpoint is to evaluate the effectiveness of Rixathon measured by complete response (CR) rate at the end of treatment. Secondary endpoints are overall response rate (ORR), progression-free survival at 24 months and adverse events (AEs). Data were collected at baseline and all scheduled treatment and follow-up visits, which is still ongoing. No imputation was made for missing values, and endpoints are summarized descriptively. **Results:** As of Sep 30, 2019, 170 pts were enrolled, and R-CHOP treatment was close to completion. The median age of pts was 70 years, and 52% were women. Overall, 38% of pts completed the first 12-month observation period, 41% were ongoing, while 21% of pts discontinued. Most of the pts (~80%) had an ECOG score of 0 (35%) or 1 (46%). Early staging (I–II2), low to intermediate disease risk (IPI 0-2), and known B symptoms were reported for 55%, 50%, and 30% of pts, respectively. CR rate at the end of treatment was 57% (defined as the revised response criteria for malignant lymphoma by Cheson et al, 2007 that excludes complete remission/unconfirmed [CRu]). Summary of efficacy is reported in the Table. Overall, 83% of pts experienced AEs, the most common being anemia (23%), fatigue (21%), and polyneuropathy (15%). Treatment-related AEs were reported for 28% of pts. Rates of any serious AEs (SAEs) and treatment-related SAEs were 37% and 6.5%, respectively. On-treatment deaths and all deaths were reported in 2.4% and 4.7% of pts, respectively. **Conclusions:** REFLECT is the first prospective post-approval study to evaluate a rituximab biosimilar as a curative therapy in untreated pts with DLBCL. This interim analysis results re-confirms the expected safety and efficacy profile for DLBCL patients treated with R-CHOP. Research Sponsor: Sandoz Group, a Novartis Division.

Summary of response.

Response (%)	All patients (N = 170)
ORR	88%
CR	57%
PR	31%
Not available	3%
Missing	9%

8061 Poster Session (Board #394), Fri, 8:00 AM-11:00 AM

Clinicopathologic features and outcomes of de novo transformed indolent lymphoma. *First Author: Collin K Chin, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Untreated transformed indolent lymphoma (unTIL) can present as a composite lymphoma (COM), 2 or more separate sites of disease with one site transformed (discordant; DIS) or following indolent lymphoma sequentially (SEQ). Current practices are guided by small retrospective studies or extrapolated from trials involving non-transformed lymphomas. **Methods:** 353 patients (pts) with biopsy-proven unTIL treated with curative chemoimmunotherapy between 01/2000 to 01/2019 were included (intention to treat). All indolent B-cell lymphomas (iNHL) were included except CLL/SLL. Patients with MCL and non-DLBCL transformation were excluded. Prior therapy for iNHL was not allowed except one line of non-chemotherapy-based therapy. Kaplan-Meier method was used for time-to-event analysis including progression-free (PFS) and overall survival (OS). **Results:** 252 (71%) pts presented with COM, 50 (14%) DIS and 51 (14%) SEQ lymphoma. The underlying iNHL was: 308 (87%) follicular lymphoma, 37 (10%) nodal MZL, 7 (2%) MALT lymphoma, and 1 (0.3%) WM. Frontline therapy (FLT) included: RCHOP for 271 (77%), DAEPOCHR for 60 (17%), clinical trial for 7 (2%), BR for 4 (1%), RHCVAD for 2 (1%), RCEOP for 2 (1%), radiation therapy for 2 (1%), RFND for (1%) 2, RCVP for 2 (1%), and rituximab only for 1 (0.3%). 9 (3%) pts had ASCT in first remission. 50 (15%) pts received maintenance rituximab (MR) with fewer cases of HGBL-DH compared to the non-MR cohort (0% *v* 10%). With a median follow-up of 3.4 years (range 0.1-19.1), 4-year PFS and OS rates were 59% and 88%. By univariate analysis (UVA) the underlying type of iNHL, cell-of-origin and choice of induction therapy (DAEPOCHR *v* RCHOP) were not associated with inferior outcomes. SEQ transformations were associated with inferior OS on UVA ($P = 0.02$) which was not significant on multivariable analysis (MVA) ($P = 0.3$). MVA identified ECOG PS $>$ 1, B symptoms and HGBL-DH as independent prognostic factors for inferior PFS and OS. In patients who achieved PR or greater following FLT, MR was associated with improved PFS on MVA (HR 0.6, 95% CI 0.3-0.9, $P = 0.04$) without an OS benefit ($P = 0.2$). 39 (31%) pts relapsed with iNHL only (mPFS 2.4 yrs, 4-yr OS 94%) and 88 (69%) relapsed with transformed lymphoma (mPFS 1.1 yrs, 4-yr OS 69%) with no significant difference in pattern of relapse with MR ($P = 0.2$). **Conclusions:** The clinicopathologic features of unTIL are similar to those of *de novo* DLBCL. Escalation of therapy beyond R-CHOP may not be required in the absence of HGBL-DH. unTIL should be included in future clinical trials involving *de novo* DLBCL given the similar clinicopathologic features. Research Sponsor: None.

8062 Poster Session (Board #395), Fri, 8:00 AM-11:00 AM

Alternative anti-CD20 antibody versus desensitization for lymphoma patients with drug hypersensitivity reactions requiring discontinuation of rituximab, obinutuzumab, or ofatumumab. *First Author: Paola Ghione, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immunotherapy with anti CD20 is often associated with mild easily manageable infusion reactions. In rare cases, patients experience severe drug hypersensitivity reactions (DHR) serum sickness or anaphylaxis. These in turn may lead to discontinuation of the drug. In our experience, switching to a different anti-CD20 agent is a feasible alternative to discontinuation or desensitization protocols. **Methods:** From our pharmacology database we identified all the patients that received rituximab and/or obinutuzumab, and/or ofatumumab, and/or all the patients who received a flat dose of less than 50 mL of the same drugs and were followed at our institution. From the medical record, we identified all the cases where the anti-CD20 antibody was changed due to allergy, serum sickness or other types of DHR, and all those who received minimal doses of anti-CD20 in the context of a desensitization protocol. DHRs were evaluated either by an allergist, or by retrospective review following the World Allergy Organization guidelines. Our primary comparison, was to assess the proportion of pts able to completed planned infusion of abs using either approach (Fisher's exact Test). **Results:** Among 343 patients receiving at least two different anti-CD20 antibodies or a flat dose of $<$ 50 mL, we identified 44 patients experiencing severe DHRs needing intervention. At the time of the reaction, 16 (36%) received the anti-CD20 as single agent, 24 (54%) in combination with chemotherapy, 4 (9%) in combination with ibrutinib or lenalidomide. In 9 (20%) patients the reaction was defined as anaphylactoid (8 rituximab; 1 obinutuzumab) and in 8 (18%) patients, all receiving rituximab, as serum sickness. Episodes of DHR were addressed with either desensitization (n = 29) or change of anti-CD20 agent (n = 25), 9 patients received both of these approaches, one patient switched anti-CD20 antibodies twice. Overall, 21 desensitizations were successful (72.4%), 8 failed; 23 changes of anti-CD20 were successful (92%) and 2 failed ($p = 0.09$). **Conclusions:** In patients with DHR use of an alternative anti-CD20 antibody is safe and is an alternative or complementary approach to anti-CD20 desensitization. Research Sponsor: None.

8063 Poster Session (Board #396), Fri, 8:00 AM-11:00 AM

CNS involvement by North American-ATLL (NA-ATLL) is associated with discrete patterns and molecular profile involving XPO1 E571 and KLF2/PI3KCD in selected cases. *First Author: Nishi Shah, Montefiore Einstein Center for Cancer Care, Bronx, NY*

Background: Information on central nervous system (CNS) involvement with NA-ATLL is limited. In this study, we describe CNS involvement in ATLL patients at a tertiary hospital in New York City. **Methods:** We considered CNS involvement if one of the following criteria was met 1) cerebrospinal fluid (CSF) cytology or flow cytometry was positive 2) CNS imaging was positive for disease involvement or 3) Physical exam findings were compatible with neurologic involvement. **Results:** Of 94 NA-ATLL patients, 21 (22.3%) had CNS involvement by ATLL. CSF was involved in 13/21 and 5/21 patients at diagnosis and relapse respectively. At diagnosis, MRI showed CNS involvement in brain and spine in 5/21 (24%) and 3/21 (14%) cases respectively. At relapse, imaging revealed brain and spine involvement in 2 patients each. Neurological exam was abnormal in 7 (33%) and 3 (14%) cases at diagnosis and relapse respectively. Next generation exon targeted sequencing was performed in 9 cases. Table shows the mutations (mtn) and functional groups with frequencies. XPO1 E571K mutation was present in 2 patients with extensive CNS disease and refractory to conventional treatment with an overall survival (OS) of 2 months. To our knowledge, this is the first time that XPO1 E571K is reported in a T-Cell malignancy. We also describe here a second set of mutations with CNS involvement (KLF2 and PI3KCD) in 2 patients. Median OS was 8.5 months, Median RFS was 6.5 months in our series. In most cases, the lymphomatous phenotype appeared to have direct mass-like extension (5/21) with several cases of accompanying osteolytic spine or skull lesions, whereas cases with hematogenous involvement tends to spread to the CSF by traversing the brain blood barrier. **Conclusions:** In this report we describe patterns of CNS involvement in ATLL and the associated mtns. We also describe two unique cases of XPO1E571K mtn in a TCL. Research Sponsor: None.

Safety of acalabrutinib (Acala) monotherapy in hematologic malignancies: Pooled analysis from clinical trials. *First Author: Richard R. Furman, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY*

Background: Acala is a next-generation, highly selective, covalent Bruton tyrosine kinase inhibitor approved in the US for patients (pts) with chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) and previously treated mantle cell lymphoma (MCL). We evaluated the safety profile of acala monotherapy (monotx) in multiple B cell malignancies. **Methods:** Data from pts with activated B-cell diffuse large B-cell lymphoma, CLL, follicular lymphoma, MCL, multiple myeloma, prolymphocytic leukemia, Richter syndrome, SLL, or Waldenström macroglobulinemia treated with ≥1 dose of acala monotx in 9 studies were pooled. Acala was administered at 100 mg BID in most pts (100–400 mg total dose daily). Adverse events (AE) were assessed. **Results:** A total of 1040 pts were included (median age: 67 y [range: 32–90]; ECOG status ≤1: 93%; median exposure duration: 24.6 mo [range: 0–58.5]). A total of 360 (34%) pts discontinued acala, most commonly due to progressive disease (PD; 17%). AEs led to acala discontinuation in 97 (9%) pts; those in > 2 pts were pneumonia (n = 5) and thrombocytopenia (n = 4). Incidence of AEs, including the most common (any grade and grade ≥3), are shown in the Table. Events of clinical interest (ECIs) included atrial fibrillation (afib) of any grade in 46 (4%) pts and grade ≥3 in 13 (1%) pts; major hemorrhage (any grade) in 37 (4%) pts; grade ≥3 infection in 183 (18%) pts; hypertension (any grade) in 79 (8%) pts and grade ≥3 in 36 (4%) pts; and second primary malignancies (SPM) excluding non-melanoma skin cancer (NMSC; any grade) in 68 (7%) pts. Median (range) time to first onset in days for each ECI (any grade) was: afib, 522 (8–1280); major hemorrhage, 293 (4–1327); infections, 92 (1–1317); hypertension, 157 (2–1345); SPM excluding NMSC, 339 (7–1499). Death was reported in 139 (13%) pts, most commonly due to PD (6%) and AEs (5%). **Conclusions:** Acala monotx has a favorable tolerability profile with increased exposure across multiple mature B cell malignancies. Additional analyses will further explore the longitudinal characteristics of AEs. Research Sponsor: Acerta Pharma, a member of the AstraZeneca group.

Incidence of any AEs, serious AEs, and most common AEs (any grade occurring in ≥15% of pts and grade ≥3 occurring in ≥5% of pts).

	Any Grade, n (%)	Grade ≥3, n (%)

8065 Poster Session (Board #398), Fri, 8:00 AM-11:00 AM

A phase I/II study to assess safety and dose of ixazomib in combination with cyclophosphamide and dexamethasone in newly diagnosed patients with light chain (AL) amyloidosis. *First Author: Keren Osman, Rockefeller Univ, New York, NY*

Background: AL amyloidosis is an incurable clonal plasma cell disorder characterized by tissue deposits of immunoglobulin light chain fragments leading to organ dysfunction and death. Standard treatment for newly diagnosed patients (pts) has traditionally included oral melphalan + dexamethasone as well as high-dose melphalan + ASCT. Here we report preliminary results of a Phase 1/2, open-label, multi-institution study of ixazomib (I) in combination with cyclophosphamide (Cy) and dexamethasone (D) in newly diagnosed AL amyloidosis. **Methods:** Eligible pts are ≥18 years with newly diagnosed, untreated biopsy-proven AL amyloidosis. A total of up to 30 pts will be enrolled, with up to 18 in the dose escalation arm (phase 1) and 12 in the maximum tolerated dose (MTD) expansion arm (phase 2) according to a classical 3+3 design. Four dose levels were evaluated in phase 1. I and Cy are given orally (PO) on days 1, 8, 15, and D 20mg PO on days 1, 8, 15, 22 of each 28-day cycle. Treatment continues for a total of 6 cycles or until disease progression, significant toxicity or withdrawal. The primary study objective in phase 1 is to establish the MTD and in phase 2 is to determine hematologic/organ response rate. **Results:** As of February 2020, 120 pts have been enrolled; 16 in phase 1 and 4 in phase 2. The MTD was established at dose level 3 (I 4mg and Cy 500mg). Median age is 65 years (range 46-79), 12 (67%) are male. Light chain isotype is lambda in 14 (78%). Seven pts (39%) have cardiac, 10 (56%) renal, 4 (22%) gastrointestinal, 1 (6%) hepatic, 2 (11%) soft tissue involvement, with 22% having multi-organ involvement. Four pts (22%) completed 6 cycles of therapy and 6 (33%) remain on study with a median of 3 cycles completed. Eight of 16 pts (50%) had at least 1 drug-related adverse event (AE) (any grade), most commonly edema (19%), fatigue (19%), dizziness/lightheadedness (13%) and lymphopenia (13%). Grade 3/4 AEs were rare with grade 3 lymphopenia, anemia, and hyponatremia occurring in 13%, 6%, and 6% of pts, respectively. Of 18 evaluable pts, 7 (39%) achieved ≥VGPR with the median time to best response 2 cycles (1-5). **Conclusions:** The combination of ICyD for pts with newly diagnosed AL amyloidosis is safe and well tolerated. Phase 1 is completed and the recommended phase 2 dose has been established. Deep hematologic responses (≥VGPR) have occurred and time to response appears similar to standard of care induction regimens, ie CyBorD. Phase 2 response data will be updated at the meeting. Research Sponsor: Takeda.

TPS8066 Poster Session (Board #399), Fri, 8:00 AM-11:00 AM

Trial in progress: a phase II, multicenter, single-arm study of zanubrutinib (BGB-3111) in patients with previously treated chronic lymphocytic leukemia/small lymphocytic lymphoma intolerant of prior treatment with ibrutinib. *First Author: Ian Flinn, Sarah Cannon Research Institute/ Tennessee Oncology, Nashville, TN*

Background: Ibrutinib (ibr), a Bruton tyrosine kinase inhibitor (BTKi), was shown to improve patient outcomes in chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL); however, adverse events (AEs) were the most common reason for discontinuing ibr (50% and 63% of discontinuations in relapse/refractory (R/R) and frontline patients, respectively; *Haematologica.* 2018:103:874). Zanubrutinib, an approved BTKi for mantle cell lymphoma, was specifically engineered to optimize selectivity. Pooled clinical data from 6 zanubrutinib monotherapy trials in B-cell malignancies (N=682 patients; R/R CLL/SLL [n=91]) suggested that zanubrutinib monotherapy was well tolerated and demonstrated a low rate of treatment discontinuation from AEs (9%; Tam, EHA 2019). Presented here is a trial-in-progress that will evaluate whether zanubrutinib monotherapy may serve as a therapeutic option for patients with CLL/SLL who have become ibr intolerant. **Methods:** The ongoing phase II, multicenter, US, single-arm, open-label study (NCT04116437, BGB-3111-215) will evaluate zanubrutinib monotherapy (160mg twice daily) as a treatment option for patients with CLL/SLL intolerant to prior ibr treatment. Approximately 60 patients will be enrolled from ~30 community medical centers. Key inclusion criteria include CLL/SLL requiring treatment per International Workshop on CLL criteria (*Blood.* 2018;131:2745) before ibr therapy, intolerance to ibr (defined as an unacceptable AE for which, per investigator's opinion, ibr treatment should be discontinued despite optimal supportive therapy), resolution of ibr-related AEs to grade ≤1 or baseline, and an ECOG PS 0-2. Key exclusion criteria include having an intervening cancer therapy between ibr and zanubrutinib, a documented disease progression during ibr treatment up to the time of enrollment, and a history of central nervous system (CNS) hemorrhage. The primary endpoint is frequency and severity of protocol-specified treatment-emergent AEs (diarrhea, myalgia, muscle spasm, arthralgia, hypertension, fatigue, rash, atrial fibrillation, and hemorrhage excluding CNS hemorrhage). The secondary endpoints include overall response rate, progression-free survival, and patient-reported outcomes. An exploratory endpoint was added to evaluate clinical effects (physical activity, treatment-related symptoms, and quality of life) using a smartphone app. Recruitment is ongoing. Clinical trial information: NCT04116437. Research Sponsor: BeiGene.

TPS8067 Poster Session (Board #400), Fri, 8:00 AM-11:00 AM

An intergroup collaboration for advanced stage classical Hodgkin lymphoma (cHL) in adolescents and young adults (AYA): SWOG S1826. *First Author: Sharon M. Castellino, Emory University, Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: Treatment for pediatric cHL varies considerably from that in adult cHL. Hence there are gaps in risk prediction and optimal therapy for de-novo advanced stage disease across the adolescent and young adult (AYA) age spectrum. Early access to novel agents for AYA could be facilitated via collaboration with adult research groups through the U.S. National Cancer Institute's National Clinical Trials Network (NCTN). The PD-1 inhibitor Nivolumab (Nivo) has safety and efficacy in relapsed and refractory disease in children and adults, but has not been evaluated in de-novo disease to date. **Methods:** North American cooperative group lymphoma chairs, Cancer Therapy Evaluation Program (CTEP) representatives and patient advocates met to establish consensus on the comparison arms and study design, based on recent historical approaches across adult and pediatric groups. Study champions were identified across North American cooperative groups and include expertise in imaging, radiation oncology, biology and patient-reported outcomes. A therapeutic study was designed with the primary aim being to compare progression-free survival with novel targeted agents in advanced stage cHL. S1826 (NCT03907488), led by SWOG Cancer Research Network, opened to accrual in July 2019. Eligibility criteria include age > 12 years, and Stage III or IV cHL. Patients are randomized (1:1) to 6 cycles of either Nivo-Adriamycin, Vinblastine, Dacarbazine (AVD) or Brentuximab vedotin (Bv)-AVD. Enrollment is stratified by age, baseline International Prognostic Score, and provider intent to use involved site radiation therapy (ISRT). Protocol-prescribed ISRT is response-adapted, based on end of therapy imaging. The primary endpoint is a comparison of progression-free survival between arms. Secondary clinical endpoints include comparison of: overall survival, metabolic response at the end of therapy, physician-reported adverse events, patient-reported adverse events, and health-related quality of life (overall, and specific to fatigue and neuropathy). This unique intergroup collaboration demonstrates the process and the feasibility of consensus study designs toward early adoption of targeted therapies and harmonization of treatment approaches for AYA populations. Clinical trial information: NCT03907488. Research Sponsor: U.S. National Institutes of Health.

TPS8068 Poster Session (Board #401), Fri, 8:00 AM-11:00 AM

Brentuximab vedotin in combination with nivolumab, doxorubicin, and dacarbazine in newly diagnosed patients with advanced-stage Hodgkin lymphoma (Trial in Progress). *First Author: Judah D. Friedman, University Hospitals Seidman Cancer Center, Cleveland, OH*

Background: Brentuximab vedotin (BV, ADCETRIS) is approved for the treatment of adults with treatment-naïve Stage III or IV cHL in combination with AVD (Connors 2017). Nivolumab is approved for treatment of adults with relapsed/refractory cHL. Both agents have been well tolerated with promising activity when combined with multi-agent chemotherapy. The combination of BV plus nivolumab was evaluated as a frontline treatment option for patients (pts) with cHL who are over 60 years and ineligible for or declined conventional combination chemotherapy (Friedberg, 2018). The ongoing study reported an ORR of 82% in 11 pts and appears well tolerated in this population. In another trial in 93 patients in the first salvage setting, the combination produced a 67% CR rate (Herrera 2018, Moskowitz 2019) and the majority of patients were able to undergo subsequent stem cell transplant. It is reasonable to expect that the combination of BV, nivolumab, A, and D (AN + AD) will result in high response rates and be well tolerated, with potentially less toxicity. **Methods:** SGN35-027 (NCT03646123) is a phase 2 study designed to evaluate the efficacy and safety of A+AVD when administered with growth factor prophylaxis in pts with stage III/IV cHL (Part A). Part B will evaluate the combination of AN + AD in a similar patient population. The primary objective of Part B is to estimate the CR rate at EOT in pts with treatment-naïve advanced cHL. Patients in Part B will have Ann Arbor Stage IIB/III/IV cHL or Stage IIA cHL with bulky mediastinal disease. Enrollment is ongoing in both parts of the study. Approximately 50 pts will be enrolled in Part B. All pts will be treated with BV 1.2 mg/kg, nivolumab 240 mg, doxorubicin 25 mg/m^2, and dacarbazine 375 mg/m^2, administered separately by IV infusion on Days 1 and 15 of each 28-day cycle for up to 6 cycles. Efficacy will be assessed by PET/CT scans at C2 and EOT. Disease assessments will be performed periodically during follow up. Disease response and progression will be assessed using Lugano with the incorporation of LYRIC (Cheson 2016). Clinical trial information: NCT03646123. Research Sponsor: Seattle Genetics, Inc.

TPS8069 Poster Session (Board #402), Fri, 8:00 AM-11:00 AM

Frontline brentuximab vedotin in Hodgkin lymphoma and CD30-expressing peripheral T-cell lymphoma for older patients and those with comorbidities. *First Author: Christopher A. Yasenchak, Willamette Valley Cancer Institute and Research Center/US Oncology Research, Eugene, OR*

Background: Older patients and those with significant comorbidities have not attained outcomes seen in younger patients with classical Hodgkin lymphoma (cHL) and CD30-expressing peripheral T-cell lymphoma (PTCL). Five-year progression-free survival (PFS) was 30%–45% in older HL patients treated with combination chemotherapy versus 75%–80% in younger patients (Evens 2008; Proctor 2009). Similarly, when adjusted for age, a Charleston Comorbidity Index ≥2 was independently associated with worse overall survival (HR=1.63) and PFS (HR=1.54) (Ellin 2018). Brentuximab vedotin (BV, ADCETRIS), a CD30-directed antibody-drug conjugate, has robust activity in cHL patients refractory to several lines of chemotherapy. BV monotherapy in 27 cHL patients aged ≥60 years had a 92% objective response rate (ORR) and 73% achieved complete remission (Forero-Torres, 2015). BV was also active and well-tolerated in CD30-expressing PTCL patients with relapsed or refractory disease (Horwitz 2014). Frontline BV monotherapy may have the potential to be an active and well-tolerated treatment for cHL and PTCL patients who are older or have significant comorbidities, which are populations with high unmet need. **Methods:** This phase II, open-label study, SGN35-015 (NCT01716806), has added 2 cohorts to evaluate the efficacy and tolerability of BV monotherapy in treatment naive patients with cHL, (Part E), or CD30-expressing PTCL (Part F, n~50 each) who are unsuitable for conventional combination therapy due to comorbidity-related factors as determined by a Cumulative Illness Rating Scale (CIRS) score ≥10 or dependence on others for any instrumental activities of daily living. Eligible patients must also have an Eastern Cooperative Oncology Group (ECOG) performance status ≤3 and measurable disease ≥1.5 cm per radiographic techniques. BV (1.8 mg/kg) will be administered as a single intravenous infusion on day 1 of each 2-day cycle. Patients achieving a complete remission, partial remission, or stable disease will receive up to 16 cycles of treatment. Response will be assessed by blinded independent central review of spiral CT and PET scans at Cycles 2, 6, 11, and at end of treatment to be graded per Lugano 2014. The primary objective of these cohorts is to assess ORR of frontline therapy with single-agent BV in patients who have significant comorbidities. Clinical trial information: NCT01716806. Research Sponsor: Seattle Genetics.

TPS8070 Poster Session (Board #403), Fri, 8:00 AM-11:00 AM

POLARGO: Randomized Phase III study of polatuzumab vedotin plus rituximab, gemcitabine, and oxaliplatin (R-GemOx) in relapsed/refractory diffuse large B-cell lymphoma (R/R DLBCL). *First Author: Corinne Haioun, Lymphoïd Malignancies Unit, Groupe Hospitalier Henri Mondor, Créteil Cedex, France*

Background: The antibody-drug conjugate polatuzumab vedotin (pola; POLIVY) targets CD79b on B-cell malignancies. Pola plus bendamustine and rituximab (BR) has significantly improved efficacy vs BR alone in patients (pts) with R/R DLBCL. As a result, pola-BR was approved by the FDA for pts with R/R DLBCL after ≥2 prior therapies. This year, the EU granted conditional marketing authorization for pola-BR in pts with stem cell transplant (SCT)-ineligible R/R DLBCL. A range of therapies are used for R/R DLBCL; one recommended option is R-GemOx. Platinum-based chemotherapies such as oxaliplatin are a preferred salvage therapy. In the POLARGO study, the safety and efficacy of pola-R-GemOx vs R-GemOx alone will be assessed in pts with R/R DLBCL. **Methods:** POLARGO (MO40598; NCT04182204) is a multicenter, open-label, Phase III study, comprising a safety run-in stage (pola-R-GemOx; n=10) and a randomized controlled trial (RCT) stage (pola-R-GemOx vs R-GemOx alone; expected n=206). Pts must have histologically confirmed R/R DLBCL and ECOG PS of 0–2. Exclusion criteria include prior allogeneic SCT and/or planned autologous/allogeneic SCT, and baseline grade >1 peripheral neuropathy (PN). Pts in the RCT stage will be recruited from 80–90 sites globally. The primary endpoint of the safety run-in stage is the safety and tolerability of pola-R-GemOx (pola, 1.8mg/kg; R, 375mg/m^2; Gem, 1000mg/m^2; Ox, 100mg/m^2) administered in 21-day cycles, with a focus on PN. In the RCT stage, pts will be stratified by number of prior lines of therapy, outcome of last systemic therapy and age, and randomized (1:1) to receive up to eight 21-day cycles of pola-R-GemOx or R-GemOx. The RCT stage primary endpoint is overall survival. Key secondary endpoints are independent review committee-assessed complete response (CR) and objective response rate (ORR; Lugano 2014 criteria). Other secondary efficacy endpoints include investigator-assessed best overall response, CR rate and ORR. Safety and health-related quality of life during treatment will be assessed. PET-CT and CT scans will be obtained at screening, during, and after the treatment period; follow-up will continue for up to 2 years. POLARGO is currently open and recruiting. Acknowledgment: POLARGO is sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of Prof. Haioun, Dr McMillan and Dr Hernandez, was provided by Lucinda Sinclair of Gardiner-Caldwell Communications and was funded by F. Hoffmann-La Roche Ltd. Clinical trial information: NCT04182204. Research Sponsor: F. Hoffmann-La Roche Ltd.

TPS8071 Poster Session (Board #404), Fri, 8:00 AM-11:00 AM

Trial in progress: A phase III, randomized, open-label study comparing zanubrutinib plus rituximab versus bendamustine plus rituximab in patients with previously untreated mantle cell lymphoma (MCL). *First Author: Martin H. Dreyling, University Hospital Großhadern, Ludwig Maximilians-University, Munich, Germany*

Background: Bruton tyrosine kinase (BTK) mediates B-cell proliferation, migration, and adhesion. BTK inhibition has emerged as a strategy for targeting B-cell malignancies, including MCL. Zanubrutinib is a next-generation BTK inhibitor that was designed to maximize BTK occupancy and minimize off-target inhibition of TEC- and EGFR-family kinases, with favorable pharmacokinetic and pharmacodynamic properties. Zanubrutinib monotherapy has been evaluated in 118 patients (pts) with relapsed/refractory MCL in 2 single-arm studies: BGB-3111-206 [NCT03206970] and BGB-3111-AU-003 [NCT02343120]. The overall response rate (ORR) by independent review committee (IRC) in both trials was 84% with median durations of response of 19.5 and 18.5 months, respectively. First-line treatment for MCL has failed to cure most pts, particularly elderly or transplant-ineligible groups, and chemotherapy-based approaches result in cumulative, long-term risks. The study described herein is designed to evaluate the safety and efficacy of zanubrutinib plus rituximab versus bendamustine plus rituximab in elderly pts and pts with comorbidities with previously untreated MCL who are ineligible for stem cell transplant. **Methods:** This ongoing phase 3, open-label study will enroll ≈500 pts to be randomized 1:1, stratified by MCL International Prognostic Index score (low vs intermediate/high), age (< 70 vs ≥70 years), and geographic region (North America/Europe vs Asia-Pacific). In arm A, pts will receive up to six 28-day cycles of oral zanubrutinib 160 mg twice daily in combination with intravenous (IV) rituximab 375 mg/m^2 on day 1 of each cycle. After 6 cycles, zanubrutinib will continue as a monotherapy until progressive disease, unacceptable toxicity, or withdrawal of consent. In arm B, pts will receive up to six 28-day cycles of IV bendamustine 90 mg/m^2 on days 1 and 2 of each cycle and rituximab 375 mg/m^2 on day 1 of each cycle, followed by observation. Eligible pts must have histologically confirmed MCL and be aged ≥70 years, or 65-69 years with defined comorbidities. Disease response will be assessed per the 2014 Lugano Classification for non-Hodgkin lymphoma. The primary endpoint is progression-free survival (PFS) determined by IRC. Key secondary end points include PFS by investigator assessment, ORR, time to and duration of response, overall survival, and safety. Recruitment is ongoing. Clinical trial information: NCT04002297. Research Sponsor: BeiGene.

TPS8072 Poster Session (Board #405), Fri, 8:00 AM-11:00 AM

A phase I and randomized phase II etctn study of KW-0761 (Mogamulizumab) and MK-3475 (Pembrolizumab) in relapsed and refractory diffuse large B-cell lymphoma. *First Author: Erel Joffe, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Diffuse large B-cell lymphoma (DLBCL) escapes host immune responses via inhibition of the B2M and CD58 pathways and upregulation of PD-1 ligands. However, treatment results with PD-1 blockade have been disappointing. One potential mechanism is the recruitment of intra-tumoral regulatory T-cells (Tregs) which suppress anti-tumor immunity and inhibit NK cell cytotoxicity. Targeting regulatory T cells with the CCR4 antibody mogamulizumab (KW-0761) represents a molecularly informed strategy to overcome this resistance. Mogamulizumab has been safely administered in combination with pembrolizumab (MK-3475) in patients with solid malignancies and may promote CD8 T-cell dependent effector and NK cell-dependent cytotoxicity in lymphomas. **Methods:** This is a multi-center NIH-ETCTN phase Ib/randomized phase II study. The phase I will evaluate the safety and tolerability of mogamulizumab in combination with pembrolizumab in patients with R/R DLBCL and determine the recommended phase II dose (RP2D). A traditional 3+3 design with a starting dose of pembrolizumab 200mg IV on day 1 of a 21-day cycle and mogamulizumab 1mg/kg IV on days 1, 8, 15 and then 1.5 mg/kg IV every 21 days. The phase II will evaluate the efficacy of the combination by PFS (primary endpoint) ORR and CR (secondary endpoints). This will be a randomized 1:1 study with allowed crossover, comparing the combination to single agent pembrolizumab Correlative studies will evaluate the association of tumor infiltrating CD8 and NK cells with response to treatment, somatic mutations in B2M and CD58 and with MHC-I expression on DLBCL cells. Functional characterization of circulating immune cells in the peripheral blood and measurement of pro and anti-inflammatory cytokines will be used to assess the levels, activation status and effector function of Tregs and circulating T cells. Inclusion criteria include measurable disease, $\geq$2 prior lines of therapy including or ineligible for autologous stem cell transplant, ECOG $\leq$ 2 and normal organ function. Prior or planned allogeneic stem cell transplant, as well as prior treatment with an anti PD-1/PD-L1/CTLA4 antibody, preexisting autoimmune disease or CNS involvement by lymphoma are exclusion criteria. The study aims to enroll up to 12 patients on the phase I and up to 58 patients on the phase II and can be opened at any ETCTN participating site. To date it has been opened at two sites and is accruing the first patients for the phase I portion. Clinical trial information: NCT03309878. Research Sponsor: U.S. National Institutes of Health.

TPS8073 Poster Session (Board #406), Fri, 8:00 AM-11:00 AM

Phase I/II study of R-ICE (rituximab-ifosfamide-carboplatin-etoposide) with lenalidomide (R2-ICE) in patients with first-relapse/primary refractory diffuse large B-cell lymphoma (DLBCL) in academic and community cancer research united (ACCRU) network. *First Author: Francis Guerra-Bauman, Mayo Clinic, Rochester, MN*

Background: Response rates to salvage immunochemotherapy in patients with DLBCL relapsing after or refractory (R/R DLBCL) to front line therapy remain unsatisfactory. Lenalidomide (Len) has significant single agent activity in relapsed/refractory DLBCL. The addition of lenalidomide (Len) days 1-7 to rituximab plus ifosfamide-carboplatin-etoposide (RICE) was shown to be feasible with promising efficacy in phase 1b study (Feldman T, et al. BJH, 2014). We developed phase I/II study to evaluate the safety and efficacy of the addition of Len (extended to 14 day schedule) to RICE (R2-ICE) for R/R-DLBCL patients who are candidates for stem cell transplant. **Methods:** The phase I portion was designed to determine the maximally tolerated dose Len in combination with RICE using the standard cohort 3+3 design. The escalation dose levels were 15 mg and 20 mg daily x 14 days. Prophylactic aspirin and growth factor support is mandatory. After 2 cycles of therapy response is evaluated with a PET/CT scan; the responding patients are eligible for 1-2 additional cycles of R2ICE as a bridging before HDC/SCT. The estimated overall response rate for two cycles of R-ICE in R/R DLBCL to RCHOP was estimated to be approximate 45%. We hypothesize that the addition of lenalidomide in the relapse setting could increase the overall response rate by approximately 20%. The one-stage design with an interim analysis being utilized in phase 2 requires 45 evaluable patients (one sided alpha = 0.09, power 90%). For Phase I, all types of B-cell lymphomas were eligible. For phase II portion only DLBCL patients are eligible per central pathology review. Other eligibility criteria include: received one line of previous anti-lymphoma therapy, $\geq$ 2 weeks from completion of prior anti-lymphoma therapy, candidate for HDC and SCT, adequate organ (creatinine clearance $\geq$ 60ml/min by Cockcroft-, total bilirubin $\leq 2 \times$ ULN) and bone marrow function (ANC) $\geq$1500/mm^3; platelet count $\geq$75,000/mm3). The use of steroids and/or rituximab up to 1 week prior to registration for management of symptoms is allowed. 9 patients cleared phase 1 without DLT and dose of 20 mg days 1 -14 was recommend for phase 2 part (RP2D) of the study. The phase 2 study passed interim futility analysis and accrual continues. Correlatives include cell of origin by Nanostring, Myc/bcl2 expression and by FISH and minimal residual disease. PET scans are centrally reviewed including metabolic tumor volume. Clinical trial information: NCT02628405. Research Sponsor: Celgene/BMS.

TPS8074 Poster Session (Board #407), Fri, 8:00 AM-11:00 AM

A phase II study of MT-3724, a novel CD20-targeting engineered toxin body, to evaluate safety, pharmacodynamics, and efficacy in subjects with relapsed or refractory diffuse large B-cell lymphoma. *First Author: Adolfo Enrique Diaz Duque, University of Texas Health at San Antonio, San Antonio, TX*

Background: Engineered toxin bodies (ETBs) are comprised of a proprietarily engineered form of Shiga-like Toxin A subunit (SLT-A) genetically fused to antibody-like binding domains. ETBs work through novel mechanisms of action and are capable of forcing internalization, self-routing through intracellular compartments to the cytosol, and inducing potent cell-kill via the enzymatic and permanent inactivation of ribosomes. MT-3724 represents a novel ETB modality comprised of an anti-CD20 single-chain variable fragment genetically fused to SLT-A. It is capable of efficient internalization once bound to CD20 and can induce potent direct cell-kill via enzymatic ribosome inactivation. MT-3724 is currently being studied in three ongoing Phase 2 studies for relapsed or refractory diffuse large B-cell lymphoma (r/rDLBCL). **Methods:** The primary objective of this single-arm, Phase 2 study (NCT02361346) is to determine the efficacy of MT-3724 monotherapy in r/rDLBCL based on overall response rate (ORR), defined as the proportion of subjects with a complete/partial response according to the Lugano criteria, as assessed by independent, central review. Key secondary objectives include safety, progression-free survival, investigator-assessed ORR, duration of response, overall survival, and pharmacodynamics. Adverse events will be assessed and documented according to Common Terminology Criteria for Adverse Events version 5.0. Key eligibility criteria include adult subjects with histologically confirmed, r/rDLBCL, with $\geq$2 prior standard of care systemic NHL treatment regimens, and $\geq$1 measurable lesion. As rituximab and other CD20-targeting antibodies compete with MT-3724 for the same CD20 domain, minimum washout periods from these agents must be observed. Subjects remain eligible post stem cell transplant or chimeric antigen receptor T-cell therapy. Subjects will receive 50 μg/kg MT-3724 IV over 1 hour on Days 1, 3, 5, 8, 10 and 12 of a 21-day treatment cycle. The anticipated sample size is N = 100. Interim analyses will be performed to confirm minimum efficacy thresholds based on the encouraging data observed in the completed phase 1 portion of the study [Hamlin et al. Blood 2019;134(Suppl 1):4098]. Multiple global sites are enrolling subjects. Clinical trial information: NCT02361346. Research Sponsor: Molecular Templates, Inc.

TPS8075 Poster Session (Board #408), Fri, 8:00 AM-11:00 AM

Phase I study of radiotherapy (RT) & durvalumab in relapsed/refractory diffuse large B-cell lymphoma (DLBCL) & follicular lymphoma (FL): The RADD study. *First Author: Eliza Anne Hawkes, Austin Health and Olivia Newton-John Cancer Research Institute, Heidelberg, Australia*

Background: Most DLBCL & FL responds well to first line treatment, yet relapsed disease outcomes are poor. PD1/PDL1 inhibitors yield high response rates in some lymphomas, but single agent therapy in heavily pretreated pts are disappointing. RT stimulates anti-tumor immunity through several mechanisms and may enhance response to immune checkpoint inhibition (ICI). Concurrent ICI & RT is synergistic in preclinical studies & solid tumors, improving local & distant (abscopal) response. RT to multiple disease sites may broaden the spectrum of tumor antigen release and overcome clonal variation between disease sites to further augment the immune response. **Methods:** RaDD (NCT03610061) is a phase I, 3+3 dose escalation study to determine the safety profile of escalating dose & number of sites of RT in combination with Durvalumab (anti-PD-L1 antibody) in RR DLBCL & FL. Eligible pts (i.e. $\geq$1 prior therapy, ineligible for auto-SCT, no contraindication to PDL1i) receive 5 fractions of external beam RT to target site(s). 5 RT dose & site levels are included (dose range 2.5Gy-20Gy to 1-3 sites). Durvalumab 1500mg IV commences day 2 of RT and continues 4-weekly until confirmed disease progression. The DLT period is 28 days from start of RT. Primary endpoint is the recommended phase two dose (RP2D) of RT in combination with durvalumab. Secondary endpoints include response rates, PFS & OS. Correlative studies will examine the tumour-immune system interaction; an exploratory PET substudy with novel tracers for durvalumab (^{89}Zr-Durvalumab) & CD8+ T cells (^{89}Zr -Df-IAB22M2C) will also be performed. Projected enrollment for determination of maximum tolerated dose (MTD) & RP2D is 6-30 pts pending toxicity. Recruitment will continue to 36 pts for secondary endpoint analysis. 9 pts are enrolled across cohorts 1-3 to date. Clinical trial information: NCT03610061. Research Sponsor: Victorian Cancer Agency (grant funding - TRP16006), Pharmaceutical/Biotech Company.

8500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

First-in-human phase I study of the novel CELMoD agent CC-92480 combined with dexamethasone (DEX) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: CC-92480 is a novel cereblon E3 ligase modulator (CELMoD) agent designed for rapid, maximal degradation of Ikaros and Aiolos. In vitro, it has enhanced antiproliferative and tumoricidal activity in MM cell lines, including those resistant to lenalidomide (LEN) and pomalidomide (POM), with strong immune stimulatory activity. **Methods:** A phase 1, multicenter, dose-escalation study evaluated the maximum tolerated dose (MTD), recommended phase 2 dose, safety, tolerability, and pharmacokinetics of CC-92480 + DEX in heavily pretreated RRMM pts. Eligible pts had progression on or within 60 days of their last MM therapy and were either resistant or intolerant to, or not otherwise candidates for currently available therapies. Several treatment schedules tested escalating doses of CC-92480 + DEX (40 mg; 20 mg if ≥75 yrs). **Results:** As of Dec 24, 2019, 66 pts had received CC-92480 + DEX. Median age was 67 yrs (range 40–78), median number of prior regimens was 6 (range 2–13). Prior therapies included stem cell transplantation (67%), bortezomib (92%), LEN (89%), POM (83%), and anti-CD38 antibodies (78%). CC-92480 doses explored included 0.1–1.0 mg QD (10/14 days × 2), 0.8–1.0 mg QD (21/28 days), 0.2–0.8 mg BID (3/14 days × 2), and 1.6–2.0 mg QD (7/14 days × 2). MTD was 1.0 mg for both 10/14 × 2 and 21/28 schedules. Grade 3–4 treatment-emergent adverse events (TEAEs) were reported in 58 (88%) pts. Most frequent grade 3–4 TEAEs included neutropenia (53%), infections (30%), anemia (29%), and thrombocytopenia (17%), with 9% grade 3 fatigue. Among different cohorts, 10 pts had dose-limiting toxicities (the majority related to neutropenia). Overall response rate (ORR) was 21% (9 very good partial responses [VGPRs]; 5 PRs) for efficacy evaluable population (n = 66). Efficacy was dose and schedule dependent; across two 1.0 mg QD schedules (10/14 × 2 and 21/28), 10 of 21 (48%) pts responded (7 VGPR and 3 PR), with response independent of immunomodulatory drug (IMiD) refractoriness. Plasma exposure increase and peripheral blood Ikaros and Aiolos degradation were dose dependent. Ikaros and Aiolos significantly decreased in bone marrow plasma cells of LEN- and POM-refractory pts. **Conclusions:** TEAEs of CC-92480 were mainly related to myelosuppression in heavily pretreated, including triple-class-refractory, RRMM pts. Promising activity with 48% ORR at therapeutic doses was observed. The study is ongoing to further optimize dose and schedule, with combination studies underway and dose expansion cohorts planned. Clinical trial information: NCT03374085. Research Sponsor: Bristol-Myers Squibb.

8501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Weekly selinexor, bortezomib, and dexamethasone (SVd) versus twice weekly bortezomib and dexamethasone (Vd) in patients with multiple myeloma (MM) after one to three prior therapies: Initial results of the phase III BOSTON study. *First Author: Meletios A. Dimopoulos, National and Kapodistrian University of Athens School of Medicine, Athens, Greece*

Background: Selinexor is an oral, selective inhibitor of XPO1-mediated nuclear export, leading to the reactivation of tumor suppressor proteins. In a phase 1b/2 study, the combination of once weekly (QW) selinexor with bortezomib and dexamethasone (SVd) was well tolerated with anti-MM activity in patients (pts) with PI-sensitive and PI-refractory disease. While twice weekly (BIW) bortezomib in combination therapy is efficacious, prolonged use is limited due to peripheral neuropathy (PN, 50-60%). The BOSTON study was designed to determine if SVd improves progression free survival (PFS), overall response rates (ORR) and reduces the rate of PN vs Vd. **Methods:** BOSTON is a global, phase 3, randomized study of QW SVd vs BIW Vd after 1-3 prior anti-MM regimens. The primary endpoint is PFS. Secondary endpoints include ORR, overall survival (OS) and PN (rates and EORTC QLQ-CIPN20 outcomes). Randomization is stratified by treatment with prior PI therapies, number of prior anti-MM regimens (1 vs > 1), and Revised International Staging System (R-ISS; Stage III vs I or II). Following confirmation of progressive disease, pts on Vd could cross over to either: 1) SVd for pts able to tolerate continued bortezomib or 2) selinexor and dexamethasone for pts with bortezomib intolerance. **Results:**402 pts were enrolled; 195 and 207 to SVd and Vd, respectively. Median age was 67 (range: 38-90). Most (59.6%) pts were > 65 years and 57.1% were male. R-ISS stage at the time of MM diagnosis was III for 18.5% of pts. Baseline characteristics were balanced across the 2 arms. SVd significantly prolonged PFS vs Vd (median 13.93 vs 9.46 months, HR = 0.70, P = 0.0066). SVd was associated with a significantly higher ORR (76.4% vs 62.3%, P = 0.0012). Median OS was not reached on SVd vs 25 months on Vd (P = 0.28). Most frequent treatment-related adverse events (grade ≥3) for SVd vs Vd were thrombocytopenia (35.9% vs 15.2%), fatigue (11.3% vs 0.5%) and nausea (7.7% vs 0%). Clinically important differences were reported on the motor, autonomic and sensory scales on CIPN20. PN rates (grade ≥2) were significantly lower with SVd vs Vd (21.0% vs 34.3%, P = 0.0013). **Conclusions:** BOSTON is the first phase 3 study to evaluate the clinical benefit of SVd for relapsed/refractory MM. The study met the primary endpoint: once weekly SVd significantly improved PFS and ORR compared to twice weekly Vd. Rates of PN were significantly reduced with numerically fewer deaths on SVd vs Vd. Full dataset will be presented at the meeting. Clinical trial information: NCT03110562. Research Sponsor: Karyopharm Therapeutics Inc.

8502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

DREAMM-6: Safety and tolerability of belantamab mafodotin in combination with bortezomib/dexamethasone in relapsed/refractory multiple myeloma (RRMM). *First Author: Ajay K. Nooka, Emory University Hospital, Winship Cancer Institute, Atlanta, GA*

Background: Belantamab mafodotin, a B-cell maturation antigen targeting immunoconjugate, demonstrated clinically meaningful, single-agent activity in patients with heavily pre-treated RRMM refractory to an immunomodulatory agent, a proteasome inhibitor, and refractory and/or intolerant to an anti-CD38 monoclonal antibody (DREAMM-2, NCT03525678, *Lancet Oncol*.2020). The multimodal mechanism of action and manageable safety profile make belantamab mafodotin a promising candidate for use in different RRMM combination regimens. **Methods:** DREAMM-6 (NCT03544281) is an ongoing, two-part, two-arm, study evaluating the safety, tolerability, and clinical activity of belantamab mafodotin in combination with bortezomib/dexamethasone (BorDex) and lenalidomide/dexamethasone in patients previously treated with ≥1 prior therapy line. Here, we present data for belantamab mafodotin in combination with BorDex. Part 1 (dose escalation) and Part 2 (dose expansion) evaluated belantamab mafodotin (2.5 and 3.4 mg/kg) administered as SINGLE (Day 1) or SPLIT dose (divided equally on Days 1 and 8) in combination with BorDex. **Results:** As of February 6, 2020, 52 patients were enrolled: 6 patients were enrolled at 2.5 mg/kg single dose and 7 at 3.4 mg/kg single dosing in Part 1, and 45 patients in Part 2. No dose-limiting toxicities were observed. Corneal events (including keratopathy, blurred vision, and dry eye) and thrombocytopenia were the most frequently reported AEs and were clinically manageable. **Conclusions:** In DREAMM-6, preliminary data demonstrate that the combination of belantamab mafodotin and BorDex has an acceptable safety profile, with no new safety signals identified. Funding: GlaxoSmithKline (207497). Drug linker technology licensed from Seattle Genetics; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT03544281. Research Sponsor: GlaxoSmithKline.

8503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Idecabtagene vicleucel (ide-cel; bb2121), a BCMA-targeted CAR T-cell therapy, in patients with relapsed and refractory multiple myeloma (RRMM): Initial KarMMa results. *First Author: Nikhil C. Munshi, Dana-Farber Cancer Institute, VA Boston Healthcare System, and Harvard Medical School, Boston, MA*

Background: Outcomes are poor in triple-class exposed RRMM patients (pts) who progress on immunomodulatory agents (IMiDs), proteasome inhibitors (PIs), and CD38 antibodies (mAbs). Ide-cel, a BCMA targeted CAR T cell therapy, showed promising tolerability and efficacy in RRMM pts in the phase I CRB-401 study (*NEJM*2019;380:1726). We present primary efficacy and safety data from the pivotal phase II KarMMa trial of ide-cel in RRMM (NCT03361748). **Methods:** Enrolled pts had ≥3 prior regimens (including IMiD, PI, and CD38 mAb) and were refractory to their last regimen per IMWG criteria. After lymphodepletion (cyclophosphamide 300 mg/m^2+ fludarabine 30 mg/m^2 x 3), pts received 150–450 × 10^6 CAR+ T cells (target dose range). Endpoints included overall response rate (ORR; primary), complete response (CR) rate, duration of response (DoR), and PFS. **Results:** Of 140 pts enrolled, 128 received ide-cel. Median age was 61 y; median no. of prior regimens was 6; 84% were triple- and 26% were penta-refractory. Most pts (88%) had bridging therapy. At data cutoff (16 Oct 2019), median follow up was 11.3 mo. ORR was 73% and median PFS was 8.6 mo; both increased with higher dose (Table). All subgroups had an ORR ≥50%, including older and high-risk pts. Most common any-grade (Gr) toxicities were cytopenias (97%) and cytokine release syndrome (CRS; 84%). CRS was mainly Gr 1/2; 5 pts (5%) had Gr 3, 1 had Gr 4, and 1 had Gr 5 (at 300 × 10^6). Neurotoxicity developed in 23 pts (18%); 4 (3%) Gr 3 and 0 Gr ≥4. Median peak CAR+ T cell expansion occurred at 11 d. Expansion was higher in responders and parameters (AUC_{0-28d}, C_{max}) increased with higher dose, with exposure overlap across doses. Persistence was durable, with CAR+ T cells detected in 29/49 (59%) and 4/11 pts (36%) at 6 and 12 mo. **Conclusions:** Ide-cel demonstrated deep, durable responses in heavily pretreated RRMM pts. Efficacy and safety reflected prior reports and support a favorable ide-cel clinical benefit-risk profile across the target dose range. Clinical trial information: NCT03361748. Research Sponsor: Bristol-Myers Squibb and bluebird bio.

8504 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Orvacabtagene autoleucel (orva-cel), a B-cell maturation antigen (BCMA)-directed CAR T cell therapy for patients (pts) with relapsed/refractory multiple myeloma (RRMM): update of the phase 1/2 EVOLVE study (NCT03430011). *First Author: Sham Mailankody, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Orva-cel is an investigational, BCMA-directed CAR T cell product with a fully human binder. Over 100 pts have been treated in the EVOLVE phase 1 study. Pts treated at 50 and 150 $\times$ 10^6 CAR+ T cells were previously reported (Mailankody ASH 2018 #957). We now report results of the higher dose levels (DLs) in 51 pts who received orva-cel manufactured using the process intended to support commercial use. **Methods:** Pts with RRMM who had $\geq$3 prior regimens, a proteasome inhibitor (PI), an immunomodulatory drug (IMiD), and an anti-CD38 monoclonal antibody (mAb), received orva-cel at 300, 450, and 600 $\times$ 10^6 CAR+ T cells after lymphodepletion with fludarabine/cyclophosphamide. **Results:** Median pt age was 61 (range, 33–77) y; median time from diagnosis was 7.0 (range, 1.7–23.6) y, with a median of 6 (range, 3–18) prior regimens. Overall, 92% of pts were penta-exposed (2 IMiDs, 2 PIs, and an mAb); 61% of pts received bridging therapy (77% were refractory to bridging therapy). Two pts had dose-limiting toxicities: grade 3 neurological event (NE) for $>$7 d at 300 $\times$ 10^6 CAR+ T cells and grade 4 neutropenia for $>$28 d at 450 $\times$ 10^6 CAR+ T cells. Key efficacy and safety outcomes are shown in the Table. Cytokine release syndrome (CRS)/NEs were managed with tocilizumab and/or steroids (78%), anakinra (14%), and/or vasopressors (6%). Grade $\geq$3 anemia, neutropenia, and thrombocytopenia at 29 d occurred in 21%, 55%, and 44% of pts (median time to resolution to grade $\leq$2 of any cytopenia, $\leq$2.1 mo). Grade $\geq$3 infections occurred in 14%. After a median follow-up (F/U) of 5.9 mo, median progression-free survival was not reached. **Conclusions:** Orva-cel at 300, 450, and 600 $\times$ 10^6 CAR+ T cells demonstrated manageable safety (CRS grade $\geq$3: 2%; NE grade $\geq$3: 4%) and compelling efficacy in heavily pretreated pts with RRMM, with a 91% objective response rate (ORR) and 39% complete response (CR)/stringent CR (sCR) rate. Updated results will be presented, including minimal residual disease, durability of response, and recommended phase 2 dose. Clinical trial information: NCT03430011. Research Sponsor: Juno Therapeutics, a Bristol-Myers Squibb company.

8505 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Update of CARTITUDE-1: A phase Ib/II study of JNJ-4528, a B-cell maturation antigen (BCMA)-directed CAR-T-cell therapy, in relapsed/refractory multiple myeloma. *First Author: Jesus G. Berdeja, Sarah Cannon Research Institute, Nashville, TN*

Background: JNJ-68284528 (JNJ-4528) is a chimeric antigen receptor T (CAR-T) cell therapy containing 2 BCMA-targeting single-domain antibodies. Here we present updated CARTITUDE-1 (NCT03548207) phase 1b results with longer follow-up. **Methods:** Pts had MM per IMWG criteria, measurable disease, received $\geq$3 prior regimens or were double refractory to a PI and IMiD, and received anti-CD38 antibody. Cyclophosphamide 300 mg/m^2+ fludarabine 30 mg/m^2 over 3 days were used for lymphodepletion. JNJ-4528 (median, 0.73x10^6 CAR+ viable T cells/kg) was given as a single infusion. Cytokine release syndrome (CRS) was graded by Lee *et al*2014 and neurotoxicity by CTCAE, v5.0 and ASTCT grading. Response was assessed per IMWG criteria. **Results:** As of 17 Jan 2020, median follow-up is 9 mo (3–17). Phase 1b enrollment is complete (N = 29 treated; median 5 (3–18) prior lines, 76% penta-exposed, 86% triple-refractory, 31% penta-refractory, 97% refractory to last line of therapy). Most frequent adverse events (AEs) were neutropenia (100%), CRS (93%), and thrombocytopenia (93%). Grade (Gr) $\geq$3 hematologic AEs were neutropenia (100%), thrombocytopenia (69%), and leukopenia (59%). 27 (93%) pts had CRS; 25 Gr 1–2, 1 Gr 3, and 1 Gr 5 (day 99 subsequent to dose-limiting toxicity of prolonged Gr 4 CRS). Median time to onset of CRS was 7 days (2–12). 4 pts had treatment-related neurotoxicity: 3 Gr 1–2 and 1 Gr 3. ORR was 100%, with 22 (76%) stringent complete responses (sCRs), 6 (21%) very good partial responses (VGPRs), and 1 (3%) PR. Median time to $\geq$CR was 2 mo (1–9). 26/29 pts are progression-free, with 6-mo progression-free survival rate of 93% and longest response ongoing at 15 mo. 1 death due to CRS and 1 to acute myeloid leukemia (not treatment-related) occurred during the study. All 16 pts (14 sCR, 2 VGPR) evaluable at 6 mo were minimal residual disease negative at 10^{-5} or 10^{-6}. JNJ-4528 CAR+ T cell expansion peaked between day 10–14. At 6-mo individual follow-up, 22/28 pts had JNJ-4528 CAR+ T cells below the level of quantification (2 cells/μL) in peripheral blood, suggesting CAR-T persistence in peripheral blood did not seem to correlate with deepening of response. At peak expansion, preferential expansion of CD8+ CAR-T cells with a central memory phenotype was observed in peripheral blood. **Conclusions:** JNJ-4528 treatment led to responses in all pts. These responses were early, deep, and durable at a low dose of CAR-T cells with 26/29 (90%) pts progression free at median 9-mo follow-up. CRS was manageable in most pts, supporting outpatient dosing. Clinical trial information: NCT03548207. Research Sponsor: Janssen Research & Development, LLC.

8506 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Long-term follow-up of BMT CTN 0702 (STaMINA) of postautologous hematopoietic cell transplantation (autoHCT) strategies in the upfront treatment of multiple myeloma (MM). *First Author: Parameswaran Hari, CIBMTR (Center for International Blood and Marrow Transplant Research), Department of Medicine, Medical College of Wisconsin, Milwaukee, WI*

Background: STaMINA was a phase III trial comparing progression-free survival (PFS) among 758 pts randomized to: 1. second autoHCT then lenalidomide (Len) maintenance (Auto/Auto, n = 247); 2. consolidation with Len/bortezomib/dexamethasone (RVD) followed by Len maintenance (Auto/RVD, 254); 3. Len maintenance (Auto/Len, 257). All three arms were similar (Stadtmauer JCO 2018). Len maintenance was designed to continue for 3 years and amended to allow continuation until disease progression through a follow up protocol (07LT, NCT#02322320). We report 6 yr follow up for STaMINA and the results of Len discontinuation beyond 3 years. **Methods:** 07LT was offered to pts who were progression-free at 38 mo; completed planned Len maintenance and were within 4 years of BMT CTN 0702 follow up. Among 431 07LT eligible patients, 273 enrolled and 179 opted to continue maintenance until disease progression. All patients enrolled in STaMINA were reported to the Center for International Blood and Marrow Transplant Research (CIBMTR) and long-term outcomes for patients not enrolled on 07LT (N = 166) were available through this mechanism. Before combining 07LT data and CIBMTR data for LTFU analysis, outcomes in both databases were analyzed separately and confirmed to be comparable. **Results:** Using intent-to-treat (ITT), 6yr PFS and overall survival (OS) was the same among Auto/Auto (43.9%; 73.1%), Auto/RVD (39.7%, 74.9%) and Auto/Len (40.9%, 76.4%)(p = 0.6; p = 0.8). Protocol defined high risk disease, (HR = 1.53, p $<$ 0.0001) and age (p = 0.03) were adverse risks for PFS. In as treated analysis, 6yr PFS were 49.4%, 39.7% and 38.6% for Auto/auto (170), Auto/RVD (222) and Auto/Len (361), respectively (p = 0.01). 6yr PFS in high risk pts as treated analysis were 43.6% and 26% for Auto/auto and Auto/Len, respectively (p = 0.03). Landmark analysis at 38 mo included 215 pts who continued Len maintenance (either on 07LT study or commercial Len) vs. 207 who stopped. Baseline demographics; study arm on 0702, induction pre-autoHCT were similar. Len discontinuation after 38 mo was associated with inferior PFS (79.5% vs. 61% at 5yr; HR = 1.91, p = 0.0004) but similar OS. Incidence of all second primary malignancies (SPM)(81 cases with 43 heme-malignancies) was associated with age. **Conclusions:** Long term outcomes are similar using ITT, but as treated analysis suggested a PFS benefit for tandem autoHCT, driven mainly by pts with high risk MM. Len discontinuation even at 38 mo was associated with inferior PFS. Clinical trial information: NCT02322320. Research Sponsor: U.S. National Institutes of Health.

8507 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Primary analysis of the randomized phase II trial of bortezomib, lenalidomide, dexamthasone with/without elotuzumab for newly diagnosed, high-risk multiple myeloma (SWOG-1211). *First Author: Saad Zafar Usmani, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: The introduction of immunomodulatory agents, proteasome inhibitors, and autologous stem cell transplantation (ASCT) has improved outcomes for patients with multiple myeloma (MM), but those with high risk MM (HRMM) have a poor long-term prognosis. To date, no trials have addressed optimal treatment for these patients. **Methods:** S1211 is a randomized phase II trial (NCT01668719) comparing 8 cycles of lenalidomide, bortezomib and dexamethasone (RVd) induction followed by dose-attenuated RVd maintenance until disease progression with or without elotuzumab. Stem cell collection was allowed, but ASCT was deferred until progression. HRMM was defined by one of the following: gene expression profiling high-risk (GEP^{hi}), t(14; 16), t(14; 20), del(17p) or amplification 1q21, primary plasma cell leukemia (pPCL) and elevated serum LDH ($>$ 2X ULN). Median progression-free survival (PFS) was the primary end-point, using a one-sided stratified log-rank test at a one-sided significance level of 0.1. Secondary endpoints included overall response rate (ORR), adverse events (AE), serious adverse events (SAE) and OS. Response was assessed using the IMWG 2009 criteria. **Results:** S1211 enrolled 103 evaluable patients, RVd n = 54, RVd-Elo n = 49. 75% had ISS II/III, 47% amp1q21, 38% del17p, 12% t(14; 16), 9% GEP^{hi}, 7% pPCL, 5% t(14; 20) and 4% elevated serum LDH (18.5% $>$ 1 feature). With median follow-up of 53 months (mos.), no difference in median PFS was observed [RVd-Elo = 31 mos., RVd = 34 mos.,HR = 0.968 (80% CI = 0.697-1.344), p = 0.449]. No difference in OS was observed [RVd-Elo = 68 mos, RVd = not reached, HR = 1.279 (80% CI: 0.819, 2.000), p-value = 0.478]. 72% pts had $>$ Grade 3 AEs, no differences in the safety profile were observed except $>$Grade 3 infections (RVd 8%, RVd-Elo 16%), $>$Grade 3 sensory neuropathy (RVd 8%, RVd-Elo 13%). **Conclusions:** In the first randomized HRMM study reported to date, the addition of elotuzumab to RVd induction and maintenance did not improve patient outcomes. However, the PFS and OS seen in both arms of the study exceeded the original statistical assumptions and support the role for PI/IMiD combination maintenance therapy for this patient population. The S1211 data will serve as an important benchmark for future HRMM clinical trials. Clinical trial information: NCT01668719. Research Sponsor: U.S. National Institutes of Health.

8508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Depth of response to isatuximab, carfilzomib, lenalidomide, and dexamethasone (Isa-KRd) in front-line treatment of high-risk multiple myeloma: Interim analysis of the GMMG-CONCEPT trial. *First Author: Katja Weisel, University Medical Center of Hamburg-Eppendorf, Hamburg, Germany*

Background: High-risk (HR) multiple myeloma (MM) still has a significant impaired prognostic outcome. Addition of CD38 monoclonal antibodies to standard-of-care regimens significantly improved response rates and depth of response in newly diagnosed (ND) and relapsed/refractory MM patients (pts). Here, we report the prespecified end of induction interim analysis (IA) of the investigator-initiated GMMG-CONCEPT trial (NCT03104842), evaluating the quadruplet regimen isatuximab plus carfilzomib, lenalidomide and dexamethasone (Isa-KRd) in HR NDMM pts. **Methods:** 153 pts with HR NDMM are planned to be included into the trial. HR MM is defined by the presence of del17p or t(4;14) or t(14;16) or >3 copies 1q21 and ISS 2 or 3 stage disease. Pts receive 6 cycles of Isa-KRd induction, 4 cycles of Isa-KRd consolidation and Isa-KR maintenance. Transplant eligible pts (arm A) undergo high-dose therapy. Transplant ineligible pts (arm B) receive 2 additional cycles of Isa-KRd induction. The primary endpoint is MRD negativity measured by next-generation flow after consolidation. This IA reports on overall response rates (ORR) after induction. Additional MRD analysis will be presented. **Results:** 50 pts (46 arm A, 4 arm B) were included in the IA population for ORR. HR MM was defined by del17p in 52%, t(4;14) in 38%, t(14;16) in 12% and >3 copies 1q21 in 42%. 39/46 pts in arm A and 4/4 pts in arm B completed induction treatment. ORR was 100%, with 5 pts (10.0%) showing partial response (PR), 22 (44.0%; including 4 in arm B) very good partial response (VGPR) and 23 (46.0 %) complete response (CR). Median stem cell yield was 6.6×10^6CD34+ cells/kg. Grade 3/4 treatment-emergent adverse events ($\geq$ 10%) with Isa-KRd included neutropenia (34.0%), leukopenia (26.0%) and thrombocytopenia (14.0%). Main non-hematologic toxicities grade 3/4 were hypertension (12.0%) and infection (8.0%). **Conclusions:** To the best of our knowledge, we report for the first time on a trial investigating solely HR NDMM and Isa-KRd quadruplet treatment. Isa-KRd induction induces deep responses in HR MM pts. The overall safety profile of Isa-KRd is expected and consistent with previous reports. The study is ongoing, with pts continuing to be included. Clinical trial information: 03104842. Research Sponsor: Sanofi, Celgene, Amgen.

Updated results from BELLINI, a phase III study of venetoclax or placebo in combination with bortezomib and dexamethasone in relapsed/refractory multiple myeloma. *First Author: Shaji Kumar, Mayo Clinic, Rochester, MN*

Background: Venetoclax (Ven) is a selective, potent, oral BCL-2 inhibitor. In the Phase 3 BELLINI trial, addition of Ven to bortezomib (B) + dexamethasone (d) significantly improved response rates and progression-free survival (PFS) vs placebo (Pbo) and showed significant efficacy in patients (pts) with either t(11;14) or BCL2high gene expression. Here we present updated safety and efficacy data from the prespecified second interim overall survival (OS) analysis. **Methods:** In this multicenter, randomized, double-blind study (NCT02755597), pts with relapsed/refractory multiple myeloma (RRMM) with 1-3 prior lines of therapy were randomized 2:1 to Ven (800 mg) or Pbo in combination with B (1.3 mg/m2) and d (20 mg). The primary endpoint was PFS; key secondary endpoints included overall response and overall survival (OS). **Results:** 291 pts were randomized; 194 to Ven, 97 to Pbo. Pt characteristics were well balanced among arms. In the Ven arm, median age was 66, 17% had high-risk cytogenetics, 11% had t(11;14), and 34% had BCL2high gene expression. As of 13 Sept 2019, 59 pts were still on study, 45 (23%) Ven vs 14 (14%) Pbo. At a median follow-up of 28.6 months, there were 64 (33%) deaths in the Ven arm vs 24 (25%) in Pbo. At the initial data cutoff (26 Nov 2018), PFS HR was 0.63 (0.44,0.90) and OS HR was 2.03 (1.04,3.95). Table shows updated PFS and OS. Most common treatment-emergent adverse events (TEAEs) with Ven were diarrhea (59%), nausea (37%), and constipation (35%). Most common grade 3/4 AEs (Ven/Pbo) were neutropenia (21%/8%), thrombocytopenia (15%/30%), anemia (16%/15%), diarrhea (15%/12%), and pneumonia (18%/13%). Serious AEs occurred in 54% Ven and 52% Pbo pts. 24% discontinued Ven due to AEs vs 12% Pbo. There were 14 treatment-emergent deaths in the Ven arm and 1 in Pbo. **Conclusions:** The addition of Ven to Bd significantly improves PFS but resulted in increased mortality vs Pbo in the total population. Greatest PFS improvement with Ven was observed in pts with t(11;14) or BCL2high gene expression, where Ven shows a favorable benefit-risk profile. The study continues for final OS analysis. Clinical trial information: NCT02755597. Research Sponsor: Abbvie, Inc, Pharmaceutical/Biotech Company.

PFS and OS by subgroup.

Selinexor, daratumumab, and dexamethasone in patients with relapsed/refractory multiple myeloma (MM). *First Author: Cristina Gasparetto, Duke University Cancer Center, Durham, NC*

Background: Selinexor is a first-in-class oral Selective Inhibitor of Nuclear Export (SINE) compound that binds and inactivates exportin 1 (XPO1). Selinexor in combination with low dose dexamethasone (Sel-dex) was approved by the FDA, based on data from the STORM study, wherein Sel-dex induced an overall response rate (ORR) of 26.2% in patients (pts) with relapsed/refractory MM (RRMM). Single agent daratumumab has demonstrated an ORR of 29% in MM reftactory to proteasome inhibitors (PIs)/immunomodulatory drug (IMiDs). We evaluated the safety, tolerability and preliminary efficacy of the combination of Sel-dex and daratumumab (SDd) in pts with MM refractory to PIs/IMiDs. **Methods:** This is a multicenter, open-label, phase 1b/2 dose escalation and expansion study. Pts were eligible if they had received $\geq$ 3 prior lines of therapy, including a PI and an IMiD, or whose MM was refractory to a PI and an IMiD. In the expansion phase, pts were required to be anti-CD38 monoclonal antibody-naïve. One dose level was tested at each schedule: selinexor once-weekly (QW at 100 mg) or twice-weekly (BIW at 60 mg) with dexamethasone 40 mg. Daratumumab 16 mg/kg IV was administered per label. Primary objective was to determine the maximum tolerated dose and recommended phase 2 dose (RP2D), and assess safety, tolerability and efficacy of SDd in pts with RRMM. **Results:** A total of 34 pts were enrolled; 3 in the 60 mg BIW and 31 in the 100 mg QW cohorts. Median age was 69 and median number of prior treatment regimens was 3 (range, 1–10). Out of 34 pts, 62% and 65% were refractory to bortezomib and lenalidomide respectively. Common treatment related adverse events (all grades, grades 3/4) included: thrombocytopenia (71%, 47%), fatigue (62%, 18%), nausea (71%, 9%), anemia (62%, 32%) and neutropenia (50%, 26%). Two dose limiting toxicities (DLTs) were reported in the 60 mg BIW cohort: Grade 3 thrombocytopenia and Grade 2 fatigue requiring dose reduction in selinexor to 100 mg QW. In the 100 mg QW escalation cohort (n = 6), no DLTs occured. 32 patients were evaluable for efficacy. The ORR was 73% (11 VGPR, 11 PR) for 30 daratumumab-naïve pts. Median progression-free survival was 12.5 months in both groups. **Conclusions:** Based on tolerability and efficacy, the RP2D of SDd is selinexor 100 mg, daratumumab 16 mg/kg and dexamethasone 40 mg, administered QW. In pts with PI and IMiD refractory MM, weekly SDd demonstrated promising activity with an ORR of 73% in daratumumab-naïve pts and a median PFS of 12.5 months. This supports further development of a novel non-PI, non-IMiD backbone in earlier lines of therapy. Clinical trial information: NCT02343042. Research Sponsor: Karyopharm Therapeutics Inc.

8511 Poster Discussion Session; Displayed in Poster Session (Board #411), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Updated analysis of a phase I/II study of venetoclax in combination with daratumumab and dexamethasone, +/- bortezomib, in patients with relapsed/refractory multiple myeloma. *First Author: Jonathan L. Kaufman, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Venetoclax (Ven) is a selective, potent, oral BCL-2 inhibitor that induces apoptosis in multiple myeloma (MM) cells *in vitro.* It has shown synergistic activity with bortezomib (V) and dexamethasone (d). Combination of the CD38 monoclonal antibody daratumumab (D) with Ven is hypothesized to further increase anti-myeloma activity based on dual mechanisms of pro-apoptotic effects on tumor cells and enhanced immune stimulation. **Methods:** This ongoing Phase 1/2, nonrandomized, multicenter study (NCT03314181) is evaluating safety, efficacy and pharmacokinetics (PK) of VenDd +/- V in patients (pts) with relapsed/refractory MM. In Part 1, pts with t(11;14) who received $\geq$1 prior line of therapy (PI and an immunomodulatory drug) were treated with VenDd [Ven QD + D 16 mg/kg IV + d 40 mg weekly]. In Part 2, pts irrespective of t(11;14) status, non-refractory to PIs and who received 1–3 prior lines of therapy were treated with VenDVd [Ven QD + D 16 mg/kg IV + V (1.3 mg/m^2) + d (20 mg)]. A randomized, open-label expansion (Part 3) will further evaluate and compare safety and efficacy of VenDd (400 or 800 mg Ven dose levels) with control DVd in pts with t(11;14). **Results:** As of Dec 05, 2019, 48 pts were enrolled. Part 1 included 24 pts with t(11;14), median age 63 (range 51–76). Part 2 included 24 pts, median age 65 (range 41–80) of which 6 (25%) had t(11;14). Frequent adverse events (AEs; VenDd/VenDVd) were fatigue (71%/25%), diarrhea (58%/46%), nausea (46%/50%), insomnia (33%/50%), upper respiratory tract infection (33%/21%), cough (42%/9%), and dyspnea (25%/25%). Frequent Grade $\geq$ 3 AEs in pts on VenDd were neutropenia (17%), hypertension (12%), fatigue and hyperglycemia (8% each), and in pts on VenDVd were insomnia (21%), diarrhea and thrombocytopenia (8% each). Nine pts had infection-related Grade $\geq$ 3 AEs (5 VenDd, 4 VenDVd). Eighteen pts had a serious AE (11 VenDd, 7 VenDVd) with pyrexia (n = 3) being most common. One pt on VenDVd died of progressive disease. PK analyses showed that addition of D and V did not impact Ven exposure. Median follow-up time (VenDd/VenDVd) was 10 and 9 months. Overall response rate in VenDd/VenDVd was 96%/92% and 96%/79% had $\geq$ very good partial response rate. Median progression free survival and duration of response were not reached. **Conclusions:** Pts treated with VenDd +/- V continue to demonstrate a tolerable safety profile with encouraging efficacy, notably among pts with t(11;14) treated with VenDd. Safety, efficacy, PK, and cytogenetics analyses will be updated for presentation. Clinical trial information: NCT03314181. Research Sponsor: AbbVie.

Analysis of treatment efficacy in the GEM-CESAR trial for high-risk smoldering multiple myeloma patients: Comparison between the standard and IMWG MRD criteria and QIP-MS including FLC (QIP-FLC-MS). *First Author: Noemí Puíg, Hospital Universitario de Salamanca, Salamanca, Spain*

Background: The GEM-CESAR trial is a potentially curative strategy for high-risk smoldering multiple myeloma (HRsMM) patients (pts) in which the primary endpoint is the achievement of sustained minimal residual disease (MRD) negativity in the bone marrow (BM) by next generation flow (NGF). The value of BM MRD assessment in MM is proven, but alternative, non-invasive methods, accurately reflecting disease burden are needed. **Methods:** Pts received six 4-week cycles of KRd as induction (K:36mg/m2 twice weekly, R: lenalidomide 25mg po od days 1-21 and d:dexamethasone 40mg po weekly) followed by melphalan 200mg/m2, two further cycles of KRd as consolidation and up to 2 years of Rd (R: 10mg/d, d:20mg/week). Efficacy was analyzed in parallel in BM samples by NGF and in serum by SPEP/IFE and QIP-MS/QIP-FLC-MS in 52 out of the 90 pts enrolled in the trial. Standard and MRD responses were carried out as per the IMWG guidelines. For QIP-MS serum immunoglobulins were purified using polyclonal antibodies (anti-IgG, -IgA, -IgM, -total κ and -total λ light chain, -free κ and -free λ light chain). Mass spectra were generated on a MALDI-TOF-MS system. **Results:** Overall response rate (ORR) was 98% post-induction, 98% post-ASCT, and 100% post-consolidation; 38.4%, 61.5% and 68.6% of pts reached ≥ complete response at each time-point and, among them, 23%, 44% and 55% achieved flow MRD-negativity. Using the combination of QIP-MS/QIP-FLC-MS, the percentage of pts without detectable disease at each timepoint lowered to 12%, 27% and 38% reflecting the higher sensitivity of the method. Against NGF, QIP-MS/QIP-FLC-MS provided negative predictive values of 67%, 92% and 89% (p = 0,0206; p < 0,001; p = 0,003) and identified disease in 95%, 97% and 92% of pts that were positive by NGF-MRD at each respective timepoint. Three pts from this cohort have progressed so far: two were NGF+/MS+ at the three timepoints whilst 1 remained NGF- but QIP-MS/FLC-MS+ throughout. **Conclusions:** The GEM-CESAR treatment strategy induces a high ORR in HRsMM pts, and the % of cases achieving flow-MRD negativity post-ASCT meets the primary endpoint of the trial. The combined use of QIP-MS and FLC-MS offers higher sensitivity relative to standard methods and may provide relevant information about the right timing for performing a BM aspirate/biopsy. Clinical trial information: NCT02415413. Research Sponsor: None.

Measurable residual disease (MRD) assessed by mass spectrometry (MS) in peripheral blood versus next generation sequencing (NGS) in bone marrow in multiple myeloma treated on phase II trial of KRd+ASCT. *First Author: Benjamin Avi Derman, University of Chicago Medical Center, Chicago, IL*

Background: MRD-negativity in multiple myeloma (MM) assessed by NGS in bone marrow (BM) aspirate is associated with longer progression free survival (PFS) and overall survival. MS can detect monoclonal protein at a heightened sensitivity in peripheral blood (PB). We sought to assess the concordance of MS in PB and NGS in BM, comparing outcomes by MRD status. **Methods:** MRD was tested on paired PB and BM samples from transplant (ASCT)-eligible pts with newly diagnosed secretory MM who received treatment on a phase II clinical trial (NCT01816971) with KRd for 4 cycles, ASCT, KRd for 14 cycles, and lenalidomide maintenance (LM). Both NGS and MS were evaluable in 36 pts after a total of 18 cycles of KRd (C18) and in 24 pts after 1 year of LM. MS signatures were identified in pretreatment PB samples. C18 and after 1 year of LM PB samples were evaluated using both MALDI-TOF and liquid-chromatography-MS (LCMS) by the Binding Site Group. Paired MRD by NGS was performed by ClonoSEQ. 20/60 samples reached the limit of detection for 10^{-6} and 40/60 for 10^{-5}. **Results:** There was substantial concordance between NGS and MALDI-TOF among the 60 samples (κ= 0.667, 83% agreement) and fair concordance between NGS and LCMS (κ= 0.348, 63% agreement). However, all 22 discordant samples (8 with NGS depth 10^{-6}, 14 with NGS depth 10^{-5}) were $NGS^{-}/LCMS^{+}$. 4/16 (25%) of these pts converted to NGS^{+}, and 3/16 (19%) clinically progressed. There was stronger concordance between LCMS and NGS 10^{-6}(κ= 0.615) than with NGS 10^{-5}(κ= 0.375). At a median follow-up of 56 months, C18 $LCMS^{-}$(n = 9) was associated with superior PFS vs all $LCMS^{+}$(n = 27; p = 0.03) and independently vs $NGS^{-}/LCMS^{+}$ (n = 14; p = 0.04). There were 10 events (including 4 deaths) in the C18 $LCMS^{+}$ group vs 0 in the $LCMS^{-}$ group. **Conclusions:** MRD assessment by LCMS in PB appears to reach and possibly exceed the sensitivity of MRD by NGS in BM at a depth of 10^{-5}-10^{-6}. LCMS positivity predicted conversion from NGS^{-} to NGS^{+} in 25% of discordant cases, and LCMS negativity was a better predictor of superior PFS than MRD negativity by NGS. These observations need confirmation in larger prospective studies. Research Sponsor: None.

Clinical implications of loss of minimal residual disease (MRD) negativity in multiple myeloma. *First Author: Meera Mohan, UAMS Myeloma Center, Little Rock, AR*

Background: Attainment of MRD negativity in multiple myeloma (MM) patients is increasingly considered an optimal therapeutic endpoint, but little is known about the MRD evolution in those who achieve this milestone. We investigated the clinical implication of loss of MRD negativity or MRD conversion in patients with ≥VGPR. **Methods:** We identified and followed 606 patients achieving a sustained ≥VGPR with bone marrow MRD negativity(≥ 2 consecutive reading) following treatment on a total therapy protocol and with a median follow-up of 10 y. All patient had negative PET and MRI DWIBS at enrollment. Serial BM aspirate MRD was determined by 8-color next generation flow (NGF, EuroFlow) with a minimal sensitivity of 10^{-5} cells. **Results:** Most MM patients were considered low risk with a UAMS GEP70 score of ≤ 0.66 (92%; 495/538) . While 60% (364/606) of patients had sustained MRD negativity, the remaining 40% (242/606) experienced MRD conversion with a 5.7 y median time from ASCT and 6.3 y from diagnosis. The risk of clinical relapse was significantly elevated in patients with MRD conversion compared to sustained MRD negativity (73%, 177/242 *vs.* 5%, 18/364; R.R. = 3.5; P< 0.0001). The median level of MRD positivity (> 0.2 ratio of MM cells to normal plasma cells) also highly correlated with relapse (P< 0.0001). Loss of MRD negativity preceded clinical relapse by a median time of 1.1 years. Loss of MRD negativity without clinical relapse was seen in 27% (65/242). MRD conversion was associated with an inferior PFS and OS (PFS: 10.2 y *vs.* NR; P < 0.0001, H.R. 18.7; 95% CI 13.3 - 26.3 and OS: 26.1 y *vs.* NR; P= 0.01, H.R. 1.7; 95% CI 1.1 - 2.6). Furthermore, when MRD conversion was within 5 y of diagnosis compared > 5 y, patients had a worse OS (P < 0.0001, H.R. 17.2; 95% CI 7.8 – 37.8). We also observed that MRD conversion later than 5 years from diagnosis did not affect the OS. In a subset of patients (n = 144) the timing of first MRD negativity following treatment was available. Attainment of MRD negativity within 6 months of diagnosis compared to any time after 6 months was predictive of future MRD conversion (65%, 17/26 *vs.*42%, 49/118; P = 0.03) and clinical relapse (54%, 14/26 *vs.*28%, 33/118; P = 0.02). **Conclusions:** MRD conversion occurs in a significant proportion of MM patients (40%) on long-term follow-up and predicts future clinical relapse. Significance of MRD conversion has a temporal relationship from diagnosis and portray inferior clinical outcome particularly within 5 years of diagnosis. Research Sponsor: None.

Bortezomib induction prior to autologous hematopoietic cell transplantation (AHCT) for newly diagnosed light chain amyloidosis (AL): A study of 426 patients. *First Author: Robert F. Cornell, Vanderbilt University Medical Center, Nashville, TN*

Background: AL is a clonal plasma cell (PC) disorder causing multiorgan dysfunction from amyloid fibril deposition. While bortezomib (B) induction has been used prior to AHCT recently, AHCT without prior induction has been a common practice. The primary objective of this study was to compare outcomes of AL patients who proceeded to AHCT without induction to those receiving pre-AHCT induction with B. **Methods:** Outcomes of 426 systemic AL AHCT recipients between 2014-2018 reported to the Center for International Blood and Marrow Transplant Research (CIBMTR) were reviewed. Patients receiving induction with therapy other than B, AHCT occurring > 9 months after diagnosis, no documented AL end-organ involvement, myeloma-defining events and conditioning other than melphalan (MEL) monotherapy were excluded. Multivariate analysis (MVA) was conducted to identify prognostic factors associated with relapse, PFS and overall survival (OS). **Results:** 286 patients received B induction therapy vs 140 patients receiving no induction. Age, gender, number and type of organs involved, and AL AHCT center volume were similar between the groups. Patients receiving induction had greater PC burden compared with no induction (PC ≥ 10%, 41% vs 11%, p < 0.01). Induction was B, cyclophosphamide and dexamethasone (D) in 83% followed by B, lenalidomide and D (10%) or B+D (7%). Median follow-up was 24.9 months. At 2 years, B induction vs. no induction was associated with 13% (95% CI 10-17%) vs 22% (95% CI 15-30%) relapse risk (p = 0.03); 83% (95% CI 79-87%) vs 74% (95% CI 66-81%) PFS (p = 0.04); 93% (95% CI 90-95%) vs 94% (95% CI 89-97%) OS (p = 0.7). On MVA, the B induction group had improved PFS (HR 0.46, 95% CI 0.3-0.7, p < 0.001) with similar OS (HR 0.6, 95% CI 0.3-1.2, p = 0.1) compared with no induction. Creatinine < 2 mg/dl (HR 0.55, 95% CI 0.3-0.9, p = 0.02) and Karnofsky score ≥90 (HR 0.51, 95% CI 0.33-0.78, p < 0.01) were also associated with improved PFS. MEL dose < 180 mg/m^2 was associated with inferior PFS (HR 2.17, 95% CI 1.31-3.61, p < 0.01) and OS (HR 3.6, 95% CI 1.5-8.6, p < 0.01). No deaths were seen in the first 100 days post-AHCT. At last follow-up, 32 deaths occurred, 26 (81%) due to AL. **Conclusions:** Compared with prior CIBMTR analyses, B induction use has increased in AL AHCT recipients and a higher PC burden was the only clinical determinant. Furthermore, B induction was associated with lower relapse and improved PFS at 2 years with no OS difference despite higher proportion of patients with > 10% PC, which has been associated with poor outcomes. Research Sponsor: U.S. National Institutes of Health.

Depth of response prior to autologous stem cell transplantation to predict survival in light chain amyloidosis. *First Author: Iuliana Vaxman, Israel Sackler Faculty of Medicine Tel-Aviv University, Tel-Aviv, Israel*

Background: The role of induction therapy prior to autologous stem cell transplant (ASCT) in immunoglobulin light chain (AL) amyloidosis remains controversial. Data on the prognostic impact of response to induction in a transplanted cohort are lacking. The aim of this study was to assess the impact of response to induction therapy on survival in patients undergoing ASCT for AL amyloidosis. **Methods:** We conducted a retrospective study of all newly diagnosed AL amyloidosis patients who received induction prior to ASCT between January 2007 and August 2017 at Mayo Clinic, Rochester, Minnesota. Patients receiving only corticosteroids prior to transplant were excluded as were those with an involved light chain of less than 5 mg/dL (not measurable for response). **Results:** 134 patients met inclusion criteria. The median age at diagnosis was 60 (range 36-74) and 85 (63%) were men. The most commonly used induction regimen was proteasome inhibitor-based (73.1%, n=98). The overall response rate to induction was 83% (complete response 17%, very good partial response 30% and partial response 36%). With a median follow up of 56.5 months, the median PFS and OS was 48.5 months and not reached, respectively. Response depth to induction therapy was associated with improved PFS and OS and was independent of the bone marrow plasma cell percentage. The median PFS was not reached for patients achieving ≥VGPR prior to ASCT and 33.8 months for patient achieving PR or less (P=0.001). The median OS was longer in patients with deeper responses (not reached for patients achieving ≥VGPR vs. 128 months for patients achieving PR or less (P=0.02). On multivariable analysis, independent predictors of OS were melphalan conditioning dose (RR= 0.38; P=0.018) and depth of response prior to transplant (RR 2.52; P=0.039). **Conclusions:** Hematologic response prior to transplant predicts post-transplant outcomes in patients with AL amyloidosis. Research Sponsor: None.

Univariable and multivariable analysis for overall survival.

	Univariable		Multivariable	
Variable	**RR (95% CI)**	**P**	**RR (95% CI)**	**P**
Age ≥ 65 years	3.5 (0.99 to 4.99)	0.05	1.76 (0.76 to 4.05)	0.185
More than 2 organs involved	1.63 (0.27 to 3.9)	0.268		
BMPC≥10%	0.45 (0.8 to 2.36)	0.83

Will adding alkylating agent to bortezomib improve survival of newly diagnosed AL amyloidosis patients? *First Author: Yumeng Zhang, University of South Florida, Tampa, FL*

Background: The combination of bortezomib (Bort) and alkylating agent (AA) is a frequently used first-line therapy for AL amyloidosis. Kastritis et al. compared melphalan and dexamethasone with or without bortezomib as primary therapy and demonstrated increased hematologic response rate with the bortezomib and melphalan combination. However, the role of AA is unclear. This study aimed to evaluate if adding AA to Bort improved patient outcomes in AL amyloidosis. **Methods:** We retrospectively reviewed clinical data on 209 patients with systemic AL Amyloidosis at Moffitt Cancer Center between 2008 and 2020. We excluded patients with localized amyloidosis or amyloid other than AL. Patients were divided into two groups based on upfront therapy: A) Bort and B) Bort + AA. All patients also received dexamethasone. The staging was per Mayo 2012. Organ involvement, response, and progression were defined based on the 2005 criteria. Overall survival (OS) was defined as the time from initial diagnosis until death or last contact. Time to next therapy (TTNT) was calculated in patients with the documented hematologic response from the time of initiation of therapy to time of the next therapy/last follow up/death. **Results:** Of 209 patients, 36% (n=76) received Bort+AA; 30% (n=62) received Bort. No significant difference in clinical characteristics was seen in both groups except for age (which was higher for arm A: median 65 and 62 years, respectively, p=0.043) (table). In addition, Bort+AA became more commonly used as a frontline therapy after 1/1/2014 (p=0.001). Group A and B had similar median OS (69.9 months [95% CI. 44.7-95.2] and 64.4 mo [95% CI 40.5-88.3] respectively, p=0.60). 86% of patients in group B achieved a hematologic response as compared to 74% of patients in group A (p=0.15). Similarly, 47% of patients in group B achieved an organ response as compared to 34% of patients in group A (p=0.22). TTNT was higher in group A than group B (16.9 mo [95% CI, 0-41.5] and 7.8 mo [95% CI, 3.5-12.0], respectively, p=0.08). **Conclusions:** While Bort+AA is a commonly used regimen for amyloidosis, the addition of AA to Bort did not result in superior OS, TTNT compared to Bort alone in this retrospective study. This finding should be confirmed in prospective studies. Baseline Characteristics. Research Sponsor: None.

Impact of lenalidomide-bortezomib-dexamethasone (RVd) induction on patients with newly diagnosed multiple myeloma and renal impairment: Results from the Connect MM Registry. *First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL*

Background: Patients (pts) with newly diagnosed multiple myeloma (NDMM) and renal impairment (RI) are often excluded from clinical trials. Data are limited on the effects of induction treatment in these pts, who may also be ineligible for autologous stem cell transplant (SCT) due to severity of RI. This analysis investigated the impact of RVd induction on renal function in transplant eligible (TE) and noneligible (TNE) pts from the Connect MM Registry, a US, multicenter, prospective, observational study. **Methods:** Eligible pts were ≥ 18 y and had symptomatic MM diagnosed ≤ 2 mos prior to enrollment, as defined by the International Myeloma Working Group criteria. For this analysis, pts that received frontline RVd for ≥ 3 cycles were grouped per transplant eligibility and renal function at baseline (BL; creatinine clearance [CrCl] < 30, 30-50, > 50-80, and > 80). Pts with progressive disease at BL were excluded. Renal function at 3 mos was measured. Median unadjusted progression-free survival (PFS) was calculated from start of regimen in TE and TNE populations, with pts grouped by CrCl (≤ 60 or > 60) at BL. **Results:** As of 7/23/19, 421 TE and 212 TNE pts received RVd for ≥ 3 cycles. TE and TNE pts were grouped by BL CrCl of < 30 (20 and 16 pts), 30-50 (36 and 50 pts), > 50-80 (117 and 63 pts), and > 80 (248 and 83 pts). Renal function improvement was observed in all pts receiving RVd, including those with moderate (30-50 CrCl) and severe (< 30 CrCl) RI at BL (Table). In pts with > 60 CrCl and ≤ 60 CrCl at BL, median PFS in TE pts was 48.6 mos and 43.2 mos, respectively. In TNE pts, median PFS was 36.4 mos and 30.6 mos, respectively. **Conclusions:** The results from the Connect MM Registry indicate that pts with NDMM and RI (including moderate and severe) who receive front-line RVd for ≥ 3 cycles may see improvement in renal function at 3 mos, regardless of transplant eligibility. RVd therefore can potentially be used in pts with RI. This analysis provides real-world data that support further investigation of RVd treatment in pts with moderate or severe RI. Clinical trial information: NCT01081028. Research Sponsor: Celgene Corporation.

DREAMM-2: Single-agent belantamab mafodotin (GSK2857916) in patients with relapsed/refractory multiple myeloma (RRMM) and renal impairment. *First Author: Hans Chulhee Lee, MD Anderson Cancer Center, Houston, TX*

Background: Renal impairment, a frequent complication and poor prognostic factor in RRMM, often leads to poor tolerability of standard regimens. We report outcomes in patients with renal impairment receiving single-agent belantamab mafodotin (2.5 or 3.4 mg/kg; B-cell maturation antigen targeting immunoconjugate not renally metabolized) from the DREAMM-2 post-hoc analysis (NCT03525678). **Methods:** Eligible patients with RRMM had no active renal conditions and adequate renal function (based on albumin/creatinine ratio [<500 mg/g] and eGFR [mL/min/1.73 m^2]: normal [≥90], mild impairment [mild, ≥60≤90], moderate impairment [mod, ≥30≤60]). **Results:** Overall response rates (95% CI) in patients with mild/mod impairment (2.5 mg/kg: 32% [21.4–44.0]; 3.4 mg/kg: 36% [25.6–48.5]) were similar to those in the overall population (*Lancet Oncol.*2020). The median duration of response (DoR) was not reached (NR) in 2.5 mg/kg mild/mod subgroup (95% CI estimate: 4.2 months–NR); median DoR was 7.5 months (4.9–NR) in 3.4 mg/kg mild/mod subgroup. Rates of keratopathy and albuminuria were similar regardless of renal function; rates of anemia, pyrexia, and thrombocytopenia were more frequent in patients with impaired renal function (Table). eGFR did not change or changed to normal in most patients. **Conclusions:** Following treatment with single-agent belantamab mafodotin, patients with mild/mod renal impairment achieved a similar efficacy and safety profile as patients with normal renal function. Funding: GlaxoSmithKline (205678). Drug linker technology licensed from Seattle Genetics; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT03525678. Research Sponsor: GlaxoSmithKline.

A phase II, single-arm study of denosumab in multiple myeloma patients with renal insufficiency. *First Author: Elizabeth O'Donnell, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Bone destruction is a devastating consequence of multiple myeloma (MM). An unmet medical need exists for the management of skeletal complications in MM patients with renal insufficiency. Despite the effectiveness of intravenous bisphosphonates, their use is limited in situations where renal dysfunction is present. Denosumab is a fully human monoclonal IgG2 antibody to RANKL that has been shown to be non-inferior to zoledronic acid for SRE rates in MM (Raje, et al. Lancet Oncol). More importantly, it does not have the same renal toxicity as the bisphosphonates. We hypothesize that denosumab can be safely and effectively administered in MM patients with renal insufficiency to improve bone health. This may fill a gap in clinical care for bone-directed therapy in this patient population. **Methods:** This multi-center study will include forty adult patients with newly diagnosed or relapsed MM with a creatinine clearance of less than 30 mL/min (NCT02833610). All patients will receive a subcutaneous injection of denosumab 120 mg Q4W for a total of 12 cycles. In addition, it is required that all subjects receive daily vitamin D and calcium supplementation at standard doses (at least 2000 mg calcium citrate and1000 IU of vitamin D), unless documented hypercalcemia develops on study. The primary objective is to assess the effect of denosumab 120 mg Q4W on serum c-terminal telopeptide (sCTX). Secondary objectives include evaluation of safety and tolerability of denosumab in patients with renal insufficiency, incidence of hypocalcemia, effect on bone mineral density, effect on urinary n-terminal telopeptide, and proportion of patients who have a documented skeletal-related event. **Results:** At the time of this analysis, a total of 20 out of a planned 40 patients have been enrolled, including 9 women, 11 men. Of those treated, 8 patients have completed the planned 12 cycles of therapy. Hypocalcemia was observed in 7 (35%) patients. Four patients (20%) experienced grade 3 hypocalcemia, 3 (15%) grade 2 or less. Two patients developed osteonecrosis of the jaw, one (5%) grade 1 and one (5%) grade 4 event. Data for the analysis of the primary endpoint of sCTX levels will be presented. **Conclusions:** Investigation of denosumab in MM patients with renal insufficiency defined as a creatinine clearance less than 30 mL/min is ongoing. Early data support that denosumab can be safely administered in this population. However, incidence of hypocalcemia despite aggressive prophylactic calcium dosing underscores the importance of the trial to inform safe practice in this more fragile population. Clinical trial information: NCT02833610. Research Sponsor: Amgen.

8521 Poster Session (Board #421), Fri, 8:00 AM-11:00 AM

Bortezomib, lenalidomide, and dexamethasone (VRD) is superior to lenalidomide, adriamycin, and dexamethasone (RAD) prior to risk-adapted transplant in newly diagnosed myeloma. *First Author: Stefan Knop, Medizinische Klinik und Poliklinik II, Julius Maximilians Universität Würzburg, Würzburg, Germany*

Background: High-dose chemotherapy (HDT) followed by autologous stem cell transplant (SCT) remains a standard of care in patients (pts) with newly diagnosed (ND) multiple myeloma (MM). While lenalidomide (R) maintenance is acknowledged to improve outcomes, intensified consolidation (such as tandem-SCT) has yielded conflicting results. Allogeneic (allo) SCT holds the promise of curative potential at the cost of higher treatment-related mortality (TRM). In a previous phase 2 study, we showed a very low TRM rate (6.1%) and feasibility of 12 months (mos) of R maintenance (maint), with auto/allo SCT after R/adriamycin/dexamethasone (RAD). This prompted us to compare, on a randomized rather than a "biological assignment" basis, a second auto- versus (vs) an allo-SCT in pts with an unfavorable prognosis. **Methods:** The current protocol (DSMM XIV, NCT01685814) was set up according to a double 2x2-factorial design. Post-induction (PInd) CR rate was the efficacy endpoint for the comparison of RAD vs bortezomib (V)/RD (VRD; 3 cycles each). If pts had achieved >VGPR to HDT, a second randomization (2ndR) compared immediate R maint (arm A2) with a second auto-SCT (B2). In case of < VGPR, pts were randomized between a second auto- (C2) and allo-SCT (D2). Planned R maint. duration was 36 mos, except after allo (12 mos). **Results:** Between 05/2012-06/2016, 476 pts were randomized and 469 received at least one dose of study drug. Pts' median age was 55 (range, 32–65) years. 11.3% of pts had FISH del17p; 11.6% had t(4;14); and 4.4% had t(14;16). PInd CR rate was 11.8% (90% CI, 7.9%-16.3%) with RAD and 13.0% (90% CI, 8.9-18.0) with VRD (P = .697). 382 pts underwent R2 with 279 pts. (73%) in >VGPR and 103 (27%) in < VGPR, respectively. Median duration of R maint (N = 298) was 21.2 mos for A2, 23.1 mos for B2, 27.4 mos for C2, and 11.0 mos. for D2. At a median follow-up of 40.2 (0.5-87.0) months, median PFS from first randomization with RAD was 41.7 (95% CI, 35.4-48.5) mos vs. 53.7 (95% CI, 46.2-63.1) mos with VRD (P = .0439). Median PFS from 2ndR was 38.7 (95% CI, 30.3-47.3) mos for the 181 RAD vs. 50.7 (95% CI, 44.4-64.9) mos for the 201 VRD pts (P = .0126). Median overall survival (OS) cannot be estimated. With 47 deceased RAD vs 36 VRD pts, HR was .671 (95% CI, .435-1.037; P = .0703). **Conclusions:** In this study, median PFS benefit was 12 mos in favor of VRD vs. RAD despite comparable PInd CR. We show for the first time a len-PI to be superior to a len-chemo triplet, confirmed with positive OS trends. 3-year PFS for all consolidation arms will be presented. Clinical trial information: NCT01685814. Research Sponsor: Celgene, AMGEN.

Genetic polymorphisms associated with clostridium difficile infection in multiple myeloma patients undergoing autologous stem cell transplantation. *First Author: Issam Hamadeh, Levine Cancer Institute, Charlotte, NC*

Background: CDI is the primary cause of infectious diarrhea in immunocompromised patients including those undergoing autologous stem cell transplant (SCT). Given the key role of gut microbiome and its interaction with host immune system, we investigated whether polymorphisms in innate immunity genes (identified through Ingenuity Pathway Analysis) were associated with CDI. **Methods:** We queried our database to identify MM patients who underwent an autologous SCT between April 2015-June 2019. Patients who had their buccal swabs collected through an IRB approved specimen collection protocol were included herein. Data were collected on age, conditioning regimen, CDI diagnosis, time from admission until CDI diagnosis, absolute neutrophil count (ANC) at time of CDI diagnosis, and antibiotic prophylaxis. Genomic DNA was extracted from buccal swabs and genotyped for 62 single nucleotide polymorphisms (SNPs) in *ASPH, RLBP1L1, ATP7B, IL-8, FAK, TNFRSF14, CTH, TLR* and *IL-4*. Univariate and multivariate logistic regression analyses were performed to assess association between CDI and presence of SNPs in these genes. **Results:** A total of 83 patients were identified (25 cases and 58 controls). Baseline characteristics were comparable between two groups. Median age was 67 years (range: 50-79). All patients received high dose melphalan as conditioning, and the same antibiotic prophylaxis during peri-transplant period. Median time from hospitalization until CDI diagnosis was 10 days (IQR:9 days), and median ANC was 0.7/mL (IQR:1.6/mL). Two SNPs (rs2227307 T > G in *IL-8* and rs2234167 G > A in *TNFRSF14*) were significantly associated with CDI risk in both univariate and multivariate logistic regression analyses (Table). **Conclusions:** Our findings suggest that rs227307G (in *IL-8*) and rs2234167A (in *TNFRSF14*) alleles are potential risk factors for CDI after autologous SCT. Our findings, if validated in a larger cohort, would support genetic testing as a screening tool to identify patients who might benefit from prophylaxis against CDI. Research Sponsor: Carolinas Myeloma Research Foundation.

8523 Poster Session (Board #423), Fri, 8:00 AM-11:00 AM

A first-in-class ex vivo combination between cytokine-induced memory like (CIML) NK cells and a CD38 targeting antibody recruiting molecule (ARM) as a novel approach to target NK cells without cellular engineering for the treatment of multiple myeloma. *First Author: Luca Rastelli, Kleo Pharmaceuticals, New Haven, CT*

Background: Cytokine-induced memory-like (CIML) NK cells differentiate after a brief preactivation with interleukin-12 (IL-12), IL-15, and IL-18 and exhibit enhanced responses to cytokine or activating receptor restimulation for several weeks to months. Antibody Recruiting Molecules (ARM) are bifunctional molecules that simultaneously bind a given tumor marker and engage endogenous IgG antibodies, therefore binding and activating NK cells via their FcR and targeting them to kill tumors cells. A first in class therapy that has the potential to improve the activity of CIML NK cells by combining them with KP1237, a CD38-ARM is presented for the treatment of newly diagnosed multiple myeloma (MM) patients who are minimal residual disease positive (MRD+) and eligible for autologous stem cell transplant (ASCT). **Methods:** Specific killing of CD38 expressing MOLP-8 cells by CIML NK cells alone or in combination with KP1237 was measured. Additionally, NK and CIML NK cells from healthy volunteers and MM patients at various stages of the disease were tested for activity against autologous and allogeneic tumor cell targets. In these experiments, surface phenotype and activation status of NK cells were determined. **Results:** A statistically significant increase in specific killing was observed when KP1237 was used in combination with CIML NK cells in an ADCC assay against CD38 expressing MOLP-8 ($p = 0.0105$, mean 61.8 ± SD 9.1 and mean 83.7 ± SD 13.58 for CIML NK alone and CIML NK+KP1237, respectively). This effect was accompanied by an increase in plasma membrane retention of CD107a. Surface phenotype of NK and CIML NK cells from healthy volunteers and MM patients was compared since the functional activity of NK cells from such patients is debated. We report surface expression of CD56, CD16, CD57, NKG2D, Nkp44, Nkp46, CD107a, KIR2DL2/3/DS2, and CD69 as well as frequencies of CD57hi CD56+ mature versus CD57lo CD56+ immature NK cell subsets. Further, autologous CIML NK cells + KP1237 exhibit cytotoxicity towards patient plasma cells. **Conclusions:** The activity of CIML NK cells towards CD38 expressing MM target cells is improved by the addition of KP1237 avoiding the need for cellular engineering with chimeric antigen receptors. This led to the development of the combination drug product consisting of patient autologous CIML NK cells, KP1237 and IVIG. Clinical development is under way for (MRD+) MM patients eligible for ASCT. Research Sponsor: Kleo Pharmaceuticals.

Prospective evaluation of spatial heterogeneity at single cell resolution in multiple myeloma. *First Author: Maximilian Merz, Roswell Park Cancer Institute, Buffalo, NY*

Background: Osteolytic lesions (OL) characterize symptomatic multiple myeloma (MM). It is still unclear why plasma cells (PC) cause OL in certain regions of the body while other areas show no signs of bone destruction despite significant bone marrow infiltration. We conducted the first study of single cell RNA sequencing (scRNA-seq) and whole-exome sequencing (WES) of PC obtained from random bone marrow samples (RS) and paired OL. **Methods:** As part of a prospective clinical trial, patients consented to an imaging-guided biopsy of new OL identified by PET/CT in addition to the RS from the iliac crest. Both samples were acquired in the same session. On the same day PC were isolated using a CD138 positive selection kit and single cell gene expression libraries were generated for scRNA-seq. Frozen PC were subjected to DNA extraction and WES. **Results:** We sequenced 93569 purified, viable PC from paired samples from 15 different locations in the first 7 consecutive patients (median PC from location: 7203; range 1121-10279). Quality assessment of scRNA-seq data revealed no differences between PC in OL and RS. Based on scRNA-seq, 9-24 different subpopulations of PC in individual patients were identified. Over 90% of clusters found in the RS were also present in corresponding OL suggesting a common ancestor. This was true for patients with overlapping as well as divergent mutational profiles in RS and OL as shown by WES. In each patient we found PC clusters that were predominantly present in OL. Respective clusters were characterized by expression of Wnt-signaling inhibitors like DKK-1, Frzb and sFRP-2 and other genes linked to MM bone disease (HGF, CXCL-12, CCL3). Lysosome-associated membrane protein-like molecule 5 (LAMP5) and J-chain were overexpressed in OL clusters. Analysis of genes (IKZF1 and IKZF3) associated with response to treatment and outcome revealed vast heterogeneity and differences in risk scores (UAMS70 and IFM15) on a single cell level from different locations in individual patients. **Conclusions:** Our study provides the first evidence that PC from OL have distinct transcriptomic profiles that link site-specific gene expression to development of bone disease and adverse outcome. Research Sponsor: German Cancer Aid.

8525 Poster Session (Board #425), Fri, 8:00 AM-11:00 AM

KarMMa-RW: A study of real-world treatment patterns in heavily pretreated patients with relapsed and refractory multiple myeloma (RRMM) and comparison of outcomes to KarMMa. *First Author: Sundar Jagannath, Mount Sinai Medical Center, New York, NY*

Background: RRMM patients (pts) triple-class exposed (to immunomodulatory drugs [IMiDs], proteasome inhibitors [PIs] and anti-CD38 monoclonal antibodies [mAbs]) have limited treatment (tx) options. The ongoing phase II KarMMa study (NCT03361748) is examining idecabtagene vicleucel (ide-cel; bb2121), a BCMA targeted CAR T cell therapy, in RRMM pts with ≥3 prior regimens (IMiD, PI and CD38 mAb inclusive) who are refractory to their last tx per IMWG criteria. This study aimed to 1) assess tx patterns and outcomes in real world (RW) RRMM pts similar to the KarMMa population and; 2) compare outcomes with SoC in a synthetic cohort vs ide-cel in KarMMa. **Methods:** In this global, noninterventional, retrospective study (KarMMa-RW), pt-level data from clinical sites, registries and databases were collated into a single data model. RW pts meeting KarMMa eligibility criteria (eligible cohort; EC) were compared with KarMMa (N = 128) using trimmed stabilized inverse probability of tx weighted propensity scores (IPTW PS) for pts in both studies with Poisson regression for ORR and ≥VGPR, and Cox models with study as a term for PFS. All models were adjusted for unbalanced covariates. **Results:** Of 1949 RW pts, 1171 were refractory to last regimen (median age, 68 y; median no. of prior regimens, 5; triple-class refractory, 41%). Further selection for subsequent tx, organ function and no comorbidities yielded 190 EC pts who had > 90 distinct tx regimens. With a median follow-up of 11.3 mo (KarMMa) and 10.2 mo (EC) at data cutoff (Oct 30, 2019), ORR, ≥VGPR and PFS were significantly improved in KarMMa vs EC (Table). **Conclusions:** Results from the KarMMa-RW study confirm that there is no clear SoC for heavily pretreated RW RRMM pts and responses are suboptimal with currently available therapies. Ide-cel showed deep, durable responses and significantly improved PFS in RRMM pts, representing a potential new tx option in RRMM. Clinical trial information: tbd. Research Sponsor: Bristol-Myers Squibb and bluebird bio.

8526 Poster Session (Board #426), Fri, 8:00 AM-11:00 AM

Efficacy and safety of carfilzomib, dexamethasone, daratumumab (KdD) twice-weekly at 56 mg/m^2 and once-weekly at 70 mg/m^2 in relapsed or refractory multiple myeloma (RRMM): Cross-study comparison of candor and MMY1001. *First Author: Xavier Leleu, Hopital Claude Huriez, Lille, France*

Background: CANDOR, a randomized phase 3 study, showed significantly improved progression-free survival (PFS) and overall response rate (ORR) for twice-weekly KdD 56 mg/m^2(TW KdD56) vs Kd in RRMM, with a 37% risk reduction in disease progression or death (Usmani, 2019). The benefit of once-weekly carfilzomib (K) at 70mg/m^2 for the same triplet, KdD (OW KdD70), in RRMM was shown in the nonrandomized MMY1001 study. We performed robust cross-study comparisons to investigate how TW KdD56 compares to OW KdD70. **Methods:** For alignment of inclusion criteria, the primary analysis set for this cross-study comparison included individual data from CANDOR pts with prior exposure to bortezomib and immunomodulatory drug, and all pts in MMY1001. Propensity score method (Rambaldi, 2019; Kumar, 2019) allowed reliable cross-study comparison, controlling for baseline prespecified covariates such as age, creatinine clearance, performance status, prior treatment exposure/refractoriness, and time from initial diagnosis and relapse. Propensity score adjustment based on inverse probability of treatment weighting (IPTW) was implemented on efficacy endpoints, while safety was evaluated side-by-side. **Results:** The unadjusted and adjusted propensity score comparison of CANDOR and MMY1001 showed similar efficacy in terms of ORR and PFS in the TW KdD56 and OW KdD70 groups (Table). As propensity score comparisons were for efficacy only, safety comparisons between CANDOR and MMY1001 included differing sample sizes and treatment duration (Table). The safety of KdD56 and KdD70 was consistent with the known safety profiles of individual study treatments. **Conclusions:** OW KdD70 is an efficacious dosing option with favorable benefit-risk, comparable to TW KdD56. The OW KdD70 dosing option represents a more convenient regimen that might encourage adherence and potentially lead to better outcomes for RRMM pts. Clinical trial information: NCT03158688. Ixazomib vs placebo maintenance for newly diagnosed multiple myeloma (NDMM) patients not undergoing autologous stem cell transplant (ASCT): The phase III TOURMALINE-MM4 trial. *First Author: Meletios A. Dimopoulos, National and Kapodistrian University of Athens School of Medicine, Athens, Greece*

Background: Maintenance therapy delays disease progression in non-ASCT NDMM patients. However, in practice, currently used maintenance therapies may be limited to fixed duration due to toxicity and route of administration; additional options are needed. **Methods:** 706 non-ASCT NDMM patients who received 6–12 months of standard-of-care induction therapy and achieved at least a partial response (≥PR) were randomized 3:2, double-blind, to the oral proteasome inhibitor (PI) ixazomib (n = 425; 3 mg, cycles 1–4, then, if tolerated, 4 mg, cycle 5 onwards) vs placebo (n = 281) on days 1, 8, and 15 of 28-day cycles for ≤2 yrs. Patients were stratified by prior PI exposure (yes vs no), pre-induction International Staging System (ISS) disease stage (I/II vs III), age (< 75 vs ≥75 yrs), and post-induction best response (complete or very good partial response [CR/VGPR] vs PR). Primary endpoint was progression-free survival (PFS). **Results:** Baseline characteristics were well balanced. Overall median age was 73 yrs, 38% of patients were aged ≥75 yrs, 35% were ISS stage III, and 22%/40%/38% had CR/VGPR/PR post induction. Overall, 82% of patients received a PI and 33% an immunomodulatory drug as part of their induction regimen. At a median follow-up of 21.1 months, median PFS was 17.4 months with ixazomib vs 9.4 months with placebo (hazard ratio [HR] 0.659, 95% confidence interval [CI] 0.542–0.801, p < 0.001). Significant (p < 0.001) PFS benefit was seen in patients who achieved CR/VGPR post induction (Table). Overall survival data are not yet mature (19% of events); follow-up is ongoing. Treatment-emergent adverse events (TEAEs) were mostly grade 1–2 (37% vs 23% of patients had grade ≥3 TEAEs with ixazomib vs placebo). Common TEAEs for ixazomib vs placebo included nausea (27% vs 8%), vomiting (24% vs 4%), and diarrhea (23% vs 12%); 5% vs 6% of patients had new primary malignancies. No cumulative toxicities were observed. **Conclusions:** Ixazomib maintenance therapy in non-ASCT NDMM patients showed a clinically meaningful 34% reduction in the risk of progression or death, with a well-tolerated safety profile. Ixazomib is the first oral PI maintenance option for non-ASCT NDMM patients. Clinical trial information: NCT02312258. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Multiple myeloma (MM) vaccination (influenza, FV and pneumococcal, PV) rates worldwide and impact on infection, hospitalization, and death. *First Author: Michael A. Thompson, Aurora Cancer Care, Aurora Research Institute, Advocate Aurora Health, Milwaukee, WI*

Background: MM is a cancer of the immune system. Infections are common reasons for hospitalization and death in MM. As MM patients (pts) are living longer, with prolonged exposure to systemic therapy, there is a need to vaccinate pts and to determine the effectiveness of these vaccines. Vaccination in MM pts is underutilized, based on a study of vaccination patterns in a large health system (Alemu JPCRR 2017) and data collected via a pt self-report online portal (Thompson ASCO 2020). We analyzed FV and PV patterns and associated outcomes in INSIGHT MM, the largest global, prospective, observational study in MM to date. **Methods:** INSIGHT MM aims to understand MM pt and disease characteristics at diagnosis and relapse, treatment patterns, clinical outcomes, and treatment-associated tolerability, effectiveness, quality of life, and healthcare resource utilization. INSIGHT MM has enrolled 4318 MM pts from 15 countries worldwide; pts are being followed up prospectively for ≥5 yrs. Vaccine status is collected at study entry and yearly. We analyzed FV and PV patterns and associated outcomes of pts enrolled in July 2016–2019. **Results:** At data cutoff (Sep 1, 2019), 2562/2523 pts had study entry data on FV/PV status. Overall vaccination rates were low (FV 40%, PV 30%) and varied by region: FV 56%/38%/27%/4% and PV 43%/28%/21%/5% in US/Europe/Latin America/Asia. In evaluable pts, lack of vaccination was associated with higher infection and hospitalization rates for FV, and with increased risk of death (univariate analysis) for both FV and PV (Table; multivariate analysis underway). Infections, including influenza and pneumonia, were the cause of death in 19% (43/226) / 8% (9/108) (P = 0.018) of pts who did not receive FV / received it in the past 2 yrs and 19% (46/236) / 9% (9/100) (P = 0.027) of pts who did not receive PV / received it in the past 5 yrs, and in 7%/15%/20%/40% of pts who died in US/ Europe/Latin America/Asia (P < 0.0001). **Conclusions:** Global vaccination rates in MM pts were low and varied by region. Lack of vaccination correlated with rates of infection (FV), hospitalization (FV), and death (FV and PV). Further MM datasets should be analyzed to confirm the findings. Vaccination data should be collected in prospective clinical trials as it may affect survival. Vaccination is important in MM and should be encouraged. Clinical trial information: NCT02761187. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

8529 Poster Session (Board #429), Fri, 8:00 AM-11:00 AM

Updates from a phase Ib study of isatuximab (Isa), bortezomib (V) and dexamethasone (D) plus cyclophosphamide (C) or lenalidomide (R) in transplant-ineligible, newly diagnosed multiple myeloma (NDMM). *First Author: Enrique M. Ocio, Marqués de Valdecilla University Hospital (IDIVAL), University of Cantabria, Santander, Spain*

Background: We report updated data from a Phase Ib study of Isa, a CD38 monoclonal antibody, plus VCd or VRd in transplant ineligible patients (pts) with NDMM (NCT02513186). **Methods:** Isa-VCd: Isa (10 or 20 mg/kg; weekly [QW] cycle 1 [C1], then Q2W), V (1.3 mg/m^2; twice weekly C1, then QW), C (300 mg/m^2; QW C1, then Days [D] 1, 8, 15 to C12), d (20 mg; twice weekly C1, then D1, 2, 8, 9, 15, 16, 22, 23 to C12). Isa-VRd: Isa (10 mg/kg), V and d as described above; R (25 mg/day; D1–14 and D22–35). Efficacy and safety were evaluated. Conventional (M-protein levels) and minimal residual disease (MRD) IMWG response assessments were compared. MRD negativity was assessed at 10^{-5} by next-generation sequencing and flow. Mass Spectrometry (MS) negativity (no detectable serum M-protein) was assessed for 13 pts by Immuno-Capture and Liquid Chromatography coupled to High Resolution MS. **Results:** As of Nov 18, 2019, 17 pts were treated with Isa-VCd (10 mg/kg, n = 13; 20 mg/kg, n = 4), 27 with Isa-VRd; 53% and 63% remained on treatment, respectively. Infusion reactions were seen in 53% of Isa-VCd and 63% of Isa-VRd pts; Grade ≥3 infections in 23% and 37%; serious adverse events in 47% and 52%. See table for efficacy. 3 MRD positive pts were MS positive with persistent detectable M-protein (> 10 μg/mL). 8/10 MRD negative pts were MS positive (4 at 5-10 μg/mL; 4 at > 10 μg/mL) and 2/10 were MS negative (< 5 μg/mL). Stable residual M-protein was observed by MS up to 23 months post-MRD negativity. All pts tested by MS are still progression-free. **Conclusions:** Isa-VCd/VRd shows encouraging efficacy and tolerability in NDMM. MS seems to be more sensitive than MRD; low levels of M-protein were detectable even in MRD negative pts. Clinical trial information: NCT02513186. Research Sponsor: Sanofi.

Once weekly selinexor, carfilzomib, and dexamethasone (SKd) in patients with relapsed/refractory multiple myeloma (MM). *First Author: Cristina Gasparetto, Duke University Cancer Center, Durham, NC*

Background: Selinexor is a novel, first-in-class selective inhibitor of nuclear export (SINE), which blocks exportin 1 (XPO1), forcing the nuclear retention and activation of tumor suppressor proteins. Selinexor in combination with low dose dexamethasone (Sel-dex) was approved by the FDA, based on data from the STORM study wherein Sel-dex induced an overall response rate (ORR) of 26.2% in patients (pts) with refractory MM. We hypothesize that once weekly (QW) SKd may be an active well tolerated regimen and evaluated this combination in a dose escalation/expansion study. **Methods:** STOMP is a phase 1b/2 study evaluating various doses and enrolled pts with carfilzomib naive relapsed MM. Oral selinexor was dosed QW at 80 or 100 mg. Carfilzomib was dosed QW (on days 1, 8 and 15 of 28-day cycle) at 56 mg/m^2 or 70 mg/m^2. Dexamethasone was dosed at 40 mg QW. The primary objectives of the study are to assess the maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), as well as explore the efficacy and safety of SKd. **Results:** As of January 2020, 18 pts were enrolled. Median age was 71 years (range: 50-76). Median number of prior regimens was 4 (range: 1-8). All pts (n = 18) were previously treated with bortezomib and lenalidomide, and 50% and 56% pts were refractory to bortezomib and lenalidomide respectively. Nine (50%) pts received prior pomalidomide treatment and 8 (44%) pts were refractory. Eleven (61%) pts received prior daratumumab treatment and 9 (50%) were refractory. The MTD was selinexor 80 mg QW, carfilzomib 56 mg/m^2 QW and dexamethasone 40 mg QW. The ORR and CBR were 72% and 79% respectively with 4 complete responses, 7 very good partial responses, 2 partial responses, and 1 minimal response. Stable disease was observed in 3 pts. With a median follow-up period of 4.7 (1.8-16.3) months, median progression-free survival has not been reached. Common treatment-related adverse events (total, Grade ≥3) were thrombocytopenia (83.3%, 66.7%), nausea (66.7%, 0%), anemia (55.6%, 11.1%), fatigue (50%, 11.1%), anorexia (44%, 5.6%), weight loss (44%, 0%), and neutropenia (33.3%, 11.1%). **Conclusions:** Once weekly SKd demonstrated an encouraging ORR of 72% in pts with a median of 4 lines of prior therapy. The majority of responses are deep and predominantly CR and VGPR. The combination is well tolerated with no new safety signal, no Grade ≥3 nausea, vomiting, diarrhea, weight loss or anorexia. The side effects are a function of the dose and schedule and can be managed with dose modification and supportive care. Enrolment is ongoing and supports a phase 3 study of SKd. Clinical trial information: NCT02343042. Research Sponsor: Karyopharm Therapeutics Inc.

8531 Poster Session (Board #431), Fri, 8:00 AM-11:00 AM

Pharmacodynamic (PD) responses drive dose/schedule selection of CC-92480, a novel CELMoD agent, in a phase 1 dose-escalation study in relapsed/refractory multiple myeloma (RRMM). *First Author: Lilly Wong, Bristol-Myers Squibb, San Diego, CA*

Background: CC-92480 is a novel cereblon (CRBN) E3 ligase modulator (CELMoD) agent under investigation in a first-in-human phase 1 study (NCT03374085) in RRMM patients (pts). In preclinical studies, CC-92480 demonstrated efficient and sustained degradation of Ikaros/Aiolos leading to broad antiproliferative effects and induction of apoptosis in MM cell lines, and enhanced immune stimulatory effects. **Methods:** Eligible RRMM pts received escalating doses of CC-92480 + dexamethasone. Several dosing schedules were evaluated in parallel; more continuous with 4-day or 7-day breaks and intensive with longer breaks in a 28-day cycle. Peripheral blood and bone marrow aspirates (BMA) were taken before and during treatment at multiple time points. Levels of Ikaros/Aiolos in T cells, and effects on immunomodulation were assessed by flow cytometry. Weekly levels of free light chain (sFLC) and B-cell maturation antigen (sBCMA) were determined in serum during the first 2 cycles of treatment. BMA clots were analyzed by immunohistochemistry for CRBN, Ikaros, Aiolos, ZFP91, c-Myc, and IRF-4. **Results:** The rate and depth of Ikaros/Aiolos degradation in T cells increased with dose and reached maximal at ≥0.6 mg QD with sustained degradation over 24 hrs. Substrate recovery occurred during drug holidays with faster recovery at lower doses, and reached full recovery with ≥7-day break for all dose levels tested. B cells decreased with increasing dose, and T-cell proliferation was demonstrated at all doses/schedules. Substrate degradation was also evident in bone marrow plasma cells including in the setting of low CRBN levels. In these heavily pretreated, including triple-class-refractory, RRMM pts, CC-92480 dosing periods led to rapid and sustained decreases in sFLC and sBCMA. This was dose and schedule dependent and correlated with plasma exposure; the longer breaks in the intensive schedules led to rapid rebound of these markers, while the more continuous schedules maintained the depth of suppression. **Conclusions:** PD responses correlated with dose and schedule. PD samplings at multiple time points during treatment allowed dynamic changes and kinetics of each biomarker in all schedules to be followed and to inform next steps. Ikaros/Aiolos degradation and recovery, coupled with changes in sFLC and sBCMA, guided the adjustment of the dosing schedule during dose escalation in order to optimize efficacy and tolerability. The study is ongoing and selection of the recommended phase 2 dose is pending. Research Sponsor: Bristol-Myers Squibb.

Diagnostic performance of skeletal survey versus 18F-FDG-PET/CT for detecting lytic lesions in smoldering multiple myeloma. *First Author: Elizabeth M. Hill, NCI/NHLBI, Bethesda, MD*

Background: Per NCCN Guidelines for smoldering multiple myeloma (SMM), whole body radiography, i.e. skeletal survey (SS), should be used to rule out osteolytic bone lesions. If negative, more sensitive imaging techniques such as whole body ^{18}F-FDG-PET/CT(PET/CT), MRI, or low dose CT should be used to differentiate between SMM and multiple myeloma (MM). The false-negative rate of SS is high (30-70%). The frequency of false-positive SS in SMM is less well known but important because of its common use in community practice. We examine the specificity of SS in patients with a presumed diagnosis of SMM and question if SS is still warranted prior to modern imaging techniques to confirm a diagnosis of SMM. **Methods:** Records of patients sequentially referred from the community and evaluated for a presumed diagnosis of SMM at the National Institutes of Health Myeloma Program between April 2010 to January 2020 were reviewed. Patients with a SS and PET/CT performed within 30 days were included. Positive findings on PET/CT were defined per the 2014 IMWG criteria as one or more sites of osteolytic bone destruction seen on CT. The sensitivity and specificity of SS were calculated using PET/CT as the reference test. **Results:** Charts from 144 patients with presumed SMM were reviewed. A total of 76 SMM patients had both a SS and PET/CT performed within 30 days of each other. Sixty-four patients (84.2%) showed concordant results. Twelve (15.8%) patients had discordant imaging results. SS was falsely negative in 3 (4.7% (95% CI: 1.2%-14.2%)) patients and falsely positive in 9 (69.2% (95% CI: 38.9%-89.6%)) patients. SS had a sensitivity of 57.1% (95% CI: 20.2%-88.2%) and a specificity of 86.9% (95% CI: 76.2-93.5). **Conclusions:** In patients presumed to have SMM, disease burden is low thus highly sensitive imaging modalities are needed to rule out bone disease. This study confirms the low sensitivity of SS in the SMM population. It more importantly points out the low specificity of SS in SMM. The IMWG no longer recommends conventional SS prior to whole body CT (or PET/CT) as first imaging choice in SMM. While the argument may be made that SS should still be used upfront due to low cost and widespread availability, this study shows the risk of overestimating disease. Over 10% of patients in this series had false positive disease on SS and thus at risk of receiving unnecessary treatment. Not only concerning for patient toxicity but more so financial toxicity. If SS is used, it is important to review positive findings directly with a radiologist and consider follow-up confirmatory imaging. Research Sponsor: None.

Multiparameter flow cytometry (MFC) and next generation sequencing (NGS) for minimal residual disease (MRD) evaluation: Results of the FORTE trial in newly diagnosed multiple myeloma (MM). *First Author: Stefania Oliva, GIMEMA, European Myeloma Network, Italy*

Background: The role of MRD by MFC and NGS is well known in MM, with few data on the concordance of the two techniques. We analyzed and compared MRD data from the FORTE trial both by MFC and NGS. **Methods:** Newly diagnosed MM patients (pts) ≤65 years were randomized to: carfilzomib, lenalidomide, dexamethasone (KRd) induction-autologous stem cell transplant (ASCT) - KRd consolidation (KRd_ASCT); 12 KRd cycles (KRd12); carfilzomib, cyclophosphamide, dexamethasone (KCd) induction-ASCT-KCd consolidation (KCd_ASCT). Pts were then randomized to maintenance: lenalidomide alone or plus carfilzomib. MRD was assessed by 8-color second generation flow cytometry (sensitivity 10^{-5}) in pts with ≥very good partial response (VGPR) before maintenance. In a subgroup of these pts, next generation flow (NGF; sensitivity 10^{-5}-10^{-6}) was performed. In ≥CR pts, MRD pre-maintenance was also assessed by NGS (Adaptive Biotechnologies; sensitivity 10^{-5}-10^{-6}). Thus, both MFC and NGS evaluations were available only in ≥CR pts. 1-year sustained MRD negativity by MFC and NGS was also analyzed in pts with at least one sample available at least 1 year apart. **Results:** MFC and NGS data were available in 184/233 (79%) CR pts (66 KRd_ASCT, 67 KRd12 and 51 KCd_ASCT). Median age of this ≥CR population was 57 years (IQR 52-62), 13% had International Staging System (ISS) III and 27% high risk cytogenetics by FISH [either del(17p) or t(4;14) or t(14;16)]. Table reports MRD negativity rate by MFC and NGS at a cut-off of 10^{-5} and 10^{-6} among ≥CR negative pts in the 3 arms. NGS negativity at a cut-off 10^{-6} was found in 36/133 (27%) ≥CR pts (for 51/184 CR pts 10^{-6} sensitivity was not reached). In evaluable pts, 1-year sustained 10^{-5} MRD negativity by MFC and NGS was superimposable (83%). We evaluated concordance of MRD results by the two techniques and observed agreement was 86% for MFC and NGS at 10^{-5} evaluable samples (n: 335; r: 0.61) and 78% for MFC and NGS at 10^{-6} evaluable samples (n: 56; r: 0.77). **Conclusions:** In pts who achieved ≥CR, similar rate of pre-maintenance 10^{-5} negativity by MFC and NGS has been reached in each arm, with 83% pts maintaining 1-year MFC or NGS 10^{-5} sustained MRD negativity. Concordance between MFC and NGS was good, particularly when the same sensitivity was reached. Longer follow up is needed to draw definitive conclusions. Clinical trial information: NCT02203643. Research Sponsor: Amgen.

Association of elevated red cell distribution width and overall survival in multiple myeloma. *First Author: Sam Rubinstein, Vanderbilt University Medical Center, Nashville, TN*

Background: The most widely used multiple myeloma (MM) staging system, the Revised International Staging System (R-ISS), is based on lactate dehydrogenase, albumin, cytogenetics, and beta-2 microglobulin (B2M). B2M has limited clinical utility, is often only obtained to compute R-ISS, and is often a send-out test. Prior studies have shown that elevated red cell distribution width (RDW), a common test that is part of the routine complete blood count, is associated with reduced overall survival (OS) in MM. We hypothesized that a MM staging system could be constructed replacing B2M with RDW. **Methods:** Patients treated at Vanderbilt University Medical Center from 2000 to 2018 with cancer registry-confirmed MM diagnoses were included. OS was computed by registry-curated death and diagnosis dates; living patients were censored at date last known alive or of last follow up. A Cox proportional hazards model determining the independent effects of R-ISS, age, and RDW on OS was built. An alternate staging system (RDW-SS) was developed, replacing the B2M cutoffs in R-ISS with RDW (stage 1: RDW $<$ 14.0% stage 2: RDW 14.0-15.5%; stage 3: RDW $>$ 15.5%). Cox models comparing RDW-SS and R-ISS after adjustment for age and category of induction therapy (proteasome inhibitor [PI] and immunomodulatory drug [IMiD]), PI only, IMiD only, other) were built. **Results:** In 604 MM patients with available data, RDW was independently associated with OS after adjustment (HR = 1.069 per 1% RDW increase, $p < 0.001$). RDW-SS stages were associated with reduced OS (RDW-SS 2 HR 1.52, 95% CI 1.09 – 2.11, $p = 0.01$; RDW-SS 3 HR 2.13, 95% CI 1.37 – 3.28, $p < 0.001$) after adjustment; R-ISS stages were not (Table). **Conclusions:** RDW at MM diagnosis was independently associated with reduced OS, after adjustment for the clinical factors of age and treatment exposure; notably, R-ISS was not. The RDW-SS is simpler to obtain than R-ISS and may have improved prognostic value pending independent validation. If confirmed, mechanistic study of the etiology of this relationship is warranted. Research Sponsor: U.S. National Institutes of Health.

Oncolytic virus pelareorep plus carfilzomib phase I trial in carfilzomib-refractory patients (NCI 9603): Responses with cytokine storm. *First Author: Douglas Weston Sborov, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Viral oncolytic therapy with intravenous Pelareorep, the infusible form of reovirus, is supported by preclinical data indicating that its antitumor activity results from direct cytolysis and an immune response against infected MM cells. Our preclinical data has shown that monocytes serve as carriers of reovirus from the peripheral blood to the bone marrow (Dona et al, ASH, 2019). In this abstract we present patients treated to date that were Carfilzomib refractory at enrollment. **Methods:** Pelareorep (P), Carfilzomib (K), and dexamethasone (d) were all infused on days 1, 2, 8, 9, 15 and 16 of a 28-day cycle. Patients were pretreated with dexamethasone 20 mg intravenously, then Carfilzomib 20 mg/m^2 on days 1 and 2 of cycle 1, and 56 mg/m^2 thereafter. Pelareorep dose levels were at $3x10^{10}$, $4.5*10^{10}$, and planned $9*10^{10}$ median tissue culture infectious dose ($TCID_{50}$). **Results:** All 6 evaluable patients showed reovirus infection in the post-treatment marrow aspirates cycle 1 day 9. Despite all patients having Carfilzomib-refractory disease, 2 patients achieved partial responses, two patients with short duration stable disease but few side effects, and 2 patients with PD. Of the two responders, one patient developed fever and grade 4 thrombocytopenia during cycle 1 and withdrew mid cycle. The other patient with a PR developed a cytokine storm - this patient presented cycle 1 day 3 hypoxemic with pneumonia, systolic failure (LVEF 69%-- $>$ 26%), with biochemical evidence of hemophagocytic syndrome with elevated IL-2R, IL-6, and ferritin $>$ 25K. This patient responded to tocilizumab, but ultimately died two weeks later with sepsis. Autopsy revealed pneumonia, no areas of reovirus infection other than in myeloma cells, and reovirus productive infection in 5-35% of myeloma cells (i.e. capsid protein). **Conclusions:** While infection of myeloma cells was seen in all evaluable patients on cycle 1 day 9, those with a clinical response demonstrated concomitant CD8 & NK cell recruitment, PD L1 upregulation, activated caspase-3 expression, increased viral protein production within the myeloma cells, and these patients demonstrated mild to severe signs and symptoms consistent with secondary HLH. This is the first report of cytokine storm after oncolytic virus in a patient with a blood cancer, a syndrome thought to be related to T-cell activation from the combination treatment. This trial was supported by the NCI Division of Cancer Treatment & Diagnosis Cancer Therapy Evaluation Program (CTEP). Clinical trial information: NCT02101944. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

8536 Poster Session (Board #436), Fri, 8:00 AM-11:00 AM

Pivotal DREAMM-2 study: Single-agent belantamab mafodotin (GSK2857916) in patients with relapsed/refractory multiple myeloma (RRMM) refractory to proteasome inhibitors (PIs), immunomodulatory agents, and refractory and/or intolerant to anti-CD38 monoclonal antibodies (mAbs). *First Author: Sagar Lonial, Emory University Hospital, Winship Cancer Institute, Atlanta, GA*

Background: Single-agent belantamab mafodotin (B-cell maturation antigen targeting immunoconjugate) showed clinically meaningful activity and manageable safety in patients with heavily pre-treated RRMM (DREAMM-2, NCT03525678, *Lancet Oncol.*2020). We report updated results (median follow-up 9 months). **Methods:** DREAMM-2 is an ongoing single-agent belantamab mafodotin (2.5 or 3.4 mg/kg) study in patients with RRMM after ≥3 prior therapy lines and refractory to an immunomodulatory agent, a PI, and refractory and/or intolerant to an anti-CD38 mAb. Primary endpoint: overall response rate (ORR; ≥partial response per independent review committee). **Results:** ORR was 31% in the 2.5 mg/kg (19% with ≥very good partial responses [VGPR]) and 35% (24% with ≥VGPR) in the 3.4 mg/kg groups (Table). Duration of response (DoR) was not reached (NR) in the 2.5 mg/kg and 6.2 months in the 3.4 mg/kg groups; 1-year overall survival (OS) estimate was 53%. Common Grade 3/4 AEs (> 10% in either group) were keratopathy (2.5: 29%; 3.5: 24%), thrombocytopenia (2.5: 21%; 3.4: 32%), anemia (2.5: 20%; 3.4: 27%), pneumonia (2.5: 6%; 3.4: 13%), and neutropenia (2.5: 11%; 3.4: 16%). AEs were managed with dose delays (2.5: 54%; 3.4: 62%) and reductions (2.5: 34%; 3.4: 43%); discontinuations due to AEs were uncommon (2.5: 9%; 3.4: 12%). **Conclusions:** Single-agent belantamab mafodotin was well-tolerated, and clinically meaningful responses were sustained despite dose modifications with longer follow-up. Funding: GlaxoSmithKline (205678). Drug linker technology licensed from Seattle Genetics; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT03525678. Research Sponsor: GlaxoSmithKline.

8537 Poster Session (Board #437), Fri, 8:00 AM-11:00 AM

Corticosteriod tapering in patients (Pts) with relapsed or refractory multiple myeloma (RRMM) receiving subcutaneous daratumumab (DARA SC): Part 3 of the open-label, multicenter, phase Ib PAVO Study. *First Author: Hareth Nahi, Karolinska Institute, Department of Medicine, Division of Hematology, Karolinska University Hospital at Huddinge, Stockholm, Sweden*

Background: Intravenous DARA (DARA IV) is approved for the treatment of MM. In Part 2 of PAVO, DARA SC, a concentrated, pre-mixed SC co-formulation of DARA and recombinant human hyaluronidase PH20 (rHuPH20), was well tolerated, with a low infusion-related reaction (IRR) rate, and showed consistent serum concentrations and similar efficacy to DARA IV in RRMM pts. In PAVO Part 3, we evaluated the safety of pre- and post-dose corticosteroid tapering during DARA SC administration. **Methods:** RRMM pts with ≥2 prior lines of treatment, including a proteasome inhibitor (PI) and immunomodulatory drug (IMiD), received DARA SC (DARA 1,800 mg + rHuPH20 30,000 U in 15 mL) by manual SC injection per approved IV monotherapy dosing schedule. Pts received a 3-week (wk) tapering schedule (corticosteroid-free by Cycle [C] 1 Day [D] 22), with methylprednisolone (MP) given PO/IV pre-dose (C1D1, 100 mg; C1D8, 60 mg; C1D15, 30 mg) and PO post-dose (C1D1, 20 mg for 2 days; C1D8, 20 mg for 1 day; C1D15, 20 mg for 1 day), or a 2-wk tapering schedule (corticosteroid-free by C1D15), with MP given PO/IV pre-dose (C1D1, 100 mg; C1D8, 60 mg) and PO post-dose (C1D1, 20 mg for 2 days; C1D8, 20 mg for 1 day). **Results:** Pts (3-wk group, n = 15; 2-wk group, n = 15) received a median of 2 (range: 2-7) prior lines of therapy, with 37% refractory to a PI and an IMiD. The 3-wk and 2-wk groups received a median (range) of 14 (2-19+) and 8 (2-16+) DARA SC doses without corticosteroids, respectively. No IRRs were reported in the 3-wk group. 3 pts (20%) in the 2-wk group experienced IRRs on C1D1 (grade 3 hypertension, grade 2 chills, grade 1 pyrexia, grade 1 oropharyngeal pain, and grade 1 tachycardia). IRRs occurred within 2 h of the first DARA SC administration; no IRRs were reported at later administrations. Most common (≥25%) treatment emergent adverse events (TEAEs) were upper respiratory tract infection (40%) and fatigue and nausea (27% each). Most common (≥5%) grade 3/4 TEAEs were anaemia, lymphopenia, neutropenia, and hypertension (7% each). At median follow-up of 6.8 mo (3-wk group) and 2.4 mo (2-wk group), the overall response rates were 40% (95% CI, 16-68%) and 27% (95% CI, 8-55%) and ≥very good partial response rates were 13% (95% CI, 2-40%) and 7% (95% CI, 0-32%), respectively. **Conclusions:** Rapid corticosteroid tapering over 2 wks is safe in RRMM pts receiving DARA SC. These data help guide future DARA SC combinations (ie, T-cell redirectors, CAR-T, or checkpoint inhibitors), where limiting concurrent corticosteroids may be preferred. Clinical trial information: NCT02519452. Research Sponsor: Janssen Research & Development, LLC.

8538 Poster Session (Board #438), Fri, 8:00 AM-11:00 AM

Daratumumab + bortezomib, thalidomide, and dexamethasone (D-VTd) in transplant-eligible newly diagnosed multiple myeloma (TE NDMM): Baseline SLiM-CRAB based subgroup analysis of CASSIOPEIA. *First Author: Cyrille Touzeau, Centre Hospitalier Universitaire, Nantes, France*

Background: In the phase 3 CASSIOPEIA study, D-VTd significantly improved outcomes vs VTd in TE NDMM pts at an 18.8-mo median follow-up. To allow earlier diagnosis and treatment of MM, the IMWG added 3 validated biomarkers (≥60% clonal bone marrow plasma cells, serum free light chain ratio ≥100, and > 1 focal bone lesion by MRI; "slim") to the conventional "CRAB" diagnostic criteria. We present a subgroup analysis of CASSIOPEIA based on baseline slimCRAB criteria. **Methods:** TE NDMM pts were randomized 1:1 to 4 pre-ASCT induction and 2 post-ASCT consolidation cycles of D-VTd or VTd. The "slim-only" subgroup excludes pts with ≥1 conventional CRAB criterion based on data collected at baseline; the remaining pts were included in the "CRAB" subgroup. **Results:** Of 1085 randomized pts (543 D-VTd; 542 VTd), 81 were included in the slim-only subgroup (36 D-VTd; 45 VTd) and 1004 were included in the CRAB subgroup. In slim-only vs CRAB pts, 22% vs 54% had an ECOG score of ≥1, 4% vs 16% had ISS Stage III disease, and 11% vs 16% had high-risk cytogenetics. For D-VTd vs VTd pts in the slim-only group, these rates were 22% vs 22%, 8% vs 0%, and 6% vs 16%, respectively. Overall response rates (ORR) and rates of sCR, ≥CR, and MRD negativity were similar between slim-only and CRAB pts; for slim-only pts, rates were significantly higher for D-VTd vs VTd (Table). After an 18.8-mo median follow-up, progression-free survival (PFS) was not significantly different in slim-only vs CRAB pts, or in D-VTd vs VTd slim-only pts (Table). For D-VTd vs VTd CRAB pts, 18-mo PFS rates were 92% vs 84%, and 24-mo PFS rates were 89% vs 76%. **Conclusions:** Baseline characteristics indicate that slim-only pts were slightly fitter and of lower risk status vs CRAB pts; however, response rates, MRD-negativity rates, and PFS did not differ significantly between these groups. Among slim-only pts, significantly higher response and MRD-negativity rates were achieved with D-VTd vs VTd. Among CRAB pts, PFS rates were higher with D-VTd vs VTd. Clinical trial information: NCT02541383. Research Sponsor: Janssen Research & Development, LLC.

A phase Ib study of TAK-079, an investigational anti-CD38 monoclonal antibody (mAb) in patients with relapsed/ refractory multiple myeloma (RRMM): Preliminary results. *First Author: Amrita Y. Krishnan, City of Hope, Duarte, CA*

Background: TAK-079 is a subcutaneously (SC) administered mAb with multiple modes of action for killing target cells. Here we report data from an ongoing dose finding study of TAK-079 monotherapy in patients with RRMM (NCT03439280). **Methods:** Pt were eligible after ≥ 3 lines of therapy and previous exposure to immunomodulatory drug (IMiD), proteasome inhibitor (PI), alkylating agent, and corticosteroid; prior anti-CD38 therapy allowed. Patients were refractory or intolerant to at least 1 PI and 1 IMiD. TAK-079 given as a SC injection weekly for 8 doses, every other week for 8 doses, then monthly until disease progression (PD) or unacceptable toxicity. SC injection was 2 mL administered in ≤ 1 minute. **Results:** 34 patients were enrolled across 5 fixed dose cohorts (TAK-079 45-135-300-600-1200 mg SC) as of 09 December 2019. Median age was 65 (50–81) years. At study entry, 65% were refractory to both an IMiD and PI; 82% refractory to last line of therapy, 21% of patients were previously exposed to at least 1 anti-CD38 monoclonal antibody. Median number of prior therapies was 4 (2,12). No ≥ Grade 1 early or late systemic infusion reactions (IRR) reported. Three (< 1%) injection site reactions described in > 1200 injections administered; 2 mild pruritis and 1 moderate swelling. Drug related adverse events (AEs), any grade, occurring in at least 10% of patients were: fatigue (21%), anemia (18%), neutropenia (18%), leukopenia (15%). Neutropenia was the only drug related grade 3 AEs in 2 or more patients (n = 2); only drug related SAE was 1 Grade 3 diverticulitis. No drug-related grade 4 AEs, AEs leading to study discontinuation, or on-study deaths reported. Recommended phase 2 dose (RP2) is to be 600 mg based on no reported DLTs, no MTD identified, and preliminary efficacy (PFS and response [ORR]). At the RP2 dose, 9 patients received at least 6 cycles of therapy by the data cutoff; their ORR was 33%, median duration of response was not estimable. The clinical benefit rate (minimal response or better) in all 12 patients enrolled at the RP2 dose was 67%. At a median follow-up of 7.5 months, PFS not estimable at the RP2 dose. **Conclusions:** TAK-079 monotherapy is safe, generally well tolerated, and active in patients with RRMM through tested doses. Clinical activity occurred early and was durable. With no MTD identified, no IRRs, no significant hematologic toxicity, the RP2 dose is 600 mg. PFS, with a median FU of 7.5 months at the data-cut off, is not estimable at the RP2 dose. Updated safety and efficacy data will be presented. Clinical trial information: NCT03439280. Research Sponsor: Takeda Pharmaceuticals, Inc.

8540 Poster Session (Board #440), Fri, 8:00 AM-11:00 AM

Efficacy of daratumumab in the treatment of multiple myeloma with high-risk cytogenetics: Meta-analysis of randomized phase III trials. *First Author: Smith Giri, University of Alabama at Birmingham, Birmingham, AL*

Background: The addition of Daratumumab (D) to backbone multiple myeloma (MM) regimens leads to improved response rates and progression free survival (PFS). Whether improved outcomes are also seen among patients with high-risk cytogenetics (HRC) remains unclear, particularly in first-line (FL) setting. **Methods:** We conducted a systematic search of bibliographic databases, clinical trials registries and meeting libraries from inception to December 2019, for phase III randomized trials that compared backbone MM regimens vs. same regimen plus D either in FL or relapsed/refractory (R/R) setting and reported outcomes by cytogenetic risk (HRC vs standard risk cytogenetics, SRC). We defined HRC as presence of t(4;14), t(14;16) or del(17p). The primary endpoint was PFS. We pooled relative log-hazard ratios using DerSimonian-Laird random-effects model. We assessed heterogeneity using Cochran's Q and the I^2 statistic. **Results:** Of 3,070 studies screened, 6 phase III trials were included. This included 3 trials in FL setting (Alcyone, Maia and Cassiopeia, 2,528 patients, 358 HRC) and 3 trials in R/R setting (Castor, Pollux and Candor, 1,533 patients, 222 HRC). The addition of D to FL backbone regimens among patients with HRC led to improved PFS (pooled HR 0.67; 95% CI 0.47-0.95, p = 0.02) with little heterogeneity (Cochran's Q p = 0.77, I^2= 0), similar to R/R setting (pooled HR 0.45; 95% CI 0.30-0.67, p < 0.01, Cochran's Q = 0.63, p < 0.01, I^2= 0). Similar results were seen in SRC MM patients in FL setting (pooled HR 0.45; 95% CI 0.37-0.54, p < 0.01, Cochran's Q p = 0.49, I^2= 0) and R/R setting (pooled HR 0.38; 95% CI 0.25-0.56; p < 0.01, Cochran's Q p = 0.04, I^2= 70%). **Conclusions:** Incorporating D to backbone regimens led to improved PFS among patients with HRC MM in both FL and R/R setting. Lack of substantial heterogeneity suggests benefit of D regardless of backbone regimen. D based regimens are appropriate choices in FL and R/R setting for both SRC and HRC patients. Longer follow up with mature overall survival data is needed to validate these findings. Research Sponsor: None.

Impact of Daratumumab on PFS among MM patients with high-risk cytogenetics.

8541 Poster Session (Board #441), Fri, 8:00 AM-11:00 AM

DREAMM-2: Single-agent belantamab mafodotin (GSK2857916) in patients with relapsed/refractory multiple myeloma (RRMM) and high-risk (HR) cytogenetics. *First Author: Adam D. Cohen, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Patients with RRMM and HR cytogenetics have a poor prognosis and need effective therapies. In DREAMM-2 (NCT03525678), single-agent belantamab mafodotin (an immunoconjugate targeting B-cell maturation antigen) demonstrated clinically meaningful activity and a manageable safety profile in patients with heavily pretreated RRMM (*Lancet Oncol*.2020). We present outcomes in patients with HR-cytogenetics (9-month follow-up). **Methods:** Patients with RRMM received single-agent belantamab mafodotin (2.5 or 3.4 mg/kg). For this post hoc analysis, HR-cytogenetics included t(4;14), t(14;16), 17p13del, or 1q21+ (tested locally). **Results:** The median number of cycles was 3 (2.5: range: 1–15) and 4 (3.4: range: 1–14). Overall response rate (ORR; ≥partial response [PR] per independent review committee) was 27% in the 2.5 mg/kg group (22% with ≥very good partial response [VGPR]) and 40% in the 3.4 mg/kg group (27% with ≥VGPR). The median duration of response (DoR) was not reached in the 2.5 mg/kg group and was 6.2 months in the 3.4 mg/kg group. The most common adverse events (> 30% in either group) were consistent with the overall population (*Lancet Oncol*.2020): keratopathy (2.5: 59%; 3.4: 79%), thrombocytopenia (2.5: 44%; 3.4: 65%), nausea (2.5: 27%; 3.4: 33%), anemia (2.5: 24%; 3.4: 42%), and blurred vision (2.5: 20%; 3.4: 42%). **Conclusions:** Patients with HR-cytogenetics maintain deep and durable clinical responses with single-agent belantamab mafodotin, comparable to that reported in the overall population. The safety profile remained consistent with previous reports. Funding: GlaxoSmithKline (205678). Drug linker technology licensed from Seattle Genetics; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT03525678. Research Sponsor: GlaxoSmithKline.

Prevalence and significance of clonal hematopoiesis of indeterminate prognosis (CHIP) in multiple myeloma. *First Author: Leslie Jane Padrnos, Mayo Clinic, Scottsdale, AZ*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is defined by the presence of leukemia-associated somatic mutations in clonally expanded hematopoietic stem cells with a VAF of ≥2%. CHIP has been associated with myeloid malignancies and increased all cause mortality largely from atherovascular disease. The prevalence and impact of CHIP in patients with myeloma (MM) is yet to be defined. Aims: Evaluate the prevalence and significance of CHIP in 101 lenalidomide exposed patients with multiple myeloma. **Methods:** 101 MM patients, the majority exposed to > 2 years of lenalidomide (Len), with stored mononuclear blood samples were identified for Next Generation Sequencing (NGS) using a panel encompassing 42 gene mutations associated with CHIP. Electronic medical records were reviewed and outcomes of secondary malignancy, macrocytosis, thrombosis and mortality were extracted. **Results:** Thirty of 101patients were found to have CHIP with the most frequent mutations: DNMT3A (12%), TET2 (5%), and TP53 (4%). One third of patients with CHIP had > 1 mutation (37%). At 68 months median follow up over a quarter of patients experienced thrombosis (31%) and 13% developed subsequent malignancy/premalignant condition including myelodysplastic syndrome (3%). There was no significant difference in age, gender, duration of Len prior to NGS testing, thrombosis complication, or survival in those with versus without a CHIP mutation. At last F/U 30% had died, 25% remained on therapy, 27% were on maintenance therapy and 11% were on observation alone. **Conclusions:** CHIP mutations are common in plasma cell neoplasms, with 30% of patients in this study retrospectively found to have CHIP mutations by NGS testing. CHIP mutations have been associated with cardiovascular events and malignancy development, however no associations were identified in this small study. Limitations to this study include small sample size, retrospective nature and duration of follow up. Further study of this very common finding in MM patients regarding timing of development and subsequent impact of these mutations could help risk stratify and inform therapy selection. Research Sponsor: U.S. National Institutes of Health, Mayo Clinic Center for Individualized Medicine.

FDA analysis: Impact of BMI on efficacy outcomes in multiple myeloma trials. *First Author: Rachel Ershler, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Obesity has been implicated as a risk factor for the development of certain types of cancers, including multiple myeloma. Previous studies in other tumor types suggest that overweight subjects may have better outcomes, however, in relapsed/refractory multiple myeloma (RRMM), it is unknown whether body weight affects outcomes to therapy. **Methods:** We conducted a retrospective analysis of 13 RRMM clinical trials submitted to the FDA between 2012-2018. Patients were divided into four groups, underweight (BMI < 18.5 kg/m^2), normal weight (BMI 18.5- < 25 kg/m^2), overweight (BMI 25.0- < 30 kg/m^2) and obese (BMI > 30.0 kg/m^2). A multivariate analysis for progression free survival (PFS) and overall survival (OS), stratified by study and adjusted for age, cytogenetic risk group (Standard, High, Unknown), immunoglobin subtype (IgG Y/N), ECOG status (0-1, > 1, UNK), sex (M/F) was used to estimate the HR. **Results:** A total of 5898 patients were included in this analysis. The median age was 65 years (range 30-91 years). A total of 87(1.5%) patients were underweight, 1853 (31%) were normal weight, 2212 (38%) were overweight, 1332 (23%) were obese, and 414 (7%) had missing BMI. The results of the multivariate analysis of PFS and OS are shown in the Table. **Conclusions:** Exploratory analysis of patients with RRMM found that patients who were overweight and obese had a trend towards slightly improved PFS and OS when compared to normal weight patients. Similar trends were observed in the analyses of overall response rate and BMI (not presented in the abstract). These results are consistent with previous studies in other malignancies. Limitations include the lack of adjustment for multiple testing, the small sample of patients in the underweight category, and heterogeneity in the treatment regimens and PFS assessments in the clinical trials included in the analysis. Future studies are needed to evaluate safety and impact of treatment regimens on efficacy outcome measures based on body weight. Research Sponsor: None.

Multivariate analysis of PFS and OS.

BMI Category	PFS HR (95% CI)	OS HR (95%CI)
Under vs Normal	1.15 (0.86,1.54)	1.10 (0.77,1.56)
Over vs Normal	0.90 (0.82, 0.99)	0.91 (0.81, 0.99)
Obese vs Normal	0.88 (0.79, 0.97)	0.84 (0.75, 0.95)
Missing vs Normal	1.48 (1.21, 1.81)	1.20 (0.93, 1.56)

8544 Poster Session (Board #444), Fri, 8:00 AM-11:00 AM

The significance of beta-II microglobulin (β2M) and International Staging System (ISS) in multiple myeloma (MM) patients (pts.) with renal impairment (RI). *First Author: Gloria Lin, Medical College of Wisconsin, Milwaukee, WI*

Background: ISS stage which underlies prognostic models used in MM, is derived from albumin and β_2M at diagnosis. β_2M, a low molecular polypeptide, is present on all nucleated cells and is elevated in pts. with RI. In MM, although the association between β_2M and prognosis has been interpreted to reflect a higher tumor burden, RI by itself may explain at least in part the higher levels of β_2M seen with this disease. Historically, those presenting with MM and severe RI had a poor prognosis and quite likely the β_2M elevation irrespective of kinetics predicted poor prognosis. In this study, we investigated the significance of β_2M and ISS staging in MM patients in the setting of RI in the modern era when renal recovery is more common after induction. **Methods:** MM pts. treated at our institution from 2012-2014 were included and divided into two groups by creatinine (Cr) level at diagnosis: <2 and ≥ 2 mg/dl. Demographic and disease characteristics were compared between the two groups using ANOVA and chi-square tests as appropriate. COX regression was used for the multi-variate analysis for survival and the effect of β_2M levels, adjusting for albumin levels, on survival was allowed to vary by Cr level to evaluate potential interaction. **Results:** Of 201 total pts., 163 (81.6%) had Cr <2 mg/dL and 38 (18.4%) $\geq$ 2mg/dL at diagnosis with higher β_2M and ISS stage in Cr$\geq$2 group. On adjusted analysis, albumin was significantly associated with overall survival (OS) (hazard ratio, HR 0.60; 95% CI 0.36-1; p = 0.04); however, β_2M was associated with OS only when Cr <2 mg/dl (HR 1.13, 95% CI 1.06-1.19; p $<$ 0.0001) but not when Cr$\geq$2 mg/dl (HR 0.98, 95% CI 0.91-1.06; p = 0.65) with significant interaction (p = 0.004). Likewise, the effect of β_2M on progression-free survival was significant when Cr <2 (HR 1.1, 95% CI 1.05-1.19; p = 0.0002), but not Cr$\geq$2 (HR 1.02; 95% CI 0.97-1.08; p = 0.42) with significant interaction (p = 0.03). **Conclusions:** Our results show that in the era of modern induction therapy and rapid improvement in kidney function, a high β_2M may not impact prognosis as adversely, at least in those with RI, since an elevated β_2M may be disproportionate to true tumor burden. Thus, ISS staging in these patients should be reevaluated after induction and potential renal recovery. Novel biomarkers may refine MM staging independent of the level of kidney function. 8545 Poster Session (Board #445), Fri, 8:00 AM-11:00 AM

Sporadic late-onset nemaline myopathy with monoclonal paraprotein as a malignancy rather than disimmunity and treatment with chemotherapy-based approach. *First Author: Rouslan Kotchetkov, Simcoe Muskoka Regional Cancer Program, Barrie, ON, Canada*

Background: A subset of sporadic late-onset nemaline myopathy (SLONM) associated with monoclonal gammopathy of undetermined significance (MGUS) has more aggressive course, often fatal. Whether SLONM+MGUS is a malignancy or dysimmunity is unclear. Two approaches are used to treat SLONM+MGUS: 1) immunosuppression (IS) ± plasmapheresis/exchange; 2) chemotherapy (ChT) ± autologous stem cell transplantation (ASCT). Due to the rare occurrence of the disease the best treatment modality is not known. **Methods:** We conducted a literature search to identify previous treatment for patients with SLONM+MGUS using PubMed, Elsevier, Medline, and CINAHL databases from 1975 to 2019. All publications were carefully reviewed to remove "duplicate" patients. Overall, 28 reports were included for the final analysis. **Results:** 38 unique patients with SLONM+MGUS received either IS (n = 19) or ChT ± ASCT (n = 19). The median age was 48 years [24-75]. In the IT group 74% (n = 14) were males vs 53% (n = 10) in the ChT group. All patients had IgG monoclonal protein (MP): kappa in 57% (n = 11) in the IT, 42% (n = 8) in the ChT group. In the IT group MP values were 0.42 & 0.2 g/L (n = 2); in the ChT group median MP was 2.7 g/L [0.1-14, n = 14]. In the IT group 84% (n = 16) received steroids, 26% (n = 5) plasmapheresis, 53% (n = 10) non-steroid immunosuppressants, 11% (n = 2) rituximab, and 53% (n = 10) IVIG. Six patients (32%) had one IT modality; 13 (68%) had 2 or 3. In the ChT group 10 patients (53%) had ASCT; 6 patients (31%) had CyBorD or Lenalidomide+Dexamethasone + ASCT; 3 patients (16%) had chemotherapy without ASCT. 10 patients in IT group had neurological improvement (NI): 53% overall response (OR) with 16% (n = 3) complete remission (CR), and 37% (n = 7) partial response (PR). No improvement/progression had 9 patients (47%). In 2 patients (10%), neurological CR was associated with resolution of MP. Mean time to best response was 19 months. In ChT group 18 patients achieved NI: 94.7% OR with CR in 73.7% (n = 14) and PR in 21.0% (n = 4). Only one patient had no response to therapy. The best NI correlated with resolution of MP. Mean time to best response was 10 months. **Conclusions:** Our study with the most extensive cohort of patients with SLOMN+MGUS supports ChT ± consolidative ASCT aimed at complete elimination of the malignant plasma cell clone as the preferred treatment. Superior clinical benefits of ChT suggest that the presence of MP has clinical rather than undetermined significance, and SLOAN + MP should be considered as a malignancy rather than dysimmunity. 8546 Poster Session (Board #446), Fri, 8:00 AM-11:00 AM

Ixazomib-dexamethasone (Ixa-Dex) vs physician's choice (PC) in relapsed/refractory (RR) primary systemic AL amyloidosis (AL) patients (pts) by prior proteasome inhibitor (PI) exposure in the phase III TOURMALINE-AL1 trial. *First Author: Efstathios Kastritis, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece*

Background: The PI bortezomib is commonly used in first-line therapy of AL, but new therapies are needed that are tolerable in the context of multi-organ dysfunction and that, in RRAL, offer improved outcomes following prior bortezomib. Ixazomib is an oral PI, and in TOURMALINE-AL1, the first phase 3 trial conducted in RRAL, while the first primary endpoint of hematologic overall response rate (ORR) was not met, all clinically relevant time-to-event endpoint data favored Ixa-Dex vs PC (Dispenzieri et al, ASH 2019). **Methods:** RRAL pts with 1–2 prior therapies were randomized (1:1) to Ixa-Dex (n = 85) or PC (n = 83; Dex plus lenalidomide [n = 47], melphalan [n = 24], cyclophosphamide [n = 10], or thalidomide [n = 2]), stratified by cardiac stage, relapsed vs refractory disease, and prior PI exposure. The primary endpoints were hematologic ORR and 2-yr rate of vital organ deterioration or death. We report subgroup analyses of ORR and outcomes by prior PI exposure. **Results:** Of the 168 pts enrolled, 90 were PI-naïve and 78 PI-exposed (46 and 39 in the Ixa-Dex arm; 44 and 39 in the PC arm) per stratification; 28 and 27 pts in the Ixa-Dex and PC arms had received bortezomib in their last prior line. Hematologic ORR was 63% vs 50% for Ixa-Dex vs PC (odds ratio [OR] 1.71; 95% confidence interval [CI] 0.74–3.96) in PI-naïve pts, and 41% vs 51% (OR 0.66; 95% CI 0.27–1.62) in PI-exposed pts. For time-to-event outcomes (Table), hazard ratios (HRs) were 0.46–0.85 in favor of Ixa-Dex vs PC in both PI-naïve and PI-exposed pts. **Conclusions:** Hematologic ORR was higher with Ixa-Dex vs PC in PI-naïve pts but lower in PI-exposed pts (although not statistically significant), and long-term clinically relevant outcomes favored Ixa-Dex in both groups. Based on HRs, the magnitude of benefit appeared similar or greater in PI-naïve vs PI-exposed pts. Clinical trial information: NCT01659658. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Evaluation of minimal residual disease in relapsed/refractory multiple myeloma patients treated with venetoclax or placebo in combination with bortezomib and dexamethasone: BELLINI study analyses. *First Author: Philippe Moreau, Hematology Department, CHU Nantes, Nantes, France*

Background: Venetoclax (Ven) is a selective, potent BCL-2 inhibitor that has synergistic activity with bortezomib (B) and dexamethasone (d). In the Phase 3 BELLINI trial, addition of Ven to Bd significantly improved median progression-free survival (PFS) and response rates, including minimal residual disease (MRD) negativity, but resulted in increased mortality vs placebo (Pbo). Here, we determine whether MRD negativity was associated with longer PFS and OS in relapsed/refractory multiple myeloma (RRMM) patients treated with Ven+Bd in the BELLINI dataset. **Methods:** In BELLINI (NCT02755597), RRMM patients (pts) sensitive or naïve to proteasome inhibitors with 1-3 prior lines of therapy were randomized 2:1 to Ven (800 mg) or Pbo plus B (1.3 mg/m^2) and d (20 mg). Next-gen sequencing MRD assessments were done on bone marrow aspirates at the time of suspected CR/sCR, and 6- and 12-months post confirmation of CR/sCR. Patients with a missing or indeterminate assessment were considered MRD positive. Evaluation of MRD in biomarker-defined subgroups (cytogenetics and *BCL2* expression) was also performed and will be presented. **Results:** In total, 291 pts were randomized; 194 to Ven, 97 to Pbo. As of 13 Sep 2019, the median follow-up was 29 months. Ven + Bd demonstrated significantly higher MRD negativity rates ($< 10^{-5}$), including a higher proportion of pts achieving sustained MRD negativity (Table). In the Ven arm, the median (m)PFS was not reached for MRD negative pts vs 16.2 months for MRD positive pts (HR = 0.23, 95% CI: 0.10-0.54, p $<$ 0.001). While the mOS was not reached in the Ven arm, OS was significantly longer for MRD negative vs MRD positive pts (HR = 0.25, 95% CI: 0.08-0.80, p = 0.0194). **Conclusions:** The addition of Ven to Bd resulted in deep and durable responses, including higher rates of MRD negativity. MRD negativity in the context of Ven was associated with prolonged survival in patients with RRMM, consistent with the broader MRD body of evidence with other therapies in MM. Clinical trial information: NCT02755597. Research Sponsor: AbbVie and Genentech.

MRD negativity rates in the ITT population.

MRD negativity status ($< 10^{-5}$), % (n/N)	**Ven + Bd**	**Pbo + Bd**	**p-value**
MRD negativity rate	**15%** (29/194)	**2%** (2/97)	p = 0.0016
MRD negative ≥CR rate	**13%** (26/194)	**1%** (1/97)	p = 0.0013
MRD negativity rate in pts achieving ≥CR	**46%** (26/57)	**14%** (1/7)	p = 0.2386
≥6-month sustained MRD negativity rate in pts achieving ≥CR	**16%** (9/57)	**0%** (0/7)	p = 0.5768
≥12-month sustained MRD negativity rate in pts achieving ≥CR	**7%** (4/57)	**0%** (0/7)	p = 1.0000

8548 Poster Session (Board #448), Fri, 8:00 AM-11:00 AM

Castleman disease spectrum. *First Author: Johnson Khor, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Castleman disease (CD) describes a group of lymphoproliferative disorders that share characteristic histopathology. Unicentric CD (UCD) and idiopathic multicentric CD (iMCD) are differentiated by the number of enlarged lymph node (LN) regions: UCD involves 1 region and iMCD involves > 1 region. UCD typically has mild or no symptoms whereas iMCD requires abnormal labs and symptoms for diagnosis and can progress to life-threatening multi-organ failure. Review of an international natural history registry of CD revealed patients across a broad spectrum with regards to number of enlarged LN regions and disease severity. We hypothesize that there is a positive correlation between disease activity and the number of enlarged LNs and that the spectrum of CD is more complex than a binary UCD-iMCD dichotomy. **Methods:** Herein, enrolled UCD and iMCD patients whose diagnosis was confirmed by an expert-panel were selected for analysis (N = 81). A standardized disease activity score (scale 0-1) was computed for each patient using available diagnostic values of C-reactive protein, hemoglobin, and albumin (CHA score). **Results:** We looked at the association between number of enlarged LNs and CHA and found a significant positive correlation (R = 0.65, $p < 0.0001$). Given this, we divided the cohort into groups of mild, moderate, and extensive lymphadenopathy according to the number of regions of enlarged LNs at the time of diagnosis: group 1 (1 enlarged LN region); group 2 (2-4 enlarged LN regions); and group 3 (≥5 enlarged LN regions). We identified 20 patients in group 1, 19 in group 2, and 42 in group 3 with no statistical differences in sex, race, or age at diagnosis. Histopathological subtype differed significantly among groups. Group 1 was 89% hyaline vascular (HV)/ hypervascular (HpV) and 11% mixed (Mx); group 2 was 74% HV/HpV, 21% Mx, and 5% plasmacytic (Pl); and group 3 was 64% HV/HpV, 32% Mx, and 5% Pl. We then looked at CHA score in these groups and found that group 3 patients have a significantly greater CHA score (median [IQR]: 0.46 [0.49]) than both group 2 (0.08 [0.14]) and group 1 (0.0 [0.10]) (adjusted $p < 0.001$ for both) while there was no difference between groups 1 and 2. **Conclusions:** These results suggest that disease severity is positively associated with the number of enlarged LNs. The different proportions of histopathological subtypes between the three groups could indicate different pathologic mechanisms are involved. Further work is needed to determine if patients with a few enlarged LNs exhibit disease more closely to UCD or iMCD and to understand long-term outcomes for these patients. Research Sponsor: EUSA Pharma.

8549 Poster Session (Board #449), Fri, 8:00 AM-11:00 AM

Correlation between 24-hour proteinuria and spot urine albumin to creatinine ratio in systemic light chain amyloidosis. *First Author: Alissa Visram, Mayo Clinic, Rochester, MN*

Background: Proteinuria evaluation is essential for diagnosing and monitoring of renal involvement in light chain (AL) amyloidosis. A 24 hour protein collection (24h UP) is the gold standard for proteinuria assessment however it is cumbersome and can be inaccurate. A spot urine albumin to creatinine ratio (uACR) has been proposed as a convenient method to estimate 24hUP. We aimed to validate the correlation between uACR and 24hUP in a large cohort of patients. **Methods:** We retrospectively studied systemic AL amyloidosis patients evaluated between 2010 and 2019 at Mayo Clinic, with a uACR and 24hUP collected less than 7 days apart. Linear regression analysis was used to construct a prediction model for 24hUP with uACR as the primary predictor. Possible confounders (age, gender, body mass index, morning versus afternoon spot urine collection, estimated glomerular filtration rate) for the primary relationship between uACR and 24h UP were evaluated in the model. We used receiver operating characteristic (ROC) analysis to identify the best uACR cutoff to predict significant proteinuria (defined as a 24hUP > 500mg). **Results:** We included 665 patients, with a median age of 66 years (IQR 59-72). The spot urine was collected in the morning (before 1200 hours) in 382 (57%) patients, and in the afternoon in 283 (43%) patients. The median 24hUP was 321 (IQR 129-2512.5) mg, median uACR was 107 (IQR 13.5-1845) mg/g, and median serum creatinine was 1.2 (IQR 1-1.8) mg/dL. The uACR correlated well with 24h UP (Pearson's r= 0.83, 95% CI 0.80-0.85). Linear regression showed that $E(24h\ UP_i) = 362 + 1.05(uACR_i)$, and this model was statistically and clinically significant ($p < 0.001$ and R^2 of 0.68, respectively). Age, gender, body mass index, eGFR, and time of day of spot urine collection did not confound the primary relationship between uACR and 24hUP, and no collinearity was observed. A uACR cutoff of > 280 mg/g was the best predictor of a 24hUP > 500 mg (area under the ROC curve 0.98, sensitivity 92%, specificity 97%). For simplicity, we assessed the predictive value of uACR > 300 mg/g for 24h UP > 500 mg. Among patients with 24huACR > 300 mg/g 264 (96%) had a 24hUP > 500 mg, and 31 (7%) of patients with uACR < 300 mg/g had a 24h UP > 500 mg ($p < 0.001$). **Conclusions:** In systemic AL amyloid patients, we showed that uACR on a random urine sample correlated well with 24h UP, and can be used to estimate proteinuria with a linear regression model. Based on these findings, and the convenience of uACR testing for patients, we propose that uACR should be used to monitor renal response to AL amyloidosis therapy. Research Sponsor: None.

8550 Poster Session (Board #450), Fri, 8:00 AM-11:00 AM

Characteristics and outcome of patients with MYD88 wild-type Waldenström Macroglobulinemia. *First Author: Saurabh Zanwar, Mayo Clinic, Rochester, MN*

Background: Waldenström Macroglobulinemia (WM) is a rare lymphoplasmacytic malignancy characterized by the presence of a recurrent point mutation in the *MYD88* gene ($MYD88^{L265P}$) in 80-95% of cases. Patients with $MYD88^{WT}$ genotype comprise a small subset that responds poorly to ibrutinib and other Bruton tyrosine kinase inhibitors. We examined the characteristics and outcome of WM patients with $MYD88^{WT}$ genotype predominantly treated with non-BTK inhibitor based therapies. **Methods:** Patients with a diagnosis of WM seen at Mayo Clinic, Rochester, between 1996 and 2018 were included. Their characteristics and outcomes were assessed from the time of active disease. Marrow MYD88 genotyping was assessed with an allele specific PCR assay (analytic sensitivity 1%). Categorical and continuous variables were compared using Chi square and Wilcoxon tests, respectively. Time-to-event analyses were performed using Kaplan Meier test. **Results:** Of 986 patients with active WM, MYD88 genotype data were available in 331 (34 %) patients; 72 (22%) and 260 (78%) patients harbored $MYD88^{WT}$ and $MYD88^{L265P}$ genotypes, respectively. The median follow-up was 5.8 years (95% CI: 5.0-6.5 years) from active WM; 6 years $MYD88^{WT}$ vs 5.4 years for $MYD88^{L265P}$ cohort. Median age was 63 years and 66 years in the $MYD88^{WT}$ and $MYD88^{L265P}$ cohorts, respectively ($p = 0.07$) with 46% and 53% patients being ≥65 years of age, respectively ($p = 0.36$). Pre-treatment marrow lymphoplasmacytic (LPL) infiltrate (median 40% for $MYD88^{WT}$ vs 60% for $MYD88^{L265P}$; $p = 0.001$) and beta-2 microglobulin (median 3 μg/mL for $MYD88^{WT}$ vs 3.9 μg/mL for $MYD88^{L265P}$; $p = 0.02$) were lower in the $MYD88^{WT}$ compared to the $MYD88^{L265P}$ cohort; other laboratory parameters at active disease were comparable. Per IPSSWM prognostic criteria, $MYD88^{WT}$ had fewer patients in the high risk group (18% for $MYD88^{WT}$ vs 42% $MYD88^{L265P}$; $p = 0.03$). Patients with $MYD88^{WT}$ had higher likelihood of histological transformation [18% for $MYD88^{WT}$ vs 4% for $MYD88^{L265P}$; odds ratio 5.8 (95% CI: 2.5-13.5; $p < 0.0001$)]. Among patients with treatment data available, only 35 (11%) patients received ibrutinib. The 5-year overall survival (OS) from active disease was comparable (85% in $MYD88^{WT}$ vs 82% in $MYD88^{L265P}$ cohort; $p = 0.7$). **Conclusions:** $MYD88^{WT}$ genotype in WM is associated with lower marrow LPL infiltration, lower likelihood of high-risk IPSSWM categorization and a higher likelihood of histological transformation in comparison to $MYD88^{L265P}$ mutant subpopulation. MYD88 genotype does not affect the OS from active disease in predominantly non-BTK inhibitor treated patients. Research Sponsor: None.

TPS8551 Poster Session (Board #451), Fri, 8:00 AM-11:00 AM

GO39775: A multicenter phase I trial evaluating the safety, pharmacokinetics, and activity of BFCR4350A, a FcRH5/CD3 T-cell dependent bispecific antibody, in patients with relapsed or refractory multiple myeloma. *First Author: Adam D. Cohen, Abramson Cancer Center and University of Pennsylvania, Philadelphia, PA*

Background: Multiple myeloma (MM) remains an incurable disease, with estimated median survival of 8–9 months in patients with relapsed or refractory (R/R) disease (Kumar et al. 2014; Usmani et al. 2016). There is no uniform standard of care for R/R MM, and combinations used in later lines have diminishing responses, especially after re-exposure to previously received classes of therapy (Gandhi et al. 2019). New targets and treatment modalities are needed. Fragment crystallizable receptor-like 5 (FcRH5) is expressed on myeloma cells across lines of therapy, and is overexpressed by myeloma cells with 1q21 gain; expression in healthy tissue is restricted to the B-cell lineage, and is retained in plasma cells (Li et al. 2017). BFCR4350A is an IgG-based T-cell-dependent bispecific antibody that was specifically engineered to target the most membrane-proximal domain of FcRH5 on myeloma cells and cluster of differentiation 3 (CD3) on T cells, with dual binding resulting in efficient immune synapse formation and T-cell killing of myeloma cells. BFCR4350A demonstrates potent killing of plasma cells and patient-derived myeloma cells (including those with low levels of FcRH5 expression) *in vitro*, and complete depletion of bone marrow plasma cells in primates, without severe or prolonged cytokine release (Li et al. 2017). GO39775 (NCT03275103) is an open-label, multicenter Phase I dose-escalation and dose-expansion trial evaluating the safety, pharmacokinetics (PK), and activity of BFCR4350A monotherapy in patients with R/R MM. **Methods:** Patients must be aged ≥18 years and must have R/R MM for which no established therapies are available or appropriate, or be intolerant to those therapies. Patients with prior CAR-T therapy and/or prior BCMA-directed therapy are not excluded. BFCR4350A is administered by intravenous infusion, and q3w dosing with Cycle 1 single-step or multi-step dosing is being investigated in dose-escalation (Arms A and B, respectively). Enrolment into both arms is ongoing, with patients receiving up to 17 cycles of treatment until disease progression or unacceptable toxicity. Primary objectives are to evaluate safety (including the maximum tolerated dose and dose-limiting toxicities) and to identify a recommended Phase II dose. Secondary objectives include assessment of PK, activity, immunogenicity, and pharmacodynamic biomarkers. Clinical trial information: NCT03275103. Research Sponsor: Genentech, Inc. Third-party medical writing assistance, under the direction of Adam Cohen and James Cooper, was provided by Stephanie Lacey of Gardiner-Caldwell Communications, and was funded by F. Hoffmann-La Roche Ltd.

TPS8552 Poster Session (Board #452), Fri, 8:00 AM-11:00 AM

DREAMM-5 platform trial: Belantamab mafodotin in combination with novel agents in patients with relapsed/refractory multiple myeloma (RRMM). *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: Single-agent belantamab mafodotin (GSK2857916), a B-cell maturation antigen targeting immunoconjugate, induced deep and durable responses in patients with RRMM, with a manageable safety profile (DREAMM-2, NCT03525678, *Lancet Oncol.*2020). A platform trial design allows efficient evaluation of belantamab mafodotin in combination with other anti-myeloma agents, such as a humanized wild-type IgG1 anti-OX40 agonist, an IgG4 inducible T-cell costimulatory (ICOS) agonist, and a gamma-secretase inhibitor. The unique, multimodal mechanisms of action (MoAs) of belantamab mafodotin, in combination with MoAs of these agents, has the potential to achieve synergistic effects in MM, to further enhance anti-myeloma activity without compromising safety. **Methods:** DREAMM-5 (NCT04162210) utilizes a master protocol with separate sub-studies comprised of sequential dose exploration (DE) and cohort expansion (CE) phases, to identify promising, effective belantamab mafodotin combinations when compared with a shared belantamab mafodotin monotherapy control arm (CE phase only). DE phases consist of multiple dosing cohorts with belantamab mafodotin combinations where patients are assigned to treatment slots by predetermined algorithmic approach (modified toxicity probability interval; N≤10 per cohort). Recommended phase 2 doses (RP2D) will be based on dose-limiting toxicities, safety, and pharmacokinetics. Interim analyses, based on overall response rate (ORR), determine if a RP2D is moved forward to a CE phase (N≥35 per cohort). Patients in the CE (stratified by number of prior therapies) will be randomized equally to open sub-studies. Eligible patients will have received ≥3 prior therapy lines which must include ≥1 immunomodulatory agent, proteasome inhibitor, and anti-CD38 antibody. The primary objectives are to identify RP2D for each combination (DE phase) and ORR (≥partial response, CE phase). Sub-studies 1 (combination with GSK3174998, OX40 agonist antibody) and 2 (combination with GSK3359609, ICOS agonist antibody) are currently enrolling. Sub-study 3 (combination with nirogacestat [PF-03084014; SpringWorks Therapeutics]) is projected to begin enrollment in the first half of 2020. Additional sub-studies will be explored based on scientific rationale and/or preclinical combination study results. Funding: GlaxoSmithKline (207495). Drug linker technology licensed from Seattle Genetics; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT04162210. Research Sponsor: GlaxoSmithKline.

TPS8553 Poster Session (Board #453), Fri, 8:00 AM-11:00 AM

Subcutaneous daratumumab in patients with multiple myeloma who have been previously treated with intravenous daratumumab: A multicenter, randomized, phase II study (LYNX). *First Author: Nizar J. Bahlis, University of Calgary, Arnie Charbonneau Cancer Institute, Calgary, AB, Canada*

Background: The intravenous (IV) formulation of daratumumab (DARA), a human CD38-targeted monoclonal antibody, is approved in many countries for use as monotherapy in relapsed/refractory multiple myeloma (RRMM) and in combination with standard-of-care regimens in RRMM or newly diagnosed MM. A subcutaneous (SC) formulation of DARA is under investigation in several ongoing studies. In the phase 3 COLUMBA study, DARA SC was shown to be non-inferior to DARA IV, demonstrating similar efficacy and pharmacokinetics, with a significantly decreased rate of infusion-related reactions and reduced administration time. The phase 2 LYNX (MMY2065) study will evaluate the efficacy and safety of retreatment with DARA. **Methods:** In this ongoing, multicenter, open-label, randomized phase 2 study, ~230 patients (pts) with prior exposure to DARA will be randomized 1:1 to receive carfilzomib and dexamethasone (Kd) ± DARA. Pts must have received 1 to 2 prior lines of therapy (at least one of which included DARA IV), with DARA-based therapy completed ≥3 months prior to randomization. Eligible pts have achieved a partial response or better (IMWG criteria) to DARA-based therapy, with a duration of response of ≥4 months. Pts must not have discontinued DARA due to a related adverse event or received prior treatment with carfilzomib. Pts will receive 20 mg/m^2 carfilzomib IV on Day 1 of Cycle 1, escalated to 70 mg/m^2 on Days 8 and 15; carfilzomib 70 mg/m^2 will be administered on Days 1, 8, and 15 of each 28-day cycle thereafter. Dexamethasone 40 mg will be administered (IV or PO) QW for Cycles 1-9 and then on Days 1, 8 and 15 from Cycle 10 onwards. Pts in the D-Kd group will also receive DARA SC (1,800 mg co-formulated with recombinant human hyaluronidase PH20 [rHuPH20; Halozyme]) QW in Cycles 1-2, Q2W in Cycles 3-6, and Q4W thereafter. The primary endpoint is the rate of pts achieving a very good partial response or better. Secondary endpoints include overall response rate, rate of pts achieving complete response or better, progression-free survival, overall survival, overall minimal residual disease-negativity rate, time to next treatment, pharmacokinetics, and safety. Clinical trial information: NCT03871829. Research Sponsor: Janssen Research & Development, LLC.

TPS8554 Poster Session (Board #454), Fri, 8:00 AM-11:00 AM

A phase III, randomized, multicenter, open-label study of venetoclax or pomalidomide in combination with dexamethasone in patients with t(11;14)-positive relapsed/refractory multiple myeloma. *First Author: Maria--Victoria Mateos, Hospital Clinico Univ de Salamanca, Salamanca, Spain*

Background: BCL-2 is an anti-apoptotic protein important for myeloma cell survival. Venetoclax (Ven) is a highly selective, potent, oral BCL-2 inhibitor, that has shown promise in clinical studies as monotherapy or in combination with other agents in patients with t(11;14)-positive relapsed/refractory multiple myeloma (RRMM; Kumar et al. *Blood.* 2017; Costa et al. ASH 2018. Abstr. #303; Harrison et al. ASH 2019. Abstr. #142; Bahlis et al. ASH 2019. Abstr. #925; Kaufman et al. ASH 2019. Abstr. #926). Notably, t(11;14)-positive MM is more dependent on BCL-2 for cell survival, which, together with these clinical data, suggests that Ven combined with dexamethasone (Dex) may provide greater clinical benefit versus standard therapies, like pomalidomide (Pom), in this biomarker-defined patient population. This ongoing Phase 3 study (CANOVA; NCT03539744) aims to evaluate the safety and efficacy of VenDex vs PomDex in t(11;14)-positive RRMM. **Methods:** Eligible patients (≥18 years) must have t(11;14)-positive RRMM per central lab, an ECOG performance status ≤2, received ≥2 prior lines of therapy, previously received a proteasome inhibitor, and must be refractory to lenalidomide and last line of therapy. Patients cannot have history of treatment with Ven, Pom, or other BCL-2 inhibitors. Patients will be randomized 1:1 to Ven (800 mg orally, once-daily) or Pom (4 mg orally, once-daily on days 1-21 of 28-day cycles). Patients in both groups will receive 40 mg Dex (20 mg for patients ≥75 years) once weekly. Treatment will continue until disease progression, unacceptable toxicity, or withdrawal from study. Patients will be stratified based on age at randomization (< 65 vs ≥65 years), prior lines of therapy (2 to 3 vs ≥4), and International Staging System stage at screening (I vs II vs III). The primary endpoint is progression-free survival (PFS) per independent review committee (IRC) assessment based on International Myeloma Working Group criteria. The final PFS analysis will be performed when approximately 147 PFS events per IRC are observed. Secondary endpoints are response rate, patient-reported outcomes, overall survival, duration of response, times to response and progression, minimal residual disease negativity rate, safety, and Ven pharmacokinetics. Approximately 244 patients will be enrolled; as of January 21, 2020, 28 patients have been randomized (from 19 sites in 12 countries) and enrollment is ongoing. Clinical trial information: NCT03539744. Research Sponsor: Abbvie, Inc, Pharmaceutical/Biotech Company.

TPS8555 Poster Session (Board #455), Fri, 8:00 AM-11:00 AM

Open-label pilot study of genetically engineered NY-ESO-1–specific t cells (GSK3377794) alone or in combination with pembrolizumab in relapsed/refractory multiple myeloma. *First Author: Aaron Rapoport, University of Maryland Greenebaum Comprehensive Cancer Center and School of Medicine, Baltimore, MD*

Background: Adoptive cellular therapy may be practice-changing in relapsed/refractory multiple myeloma (MM). NY-ESO-1 TCR T (GSK3377794) are autologous polyclonal T cells transduced by a self-inactivating lentiviral vector to express an affinity-enhanced TCR capable of recognizing NY-ESO-1 or LAGE-1a antigenic peptides in complex with HLA-A*02. GSK3377794 has shown clinical activity in synovial sarcoma, melanoma, myxoid/round cell liposarcoma, and MM after autologous stem cell transplant. NY-ESO-1 and LAGE-1a are cancer/testis antigens frequently overexpressed in MM and linked to poor clinical outcome. PD-1 expression on CD8 T cells, which has been observed in MM patients previously treated with GSK3377794 as well as with CD19 CAR T-cell therapy, can limit adaptive immune response. We hypothesize that GSK3377794 alone, or in combination with the anti-PD-1 inhibitor pembrolizumab, may result in an antitumor effect in MM. **Methods:** This is an open-label, pilot study (NCT03168438) of GSK3377794 in patients with relapsed/refractory MM positive for HLA-A*02:01, HLA-A*02:05, ± HLA-A*02:06 and NY-ESO-1/LAGE-1a. Patients (n = 20) who have received ≥3 prior therapies containing ≥1 immunomodulatory imide, proteasome inhibitor, alkylator, CD38 monoclonal antibody, or glucocorticoid will be assigned to either single-infusion GSK3377794 (Arm 1, n = 10) or single-infusion GSK3377794 + pembrolizumab 200 mg IV every 3 weeks (Arm 2, n = 10). Arm 1 enrollment will be completed first. In Arm 2, pembrolizumab will begin in Week 3 (Week 6 if precluded by toxicity). Patients in both arms will provide cells via leukapheresis to manufacture autologous NY-ESO-1–specific T cells, undergo lymphodepletion (fludarabine + cyclophosphamide), and then receive GSK3377794 infusion ($1-8 \times 10^9$ transduced T cells). Primary and secondary objectives are to assess safety/tolerability and antitumor activity, respectively, of GSK3377794 (± pembrolizumab). Arm 2 enrollment will pause for a 3-week safety review after 3 patients have received a first dose of pembrolizumab. Efficacy, safety, and biomarkers will be assessed every visit. The treatment phase will last 108 weeks, or until disease progression; follow-up will last ≤15 years. As of January 2020, 3 patients have been treated. Funding: GlaxoSmithKline (208470) Clinical trial information: NCT03168438. Research Sponsor: GlaxoSmithKline.

TPS8556 Poster Session (Board #456), Fri, 8:00 AM-11:00 AM

DREAMM-9: Phase III study of belantamab mafodotin plus VRd versus VRd alone in transplant-ineligible newly diagnosed multiple myeloma (TI NDMM). *First Author: Saad Zafar Usmani, Levine Cancer Institute, Charlotte, NC*

Background: Bortezomib, lenalidomide, and dexamethasone (VRd) is the standard of care for transplant-eligible and TI NDMM, but relapse is usually inevitable. The median progression-free survival (PFS) is ~3 years for patients with TI NDMM, and with each relapse, the duration of response (DoR) diminishes, highlighting the need for novel, effective, targeted agents. Single-agent belantamab mafodotin is a first-in-class B-cell maturation antigen–binding, humanized, afucosylated, monoclonal immunoconjugate, showing deep and durable responses in heavily pretreated patients with relapsed/refractory multiple myeloma (*Lancet Oncol*2020). Preclinical work suggests belantamab mafodotin plus bortezomib or lenalidomide enhances anti-myeloma activity. Therefore, studying clinical activity of belantamab mafodotin in combination with these agents is warranted. **Methods:** DREAMM-9 (NCT04091126) is a two-part, open-label study to determine efficacy and safety of single-agent belantamab mafodotin with VRd vs. VRd alone in patients with TI NDMM. Patients aged ≥18 years with ECOG status 0–2 and adequate organ system functions will be eligible. Part 1 (dose selection) will evaluate safety/tolerability of belantamab mafodotin with VRd administered by single (Day 1) or split dosing (Days 1 and 8) in ≤5 cohorts (n = 12/cohort): 1.9 mg/kg, 2.5 mg/kg split and single, and 3.4 mg/kg split and single. Six more patients may be added to cohort(s) most likely to be selected as recommended Phase III dose (RP3D). Dose-limiting toxicities and adverse events (AEs) will be assessed, and belantamab mafodotin RP3D determined through modified toxicity probability interval criteria. Part 2 (randomized Phase III) will determine efficacy and safety of belantamab mafodotin at RP3D with VRd vs. VRd alone (n = 750) in two arms randomized 1:1. Dual primary endpoints will be rate of minimal residual disease (MRD) negativity and PFS. Secondary endpoints will be response rates (overall response, complete response, very good partial response or better, sustained MRD negativity), DoR, time to progression, and overall survival. Safety assessment will include AEs, serious AEs and ocular findings. In both parts, belantamab mafodotin will be given with VRd for eight induction cycles and then with Rd for maintenance until disease progression or unacceptable toxicity. Funding: GlaxoSmithKline (209664). Drug linker technology licensed from Seattle Genetics; monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT04091126. Research Sponsor: GlaxoSmithKline.

9000 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Randomized phase II clinical trial of cisplatin/carboplatin and etoposide (CE) alone or in combination with nivolumab as frontline therapy for extensive-stage small cell lung cancer (ES-SCLC): ECOG-ACRIN EA5161. *First Author: Ticiana Leal, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: Immune checkpoint inhibition is now given in combination with chemotherapy for first line (1L) therapy of extensive stage small cell lung cancer (ES-SCLC). We conducted a randomized phase II study of nivolumab (anti-PD1) in combination with platinum-etoposide (CE) as 1L treatment for patients with ES-SCLC (EA5161, NCT03382561). **Methods:** Patients with measurable (RECIST v1.1) ES-SCLC, ECOG performance status 0 or 1, who had not received prior systemic treatment for ES-SCLC were enrolled. Patients were randomized 1:1 to nivolumab 360 mg + CE every 21 days for 4 cycles followed by maintenance nivolumab 240 mg every 2 weeks until progression or up to 2 years (arm A) or CE every 21 days for 4 cycles followed by observation (arm B). Prophylactic cranial irradiation (PCI) was permitted at the investigator's discretion. Investigator's choice of cisplatin or carboplatin was allowed across both arms. The primary endpoint was PFS in eligible and treated patients. Secondary endpoints included OS, ORR, and safety. Adverse events (AEs) were graded per NCI-CTCAE v4.0. **Results:** This study was activated in May 2018 and completed accrual in December 2018. 160 patients were enrolled. Baseline characteristics were well balanced between arms. In the ITT population (n = 160), nivolumab + CE significantly improved the PFS compared to CE with HR 0.65 (95% CI, 0.46, 0.91; p = 0.012); mPFS 5.5 versus 4.6 months, respectively. Secondary endpoint of OS was also improved with nivolumab + CE versus CE with HR 0.67 (95% CI, 0.46, 0.98; p = 0.038); mOS 11.3 versus 8.5 months. Among patients who initiated study therapy, nivolumab + CE significantly improved the PFS compared to CE with HR 0.68 (95% CI, 0.48, 1.00; p = 0.047); mPFS 5.5 versus 4.7 months, respectively; in this population, OS was also improved with nivolumab + CE versus CE with HR 0.73 (95% CI, 0.49, 1.11; p = 0.14); mOS 11.3 versus 9.3 months. The ORR was 52.29% versus 47.71%. The incidence of treatment-related grade 3/4 AEs was 77% versus 62% and AEs leading to discontinuation 6.21% versus 2.07%. Ten patients remain on maintenance nivolumab. Lethal adverse events independent of treatment were similar between the two arms (9 in arm A; 7 in arm B). **Conclusions:** The addition of nivolumab to CE as 1L treatment for ES-SCLC significantly improved PFS and OS. No new safety signals were observed. Clinical trial information: NCT03382561. Research Sponsor: ECOG-ACRIN.

9001 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

KEYNOTE-604: Pembrolizumab (pembro) or placebo plus etoposide and platinum (EP) as first-line therapy for extensive-stage (ES) small-cell lung cancer (SCLC). *First Author: Charles M. Rudin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pembro monotherapy showed durable antitumor activity as third-line or later therapy for metastatic SCLC, leading to FDA approval in that setting. KEYNOTE-604 was a double-blind, phase 3 study of pembro + EP vs placebo + EP as first-line therapy for ES-SCLC (NCT03066778). **Methods:** Eligible patients (pts) with previously untreated ES-SCLC and no untreated CNS metastases were randomized 1:1 to pembro 200 mg Q3W or saline placebo for up to 35 cycles plus 4 cycles of standard-dose EP. Pts with CR or PR after cycle 4 could receive PCI at investigator discretion. Randomization was stratified by platinum choice (carboplatin vs cisplatin), ECOG PS (0 vs 1), and LDH (≤ULN vs > ULN). Primary endpoints were OS and PFS (RECIST v1.1, blinded central review) in the ITT population. ORR, DOR, and safety were secondary endpoints. OS and PFS treatment differences were assessed by the stratified log-rank test. The protocol specified 2 interim analyses (IAs) and a final analysis (FA). Prespecified efficacy boundaries were one-sided $P = 0.0048$ for PFS at IA2 (prespecified final PFS analysis) and 0.0128 for OS at FA. **Results:** 453 pts were randomized. 223/228 pts assigned to pembro + EP and 222/225 assigned to placebo + EP received ≥1 dose of assigned treatment; 1 pt assigned to pembro + EP received placebo + EP in error. Median age was 65 y, 74% had ECOG PS 1, and 57% had LDH > ULN; more pts in the pembro + EP arm had baseline brain metastases (14% vs 10%). At FA (median follow-up, 21.6 mo), 9% of pts in the pembro + EP arm and 1% in the placebo + EP arm remained on study treatment; 12% and 14% received PCI. At IA2 (median follow-up, 13.5 mo), pembro + EP significantly improved PFS in the ITT population (HR 0.75 [95% CI 0.61-0.91], $P = 0.0023$; median 4.5 vs 4.3 mo). At FA, pembro + EP prolonged OS in the ITT population, but the significance threshold was not met (HR 0.80 [95% CI 0.64-0.98], $P = 0.0164$; median 10.8 vs 9.7 mo). In a post hoc analysis of OS in the as-treated population, the nominal P value was smaller than the significance threshold (HR 0.78 [95% CI 0.63-0.97], $P = 0.0124$). ORR at FA was 71% for pembro + EP vs 62% for placebo + EP; median DOR was 4.2 vs 3.7 mo. Observed AEs were as expected; any-cause AEs were grade 3-4 in 77% vs 75%, grade 5 in 6% vs 5%, and led to discontinuation in 15% vs 6%. **Conclusions:** Pembro + EP significantly improved PFS and prolonged OS compared with placebo + EP as first-line therapy for pts with ES-SCLC. No unexpected toxicities were seen with pembro + EP. These data support the benefit of pembro-containing regimens for ES-SCLC. Clinical trial information: NCT03066778. Research Sponsor: Merck & Co., Inc., Kenilworth, NJ, USA.

9002 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Durvalumab ± tremelimumab + platinum-etoposide in first-line extensive-stage SCLC (ES-SCLC): Updated results from the phase III CASPIAN study. *First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: CASPIAN is an open-label, Phase 3 study of durvalumab (D) ± tremelimumab (T) + etoposide and either cisplatin or carboplatin (EP) for pts with 1L ES-SCLC. At the planned interim analysis (data cutoff Mar 11, 2019; 63% maturity), D + EP demonstrated a statistically significant improvement in OS compared with EP alone (HR 0.73 [95% CI 0.59–0.91]; p=0.0047). Here we present a planned updated analysis of OS for D + EP vs EP and the first results for D + T + EP vs EP. **Methods:** Treatment-naïve pts with ES-SCLC (WHO PS 0/1) were randomized 1:1:1 to D 1500 mg + EP q3w, D 1500 mg + T 75 mg + EP q3w, or EP q3w. In the IO arms, pts received 4 cycles of EP + D ± T, followed by maintenance D 1500 mg q4w until disease progression. Pts received one additional dose of T 75 mg post EP in the D + T + EP arm. In the EP arm, pts received up to 6 cycles of EP and optional PCI (investigator's discretion). The two primary endpoints were OS for D + EP vs EP and for D + T + EP vs EP. **Results:** 268, 268 and 269 pts were randomized to D + EP, D + T + EP and EP, respectively; baseline characteristics were generally well balanced across arms. As of Jan 27, 2020, the median follow-up was 25.1 mo, 82% maturity. D + EP continued to demonstrate improvement in OS vs EP, with a HR of 0.75 (95% CI 0.62–0.91; nominal p=0.0032); median OS 12.9 vs 10.5 mo, respectively. 22.2% of pts were alive at 2 y with D + EP vs 14.4% of pts with EP. D + T + EP numerically improved OS vs EP, however this did not reach statistical significance per the prespecified statistical plan: HR 0.82 (95% CI 0.68–1.00; p=0.0451 [p≤0.0418 required for stat sig]); the median OS was 10.4 mo and 23.4% of pts were alive at 2 y. Secondary endpoints of PFS and ORR remained improved with D + EP vs EP and will be presented. Confirmed investigator-assessed ORR was similar for D + T + EP vs EP (58.4% vs 58.0%). Median PFS was similar for D + T + EP vs EP (4.9 mo vs 5.4 mo), but the 12-mo PFS rate was numerically higher (16.9% vs 5.3%); PFS HR 0.84 (95% CI 0.70–1.01). In the D + EP, D + T + EP and EP arms, respectively, incidences of all-cause AEs of Grade 3/4 were 62.3%, 70.3% and 62.8%; AEs leading to discontinuation 10.2%, 21.4% and 9.4%; and AEs leading to death 4.9%, 10.2% and 5.6%. **Conclusions:** The addition of durvalumab to EP continued to demonstrate improvement in OS compared with a robust control arm, further supporting this regimen as a new standard of care for 1L ES-SCLC offering the flexibility of platinum choice. No additional benefit was observed when T was combined with D + EP in this pt population. Safety findings in all arms remained consistent with the known safety profiles of all agents. Clinical trial information: NCT03043872. Research Sponsor: AstraZeneca.

9003 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

PrE0505: Phase II multicenter study of anti-PD-L1, durvalumab, in combination with cisplatin and pemetrexed for the first-line treatment of unresectable malignant pleural mesothelioma (MPM)—A PrECOG LLC study. *First Author: Patrick M. Forde, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: First-line CP was FDA-approved in 2004 for unresectable MPM. Given the role of inflammation in MPM and promising responses to PD-1 pathway blockade in pretreated MPM, we conducted a phase 2 single arm study of the anti-PD-L1 antibody, durvalumab (durva), combined with CP for patients (pts) with untreated MPM of any subtype. **Methods:** Eligible pts were treatment-naïve with surgically unresectable MPM. Primary endpoint was overall survival (OS); pts received up to 6 cycles of durva-CP, followed by maintenance durva up to 1 year. Carboplatin was permitted for pts with baseline hearing or renal impairment. The first 15 pts were monitored for dose-limiting toxicities (DLTs). Secondary endpoints included toxicity, objective response by modified RECIST, progression-free survival (PFS), and correlative analyses. With a sample size of 55 patients and 32 events, the study had 90% power to detect a 58% improvement in median OS from 12 months (m) (historical control) to 19 m with durva-CP. **Results:** PrE0505 enrolled 55 patients at 15 US-based sites between 06/2017 and 06/2018. Histologic subtypes were epithelioid (75%), biphasic (11%), sarcomatoid (13%), and desmoplastic (2%). There were no DLTs during the run-in period. As of January 2020 the median follow up is 20.6 m and 29 deaths have occurred. The median OS at the time of report is 21.1 m. The 12 m OS rate was 70% with a 2 sided 95% confidence interval (56%, 81%) and two-sided 80% CI (62%, 78%). Analyses for the secondary endpoints were ongoing at abstract submission. Exome sequencing, TCR sequencing and dual PD-L1/CD8 staining have been completed on baseline tumors from at least 45 of the 55 patients enrolled as well as RNA sequencing for those with adequate tissue. Initial results show that tumors harbored an average tumor mutation burden of 22 somatic sequence alterations and varying levels of aneuploidy were detected. **Conclusions:** The combination of chemotherapy with durvalumab delivered a promising median OS for previously untreated pts with unresectable MPM. Full results from the study along with the extensive correlative analyses performed will be reported. The phase 3 PrE0506/DREAM3R trial evaluating CP-durvalumab versus CP alone will commence enrollment in the United States and Australia in 2020. Clinical trial information: NCT02899195. Research Sponsor: AstraZeneca, U.S. National Institutes of Health.

9004 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Randomized phase II study on gemcitabine with or without ramucirumab as second-line treatment for advanced malignant pleural mesothelioma (MPM): Results of Italian Rames Study. *First Author: Maria Pagano, Oncology Unit, Clinical Cancer Center, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy*

Background. The RAMES Study (EudraCT Number 2016-001132-36) is a multicenter, double-blind, randomized phase II trial exploring the efficacy and the safety of the addition of ramucirumab to gemcitabine as the second-line treatment in MPM patients (pts) after platinum/pemetrexed regimens. **Methods.** The pts were assigned (1:1) to receive Gemcitabine 1000 mg/m^2 i*v* on days 1 and 8 every 21 days with Placebo (Arm A) or Ramucirumab 10 mg/kg i*v* on day 1, of a 21-day cycle (Arm B), until tolerability or progressive disease. Pts was stratified by ECOG/PS (0-1 vs 2), age ($\leq$ 70 vs $>$ 70 yrs), histology (epithelioid vs non-epithelioid) and time to progression (TTP) after first-line therapy. The primary endpoint was overall survival (OS). Assuming a proportion of OS equal to 40% at 1 year in arm A, a 12% absolute improvement in OS at 1 yrs was expected in Arm B (hazard ratio = 0.70).114 events (156 subjects) are required for a one-sided log-rank test with α = 0.15 to have 80% power. **Results.** From December 2016 to July 2018, 164 pts were randomized, 81 pts in Arm A and 80 Arm B; 3 pts were randomized but not treated. Characteristics of pts were: median age 69 yrs (44-81), males 119 (73.9%), females 42 (26.1%); ECOG/PS0 96 (59.6%) ECOG/PS1-2 65 (40.4%); histotype epithelioid 132 (81.9%), non-epithelioid 29 (18.1%); stage III 98 (60.7%), stage IV 60 (37.3%), 3 (2.0%) missing; asbestos exposure assessed 80 (49.7%). Median of courses was 3.50 in Arm A and 7.50 in Arm B. OS was significantly longer in Arm B with median 13.8 mths (70% CI 12.7-14.4) vs Arm A with 7.5 mths (70% CI 6.9-8.9), HR 0.71 (70% CI 0.59-0.85, p = 0.057). OS at 6 and 12 mths was in Arm A 63.9% and 33.9%, and in Arm B 74.7% and 56.5%, respectively. In Arm B OS was not correlated to TTP at first-line therapy (13.6 mths in TTP $\leq$6 mths and 13.9 mths in TTP $>$ 6 mths) and histotypes (13.8 months in the epithelioid and 13.0 months in non-epithelioid). No significant differences in thromboembolism G3-4 events were observed in Arm A vs Arm B (p= 0.64). None hypertension G3-4 was reported in Arm A vs 5 pts (6.3%) in Arm B (p= 0.022). No significant differences in G3-4 haematological toxicities between the two arms were reported. **Conclusion:** In the RAMES Study the addition of Ramucirumab to Gemcitabine significantly improved OS regardless of age of pts, tumor histotype and TTP at the first-line treatment. Gemcitabine plus Ramucirumab can be considered a manageable regimen in second-line treatment of advanced MPM pts.Clinical trial information: NTC03560973. Research Sponsor: None.

9005 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

CTONG1104: Adjuvant gefitinib versus chemotherapy for resected N1-N2 NSCLC with EGFR mutation—Final overall survival analysis of the randomized phase III trial 1 analysis of the randomized phase III trial. *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, School of Medicine, South China University of Technology, Guangzhou, China*

Background: ADJUVANT-CTONG1104, a randomized phase 3 trial showed adjuvant gefitinib treatment significantly improved disease-free survival (DFS) vs standard doublet chemotherapy in patients (pts) with epidermal growth factor receptor (*EGFR*) mutation-positive resected stage II-IIIA (N1-N2) non-small-cell lung cancer (NSCLC). 5-year survival rate of N1N2 were 38%-50% in IASLC staging system. Here, we present the final overall survival (OS) results from the study. **Methods:** From Sep 2011 to April 2014, 222 patients, aged 18-75 years, with *EGFR* activating mutation through completely resection and diagnosed as stage II-IIIA (N1-N2) NSCLC pathologically from 27 sites were enrolled. The enrolled patients were 1:1 randomized to receive adjuvant gefitinib (250 mg once per day) for 24 months (G, n=111) or vinorelbine (25 mg/m^2, d1 and d8) plus cisplatin (75 mg/m2, d1) every 3 weeks for 4 cycles (C, n=111). The primary endpoint was DFS in the ITT population. Secondary endpoints included OS, 3 and 5-year DFS rate, 5-year OS rate. The subsequent therapy data were collected, including crossover from C to G, re-challenge TKI and other treatment. Data cut-off date was Jan. 13, 2020. **Results:** A median follow-up was 76.9 months. The median OS (mOS) was 75.5 months based on 95 (42.8%) events in ITT whole population. The mOS was 75.5m in G arm and 79.2m in C arm (HR 0.96, 95%CI 0.64-1.43, p=0.823). The 3, 5-year OS rate were 68.6%, 53.8% in G and 67.5%, 52.4% in C respectively. DFS in 3, 5-y were 40.3%, 23.4% in G and 33.2%, 23.7% in C, respectively ($P_{3\text{-}y}$=0.395, $P_{5\text{-}y}$=891). All predefined subgroups including age, gender, lymph node, EGFR mutation type had no significant difference in statistics but in favor of G arm in trend. Subsequent treatment especially targeted therapy contributed most to OS (HR = 0.46, 95% CI 0.26 – 0.83). Median OS of patients receiving subsequent target therapy was75.5m (n=35), 36.4m in other treatment (n=33; (P$<$0.001). For G mOS were 75.5 (n=15; target therapy) and 35.0 (n=18; other, p$<$0.001), for C 62.8m (n=20) and 46.8m (n=15; p=0.251). The RR was 26.7%, DCR 66.7%, mPFS 14.1m and mOS 19.6m for patients with rechallenged EGFR TKI in G arm (n=15). No novel unexpected SAE was observed during follow up. **Conclusion** The DFS survival advantage did not translate to OS difference in ADJUVANT trial. The OS with 75.5m was the best one of survival in completely resected N1N2 NSCLC comparing with historical data and sequent TKI treatment contribute to overall survival. Clinical trial information: NCT01405079. Research Sponsor: Chinese Thoracic Oncology Group (CTONG), Chinese Thoracic Oncology Group (CTONG).

9006 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Randomized phase III study of irinotecan/cisplatin (IP) versus etoposide/cisplatin (EP) for completely resected high-grade neuroendocrine carcinoma (HGNEC) of the lung: JCOG1205/1206. *First Author: Hirotsugu Kenmotsu, Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: In the WHO classification, small cell lung cancer (SCLC) and large cell neuroendocrine carcinoma (LCNEC) are considered as high-grade neuroendocrine carcinoma (HGNEC) of the lung. Although there were no randomized trials evaluating adjuvant chemotherapy for patients (pts) with resected HGNEC, EP was considered to be a standard regimen for this population. A phase III study showed the superiority of IP to EP in pts with extensive stage SCLC (JCOG9511). **Methods:** Pts with completely resected HGNEC were randomized in a 1:1 ratio to receive either etoposide (100 mg/m^2, days 1-3)/cisplatin (80 mg/m^2, day 1) or irinotecan (60 mg/m^2, days 1, 8, 15)/cisplatin (60 mg/m^2, day 1), using the minimization method according to sex, pathologic stage, histology and institution. The primary endpoint was changed from overall survival (OS) to relapse-free survival (RFS) during the study period. We assumed a 3-year RFS of 59% of EP arm and 72% of IP arm (hazard ratio (HR) of 0.623). Planned sample size was 220 in total to give a power of 80% with a one-sided alpha of 5%, an accrual period of 6 years and a follow-up period of 3 years. **Results:** Between April 2013 and October 2018, 221 pts with a median age of 66 years, pathological stage I (54%), SCLC (53%), were randomly assigned to the EP arm (n = 111) or the IP arm (n = 110). In the second interim analysis, the predictive probability that IP would be superior to EP at the time of the primary analysis was 15.9%, which led to early termination of the trial. With a median follow-up of 24.1 months, 3-year RFS was 65.4% versus 69.0% with HR of 1.076 (95% CI, 0.666-1.738; log-rank test, one-sided *P*= 0.619). In the subgroup analyses of histology, 3-year RFS in SCLC was 65.2% versus 66.5% with HR of 1.029 (95% CI, 0.544-1.944), and 3-year RFS in LCNEC was 66.5% versus 72.0% with HR of 1.072 (95% CI, 0.517-2.222). Overall survival at 3 years was 84.1% versus 79.0% with HR of 1.539 (95% CI, 0.760-3.117). Proportions of treatment completion were 87.4% (EP) and 72.7% (IP). Incidences (EP/IP) of grade 3 or 4 febrile neutropenia (20.2/3.7%) or neutropenia (97.2/35.8%) were more common in EP. Grade 3 or 4 diarrhea (0.9/8.3%) or anorexia (6.4/11.1%) were more common in IP. One treatment-related death due to tracheal bleeding was observed in IP. **Conclusions:** This study failed to show the superiority of IP to EP in RFS for pts with completely resected HGNEC. EP is still a standard treatment for this population. Clinical trial information: UMIN000010298. Research Sponsor: the Japan Agency for Medical Research and Development.

9007 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Randomized phase II trial comparing the efficacy of standard-dose with high-dose twice-daily thoracic radiotherapy (TRT) in limited disease small-cell lung cancer (LD SCLC). *First Author: Bjorn Henning Gronberg, Department of Clinical and Molecular Medicine, NTNU, Norwegian University of Science and Technology and Department of Oncology, St. Olav's Hospital, Trondheim University Hospital, Trondheim, Norway*

Background: Concurrent chemoradiotherapy is the standard treatment of LD SCLC. Some patients are cured, but most relapse and better treatment is needed. 45 Gy in 30 fractions BID is the most recommended TRT-schedule. Studies suggest that a higher TRT-dose might prolong survival, but hitherto, this has not been confirmed in randomized trials. We aimed to investigate whether high-dose BID TRT of 60 Gy in 40 fractions was feasible, tolerated, and improved survival. **Methods:** Patients $>$ 18 years, performance status (PS) 0-2 and confirmed LD SCLC were to receive 4 courses of platinum/etoposide and were randomized to BID TRT of 60 or 45 Gy. Responders were offered prophylactic cranial irradiation of 25-30 Gy. Primary endpoint was 2-year survival; secondary endpoints were toxicity, progression free survival (PFS), and overall survival (OS). To demonstrate a 25% improvement of 2-year survival from 53% to 66% with a one-sided α = .10 and β = .80, 75 patients were required on each arm. **Results:** Between 2014-2018, 176 patients were enrolled at 22 Scandinavian hospitals. 160 completed TRT per protocol and were eligible for the present analyses (60 Gy: n = 84, 45 Gy: n = 76). Median age was 65, 58% women, 90% PS 0-1. There were no significant differences in grade 3–4 esophagitis (60 Gy: 19%, 45 Gy: 18%, p = .92) or grade 3–4 pneumonitis (60 Gy: 4%, 45 Gy: 0%, p = .10). There was a trend towards more neutropenic infections on the 45 Gy arm (60 Gy: 21%, 45 Gy: 36%, p = .05). There were no significant differences in other grade 3-4 toxicity. Three patients died during the study treatment period (60 Gy: one neutropenic infection and one aortic dissection; 45 Gy: one thrombocytopenic bleeding). There were no statistically significant differences in response rates (60 Gy: 88% [95% CI 81-95], 45 Gy: 85% [95% CI 76-93], p = .52) or median PFS (60 Gy: 20 months [95% CI 11-29], 45 Gy: 14 months [95% CI 10-19], p = .31). Significantly more patients on the 60 Gy arm were alive after 2 years (60 Gy: 73% [95% CI 63-83], 45 Gy: 46% [95% CI 36-60], p = .001), and they had a significantly longer median overall survival (60 Gy: 42 months [95% CI 32-51], 45 Gy: 23 months [95% CI 17-28], HR .63 [95% CI .41-.96], p = .031). **Conclusions:** LD SCLC patients who received BID TRT of 60 Gy had a statistically significant and numerically substantial benefit in terms of 2-year survival (primary endpoint) and median overall survival compared with those who received BID TRT of 45 Gy. The higher TRT dose did not cause more toxicity than the standard dose. Clinical trial information: NCT02041845. Research Sponsor: The Norwegian Cancer Society and The Liaison Committee for Education, Research and Innovation in Central Norway.

9008 Poster Discussion Session; Displayed in Poster Session (Board #201), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Phase II study of pembrolizumab (pembro) plus platinum doublet chemotherapy and radiotherapy as first-line therapy for unresectable, locally advanced stage III NSCLC: KEYNOTE-799. *First Author: Salma K. Jabbour, Department of Radiation Oncology, Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ*

Background: KEYNOTE-799 (NCT03631784) evaluates pembro plus concurrent chemoradiation therapy (CCRT) in pts with unresectable, locally advanced stage III NSCLC. **Methods:** In this phase 2, nonrandomized, open-label trial, pts with previously untreated, unresectable, pathologically confirmed stage IIIA–C NSCLC with measurable disease (RECIST 1.1) received up to 17 cycles of pembro 200 mg Q3W starting with cycle 1 plus standard thoracic radiotherapy (60 Gy in 30 daily 2-Gy fractions) in cycles 2–3 and investigator's choice of paclitaxel 200 mg/m^2 + carboplatin AUC 6 Q3W for cycle 1, then paclitaxel 45 mg/m^2 + carboplatin AUC 2 QW for cycles 2–3 (cohort A), or cisplatin 75 mg/m^2 + pemetrexed 500 mg/m^2 Q3W (nonsquamous only) in cycles 1–3 (cohort B). Primary endpoints were ORR (CR/PR per RECIST 1.1 by blinded independent central review) and rate of grade ≥3 pneumonitis (per NCI CTCAE v4.0). CIs were estimated using the Clopper-Pearson method. Safety was assessed in all treated patients; efficacy was assessed in pts with ≥15 wks follow-up. **Results:** As of Jan 3, 2020, 112 and 73 pts have been enrolled in cohorts A and B, respectively; 63 in cohort A and 52 in cohort B continue on treatment. Median (range) follow up was 8.3 (0.7–14.0) mo in cohort A and 5.8 (0.2–13.7) mo in cohort B. ORR (90% CI) was 67.0% (58.9%–74.3%) in cohort A and 56.6% (44.4%–68.2%) in cohort B (Table). Grade ≥3 pneumonitis occurred in 9 pts (8.0%; 90% CI, 4.3%–13.6%) in cohort A and 4 pts (5.5%; 90% CI, 1.9%–12.1%) in cohort B. Treatment-related grade ≥3 AEs occurred in 72 pts (64.3%) in cohort A and 30 pts (41.1%) in cohort B. 4 pts had treatment-related grade 5 pneumonitis (all in cohort A). Enrollment is complete for cohort A and ongoing in cohort B. **Conclusions:** Pembro plus CCRT shows promising antitumor activity in pts with unresectable, locally advanced stage III NSCLC. Toxicity was as anticipated with pembro plus CCRT. Clinical trial information: NCT03631784. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

A phase I safety and feasibility study of neoadjuvant chemoradiation plus pembrolizumab followed by consolidation pembrolizumab in resectable stage IIIA non-small cell lung cancer. *First Author: Christopher Lemmon, Cleveland Clinic Foundation, Cleveland, OH*

Background: Patients (pts) with resectable stage IIIA non-small cell lung cancer (NSCLC) have high rates of recurrence despite concurrent chemoradiation (CRT) followed by surgery. Immune checkpoint inhibitor consolidation has improved outcomes in unresectable stage III pts. Here we report the addition of concurrent neoadjuvant pembrolizumab (P) to CRT in stage IIIA patients to determine the safety and feasibility of this approach. **Methods:** Pts with stage IIIA NSCLC deemed resectable by a thoracic surgeon received neoadjuvant CRT consisting of cisplatin, etoposide, and concurrent P (200mg every 3 weeks x 3) with 45 Gy in 25 fractions. Pts without progression underwent resection followed by 6 months of consolidation P. The primary objective was feasibility and safety (defined as ≤30% grade 3 or higher pulmonary toxicity or any grade 4/5 nonhematologic toxicity). Ten pts were to be enrolled in Part 1, and if 2 or fewer pts had events then an additional 10 pts were to be enrolled. Secondary objectives were progression free survival (PFS), overall response rate (ORR), and pathologic complete response rate (pCR). **Results:** The median age of 9 enrolled pts was 66 years (range 49-76). 67% were female. 8 pts were assessable for radiographic response with an ORR of 75%. One pt came off study for progression prior to surgery and one had pleural metastases found during surgery so resection was aborted. Six pts underwent complete resection with a pCR rate of 67% (4/6). Consolidation P was started on 4 pts, with 3 completing treatment and 1 declined further treatment after 3 cycles. Median follow-up is 19.6 months and median PFS has not been reached. None of the patients who underwent resection have recurred. Serious adverse events were reported in all 9 pts with most significant being 2 grade 5 events: 1 due to pneumocystis pneumonia after resection but prior to consolidation, and 1 due to cardiac arrest during the neoadjuvant phase. Grade 3 events included 1 episode each of pneumonitis, bronchopleural fistula, acute kidney injury, colon perforation, and febrile neutropenia. **Conclusions:** The addition of P to neoadjuvant CRT in resectable stage IIIA pts resulted in a high pCR rate at resection. Although the relationship between grade 5 events and the addition of P was not clear, the stopping rule for infeasibility was met. As other larger studies are underway, the trial was halted rather than amended. This investigator initiated trial was funded by Merck. Clinical trial information: NCT02987998. Research Sponsor: Merck.

Consolidation nivolumab/ipilimumab versus nivolumab following concurrent chemoradiation in patients with unresectable stage III NSCLC: A planned interim safety analysis from the BTCRC LUN 16-081 trial. *First Author: Melissa Yan, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Consolidation PD-1/PD-L1 inhibition after chemoradiation (CRT) for unresectable stage III NSCLC improves overall survival. In stage IV NSCLC, the combination of nivolumab/ipilimumab improved overall survival compared to chemotherapy in patients with PD-L1 > 1% and performed favorably in patients with PD-L1 < 1%. The safety of consolidation nivolumab/ipilimumab after CRT has not been previously assessed. **Methods:** In this randomized, multi-center, phase II study, a total of 105 planned pts with unresectable stage IIIA/IIIB NSCLC will receive chemoradiation, then randomize 1:1 to either nivolumab 480mg IV q4 wks (Arm A) or nivolumab 3mg/kg IV q2 wks + ipilimumab 1mg/kg IV q6 wks (Arm B), for up to 24 wks. In this planned interim analysis, the safety of the first 50 patients, with 25 patients treated on each arm, is assessed. **Results:** From 9/2017 to 6/2019, the first 50 patients were accrued and analyzed for this planned safety analysis. Baseline characteristics for Arm A/B: median age 64/62, stage IIIA 17/16, stage IIIB 8/9, nonsquamous 14/13, squamous 11/12. The median number of cycles completed in Arm A was 6 (range 1-6, cycle length q4 wks) and in Arm B was 4 (range 1-4, cycle length q6 wks). The rate of treatment-related adverse events leading to discontinuation of therapy was 16% in Arm A and 40% in Arm B. The percentage of patients with any > grade 3 adverse event (AE) was 32% in Arm A and 44% in Arm B. With respect to immune-related AE (irAEs), the percentage of patients with any ≥grade 2 was 44% in Arm A and 60% in Arm B; any ≥ grade 3 irAEs was 16% in Arm A and 32% in Arm B. The incidence of > grade 2 pneumonitis was 16% in Arm A and 36% in Arm B. The percentage of patients with > grade 3 pneumonitis was 4% in Arm A and 20% in Arm B. No treatment-related deaths were reported on either arm. **Conclusions:** In the post chemoradiation setting, the incidence of > grade 3 toxicity was greater in the consolidative nivolumab/ipilimumab arm, which resulted in a higher rate of treatment discontinuation than nivolumab alone. The Data and Safety Monitoring Board recommended continued enrollment without modification to the trial and the study currently remains open to accrual (66 of 105 patients have been enrolled as of 1/17/2020). Clinical trial information: NCT03285321. Research Sponsor: Bristol-Myers Squibb.

Atezolizumab plus stereotactic ablative therapy for medically inoperable patients with early-stage non-small cell lung cancer. *First Author: Karen Kelly, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Stereotactic ablative radiation therapy (SABR) is the standard-of-care for medically inoperable, early stage non-small cell lung cancer (NSCLC), but regional and distant failures remain problematic. Based on our *in vivo* data showing synergy between radiation and immune checkpoint inhibitors (ICI) and the known efficacy and mild toxicity profile of ICI in NSCLC, we conducted a phase I study to determine the maximum tolerated dose of neoadjuvant, concurrent, and adjuvant atezolizumab with SABR for early stage NSCLC patients (pts). **Methods:** Eligible pts had histologically confirmed T1-3 NSCLC with at least one feature predictive of increased recurrence risk: diameter ≥1 cm, SUV ≥6.2 on PET, or moderately/poorly differentiated histology, were medically inoperable or refused surgery and had a Zubrod PS ≤2. Patients received 6 cycles of atezolizumab. A 3+3 dose finding design was employed with 3 dose levels: 3 mg/kg, 10 mg/kg, and 1200 mg flat dosing. SABR was delivered starting cycle 3 to 50 Gy over 4-5 fractions. Dose limiting toxicity (DLT) was assessed during the first 9 weeks. **Results:** 20 pts were enrolled, 15 pts in the dose finding and 5 pts at the recommended phase II dose (RP2D). Patient factors: Medlan age 77; 45% male, 85% smoking history, 85% PS 0-1 and 35% squamous. One pt on dose level 2 had a DLT – a grade 3 rash. Atezolizumab 1200 mg flat dosing was the RP2D. Grade 3 pneumonitis was not observed. Partial responses after 2 cycles were seen in 3/17 evaluable pts (18%) and 1 pt had a minor response. No patient progressed on treatment. PD-L1 expression was 0% 8/13 (62%), >1% - 50% 4/13 (31%), >50% 1/13 (8%) in pts with sufficient tissue. Of 5 pts with PD-L1 expression 3 (60%) were responders and 1 (12.5%) of 8 pts with 0% PD-L1 expression responded. Multi-plex Quantitative Immunofluorescence (QIF) using a T cell activation panel demonstrated to correlate with ICI response was performed on 9 samples (including 2 responders, 1 minor responder). The CD3 QIF score was > two-fold higher in the responders compared to non-responders, and the levels of proliferating and activated T cells were likewise > two-fold higher. Comprehensive stool and serial blood analyses have been completed. Correlative endpoints will be reported along with additional efficacy outcomes. **Conclusions:** Atezolizumab plus SABR is feasible, safe and shows an efficacy signal in medically inoperable early stage NSCLC. This combination will be tested in a randomized phase III trial SWOG/NRG S1914. Funding: This work was supported by the DOD CDMRP W81XWH-15-2-0063 and Genentech. Clinical trial information: NCT02599454. Research Sponsor: DEPARTMENT OF DEFENSE - CONGRESSIONALLY DIRECTED MEDICAL RESEARCH PROGRAM, Pharmaceutical/Biotech Company.

***KEAP1/NFE2L2* mutations to predict local recurrence after radiotherapy but not surgery in localized non-small cell lung cancer.** *First Author: Michael S Binkley, Stanford University School of Medicine, Stanford, CA*

Background: Tumor genotyping in localized non-small cell lung cancer (NSCLC) is not broadly performed due to lack of actionable associations of mutations with treatment or outcome. We sought to identify recurrent mutations in localized NSCLC that are associated with local recurrence (LR) after radiotherapy (RT) or surgery. **Methods:** We identified consecutive patients with NSCLC treated with chemoradiotherapy (CRT), stereotactic ablative radiotherapy (SABR) or surgery from 2009-2018 at our institution with stage IA1-IIIC NSCLC who had genotyping performed on tumor tissue using a targeted gene panel. Our primary objective was to identify somatic tumor mutations that predicted LR after RT but not surgery. We also performed functional screening assays by expressing open reading frame constructs harboring patient-derived mutations in knock-out cell lines generated by CRISPR-Cas9 and evaluating effects on in vitro radioresistance. **Results:** We identified 232 consecutive patients with localized NSCLC (87.1% adenocarcinoma, 10.3% squamous, 2.3% other) who received tumor biopsy or resection specimen and underwent tumor genotyping. 47 patients with locally advanced NSCLC received CRT, 50 patients with early stage NSCLC received SABR, and 135 patients with early stage NSCLC underwent surgical resection. Of all recurrent mutations ($>$ 5% mutation frequency), only mutations in Kelch-like ECH-associated protein 1 (*KEAP1)* or Nuclear Factor Erythroid 2-Related Factor 2 (*NFE2L2)* genes *(K/N^{MUT})* were significantly associated with LR after CRT or SABR, with 2-year LR in the combined RT cohort of 42.4% for K/N^{MUT} versus 12.5% for wildtype (P = 0.005). Furthermore, K/N^{MUT} were present in nearly half of all LR events. Strikingly, there was no significant difference in LR for K/N^{MUT} tumors following CRT versus SABR (P = 0.47). Local recurrence was rare for patients who received surgery (n = 2) and was not associated with *K/N* mutation status (P = 0.60). Functional evaluation by expression of *K/N* mutations in knock-out cell lines revealed that LR only occurred in patients with mutations that induced radioresistance (i.e. pathogenic) but not passenger mutations (P = 0.04). In contrast to genotyping, NFE2L2 target gene expression analysis via RNA-seq did not predict LR (P = 0.93). **Conclusions:** Our findings suggest that *KEAP1/NFE2L2* mutations are a predictive biomarker of clinical radioresistance and a dominant cause of LR after RT. Genotyping for *KEAP1/NFE2L2* mutations could therefore facilitate treatment personalization in localized NSCLC. Research Sponsor: U.S. National Institutes of Health.

A phase II trial of atezolizumab and bevacizumab in patients with relapsed/refractory and unresectable malignant peritoneal mesothelioma. *First Author: Kanwal Pratap Singh Raghav, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Malignant peritoneal mesothelioma (MPeM) is an orphan malignancy. No recommended/FDA approved therapies exist for salvage treatment beyond first-line platinum and pemetrexed based chemotherapy. While immune checkpoint inhibition has shown preliminary efficacy in mesotheliomas, data and efficacy is limited in MPeM patients (pts) [objective response rate (ORR) ~ 11%; median progression-free survival (mPFS) ~ 4 months (m); median overall survival (mOS) ~ 11 m]. We aimed to prospectively assess the safety and efficacy of combined anti-PD1 (atezolizumab) and VEGF (bevacizumab) blockade (AtezoBev) in pts with MPeM. **Methods:** In this phase 2 study, eligible pts with histologically confirmed MPeM, ECOG PS 0-1, and prior platinum and pemetrexed treatment were treated with 1200 mg of atezolizumab and 15 mg/kg of bevacizumab IV every 21 days until disease progression, unacceptable toxicity, or withdrawal. Primary endpoint was confirmed ORR by RECIST 1.1 by independent radiology review. Duration of response (DOR), PFS and OS were prespecified secondary endpoints. **Results:** Among 20 enrolled pts (3/2017 - 2/2019), median age was 63 (range, 33-87) years, 12 (60%) were female, 12 (60%) had PS 0, and 2 (10%) had biphasic MPeM. Among 20 evaluable pts (median cycles 14), confirmed ORR was 35% (7 pts; 95% CI: 15.4-59.2) (median DOR 8.8 m). Responses were ongoing in 5/7 (71.4%) pts at data cutoff. The median follow-up was 20.5 months. Six deaths were observed during follow-up, and the 1-year OS was 79% (95% CI: 52 – 91) (median OS ~ NR). Median PFS was estimated as 17.6 m (95% CI: 9.1 – NR). The 1-year PFS was 54% (95% CI: 28 – 74). Grade 3 (no grade 4/5) treatment-emergent adverse events occurred in 10 (50%) pts; most common being hypertension (40%) and anemia (10%). Two (10%) pts had grade 3 immune-related adverse events. Translational studies are ongoing. **Conclusions:** AtezoBev showed promising and durable efficacy in relapsed/refractory MPeM with acceptable safety profile. Ongoing multiomic analyses of pre and on-treatment tissue/liquid biopsies obtained on all these pts will provide additional insight into mechanisms and biomarkers of response and resistance. Clinical trial information: NCT03074513. Research Sponsor: Genentech Inc., MD Anderson Cancer Center

PIT-1: Randomized phase II trail of pemetrexed-cisplatin plus bevacizumab or concurrent thoracic radiation therapy followed by surgery in stage IIIA (N2) nonsquamous non-small cell lung cancer. *First Author: Kazuya Takamochi, Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan*

Background: PIT-1 (Personized Induction Therapy-1) is a multicenter, open-label, randomized phase II study using selection design of platinum doublet chemotherapy plus angiogenesis inhibitor or concurrent thoracic radiation therapy (TRT) as induction therapy followed by surgery in patients with stage IIIA (N2) nonsquamous non-small cell lung cancer (NSCLC) to investigate the efficacy and safety of these treatment strategies. **Methods:** Patients with stage IIIA (pathologically proven N2) nonsquamous NSCLC randomly received (1:1) induction therapy consisting of pemetrexed (500 mg/m^2) and cisplatin (75 mg/m^2) plus bevacizumab (15 mg/kg) intravenously every 3 weeks for three cycles (arm A) or concurrent TRT (45 Gy in 25 fractions) (arm B) followed by surgery. The primary endpoint was 2-year progression-free survival (PFS) rate and key secondary endpoints included overall survival (OS), the objective response rate (ORR) as defined by the Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1, the pathological complete remission (pCR) rate, feasibility and toxicity. **Results:** Eighty-eight patients were randomly assigned (each arm, n = 44) between October 2013 and June 2017 and 82 (arm A, n = 42; arm B, n = 40) were treated. Patient demographics were balanced between the two arms. The percentage of patients who received induction therapy followed by surgery was 88.1% (37/42) in arm A and 92.5% (37/40) in arm B. The complete resection rate was 81.1% (30/37) in arm A, and 91.9% (34/37) in arm B. The 2-year PFS rate was 36.8% (95% CI: 22.4-51.2) in arm A, and 50.0% (95% CI: 33.8-64.2) in arm B. The 2-year OS rate was 80.5% (95% CI: 64.7-89.7) in arm A, and 80.0% (95% CI: 64.0-89.5) in arm B. The ORR was 50.0% (21/42) in arm A and 60.0% (24/40) in arm B. The pCR rate was 8.1% (3/37) in arm A and 10.8% (4/37) in arm B. Grade 3 or 4 toxicities occurred during induction therapy in 35.7% of the patients in arm A and 22.5% of the patients in arm B. Grade 3 or 4 surgical complications occurred in 21.4% of the patients in arm A and 20.0% of the patients in arm B. Although no fatal toxicity was observed during induction therapy in either arm, two patients in arm A died after surgery due to bronchopleural fistula. **Conclusions:** The 2-year PFS rate in arm B was higher than that in arm A. Fatal surgical complications were only observed in arm A. Therefore, we chose pemetrexed-cisplatin plus concurrent thoracic radiation therapy as the investigational induction treatment strategy for a future phase III study. Clinical trial information: 000011941. Research Sponsor: None.

SAKK 16/14: Anti-PD-L1 antibody durvalumab in addition to neoadjuvant chemotherapy in patients with stage IIIA(N2) non-small cell lung cancer (NSCLC)—A multicenter single-arm phase II trial. *First Author: Sacha Rothschild, Department of Medical Oncology, University Hospital Basel, Basel, Switzerland*

Background: For patients (pts) with resectable stage IIIA(N2) non-small cell lung cancer (NSCLC) neoadjuvant chemotherapy (chemo) with 3 cycles cisplatin (cis)/docetaxel (doc) followed by surgery is an accepted standard of care leading to a 1-year (yr) event-free survival (EFS) of 48% and a 5-yr overall survival (OS) of 37%. PD-1/PD-L1 inhibitors have recently shown to lead to high response rates in resectable NSCLC. **Methods:** SAKK 16/14 is an open-label single-arm phase II study including 68 pts with resectable NSCLC stage IIIA(N2) (T1-3 N2 M0), irrespective of histological subtype, genomic aberrations or PD-L1 expression status. Neoadjuvant treatment consisted of 3 cycles of cis 100 mg/m^2 and doc 85 mg/m^2 q3w followed by 2 cycles of durvalumab 750 mg q2w. Durvalumab was continued after surgery q2w for 1 yr. The primary endpoint is EFS at 1 yr. The statistical hypothesis is to improve EFS at 1 yr from 48% based on the SAKK 16/00 study to 65%. Here, we report the primary endpoint and response data from 67 evaluable pts included in the study. **Results:** 68 pts were included from 06/16 to 01/19 and 67 pts (35 males, 32 females) were evaluable. Median age was 61 yrs (range, 41-74). 52 pts (77.6%) had a WHO PS of 0. 95.5% were current or former smokers. The majority of tumors were adenocarcinoma (55.2%) followed by squamous cell histology (32.8%). Clinical stage T1, T2 and T3 were present at diagnosis in 22.4%, 49.3% and 28.4%, respectively. 81.1% of pts underwent resection. The main reason for not undergoing surgery was disease progression (33.3%). Pneumonectomy was performed in 5 pts (9.1%), 43 pts underwent lobectomy and 7 pts bilobectomy. 30-day postoperative mortality was observed in one patient (1.8%). One patient died due to a bleeding complication after surgery most likely not related to neoadjuvant therapy. Radiographic response was 44.8% (95%CI: 32.6-57.4) after neoadjuvant chemo and 59.7% (95%CI: 46.4-71.9) after additional neoadjuvant immunotherapy. 1-yr EFS was 73.3% (90%CI: 62.5-81.4). Results for pathologic remission rate as well as correlation with PD-L1 status will be presented during the meeting. **Conclusions:** We report on treatment outcomes of the largest cohort of pts with resectable stage IIIA(N2) NSCLC receiving perioperative immune checkpoint inhibitor therapy. The addition of perioperative durvalumab to standard of care cis/doc is safe and leads to a high response rate and a very encouraging 1-yr EFS rate that appears substantially higher than with chemo alone. Clinical trial information: NCT 02572843. Research Sponsor: AstraZeneca, Other Foundation.

The anti-disialoganglioside (GD2) antibody dinutuximab (D) for second-line treatment (2LT) of patients (pts) with relapsed/refractory small cell lung cancer (RR SCLC): Results from part II of the open-label, randomized, phase II/III distinct study. *First Author: Martin Edelman, Fox Chase Cancer Center, Philadelphia, PA*

Background: Although SCLC is highly responsive to initial therapy, most pts relapse < 1 y. Topotecan (T) and irinotecan (I) are used in 2LT of SCLC; however, treatment response is low: ≤10-25% and median survival is ~4-5 months. Preclinical studies support GD2 as an SCLC target. This study evaluated the combination of D+I vs. I alone or T alone in 2LT of SCLC pts. **Methods:** Pts with RR SCLC, Eastern Cooperative Oncology Group 0-1, were randomized 2:2:1 to receive D 16-17.5 mg/m^2 intravenously (IV) plus I 350 mg/m^2 IV (Day 1 q21d), I 350 mg/m^2 IV (Day 1 q21d), or T 1.5 mg/m^2 IV (Days 1-5 q21d). Randomization was stratified by duration of response to prior platinum therapy. Primary endpoint was overall survival (OS) in pts treated with D+I vs. I alone and was analyzed using stratified log-rank test and COX regression. Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), and clinical benefit rate, ORR + stable disease (CBR). Safety was assessed. **Results:** 471 pts were randomized to D+I (n = 187), I (n = 190), or T (n = 94). Baseline characteristics were balanced (24.2% women; mean ± SD age 61.6 ± 8.7 y). Median OS was similar in pts receiving D+I (6.9 [3.5,10.9] months) vs. I alone (7 [3.6,13.1] months) (HR [95% CI]: 1.12 [0.9,1.4]; P = 0.3132) or T alone (7.4 [3.8,12.8] months) (HR [95% CI]: 1.05 [0.8,1.37]; P = 0.7233). Median PFS was similar in pts receiving D+I (3.5 [1.5,6.2] months) vs. I (3 [1.4,5.7] months) or T (3.4 [1.6, 6.1] months) alone. ORR was similar in pts receiving D+I (17.1%) vs. I (18.9%) or T (20.1%) alone. CBR was similar in pts receiving D+I (67.4%) vs. I (58.9%) or T (68.1%) alone. Grade 3 or higher adverse events were experienced by 77% D+I, 69.5% I, and 86.4% T pts. **Conclusions:** Treatment with D+I was not superior to established 2LT for RR SCLC. Exploratory analyses are ongoing to evaluate GD2 expression in circulating tumor cells, select protein biomarkers, and any correlative impact on observed response. Clinical trial information: NCT03098030. Research Sponsor: United Therapeutics.

Molecular subtypes and clinical outcomes to initial systemic treatment in patients with small cell lung cancer. *First Author: Wei-Chu Victoria Lai, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Investigators have proposed that differential expression of the transcription regulators ASCL1 and NeuroD1 can be used to define molecular subtypes of small cell lung cancers (SCLCs). Here we evaluate SCLC subtypes based on ASCL1 and NeuroD1 expression in patients (pts) treated with first-line (1L) chemotherapy profiled with targeted next-generation sequencing (NGS). **Methods:** We used NGS (MSK-IMPACT) to profile tumors from pts with SCLCs. We performed IHC to assess ASCL1 (A) or NeuroD1 (N). Objective response rate (ORR) to therapy was determined using RECIST. PFS and OS were analyzed using Kaplan-Meier. **Results:** 281 pts with SCLCs were profiled with NGS (102 LS-SCLC; 179 ES-SCLC). Most frequently mutated genes were *TP53* (90%), *RB1* (68%), *KMT2D* (22%), *NOTCH1* (15%), *FAT1* (14%), *PTPRD* (12%). Mutations in *BIRC3*, *FOXL2*, *TENT5C*, *TET1*, *NRAS*, *KIT*, *TSHR*, *ESR1* were enriched in ASCL1-/NeuroD1+ (A-/N+), and mutations in *KMT2D* and *EP300* were enriched in A-/N- ($p<0.05$). Copy number alterations in *WWTR1*, *ATR*, *IKZF1*, *PALB2*, *PIK3CB* were enriched in A-/N+ ($p<0.05$). IHC for ASCL1 and NeuroD1 was performed on 78 samples: 11 A-/N-, 32 A+/N-, 4 A-/N+, 31 A+/N+. Overall survival at 1 year based on subtype was 25% in A-/N- (2/9), 60% in A-/N+ or A+/N- (13/32), and 55% in A+/N+ (10/25). For the 10 pts who survived 2 years, 5 were A+/N- and 5 were A+/N+. 146 pts treated with 1L platinum had RECIST-evaluable disease. ORR was 75% (110/146; 95% CI 68-82%). Median PFS was 7 months with CR/PR and 3.5 months with SD/PD (HR 0.32; 95% CI 0.18-0.56). Median OS was 17 months with CR/PR and 11 months with SD/PD (HR 0.55; 95% CI 0.34-0.9). Mutations in *RUNX1*, *EPHA7*, *CDKN2A*, *FLT1* and copy number alterations in *FGFR1*, *CCND1* were enriched in patients with SD/PD ($p<0.05$). PFS rate at 6 months was 25% in A-N- (1/4), 60% in A-/N+ or A+/N- (9/15), and 55% in A+/N+ (6/11). For the 7 pts who survived 2 years, 3 were A+/N- and 4 were A+/N+. **Conclusions:** Molecular subtypes defined by ASCL1 and NeuroD1 encompass molecular characteristics that may predict patient outcomes. Further investigation is needed to delineate the underlying biological differences among the various subtypes to help define therapeutic vulnerabilities of each subtype of SCLC. Completion of IHC for ASCL1, NeuroD1 and additional key transcription factors POU2F3 and YAP1 are in progress for the entire cohort. WES and RNA sequencing are occurring in parallel and will be correlated with IHC results and clinical outcomes. Research Sponsor: None.

YAP1 positive small-cell lung cancer subtype is associated with the T-cell inflamed gene expression profile and confers good prognosis and long term survival. *First Author: Taofeek Kunle Owonikoko, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: The dominant expression of transcription factors ASCL1, NeuroD1, YAP1 or POU2F3 characteristically defines four small cell lung cancer (SCLC) subtypes (SCLC-A, SCLC-N, SCLC-Y and SCLC-P). The clinical validation and biological relevance of these emerging SCLC subtypes is currently lacking. **Methods:** Using the Illumina TruSeq RNA Exome Kit, we generated RNA-Seq data from 61 cases of SCLC and pulmonary carcinoid to interrogate gene expression differences in SCLC subtypes as well as in survival outliers (top and bottom decile) matched for clinically relevant prognostic factors and treatment. We also assessed YAP1 protein expression in a blinded fashion by immunohistochemistry in 130 SCLC cases. **Results:** We successfully classified 68% of SCLC into one of the four SCLC subtypes whereas 81.5% of carcinoids did not fit into any of these categories. GSEA for differentially expressed genes between outlier subgroups showed significant upregulation of interferon gamma and interferon alpha response genes in late survivors. Moreover, a previously validated 18-gene T-cell inflamed gene expression profile was upregulated in late survivors and in the SCLC-Y subtype. Furthermore, the SCLC-Y subtype and late survivors showed higher expression of HLA gene family and reduced expression of cancer testis antigens. The median (95% CI) OS was 14 (4.3, 28.8), 16.7 (0.9, NA), 8.1 (2, 9.7) and 20.1 (0.6, 39.5) months respectively, for SCLC-A, N, P and Y subtypes. YAP-1 protein expression was positive in 17 of 130 (13%) SCLC cases. The majority of cases with positive YAP1 expression by immunohistochemistry, 12 of 17 cases (70.6%), were limited stage SCLC at the time of original diagnosis. **Conclusions:** SCLC subtypes have clinical implication as predictive and prognostic biomarker. SCLC-Y subtype is enriched for T-cell inflamed phenotype and long term survival, and may predict for clinical benefit of immunotherapy. Research Sponsor: Novartis Oncology.

9020 Poster Session (Board #213), Fri, 8:00 AM-11:00 AM

Validation of tumor DNA in bronchial lavage as a diagnostic tool in lung cancer. *First Author: Sara Witting Christensen Witting Christensen Wen, Department of Oncology, Vejle Hospital, University Hospital of Southern Denmark, and Institute of Regional Health Research, University of Southern Denmark, Vejle, Denmark*

Background: Diagnosing lung cancer requires invasive procedures with risk of complications for the patient. The HOXA9 gene is highly methylated in lung cancer, and methylated tumor DNA (meth-tDNA) in bronchial lavage has previously shown potential as a diagnostic biomarker. The aim of the present study was to validate these preliminary results. **Methods:** Patients were referred by the general practitioner on suspicion of lung cancer. The Danish diagnostic package includes chest and abdominal CT scan, bronchoscopy, blood tests, and histopathological or cytological verification. Twelve ml lavage fluid was collected at bronchoscopy for analysis of meth-tDNA based on droplet digital PCR according to our published method. A positive test was defined as ≥ 4 droplets containing meth-tDNA and a ratio between HOXA9 and Albumin of > 0.15%. The analysis was performed blinded to clinical data and meth-tDNA status was compared with the final diagnosis. **Results:** The study population was 204 consecutively enrolled patients. The material consisted of a discovery cohort (n = 105, presented at ASCO 2019) used for establishing the cut-points, and a validation cohort (n = 99). Six were excluded from analysis due to malignancy other than lung cancer and one due to failed analysis. In the discovery cohort, the sensitivity was 68.7% (95% CI 56.2-79.4%), specificity 88.2% (95% CI 72.6-96.7%), and positive predictive value (PPV) 92.0% (95% CI 80.8-97.8%). In the validation cohort, the same values were 76.9% (95% CI 63.2-87.5%), 77.3% (95% CI 62.2-88.5%), and 80.0% (95% CI 66.3-90.0%), respectively. Analyzing the entire patient material (n = 197) the sensitivity, specificity, and PPV were 72.3% (95% CI 63.3-80.1%), 82.1% (95% CI 71.7-89.8%), and 86.0% (95% CI 77.6-92.1%), respectively. The false positive samples were equally distributed among patients with cryptogenic organizing pneumonia, granulomatous inflammation, and acute inflammatory disease. The false negative samples were mainly from patients with peripheral tumor, no radiologically detectable tumor, and mesothelioma. **Conclusions:** Meth-tDNA in bronchial lavage holds potential as a supplementary tool in the diagnosis of lung cancer with a clinically relevant sensitivity and specificity. Routine clinical application awaits further validation in a clinical trial. Research Sponsor: The grant for early detection of cancer, Region of Southern Denmark, Denmark.

meth-tDNA status	Lung cancer	No lung cancer

Total: Positive	86	14
Total: Negative	33	64

9022 Poster Session (Board #215), Fri, 8:00 AM-11:00 AM

Role of adjuvant chemotherapy in patients with pathological stage I NSCLC with high-risk features. *First Author: Lubina Arjyal, Gundersen Health System, La Crosse, WI*

Background: Lobectomy is the current standard of care for patients with stage I non-small cell lung cancer (NSCLC). There is a lack of prospective data on the benefit of adjuvant chemotherapy (CT) in patients with negative margins but with high-risk features: lympho-vascular invasion (LVI) or visceral pleural invasion (VPI). We aimed to investigate the benefit of adjuvant CT in patients with pathological stage I NSCLC with high-risk features. **Methods:** The 2016 National Cancer Database was queried to identify patients with pathological stage I NSCLC (8^{th} edition AJCC staging) diagnosed from 2010-2015 who received lobectomy/pneumonectomy with clear surgical margins. Patients were stratified into high risk (tumor size ≥2 cm with LVI and/or VPI) or low risk group. Multivariate Cox proportional hazards regression and propensity score matched Kaplan-Meier survival analysis were used to compare overall survival between those who received adjuvant CT and those who did not. **Results:** 34,556 patients were identified with 1114 (3.2%) receiving adjuvant CT. On multivariate Cox regression analysis, high risk tumors (hazard ratio [95% confidence interval] = 1.31 [1.25-1.38]) and lack of adjuvant chemotherapy (1.25 [1.09-1.44]) were associated with worse overall survival (OS). Additionally, male sex, age ≥ 60 years, higher comorbidity burden, lack of insurance, low facility volume, low median income, non-squamous histology were associated with worse OS. After propensity score matching, Kaplan-Meier survival analysis of the high risk subgroup (n = 2923) showed a significant difference in overall survival (OS) between those who received adjuvant CT (n = 1032, 5 year OS, 74.7%; 95% CI, 70.9%-78.0%) and those who did not (n = 1891, 5 year OS, 66.9%; CI, 63.9%-69.6%; p = 0.0002). In patients with no high risk factors for recurrence (n = 384), OS was not significantly different between the patients who received adjuvant CT (n = 78, 5 year OS, 75.8%; CI, 61.3%-85.5%) and those who did not receive adjuvant CT (n = 306, 5 year OS, 77.1%; CI, 70.0%-82.7%; p = 0.3). **Conclusions:** Our study showed better survival with adjuvant CT in patients with pathological stage I NSCLC who have tumor size greater than 2 cm, LVI and/or VPI. Research Sponsor: None.

9023 Poster Session (Board #216), Fri, 8:00 AM-11:00 AM

Circulating tumor DNA (ctDNA) analysis predicts recurrence following surgery in patients with stage I-IIIA non-small-cell lung cancer (NSCLC): Results of GASTO1035 and GASTO1018. *First Author: Si-Yu Wang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Circulating tumor DNA can be detected in the plasma and serum of patients with solid tumors and has emerged as a noninvasive biomarker for dynamically monitoring tumor. Postsurgical ctDNA analysis of early-stage NSCLC may identify patients at high risk of recurrence and facilitate early intervention and personalized cancer therapy. **Methods:** These studies recruited 123 patients with newly diagnosed resectable stage I-IIIA NSCLC. Preoperative and postoperative plasma and postoperative tissue samples were subjected to next-generation sequencing (Nanjing Shihe Jiyin Biotechnology Inc.) using a 425 cancer-related genes panel. Peripheral blood samples were collected before surgery, postoperatively within 1 month, and every 3-6 months for up to 3 years. Plasma samples with at least 1 variants detected in tissue samples were defined as ctDNA positive. **Results:** After 4 exclusions, 119 eligible patients were enrolled from June 2016 to February 2019. Presurgical ctDNA was detectable in 31 of 117 (26.5%) patients and was associated with inferior recurrence-free survival (HR, 3.90, 95% CI, 1.44-10.58, P = 0.004). Similarly, ctDNA was detected in 13 of 116 (11.2%) of the first postsurgical samples and was associated with shorter RFS (HR, 3.54, 95% CI, 1.22-10.23, P = 0.002). During surveillance after surgery, ctDNA-positive patients (38/119, 31.9%) were more than 9 times more likely to experience disease recurrence than ctDNA-negative patients (HR, 9.17, 95% CI, 2.60-32.42, P < 0.001). Serial ctDNA detection preceded radiologic disease recurrence by a median lead time of 4.23 months (95% CI, 0.91-7.54 months). We also observed a positive correlation between the ctDNA detection rate and the disease stage. **Conclusions:** These results suggest that detection of ctDNA before and after surgery is associated with the identification of a high risk of disease recurrence of resectable NSCLC. Perioperative ctDNA analyses identify disease recurrence earlier than standard-of-care radiologic imaging, and thus could facilitate personalized cancer treatment at early time points. Clinical trial information: NCT03465241 and NCT03172156. Research Sponsor: None.

9024 Poster Session (Board #217), Fri, 8:00 AM-11:00 AM

Validation of 4-marker protein panel for the early detection of lung cancer using PLCO samples. *First Author: Johannes Fahrmann, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We have previously demonstrated that a protein panel consisting of ProSFTPB, CEA, CA125 and CYFRA21.1 may improve lung cancer risk assessment and has potential to define eligibility for computed tomography screening. Herein, we aimed to validate the classifier performance of the 4-marker protein panel using pre-diagnostic serum samples from the PLCO cohort. We additionally explored the additive value of diacetylspermine (DAS) with the 4-marker protein panel for identifying lung cancer cases. **Methods:** ProSFTPB, CEA, CA125 and CYFRA21.1 levels were measured in baseline sera of 537 lung cancer cases (76 SCLC/461 NSCLC) diagnosed within 6 years of baseline blood draw and 3772 cancer-free controls using bead-based immunoassays. DAS was measured using ultrahigh performance liquid chromatography mass spectrometry. Samples were analyzed in a double-blinded randomized fashion. **Results:** Overall classification performance (receiver operating characteristic area under the curve (ROAUC)) of the 4-marker panel for delineating lung cases diagnosed within 1 year and 1 to 2 years of baseline blood draw from cancer-free controls was 0.78 (95% CI: 0.74-0.82) and 0.73 (95% CI: 0.68-0.78), respectively. Classification performances of the 4-marker panel amongst lung cancer cases diagnosed within 1 year of baseline blood draw stratified into adenocarcinoma, squamous cell carcinoma and small cell lung cancer subtypes yielded ROAUCS of 0.78 (95% CI: 0.72-0.85), 0.76 (95% CI: 0.69-0.83) and 0.79 (95% CI: 0.68-0.90), respectively. Sub-analyses adjusting for smoking status yielded comparable ROAUC point estimates. Comparison of the 4-marker performance amongst non-NLST and NLST eligible lung cancer patients diagnosed within 1 year of baseline blood draw in comparison to matched cancer-free controls resulted in ROAUCs of 0.71 (95% CI: 0.63-0.79) and 0.74 (95% CI: 0.69-0.80), respectively. Analyses evaluating the additive classifier performance of serum DAS with that of the 4-marker protein panel revealed statistically significant improvement (McNemar Exact Test 2-sided $p < 0.05$) in sensitivity at high specificity derived from youden index for SCLC and squamous cell carcinoma cases diagnosed within 2 years from baseline blood draw, respectively, in comparison to the 4-marker protein panel alone. **Conclusions:** We have validated the performance of the 4-marker panel for early detection of lung cancer in the PLCO pre-diagnostic cohort. We further demonstrate that DAS can complement the 4-marker protein panel and identify more SCLC and squamous cell carcinoma cases. Research Sponsor: U.S. National Institutes of Health.

9025 Poster Session (Board #218), Fri, 8:00 AM-11:00 AM

Reliable detection of the presence of pulmonary carcinoma on whole-slide images by a deep learning model. *First Author: Gouji Toyokawa, Department of Thoracic Surgery, Clinical Research Institute, National Hospital Organization, Kyushu Medical Center, Fukuoka, Japan*

Background: Lung cancer is one of the leading causes of cancer-related death worldwide, and its histopathological diagnosis is crucial for deciding on optimum treatment strategies. Recently, artificial intelligence (AI) models have been widely shown to be useful in various medical fields, particularly image and pathological diagnoses; however, AI models for the pathological diagnosis of pulmonary lesions that have been validated in large-scale test sets are yet to be seen. **Methods:** We trained a convolution neural network based on the Efficient Net B3 architecture to classify carcinoma from whole slide images (WSIs) using a training dataset of 3640 images. WSI diagnoses were available. We used a transfer learning approach, in which the starting weights were obtained from a pre-trained model on ImageNet. The model was then trained on our dataset using multiple instance learning, a semi-supervised learning approach. To classify a WSI, the model was applied in a sliding window fashion with an input tile size of 512x512 and a stride of 256. The maximum probability was then used as a WSI diagnosis. **Results:** We evaluated our model on a total of 2680 WSIs originating from five independent sources (two hospitals in Japan and three public datasets from around the world). The model achieved a Receiver Operator Curve Area Under the Curves (ROC AUCs) of 0.974, 0.974, 0.996, 0.988, and 0.981, respectively. **Conclusions:** We successfully established a reliable AI model for differentiating between lung carcinoma and non-neoplasm with a high ROC AUC on five independent test sets. If used in clinical practice, our model could help reduce the burden on pathologists and be useful for diagnosing pulmonary lesions in areas in which there are shortages of pathologists. Further prospective multicenter studies are warranted in order to validate the results obtained in the current study. Research Sponsor: None.

Role of T0 status in overall survival for unresectable stage III non-small cell lung cancer. *First Author: Takefumi Komiya, Parkview Cancer Institute, Fort Wayne, IN*

Background: Occult (T0) primary non-small cell lung cancer (NSCLC) with mediastinal involvement is a known but rare clinical condition. Its prognosis has not been evaluated well in the literature. **Methods:** Using National Cancer Database (NCDB), cases diagnosed between 2004 and 2016 with unresectable clinical stage III NSCLC with N2 or N3 involvement were selected and assigned to T0 or T1-4 group according to AJCC staging version 6th or 7th. Clinical demographics including use of chemotherapy/immunotherapy in first course of treatment were collected. As validation, independent data using Surveillance, Epidemiology, and End Results Program (SEER) was analyzed accordingly. Survival analyses were conducted using Kaplan-Meier and log-rank tests. **Results:** A total of 458 and 84,263 cases met criteria for unresectable, N2/N3 stage III NSCLC with T0 and T1-4 status, respectively. T0 status was associated with younger age, recent diagnosis, adenocarcinoma histology, N3, and use of chemotherapy. Overall survival (OS) was improved in T0 over T1-4 group ($p < 0.0001$) with a five-year survival rate of 30.5% and 12.7%, respectively, with a validation with multivariate proportional hazard models. Propensity score matching analyses using all 458 patients in each group demonstrated a significant difference in OS ($p < 0.0001$). The difference was also significant in a subset of those who have undergone chemoradiation ($p < 0.0001$). Independent analysis using SEER data confirmed its superior survival of T0 over T1-4 with a five-year survival rate of 35.3% and 13.5%, respectively. **Conclusions:** Both NCDB and SEER analyses demonstrated better survival of T0 than T1-4 counterpart in the setting of unresectable stage III NSCLC, irrespective of chemotherapy status. This group may require a distinct assignment to new staging group after further investigation. Research Sponsor: None.

9027 Poster Session (Board #220), Fri, 8:00 AM-11:00 AM

Base excision repair (BER) inhibitor TRC 102 (Methoxyamine) combined with pemetrexed (PEM)-based chemo-radiation (CRT) for locally advanced non-squamous non-small cell lung cancer (NS-NSCLC): Results of a phase I trial. *First Author: Tithi Biswas, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: About 35% of all NSCLC presents with locally advanced disease and chemo-radiation results in 5-year OS of only ~31%. PEM-platinum combination is approved in stage IV NSCLC and has similar efficacy to platinum-etoposide in stage 3 NSCLC and a favorable toxicity profile (Proclaim trial). TRC102 is an oral small molecule inhibitor of BER. TRC102 potentiates the cytotoxicity of antimetabolites and alkylators and reverses chemotherapy resistance by rapidly and covalently binding to chemotherapy-induced abasic sites in DNA. TRC102 increased radio-sensitization by PEM of NSCLC cell lines and H1299 and A549 xenografts. **Methods:** Between 11/2015 and 5/2019, 15 patients were enrolled in a 3+ 3 design: 12 with stage III and 3 with oligometastatic stage IV NS-NSCLC. The primary objective was to determine dose-limiting toxicities (DLT's) and recommended Phase 2 dose (RP2D) of TRC102 in combination with PEM, cisplatin and radiotherapy. Secondary objectives were to assess toxicity, tumor response and PFS at 6 months. Based on pre-clinical data, PEM-TRC102 was given on day 1, and cisplatin/radiotherapy was initiated on day 3. This schedule was duplicated on day 21 and day 23 of the second cycle. After completion of radiotherapy, two additional cycles of PEM-cisplatin were given. Toxicities were assessed by NCI CTACAE version 4 and 5. **Results:** Median patient age was 69 years (45-79) and median follow up was 16.6 months (3.1-38.6). There were no DLTs or grade 5 toxicity. Hematologic and GI toxicities were the most common adverse events (Table) and radiation pneumonitis was not seen. The RP2D of TRC102 was 200 mg when given with cisplatin/radiotherapy and PEM. Of 15 evaluable patients, 3 had CR (20%) and 12 had PR (80%). The 2-year PFS rate was 49%. **Conclusions:** PEM-TRC102 combined with cisplatin/radiotherapy in non-squamous NSCLC was safe and well tolerated, and did not cause safety signals beyond those expected from CRT. Preliminary response data and PFS in this cohort was encouraging. A phase 2 trial, integrating post-CRT immunotherapy with this aggressive DNA-damaging regimen is warranted. Clinical trial information: NCT02535325. Research Sponsor: Lucille and Robert Gries Endowed Fund, the Vincent K. Smith Fund, and Early Phase Clinical Research Support (EPCRS) P30 Funding at the Case Comprehensive Cancer Center.

Detection of early-stage lung cancer by exhaled volatile organic compounds using a high-pressure photon ionization time-of-flight mass spectrometry. *First Author: Mantang Qiu, Peking University People's Hospital, Beijing, China*

Background: Exhaled breath-based test is an attractive option for cancer detection due to its non-invasive nature. Exhaled volatile organic compounds (VOCs) are produced in various biochemical processes and might be sensitive tumor biomarkers. Here, we reported an exploratory study to investigate the performance of exhaled VOCs for detection of early-stage lung cancer using a high-resolution high-pressure photon ionization time-of-flight mass spectrometry (HPPI-TOFMS). **Methods:** Treatment-naïve patients with pulmonary nodules who received surgery at our department and without history of cancer were enrolled. Exhaled breath samples were collected before surgery and stored in Tedla bags. A CO_2 sensor was applicated during sample collection to ensure only "alveolar air" was collected. Exhaled samples were directly detected by HPPI-TOFMS, which has a resolution > 3000. Deep learning algorithm was used to build detection model based on HPPI-TOFMS data. **Results:** A total of 171 patients were included in this study, including 139 patients with lung cancer (114 of TNM stage I, 14 of stage II, 9 of stage III, and 2 of stage IV) and 32 patients with benign nodules. Mass spectrum peaks with $m/z <$ 500 detected by HPPI-TOFMS were retained and 32500 features were extracted from each exhaled breath samples. Based these extracted features, participants who were pathologically diagnosed as lung cancer could be discriminated from those with benign diseases with an accuracy of 96.19%, sensitivity of 96.43%, and specificity of 84.38%. Discrimination of lung cancer patients with lymph node metastasis (n = 12) from those without lymph node metastasis (n = 127) had an accuracy of 83.23%. **Conclusions:** Exhaled VOCs as detected by a high-resolution HPPI-TOFMS might be sensitive biomarkers for detection of early-stage lung cancer. 9031 Poster Session (Board #224), Fri, 8:00 AM-11:00 AM

CT and PET radiomic features associated with major pathologic response to neoadjuvant immunotherapy in early-stage non-small cell lung cancer (NSCLC). *First Author: Erica C. Nakajima, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: An early biomarker of response to immunotherapy (IO) is needed urgently to identify the patients (pts) who will derive benefit. We reported the first clinical trial of neoadjuvant IO (nIO) in resectable non-small cell lung cancer (NSCLC) (NCT02259621). In this study, we investigated whether there was an association between MPR and radiomic features (RF) in [^{18}F]-fluorodeoxyglucose ([^{18}F]-FDG) PET and standard CT images obtained at baseline and after nIO in early stage NSCLC tumors. **Methods:** Prior to receiving neoadjuvant nivolumab or nivolumab/ipilimumab, patients with Stage I-IIIA NSCLC underwent two [^{18}F]-FDG PET-CTs and/or plain CTs: a baseline scan at enrollment (PRE), and after nIO (POST). After neoadjuvant treatment, tumors were resected and evaluated for MPR. Volumes of interest (VOIs) were drawn around primary tumors on the scans. Using our novel radiomic software, Imager-4D, VOIs were evaluated for 20 RFs assessing [^{18}F]-FDG standard uptake value (SUV) or Hounsfield unit (HU) heterogeneity and spatial distribution in PET and CT images respectively. The baseline, post-treatment, and percent change in RFs before and after nIO were compared between tumors with and without MPR. Wilcoxon test was used for the comparisons. **Results:** The PRE and POST scans of 24 pts were analyzed. All pts had PRE and POST CTs performed, and 17 pts had PRE and POST [^{18}F]-FDG PET-CT scans. 7 of 24 (29%) had MPR. In the CT scan analysis, HU-based RFs of voxel count, total volume, energy, entropy, homogeneity, contrast, and dissimilarity in POST CT scans each significantly association with MPR. In the PET scan analysis, SUV mean and voxel count RFs in the POST scans, and the percent change in the cluster shade RF between PRE and POST scans were significantly associated with MPR. **Conclusions:** Collectively, we identified a significant increase in heterogeneity in the POST CT images of NSCLC tumors that had MPR. This association may reflect increased T cell infiltration or tumor necrosis. In contrast, most [^{18}F]-FDG-based RFs did not distinguish MPR vs non-MPR tumors, although the sample size was limited. We will further investigate these HU-based RFs as non-invasive markers of response to IO in conjunction with pathologic markers of IO response and in a larger patient cohort. 9032 Poster Session (Board #225), Fri, 8:00 AM-11:00 AM

The association between immune-related adverse events and efficacy outcomes with consolidation pembrolizumab after chemoradiation in patients with stage III NSCLC: an analysis from HCRN LUN 14-179. *First Author: Nikhil Shukla, Indiana University, Indianapolis, IN*

Background: Consolidation checkpoint inhibitor therapy (CPI) for up to 1 year following chemoradiation (CRT) is a current standard of care for pts with inoperable stage III NSCLC. However, some pts are not able to complete 1 year of CPI due to immune-related adverse events (irAES). In multiple retrospective studies, pts with stage IV NSCLC treated with CPI who experience irAEs generally receive fewer cycles of CPI without a significant detrimental effect on efficacy. The association between irAEs and outcomes with consolidation CPI after CRT has never been reported. Here we report the association between irAEs and efficacy outcomes from the HCRN LUN 14-179, a single-arm phase II trial of consolidation pembrolizumab following concurrent CRT in pts with unresectable stage III NSCLC. **Methods:** After completion of CRT eligible pts with stage III NSCLC without PD received pembrolizumab 200 mg IV q 3 wks for up to 1 yr. Demographics, disease characteristics, and number of cycles of pembrolizumab received were reported in pts who had any grade irAEs (except pneumonitis which included grade >2 only) [Group A] and those without irAEs (except grade 1 pneumonitis) [Group B]. Chi-square test (or Fisher's Exact test) were used for comparisons for categorical variables and Wilcoxon test for continuous variables. The Kaplan-Meier method was used to analyze time to metastatic disease (TMDD), PFS, and OS. A log-rank test was used to compare groups. **Results:** 92 eligible pts for efficacy analysis were enrolled from March 2015 to November 2016. 4 yr OS estimate for all pts is 46.2%. Any grade irAEs (except grade I pneumonitis) (n = 37 pts) included pneumonitis (18.5%), colitis (3.3%), increased creatinine (5.4%), elevated transaminases (3.3%), hyperthyroidism (7.6%), hypothyroidism (13.0%). Grade ≥ 2 irAEs (n = 32 pts) included pneumonitis (18.5%), hypothyroidism (10.8%), and colitis (3.3%). Group A/B: male (21/38), female (16/17), current or former smoker (35/52), stage IIIA (20/35), stage IIIB (17/20), non-squamous (21/30), squamous (16/25). Median number of pembrolizumab cycles received in Group A/B pts were 9 vs 15 (p = 0.0942) respectively. 4 yr efficacy endpoints in Groups A/B were TMDD 35.3% vs 41.3% (p = 0.83), PFS 27.8% vs 28.7% (p = 0.97), OS 43.5% vs 47.9% (p = 0.99), respectively. **Conclusions:** Despite receiving fewer cycles of consolidation pembrolizumab, pts who experienced any grade irAEs (excluding grade 1 pneumonitis) did not have significantly reduced efficacy outcomes. Clinical trial information: NCT02343952. Research Sponsor: Merck Sharp & Dohme Corp.

9033 Poster Session (Board #226), Fri, 8:00 AM-11:00 AM

Outcomes of patients with stage III non-small cell lung cancer (NSCLC) that harbor a *STK11* mutation. *First Author: Josiah An, University of Iowa Hospitals and Clinics, Iowa City, IA*

Background: *STK11* mutation ($STK11^m$) in patients with stage IV NSCLC is associated with inferior survival and poor response to immune check point inhibitors (ICI). The significance of $STK11^m$ in patients (pts) with stage III NSCLC treated with concurrent chemoradiation (CCRT) with and without consolidation ICI is unknown. **Methods:** Patient demographics, disease characteristics, treatment received and outcomes in pts with stage III NSCLC that harbor $STK11^m$ were retrospectively reviewed from 4 cancer centers. A cohort of pts with stage III NSCLC and wild type *STK11 (*$STK11^w$*)* from the University of Iowa served as a comparison group. SPSS version 25 was used for data analysis. **Results:** 75 pts with stage III NSCLC who had gene sequencing were included. 16/75 (21%) had $STK11^m$. The clinical characteristics for the 16 $STK11^m$ and 59 $STK11^w$ pts showed ($STK11^m$ vs. $STK11^w$): mean age: 58 vs. 64 yrs, non-squamous histology: 11/16 (69%) vs. 37/59 (63%), *KRAS* co-mutation: 6/16 (38%) vs. 11/59 (19%), *TP53* co-mutation: 9/16 (56%) vs. 15/59 (25%), PD-L1 ≥ 50%: 2/16 (13%) vs. 10/59 (17%), received CCRT 11/16 (69%) vs. 59/59 (100%) and consolidation ICI 6/16 (38%) vs. 17/59 (29%). Regarding the 6 $STK11^m$ pts who received ICI (4 pembrolizumab, 2 durvalumab), the median number of ICI infusions was 8 (range, 3-17) vs. 7 (range, 1-25) in the 17 pts with $STK11^w$ who received ICI (durvalumab). Progression free survival (PFS) for the $STK11^m$ vs. $STK11^w$ pts who received CCRT but not ICI was (4.2 vs. 34.3 months, respectively. P = 0.168), for the $STK11^m$ vs. $STK11^w$ pts who received CCRT and ICI was (11.3 vs. 17.5 months, respectively. P = 0.174), and for the $STK11^m$ vs. $STK11^w$ pts who received CCRT regardless of receiving ICI (11.3 vs. 32.9 months, respectively. P = 0.021). The median overall survival for $STK11^m$ pts (16 pts) was 25.5 months (95% CI, 13.7 to 37.2) while not yet reached for the $STK11^w$ group. **Conclusions:** In stage III NSCLC, $STK11^m$ was associated with inferior clinical outcomes. Larger studies are needed to identify the prognostic implications of $STK11^m$ in stage III NSCLC and whether ICI impacts survival for this subgroup. Research Sponsor: None.

9034 Poster Session (Board #227), Fri, 8:00 AM-11:00 AM

Evaluation of the incidence of pneumonitis in United States veterans with non-small cell lung cancer receiving durvalumab following chemoradiation. *First Author: Theodore Seth Thomas, Washington University, St Louis, MO*

Background: Locally advanced, unresectable non-small cell lung cancer is commonly treated with concurrent chemoradiation therapy (CRT). Durvalumab is a PD-L1 immune checkpoint inhibitor (ICI) administered following completion of CRT. Pneumonitis is a known toxicity of ICI therapy. In the landmark PACIFIC study the incidence of pneumonitis in patients receiving durvalumab was 33.9% (any grade) and 3.4% (grade 3/4) compared to placebo 24.8% and 2.6% (*Antonia et al, NEJM 2017)*. The incidence of pneumonitis is thought to be higher in real-world populations. This study evaluated the incidence of pneumonitis in a cohort of U.S. Veterans. **Methods:** Durvalumab recipients were identified using VA Informatics and Computing Infrastructure databases. Using pharmacy records we confirmed durvalumab and corticosteroid prescriptions. Clinical information was obtained via the electronic medical record. The primary outcome was the development of pneumonitis. We defined asymptomatic pneumonitis as the presence of new radiographic findings consistent with pneumonitis without documented clinical symptoms. We recorded pneumonitis grade as reflected in clinical documentation. If not specifically graded, we used Common Terminology Criteria for Adverse Events (CTCAE v4.0) to assess severity. Logistic regression analysis evaluated associations between pneumonitis and age, comorbidities, radiation dose and stage. Cox proportional hazards analysis evaluated associations between pneumonitis and risk of death. **Results:** A total of 123 veterans received durvalumab through 3/31/2019 (with follow up through 11/15/2019). Asymptomatic radiographic infiltrates occurred in 49 (39.8%) patients. There were 26 cases of clinically important pneumonitis Grade 2: 9(7.3%), Grade 3: 14 (11.4%), Grade 4: 2(1.6%), and grade 5: 1 (.08%). Acute hypersensitivity reactions occurred in five (4.1%) patients. Reported reasons for discontinuation of durvalumab included: disease progression [38 (31%)], toxicity [30 (24.3%)], and patient death [1 (1.6%)]. There was no association between age, time from radiation end to durvalumab initiation, radiation dose, smoking history, chemotherapy used or disease stage on development of pneumonitis. Cox analysis did not demonstrate an association between pneumonitis and risk of death. **Conclusions:** Clinically significant pneumonitis was more frequent in this cohort than reported in prior clinic trial populations. Further studies to identify pneumonitis risk factors are needed. Research Sponsor: None.

9035 Poster Session (Board #228), Fri, 8:00 AM-11:00 AM

I-SABR phase II randomized study of nivolumab immunotherapy and stereotactic ablative radiotherapy in early stage NSCLC: Interim analysis adverse effects. *First Author: Joe Y. Chang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Stereotactic Ablative Radiotherapy (SABR) provides > 95% local control and has become standard care of medically inoperable stage I NSCLC. However, cumulatively about 40% of patients develop recurrence in the regional lymph nodes, distant organs, or secondary lung cancer. Combined immunotherapy and SABR (I-SABR) may reduce these recurrences by stimulating stronger cancer specific immune response. **Methods:** This is an ongoing phase II randomized study (SABR vs. I-SABR) to evaluate the efficacy and toxicity of I-SABR in medically inoperable, early stage (T1-T3: < 7 cm, including multi-primary tumors), isolated recurrence NSCLC without lymph node or distant metastasis. The primary objective is event-free survival (any recurrence and/or death). Secondary objectives include rates of ≥Grade 2 toxicity. 4-D CT image guided SABR (50 Gy in 4 fractions or 70 Gy in 10 fractions) was delivered to all patients. Patients randomized to I-SABR received additional concurrent Nivolumab (240 mg, every two weeks for total of 7 doses or 480 mg every four weeks for total of 4 doses). 140 patients are anticipated to enroll. We report here interim analysis of toxicity. **Results:** 92 patients (median age: 72, range: 57 to 90) were enrolled and randomized (47 to SABR; 45 to I-SABR). With median follow up of 14.5 months (range 2 to 28 months), there were no treatment-related grade 4/5 adverse events. For the I-SABR arm, there was one case of possible related grade 3 dyspnea, skin rash and 2 cases of probable grade 3 fatigue. There were possible/probable treatment related 2 cases of grade 2 pneumonitis, fatigue, pruritus and 1 case of grade 2 hyperthyroidism and arthralgia. No patients discontinued treatment due to adverse effects. For the SABR arm, there were possible treatment related 1 case of grade 2 fatigue and pneumonitis. All symptoms resolved with or without treatment. **Conclusions:** Combined Nivolumab immunotherapy and SABR (I-SABR) appear to be well-tolerated in this fragile patient population with no grade 4/5 toxicity. All toxicities were tolerable and resolved. The major barrier for patient enrollment and/or randomization is patient's perception of potential toxicities and additional clinic visits. Continued enrollment and additional follow up are needed to validate these findings. Clinical trial information: NCT03110978. Research Sponsor: BMS.

9036 Poster Session (Board #229), Fri, 8:00 AM-11:00 AM

Efficacy of DNA versus RNA NGS-based Methods in MET Exon 14 skipping mutation detection. *First Author: Magdalena Jurkiewicz, Columbia University Medical Center, New York, NY*

Background: Exon 14 skipping mutations in the mesenchymal-epithelial transition (*MET*) gene are reported in 2-5% of lung adenocarcinomas and are mutually exclusive of other driver mutations. Small-molecule *MET* tyrosine kinase inhibitors, capmatinib and tepotinib, showed durable responses in previously treated and treatment-naïve patients harboring *MET*-exon-14 skipping mutations. Studies suggest that for detection of *MET*-ex14 mutations, DNA-based assays alone may be sub-optimal when compared to RNA-based NGS assays. We compared the performance of DNA and RNA-based assays for detection of MET-ex14 variants. **Methods:** We examined NGS-based profiling data of lung adenocarcinomas (or when this diagnosis could not be excluded) to identify MET-ex14 mutations missed by DNA but identified by RNA analysis. The carcinomas were profiled by a DNA-based NGS panel that targets MET exons 2, 14, 16, 18 and 19. Cases without driver mutations were reflexed to an NGS-based RNA fusion panel (Archer's Anchored Multiplex PCR). **Results:** Over a 21-month period, MET-ex14 skipping events were detected in 16/644 (2.5%) lung carcinomas by DNA profiling. RNA analysis on driver-negative cases identified 9 additional MET-ex14 mutations. All 16 MET-ex14 DNA variants occurred at or around the intron 14 splice donor site, as the assay did not include the intron 13 splice acceptor site. Clinical characteristics of the *MET* positive cohort include a male to female ratio of 0.8:1.0, an average age of 76.5 years and 52% non-smoker status. All tumors were adenocarcinomas (including one with a $<$ 10% spindle/pleomorphic component) with the exception of 3 adenosquamous carcinomas and 1 squamous cell carcinoma. **Conclusions:** DNA based NGS-panels can potentially miss MET-ex14 skipping events in lung carcinomas, when the primers do not target both 3′ splice site of intron 13, and the 5′ splice site of intron 14. A reflex work flow interrogating RNA fusions can potentially capture such events. The clinical and molecular characterization of the variants detected only by RNA NGS assays warrants further exploration. Research Sponsor: None.

9037 Poster Session (Board #230), Fri, 8:00 AM-11:00 AM

Artificial intelligence based on deep learning for differential diagnosis between benign and malignant pulmonary nodules: A real-world, multicenter, diagnostic study. *First Author: Tao Xu, Department of Respiratory and Critical Care Medicine, the Affiliated Hospital of Qingdao University, Qingdao, China*

Background: Lung cancer is the most common cancer worldwide. Artificial intelligence (AI) platform using deep learning algorithms have made a remarkable progress in improving diagnostic accuracy of lung cancer. But AI diagnostic performance in identifying benign and malignant pulmonary nodules still needs improvement. We aimed to validate a Pulmonary Nodules Artificial Intelligence Diagnostic System (PNAIDS) by analyzing computed tomography (CT) imaging data. **Methods:** This real-world, multicentre, diagnostic study was done in five different tier hospitals in China. The CT images of patients, who were aged over 18 years and never had previous anti-cancer treatments, were retrieved from participating hospitals. 534 eligible patients with 5-30mm diameter pulmonary nodules identified by CT were planning to confirm with histopathological diagnosis. The performance of PNAIDS was also compared with respiratory specialists and radiologists with expert or competent degrees of expertise as well as Mayo Clinic's model by area under the curve (AUC) and evaluated differences by calculating the 95% CIs using the Z-test method. 11 selected participants were tested circulating genetically abnormal cells (CACs) before surgery with doctors suggested. **Results:** 611 lung CT images from 534 individuals were used to test PNAIDS. The diagnostic accuracy, valued by AUC, in identifying benign and malignant pulmonary nodules was 0.765 (95%CI [0.729 - 0.798]). The diagnostic sensitivity of PNAIDS is 0.630(0.579 – 0.679), specificity is 0.753 (0.693 – 0.807). PNAIDS achieved diagnostic accuracy similar to that of the expert respiratory specialists (AUC difference: 0.0036 [-0.0426 - 0.0497]; p = 0.8801) and superior when compared with Mayo Clinic's model (0.120 [0.0649 - 0.176], p $<$ 0·0001), expert radiologists (0.0620 [0.0124 - 0.112], p = 0.0142) and competent radiologists (0.0751 [0.0248 - 0.125], p = 0.0034). 11 selected participants were suggested negative in AI results but positive in respiratory specialists' result. 8 of them were malignant in histopathological diagnosis with tested more than 3 CACs in their blood. **Conclusions:** PNAIDS achieved high diagnostic accuracy in differential diagnoses between benign and malignant pulmonary nodules, with diagnostic accuracy similar to that of expert respiratory specialists and was superior to that of Mayo Clinic's model and radiologists. CACs may be able to assist CT-based AI in improving their effectiveness but it still need more data to be proved. Clinical trial information: ChiCTR1900026233. Research Sponsor: None.

9038 Poster Session (Board #231), Fri, 8:00 AM-11:00 AM

Clinical impact of targetable gene alterations on therapeutic outcomes in stage II/III locally advanced non-small cell lung cancer patients. *First Author: Yoshitaka Zenke, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The clinical significance of genetic alterations in stage II/III non-small cell lung cancer (NSCLC) patients has not yet been clarified. We have prospectively analyzed NSCLC patients for cancer-related gene alterations and have followed up clinical course of the patients, establishing a large-scale clinico-genomic database in our nationwide genome screening project (LC-SCRUM-Japan). **Methods:** Submitted tumor samples were subjected to a targeted next-generation sequencing (NGS) system, Oncomine™ Comprehensive Assay. Therapeutic and prognostic data were collected and updated every year. **Results:** Since March 2015 to May 2019, 5166 non-squamous NSCLC patients from 263 institutions had been enrolled in the LC-SCRUM-Japan, and 754 of them were diagnosed as stage II/III. The median age of the 754 patients was 67 years (range, 21-92), and 503 (67%) were male, 595 (79%) smokers and 631 (84%) stage III. Of 640 available samples, 258 (40%) had targetable gene alterations, comprising 106 KRAS mut, 42 EGFR mut, 29 BRAF mut, 20 MET ex14skip/amp, 16 ALK fus, 12 ROS1 fus, 11 ERBB2 ex20ins, 8 RET fus, 7 EGFR ex20ins, 5 AKT1 mut, 1 NRG1 fus, 1 FGFR2/3 fus. In patients who received surgery (n = 159), 3-year disease-free survival rate was worse in patients with targetable gene alterations than in those without (40% vs 58% months; p = 0.03). In patients who received cytotoxic chemo-radiotherapy (n = 148), the response rate was similar in patients with targetable gene alterations and those without (70% vs. 77%); however, 3-year progression-free survival rate tended to be shorter in patients with targetable gene alterations than in those without (19% vs 35%; p = 0.08). **Conclusions:** In stage II/III NSCLC, the total frequency of targetable gene alterations was similar to that previously evaluated in our stage IV cohort (45%), and the current standard therapies showed early progression in the targetable gene-altered patients. A novel effective multimodality treatment in combination with targeted therapies is needed for this population. Research Sponsor: Japan Agency for Medical Research and Development.

9039 Poster Session (Board #232), Fri, 8:00 AM-11:00 AM

Real-world survey of pneumonitis/radiation pneumonitis among patients with locally advanced non-small cell lung cancer treated with chemoradiotherapy after durvalumab approval: A multicenter retrospective cohort study (HOPE-005/CRIMSON). *First Author: Go Saito, Department of Respirology, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background: Durvalumab was approved as a consolidation therapy after chemoradiotherapy (CRT) for locally advanced non-small cell lung cancer (NSCLC) and established as the standard of care. However, since the approval of durvalumab, little has been reported on the frequency, severity, or clinical course of pneumonitis/radiation pneumonitis throughout the course of CRT. **Methods:** We conducted a 17-center, retrospective cohort study of consecutive patients with locally advanced NSCLC who received concurrent chemoradiotherapy (CCRT) with platinum-based chemotherapy between May 2018 and May 2019. **Results:** A total of 275 patients were included; their median age was 69.9 (range, 40.3-87.5), mean V_{20} was 19.4% (range, 1.4-37.9), and mean "mean lung dose" was 10.9 Gy (range, 1.5-31.3). Of these, 204 patients received durvalumab consolidation therapy (74.2%). Median follow-up time from the initiation of CCRT was 8.4 months (range, 1.5-15.7). During follow-up, 225 patients (81.8%) developed any-grade pneumonitis/radiation pneumonitis. Of these, more than half (134 of 225) were asymptomatic (grade 1), 18 (6.5%) were ≥grade 3, and 4 patients (1.5%) had fatal pneumonitis/radiation pneumonitis. By the time of initial assessment of response to CCRT, 64 (23.3%) patients had developed radiation pneumonitis. Logistic regression revealed that only V_{20} ≥25 % was an independent risk factor of symptomatic (≥grade 2) pneumonitis/radiation pneumonitis (OR: 2.74, 95% CI: 1.35-5.53, p = 0.0045). Of the 275 patients, 67 were treated with corticosteroids for pneumonitis/radiation pneumonitis (24.7%), and 14 (5.1%) needed home oxygen therapy after the treatment of pneumonitis/radiation pneumonitis. Among patients treated with corticosteroids, 21 patients received durvalumab rechallenge. Of the 21 patients, 6 (29%) showed pneumonitis/radiation pneumonitis relapse, of which 3 (14%) resulted in suspension of durvalumab rechallenge, but none were fatal. **Conclusions:** Although over four-fifths of the patients treated with CCRT after the approval of durvalumab developed pneumonitis/radiation pneumonitis, more than half of them were asymptomatic, and ≥grade 3 events accounted for 6.5%. Sometimes patients needed corticosteroid therapy, which was in many occasions effective, and some also underwent durvalumab rechallenge. V_{20} was an independent risk factor of symptomatic pneumonitis/radiation pneumonitis. Research Sponsor: None.

9040 Poster Session (Board #233), Fri, 8:00 AM-11:00 AM

Prognostic role of mid-treatment PET/CT and plasma cytokines in patients undergoing chemoradiation for locally advanced non-small cell lung cancer (LA-NSCLC). *First Author: Jing Zeng, University of Washington, Seattle, WA*

Background: Patients with unresectable LA-NSCLC are treated with concurrent chemoradiation (CRT) and consolidation immunotherapy with survival that range from months to years or even decades. Early predictive biomarkers have potential to identify patients who are unlikely to benefit from continuing standard of care therapy and require a change in management. We investigated biomarkers that are widely available (PET/CT scan and plasma cytokine levels) to develop early predictors (mid-CRT) of survival in a phase II clinical trial of chemoradiation for LA-NSCLC. **Methods:** 37 Patients with AJCC v7 stage IIB-IIIB NSCLC were prospectively enrolled on the FLARE-RT trial (NCT02773238) from 2016-9. All patients underwent chemoradiation; 18 also received adjuvant durvalumab. PET/CT exams were performed at week 3 of CRT and response status was pre-defined by published metrics. 21 patients consented to peripheral blood collection at baseline and week 3, and plasma levels of 43 common inflammatory cytokines were measured. Bootstrapping over 100 iterations of the least absolute shrinkage and selection operator (LASSO) was performed to reduce feature dimensionality and guard against false discoveries. Cox regression of selected cytokine levels and PET response status, as well as time-dependent receiver-operating characteristic (ROC) analysis, were evaluated for associations to overall survival (OS). **Results:** Median follow-up was 18 months with 1-year OS 81% and PFS 52%. Mid-CRT PET response (as determined by pre-defined metrics) was strongly associated with OS (HR 5.6 [1.4-22.0], p = 0.015) after adjusting for radiation target volume, with 1-yr OS 94% for responders vs. 68% for non-responders (p = 0.017). Plasma TNFα level was also prognostic for OS (HR 1.9 [1.1-3.5], p = 0.030). TNFα retained significance for OS (HR 2.3 [1.2-4.6], p = 0.016) after adjusting for PET response. Bivariate mid-CRT PET response and TNFα generated a parsimonious model to predict OS (AUC = 0.85, 18-month horizon). **Conclusions:** Risk stratification for long-term survival after chemoradiation in patients with LA-NSCLC may be achievable based on mid-chemoradiation assessment of widely available biomarkers (PET imaging and plasma TNFα level). Combined functional imaging and peripheral blood biomarkers will be validated in a larger sample of our trial cohort, along with other independent patient populations. Clinical trial information: NCT02773238. Research Sponsor: U.S. National Institutes of Health.

9041 Poster Session (Board #234), Fri, 8:00 AM-11:00 AM

Peripheral blood T-cell receptor immune repertoire characterization of resectable stage IIIA non-small cell lung cancer patients receiving neoadjuvant chemo-immunotherapy treatment from NADIM study. *First Author: Alberto Cruz Bermudez, Instituto Investigacion Sanitaria Puerta de Hierro-Segovia de Arana, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain*

Background: Characterization of the peripheral blood T-cell receptor (TCR) repertoire has become a novel approach to predict the clinical benefit to anti-PD1/PDL1 therapy. However, there is lack of knowledge about the clinical relevance of TCR repertoire in terms of pathological response and clinical outcomes (PFS and OS) in chemo-immunotherapy. To answer this question we have analysed samples from the NADIM study (NCT03081689), in which resectable stage IIIA NSCLC patients were treated with neoadjuvant chemo-immunotherapy with Nivolumab. **Methods:** Using ION Torrent-based next-generation sequencing we have analysed TCR repertoire of peripheral blood from 30 patients receiving chemo-immunotherapy. Using 25ng of total RNA from PBMCs, clonal convergence, evenness and diversity were calculated at diagnosis (pre-treatment) and after 3 cycles of Nivolumab plus carboplatin (post-treatment). Regarding pathological responses, patients were classified in 3 groups: complete response (pCR) (0% viable tumour at the resection specimen), mayor response (pMR) ($<$ 10% viable tumour) and incomplete response (pIR) ($>$ 10% of viable tumour). At data analysis, PFS and OS median follow-up times were longer than 20 months. **Results:** No statistically significant differences in TCR repertoire in terms of evenness (p = 0,373), diversity (p = 0,691) or convergence (p = 0,054) between pre- and post-neoadjuvant treatment were observed. Similarly, no significant differences were observed in these metrics between pathological response groups. However, a detailed analysis of the clones showed that the percentage of frequent clones (greater than 0.1%) that increase after neoadjuvant therapy does show differences between the different pathological response groups (pIR vs pMR), being elevated in patients who presented responses greater than 90% (p = 0.0385). Regarding the clinical benefit, having this parameter higher than the median (43,90% in this cohort) is associated with a higher PFS (p = 0.0490) and OS (p = 0.078) using KM Log-rank test. **Conclusions:** Evenness, Diversity and Convergence derived from immune repertoire analysis do not appear to be clinically useful in the context of neoadjuvant chemo-immunotherapy in lung cancer. However, the detailed analysis of the clones seems promising. The increase of the most frequent clones after treatment seems to be associated to different clinical variables such as pathological response and PFS in these patients. Clinical trial information: NCT03081689. Research Sponsor: BRISTOL MYERS SQUIBB.

9042 Poster Session (Board #235), Fri, 8:00 AM-11:00 AM

Clinical characteristics, genomic features, and recurrence risk of early-stage MET exon 14 mutant non-small cell lung cancer (NSCLC). *First Author: Gonzalo Recondo, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: *MET* exon 14 alterations occur in ~3% of patients (pts) with NSCLC. Although clinical and genomic features of *MET* exon 14 mutant (mut) NSCLC are better characterized in the metastatic setting, less is known about early-stage disease for this molecular subtype. **Methods:** Clinicopathologic and genomic data were collected from patients (pts) with resected stage I-III *MET* exon 14 mutant NSCLC at the Dana-Farber Cancer Institute (DFCI) and the Memorial Sloan Kettering Cancer Center (MSKCC). We estimated the disease-free survival (DFS) and overall survival (OS) of patients from the date of surgical resection. The prevalence of *MET* exon 14 mutations in stage I-III NSCLC was assessed using OncoPanel NGS v3.0 at DFCI. **Results:** The prevalence of *MET* exon 14 alterations in resected tumors of pts with stage I-III NSCLC at DFCI using Oncopanel v3 was 2.8% (17/613) overall: 2.9% (16/542) in non-squamous and 1.4% (1/71) in squamous histology. We identified 131 pts with resected stage I-III (I = 73, II = 28, III = 30) *MET* exon 14 mut NSCLC at DFCI (Oncopanel v1-v3) and MSKCC (MSK-IMPACT), with a median age of 71 years (yrs) (range: 43-88). There were no significant differences in sex, smoking status, or type of *MET* alteration across stages. In stage I resected tumors there was a higher proportion of adenocarcinoma histology compared to stages II and III (p = 0.009). The median harmonized TMB (mTMB) was similar across stages (p = 0.43). Common genomic co-alterations included *MET* amplification (amp) (5.3%), *CDK4/6* amp (19.1%), *MDM2* amp (35.1%), *TP53* mut (17.6%) and *CDKN2A/B* loss (9.2%). The median DFS in stage I, II, and III NSCLC was 8.3 yrs (95% CI: 3.1-8.3), 2.6 yrs (95% CI: 1.0-2.6), and 2.1 yrs (95% CI: 0.7-2.7), respectively (p = 0.017). The median OS in stage I, II, and III NSCLC was 9.2 yrs (95% CI: 8.5 -10.5), not reached (NR) (95% CI: NR-NR), and 4.1 yrs (95% CI: 3.6-4.1), respectively (p = 0.052). Concurrent *MET* amp was independently associated with worse DFS (HR: 4.9, 95% CI: 1.8-13.1; p = 0.002) in multivariate analysis. **Conclusions:** *MET* exon 14 mutations are present in 2.8% of resected stage I-III NSCLCs. Given the prevalence of this molecular alteration in early-stage NSCLC, clinical trials exploring the role of adjuvant and neoadjuvant MET targeted therapies in this population may be warranted. 9043 Poster Session (Board #236), Fri, 8:00 AM-11:00 AM

Contemporary management and associated outcomes of 3,151 patients with stage III non-small cell lung cancer (NSCLC) in a real-world setting: Results of KINDLE, a multicountry observational study. *First Author: Abdul Rahman Jazieh, Oncology Department, King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia*

Background: Stage III NSCLC is a heterogeneous disease requiring a multimodality approach. We conducted a global study to characterise the patients (pts), treatment patterns and their associated outcomes for this disease in a real-world setting in the pre-IO era. **Methods:** KINDLE is a retrospective, multicountry, multi-centre study capturing data on patient and disease characteristics, treatments and outcomes. The study included pts with stage III NSCLC diagnosed between January 1st, 2013 and December 31st, 2017 and with at least 9 months of documented follow-up. Descriptive statistics were used to describe patient demographics, disease characteristics and treatment modalities. Inferential statistics was used to correlate various clinical and treatment variables with progression free survival (PFS) and overall survival (OS). **Results:** 3151 patients were enrolled at 125 centres in three geographical regions; 1046 pts in Middle East and North Africa, 1874 pts in Asia and 231 pts in Latin America. Median age was 63 years (range 21-92); 76.5% were male; 69.2% with a smoking history; 55.9% were staged as IIIA (AJCC 7th ed.); 53.7% had adenocarcinoma and 36.6% squamous cell, and 31.7% were known to have an EGFR mutation. 21.4% of patients underwent curative surgical resection. First line therapy included more than 25 different regimens, the most common being concurrent chemo-radiotherapy (cCRT) in 29.4%, chemotherapy (CT) alone in 17%, sequential chemo-radiotherapy (sCRT) in 10.4%, and radiotherapy (RT) alone in 8.5%. Median PFS for the whole cohort was 12.5 mos (95% CI; 12.06 – 13.14) and median OS 34.9 mos (95% CI; 32.00 – 38.01). Stage IIIA patients who were eligible for and underwent surgery + CT, had longer OS than patients who did not undergo surgery, receiving other treatments. Non-surgical approaches included CT, RT, and CRT. In stage IIIB, OS was significantly improved for cCRT vs. CT alone (p = 0.0015) or RT alone (p = $<$ 0.0001) or sCRT (p = 0.0216). Improved survival was observed with sCRT compared with RT alone and chemotherapy vs RT alone. **Conclusions:** KINDLE, a large multicountry observational study, reveals the diversity of treatment practices that exist in stage III NSCLC and provides insights on the outcomes in a real-world setting. The unmet medical need remains high and approaches are required to optimize patient outcomes including implementation of guidelines, physician education and improved access to innovative medicines and quality care. Research Sponsor: AstraZeneca.

9044 Poster Session (Board #237), Fri, 8:00 AM-11:00 AM

A retrospective evaluation of PD-L1 expression on primary non-small cell lung cancer (NSCLC) samples and associated involved hilar or mediastinal lymph nodes (N1 or N2) (REPLICA). *First Author: Eleni Karapanagiotou, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: Little is known about the PD-L1 expression in early stage NSCLC as well as the possible heterogeneity of PD-L1 expression in different sites. This study provides information on both PD-L1 expression in stage II and III NSCLC and the relationship between PD-L1 expression in the primary site (lung) and metastatic lymph nodes (LNs) N1 and/or N2. **Methods:** Samples (primary tumor and N1/N2) from 500 patients who underwent lung resection and lymphadenectomy for NSCLC without prior treatments were collected and analyzed for PD-L1 expression using the 22C3 pharmdx Agilent assay. The tumor proportion score (TPS) is documented for each sample according to the following categories: PD-L1: < 1%, 1-49%, ≥ 50%. PD-L1 stained slides were reviewed by two pathologists independently; for discrepant cases the two pathologists reviewed the stains jointly and the consensus score used for the data analysis. Agreement between the two pathologists was assessed by overall agreement and kappa statistic. The association between PD-L1 expression in the primary tumor and lymph node was assessed by cross-tabulation. **Results:** A total of 456 tumors and involved LNs were included in the analysis. Pathologist one assessed 435 primary tumor and LN pairs and pathologist 2 assessed 453 tumor and LNs pairs. The overall agreement between pathologists on PD-L1 expression in primary tumor samples was 77%; K = 0.59 (95% CI 0.57 – 0.63) and in LNs 83%; k = 0.62 (95% CI 0.56 – 0.70). Primary tumors showed PD-L1 < 1% in 235/422 (55,6%), PD-L1 1-49% in 146/422 (34,6%) and PD-L1 > = 50% in 41/422 (9.8%). 77% (327/422) showed no heterogeneity in PD-L1 expression between the primary tumor and involved LNs. In tumors with PD-L1 < 1% expression, 94% of the LNs showed PD-L1 < 1% expression and less than 1% showed PD-L1 > = 50%, 6% of the LNs showed PD-L1 1-49%. When the primary tumor was PD-L1 > = 50% nearly half (46%) of the involved LNs showed the same degree of PD-L1 positivity and 10% of them showed PD-L1 < 1%; 44% of the LNs showed PD-L1 1-49%. When the primary tumor showed 1-49% PD-L1 staining, 60% of the LNs showed the same staining pattern, 36% showed PD-L1 < 1% and only 4% showed PD-L1 > = 50% expression. **Conclusions:** In stage II and III NSCLC, half of the primary tumors show negative PD-L1 expression. Discrepant PD-L1 expression between primary tumors and LN metastases was seen in 23% of the cases, and when present, PD-L1 expression in LN tumors tended to be lower than that in primary tumors. Research Sponsor: MERCK.

9045 Poster Session (Board #238), Fri, 8:00 AM-11:00 AM

AFT-16: Phase II trial of atezolizumab before and after definitive chemoradiation (CRT) for unresectable stage III non-small cell lung cancer (NSCLC). *First Author: Helen J. Ross, Mayo Clinic, Phoenix, AZ*

Background: A minority of the > 40,000 patients (pts) diagnosed with stage III NSCLC annually in the US are cured by CRT, more recently followed by adjuvant immune checkpoint inhibitors (ICI). PD-L1 blockade with CRT may attenuate tumor-related immunosuppression via depletion of regulatory T cells and clonal expansion of effector T cells. Further, CRT may expose otherwise hidden antigens that present additional targets to the reconstituting immune system. Adjuvant ICI has improved survival. Whether ICI before CRT will further improve outcomes is unknown. **Methods:** This Alliance Foundation Trials (AFT) study evaluated safety and efficacy of atezolizumab before and after CRT. 4 cycles of atezolizumab 1200 mg IV q 21 days with restaging after cycles 2 and 4 were followed by carboplatin and paclitaxel (C/P) weekly with 60 Gy radiation and C/P consolidation followed by atezolizumab for 1 year of therapy. Primary endpoint is disease control rate (DCR) (complete response + partial response (PR) + stable disease (SD)) at 12 weeks (wks). Secondary endpoints include overall response rate, progression-free survival, overall survival, safety and quality of life assessed by EORTC QLQ-30. Correlatives include PD-L1 and tumor mutation burden as predictive biomarkers. Tumor tissue was obtained at study entry; plasma and immune cells were isolated at multiple timepoints. **Results:** 64 pts with stage III NSCLC, performance status (PS) 0-1, no active autoimmune disease or significant organ dysfunction enrolled at 13 Alliance sites from 11/2017 to 7/2019. 62 pts received ≥ 1 dose of atezolizumab and are included in the primary analysis; median age 63.9 years (38.1-86.5), 51.6% female, 77.4% white, 61.3% former smokers, 56.5% PS 0. DCR at 12 wks was 77.4% (80% confidence interval 69.2-84.3%) (30.7% PR, 46.8% SD). 54 pts reported adverse events (AEs) during induction, mostly grade (gr) 1. There were 13 serious AEs, most unrelated to study treatment; 1 gr 3 anaphylactic reaction, 1 gr 3 colitis, and 1 gr 4 Guillain-Barre syndrome were attributable to atezolizumab. Baseline PD-L1 status was available for 49 pts. DCR was 82.4% for pts with PD-L1 negative and 90.9% for pts with PD-L1 positive tumors. **Conclusions:** Atezolizumab prior to and following CRT for stage III unresectable NSCLC was well tolerated with an encouraging 12-wk DCR. Analysis of secondary endpoints is ongoing. Further study of induction ICI therapy is warranted in patients with unresectable stage III NSCLC. Support: AFT, Genentech; Clinical trial information: NCT03102242. Research Sponsor: Alliance Foundation Trials, Pharmaceutical/Biotech Company.

9046 Poster Session (Board #239), Fri, 8:00 AM-11:00 AM

A mid-chemoradiation dynamic risk model integrating tumor features and ctDNA analysis for lung cancer outcome prediction. *First Author: Everett J Moding, Stanford University, Stanford, CA*

Background: Circulating tumor DNA (ctDNA) molecular residual disease after curative intent therapy predicts disease progression in localized lung cancer. We hypothesized that integrating pre-CRT features and ctDNA levels during chemoradiation therapy (CRT) can predict patient outcomes earlier to enable response-adapted therapy. **Methods:** We identified pre-CRT features prognostic of disease progression after CRT for Stage II-III non-small cell lung cancer (NSCLC) in a historical "pre-CRT" training cohort of 109 patients. In addition, we applied CAPP-Seq ctDNA analysis pre-CRT and a median of 21 days into CRT (mid-CRT) to a "ctDNA" training cohort of 42 patients treated at MD Anderson and an independent validation cohort of 21 patients treated at Stanford. Prognostic pre-CRT features and mid-CRT ctDNA concentration were integrated using a Bayesian proportional hazards approach to generate a Continuous Individualized Risk Index (Kurtz et al. Cell 2019) for NSCLC (CIRI-NSCLC) to predict freedom from progression (FFP). **Results:** Adenocarcinoma histology (HR 2.6, P = 0.0005) and *KEAP1* mutation (HR 2.7, P = 0.002) but not stage (P = 0.16), age (P = 0.60), or gender (P = 0.98) were significantly associated with FFP in the pre-CRT training cohort. Mid-CRT ctDNA concentration as a continuous variable was significantly associated with FFP in the ctDNA training cohort (HR 1.6, P = 0.04), and applying an optimal threshold identified in the training cohort (3.2 hGE/ml) significantly stratified FFP in the independent ctDNA validation cohort (HR 4.8, P = 0.02). CIRI-NSCLC enabled individualized real-time updating of the probability of FFP as model features became available over the course of CRT. CIRI-NSCLC outperformed individual model features in the independent validation cohort when compared by C-statistic (CIRI-NSCLC: 0.85; mid-CRT ctDNA: 0.76; histology: 0.66; *KEAP1*: 0.60). Across the whole cohort, patients with a greater than 66% risk of progression predicted by CIRI-NSCLC (n = 10) had an FFP of 10.0% at 12 months while patients with a less than 33% risk of progression predicted by CIRI-NSCLC (n = 22) had an FFP of 79.7% at 12 months (HR 15.0, P < 0.001). **Conclusions:** Our results suggest that CIRI-NSCLC can identify patients at very high and low risk of progression. Prospective evaluation will be necessary to test the potential utility of adapting treatment based on CIRI-NSCLC. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

9047 Poster Session (Board #240), Fri, 8:00 AM-11:00 AM

Real-world treatment patterns and clinical outcomes in *EGFR*-mutant unresectable locally advanced NSCLC (LA-NSCLC): A retrospective multicenter study of 367 patients. *First Author: Nan Bi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Beijing, China*

Background: The chemoradiation therapy (CRT) is the standard care for unresectable LA-NSCLC. The addition of EGFR-TKIs in first-line treatment of *EGFR*-mutant subpopulation is debatable. **Methods:** We retrospectively collected data for patients with unresectable stage III NSCLC harboring *EGFR* mutations from nine major academic cancer institutions in China from Jan 2012 to December 2018. Patients with *ALK* rearrangements were excluded. Patients were categorized into three subgroups according to the primary treatment: 1) RT+TKI: Combined RT and EGFR-TKI with/out chemotherapy ; 2) no TKI: CRT alone; 3) upfront TKI: EGFR-TKI followed by RT at local-regional progression. PFS and OS were calculated from the date of diagnosis. Log-rank test was used to assess for differences and Cox proportional hazards model was used to adjust for covariates. **Results:** A total of 367 patients met selection criteria were included in the study. Patients receiving TKI were older (≥60 years: 54.7% TKI *v* 36.4% and RT+TKI 33.3% CRT; P = 0.001), and more patients receiving CRT had uncommon *EGFR* mutations (10.3% CRT *v* 2.3% RT+TKI and 4.0% TKI; P = 0.020). Other baseline characteristics were well balanced among groups. With a median follow-up of 40.8 months, the median PFS and OS were 16.6 and 55.4 months for the entire cohort. The median PFS and OS for the three subgroups were shown in the table. On multivariable analysis, after adjusting for age, KPS status, smoking status, stage, and type of *EGFR* mutations, TKI+RT was independently associated with improved PFS (HR, 0.57; 95% CI, 0.41 to 0.78) and OS (HR, 0.61; 95% CI, 0.39 to 0.97) relative to upfront TKI ; TKI+RT was also associated with improved PFS (HR, 0.38; 95% CI, 0.27 to 0.54) relative to CRT, but not OS (HR, 0.66; 95% CI, 0.40 to 1.11). **Conclusions:** The use of upfront EGFR-TKI with deferred RT at progression was associated with inferior OS in patients with *EGFR*-mutant unresectable LA-NSCLC. First-line use of radiotherapy and EGFR-TKI was associated with the longest PFS and OS, which requires further prospective, randomized evaluation. Research Sponsor: National Natural Science Foundation of China (grants 81572971) .

Endpoints	RT+TKI (N = 88) Median (95% CI)	CRT alone (N = 78) Median (95% CI)	Upfront TKI (N = 201) Median (95% CI)	P-value
PFS	21.6 (13.8 to 29.4)	12.6 (10.8 to 14.2)	16.5 (14.1 to 18.9)	< 0.001
OS	67.4 (57.5 to 77.3)	54.2 (40.0 to 68.3)	46.5 (34.5 to 58.6)	0.055

9048 Poster Session (Board #241), Fri, 8:00 AM-11:00 AM

Non-pneumonitis immune-mediated adverse events (imAEs) with durvalumab in patients with unresectable stage III NSCLC (PACIFIC). *First Author: Jarushka Naidoo, Department of Oncology, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: The phase 3 PACIFIC trial established durvalumab (durva) after chemoradiotherapy (CRT) as SoC for pts with unresectable stage III NSCLC. We report exploratory analyses to characterize non-pneumonitis (np) imAEs that occurred with durva in PACIFIC. **Methods:** PACIFIC was a double blind trial of pts without disease progression after platinum-based concurrent CRT (≥2 cycles). Pts were randomized 2:1 to receive durva 10 mg/kg or placebo (pbo) IV q2w for ≤12 months, stratified by age, sex and smoking history. We characterized the time to onset, duration, and management/outcomes of np imAEs and their association with (1) baseline pt/disease factors and (2) AEs (excluding all-cause pneumonitis). **Results:** Of 709 treated pts, 19% and 11% experienced imAEs and np imAEs of any grade, respectively; proportionally more had np imAEs with durva (71/475; 15%) vs pbo (5/234; 2%). Thyroid disorders (54/475; 11%), rash/dermatitis (9/475; 2%), and diarrhea/colitis (5/475; 1%) were the most common np imAEs with durva; rash/dermatitis had the shortest time to onset (Table). Among durva treated pts with np imAEs, 11% had grade 3/4 np imAEs, 41% had np imAEs that resolved, and none had fatal np imAEs; interventions included endocrine replacement therapy (73%), systemic corticosteroids (34%), high dose corticosteroids (16%), and discontinuation (10%). There were no apparent differences in baseline factors between pts with or without np imAEs. Durva had a broadly manageable safety profile irrespective of the occurrence of np imAEs. However, a higher proportion of durva treated pts with vs without np imAEs experienced all-cause, grade 3/4 events (41% vs 29%); none were fatal (excl. pneumonitis). **Conclusions:** Np imAEs occurred infrequently in PACIFIC, but were more common with durva vs pbo; thyroid disorders and rash/dermatitis were the most common np imAEs. Of durva treated pts with np imAEs, 11% experienced np imAEs of grade 3/4. Overall, np imAEs were broadly manageable and did not lead to high rates of discontinuation, and no association with baseline factors was seen, suggesting this should not deter use of durva in eligible pts. Clinical trial information: NCT02125461. Research Sponsor: AstraZeneca.

Timing of np imAEs in durva treated pts (≥5 pts with events)

Np imAE category (any grade)	Time to onset from 1st dose, median (range), days [n]*	Duration, median (range), days [n]†
Thyroid disorders	85.0 (14–378) [54]	63.5 (15–224) [20]
Rash/Dermatitis	37.0 (6–111) [9]	117.0 (18–738) [6]
Diarrhea/Colitis	61.0 (2–254) [5]	74.0 (12–151) [5]

*Based on the 1st event reported for each pt. †Excludes ongoing events.

9049 Poster Session (Board #242), Fri, 8:00 AM-11:00 AM

The impact of residual metabolic primary tumor volume after completion of thoracic irradiation in patients with inoperable stage III NSCLC. *First Author: Olarn Roengvoraphoj, Department of Radiotherapy and Radiation Oncology, University Hospital, LMU Munich, Munich, Germany*

Background: The metabolic tumor volume (MTV) is a functional and volumetric PET/CT parameter that has been investigated in recent years with respect to its predictive and prognostic value in different tumor entities. In this study, we investigated the role of residual MTV after completion of thoracic irradiation in inoperable stage III non-small cell lung cancer (NSCLC). **Methods:** We analyzed retrospective and prospective data of 56 patients with inoperable stage III NSCLC treated with chemoradiotherapy (CRT) and chemoradioimmunotherapy (CRT-IO). All patients received an 18F-FDG-PET/CT 3 to max. 6 months after completion of thoracic irradiation. The measurement of the residual MTV of the primary tumor was performed by calculating the SUVmean of the liver + 2SD as threshold. The patients were divided into the following groups: residual-MTV < 1ml; residual-MTV 1-25ml and residual-MTV > 26ml. Survival, local recurrence, and distant metastasis rates were calculated using the Kaplan-Meier method from the last day of thoracic irradiation. **Results:** The median follow-up was 45 months (range 16-74) in the CRT group and 16 months in the CRT-IO group (range13-19). Twenty-two (39%) patients had a residual MTV < 1ml (1st group), 19 (34%) a residual MTV between 1-25ml (2nd group) and 15 (27%) a residual MTV > 25ml (3rd group) after completion of thoracic irradiation. Median overall survival was 61, 20 and 12 months (p = 0.006) in the 1st, 2nd and 3rd groups, respectively. 12-month survival was 86%, 50% and 33% after CRT vs. 88%, 71% and 50% after CRT-IO in the 1st, 2nd and 3rd groups, respectively. The median time to in-field recurrence in the 1st, 2nd and 3rd groups was 51, 20 and 15 months (p = 0.011). The prognostic value of the residual MTV on OS was confirmed exclusively in the CRT patient cohort (p = 0.04), but not in the CRT-IO patient cohort (p = 0.174). Residual MTV demonstrated no influence on the local recurrence rate in the CRT-IO patient cohort, but only in patients treated with CRT (p = 0.007). **Conclusions:** Patients with inoperable stage III NSCLC in whom the residual MTV was < 1ml after completion of thoracic irradiation showed significantly better survival than patients with a residual MTV of 1-25ml and MTV > 25ml. The subgroup analysis confirmed the prognostic value of residual MTV only in patients who received chemoradiotherapy without consolidation immunotherapy. Research Sponsor: None.

9050 Poster Session (Board #243), Fri, 8:00 AM-11:00 AM

Neoadjuvant endobronchial delivery of gene mediated cytotoxic immunotherapy (GMCI) for non-small cell lung cancer (NSCLC): Safety and immunologic activity. *First Author: Laura K. Aguilar, Candel Therapeutics, Needham, MA*

Background: GMCI is a tumor-specific immuno-oncology approach implemented through local delivery of *aglatimagene besadenovec*(AdV-tk) followed by anti-herpetic prodrug. This leads to immunogenic tumor cell death, antigen presenting cell activation, and T cell stimulation resulting in $CD8^+$ T cell dependent protection, as demonstrated in preclinical models and clinical trials in other tumor types. This is the first study to assess endobronchial delivery of AdV-tk for NSCLC. **Methods:** This Phase I dose escalation trial enrolled patients with suspected NSCLC who were candidates for surgery. A single AdV-tk injection was performed by endobronchial ultrasound (n = 11) or mediastinoscopy (n = 1) during the diagnostic staging procedure 3 weeks prior to surgery. Three dose levels were evaluated: $2.5x\ 10^{11}$, $5x10^{11}$, and $1x10^{12}$ vector particles (vp) in a 3+3 design. Valacyclovir was administered for 14 days, starting the day after AdV-tk injection. To assess the local and systemic effects of GMCI, immune biomarkers were evaluated in blood and tumor samples before and after GMCI. **Results:** From 2017-2019, 12 patients (9 men, 3 women, median age 65 [range 55-80]) received GMCI followed by surgery. Average tumor size was 5.1 cm (largest diameter) and final pathologic stage was I (n = 4), II (n = 3), and III (n = 5). Treatment-related adverse events were CTC grade 1 fever (n = 1), flu-like symptoms (n = 1) and nausea/vomiting/diarrhea (n = 1). The only > grade 2 lab abnormality was transient grade 3 lymphopenia (n = 2). A measurable reduction in tumor size was observed in one patient. The average amount of tumor necrosis was 29.4%. Significant infiltration of $CD8^+$T cells (5.2-fold compared to baseline, p = 0.001) was found in tumor 19-22 days after AdV-tk injection. Within the $CD8^+$tumor infiltrating lymphocytes, there was increased expression of CD38 (2.5-fold, p = 0.002), Ki67 (4.8-fold, p = 0.02), PD1 (1.9-fold, p = 0.002), CD39 (2.9-fold, p = 0.04) and CTLA-4 (4.8-fold, p < 0.001), without significant detected differences in Tim3 or TIGIT. Simultaneously, peripheral blood $CD8^+$ cells displayed significant increases in CD38 (3.4-fold, p = 0.006), HLA-DR (4.2-fold, p = 0.002), and Ki67 (5.8-fold, p = 0.017). **Conclusions:** Intratumoral injection of AdV-tk into lung tumors was safe and feasible. Further, AdV-tk effectively induced peripheral blood and intra-tumoral CD8 T cell activation. Consequent upregulation of inhibitory receptors suggests a potential benefit for combination therapies. Clinical trial information: NCT03131037. Research Sponsor: Advantagene.

Neoadjuvant nivolumab (N) plus cisplatin (C)/pemetrexed (P) or cisplatin /gemcitabine (G) in resectable NSCLC. *First Author: Ralph Zinner, University of Kentucky, Department of Medical Oncology, Lexington, KY*

Background: Patients (pts) with resectable stage IB (≥4cm)-IIIA non-small-cell lung cancer (NSCLC) derive modest overall survival benefit with neoadjuvant or postoperative adjuvant chemotherapy. Neoadjuvant therapy can speed the discovery of promising regimens by using pathologic response as a surrogate for OS. Major pathologic response (MPR), defined as < 10% viable tumor, was strongly associated with improved OS. PD-(L)1 checkpoint inhibitors in combination with chemotherapy are standard of care in advanced NSCLC. We hypothesize that the addition of N to neoadjuvant CP or CG will increase the MPR rate compared to historical controls. **Methods:** This is an investigator-initiated trial for pts with newly diagnosed AJCC 8th stage IB (≥4cm)-IIIA squamous or non-squamous EGFR/ALK WT NSCLC with a plan to have surgery. Pts receive 3 courses of N 360mg IV q 3w added to C 75mg/m2 IV q 3w plus P 500 mg/m^2 IV q 3wks or G 1250mg/m^2 IV d1, d8 with surgery 3 wks after the last dose. The primary objective is MPR. To estimate pathologic response, the resected pathology specimens are cut >1 section/cm. Using the Aperio Digital scanning system©, slides were imaged, and then annotated by at least 2 pathologists for viable tumor vs. treatment effect with respective areas then automatically calculated and percentage of viable tumor calculated. Our primary endpoint will be reached if 10/34 (29%) planned pts have at least an MPR. **Results:** From 6/2018-8/2019, 13 pts were enrolled all of whom had surgery. Median age was 69 (49-80), 38% women, 31% nonsquamous, 54% stage IIIA, and 77% PD-L1 positive (≥1%, SP263). Pre-surgical grade 3 toxicity occurred in 2/13 pts, one of whom was changed to carboplatin for courses 2 and 3. Grade 3 toxicities were neutropenia (2/13), anemia (1/13), and renal (1/13). One pt. developed hypothyroidism 4 mos after surgery. One pt died 6 weeks after surgery from complications unrelated to study drugs. Our primary endpoint was met; 11/13 (85%), had at least an MPR with 6/13 (46%) and 5/13 (38%) having an MPR and pCR respectively. Radiologic response rate was 46% (PR 5, CR 1). Pts with either PD-L1+ or PD-L1- had MPRs. With a median follow-up of 10 months there are no recurrences. **Conclusions:** The combination of nivolumab added to platinum doublets was well tolerated. The primary endpoint of MPR in at least 10/34 pts was surpassed with MPR or pCR in 11/13 pts post-surgery. MPR was seen independent of PD-L1 score. Exploratory outcomes assessing markers of immune bias in tumor tissue and plasma are in process. Clinical trial information: NCT03366766. Research Sponsor: Bristol-Myers Squibb.

9052 Poster Session (Board #245), Fri, 8:00 AM-11:00 AM

Efficacy and safety of nivolumab for malignant mesothelioma in the real world. *First Author: Koji Mikami, Division of Respiratory Medicine, Department of Internal Medicine Department of Thoracic Oncology Hyogo College of Medicine, Nishinomiya, Hyogo, Japan*

Background: Until recently, the standard treatment for advanced malignant pleural mesothelioma (MPM) was only cisplatin plus pemetrexed. Nivolumab, an anti-programmed death-1 monoclonal antibody, shows efficacy against pretreated MPM and has been approved in Japan, but the data regarding the efficacy and safety of nivolumab in MPM are limited to those from a small number of patients of the MERIT study. Therefore, it is important to accumulate real-world data on the efficacy and safety of nivolumab for MPM. **Methods:** We retrospectively analyzed all patients with MPM who received nivolumab at Hyogo College of Medicine Hospital from August 2018 to December 2018. **Results:** A total of 77 patients (61 males and 16 females) were included. There were 62, 10, and 5 patients with performance statuses of 0–1, 2, and 3, respectively. There were 63, 8, and 6 patients with epithelioid, sarcomatoid, and bi-phasic histologies, respectively. Nivolumab was administered as second-, third-, and ≥fourth-line treatment to 48, 15, and 11 patients, respectively. In 66 patients who were examined for efficacy, the response rate (RR) was 24.2% and the disease control rate (DCR) was 63.6%. By the histology type, the RR and DCR were 15.1% and 62.3% for the epithelioid type, 62.5% and 87.5% for the sarcomatoid type, and 20.0% and 40.0% for the bi-phasic type, respectively. The median progression-free survival (mPFS) was 4.1 months and the median overall survival (mOS) was 13.3 months. Analyzing the efficacy based on the neutrophil-to-lymphocyte ratio (NLR) in the peripheral blood, the RRswere 14.7% in the NLR≥3.5 group and 25.8% in the NLR $<$ 3.5 group. The mPFS and mOS in the NLR≥3.5 group were 3.1 months and 11.4 months, respectively,whereas those in the NLR $<$ 3.5 group were 5.6 months and not reached, respectively. There were no significant differences in the RR, PFS, and OS between the groups, but a trend of better RRs and longer survivals wasobserved in the NLR $<$ 3.5 group than in the NLR≥3.5 group. Regarding adverse events, fatigue (grades 1 − 2) was observed in 8, hypothyroidism (grade 1–2) in 11, renal dysfunction (grade 1–3) in 6, loss of appetite (grade 1–2) in 2, pneumonitis (grade 3) in 1, rash (grade 1) in 2, and hypopituitarism (grade 3) in 1 patient(s). **Conclusions:** This retrospective study revealed the effectiveness and safety of nivolumab for MPM in the real-world setting.Nivolumab can be used as a standard second-line treatment for MPM. Furthermore, it has been suggested that the NLR may be a predictive marker of the effect of nivolumab for MPM, as pointed out in other carcinomas. Research Sponsor: None.

9053 Poster Session (Board #246), Fri, 8:00 AM-11:00 AM

A gentle therapy: Weekly epirubicin, as second-line treatment in elderly patients with malignant pleural mesothelioma (MPM). *First Author: Roberto Bollina, ASST Rhodense, Rho - Milan, Italy*

Background: MPM is a rapidly progressive tumor with a poor prognosis. Treatment options are limited for patients (pts) with PMP who experience disease progression after first-line pemetrexed-based chemotherapy (CT). This retrospective study wants to evaluate, in the age of immunotherapy, whether a gentle CT can be used as second line of treatment in elderly pts, above all maintaining quality of life (safety and tolerability) and improving progession free survival (PFS). Currently second-line CT is increasingly use, because many elderly pts are fit at the progression of the disease. No standard second/further line CT exist for MPM after failure of first-line pemetrexed based CT. The purpose of the study is to evaluate the clinical activity of weekly epirubicin as second-line CT in elderly with MPM. **Methods:** From July 2015 to March 2019, in Medical Oncology Dept. of ASST Rhodense 98 pts were elegible for analysis. Pts had histologically confermed unresectable MPM. Histology was epithelioid in 86 pts, sarcomatoid in 7 and biphasic in 5 pts. A Carboplatin(AUC4)-pemetrexed doublet was administered in 70 pts and 28 received gemcitabine as single agent how first line. A quality of life questionnaire was administered to each pt and geriatric comprehensive assessment (GCA) was performed. Epirubicin (E) was always administered with a schedule at 20 mg/msq day 1,8,15 every 28 until disease progression or intolerance. The primary endpoint was PFS, and secondary endpoints were the overall response rate (ORR) and QofL an overall survival (OS). **Results:** Of the 98 elegible pts, 71 was males, and 27 was female . Median age: 78 (range 72-86) PS: 0/1/2 was respectively in 32%, 60% and 8% of pts. A median of 5 cycles of E (range 2 -16) was delivered; 3% of pts required dose modification. PFS was of 7 months (range 3-16) . ORR was as follow: 0 CR, 18 PR (17%), 44 SD (44%) and PD occurred in 36 pts (39%). OS was 11 months (range 5-22). No life threatening event occurred. No grade 3-4 toxicities were observed . Liver toxicity grade 1-2in 10 pts (10%), thrombocytopenia grade 1 in 9 pts (9%), neutropenia grade 1-2 in 40 pts (40%), fatigue grade 2 in 33pts (32%), nausea grade 1 in 20 pts (20%). The analitical and stratified data will be exposed. **Conclusions:** Also in the era of immunotherapy, a simple treatment, E in weekly schedule has demonstrated to be a gentle therapy with a possibility to treat in second line, pre-treated elderly pts with MPM in progression after first line therapy, with an acceptable profile . Now this schedule could be considered as a safe and standard secon-line CT in elderly pts. Research Sponsor: None.

9054 Poster Session (Board #247), Fri, 8:00 AM-11:00 AM

Phase II study of olaparib in malignant mesothelioma (MM) to correlate efficacy with germline and somatic mutations in DNA repair genes. *First Author: Raffit Hassan, Thoracic and GI Malignancies Branch, National Cancer Institute, NIH, Bethesda, MD*

Background: BRCA1 associated protein 1 (*BAP1*), a nuclear deubiquitinase involved in DNA double-strand break repair is frequently mutated in MM. Because poly(ADP-ribose) polymerase inhibitors (PARPIs) induce synthetic lethality in *BRCA1/2* mutant cancers, we sought to evaluate efficacy of olaparib in patients with MM and correlate it with pathogenic germline and somatic mutations in DNA repair genes. **Methods:** Phase II single-center study (NCT03531840) enrolled patients with advanced pleural or peritoneal mesothelioma who had progressed on prior therapies, age $>$18 years, ECOG performance status $<$1, adequate organ and bone marrow function. Olaparib 300mg was given twice daily orally in 3 week cycles until disease progression or toxicity. Efficacy was assessed by CT scan every 6 weeks using RECIST criteria. Whole exome sequencing (WES) was performed on blood and tumor samples to identify pathogenic germline and somatic mutations in DNA repair genes. Primary objective was to determine response rate based on germline or somatic mutation status of DNA repair genes. **Results:** Between July 2018 to May 2019, 23 patients were enrolled, 15 pleural and 8 peritoneal MM [14 male; median age 63 (range 41-75 years); median number of prior treatments 3 (range 1-5)]. Median olaparib cycles received was 4 (2-21). WES to identify pathogenic mutations in the germline and tumor was performed in 23 and 17 patients respectively. Four patients had germline *BAP1*, 1 germline *MRE11A*, and 5 had somatic *BAP1* mutations. Of 22 evaluable patients, 1(4%) had partial response (PR), 17 (77%) had stable disease at 6 weeks and 4 (18%) had progressive disease. Patient with PR had a germline mutation in *MRE11A*. Median progression free survival (PFS) and overall survival (OS) for all patients was 3.4 months (95% CI: 2.7 – 4.8 months) and 8.1 months (95% CI: 4.5 months – not estimable) respectively. Median PFS of germline *BAP1* mutant patients (n = 4) was 2.3 months (95% CI: 1.3 – 3.6 months) compared to 4.1 months (95% CI: 2.7 – 5.5 months) for *BAP1*wild type patients (n = 18;P = 0.026). Median OS was 4.6 months (95% CI: 3.1 – 4.9 months) for patients with germline *BAP1* mutation versus not reached for those without germline *BAP1* mutation (P = 0.0058). The most common side effects of olaparib were anemia (16%), lymphopenia (24%), nausea (14%), and increased creatinine (9%). **Conclusions:** Olaparib has limited anti-tumor activity in previously treated MM patients including those with germline or somatic *BAP1* mutations. Presence of germline *BAP1* mutations was associated with decreased PFS and OS. Clinical trial information: NCT03531840. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

9055 Poster Session (Board #248), Fri, 8:00 AM-11:00 AM

Phase I study of TRC102 in combination with cisplatin and pemetrexed in patients with advanced solid tumors/Phase II study of TRC102 with pemetrexed in patients with mesothelioma refractory to pemetrexed and cisplatin or carboplatin. *First Author: Marianna Koczywas, Department of Medical Oncology and Therapeutics Research, City of Hope, Duarte, CA*

Background: Treatment options remain limited in malignant pleural mesothelioma refractory to pemetrexed +/- platinum. TRC102 (methoxyamine hydrochloride) is a novel biochemical inhibitor of the BER pathway. Available data support the hypothesis that TRC102 bound DNA is a substrate for topoisomerase II, which cleaves TRC102-bound DNA sites to produce strand breaks in cancer cells that cause cellular apoptosis and enhance the cytotoxic effects of chemotherapy. **Methods:** This was a parallel cohort trial of a Phase I of TRC102 in combination with cisplatin (CDDP) and pemetrexed in patients with advanced solid tumors (Arm A) and a Phase II of TRC102 with pemetrexed in patients with mesothelioma refractory to platinum and pemetrexed (Arm B). **Results:** In Arm A dose escalation, 16 pts (11M/5F) were treated; 9 evaluable through 3 TRC102 dose levels (50, 75, and 100 mg/day, PO), with CDDP 60 mg/m^2 and pemetrexed 500 mg/m^2 (levels 1- 3); and 5 evaluable at TRC102 100 mg/day PO, CDDP 75 mg/m^2, pemetrexed 500 mg/m^2 (level 4). Cycles were every 21 days. There were no DLT's, establishing level 4 as the RP2D. The only grade 4 treatment-related AE was thrombocytopenia on cycle 22 (level 2). Cycle 1 grade 3 AEs were 1 hypophosphatemia (level 1) and 1 leukopenia (level 2). There were 3 PRs (all parotid salivary gland tumors). Median PFS (95%CI) = 7.1% (1.4 – 15.5) mos. Arm B was designed as the first stage of a two stage Gehan design trial of patients with mesothelioma who had progressed on or recurred within 6 months of pemetrexed + platinum frontline treatment. 14 pts were treated with TRC102 50 mg/day D1-4 and pemetrexed 500 mg/m^2 every 21 days. There were 2 PRs (both in epithelioid cancer of which 1 was confirmed), meeting the pre-specified criteria for continued interest ($>$ 0/14). mPFS (95% CI) was 4.3 (1.4 - 6.8) mos. 8 pts had stable disease for at least 1 cycle (4 stable at cycles 6, 9, 10 and 12). There were 1 grade 4 neutropenia and 5 grade 3 AE's (1 each – anemia, neutropenia, leukopenia, fatigue, hyponatremia). **Conclusions:** TRC102 in combination with CDDP and pemetrexed exhibited antitumor activity, particularly in salivary gland tumors, and a tolerable safety profile at the doses tested. The combination of TRC102 and pemetrexed demonstrated activity in malignant mesothelioma that progressed on prior pemetrexed. Additional studies are warranted to confirm preliminary signals of activity. Clinical trial information: NCT02535312. Research Sponsor: U.S. National Institutes of Health.

9056 Poster Session (Board #249), Fri, 8:00 AM-11:00 AM

Genomic landscape and immune phenotype of malignant pleural mesothelioma. *First Author: Meera Patel, Wayne State University/Karmanos Cancer Institute, Detroit, MI*

Background: Malignant pleural mesothelioma (MPM) is a relatively uncommon malignancy with poor prognosis and no major therapeutic breakthroughs over the past decade. Better understanding of the genomic landscape and distribution of immune biomarkers in this disease has the potential to enable development of novel therapies. **Methods:** We analyzed molecular profiles of 222 MPM tumors using next-generation sequencing of 592 genes utilizing Caris Life Sciences platform. Genes were grouped into pathways: DNA damage repair (DDR) (*ATM, BRCA2, BRIP1, BAP1, CHEK2, ERCC2, FANCA/D2/E/L, MLH1, MSH6, MUTYH, NBN, PMS2, RAD50/51B, WRN*), cell cycle regulation including *TP53* (*RB1,CCNE1, CDKN2A, CCND1, CCND3, CDKN1B*), chromatin remodeling (CR) (*ARID2, ASXL1, DNMT3A, EP300, EZH2, KDM6A, KMT2C, KMT2D, NSD3, PBRM1, SMARCB1/A4, SETD2*), RAS/MAPK (*KRAS, MAP2K1, NF1, NF2*), and PI3K/AKT (*AKT, PIK3CA, PIK3R1/R2, PTEN, RICTOR, TSC1, TSC2, ZNF703*). Tumor mutational burden (TMB), PD-L1 expression (SP142 IHC, tumor staining), and MSI/MMR were analyzed. Seventy-two cases also had whole transcriptome sequencing data. Differences in alterations were compared for age, gender, and pathways. **Results:** Median age of patients (pts) was 72 yr (range, 37-90), 73% were male. Gene pathway alterations were seen in 81% of cases. DDR, specifically homologous recombination (HR), was the most commonly mutated pathway (36.9%), followed by RAS (25.2%) and CR (18.9%). Genes mutated in ≥5% of cases included *BAP1* (26.3%), *NF2* (23.5%), *TP53* (15.5%), *SETD2* (10.2%). PD-L1 was high (≥50% tumor cells positive) in 11.4% (n = 24), intermediate (1-49%) in 31.4% (n = 66), and negative (< 1%) in 57.1% (n = 120) pts. TMB was high (≥10 mutations/Mb) in 9.6% of tumors (n = 20). None of the tumors were dMMR/MSI-H. HR gene *BAP1* and CR gene *SETD2* mutations trended to be more prevalent in pts ≥70 yo (p = 0.02). CR trended to be more commonly mutated in females (p = 0.02). No other significant differences were found in specific gene/pathway alterations, PD-L1 expression, or TMB in the context of age and gender. Distribution of PD-L1 expression was not different among various pathways. No highly recurrent, targetable fusion isoforms were seen among the 85 identified (mean 1.1 fusions/tumor), which have not yet been characterized for pathogenicity. **Conclusions:** The majority of MPM tumors harbor alteration in one of the key cellular pathways. HR pathway mutations are the most common. The majority of tumors were PD-L1 negative and carry low TMB indicating low immunogenicity. No age and gender specific differences exist except for *BAP1* and *SETD2* mutations. Research Sponsor: None.

9057 Poster Session (Board #250), Fri, 8:00 AM-11:00 AM

MiST1: A phase IIa trial of rucaparib in patients harbouring BAP1/BRCA1 deficient relapsed malignant mesothelioma. *First Author: Dean Anthony Fennell, University Hospitals of Leicester, Leicester, United Kingdom*

Background: Malignant Mesothelioma (MM) remains an incurable cancer lacking effective treatments in the relapsed setting. Personalised therapy is still in its infancy. Homologous recombination (HR) deficiency associated with BRCA1 mutation has been shown to predict sensitivity to inhibition of poly-ADP ribose. In MM, BRCA1 associated protein 1 carboxy-terminal hydrolase (BAP1) is frequently mutated. It regulates both HR, and BRCA1 expression which is lost in 38% of mesotheliomas. Mesothelioma Stratified Therapy 1 (MiST1) was designed to test the hypothesis that BAP1/BRCA1 negative mesotheliomas would exhibit defective HR and exhibit sensitivity to PARP inhibition. **Methods:** MiST1 was a single centre, open label single arm phase IIa design with prospective molecular stratification; cytoplasmic/negative *BAP1* or *BRCA1* deficient MM was deemed eligible. Treatment was 600mg BD rucaparib (R) PO daily every 28 days for 6 cycles or until disease progression, unacceptable toxicity, withdrawal or death. Primary outcome was disease control rate at 12 weeks (DCR12w); secondary outcomes safety and toxicity profile, objective response rate (ORR) and DCR at 24 weeks (DCR24w). The null hypothesis states the true DCR12w is less than or equal to 25% and was tested against a one-sided alternative hypothesis that the DCR12w will be equal to or greater than 50%. **Results:** Between February 2019 and June 2019, 26 patients (pts) were eligible and consented to MiST1, median age 65.5 years, 85% are male and 15% female. Of these pts 15% had an ECOG performance status (PS) of 0 and 85% had an ECOG PS of 1. Molecular eligibility was 89% for BAP1 alone, 50% BRCA1 alone, and 39% BAP1+BRCA1. Primary tumour site was thoracic (96%) and subtype epithelioid (81%). DCR12w was 57.7% (95% CI, 36.9 - 76.7), DCR24w was 23.1% (95% CI, 9.0 – 43.7) and ORR was 11.5% (95%CI, 2.5 – 30.2). R was well tolerated with 9% (15/166) grade (G) 3/4 toxicities seen in 10 pts (38%), with no G5 toxicities. The most common adverse events were nausea occurring in 18 pts (69%), fatigue in 14 pts (54%), and decreased appetite in 10 pts (38%). Six cycles of R was received by 8 pts (30.8%). Dose reductions occurred in 9 pts (n = 8; 1 dose and n = 1; 2 doses). Dose delays occurred in 14 pts. **Conclusions:** MiST1 using the PARP inhibitor R met its primary endpoint of disease control rate at 12 weeks, showing promising efficacy with manageable toxicity. HR deficiency mutation signature enrichment is being investigated to refine the identification of responders to PARP inhibition. PARP inhibition warrants further investigation in MM. Clinical trial information: NCT03654833. Research Sponsor: British Lung Foundation, Pharmaceutical/Biotech Company.

9058 Poster Session (Board #251), Fri, 8:00 AM-11:00 AM

Safety and efficacy of tazemetostat, an enhancer of zeste-homolog 2 inhibitor, in patients with relapsed or refractory malignant mesothelioma. *First Author: Marjorie Glass Zauderer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Breast cancer gene 1 (BRCA1)-associated protein 1 (BAP1), a nuclear deubiquitinase, is commonly inactivated in malignant mesothelioma. Preclinical data showed that BAP1 inactivation sensitizes mesothelial cells to inhibition of enhancer of zeste-homolog 2 (EZH2), a methyltransferase implicated as an oncogenic driver in this tumor. This study evaluated the safety and efficacy of tazemetostat (TAZ), a potent and selective EZH2 inhibitor, in relapsed/refractory (R/R) malignant mesothelioma with BAP1-inactivation. **Methods:** EZH-203 (NCT02860286) was a 2-part, open-label, phase 2 study that assessed the pharmacokinetics (PK), safety, and efficacy of TAZ in pts with R/R malignant mesothelioma. In part 1, pts received TAZ 800 mg QD on day 1 (D1) and 800 mg BID, beginning day 2 of cycle 1 (C1). In part 2, pts received 800 mg of TAZ BID on D1 of C1. A two-stage Green-Dahlberg design was used for part 2. Primary endpoints were PK profiling of TAZ in all pts (part 1), and disease control rate (DCR) at week 12 in pts with BAP1-deficient R/R malignant mesothelioma (part 2). Secondary endpoints included safety, overall response rate (ORR), progression-free survival, overall survival, and duration of response (DOR). **Results:** The study enrolled 74 pts with R/R malignant mesothelioma, 70 pts (95%) were centrally confirmed to be BAP1-deficient. Median prior lines of therapy were 2 (range, 1-9). Observed clinical data in the presence of CYP3A4 inhibitors and inducers suggest a low DDI potential of TAZ. The 12 week DCR was 47% (n = 35). The ORR per RECIST version 1.1 was 3% [complete response: 0%; partial response (PR): 3% (n = 2)]. Of the 2 patients with PR, 1 had a DOR of 21 weeks and the other is ongoing (15.3 weeks at data cut off). 47 pts (64%) and 21 pts (28%) had stable disease (SD) and progressive disease, respectively. Overall, 91% pts discontinued, either due to disease progression (n = 65), death (n = 5), or treatment discontinuation (n = 1). Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in ≤5% of patients, most commonly anemia (5%) and dyspnea (4%). No pts discontinued due to TEAEs. There were no treatment related deaths. **Conclusions:** Based on disease control rate and stable disease, TAZ showed antitumor activity in pts with BAP1-deficient R/R malignant mesothelioma. TAZ monotherapy was generally well-tolerated. The current data support further clinical evaluation of TAZ in these pts. Furthermore, this trial presents an optimal paradigm for drug development in molecularly-enriched cohorts in mesothelioma. Clinical trial information: NCT02860286. Research Sponsor: Epizyme, Inc.

9059 Poster Session (Board #252), Fri, 8:00 AM-11:00 AM

Peritoneal mesotheliomas characterized by less cell-cycle alterations and more *TRAF7* alterations than malignant pleural mesotheliomas. *First Author: Michael Offin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While peritoneal mesotheliomas (PM) are clinically distinct from malignant pleural mesotheliomas (MPM) it is unknown if genetic alterations reflect these differences. Here we report the molecular alterations and clinicopathologic characteristics of a prospectively collected PM cohort as compared to MPM. **Methods:** Patients with PM (n = 59) and targeted next generation sequencing (NGS; MSK-IMPACT) from January 2014 to January 2019 were assessed and followed through February 2020. Germline variants were analyzed in consented patients. NGS was compared to patients with MPM (n = 194) assessed in the same time interval. **Results:** Median age at diagnosis was 61 (range: 20-77), 56% were women (n = 33), and 92% had epithelioid histology (n = 54). 66% had ascites (n = 39) and 24% developed extra-abdominal metastases (n = 14; including lung, pleura, and mediastinum). 68% (n = 40) underwent surgical debulking and 80% (n = 47) had infusional therapy (median lines: 3) including platinum/pemetrexed (n = 38), EPIC (n = 22), HIPEC (n = 15), and immunotherapy (n = 16). The median overall survival (OS) from diagnosis was 5.4 years (median follow up 3.5 years). The median tumor mutation burden (TMB) was 1.8 mut/Mb (range: 0-14.9) in PM vs 2.0 mut/Mb (range: 0-31.5) in MPM (p = 0.049). More patients with PM had *TRAF7* alterations than in MPM (5/59 vs 3/194; p = 0.02) while fewer had *CDKN2A*/*CDKN2B* (4 vs 55; p = 0.0004). All patients with TRAF7 altered PM had well-differentiated papillary epithelioid histology. There was no difference in the prevalence of other common alterations such as *BAP1* (32 vs 98; p = 0.66), *NF2* (12 vs 55, p = 0.24), *SETD2* (11 vs 24; p = 0.28), and *TP53* (9 vs 28; p = 0.84) in PM vs MPM respectively. Patients with *BAP1*-altered PM had shorter OS (4.6 vs 9.8 years; HR 2.6, 95% CI 1.1-6.4; p = 0.04) while *TRAF7*-altered PM had improved OS (not reached vs 4.8 years; HR 0.3, 95% CI 0.1-0.9; p = 0.04) compared to wild type. 13% (4/30) of patients with PM had pathogenic variants on germline NGS (*POT1* I78T, *MUTYH* R109Y, *BAP1* E402*, *APC* I1037K). **Conclusions:** NGS confirms the distinct biology of PM compared to MPM. Specifically, the former shows fewer cell cycle (*CDKN2*) alterations compared to MPM. In contrast to MPM, *BAP1* alteration was associated with shorter survival. As previously described, we found enrichment of *TRAF7* in well differentiated papillary epithelioid PM associated with improved survival but notably some *TRAF7* alterations were identified in poorly differentiated MPM. Consistent with other reports, the prevalence of germline alterations was 13%. Research Sponsor: National Cancer Institute of the National Institutes of Health (T32 CA009207, P30 CA008748).

9060 Poster Session (Board #253), Fri, 8:00 AM-11:00 AM

Role of immunotherapy in stage IV large cell neuroendocrine carcinoma of the lung. *First Author: Takefumi Komiya, Parkview Cancer Institute, Fort Wayne, IN*

Background: Despite approvals of immune checkpoint inhibitors in both small cell and non-small cell lung cancers, role of immunotherapy in large cell neuroendocrine carcinoma (LCNEC) in lung is undefined. **Methods:** Using National Cancer Database (NCDB), Stage IV LCNEC cases diagnosed in 2014-2016 with at least 30-day follow up were analyzed. Clinical demographics included age (20-69 vs. 70+), sex (male vs. female), race (whites vs. others), insurance (uninsured vs. others), institution (academic vs. others), Charlson-Deyo score (0-1 vs. 2-3), brain metastasis (Yes vs. No), liver metastasis (Yes vs. No). Information regarding cancer treatment was limited to first course of therapy, including surgery for primary lesion (Yes vs. No), radiation (Yes vs. No), chemotherapy (Yes vs. No), and immunotherapy (Yes vs. No). Survival analysis was performed using Kaplan-Meier curves and Log-rank tests. Cox proportional hazard model was used for multivariate analyses. A two-sided p-value < 0.05 was considered as significant. **Results:** Among 661 eligible cases, 37 patients were treated with immunotherapy. No significant association between use of immunotherapy and clinical demographics was observed except for use of chemotherapy ($p = 0.0008$). Chemotherapy was administered in 34 (92%) and 406 (65%) of cases in immunotherapy and non-immunotherapy groups, respectively. Use of immunotherapy was associated with improved overall survival (Log-rank $p = 0.0168$). Landmark analysis in the immunotherapy group showed 12 and 18-month survival of 34.0% and 29.1%, respectively, as compared with 24.1% and 15.0% in the non-immunotherapy group Multivariate analysis demonstrated that female sex, presence of liver metastases, surgery, use of chemotherapy and immunotherapy (HR = 0.64, $p = 0.0164$) had significantly improved survival. Propensity score matching in overall survival showed a nonsignificant trend ($p = 0.0733$) in favor of immunotherapy group. **Conclusions:** This retrospective study using one of the largest cancer databases suggests that use of immunotherapy may improve survival of LCNEC patients. Prospective studies are warranted for further validation. Research Sponsor: None.

9061 Poster Session (Board #254), Fri, 8:00 AM-11:00 AM

Carboplatin versus cisplatin for the treatment of extensive-stage small cell lung cancer (SCLC): A National VA Database analysis. *First Author: Ibrahim Azar, Karmanos Cancer Institute, Detroit, MI*

Background: Current standard of care first line treatment for extensive stage SCLC includes combination of platinum-etoposide doublet with an immune checkpoint inhibitor. Carboplatin is preferred over cisplatin in the extensive stage disease because of its favorable toxicity profile. Data comparing the efficacy of carboplatin with cisplatin in the metastatic setting are limited. **Methods:** Data from the National VA Cancer Cube database were compiled. Only pathologically confirmed cases of extensive stage SCLC that received platinum-based multiagent chemotherapy were included. Interval-censored Weibull and Cox proportional hazard regression models were used to estimate median overall survival (OS) and hazard ratio (HR), respectively. Two survival curves were compared by a Wald test. **Results:** Overall, 2600 SCLC cases were studied: 1968 received carboplatin-based therapy (Carbo-SCLC) while 632 received cisplatin-based therapy (Cis-SCLC). Median OS of Carbo-SCLC and Cis-SCLC was 0.71 years (95% CI 0.68-0.75) versus 0.70 years (95% CI 0.64-0.76), respectively (HR = 0.99; 95% CI 0.90-1.10; $p = 0.90$). Median OS of patients with ECOG-PS of 0, 1, 2 and 3 was similar for Carbo-SCLC and Cis-SCLC. HR of death for Carbo-SCLC compared to Cis-SCLC stratified by performance status were: ECOG-PS 0: 1.04 (95% CI 0.78-1.38; $p = 0.80$); ECOG-PS 1: 0.87 (95% CI 0.71-1.06; $p = 0.17$); ECOG-PS 2: 0.92 (95% CI 0.69-1.24; $p = 0.6$); ECOG- PS 3: 1.13 (95% CI 0.66-1.92; $p = 0.66$). Multivariable regression analysis accounting for age and ECOG-PS shows a HR of 0.92 (95% CI 0.80-1.05; $p = 0.24$). **Conclusions:** Cisplatin-based chemotherapy was not associated with a survival advantage over carboplatin-based chemotherapy in extensive-stage SCLC., including in patients with robust performance status and young patients. The findings from this large dataset along with the favorable toxicity profile of carboplatin support its use as the platinum agent of choice in extensive stage SCLC. Research Sponsor: None.

9062 Poster Session (Board #255), Fri, 8:00 AM-11:00 AM

Correlation of decreased expression of PD-L1 on circulating tumor cells and clinical benefit in SCLC Patients treated with RRx-001, a CD47 down-regulator, in a phase II trial. *First Author: Corey Carter, EpicentRx, Torrey Pines, CA*

Background: In a Phase 2 trial called QUADRUPLE THREAT (QT) (NCT02489903), where 2nd line+ small cell lung cancer (SCLC) patients were treated with RRx-001 and a platinum doublet, the programmed death-ligand 1 (PD-L1) status of circulating tumor cells (CTCs) in 14 patient samples was evaluated. **Methods:** 26 consented patients received weekly RRx-001 4 mg followed by a reintroduced platinum doublet; epithelial cell adhesion molecule (EPCAM+) CTCs from 10 ml of blood on two consecutive timepoints cycle 1 day 1 and cycle 3 day 8 (cycle duration = 1 week) were detected by EpCAM-based immunomagnetic capture and flow cytometric analysis. CTCs were further characterized for protein expression of PD-L1. Tumor response was classified as partial or complete response based on the response evaluation criteria in solid tumors (RECISTv1.1) measured every 6 weeks. **Results:** The analyzed clinical data set comprised 14 RECIST-evaluable patients. 50% were females (7/14) and the median age (years) at baseline was 64.5 (Min = 48.5, Max = 84.2, SD = 10.3). The logistic model McFadden goodness of fit score (0 to 100) is 0.477, which is a strong correlation value. The logistic model analyzing the association of CTC PD-L1 expression at two timepoints and response had an approximate 92.8% accuracy in its prediction of clinical benefit (SD/PR/CR). Accuracy is defined in the standard way as 1- (False positive rate + False negative rate). The estimated ROC displayed in Figure 1 suggests a ROC AUC of 0.93 (95% CI: 0.78, 0.99), an excellent measure of performance. **Conclusions:** Reduction of PD-L1 expression was correlated with good clinical outcome after RRx-001 + platinum doublet treatment. PD-L1 expression reduction in favor of RRx-001 RECIST clinical benefit was clinically significant as compared to non-responders with progressive disease (PD). In the ongoing SCLC Phase 3 study called REPLATINUM (NCT03699956), analyses are planned to correlate response and survival with expression of CD47 and PD-L1 on CTCs. Clinical trial information: NCT02489903. Research Sponsor: EpicentRx.

9063 Poster Session (Board #256), Fri, 8:00 AM-11:00 AM

Effect of anlotinib in advanced small cell lung cancer (SCLC) patients relapsed within three months after second-line treatment: A subgroup analysis from a randomized, double-blind phase II trial (ALTER 1202). *First Author: Jianhua Shi, Linyi Cancer Hospital, Linyi, China*

Background: Anlotinib had significantly improved progress-free survival (PFS) and overall survival (OS) of advanced small cell lung cancer (SCLC) patients received at least two lines chemotherapy in the ALTER 1202 trial. Here, we reported the effect of anlotinib in advance SCLC patients relapsed within 3 months after second-line treatment. **Methods:** The ALTER 1202 was a randomized, double-blind phase 2 trial including patients with advanced SCLC that received at least two previous lines of chemotherapy. Eligible patients were randomized in a 2:1 ratio to receive either anlotinib or placebo until tumor progression or unacceptable toxicity. The subgroup analysis assessed the effect of anlotinib in patients relapsed within 3 months after second-line treatment. The primary outcome was PFS. The secondary outcomes were OS, objective response rate (ORR), disease control rate (DCR) and safety. This trial was registered with ClinicalTrials.gov, number NCT03059797. **Results:** In the ALTER1202 trial, 67 patients in anlotinib group and 34 patients in placebo group relapsed within 3 months after second-line treatment. Among them, the median PFS was 3.98 months (95% confidence interval [CI], 2.79 to 4.24) with anlotinib versus 0.72 months (95% CI, 0.69 to 0.82) with placebo (hazard ratio [HR], 0.14; 95% CI, 0.08 to 0.26; $P < 0.0001$). Meanwhile, anlotinib significantly prolonged OS compared with placebo (7.29 months [95% CI, 6.51 to 10.51] versus 4.37 months [95% CI, 2.33 to 6.47]; HR, 0.42 [95% CI, 0.23 to 0.74]; $P = 0.0059$) in patients relapsed within 3 months after second-line treatment. ORR was 4.48% (3 PR) for anlotinib and 2.94% (1 PR) for placebo ($P = 0.708$). DCR was 73.13% for anlotinib and 11.76% for placebo ($P < 0.0001$). The most common adverse events were hypertension (38.81%), anorexia (28.36%), fatigue (22.39%) and Elevation of alanine aminotransferase (17.91%). **Conclusions:** Anlotinib improved PFS and OS in advanced SCLC patients relapsed within 3 months after second-line treatment and was well tolerated. Research Sponsor: None.

9064 Poster Session (Board #257), Fri, 8:00 AM-11:00 AM

Phase II study of gedatolisib for small-cell lung cancer (SCLC) patients (pts) with genetic alterations in PI3K/AKT/mTOR pathway based on a large-scale nationwide genomic screening network in Japan (EAGLE-PAT/LC-SCRUM-Japan). *First Author: Hibiki Udagawa, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Development of targeted therapy for SCLC based on a large-scale genomic screening is an innovative challenge. Gedatolisib is a highly potent dual inhibitor of PI3K/mTOR and is expected to have an effect for tumors with PI3K/AKT/mTOR pathway alterations. SCLC harboring this pathway alterations is rare. Thus, we conducted a phase II study based on a nationwide genomic screening network in Japan (LC-SCRUM-Japan) to develop novel targeted therapies. **Methods:** SCLC pts with targetable genetic alterations were screened at 154 institutions in Japan. A multicenter, single-arm phase II study was conducted to evaluate the efficacy and safety of gedatolisib in advanced SCLC pts with genetic alterations in the PI3K/AKT/mTOR pathway. The primary endpoint was objective response rate (ORR). The planned sample size was 19 (threshold and expected ORR of 20% and 50%, one-sided alpha of 5%, and power of 80%). **Results:** 930 SCLC pts were screened from July 2015 to January 2020. Targetable genetic alterations were identified in 148 pts (16%), including 53 PI3K/AKT/mTOR (6%), 81 MYC family (9%), 10 EGFR (1%) and 15 KRAS (2%). A total of 12 pts with genetic alterations in the PI3K/AKT/mTOR pathway (5 PIK3CA, 6 PTEN, and 1 AKT1 mutation) were enrolled in the phase II study. The median age was 67 years (range 58-79), 7 pts were male and 5 pts received 2 or more prior chemotherapy (range 1-4). The ORR was 0% and disease control rate was 25%. The median progression-free survival (PFS) was 0.9 months (95% CI, 0.4 to 3.0). The median overall survival was 5.8 months (95% CI, 1.1 to NR). Treatment-related G3 adverse events (hypertension, hypoalbuminemia, oral mucositis, ALT increased and creatinine increased) were observed in 4 pts. One patient with PTEN I8fs mutation had a long duration of stable disease (PFS; 6.7 months). **Conclusions:** This Large-scale nationwide genomic screening network was effective to identify rare targetable genetic alterations and had a potential role to develop targeted therapies in SCLC. This phase II study didn't show promising clinical benefit of gedatolisib for advanced SCLC pts with genetic alterations in the PI3K/AKT/mTOR pathway. The safety profile of gedatolisib was similar to that reported previously. Clinical trial information: UMIN000020585. Research Sponsor: Japan Agency for Medical Research and Development.

9065 Poster Session (Board #258), Fri, 8:00 AM-11:00 AM

Preliminary efficacy data of platinum-pretreated small cell lung cancer (SCLC) cohort of NCI 9881 study: A phase II study of cediranib in combination with olaparib in advanced solid tumors. *First Author: Joseph W. Kim, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Cediranib, a pan-vascular endothelial growth factor receptor tyrosine kinase inhibitor, suppresses expression of *BRCA1, BRCA2*, and *RAD51* and increases sensitivity of tumors to poly-(ADP-ribose) polymerase (PARP) inhibitors *in vitro*. Olaparib, a PARP inhibitor, demonstrated clinical efficacy in patients with advanced solid tumors carrying a germline *BRCA* mutation. We therefore tested the anti-tumor activity of cediranib and olaparib combination in patients (pts) with advanced solid tumors. Here, we report the data from the SCLC cohort. **Methods:** This multi-institutional, two-stage, phase 2 study enrolled pts with metastatic SCLC previously treated with a minimum of one prior line of platinum-based chemotherapy in advanced setting. Patients were treated with cediranib 30mg po daily plus olaparib 200mg po BID until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) by RECIST v1.1. Baseline tumor biopsies were obtained for biomarker analyses. **Results:** Baseline characteristics of the 25 pts enrolled are summarized below. The overall ORR rate was 28% (95% CI: 0.104,0.456). Median duration of response was 3.8 months (mos). Six of 8 pts had an objective response lasting longer than 3 mos up to 10.3 months. Disease control rate (# of pts with CR, PR or SD / # evaluable pts) was 88% (95% CI: 0.75,1.01). Median progression free survival was 4.1 mos (95% CI: 2.3, 6.2). Median OS was 5.5 mos (95% CI: 3.4, NA). Grade 3/4 adverse events (G3/4 AEs), irrespective of attribution, occurred in 14 of 25 (56%). G3/4 AEs occurring in $>$ 10% of pts were hypertension (21%), fatigue (17%) and weight loss (13%). **Conclusions:** The cediranib/olaparib combination resulted in promising clinical activity with ORR of 28% in biomarker-unselected pts with platinum-pretreated SCLC. The regimen required prompt initiation of antihypertensives, but AEs were overall manageable. Analyses of mutation status in homologous recombination DNA repair genes are going and will be correlated with clinical activity. Clinical trial information: NCT02498613. Research Sponsor: U.S. National Institutes of Health.

Median (range)	SCLC (n = 25)
Age	67, (46-79)
# of prior therapies	2 (1-5)
Platinum-sensitive disease (> 90 days interval to start subsequent therapy)	80%
Prior immunotherapy (IO)	52%
Interval from the last dose IO to start of study drugs, in days	97, (31-651)

9066 Poster Session (Board #259), Fri, 8:00 AM-11:00 AM

The efficacy and safety profile of anlotinib with etoposide plus cisplatin/carboplatin in treatment-naive extensive-stage small cell lung cancer(SCLC) patients: Results from a phase II single-arm trial. *First Author: Pengbo Deng, Department of Respiratory Medicine, Xiangya Hospital, Central South University, Changsha, China*

Background: Combination of etoposide and cisplatin/carboplatin is the most commonly used initial chemoptherapy regiment in extensive-stage small cell lung cancer. A meta-analysis released that, there is no significant difference was observed in Objective response rate(ORR), progression-free survival (PFS), or overall survival(OS) in patients(pts) receiving cisplatin-base versus carboplatin-based regimens. We performed a single-arm phase II trial to determine if maintain of single-agent anlotinib, an oral VEGFR, FGFR, PDGFR and c-Kit tyrosine kinase inhibitor, after 4-6 cycles of anlotinib + etoposide + cisplatin/carboplatin would improve PFS and ORR. **Methods:** SCLC pts (18~70 yrs, extensive-stage SCLC, no prior systematic chemo/ICI therapy) received anlotinib(12mg QD from day 1 to 14 of a 21-day cycle) +etoposide(100mg/m^2, d1~3 of 21-day cycle)+ cisplatin(75-80mg/m^2,Q3W)/ carboplatin(AUC = 5~6,Q3W) for 4~6 cycles, and anlotinib maintenance. The dual-primary endpoint were PFS and ORR. **Results:** Between Oct.2018 to Dec.2019, 27 pts enrolled and included in the efficacy and safety analysis: age: median 62 (range:44-71); male 93%; cisplatin/ carboplatin/ both 11%/78%/11%; 37%(10/27) of pts required chemotherapy dose modification only, and the other 30% (8/27) of pts required anlotinib+ chemotherapy dose modification.The median PFS was 9.61 months (95%CI:7.80-11.42). ORR was 77.78% (21/27), disease control rate (DCR) was 96.30% (26/27).Toxicities≥grade 3 included: neutropenia 22%, leukopenia 11%, hand-foot syndrome 15%, nausea 4%, mucositis 4%, edema 4%, anorexia 4%, xerostomia 4% and fatigue 4%; there were no grade 5 toxicities. **Conclusions:** Combined treatment with anlotinib plus etoposide and cisplatin/carboplatin for treatment-naive extensive-stage SCLC was well tolerated with promising PFS and ORR to date but showed no new risk for AEs. Based on these encouraging results, phase III trial of anlotinib plus etoposide and cisplatin/carboplatin for treatment-naive SCLC has been warranted. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

9067 Poster Session (Board #260), Fri, 8:00 AM-11:00 AM

Early ctDNA response assessment for prediction of platinum sensitivity in small cell lung cancer. *First Author: Yonina R. Murciano-Goroff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Small cell lung cancer (SCLC) is an aggressive disease, characterized by inevitable chemotherapy resistance and rapid progression. We hypothesized that circulating tumor DNA (ctDNA) analysis can rapidly identify sensitivity to platinum-based therapy. **Methods:** Patients with SCLC at Memorial Sloan Kettering Cancer Center underwent serial plasma collections, including prior to the start of treatment and prior to Cycle 2 Day 1 of therapy (C2D1). Tumor mutations were identified from pre-treatment biopsies by MSK-IMPACT and/or pre-treatment plasma by CAncer Personalized Profiling by deep Sequencing (CAPP-Seq). Median variant allele fraction (VAF) of all mutations was monitored on subsequent blood draws using CAPP-Seq. Progression free survival (PFS) was measured from the time of first pre-treatment blood draw. **Results:** Plasma was collected from 19 patients treated with carboplatin and etoposide, including three who received concurrent atezolizumab. Seven were female, and mean age was 64.5 years. ctDNA was detected in 17 patients (89%), including in the two patients in our series with limited stage disease. The most common mutations were in *TP53* and *RB1* in 14 and 6 patients, respectively. Fourteen patients had available plasma at C2D1. At baseline prior to treatment, median VAF did not differ significantly between radiologic responders and non-responders (9.4% versus 30.3%, p = 0.35). After one cycle of chemotherapy, the VAF percent decrease was significantly more in responders versus non-responders (-96.9% versus -10.3%, p $<$ 0.001). Median VAF was therefore significantly lower by C2D1 in patients who responded compared to non-responders (0.51% versus 27.2%, p = 0.02). Those who ultimately responded to therapy all had a $>$ 2 fold decrease in VAF by C2D1. With a median follow-up of 180 days, PFS was significantly longer in patients with $>$ 2 fold decrease in VAF by C2D1 (6.4 versus 1.9 months, log rank p $<$ 0.001). **Conclusions:** A 2-fold decrease in plasma VAF by C2D1 predicted platinum-sensitivity in SCLC and was associated with longer PFS. ctDNA may permit early assessment of benefit and expedite alternative treatment options for those without significant decrease in median VAF after one cycle of therapy. First-line durvalumab plus platinum-etoposide in extensive-stage (ES)-SCLC (CASPIAN): Impact of brain metastases on treatment patterns and outcomes. *First Author: Yuanbin Chen, Cancer & Hematology Centers of Western Michigan, Grand Rapids, MI*

Background: In the Phase 3, randomized, open-label CASPIAN study, first-line durvalumab (D) added to etoposide plus either cisplatin or carboplatin (EP) significantly improved OS vs EP alone (HR 0.73 [95% CI 0.59–0.91]; p = 0.0047) in pts with ES-SCLC at the planned interim analysis. Here we describe treatment patterns and outcomes for pts according to brain metastases. **Methods:** Treatment-naïve pts (WHO PS 0/1) with ES-SCLC received 4 cycles of D 1500 mg + EP q3w followed by maintenance D 1500 mg q4w until disease progression (PD) or up to 6 cycles of EP q3w and optional prophylactic cranial irradiation (PCI; investigator's discretion). Pts with either asymptomatic or treated and stable brain metastases were eligible. Brain imaging was suggested for pts with suspected brain metastases, but was not mandated at screening or during treatment. The primary endpoint was OS. Analysis of OS and PFS in pt subgroups with and without brain metastases was prespecified. Other analyses in these subgroups were post hoc. Data cutoff: Mar 11, 2019. **Results:** At baseline, 28 (10.4%) of 268 pts in the D + EP arm and 27 (10.0%) of 269 pts in the EP arm had known brain metastases; of these, only 3 pts (~11% of those with baseline brain metastases) in each arm received radiotherapy (RT) to the brain prior to study entry. D + EP consistently improved OS vs EP in pts with or without known brain metastases at baseline (HR 0.69 [95% CI 0.35–1.31] and 0.74 [0.59–0.93], respectively); PFS was also consistently improved with D + EP regardless of the presence or not of baseline brain metastases (HR 0.73 [0.42–1.29] and 0.78 [0.64–0.95]). Among pts without known brain metastases at baseline, similar proportions developed new brain metastases at first PD in the D + EP (20/240; 8.3%) and EP arms (23/242; 9.5%), despite 19 (7.9%) pts in the EP arm having received PCI. Overall, 48 of 268 (17.9%) and 49 of 269 (18.2%) pts in the D + EP and EP arms received RT to the brain subsequent to study treatment; rates remained similar across the D + EP and EP arms regardless of baseline brain metastases (11 of 28 [39.3%] and 11 of 27 [40.7%] pts with known baseline brain metastases, compared to 37 of 240 [15.4%] and 38 of 242 [15.7%] pts without known baseline brain metastases). **Conclusions:** In CASPIAN, OS and PFS outcomes were improved with D + EP vs EP regardless of baseline brain metastases, consistent with the ITT analyses. Rates of new brain metastases at first PD were similar between arms, although PCI was permitted only in the control arm. Rates of subsequent RT to the brain were also similar in both arms. Clinical trial information: NCT03043872. Research Sponsor: AstraZeneca.

9069 Poster Session (Board #262), Fri, 8:00 AM-11:00 AM

RESILIENT part I, an open-label, safety run-in of liposomal irinotecan in adults with small cell lung cancer (SCLC) who have progressed with platinum-based first-line (1L) therapy: Subgroup analyses by platinum sensitivity. *First Author: David R. Spigel, Sarah Cannon Research Institute, Nashville, TN*

Background: Most patients with extensive SCLC develop drug resistance to platinum-based 1L therapy or discontinue for other reasons, and second-line (2L) therapies are limited. RESILIENT (NCT03088813) is a two-part phase 2/3 study assessing the safety, tolerability and efficacy of 2L liposomal irinotecan monotherapy in adults with SCLC who progressed with platinum-based 1L therapy. Preliminary data from RESILIENT part 1 (cut-off May 8 2019; ≥ 12 weeks follow-up) showed that liposomal irinotecan 70 mg/m^2 free base every 2 weeks was generally well tolerated and had encouraging antitumor activity (Paz-Ares *et al*. WCLC 2019 OA03.03). Objective response rate (ORR; secondary endpoint) was 44% (11/25). Here we report efficacy analyses in *post hoc* subgroups by platinum sensitivity. **Methods:** RESILIENT part 1 was an open-label, single-arm study comprising dose-finding and dose-expansion phases. Eligible patients were aged ≥ 18 y, with an ECOG performance status score of 0/1 and adequate organ function; a single line of prior immunotherapy was allowed. Participants received liposomal irinotecan 70 mg/m^2 or 85 mg/m^2 free base every 2 weeks, with tumor assessments every 6 weeks (RECIST v1.1). Analyses were undertaken for the dose-finding phase recommended dose (RD) in subgroups of platinum-resistant/sensitive patients (with/without progression within 90 days from completion of 1L therapy). **Results:** During dose finding, 5 patients received liposomal irinotecan 85 mg/m^2 (deemed not tolerable; dose-limiting toxicity) and 12 received 70 mg/m^2 (deemed tolerable; RD for dose-expansion phase in which 13 more patients were included). Analyses included all 25 patients receiving the RD (mean exposure, 13.95 weeks [median 14.86; SD 7.222]). In the platinum-sensitive subgroup (33.3% men; median age 62.0 y) ORR was 53.3% (8/15) and 12-week disease control rate (DCR12wks) was 60% (9/15); in the platinum-resistant subgroup (50% men, median age 58.0 y) both ORR and DCR12wks were 30% (3/10). Overall and progression-free survival (secondary endpoints) are not yet mature. **Conclusions:** ORR and DCR12wks were numerically higher in platinum-sensitive than in platinum-resistant patients with SCLC who had progressed with platinum-based 1L therapy before receiving 2L liposomal irinotecan 70 mg/m^2 in this phase 2 study. RESILIENT part 2, an ongoing, phase 3, randomized controlled trial vs topotecan, will provide further data. Clinical trial information: NCT03088813. Research Sponsor: Ipsen.

9071 Poster Session (Board #264), Fri, 8:00 AM-11:00 AM

The impact of adjuvant therapy for non-metastatic thymic carcinoma: An analysis of the surveillance, epidemiology, and end results (SEER) database. *First Author: Richard Lee O'Neal, University of Kentucky, Markey Cancer Center, Greenville, KY*

Background: Thymic Carcinoma is a rare malignancy with an aggressive clinical course. While the importance of surgery in the non-metastatic setting has been well defined, the optimal role of radiation and/or systemic therapy in this setting remains controversial. This study utilized the Surveillance, Epidemiology, and End Results (SEER) database to investigate the impact of adjuvant therapy on overall survival in patients with thymic carcinoma. **Methods:** We identified adults in the SEER database with thymic carcinoma diagnosed between 1989 to 2015 for analysis. As the primary treatment for non-metastatic thymic carcinoma is surgery, we excluded patients who did not have surgery as a component of their treatment Patients were categorized into Masaoka-Koga stage groups (I-IIa, IIb, III, and IV). Kaplan-Meier estimates of 10-year OS and multivariate Cox proportional hazards regression analyses were performed. **Results:** 515 patients met the inclusion criteria, of which 125 were stage I-IIa, 46 were stage IIb, 191 were stage III, and 143 were stage IV. A multivariate analysis was performed, adjusting for age, sex, race, and tumor size. When compared to surgery, no statistical improvement in survival was seen with adjuvant radiation or chemotherapy in stage I-IIa or IIb thymic carcinoma. In stage III disease, standard of care surgery was compared with adjuvant radiation (hazard ratio 0.69 (95% confidence interval 0.29 – 1.63], p = 0.39), adjuvant chemotherapy (hazard ratio [HR] 0.84 [95% confidence interval 0.28 – 2.53], p = 0.76), and adjuvant chemo-radiotherapy (HR 0.40 [0.18 – 0.93], p = 0.03). On Kaplan-Meier analysis, triple therapy (surgery + chemo-radiotherapy) was also associated with a marked improvement in 10-year overall survival at 55.3%, compared to 39.8%, 23.9%, and 20.8% (adjuvant radiation, adjuvant chemotherapy, and surgery alone, respectively). **Conclusions:** This study finds that in stage III thymic carcinoma, surgery followed by chemo-radiotherapy is associated with improved overall survival compared to single or dual-modality treatments. Because of the rarity of this disease, there are no large randomized studies evaluating the most appropriate treatment modalities, therefore this data may assist with clinical decision making in non-metastatic thymic carcinoma. Research Sponsor: None.

Treatment strategies for thymic carcinoma in a real-life setting: Insights from the rythmic network. *First Author: Nicolas Girard, Institut Curie, Institut du Thorax Curie-Montsouris, Paris, France*

Background: Thymic carcinomas are an aggressive and difficult to treat subset of thymic epithelial tumors (TETs) that represent a heterogeneous group of rare intrathoracic malignancies. Most of the current knowledge and guidelines tumors rely on surgically-oriented databases focusing on early-stage disease, and small prospective, single-arm trials conducted in metastatic thymic carcinomas, mostly in a refractory, late-line setting. "Réseau tumeurs THYMiques et Cancer" (RYTHMIC) is the nationwide network for TETs in France. The management of any patient has to be systematically discussed on a real-time basis at a national multidisciplinary tumor board; a database is hosted by the French Thoracic Cancer Intergroup (IFCT). **Methods:** We took advantage of the RYTHMIC prospective database to describe baseline characteristics, analyze treatment strategies, and provide landmark outcomes in a cohort of consecutive patients with thymic carcinoma. The inclusion period was January 2012 to April 2017. **Results:** A total of 213 patients were analyzed. Overall, 60 (28%) patients were considered as surgical candidates upfront, 91 (43%) received primary chemotherapy, and 62 (29%) received exclusive chemotherapy. Median OS was 49.2 months (IC95%: 34.8-63.6); OS was significantly longer in patients with a lower stage at diagnosis ($p < 0.001$), who were operated on upfront, as opposed to patients who received primary or exclusive chemotherapy ($p < 0.001$). Surgery, conducted upfront or after primary chemotherapy, was significantly associated with more prolonged OS ($p < 0.001$); complete resection and postoperative radiotherapy were also predictors of better outcome (p = 0.018 and p = 0.081, respectively). Exclusive chemotherapy was delivered to 62 patients with advanced disease, who all received platinum-based regimen as first-line treatment; PAC regimen was delivered to 66% of patients. Best objective response to first-line chemotherapy was partial response in 33 (53%) patients. Median PFS was 8.0 months (IC95%: 5.0-11.1). Median OS was 32.9 months (IC95%: 20.6-45.1). Response to first-line chemotherapy and squamous histology were the only significant predictors of OS (p = 0.002 and p = 0.040, respectively). **Conclusions:** Our cohort is the first to analyze in depth outcomes and treatment strategies in a prospective cohort of consecutive patients with thymic carcinoma. While we confirm the major prognostic impact of surgery, our data highlight the need for optimized multidisciplinary management and innovative therapies as the survival of patients remains limited. Research Sponsor: None.

9073 Poster Session (Board #266), Fri, 8:00 AM-11:00 AM

Prevalence of autoimmune diseases in thymic epithelial tumors (TET) insights from RYTHMIC. *First Author: Jose Carlos Benitez, Gustave Roussy, Villejuif, Paris, YT, France*

Background: TET are associated with autoimmune disorders (AID) in up to 30% of patients (pts). However, there have been wide variations in the reported prevalence of AID in TET pts in small single-center series. RYTHMIC (Réseau tumeurs THYMiques et Cancer) is a French network mandated to systematically discuss every case of TET. We aimed to describe the prevalence of AID in a large French population. **Methods:** RYTHMIC database, hosted by IFCT (Intergroupe Francophone de Cancérologie Thoracique), prospectively includes all consecutive pts with a diagnosis of TET discussed in French national or regional tumor boards. We analyzed epidemiologic, clinical and pathological characteristics of pts with TET's related AID. **Results:** From January 2012 to December 2019, 2909 pts were included in the database. The mean age at diagnosis of TET was 54 and 52% were male. In the overall population, Masaoka Koga stages were well balanced with 12.6% (n = 187) stage I, 8.8% (n = 131) stage IIa, 8.4% (n = 124) stage IIb, 11.1% (n = 164) stage III and 8.5% (n = 125) stage IV. There were 364 (12.5%) events of AID in 302 pts. 62 pts (17%) had more than 1 AID. Among the events, 236 were myasthenia gravis (MG) (64.8%), 19 Hypogammaglobulinemia syndrome (5.2%), 15 pure red cell aplasia (4.1%), 18 thyroiditis (4.9%) and 16 systemic erythematous lupus (4.4%). Diagnosis of AID was mostly done at tumor diagnosis (n = 239, 65.7%) but some patient had AID diagnosed before diagnosis (n = 67, 18.4%) or during follow up (n = 32, 8.8%). Among pts presenting AID, B2 was the most common subtype (n = 133, 36.5%). The incidence of AID per subtype was as follow: A (n = 10/81, 12.3%), AB (n = 48/225, 21.3%), B1 (n = 35/130, 26.9%), B2 (n = 133/295, 45.0%), B3 (n = 46/113, 40.7%), thymic carcinoma (n = 16/275, 5.8%). **Conclusions:** The prevalence of AID in pts with TET was 12.5%, $>$ 40% in B2 and B3 subtypes. Diagnosis of AID can be delayed compared to the diagnosis of TET. Immunotherapy indication should be carefully assessed in pts with TET other than thymic carcinoma. Research Sponsor: None.

9074 Poster Session (Board #267), Fri, 8:00 AM-11:00 AM

Low-dose oral etoposide is an active option for patients with heavily pretreated thymic epithelial tumors. *First Author: Margaret Ottaviano, Department of Clinical Medicine and Surgery, University Federico II of Naples, Naples, Italy*

Background: Platinum based regimens are used in the first line setting for advanced Thymic Epithelial Tumors (TETs). Angiogenesis plays an important role in TETs: VEGF is overexpressed in TETs, and associated with aggressiveness and advanced stage. Etoposide inhibits angiogenesis *in vitro* and *in vivo* by decreasing VEGF production and microvessel density. The aim of this study is to assess the activity of metronomic oral etoposide, with identification of circulating predictive and pharmacodynamics biomarkers. **Methods:** Patients with advanced platinum pretreated TET referred from 2014 to 2019 at Rare Tumors Reference Center of Naples, were prospectively enrolled in this study. Oral etoposide 50 mg daily for 3 weeks on and 1 week off every 28 days, has been delivered until progression of disease, complete response or unacceptable toxicity. Response rate (RR), progression free survival (PFS), toxicity and ratio between time to etoposide progression (TTPe) and time to previous best treatment progression (TTPp) were evaluated. Serum samples were prospectively obtained from ten patients with simultaneously radiological assessment. cfDNA quantification was assessed using Qubit Fluorometric Quantitation. **Results:** 21 patients were enrolled: median age 59 years range (41 - 88); 70% male, 60% T (4 B1, 3 B2, 4 B3, 1 B1-B2); 40% had TC. A median of 5 (range 1-9) prior therapy regimens had been administered. Median follow-up since etoposide was 5 years (range 0.5-5). Obtaining an overall response rate of 85%, 3 patients achieved complete response and 15 partial response. Median PFS was 16 months [95%CI 3-60] with respectively a median PFS of 12 for T (95%CI 3-38) and 19 for TC (95%CI 6-60). No grade 3-4 related events occurred, G1-2 myelotoxicity has been registered in 20% of patients. Therapy is still ongoing for 15 patients and all are still alive. Median TTPe was 16 months, TTPp was 9 months and TTPe / TTPp ratio equal to 1.7. The median cfDNA of 8 responder patients, before starting therapy, was 2.2 ng/μl (0.178-5.24), dropping dramatically at radiological response to 0.5 ng/μl (0.323-2.56). 2 out of 3 non-responder patients had a median baseline value of 2.49 ng/μl, increasing to 4.6 ng/μl at progression. Variation of circulating VEGF correlates with radiological response. **Conclusions:** Taking into account that other antiangiogenic drugs, showing some activity in second and further lines treatment, are very expensive and associated with several side effects, we suggest that low dose oral etoposide might become the preferred treatment option in heavily pretreated TETs. Research Sponsor: CRCTR (Reference Rare Tumors Center of Campania Region).

TPS9075 Poster Session (Board #268), Fri, 8:00 AM-11:00 AM

CANOPY-A: A phase III, multicenter, randomized, double-blind, placebo-controlled trial evaluating canakinumab as adjuvant therapy in patients (pts) with completely resected non-small cell lung cancer (NSCLC). *First Author: Edward B. Garon, David Geffen School of Medicine, University of California/TRIO-US Network, Los Angeles, CA*

Background: In the CANTOS study, canakinumab (selective IL-1β inhibitor) treatment was associated with reduced incidence and mortality from NSCLC in pts with stable post-myocardial infarction with elevated high-sensitivity C-reactive protein (hs-CRP) levels. In CANOPY-A study, we investigate the therapeutic role of canakinumab in NSCLC. **Methods:** The CANOPY-A study (NCT03447769) is evaluating the efficacy and safety of canakinumab as adjuvant therapy in adult pts with completely resected NSCLC. Pts with AJCC/UICC v.8 stages II–IIIA and IIIB (T $>$ 5 cm, N2), any histology, completely resected (R0) NSCLC who completed adjuvant cisplatin-based chemotherapy ($\geq$2 cycles) and radiotherapy (if applicable) are eligible. Pts must not have had prior neoadjuvant chemotherapy or radiotherapy. Pts (~1500) are randomized 1:1 to receive canakinumab (200 mg Q3W, SC) or placebo (Q3W, SC) for 18 cycles or until disease recurrence as determined by investigator, unacceptable toxicity, treatment discontinuation at the discretion of the investigator or patient, start of a new antineoplastic therapy, death, or loss to follow-up. Randomization is stratified by AJCC/UICC v.8 stage (IIA vs IIB vs IIIA vs IIIB with T $>$ 5 cm, N2 disease), tumor histology (squamous vs non-squamous), and region (western Europe and North America vs eastern Asia vs rest of the world). Primary objective: disease-free survival (DFS) per local investigator assessment. Secondary objectives: overall survival (OS), lung cancer specific survival, safety, pharmacokinetics, immunogenicity, and patient reported outcomes. Adult pts with stage IIA–IIIA, IIIB (N2 disease only) NSCLC who are candidates for complete resection surgery (and therefore prospective candidates for the main study) will be asked to participate in a biomarker sub-study to understand how resection may impact biomarkers involved in the IL-1β inflammatory pathway and mutations present in blood. In the sub-study, the levels of hs-CRP, other cytokines, and additional biomarkers in blood will be assessed at pre- and post-surgery (endpoint: summary statistics of hs-CRP and other pharmacodynamics [PD] biomarkers). For pts who will enroll in the main study, possible associations between pre- and post-surgery biomarker levels with canakinumab efficacy will be assessed (endpoint: DFS and OS by hs-CRP and other PD biomarkers). The CANOPY-A study is currently enrolling. As of Jan 13, 2020, there are 307 study locations. Clinical trial information: NCT03447769. Research Sponsor: Novartis.

TPS9076 Poster Session (Board #269), Fri, 8:00 AM-11:00 AM

Checkmate 77T: A phase III trial of neoadjuvant nivolumab (NIVO) plus chemotherapy (chemo) followed by adjuvant nivo in resectable early-stage NSCLC. *First Author: Tina Cascone, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although surgery for early NSCLC is potentially curative, 5-year overall survival (OS) rates for patients with stage IIA–IIIB disease are historically $<$ 50%, representing a population of high unmet need. Conventional neoadjuvant or adjuvant chemo provides only a 5% absolute improvement in OS at 5 years. A rational approach to improve survival in these patients is to eradicate micrometastatic disease and potentially induce anti-tumor immunity to minimize the risk of relapse with peri-operative regimens including NIVO, a fully human anti–programmed death receptor-1 antibody. Early phase trials indicate that NIVO-based regimens have the potential to deepen pathological responses and extend survival in this setting (Reuss JE et al. Poster presentation at ASCO 2019. Abstract 8524; Cascone T et al. Oral presentation at ASCO 2019. Abstract 8504; Provencio M et al. Oral presentation at WCLC 2019. Abstract OA13.05). Data from the phase 2 single-arm NADIM trial (NCT03081689) demonstrated the highly encouraging major pathological response (MPR) rate of 83% with neoadjuvant NIVO plus chemo followed by adjuvant NIVO in patients with resectable stage IIIA NSCLC (Provencio M et al. Oral presentation at WCLC 2019. Abstract OA13.05). These results require validation in a large randomized controlled study. CheckMate 77T (NCT04025879) is a phase 3, randomized, double-blind trial evaluating neoadjuvant NIVO plus chemo followed by adjuvant NIVO in resectable early stage NSCLC. **Methods:** Approximately 452 patients aged $\geq$ 18 years with resectable stage IIA–IIIB (T3N2 only) NSCLC, ECOG performance status 0–1, and available lung tumor tissue will be enrolled at 113 sites in North America, South America, Europe, Asia, and Australia. Patients with *EGFR/ALK* mutations, brain metastasis, prior systemic anti-cancer treatment or radiotherapy, and autoimmune disease are excluded. Patients will be randomized to receive neoadjuvant NIVO plus carboplatin- or cisplatin-based doublet chemo followed by surgery and adjuvant NIVO, or neoadjuvant placebo plus carboplatin- or cisplatin-based doublet chemo followed by surgery and adjuvant placebo. The primary endpoint is event-free survival, assessed by blinded independent central review. Secondary endpoints include OS, pathological complete response and MPR assessed by blind independent pathological review, safety and tolerability. The start date was September 2019. The estimated primary completion date is May 2023. Clinical trial information: NCT04025879. Research Sponsor: Bristol-Myers Squibb.

TPS9077 **Poster Session (Board #270), Fri, 8:00 AM-11:00 AM**

ALCHEMIST: Adjuvant targeted therapy or immunotherapy for high-risk resected NSCLC. *First Author: Jacob Sands, Lahey Hospital and Medical Center, Boston, MA*

Background: ALCHEMIST (Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trial) is a clinical trial platform of the National Cancer Institute that offers biomarker analysis for high-risk resected non-small cell lung cancer (NSCLC) to support randomized trials of novel adjuvant therapies within the National Clinical Trials Network (NCTN). EA5142, a trial of adjuvant nivolumab for patients (pts) without EGFR / ALK alterations, has completed enrollment. Given the survival benefit seen with 1st-line chemo-immunotherapy (chemo-IO) for advanced NSCLC without EGFR / ALK alterations, there was compelling rationale for the launch of a trial offering concurrent immunotherapy with adjuvant chemo. Here we report updated enrollment to ALCHEMIST as of Jan 14, 2020. **Methods:** ALCHEMIST includes a screening trial (A151216, 5362 registered) that enrolls pts with completely resected clinical stage IB ($\geq$4 cm)–IIIA (per AJCC 7) NSCLC. Tissue and blood are collected, biomarker testing includes EGFR sequencing, ALK FISH and PD-L1 IHC. 733 active sites are enrolling across the NCTN. Pts with EGFR mutations may enroll to adjuvant erlotinib vs observation (A081105, 352 randomized); those with ALK fusions may enroll to adjuvant crizotinib vs observation (E4512, 99 randomized). A trial offering adjuvant nivolumab vs observation regardless of PD-L1 status (EA5142, 935 randomized) recently completed enrollment. To support ongoing investigation of adjuvant immunotherapy, ALCHEMIST is adding A081801 (opens spring 2020). Pts will be randomized to one of 3 arms: chemo-IO with pembrolizumab during and after chemo vs sequential chemo followed by pembrolizumab vs chemo alone. Pts with pathological N2 nodes are eligible and can undergo postoperative radiotherapy after completing chemo. Pts are eligible if enrolled to A151216, negative for EGFR and ALK alterations, and with PD-L1 testing completed (required for stratification). Local testing for EGFR, ALK and PD-L1 will be accepted for enrollment; central testing will not delay randomization. Pts may not have received any therapy except surgery for the lung cancer and must be age $>$18, Eastern Cooperative Oncology Group performance status 0-1, have no active autoimmune disease requiring systemic treatment within 2 years, must not be pregnant or nursing, have no active second malignancy within 3 years and meet standard organ function values. By building off the ongoing ALCHEMIST platform, we hope to facilitate rapid enrollment to A081801 across participating NCTN sites. Clinical trial information: NCT02194738. Research Sponsor: U.S. National Institutes of Health.

TPS9078 **Poster Session (Board #271), Fri, 8:00 AM-11:00 AM**

Trial in progress: Neoadjuvant immune checkpoint blockade in resectable malignant pleural mesothelioma. *First Author: Joshua E. Reuss, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: While the role of surgery in limited-stage (stage I-III) malignant pleural mesothelioma (MPM) is controversial, many centers have adopted an aggressive tri-modality approach incorporating (neo)adjuvant chemotherapy, surgical resection and radiotherapy. Despite this, most patients relapse and die from their disease. Immune checkpoint blockade (ICB) has shown promise in advanced MPM, but the mechanisms of response and resistance remain elusive. Improving the mechanistic understanding of ICB in MPM while concurrently optimizing the treatment strategy for limited-stage MPM are two urgent unmet needs. This multicenter multi-arm phase I/II study seeks to evaluate the safety and feasibility of neoadjuvant ICB in resectable MPM, incorporating novel genomic and immunologic analyses to deliver mechanistic insight into the biology of ICB in MPM. **Methods:** Patients with surgically resectable stage I-III treatment-naïve epithelioid or biphasic MPM receive neoadjuvant treatment with nivolumab every 2 weeks for 3 doses with or without 1 dose of ipilimumab (arm A: nivolumab monotherapy; arm B: nivolumab + ipilimumab). After macroscopic complete resection, patients receive optional investigator-choice adjuvant chemotherapy +/- radiation. Following this, patients will receive up to 1 year of adjuvant nivolumab. Feasibility and safety are co-primary endpoints of this study with feasibility defined by a delay in surgery of $\leq$24 days from the preplanned surgical date and safety defined by adverse events according to CTCAE v5.0. Bayesian-designed stopping rules have been implemented for feasibility and safety. Secondary endpoints include assessment of pathologic response and radiographic response using RECIST 1.1 for MPM. Correlative analyses will be performed on tissue specimens obtained pre- and post-ICB, as well as blood obtained pre, during, and post-ICB. Key correlates include multiplex immunofluorescence and longitudinal ctDNA assessment. Whole exome sequencing, T-cell receptor sequencing, and the MANAFEST functional neoantigen assay will be utilized to identify neoantigen-specific T-cell clonotypes and track these clonotypes temporally (during/post ICB) and spatially (across immune compartments). Single-cell RNA sequencing will be used to characterize the functionality of expanded T-cell clonotypes. Accrual to arm B will commence following complete accrual to arm A with a planned total enrollment of 30 patients. This study is open with 1 patient enrolled at the time of submission. Clinical trial information: NCT03918252. Research Sponsor: Bristol Meyers Squibb.

TPS9079 **Poster Session (Board #272), Fri, 8:00 AM-11:00 AM**

A phase III randomized trial of pleurectomy/decortication plus chemotherapy with or without adjuvant hemithoracic intensity-modulated pleural radiation therapy (IMPRINT) for malignant pleural mesothelioma (MPM) (NRG LU-006). *First Author: Andreas Rimner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pleurectomy/Decortication (P/D) with neoadjuvant or adjuvant chemotherapy has become a common lung-sparing surgical approach for MPM. Adjuvant hemithoracic IMPRINT was developed at Memorial Sloan Kettering Cancer Center and safe in a multi-institutional phase II study, with promising survival outcomes. The National Cancer Institute (NCI) sponsored this phase III randomized cooperative group trial to test the efficacy of this lung-sparing trimodality approach for resectable MPM. **Methods:** Patients with newly diagnosed MPM amenable to P/D are enrolled and undergo P/D followed by adjuvant platinum/pemetrexed (preferred) or neoadjuvant chemotherapy followed by P/D. Patients are stratified by histologic subtype, resection status (R0/1 vs. R2), and center patient volume ($\leq$10 vs. $>$ 10 P/Ds per year). Within 8 weeks after completion of the second modality patients are randomized 1:1 to undergo hemithoracic IMPRINT vs. no further therapy. All IMPRINT contours and treatment plans will be centrally reviewed. A contouring atlas and treatment planning constraints for target structures and organs at risk including acceptable and unacceptable variations and deviations were developed. Photon and proton therapy are permitted. The primary endpoint of the study is overall survival. Secondary endpoints include local failure-free, distant-metastases-free and progression-free survival, treatment-related toxicities (CTCAE v5.0) and change in quality-of-life (EORTC QLQ-C30 mean score changes at 9 months post randomization). The target accrual is 150 patients. This study was activated on January 29, 2020. Over 20 institutions have already committed to opening the study which is open to all National Clinical Trials Network (NCTN) sites. Treatment planning guidelines and helpful hints for photon and proton therapy will be presented. Conclusions: NRG LU-006 (clinicaltrials.gov: NCT04158141) is open to accrual. This is the first NRG Oncology randomized phase III trial on MPM and evaluates the use of IMPRINT following lung-sparing P/D and chemotherapy. This project was supported by grants U10CA180868 (NRG Oncology Operations), U10CA180822 (NRG Oncology SDMC), U24CA180803 (IROC) from the National Cancer Institute (NCI). Clinical trial information: NCT04158141. Research Sponsor: U.S. National Institutes of Health.

TPS9080 **Poster Session (Board #273), Fri, 8:00 AM-11:00 AM**

Phase I study of AMG 757, a half-life extended bispecific T-cell engager (HLE BiTE immune therapy) targeting DLL3, in patients with small cell lung cancer (SCLC). *First Author: Taofeek Kunle Owonikoko, Department of Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, GA*

Background: SCLC is an aggressive neuroendocrine tumor with poor prognosis and few treatment options. Delta-like ligand 3 (DLL3) is an inhibitory Notch ligand that is highly expressed on the surface of most SCLC tumors but minimally expressed in normal tissues. As such, DLL3 may be a promising therapeutic target. AMG 757 is an HLE BiTE immune therapy designed to redirect cytotoxic T cells to cancer cells by binding to DLL3 on cancer cells and CD3 on T cells, resulting in T cell activation and expansion and T cell-dependent killing of tumor cells. In addition to its direct antitumor effect, BiTE immune therapy can inflame the tumor microenvironment. Combining AMG 757 with a PD-1 pathway inhibitor may lead to increased antitumor activity by enabling sustained T cell-dependent killing of tumor cells. **Methods:** NCT03319940 is an open-label, ascending, multiple-dose, phase 1 study evaluating AMG 757 as monotherapy; the protocol was recently amended to also evaluate AMG 757 in combination with pembrolizumab. The study will include a dose exploration (monotherapy and combination) followed by a dose expansion (monotherapy). Key eligibility criteria: adult patients with relapsed/refractory SCLC whose disease progressed or recurred after at least 1 platinum-based chemotherapy regimen, ECOG performance status 0–2, at least 2 measurable lesions per modified RECIST 1.1, no untreated or symptomatic brain metastases, and adequate organ function. Primary objectives are to evaluate safety/tolerability and determine the maximum tolerated dose or recommended phase 2 dose of AMG 757 as monotherapy and in combination with pembrolizumab. Secondary objectives are to characterize pharmacokinetics and evaluate preliminary antitumor activity; exploratory objectives are to assess immunogenicity and changes in biomarkers in blood and tumor tissue. In the dose exploration phase, dose escalation/de-escalation decisions will be guided by a Bayesian logistic regression model; backfill enrollment at dose levels deemed safe and tolerable will be allowed. The study is open and recruiting patients. Clinical trial information: NCT03319940. Research Sponsor: Amgen Inc.

TPS9081 **Poster Session (Board #274), Fri, 8:00 AM-11:00 AM**

RESILIENT part II: an open-label, randomized, phase III study of liposomal irinotecan injection in patients with small-cell lung cancer who have progressed with platinum-based first-line therapy. *First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Although small cell lung cancer (SCLC) is often sensitive to established first-line therapies, many patients relapse and develop drug resistance, and second-line therapies are limited. RESILIENT (NCT03088813) is a two-part phase 2/3 study assessing the safety, tolerability, and efficacy of liposomal irinotecan monotherapy in patients with SCLC who progressed with platinum-based first-line therapy. Preliminary data from the dose-ranging part of the study (part 1) showed that liposomal irinotecan 70 mg/m^2 administered every 2 weeks was well tolerated and had promising antitumor activity (Paz-Ares *et al.* ASCO 2019; poster 318). Here, we present the design of the second, larger part of the study, which will evaluate the efficacy and safety of liposomal irinotecan versus topotecan in the same patient population. **Methods:** Part 2 of RESILIENT is a phase 3, open-label study with a planned sample size of 450. Patients are randomly allocated 1:1 to intravenous liposomal irinotecan or intravenous topotecan. Liposomal irinotecan is administered every 2 weeks at 70 mg/m^2 (free-base equivalent) and topotecan is administered for 5 consecutive days every 3 weeks at 1.5 mg/m^2. As of January 2020, 80 patients have been enrolled in part 2 of the trial. Tumor assessments are performed using the Response Evaluation Criteria in Solid Tumors version 1.1 and the Response Assessment in Neuro-oncology criteria for CNS lesions; symptom improvement is measured using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30. Safety assessments include monitoring for adverse events. The primary endpoint is overall survival (OS) and secondary endpoints are progression-free survival (PFS), objective response rate, and proportion of patients reporting symptom improvement. Patients will continue study treatment until disease progression, unacceptable toxicity or study withdrawal and will then be followed for survival until death or study end (when all patients have died, withdrawn consent or are lost to follow-up). Clinical trial information: NCT03088813. Research Sponsor: Ipsen.

TPS9082 **Poster Session (Board #275), Fri, 8:00 AM-11:00 AM**

NRG Oncology/Alliance LU005: A phase II/III randomized clinical trial of chemoradiation versus chemoradiation plus atezolizumab in limited stage small cell lung cancer. *First Author: Helen J. Ross, Mayo Clinic Arizona, Phoenix, AZ*

Background: Limited stage small cell lung cancer (LS-SCLC) is treated with standard of care platinum/etoposide (EP) and thoracic radiation therapy (TRT) with curative intent, however the majority of patients are not cured and median overall survival is approximately 30 months. Addition of atezolizumab to chemotherapy in extensive stage SCLC has improved progression free and overall survival in a non-curative setting leading to hope that addition of an immune checkpoint inhibitor to standard chemoradiotherapy could benefit LS-SCLC patients. LU005 is a randomized phase II/III trial of standard concurrent chemoradiation with or without atezolizumab for patients with LS-SCLC. **Methods:** Patients are randomly assigned in a 1:1 ratio to standard EP chemotherapy with concurrent TRT (45 Gy BID or 66 Gy QD) with or without atezolizumab beginning concurrently with TRT, and continued every 3 weeks for up to 12 months. Eligible patients have LS-SCLC, PS 0-2, adequate organ function, no concerning comorbidities (including no active autoimmune disease) and are eligible for TRT. Patients are randomized prior to their second cycle of EP and thoracic radiation begins with the second overall cycle of chemotherapy (first cycle of study therapy) in both treatment arms. Prophylactic cranial radiation (PCI) is recommended for patients who respond to treatment. The phase II/III primary endpoints are progression free (PFS) and overall survival (OS) respectively. Secondary endpoints include objective response rates, local and distant disease control, and quality of life/patient reported outcomes assessment. Translational science component includes blood and tissue based immune related assays. This study activated in May 2019. 50 of 506 planned patients have been accrued as of 2/1/2020. Supported by grants U10CA180868 (NRG Oncology Operations), U10CA180822 (NRG Oncology SDMC), U23CA180803 (IROC) from the National Cancer Institute (NCI) and Genentech. *Authors Ross and Higgins are co-first authors and contributed equally to this work. Clinical trial information: NCT03811002. Research Sponsor: U.S. National Institutes of Health.

TPS9083 **Poster Session (Board #276), Fri, 8:00 AM-11:00 AM**

A phase III trial-in-progress called REPLATINUM that compares RRx-001 + a platinum doublet to a platinum doublet in third-line or beyond small cell lung cancer. *First Author: Daniel Morgensztern, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Despite several recent checkpoint inhibitor approvals extensive stage small cell lung cancer (SCLC) is associated with a poor prognosis and remains an area of high unmet need. RRx-001 is a first-in-class, minimally toxic small molecule immunotherapeutic that inhibits c-Myc, downregulates the antiphagocytic checkpoint, CD47, repolarizes tumor associated macrophages (TAM) from protumor M2 to antitumor M1 and resensitizes to previously active first line therapies. On the basis of favorable results from a Phase 2 trial called QUADRUPLE THREAT (NCT02489903) in combination with a platinum doublet in later line SCLC, a Phase 3 trial called REPLATINUM was started in 3rd line or beyond SCLC in Q4 2019. Enrollment is ongoing. **Methods:** This US-based, open-label, randomized, phase 3 study (NCT03777657) compares RRx-001 4mg + a platinum doublet (carboplatin or cisplatin + etoposide) versus a platinum doublet for pts with 3rd line or beyond SCLC that have previously received a checkpoint inhibitor. Approximately 120 pts from 25 centers will be randomized 1:1 to receive RRx-001 4 mg in combination with a platinum doublet vs. a platinum doublet. The platinum doublet will be administered on both arms for up to 4 cycles; on the RRx-001 arm only patients with stable disease or better are eligible to continue on RRx-001 4 mg + carboplatin AUC 2-4 maintenance therapy. If radiologic progression occurs on the control arm prior to the 4th cycle, patients are eligible to crossover to the RRx-001 treatment arm. PFS is the primary endpoint. Secondary endpoints include OS and ORR. Exploratory endpoints include c-Myc, CD-47 and PD-L1 on circulating tumor cells and SIRP-alpha expression on circulating monocytes. Clinical trial information: NCT03777657. Research Sponsor: EpicentRx.

TPS9084 **Poster Session (Board #277), Fri, 8:00 AM-11:00 AM**

A phase Ib/II study of niraparib plus temozolomide plus atezolizumab versus atezolizumab as maintenance therapy in extensive-stage small cell lung cancer (TRIO-US L-06). *First Author: Amy Lauren Cummings, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA*

Background: Maintenance therapy is a promising therapeutic approach for extensive-stage small cell lung cancer (ES-SCLC), especially in light of IMpower 133 (Horn NEJM 2018). SCLC models of poly (ADP-ribose) polymerase (PARP) protein 1 and 2 inhibition suggested synergy with temozolomide (TMZ) (Wainberg AACR 2016). Combining PARP inhibition and TMZ with atezolizumab after first-line therapy for ES-SCLC may improve disease control. **Methods:** This is a phase 1b/2, randomized, open-label study of TMZ plus niraparib, a PARP inhibitor, with atezolizumab versus atezolizumab as maintenance therapy in adult patients with ES-SCLC after completion of platinum-based first-line chemotherapy. The primary outcome for phase 1b is the RP2D of TMZ in combination with niraparib, and for phase 2, progression-free survival (PFS). Secondary endpoints include safety, objective response rate, and overall survival. Exploratory endpoints include adverse events and patient-reported outcomes, including health-related quality of life. Phase 1b participants are required to have an advanced and incurable solid malignancy. Part one of phase 1b includes an accelerated lead-in of 12 participants treated in cohorts of 6 with an initial dose level of niraparib 200 mg po daily in 28-day cycles and low-dose TMZ 40 mg po daily on days 1-5 of each cycle. Part two includes a safety lead-in of 6 patients receiving standard-of-care atezolizumab, to which R2PD niraparib and TMZ will be added. For phase 2, participants are required to have ES-SCLC with a complete response or partial response per RECIST 1.1 following 4 to 6 cycles of platinum-based chemotherapy and ability to proceed to randomization within 7 weeks after day 1 of the last cycle of prior chemotherapy. Prophylactic WBRT is allowed prior to study. 52 participants will be stratified by a history of brain metastases and randomized 1:1 to atezolizumab with or without RP2D niraparib plus TMZ. There will be no crossover between arms. To date, cohort 1 had two DLTs. Enrollment to dose level -1 and an intermediate dose have been completed without a DLT. The atezolizumab safety lead-in begins enrollment in March 2020. Clinical trial information: NCT03830918. Research Sponsor: TESARO/GSK.

9500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Nivolumab + ipilimumab versus platinum-doublet chemotherapy as first-line treatment for advanced non-small cell lung cancer: Three-year update from CheckMate 227 Part 1. *First Author: Suresh S. Ramalingam, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: In the phase 3 CheckMate 227 Part 1 (NCT02477826; minimum follow-up, 29.3 mo), 1L NIVO + IPI significantly improved overall survival (OS) vs chemo in treatment-naive patients (pts) with aNSCLC and tumor PD-L1 expression ≥ 1% (primary analysis) or < 1% (pre-specified descriptive analysis). Here we report data with 3-y minimum follow-up. **Methods:** Pts with stage IV / recurrent NSCLC and PD-L1 ≥ 1% (n = 1189) were randomized 1:1:1 to NIVO (3 mg/kg Q2W) + IPI (1 mg/kg Q6W), NIVO (240 mg Q2W) alone, or chemo. Pts with PD-L1 < 1% (n = 550) were randomized to NIVO + IPI, NIVO (360 mg Q3W) + chemo, or chemo. Primary endpoint was OS with NIVO + IPI vs chemo in pts with PD-L1 ≥ 1%. An exploratory analysis of OS in pts by response status (CR/PR, SD, progressive disease [PD]) at 6 mo was conducted. **Results:** After a median follow-up of 43.1 mo (database lock, 28 Feb 2020), pts with PD-L1 ≥ 1% continued to derive OS benefit from NIVO + IPI vs chemo (HR: 0.79; 95% CI, 0.67–0.93); 3-y OS rates were 33% (NIVO + IPI), 29% (NIVO), and 22% (chemo). At 3 y, 18% of pts with PD-L1 ≥ 1% treated with NIVO + IPI remained progression-free vs 12% with NIVO and 4% with chemo; 38% of confirmed responders remained in response in the NIVO + IPI arm at 3 y vs 32% in the NIVO arm and 4% in the chemo arm. In pts with PD-L1 < 1%, OS HR for NIVO + IPI vs chemo was 0.64 (95% CI, 0.51–0.81); 3-y OS rates were 34% (NIVO + IPI), 20% (NIVO + chemo), and 15% (chemo); 13%, 8%, and 2% of pts remained progression-free; and 34%, 15%, and 0% of confirmed responders remained in response, respectively. Pts with PD-L1 ≥ 1% with either CR/PR at 6 mo had longer subsequent OS with NIVO + IPI vs chemo; pts with SD or PD at 6 mo had generally similar subsequent OS between treatments (Table); results in PD-L1 < 1% pts will be presented. Any-grade / grade 3–4 treatment-related AEs were observed in 77% / 33% of all pts treated with NIVO + IPI, and 82% / 36% with chemo. **Conclusions:** With 3 y minimum follow-up, NIVO + IPI continued to provide durable and long-term OS benefits vs chemo for pts in 1L aNSCLC. Pts with PD-L1 ≥ 1% who achieved CR/PR at 6 mo had marked OS benefit with NIVO + IPI vs chemo. No new safety signals were identified for NIVO + IPI. Clinical trial information: NCT02477826. Research Sponsor: Bristol-Myers Squibb and Ono Pharmaceutical.

Landmark analysis of OS by response status at 6 mo in pts with PD-L1 ≥ 1% (NIVO + IPI vs chemo).

Pts alive at 6 mo	Response status at 6 mo, %	Post-landmark 1-y OS rate, %	Post-landmark 2-y OS rate, %	Post-landmark 3-y OS rate, %

9501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Nivolumab (NIVO) + ipilimumab (IPI) + 2 cycles of platinum-doublet chemotherapy (chemo) vs 4 cycles chemo as first-line (1L) treatment (tx) for stage IV/recurrent non-small cell lung cancer (NSCLC): CheckMate 9LA. *First Author: Martin Reck, Department of Thoracic Oncology, Airway Research Center North, German Center for Lung Research, LungClinic, Grosshansdorf, Germany*

Background: NIVO + IPI was shown to improve overall survival (OS) and durability of response vs chemo in 1L advanced NSCLC in CheckMate 227 Part 1, regardless of PD-L1 expression. We hypothesized that a limited course of chemo combined with NIVO + IPI could provide rapid disease control while building on the durable OS benefit seen with dual PD-1 and CTLA-4 inhibition. CheckMate 9LA (NCT03215706) is a phase 3 randomized study evaluating NIVO + IPI + 2 cycles chemo vs chemo in 1L stage IV/recurrent NSCLC. **Methods:** Adults with tx-naive, histologically confirmed stage IV/recurrent NSCLC, ECOG performance status 0–1, and no known sensitizing *EGFR/ALK* alterations were randomized 1:1 to NIVO 360 mg Q3W + IPI 1 mg/kg Q6W + chemo (2 cycles) (n = 361) or chemo (4 cycles) alone (n = 358), stratified by PD-L1 (< 1% vs ≥ 1%), sex, and histology (squamous vs non-squamous). Chemo was based on histology. Pts with non-squamous NSCLC in the chemo-only arm could receive optional pemetrexed maintenance. Pts were treated with immunotherapy until disease progression, unacceptable toxicity, or for 2 y. The primary endpoint was OS; the interim analysis using Lan–DeMets alpha spending function with O'Brien–Fleming boundary was planned at ~80% information fraction (ie, after observing ~322 total events). Secondary endpoints included progression-free survival (PFS) and objective response rate (ORR) by blinded independent central review, and efficacy by PD-L1 subgroups. Exploratory endpoints included safety/tolerability. **Results:** Baseline characteristics were balanced across arms. At a preplanned interim analysis (minimum follow-up 8.1 mo), OS was significantly prolonged with NIVO + IPI + chemo vs chemo (HR 0.69, 96.71% CI: 0.55–0.87; $P = 0.0006$); statistically significant improvements in PFS and ORR were seen. With longer follow-up (minimum 12.7 mo), NIVO + IPI + chemo vs chemo continued to provide longer OS; median 15.6 vs 10.9 mo (HR 0.66, 95% CI: 0.55–0.80); 1-y OS rates were 63 vs 47%. Clinical benefit was consistent across all efficacy measures in key subgroups including by PD-L1 and histology. Grade 3–4 tx-related adverse events were reported in 47 vs 38% of pts in the NIVO + IPI + chemo vs chemo arms, respectively. **Conclusions:** CheckMate 9LA met its primary endpoint: a statistically significant improvement in OS was observed with NIVO + NSCLC-optimized IPI + a limited course of chemo vs chemo (4 cycles) in 1L advanced NSCLC. No new safety signals were reported. Clinical trial information: NCT03215706. Research Sponsor: Bristol-Myers Squibb and Ono Pharmaceutical.

9502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

CCTG BR.34: A randomized trial of durvalumab and tremelimumab +/- platinum-based chemotherapy in patients with metastatic (Stage IV) squamous or nonsquamous non-small cell lung cancer (NSCLC). *First Author: Natasha B. Leighl, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: First-line therapy for advanced NSCLC includes PD-1 checkpoint inhibitor (ICI) monotherapy, and in combination with chemotherapy. Combination ICI have also demonstrated better survival compared to chemotherapy (CM-227). In CCTG BR.34, we compared overall survival (OS) in patients with advanced NSCLC receiving first-line durvalumab plus tremelimumab (DT) with or without platinum doublet chemotherapy (CT). **Methods:** This international, open-label, randomized trial accrued 301 participants from Canada and Australia, with stage IV NSCLC, *EGFR/ALK* wildtype, ECOG PS 0/1. Patients were randomized to DT for 4 cycles or DT+CT (pemetrexed- or gemcitabine-platinum), with ongoing D or D + pemetrexed (non-squamous) maintenance until disease progression. Stratification factors included histology, stage IVA v. IVB and smoking status. The primary endpoint was OS; secondary endpoints included progression-free survival (PFS), objective response rate (ORR = CR + PR) and adverse events (AEs). **Results:** At a median follow up of 16.6 months, no significant difference in OS was seen between the two treatment arms, with a median OS of 16.6 months with DT+CT v. 14.1 months with DT, (estimated HR 0.88, 90% CI 0.67-1.16). PFS was significantly improved in the DT+CT arm (stratified HR 0.67, 95% CI 0.52-0.88; medians 7.7 v. 3.2 months). ORR was higher in the DT+CT arm, 28% v. 14%, (odds ratio 2.1, p=0.001). Preplanned subgroup analysis demonstrated no significant differences in treatment outcomes by plasma TMB (<20 v. ≥20 mut/Mb, Guardant OMNI), age, sex, or smoking status. There was a trend to improved OS with DT+CT in the subgroup with PD-L1 TPS≥50%, (HR 0.64, 95% CI 0.40-1.04, p=0.07). Plasma TMB<20 mut/Mb was associated with shorter survival in both treatment groups (HR 1.99, 95% 1.3-3.1). Toxicity was greater in the DT+CT arm, with grade≥3 adverse events in 82% v. 70%, (p=0.02), most commonly dyspnea, nausea and cough. The incidence of immune-related adverse events was similar between arms (colitis 11%, pneumonitis 6%, endocrinopathy 21%). Grade 5 events occurred in 2.7%, (5 with DT+CT, 3 with DT). **Conclusions:** The addition of CT to first-line DT did not improve OS in advanced NSCLC. CT+DT improved ORR and PFS, and was associated with greater toxicity. No differential effects were seen by PD-L1 TPS nor bTMB. These data suggest that adding chemotherapy to ICI may be beneficial in those with PD-L1 TPS >=50%, and warrant further analysis in independent datasets. Clinical trial information: NCT03057106. Research Sponsor: Canadian Cancer Society Research Institute, Pharmaceutical/Biotech Company.

9503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Primary analysis of a randomized, double-blind, phase II study of the anti-TIGIT antibody tiragolumab (tira) plus atezolizumab (atezo) versus placebo plus atezo as first-line (1L) treatment in patients with PD-L1-selected NSCLC (CITYSCAPE). *First Author: Delvys Rodriguez-Abreu, Hospital Universitario Insular de Gran Canaria, Las Palmas De Gran Canaria, Spain*

Background: The immunomodulatory receptor TIGIT is a novel inhibitory immune checkpoint present on activated T cells and NK cells in multiple cancers, including NSCLC. In a phase I study (GO30103), co-inhibition of TIGIT and PD-L1 signaling with tira plus atezo in CIT-naïve PD-L1 positive NSCLC potentially improved overall response rates (ORR) compared to historical ORR with PD-L1/PD-1 inhibitors. We conducted this phase II trial to confirm the efficacy and safety of tira plus atezo (TA) compared to placebo plus atezo (PA) in 1L NSCLC (GO40290, NCT NCT03563716). **Methods:** This prospective, randomized, double-blind, placebo-controlled trial enrolled patients (pts) with chemotherapy-naïve PD-L1+ (TPS ≥ 1% by 22C3 IHC pharmDx Dako assay) locally advanced or metastatic NSCLC with measurable disease, ECOG PS 0-1, and without *EGFR* or *ALK* alterations. Pts were randomized 1:1 to TA (tira 600 mg IV plus atezo 1200 mg IV) or PA (placebo plus atezo 1200 mg IV) on day 1 of every 3-week cycle. Stratification factors were PD-L1 status (TPS ≥ 50% vs TPS 1-49%), histology, and tobacco history. Co-primary endpoints were investigator assessed ORR and PFS, and additional endpoints were duration of response (DOR), OS, and safety. Exploratory endpoints were the effect of PD-L1 status on ORR and PFS. **Results:** 135 pts were randomized to PA (n = 68) or TA (n = 67). At primary analysis (30 Jun 2019), TA improved ORR and median PFS (mPFS) compared to PA, with median follow-up of 5.9 mo. In the safety population (68 in PA, 67 in TA), treatment-related AEs (TRAEs) occurred in 72% (PA) and 80.6% (TA); Grade ≥3 TRAEs occurred in 19.1% (PA) and 14.9% (TA). AEs leading to treatment withdrawal occurred in 10.3% (PA) and 7.5% (TA). Clinical trial information: NCT03563716. With an additional six months of follow-up since the primary analysis (2 Dec 2019, median follow-up of 10.9 mo), improvement in ORR and mPFS was maintained in ITT for TA (37.3% [25.0, 49.6] and 5.6 mo [4.2, 10.4]) vs PA (20.6% [10.2, 30.9] and 3.9 mo [2.7, 4.5]). The safety profile remained tolerable. **Conclusions:** Treatment with TA compared to PA showed clinically meaningful improvement in ORR and PFS in ITT. The safety profile of TA was similar to PA. 9504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Trastuzumab deruxtecan (T-DXd; DS-8201) in patients with HER2-mutated metastatic non-small cell lung cancer (NSCLC): Interim results of DESTINY-Lung01. *First Author: Egbert F. Smit, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: T-DXd is an antibody-drug conjugate composed of an anti-HER2 antibody, cleavable tetrapeptide-based linker, and topoisomerase I inhibitor payload. In a phase I trial, patients (pts) with HER2-mutated NSCLC who received T-DXd had a confirmed objective response rate (ORR) of 72.7% (8/11) (Tsurutani et al, WCLC 2018). DESTINY-Lung01 (NCT03505710) is an ongoing, multicenter, phase II study of T-DXd in pts with non-squamous NSCLC overexpressing HER2 or containing a HER2-activating mutation. We report data for the cohort with HER2 mutations after a median follow-up of 8.0 mo (range, 1.4-14.2 mo). **Methods:** Pts were treated with T-DXd 6.4 mg/kg every 3 weeks. The primary endpoint was confirmed ORR (complete response [CR] + partial response [PR]) by ICR. Additional endpoints were disease control rate (DCR; CR + PR + stable disease), duration of response (DOR), progression-free survival (PFS), and safety. **Results:** At data cutoff (25 Nov 2019), 42 pts (64.3% female) had received T-DXd. Median age was 63.0 years (range, 34-83 years; $<$ 65 y, 59.5%); 45.2% had central nervous system metastases; ECOG performance status was 0 in 23.8% of pts and 1 in 76.2%. HER2 mutations were predominantly in the kinase domain (90.5%). Most pts (90.5%) had prior platinum-based chemotherapy and 54.8% had anti–PD-1 or –PD-L1 treatment; median number of prior treatment lines was 2 (range, 1-6). Median treatment duration was 7.75 mo (range, 0.7-14.3 mo); 45.2% of pts remained on treatment. Confirmed ORR by ICR among the 42 pts was 61.9% (95% CI, 45.6%-76.4%); median DOR was not reached at data cutoff; 16 of 26 responders remained on treatment at data cutoff; DCR was 90.5% (95% CI, 77.4%-97.3%); estimated median PFS was 14.0 mo (95% CI, 6.4-14.0 mo). All pts (42/42) had treatment-emergent adverse events (TEAEs); 64.3% were grade $\geq$ 3 (52.4% drug-related), including decreased neutrophil count (26.2%) and anemia (16.7%). There were 5 cases (11.9%) of drug-related interstitial lung disease (ILD) as adjudicated by an independent committee (all grade 2, no grade $\geq$ 3) and 1 case of grade 1 ILD is pending adjudication. TEAEs led to dose interruption in 25 pts (59.5%), dose reduction in 16 pts (38.1%), and treatment discontinuation in 10 pts (23.8%). **Conclusions:** T-DXd demonstrated promising clinical activity with high ORR and durable responses in pts with HER2-mutated NSCLC. The safety profile was generally consistent with previously reported studies. Clinical trial information: NCT03505710. Research Sponsor: Daiichi Sankyo, Inc.

9505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Efficacy and safety of the antibody-drug conjugate (ADC) SAR408701 in patients (pts) with non-squamous non-small cell lung cancer (NSQ NSCLC) expressing carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5). *First Author: Anas Gazzah, Department of Drug Development (DITEP), Gustave Roussy, Villejuif Cedex, France*

Background: We report updated safety and efficacy of DM4-conjugated anti-CEACAM5 ADC from the expansion part of the first-in-human study (NCT02187848; Gazzah A et al. J Clin Oncol. 2019;37:15, 9072) in 92 NSQ NSCLC pts. **Methods:** CEACAM5 expression was assessed by immunohistochemistry on archived tumor samples. Two cohorts of pts have been analyzed: moderate and high expressors, with CEACAM5 expression at $\geq$2+ intensity between $\geq$1% to $<$ 50% and $\geq$50% of the tumor cell population, respectively. SAR408701 was administered at 100 mg/m^2 IV every 2 weeks. Tumor assessments were done every 4 cycles (8 weeks). Primary endpoint was overall response rate (ORR). **Results:** As of January 2020, 92 pts were treated: 28 moderate and 64 high expressors, with median age 62.5 years (31–91; 42.4% of pts $\geq$65), 51.1% male, 71.7% ECOG PS $\geq$1; median of 3 prior treatments (1–10 lines) for advanced disease, including anti-tubulin agents (60.9%) and anti-PD1/PD-L1 (75%). In the moderate expressor cohort, 2 confirmed partial responses (PR) were observed (ORR 7.1%). In the high expressor cohort, 13 pts had confirmed PRs (ORR 20.3% [95% confidence interval 12.27%–31.71%]); 27 (42.2%) had stable disease; ORR of 17.8% was observed in 45 pts who had prior anti-PD1/PD-L1. Pts had a median of 7 (1–49) cycles; median relative dose intensity was 0.98. Six pts discontinued due to treatment-emergent adverse events (TEAEs). Most frequent TEAEs (all grades) were asthenia (38.0%), keratopathy/keratitis (38.0%), peripheral neuropathy (26.1%), dyspnea (23.9%), and diarrhea (22.8%). 31 pts had dose modification due to a TEAE, including dose reduction for keratopathy/keratitis in 10 pts. Hematological toxicity included leukopenia (14.4%), neutropenia (4.4%), and thrombocytopenia (13.3%). Grade $\geq$3 TEAEs occurred in 47.8% of pts and were assessed as drug-related in 15.2%. **Conclusions:** SAR408701 shows promising antitumor activity in heavily pretreated advanced NSQ NSCLC pts with high CEACAM5 expression. SAR408701 was well tolerated, with minimal hematological toxicity compared to conventional chemotherapy; keratopathy was reversible and manageable with dose modification. These data support the activity of SAR408701 in NSQ NSCLC CEACAM5 high expressors. A phase 3 trial evaluating the activity of CEACAM5-DM4 ADC monotherapy in comparison with docetaxel in NSQ NSCLC CEACAM5 high expressors after failure of standard first line chemotherapy and anti-PD1/PD-L1 is underway. Clinical trial information: NCT02187848. Research Sponsor: Sanofi.

9506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

NEJ026: Final overall survival analysis of bevacizumab plus erlotinib treatment for NSCLC patients harboring activating EGFR-mutations. *First Author: Makoto Maemondo, Iwate Medical University, Morioka, Japan*

Background: In NEJ026, a phase III trial comparing bevacizumab plus erlotinib (BE) to erlotinib monotherapy (E) for EGFR-mutated non-small-cell lung cancer (NSCLC), we demonstrated the progression-free survival (PFS) of BE was significantly superior to E (Saito et al. Lancet Oncol. 2019 May;20(5):625-635.). However overall survival analysis were immature at the cutoff date. **Methods:** Chemotherapy-naïve pts with advanced non-squamous NSCLC harboring EGFR-mutation were randomly assigned to receive either combination with erlotinib (150 mg daily) plus bevacizumab (15 mg/kg iv q3w) or erlotinib (150 mg daily). The primary endpoint was PFS. Secondary endpoints were OS, RR, safety, and QoL. **Results:** The 226 pts were assigned to BE (n=112) and E (n=114). For the follow-up OS analysis, the data cut-off date was 30 November 2019. Median follow up time was 39.2 months. Median OS was 50.7 months (95% CI, 37.3 months to not reached) with BE and 46.2 months (95% CI, 38.2 months to not reached) with E (hazard ratio, 1.00; 95% CI, 0.68 to 1.48). Twenty-nine patients (25.9%) in BE and twenty-six patients (23.2%) in E were treated by osimertinib as second line treatment. The median survival time between enrollment and progressive disease of second-line treatment (median PFS2) was 28.6 months (95% CI, 22.1 months to 35.9) with BE and 24.3 months (95% CI, 20.4 months to 29.1 months) with E (hazard ratio, 0.80; 95% CI, 0.59 to 1.10). In both arms, the median OS of patients with osimertinib second-line treatment were longer than other second-line chemotherapy groups [50.7 months (95% CI, 38.0 months to 50.7 months) vs 40.1 months (95% CI, 29.5 months to not reached), (hazard ratio, 0.645; 95% CI, 0.40 to 1.03), respectively. **Conclusion:** The additional effect of bevacizumab on erlotinib monotherapy for NSCLC with EGFR mutations gradually decreased in the order of PFS2 and survival, with no significant differences. Clinical trial information: UMIN000017069. Research Sponsor: Chugai Pharmaceutical.

Concurrent osimertinib plus gefitinib for first-line treatment of EGFR-mutated non-small cell lung cancer (NSCLC). *First Author: Julia K Rotow, Dana-Farber Cancer Institute, Boston, MA*

Background: First-line treatment with an EGFR tyrosine kinase inhibitor (TKI) is standard of care for patients (pts) with *EGFR*-mutated NSCLC. The EGFR TKI osimertinib is active against the acquired gefitinib-resistant mutation *EGFR* T790M, as is gefitinib against the osimertinib-resistant *EGFR* C797S. Preclinical evidence suggests dual EGFR inhibition with gefitinib + osimertinib may delay emergence of acquired resistance. **Methods:** This ongoing phase I/II study enrolled pts with stage IV *EGFR*-mutated (L858R or del19) NSCLC, without prior therapy for metastatic disease. Treatment in dose escalation (n = 6): concurrent osimertinib 40 mg or 80 mg + gefitinib 250 mg daily. In dose expansion (n = 21): osimertinib + gefitinib at the maximum tolerated dose (MTD). Prior to protocol amendment 6 pts received alternating monthly cycles of TKI monotherapy and were excluded from this analysis. The primary endpoints in the dose escalation and expansion phases were, respectively, identification of the MTD and feasibility, defined as receipt of combination therapy for $\geq$ 6 four-week cycles. Secondary endpoints included overall response rate (ORR), survival outcomes, plasma *EGFR* mutation clearance (cell free DNA by droplet digital PCR (ddPCR)), and mechanisms of acquired resistance. **Results:** From May 2017 to July 2019 27 pts were enrolled and evaluable for the primary endpoints. The MTD was osimertinib 80 mg plus gefitinib 250 mg orally daily. In feasibility analysis, 81.5% completed $\geq$6 cycles combination therapy (1 pt discontinued for progression, 4 for toxicity). The ORR was 85.2% (95% CI 67.5%-94.1%). Best response: 85.2% partial response, 14.8% stable disease. The most common treatment-related adverse effects (TRAEs) (% any grade, % grade 3) were rash (96.3%, 3.7%), diarrhea (85.2%, 11.1%) and dry skin (70.4%, 0%). Plasma ddPCR (n = 25 pts) detected the driver *EGFR* mutation at baseline in 68% of pts. In these pts, plasma *EGFR* cleared to undetectable at 2 weeks treatment in 82.4%. At 14.8 months median follow up the median progression free survival was not yet reached. **Conclusions:** Combination therapy with osimertinib and gefitinib is tolerable for first-line treatment of *EGFR*-mutated NSCLC and resulted in rapid plasma clearance of the *EGFR* mutation. The observed ORR is consistent with previously reported first-line response rates to osimertinib. Analysis of survival outcomes and acquired resistance mechanisms are pending data maturity and will facilitate understanding of the role of first-line dual EGFR TKI therapy for this pt population. Clinical trial information: NCT03122717. Research Sponsor: AstraZeneca, U.S. National Institutes of Health.

9508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

First-line tyrosine kinase inhibitor with or without aggressive upfront local radiation therapy in patients with EGFRm oligometastatic non-small cell lung cancer: Interim results of a randomized phase III, open-label clinical trial (SINDAS) (NCT02893332). *First Author: Xiaoshan Wang, Cancer Center Hospital of University of Electronic Science and Technology of China and Sichuan Provincial People's Hospital, Chengdu, China*

Background: The effectiveness of aggressive local therapy for oligometastatic non-small-cell lung cancer (NSCLC) is unknown. This multi-institutional, randomized, open label, phase III clinical trial was performed to assess upfront stereotactic radiotherapy to all sites at diagnoses in previously untreated EGFRm oligometastatic non-small-cell lung cancer on progression-free survival and overall survival. **Methods:** The study was conducted at five centers located in different provinces of China.Eligible participants had pathologically confirmed adenocarcinoma, gene sequencing confirmed EGFRm, stage IV, five or fewer metastatic disease lesions, an ECOG performance status score of ≤ 2, systemic therapy naive, and no brain disease before randomization.Participants were randomized to receive either first-line tyrosine kinase inhibitor (TKI) treatment alone or up front stereotactic radiotherapy to all sites of disease along with TKI treatment.The primary endpoint was progression-free survival and the secondary endpoint was overall survival. **Results:** From January 2016 to January 2019, 133 participants were enrolled, including 65 (48.8%) in the TKI arm who received standard of care TKI alone and 68 (51.1%) in the stereotactic radiotherapy sites at diagnosis arm who received stereotactic radiotherapy and TKI.At a median follow-up of 19.6 months (IQR 9.4 - 41.0), the median progression-free survival for tyrosine kinase inhibitor alone was 12.5 months, and for tyrosine kinase inhibitor and stereotactic radiotherapy was 20.20months, respectively (HR 0.6188 [95% CI 0.3949-0.9697], log rank $P < .001$). The median overall survival in the TKI alone arm was 17.40 months, and for TKI and stereotactic radiotherapy arm was 25.50 months, respectively (HR 0.6824 [95% CI 0. 4654-1.001], log rank $P < .001$). Adverse events were similar between groups, with no grade 5 or deaths due to treatment. Grade 3/4 adverse events with or without radiotherapy included pneumonitis (7.3% vs. 2.9%; $P > .05$) and esophagitis (4.4%vs. 3.0% $P > .05$). **Conclusions:** Upfront stereotactic radiotherapy to sites at diagnosis along with first line TKI improved both progression-free survival and overall survival significantly compared with TKI alone. This finding suggests aggressive local therapy to sites at diagnosis should be explored further in large cohort phase III trials as a standard treatment option in this clinical scenario. Clinical trial information: NCT02893332. Research Sponsor: National scienceand technology bureau [grant numbers 3035031263], Other Foundation.

9509 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Capmatinib in patients with high-level *MET*-amplified advanced non–small cell lung cancer (NSCLC): results from the phase 2 GEOMETRY mono-1 study. *First Author: Juergen Wolf, Center for Integrated Oncology, University Hospital Cologne, Cologne, Germany*

Background: In the ongoing, multicohort, phase 2 GEOMETRY mono-1 study, capmatinib (INC280) has shown efficacy in *METex14*–mutated NSCLC patients (pts) who were pretreated (cohort 4) or treatment (tx)-naïve (cohort 5b). Here, we report the efficacy and safety of capmatinib in pts with high-level *MET*-amplified (gene copy number [GCN] $\geq$10) advanced NSCLC who were either pretreated with 1 or 2 prior lines of systemic therapy (cohort 1a) or tx-naïve (cohort 5a). **Methods:** Adult pts ($\geq$18 years), ECOG PS 0–1 who had *ALK* and *EGFR* wt, stage IIIB/IV (any histology) *MET*-amplified NSCLC with GCN$\geq$10 received capmatinib 400 mg twice daily (fasting). Primary and key secondary endpoints were overall response rate (ORR) and duration of response (DOR), respectively, by blinded independent review committee (BIRC) assessment per RECIST v1.1. Other secondary endpoints included investigator-assessed ORR, DOR, disease control rate (DCR), progression-free survival (PFS, BIRC and investigator assessment), overall survival, and safety. **Results:** As of Jan 06, 2020, 84 pts were evaluable for efficacy (cohort 1a [2nd/3rd line], 69 pts; Cohort 5a [1st line], 15 pts). Tx was ongoing for 3 pts in cohort 1a, none in cohort 5a. Per BIRC assessment in cohorts 1a and 5a, respectively, ORR was 29% and 40%, median DOR was 8.31 months (mo, 20 responders, 95% CI: 4.17–15.44) and 7.54 mo (6 responders, 95% CI: 2.56–14.26), and median PFS was 4.07 (95% CI: 2.86–4.83) and 4.17 (95% CI: 1.45–6.87) mo. Investigator assessment was in line with BIRC assessment (Table). The most common adverse events across all cohorts ($\geq$25%, all grades, N = 364) were peripheral edema (51.1%), nausea (44.8%) and vomiting (28.0%). Data for biomarker analysis and pts with brain metastasis will be presented at the ASCO 2020 meeting. **Conclusion:** Capmatinib has demonstrated activity in the subset of pts with high-level *MET*-amplified (GCN$\geq$10) NSCLC, with a higher response rate in tx-naïve pts. Safety profile remains favorable and similar to previous reports of capmatinib. Clinical trial information: NCT02414139. Research Sponsor: Novartis Pharmaceuticals.

9510 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Safety and preliminary clinical activity of the MET antibody mixture, Sym015 in advanced non-small cell lung cancer (NSCLC) patients with MET amplification/exon 14 deletion ($MET^{Amp/Ex14\Delta}$). *First Author: D. Ross Camidge, Medical Oncology Department, University of Colorado, Aurora, CO*

Background: Sym015, a mixture of 2 humanized antibodies, triggers MET degradation by a unique mechanism with superior specificity compared to tyrosine kinase inhibitors (TKIs). The Sym015-01 phase (P)1a trial met, the primary objective of identifying the recommended P2 dose (RP2D) as 18 mg/kg on cycle 1 day 1 followed by 12 mg/kg Q2W. The P2a was expanded to enroll $MET^{Amp/Ex14\Delta}$ NSCLC patients (pts) based on preliminary efficacy findings. Here we present interim safety (n = 45) and efficacy (NSCLC cohort, n = 20) results from P2a. **Methods:** The expansion NSCLC Cohort enrolled pts with $MET^{Ex14\Delta}$ (n = 12) or MET^{Amp} (n = 8 defined as $>$ 5 *MET* copies by NGS or *MET*/CEP7 ratio $>$ 2.2 updated to $\geq$3.0 by *in situ* hybridization; including 1 with $MET^{Amp+Ex14\Delta}$). Tumor *MET* status was confirmed centrally and longitudinal ctDNA was analyzed by Guardant360. **Results:** By January 2020, 45 pts (median age 61.7 years) have been treated in P2a. Median duration of exposure (DoE) was 3.8 months (m) (n = 45; range 0.4+ to 22 m). Treatment emergent adverse events occurred in 93%, treatment related AEs (TRAE) in 42.2% and TRAE $\geq$G3 in 13.3% pts. No pts discontinued or died due to TRAE. The most common TRAE in $\geq$10% pts were fatigue (13.3%) and peripheral edema (11.1%). Of 20 NSCLC pts, 5 had confirmed PR (ORR 25%; 2/8 MET^{Amp} and 3/12 $MET^{Ex14\Delta}$); 11 had SD (DCR 80%; 6/8 MET^{Amp} and 5/12 $MET^{Ex14\Delta}$); 2 had PD (2/12 $MET^{Ex14\Delta}$); and 2 were not evaluable. 10 NSCLC pts were MET TKI naive (7 MET^{Amp} and 3 $MET^{Ex14\Delta}$) and had 50% ORR and 100% DCR (5 PR and 5 SD; DoR range 1 to 18.3 m; DoE 1.5 to 22 m); 10 NSCLC pts were prior MET TKI treated (9 $MET^{Ex14\Delta}$ and 1 $MET^{Amp+Ex14\Delta}$) with DCR 60%, (6 SD; DoE 0.4-9.6 m). Median PFS was 5.5 m overall (95% CI 3.5-9.7 m). Median PFS for MET TKI naive and MET TKI pre-treated NSCLC pts was 6.5 m (95% CI 3.4-21.9 m) and 5.4 m (95% CI 1.2-9.7 m) respectively. Median OS was not reached for overall or for prior MET TKI subgroups. 89% $MET^{Ex14\Delta}$ tumor tissue to blood concordance (8/9 NSCLC pts) was observed. **Conclusions:** Sym015 was well-tolerated at the RP2D with a response rate similar to MET TKI in MET-treatment naïve $MET^{Amp/Ex14\Delta}$ NSCLC and seems to delay disease progression in MET TKI pretreated NSCLC pts. Combination with MET TKI to delay or prevent resistance should be further explored. Clinical trial information: NCT02648724. Research Sponsor: Symphogen A/S.

9511 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Characterization of 1,387 NSCLCs with MET exon 14 (METex14) skipping alterations (SA) and potential acquired resistance (AR) mechanisms. *First Author: Mark M. Awad, Massachusetts General Hospital, Cambridge, MA*

Background: *MET*ex14 SA are oncogenic drivers in NSCLC. Due to the numerous sites around ex14 that bind the spliceosome complex, many variations can result in deleterious alterations (alts). We present a comprehensive overview of these ex14 SA across 1,387 NSCLCs and characterized potential AR mechanisms. **Methods:** Hybrid-capture based comprehensive genomic profiling (CGP) was performed on samples from 60,495 NSCLC patients (pts). A scoring system was applied leveraging our large database of samples with METex14 SA to optimize accurate reporting of these variants. Paired samples were collected $\geq$ 60 days apart (median 462). **Results:** 1,393 *MET*ex14 SA were identified in samples (1,278 tissue, 109 circulating tumor DNA (ctDNA)) from 1,387 NSCLC pts (2.3%) spanning multiple functional sites: donor (42%), acceptor (4.7%), poly-pyrimidine tract (15%), acceptor and poly-pyrimidine tract (13%), D1010 (23%), Y1003 (2.1%), and whole exon deletions (0.3%). 6 samples (5 tissue, 1 ctDNA) harbored 2 *MET*ex14 SA, each including a mutation (mut) at the donor or acceptor site. *MDM2* and *CDK4* amplifications (amps) co-occurred in 32% and 19% of *MET*ex14 samples, respectively, but were more common with polypyrimidine tract (37% and 23%) vs donor site (32%, p = 0.07 and 18%, p = 0.07) alts. *MET* co-amp was present in 12% of cases and frequency did not significantly differ by functional site. 66 (4.8%) cases (57 tissue, 9 ctDNA) had known NSCLC co-drivers, including *KRAS* (68%) and *EGFR* (14%) mut, a subset of which may represent AR. Paired samples with a *MET*ex14 SA in the 1st sample were available for 36 pts. The *MET*ex14 SA was detected in the 2nd sample for 32 pts, excluding 3 with low ctDNA. 22/36 (61%) had reportable acquired alts detected including 9 with $\geq$1 acquired *MET* muts [D1228X (4), Y1230X (3), Y1003F (1), D1228A/E/H + L1195V (1)] and 3 with acquired *MET* amp. Other acquired alts included *ERBB2* amp and mut (1 each), *EGFR* ex19ins (1), *KRAS* amp (1), *PIK3CA* mut (1), *AKT2* amp (1) and others with unknown functional significance. Potential AR alts were present with primary *MET*ex14 SA spanning all functional sites. **Conclusions:** In a dataset of $>$ 60,000 advanced NSCLCs, *MET*ex14 SA were present in 2.3% of cases, and represented 6 major subtypes. Among paired cases, potential AR mechanisms included secondary *MET* alts (33%), and acquired alts in *EGFR*, *ERBB2*, *KRAS*, and PI3K pathways. Acquired alts were independent of the type of *MET*ex14 SA. Characterizing common co-occuring may be critical for predicting responses to MET inhibitors and informing rational combination strategies. Amivantamab (JNJ-61186372), an anti-EGFR-MET bispecific antibody, in patients with EGFR exon 20 insertion (exon20ins)-mutated non-small cell lung cancer (NSCLC). *First Author: Keunchil Park, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: EGFR exon20ins-mutated NSCLC is generally refractory to EGFR tyrosine kinase inhibitors (TKIs) and is associated with poor prognosis. Amivantamab (JNJ-61186372) is a novel, fully human anti-EGFR-MET bispecific antibody whose mechanism of action can target both EGFR- and MET-driven disease and has shown monotherapy activity in patients (pts) with diverse EGFR mutant disease characterized by EGFR C797S, T790M, exon20ins, and MET amplification. We present preliminary results of pts with advanced NSCLC harboring exon20ins mutations from CHRYSALIS, an ongoing phase 1 study of amivantamab (NCT02609776). **Methods:** This study comprises a dose escalation phase in pts with advanced NSCLC and a dose expansion phase in pts with EGFR- and MET-mutated disease. This analysis includes all enrolled pts with exon20ins disease who received the recommended phase 2 dose (RP2D) of 1050 mg (1400 mg, pts ≥80 kg) amivantamab. Response was assessed by investigator per RECIST v1.1. **Results:** As of 30 Oct 2019, 50 pts with exon20ins mutations had received amivantamab at the RP2D. 39/50 pts were response-evaluable and had ≥2 disease assessments or had discontinued therapy prior to the assessment period; among these pts, 29 had prior platinum-based chemotherapy (PBCT). Median age for response-evaluable pts was 61 y (40–78), 51% were female, and median prior lines was 1 (0–7). In the 50 pts harboring exon20ins mutations treated at the RP2D, the most common adverse events (AEs) reported were rash (72%), infusion related reaction (60%), and paronychia (34%). Additional EGFR-related AEs included stomatitis (16%), pruritus (14%), and diarrhea (6%). Grade ≥3 AEs were reported in 36% of pts; 6% were treatment-related. One grade 3 diarrhea and no grade ≥3 rash was reported. Among the 39 response-evaluable pts, with a median follow-up of 4 months (1–26), the overall response rate (≥partial response [PR]) was 36% (95% CI, 21–53), and 41% (95% CI, 24–61) for the 29 pts who had prior PBCT. The clinical benefit rate (≥PR or stable disease ≥11 weeks) was 67% for response-evaluable pts and 72% for pts who had prior PBCT. Among all 14 responders, median duration of response was 10 months (1–16), with ongoing responses in 9 pts at data cutoff. Median progression-free survival was 8.3 months (95% CI, 3.0–14.8) for response-evaluable pts and 8.6 months (95% CI, 3.7–14.8) for pts who had prior PBCT. **Conclusions:** Amivantamab demonstrates robust and durable antitumor activity in pts with exon20ins disease, with a manageable safety profile. Clinical trial information: NCT02609776. Research Sponsor: Janssen Research & Development, LLC.

ECOG-ACRIN 5162: A phase II study of osimertinib 160 mg in NSCLC with EGFR exon 20 insertions. *First Author: Zofia Piotrowska, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: EGFR exon 20 insertions (ins20), which comprise 4-10% of EGFR-mutant NSCLC, are generally refractory to first- and second-generation EGFR TKIs. While the clinical activity of the third-generation EGFR TKI osimertinib against EGFR ins20 is unknown, preclinical studies suggest its favorable therapeutic window may allow for inhibition of EGFR isn20 at clinically-achievable doses (Hirano, Oncotarget 2015). We report the results of EA5162, a single-arm, phase II study of osimertinib 160 mg in NSCLC pts with EGFR ins20 (NCT03191149). **Methods:** Pts with advanced NSCLC with an EGFR ins20 mutation identified by any local, CLIA-certified tissue assay were treated with osimertinib 160 mg daily until progression, intolerable toxicity or withdrawal. At least one prior line of therapy was required; stable, asymptomatic brain metastases were allowed. The primary endpoint was objective response rate (ORR). Secondary endpoints included safety, progression-free survival (PFS) and overall survival. The estimated sample size was 19 patients. **Results:** 21 pts were enrolled between 4/2018 and 7/2019 (median age 65; 15 female, 6 male; median 2 prior therapies); 1 patient did not meet eligibility criteria due to laboratory studies obtained 1 day out of window. As of 1/21/20, 6 pts remain on treatment. Among the 20 eligible pts, the best response was PR in 4 pts and CR in one pt, for a confirmed ORR of 25%; 12 (60%) pts had SD. The median PFS was 9.7 months (95% CI, 4.07, NA), median duration of response (DOR) was 5.7 months (95% CI, 4.73, NA.) Grade > 3 treatment-related adverse events (TRAE) observed in > 1 pt included anemia (n=2), fatigue (n=2), prolonged QT interval (n=2.) One pt had grade 4 respiratory failure, there were no grade 5 TRAEs. One pt discontinued study treatment due to grade 3 anemia. **Conclusions:** Osimertinib 160mg daily is well-tolerated and showed clinical activity in EGFR ins20-mutant NSCLC with a response rate of 25%, disease control rate of 85%, and mPFS of 9.7 months. The adverse events with osimertinib 160 mg QD in this cohort were consistent with other reports of this regimen; grade 3 rash and diarrhea were not observed. Clinical trial information: NCT03191149. Poziotinib shows activity and durability of responses in subgroups of previously treated EGFR exon 20 NSCLC patients. *First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment of non-small cell lung cancer (NSCLC) with EGFR exon 20 mutations is an unmet medical need. Poziotinib is a potent tyrosine kinase inhibitor (TKI) of EGFR and HER2 exon 20 insertion mutants. We evaluated the efficacy and safety of poziotinib in previously treated NSCLC patients with EGFR exon 20 insertion mutations in an independent cohort of a multi-cohort, multi-center Phase 2 study (*ZENITH20-1*). **Methods:** *ZENITH20-1* study enrolled pts with advanced NSCLC with an EGFR exon 20 insertion identified on local tissue testing who had received at least one prior line of therapy. Poziotinib (16 mg) was administered orally QD, allowing dose reductions for AEs, with follow up for 24 months. The primary endpoint was objective response rate (ORR), evaluated centrally by RECIST v1.1. Secondary endpoints included disease control rate (DCR), duration of response (DOR), progression-free survival (PFS) and safety. Efficacy was also evaluated by specific exon 20 insertions and prior lines of therapy. **Results:** 115 patients with a median age of 61 years (33-83) were enrolled. Patients had a median of 2 prior lines of therapy (range, 1-9.) The median relative dose intensity was 72% (7-100%) with 65% having dose reductions. The ORR in the as-treated population was 14.8% (95% CI 8.9 - 22.6%), and the DCR was 68.7% (95% CI 59.4 - 77.0%) with a median DoR of 7.4 months. 65% patients had tumor size reductions and the median PFS was 4.2 months. In the evaluable population (n = 88), the ORR was 19.3% and the unconfirmed ORR was 25%. Responses were predominantly observed in insertions between residues M766 to D770 of exon 20 (8/44; 18.2%). Responses were observed in patients with 2 lines (14%); ≥3 lines of therapy (16.2%). The most common treatment-related Grade ≥3 AEs were rash (28%), diarrhea (26%), stomatitis (9%) and paronychia (6%). The incidence of treatment-related pneumonitis was 4%, however some cases may have been confounded by prior checkpoint inhibitors as first line treatment. **Conclusions:** Although the ORR primary endpoint was not met, poziotinib induced tumor reduction in the majority of patients with durable responses, including the heavily pre-treated population. Responses were more common in patients with insertions between M766 to D770 of EGFR exon 20. The safety profile was overall consistent with other 2nd generation EGFR TKIs. Evaluation of these subgroups with refined dosing and improved toxicity management to maintain continuous treatment is warranted to assess the potential of poziotinib in Exon20 related tumors. Clinical trial information: NCT03318939. Research Sponsor: Spectrum Pharmaceuticals, Inc.

Registrational dataset from the phase I/II ARROW trial of pralsetinib (BLU-667) in patients (pts) with advanced RET fusion+ non-small cell lung cancer (NSCLC). *First Author: Justin F. Gainor, Massachusetts General Hospital, Boston, MA*

Background: Pralsetinib is an investigational, highly potent, selective RET kinase inhibitor targeting oncogenic RET alterations. We provide the registrational dataset for pts with RET fusion+ NSCLC with and without prior treatment from the global ARROW study. **Methods:** ARROW (75 sites in 11 countries; NCT03037385) consists of a phase I dose escalation to establish recommended phase II dose (400 mg once daily [QD] orally) and phase II expansion cohorts defined by tumor type and/or RET alteration. Primary objectives were overall response rate (ORR; blinded independent central review per RECIST v1.1) and safety. Efficacy analyses are shown for response-evaluable pts (REP) with RET fusion+ NSCLC who initiated 400 mg QD pralsetinib by July 11 2019 and safety for all pts (regardless of diagnosis) treated with 400 mg QD. **Results:** As of November 18 2019, 354 pts with advanced solid tumors had received pralsetinib at starting dose of 400 mg QD with median follow-up 8.8 months. ORR, disease control rate (DCR), and % of pts with tumor size reduction are shown in the table for pts with metastatic RET fusion+ NSCLC (n=116; 72% KIF5B; 16% CCDC6; 12% other/fusion present but type unknown) and with prior platinum treatment (n=80) or without prior systemic treatment (n=26). ORR was similar regardless of RET fusion partner, prior therapies, or central nervous system involvement. Overall there were 7 (6%) complete responses, 4 (5%) in prior platinum pts and 3 (12%) in treatment naïve pts; median time to response overall was 1.8 months and median duration of response (DOR) was not reached (95% CI, 11.3–NR). In the safety population (n=354), most treatment-related adverse events (TRAEs) were grade 1-2, and included increased aspartate aminotransferase (31%), anemia (22%), increased alanine aminotransferase (21%), constipation (21%) and hypertension (20%). 4% of pts in the safety population (all tumor types) discontinued due to TRAEs. **Conclusions:** Updated, registrational, centrally reviewed data demonstrate that pralsetinib has rapid, potent, and durable clinical activity in pts with advanced RET fusion+ NSCLC regardless of RET fusion genotype or prior therapies, and QD oral dosing is well-tolerated. Clinical trial information: NCT03037385. Research Sponsor: Blueprint Medicines Inc.

	Overall (n=116[a])	Prior platinum treatment (n=80)	No prior systemic treatment (n=26)

Intracranial activity of selpercatinib (LOXO-292) in RET fusion-positive non-small cell lung cancer (NSCLC) patients on the LIBRETTO-001 trial. *First Author: Vivek Subbiah, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with RET fusion-positive NSCLC have an ~50% lifetime prevalence of developing central nervous system (CNS) metastases. Selpercatinib is a highly selective oral RET inhibitor with CNS penetration. Its intracranial antitumor activity was previously demonstrated in an orthotopic RET fusion-positive preclinical model. The activity of selpercatinib in RET fusion-positive NSCLC patients with CNS metastases was evaluated as a prespecified subgroup analysis in LIBRETTO-001, a registrational phase 1/2 trial (NCT03157128). **Methods:** This global (89 sites, 16 countries) trial enrolled patients with advanced RET-altered solid tumors, including patients with RET fusion-positive advanced NSCLC with baseline CNS metastases. The selpercatinib recommended phase 2 dose was 160 mg twice daily, dosed orally in 28-day cycles. CNS metastases were assessed by MRI/CT scan at baseline, then every 8 weeks for 1 year, and every 12 weeks thereafter. The primary endpoint for this analysis was intracranial objective response rate (ORR, confirmed; RECIST v1.1) as assessed by independent review committee (IRC). Secondary endpoints included intracranial duration of response (DoR) by IRC. To be included in the efficacy analysis, patients were required to have adequate follow-up time (opportunity for ≥6 months follow-up from the first dose). Analyses were based on 17Jun2019 data cutoff date. **Results:** 79 patients with RET fusion-positive NSCLC and baseline CNS metastases were enrolled. Per IRC, 22 of 79 patients had measurable (≥10 mm) CNS disease; 14 of the 22 patients had adequate follow-up time for analysis. This efficacy-evaluable population had a median age of 64 yrs (range 43-80), ECOG PS 0/1 = 21% / 79%, and all had prior systemic therapy. 5 of the 14 patients received prior intracranial radiotherapy; all radiotherapy was completed > 2 months prior to selpercatinib. The intracranial ORR in the 14 patients was 93% (n = 13; 95% CI = 66.1 – 99.8), including 2 complete responses (14%) and 11 partial responses (79%). The median intracranial DoR was 10.1 months (95% CI = 6.7 – NE), with CNS progression events (n = 5) or death (n = 1) reported in 6 of 13 responders. The remaining responders (n = 7) were ongoing and censored. Presentation will include updated IRC data as of 16Dec2019. **Conclusions:** Selpercatinib had marked intracranial anti-tumor activity in RET fusion-positive NSCLC patients with CNS metastases. Tumor responses were durable, independently-confirmed, and observed in patients with prior systemic chemotherapy. Clinical trial information: NCT03157128. Research Sponsor: Loxo Oncology, a wholly owned subsidiary of Eli Lilly and Company.

Correlation of baseline molecular and clinical variables with ALK inhibitor efficacy in ALTA-1L. *First Author: D. Ross Camidge, Division of Medical Oncology, University of Colorado, Anschutz Medical Campus, Aurora, CO*

Background: Efficacy of ALK TKIs in patients (pts) with *ALK*+ non-small cell lung cancer (NSCLC) varies. We evaluated the impact of *EML4-ALK* fusion variants and other baseline (BL) molecular and clinical variables on clinical efficacy of brigatinib (BRG) vs crizotinib (CRZ) as first ALK TKI therapy in pts with *ALK*+ NSCLC in the phase 3 ALTA-1L (NCT02737501) trial. **Methods:** Plasma samples were collected at screening for molecular genetic analysis of *ALK* and other genes implicated in NSCLC by next-generation sequencing. Exploratory analyses were performed to identify associations of clinical outcomes with oncogenic alterations including *ALK* fusion variants and *TP53* status. **Results:** 124 BL samples were collected from 136 BRG-treated pts and 127 from 137 CRZ-treated pts. Pts with plasma samples were representative of the intent-to-treat population. BL *ALK* fusion detection rate was 52% (65/124) and 54% (68/127) in the BRG and CRZ arms, respectively, of which 83% (54/65) and 93% (63/68) were *EML4-ALK* fusions. In pts with detectable *EML4-ALK* fusions, the three predominant *EML4-ALK* fusion variants (V1, V2, V3) were equally distributed between arms; V1 and V3 were most prevalent (BRG/CRZ: V1, 42%/47%; V3, 42%/33%) but V1 was more frequent than V3 in pts without BL brain metastasis (47% vs 36%) or prior chemotherapy (45% vs 35%). Gender and age did not impact variant type. BRG showed higher ORR and improved mPFS vs CRZ in all variant subgroups; pts with V3 had poorer PFS compared with V1 and V2 regardless of treatment (Table). In pts with V3, BRG showed significantly improved PFS (HR=0.273, 95% CI 0.125, 0.597) and higher ORR (84% vs 67%) vs CRZ. *TP53* mutation was detected in 30% (37/124) of pts in BRG arm and 26% (33/127) in CRZ arm. In pts with detectable *ALK* fusion, *TP53* mutation showed poorer PFS in both arms than nonmutant/undetected cases (Table). BRG had better ORR and PFS vs CRZ in pts regardless of *TP53* mutation status. Additional analyses of BL variables are ongoing. **Conclusions:** *EML4-ALK* fusion variant 3 and *TP53* mutation were identified as poor prognosis biomarkers in *ALK*+ NSCLC. BRG demonstrated better efficacy than CRZ as first-line therapy in pts regardless of *EML4-ALK* fusion variant and *TP53* mutation status. These findings may help define areas of greatest unmet need. Clinical trial information: NCT02737501. Research Sponsor: ARIAD Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Updated overall survival (OS) and safety data from the randomized, phase III ALEX study of alectinib (ALC) versus crizotinib (CRZ) in untreated advanced *ALK*+ NSCLC. *First Author: Solange Peters, Lausanne University Hospital (CHUV), Lausanne University, Lausanne, Switzerland*

Background: Final, mature PFS from the global phase III ALEX study (NCT02075840) of ALC vs CRZ in untreated, advanced/metastatic *ALK*+ NSCLC have been previously published: ALC 34.8 months (m) (95% CI 17.7–NR) vs CRZ 10.9 m (95% CI 9.1–12.9), (HR 0.43, 95% CI 0.32–0.58). We report 5-year OS and updated safety data from ALEX with a further 12 m follow-up (FU) (cutoff date: Nov 29, 2019). **Methods:** Patients (pts) with stage IIIB/IV *ALK*+ NSCLC (by central IHC), ECOG PS 0–2 and no prior systemic therapy for advanced NSCLC were randomized 1:1 to ALC 600 mg BID (n = 152) or CRZ 250 mg BID (n = 151). Asymptomatic CNS metastases (mets) at baseline (BL) were allowed. OS was a secondary endpoint, and no formal statistical testing was planned. **Results:** Median duration of FU: 48.2 m with ALC vs 23.3 m with CRZ. OS data remain immature (events: 37%; stratified HR 0.67 [95% CI 0.46–0.98]); median OS with CRZ was 57.4 m (95% CI 34.6–not estimable [NE]) vs NE with ALC. The 5-year survival rate was 62.5% (95% CI 54.3–70.8) with ALC vs 45.5% (95% CI 33.6–57.4) with CRZ (Table). In pts with CNS mets at BL the OS HR was 0.58 (95% CI 0.34–1.00) and 0.76 (95% CI 0.45–1.26) in pts without CNS mets at BL. The OS benefit of ALC vs CRZ was generally consistent across all subgroups. Considering the longer treatment duration for ALC (28.1 m) vs the previous analysis (27.7 m), the safety profile of ALC remains consistent; no new safety signals were observed. With ALC, 35% of pts remain on study treatment vs 9% of pts remaining on CRZ. In pts with ≥1 known post-progression treatment (ALC: 32.2%; CRZ: 45.7%), lorlatinib was the most common ALK TKI received after first-line ALC (7.2%), compared with ceritinib after first-line CRZ (15.2%). **Conclusions:** This is the first global randomized study of a 2nd generation ALK TKI to demonstrate a clinically meaningful improvement in OS vs CRZ in *ALK*+ NSCLC (5-year survival rate: 62.5%, ALC vs 45.5%, CRZ); longer FU is required as OS data remain immature. Clinical trial information: NCT02075840. Research Sponsor: F. Hoffman-La Roche Ltd.

Phase II study of savolitinib in patients (pts) with pulmonary sarcomatoid carcinoma (PSC) and other types of non-small cell lung cancer (NSCLC) harboring MET exon 14 skipping mutations (METex14+). *First Author: Shun Lu, Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China*

Background: There are unmet medical needs for pts with METex14+ NSCLC. PSC is a rare type of NSCLC with high incidence of MET exon 14 mutations and poor prognosis. Savolitinib (AZD6094, HMPL-504, volitinib) is a highly selective oral MET tyrosine kinase inhibitor, and its anti-tumor activity has been shown in combination with osimertinib in pts with EGFR-mutant, MET-amplified NSCLC (Yu H, et al. 2019 AACR, Abstract CT032). **Methods:** This was a multicenter, multi-cohort, single-arm phase II study (NCT02897479) to evaluate the efficacy, safety, and pharmacokinetics of savolitinib in pts with unresectable or metastatic METex14+ PSC and other NSCLC. MET mutation was tested or retrospectively confirmed by central laboratory. Savolitinib was taken orally, once daily (QD) (600mg for weight ≥50kg or 400mg weight < 50kg) until disease progression or intolerable toxicity. Tumor was evaluated every 6 weeks during the 1st year and every 12 weeks thereafter. The primary endpoint was independent review committee (IRC) assessed objective response rate (ORR) (RECIST version 1.1). Here we report the results of one cohort of prior MET-treatment naïve patients. **Results:** As of October 31, 2019, 593 pts were pre-screened/screened, 87 identified with METex14+ and 70 treated. Among treated pts, median age was 68.7 years (range 51.7-85.0), 58.6% pts were male, 92.9% stage IV, 60.0% previously treated, 57.1% with adenocarcinoma, 35.7% with PSC and the rest with other pathological types. Sixty-one pts were efficacy evaluable by IRC assessment (N = 61) (including pts who had at least one measurable lesion at baseline and had ≥1 scheduled post-baseline tumor assessment or evidence of any post-baseline radiological disease progression): ORR was 47.5% (95% CI: 34.6%, 60.7%), disease control rate 93.4% (95% CI: 84.1%, 98.2%) and median duration of response not reached yet. The median progression-free survival was 6.8 months (95% CI 4.2, 13.8) among all treated pts. Efficacy results were consistent with investigators'assessments. The most common (≥20%) treatment-related adverse events (TRAEs) were peripheral edema, nausea, increased AST/ALT, vomiting and hypoalbuminemia. The incidence of ≥ grade 3 TRAEs was 41.4%. TRAEs leading to treatment discontinuation occurred in 14.3% pts, among which liver injury and hypersensitivity were most common (each 2.9%). **Conclusions:** Savolitinib demonstrated promising anti-tumor activity and acceptable tolerability in METex14+ NSCLC pts. Clinical trial information: NCT02897479. Research Sponsor: Hutchison MediPharma Limited.

Capmatinib in patients with *METex14*-mutated or high-level *MET*-amplified advanced non–small-cell lung cancer (NSCLC): results from cohort 6 of the phase 2 GEOMETRY mono-1 study. *First Author: Harry J.M. Groen, University of Groningen and University Medical Center Groningen, Groningen, Netherlands*

Background: Capmatinib (INC280) has shown promising efficacy in patients (pts) with *MET* exon 14 (*METex14*)–mutated NSCLC who were pretreated (cohort 4) or treatment (tx)-naïve (cohort 5b) in the ongoing, multicohort, phase 2 GEOMETRY mono-1 study. We report the results for pts enrolled in the expansion cohort 6 with either high-level *MET* amplification (gene copy number [GCN] ≥10) or *METex14* mutation (any *MET* GCN) whose disease progressed on 1 prior line of systemic therapy. **Methods:** Adult pts (≥18 years), ECOG PS 0–1 who had *ALK* and *EGFR* wt, stage IIIB/IV NSCLC (any histology) received capmatinib tablets 400 mg twice daily (with or without food). Key efficacy endpoints were overall response rate (ORR) and duration of response (DOR) by blinded independent review committee (BIRC) per RECIST v1.1. Other secondary endpoints included investigator-assessed ORR, DOR, disease control rate (DCR), progression-free survival (PFS; BIRC and investigator assessment) and safety. **Results:** As of Jan 6, 2020, 34 NSCLC pts with *METex14* mutation (n = 31) or high-level *MET* amplification (n = 3) were included in this analysis. Tx was ongoing for 38.2% of pts. In *METex14*-mutated NSCLC pts, per BIRC assessment: ORR was 48.4%, median DOR was 6.93 months (mo, not yet mature, 95% CI: 4.17–NE) and median PFS was 8.11 mo (not yet mature, 95% CI: 4.17–9.86). Investigator-assessed responses were similar to BIRC assessment (Table). Only 3 pts with high-level *MET* amplification were included in this cohort due to challenges in enrollment. All 3 pts had stable disease per BIRC assessment and were on treatment for 48, 85 and 97 days. Most common AEs (≥25%, all grades, N = 34) were peripheral edema (64.7%), nausea (35.3%), fatigue (29.4%), back pain (26.5%) and vomiting (26.5%). Data for pts with brain metastasis will be presented at the ASCO 2020 meeting. **Conclusions:** Capmatinib was confirmed to be efficacious in 2nd line, *METex14*-mutated NSCLC pts. This is the first cohort where capmatinib has been administered without fasting restriction and data confirm the favorable safety profile. Clinical trial information: NCT02414139. Research Sponsor: Novartis Pharmaceuticals.

Evaluation of blood TMB (bTMB) in KEYNOTE-189: Pembrolizumab (pembro) plus chemotherapy (chemo) with pemetrexed and platinum versus placebo plus chemo as first-line therapy for metastatic nonsquamous NSCLC. *First Author: Marina Chiara Garassino, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In a previous analysis of KEYNOTE-189 (NCT02578680), we showed that tissue TMB (tTMB) assessed by whole-exome sequencing was not significantly associated with efficacy in either arm and that pembro + chemo improved outcomes vs placebo + chemo in both the tTMB ≥175 and tTMB < 175 mut/exome subgroups. Here, we explored the association of bTMB with efficacy in KEYNOTE-189. **Methods:** 616 patients (pts) were randomized 2:1 to pembro + chemo or placebo + chemo. bTMB was assessed in cfDNA using the Guardant Health Omni assay. Association of bTMB (continuous square root transformed) with outcomes in each arm was assessed using Cox proportional hazards models (OS, PFS) and logistic regression (ORR) adjusted for ECOG PS; statistical significance was determined at the 0.05 level without multiplicity adjustment. The clinical utility of bTMB on outcomes was assessed using the cutoff that most closely approximated the 175 mut/exome tTMB cutoff as determined by AUROC analysis. Data cutoff was 21 Sep 2018. **Results:** 235 (38%) treated pts had evaluable tTMB and bTMB: 160 in the pembro + chemo arm and 75 in the placebo + chemo arm. bTMB as a continuous variable was not significantly associated with OS or ORR for pembro + chemo (one-sided P = .229 and .051) or placebo + chemo (two-sided P = .641 and .069); bTMB was significantly associated with PFS in the pembro + chemo arm (one-sided P = .015) but not the placebo + chemo arm (two-sided P = .058). bTMB and tTMB scores were moderately correlated (r = .61). The bTMB cutoff that most closely approximated tTMB 175 mut/exome was 15 mut/Mb (AUROC 0.81, 95% CI 0.75-0.86). 178 (76%) pts had concordant bTMB and tTMB results—101 low and 77 high by both—whereas 57 (24%) had discordant results—21 high bTMB but low tTMB, 36 low bTMB but high tTMB. Pembro + chemo improved OS, PFS, and ORR vs placebo + chemo for bTMB ≥15 and < 15 mut/exome (Table). **Conclusions:** Similar to previous findings based on tTMB, bTMB has limited clinical utility in the setting of pembro with pemetrexed and platinum given as first-line therapy for metastatic nonsquamous NSCLC. Clinical trial information: NCT02578680. Research Sponsor: Merck & Co., Inc., Kenilworth, NJ, USA.

Prevalence and association of *ARID1A* with driver alterations and immune checkpoint inhibitor (ICPi) biomarkers in cell-free circulating tumor DNA (ctDNA) from 27,000 non-small cell lung cancer (NSCLC) patients. *First Author: David R. Gandara, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Recent data suggest that the tumor suppressor gene *ARID1A* is associated with high anti-tumor immunity and may have value as a predictive biomarker for response to ICPi therapy in NSCLC. We examined *ARID1A* alterations detected in ctDNA from a large cohort of advanced NSCLC patients using a commercially available liquid biopsy assay and explored associations of *ARID1A* with lung cancer driver alterations and other putative ICPi mutational biomarkers. **Methods:** Consecutive samples from stage IIIB/IV NSCLC patients tested from March 2016 - August 2019 using a 73- to 74-gene targeted next-generation sequencing ctDNA assay (Guardant360) were queried. Testing included analysis of single nucleotide variants, insertions/deletions, fusions, and amplifications (*KEAP1* not tested). Mutation frequencies were compared using Fisher's exact test, with variants of uncertain significance and synonymous variants excluded. **Results:** Of 27,776 NSCLC patients with >1 ctDNA alteration detected, 1,094 (3.9%) had >1 functional *ARID1A* (f*ARID1A*) mutation. f*ARID1A* mutations were significantly more common in patients with squamous histology compared to adenocarcinoma (5.1% vs 3.8%, p = 0.0007). There were significantly fewer *EGFR* exon 19 deletion mutations (4.9% vs 11.1%; p < 0.0001) and *EGFR* L858R mutations (4.0% vs 7.0%; p < 0.0001), and significantly more *BRAF* V600E alterations (2.2% vs 1.4%; p = 0.0338) in patients with f*ARID1A*. There was no significant difference in the frequency of *ALK* and *ROS1* fusions, nor *STK11* mutations between patients with and without f*ARID1A* (8.0% vs 6.8%; p = 0.126). Activating *KRAS* mutations were significantly more frequent in patients with f*ARID1A* (31.1% vs 19.4%; p < 0.0001), including *KRAS* G12C (10.9% vs 7.0%; p < 0.0001). **Conclusions:** These data provide a mutational landscape for f*ARID1A* mutations in NSCLC. f*ARID1A* was associated with significant differences in the frequency of multiple lung cancer driver alterations, of particular interest in the *EGFR*-mutated cohort, where ICPi efficacy is low. The frequency of *STK11* mutations, a possible negative predictor of ICPi efficacy, was not significantly different. *KRAS* mutations were significantly more frequent in patients with f*ARID1A*, notable given recent data reporting that *KRAS* mutations, particularly *KRAS* G12C, may be a positive predictor of ICPi response in NSCLC. Determination of ICPi efficacy in patients with f*ARID1A* is in-process. Research Sponsor: None.

9524 Poster Session (Board #290), Fri, 8:00 AM-11:00 AM

PREDICT1: An observational study for identifying blood biomarkers associated with clinical benefit from carboplatin and pemetrexed (CbP) treatment in patients with non-squamous (NS) non-small cell lung cancer (NSCLC) (CJLSG1201). *First Author: Tetsunari Hase, Department of Respiratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: At present, platinum-doublet chemotherapy or in combination with an immune check point inhibitor are standard treatment for patients with metastatic or recurrent NSCLC which lacks somatic gene alterations. Although CbP is one of the commonly used treatment options for NS-NSCLC, its clinical utility is limited due to lack of optimal biomarkers. **Methods:** Chemotherapy-naïve patients with pathologically proven advanced or recurrent NS-NSCLC received carboplatin (area under the curve = 5-6, at investigator's discretion) plus pemetrexed (500 mg/m2) every 3 weeks followed by maintenance pemetrexed until disease progression. Blood samples were collected before treatment for proteomic analysis using mass spectrometry (MS). A classifier was constructed based on both an objective response assessed by radiologist independent of attending physicians in accordance with RECIST v1.1 and expression profiles of protein in a training cohort. The constructed classifier was then assessed with a validation cohort evaluating prediction accuracy of good responder, progression free survival (PFS) and overall survival (OS). **Results:** Of 244 patients with NS-NSCLC in a training cohort, proteomic profiles in blood from 96 patients who responded or progressed after treatment with CbP were analyzed to develop a classifier based on weighted voting. Details of the classifier will be presented at the 2020 ASCO Annual Meeting. The classifier was then applied to validation cohort (n = 94), and we successfully identified patients who benefit from the treatment (55 in good MS group) or not (39 in poor MS group). The objective response rate of the good MS group was significantly higher than that of the poor MS group (30.9% vs. 5.1%; p = 0.0018). The good MS group showed a significantly improved survival compared to the poor MS group (median PFS, 6.0 m vs. 2.3 m; hazard ratio [HR], 0.15; 95% confidence interval [CI], 0.09-0.27; p < 0.001; median OS, 25.7 m vs. 5.1 m; HR, 0.18; 95% CI, 0.1-0.34; p < 0.001). **Conclusions:** In the present study, we successfully developed and validated a predictive classifier using proteomic analyses with blood samples collected from patients before treatment with CbP, suggesting the clinical utility of the classifier in selecting NS-NSCLC patients for treatment with CbP. Clinical trial information: UMIN000008476. Research Sponsor: Japan Agency for Medical Research and Development.

9525 Poster Session (Board #291), Fri, 8:00 AM-11:00 AM

Comprehensive modeling of longitudinal circulating tumor DNA dynamics to predict clinical response to first-line immunotherapy and chemo-immunotherapy in advanced non-small cell lung cancer. *First Author: Joseph Christopher Murray, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD*

Background: First-line immunotherapy (IO) and chemo-immunotherapy (chemo-IO) are approved for PD-L1-expressing advanced non-small cell lung cancer (NSCLC), but PD-L1 expression does not reliably predict therapeutic response. Therefore, accurate on-therapy response assessment is needed to guide clinical decision-making. Conventional radiographic imaging is the gold-standard, but may not capture the nature and timing of an immune-mediated response. We investigated whether comprehensive longitudinal circulating tumor DNA (ctDNA) dynamics could enhance prediction of clinical response. **Methods:** We conducted targeted error correction sequencing (TEC-Seq) of longitudinal plasma specimens and matched white blood cells (WBCs) in patients with NSCLC treated with first-line IO or chemo-IO. Plasma ctDNA variants were identified by filtering out clonal hematopoiesis (CH) and germline (GL) variants found in matched WBCs. Clinical and pathological data, including PD-L1 tumor proportion score (TPS), and imaging response by RECIST1.1 were assessed. ctDNA dynamics were modeled to predict durable clinical benefit (at 6 months), progression-free survival (PFS), and overall survival (OS). **Results:** A total of 143 longitudinal plasma and 24 white blood cell samples underwent TEC-Seq for 31 patients with NSCLC treated with IO (n = 17) or chemo-IO (n = 14). ctDNA variants were found in 77% (n = 24) of patients after filtering out CH and GL variants, which comprised 53% (n = 196 of 373) of all variants. Molecular response, signified by elimination of ctDNA variants, was detected in 32% (n = 10) of patients and associated with improved PFS (p = 0.0004, log rank) and OS (p = 0.017, log rank). Time to molecular response was shorter than time to best RECIST response (median 3 vs. 7.71 weeks, p = 0.048, Mann-Whitney U test). A logistic regression model incorporating molecular response, recrudescence, or emergence of new variants predicted durable clinical benefit (sensitivity 84%, specificity 76%, AUC 0.88) better than PD-L1 TPS (AUC 0.67, p = 0.046, bootstrap method). **Conclusions:** Comprehensive modeling of ctDNA variant dynamics predicts clinical outcome independent of PD-L1 status in patients with advanced NSCLC treated with first-line IO or chemo-IO. Verification of bona fide ctDNA variants by matched WBC sequencing is essential. Molecular response can be identified earlier than imaging response and could enable on-therapy decision-making to alter clinical outcomes. 9526 Poster Session (Board #292), Fri, 8:00 AM-11:00 AM

Targeted DNA sequencing analysis to reveal genetic diversity and androgen-receptor alteration in advanced EGFR mutant lung adenocarcinoma. *First Author: Wei Wu, University of California, San Francisco, San Francisco, CA*

Background: Lung cancer remains the leading cause of death from cancer around the world. Several oncogenic drivers have been identified from large cancer genome projects focused mainly on profiling early-stage lung cancers. Targeted therapies have been developed for specific activated driver gene mutations and are used in advanced-stage patients. For instance, advanced EGFR mutant lung cancer is primarily treated with EGFR tyrosine receptor inhibitors (TKIs). However, resistance remains an obstacle to durable anti-tumor control. We hypothesize that concurrent genetic alterations co-exiting with EGFR driver mutations contribute to the failure of EGFR TKI therapy. **Methods:** To understand the complexity and diversity of genetic alterations present in EGFR mutant advanced lung cancers, we utilized 660 EGFR mutant advanced lung adenocarcinomas samples with targeted DNA sequencing from Foundation Medicine, 394 cases from MSK-IMPACT dataset, along with TCGA lung cancer data. We performed systematic co-mutation analysis, molecular simulation, functional annotation and pathway enrichment analysis. **Results:** We updated mutational profiling on EGFR gene with hotspots at exon 18, 19, 20 and 21. Among them, EGFR L858R, exon19 deletion, T790M and G719A are top ranking alleles among EGFR mutations. Interestingly, a subset (n = 26 cases) of EGFR T790M mutations parallel with other EGFR mutations, which could affect the TKI binding pocket as inferred by molecular simulations. Furthermore, in advanced lung cancer EGFR mutations co-occurred with known oncogenic mutations in KRAS, MET, NF-1, MAP2K1, ERBB2, and ALK/ROS-1/RET fusions. Functional annotation suggests that concurrent mutated genes and copy number alterations in advanced EGFR mutant lung cancer were enriched in signatures of epigenetic modifiers, genome instability, WNT signaling, and RNA splicing. Compared to early stage TCGA-lung adenocarcinomas, Cell cycle, DNA repair, WNT signaling and androgen receptor-mediated signaling pathways are predominantly altered in advanced EGFR mutant lung cancers. **Conclusions:** We characterized the genetic landscape of advanced EGFR-mutant lung adenocarcinomas and further dissected concurrent mutated genes with EGFR driver mutations. Our findings provide a rational for polytherapy roadmap for testing in advanced EGFR-mutant lung cancer. Research Sponsor: U.S. National Institutes of Health.

9527 Poster Session (Board #293), Fri, 8:00 AM-11:00 AM

RELAY study of erlotinib (ERL) + ramucirumab (RAM) or placebo (PL) in *EGFR*-mutated metastatic non-small cell lung cancer (NSCLC): Biomarker analysis using circulating tumor DNA (ctDNA) in Japanese patients (pts). *First Author: Kazuto Nishio, Department of Genome Biology, Kindai University Faculty of Medicine, Osaka, Japan*

Background: The phase III RELAY study (NCT02411448) showed significantly improved progression-free survival (PFS) for RAM+ERL vs PL+ERL in 449 pts with previously untreated *EGFR* mutation-positive metastatic NSCLC (median PFS 19.4 vs 12.4 mo, HR 0.591 [95% CI 0.461–0.760], p<.0001). To understand baseline genetic mutations and treatment-emergent (TE) resistance mechanisms, this exploratory liquid biopsy substudy examined biomarkers in ctDNA from participating Japanese pts by next-generation sequencing (NGS) and droplet digital PCR (ddPCR). **Methods:** Plasma samples were collected at baseline, during treatment (Cycle 4, 13, and every 6 cycles to Cycle 53) and post-study treatment discontinuation (30-day follow-up [30d FU]). Mutations were assessed at baseline and 30d FU by NGS (Ion AmpliSeq Colon and Lung Cancer panel). *EGFR* mutations and *MET* and *ERBB2* copy number (CN) were assessed at all time points by ddPCR. Baseline markers were analyzed in pts with any detectable baseline mutation (to confirm ctDNA presence; NGS N=84, ddPCR N=74). TE mutations were analyzed in pts with any detectable mutation at baseline and 30d FU (NGS N=26, ddPCR N=28). Among these pts, 81% and 57% for NGS and ddPCR, respectively, had progressed by 30d FU. **Results:** By plasma NGS, baseline *EGFR* activating mutations (exon 19 deletion or exon 21 [L858R] mutation) were detected in 83.3% of pts. Common co-occurring baseline mutations were *TP53* (42.9%), *PTEN* (7.1%) and *KRAS* (6.0%). Baseline *TP53* mutation rate was higher in men vs women (p=.02). No difference in PFS was detected by baseline *TP53* status (interaction predictive p=.45, prognostic p=.33). TE mutations were detected in *EGFR* (including T790M), *FGFR3*, *KRAS* and *TP53*. Slightly higher rates of TE *KRAS* (p=.03) and *TP53* (p=.07) mutations were detected in RAM+ERL than in PL+ERL. TE total *EGFR* mutations (p=.65) or TE T790M (p=.69) did not differ by arm. By ddPCR, baseline *EGFR* activating mutations were detected in all pts. T790M was detected at baseline in 2/37 pts/arm (5.4%) and was TE in 6/11 (55%) RAM+ERL pts and 7/17 (41%) PL+ERL pts. There was a trend (p=.054) for greater *ERBB2* CN in RAM+ERL vs PL+ERL at Cycle 4. *MET* CN decreased slightly at Cycle 4 in both arms (significant in PL+ERL, p=.003). Biomarker levels by ddPCR across all time points will be presented. **Conclusions:** Though limited by sample size and likely inconsistent tumor shedding, this exploratory study identified potential differences in *TP53*, *KRAS*, *ERBB2* and *MET* by demographics, treatment and/or time. Clinical trial information: NCT02411448. Research Sponsor: Eli Lilly and Company.

9528 Poster Session (Board #294), Fri, 8:00 AM-11:00 AM

Exon-16-skipping *ERBB2* (*ERBB2*ΔEx16) as a novel resistance mechanism against EGFR tyrosine kinase inhibitors in non-small cell lung cancer (NSCLC). *First Author: Xin Zhao, Department of Respiratory and Critical Care Medicine, Jiangsu Province Hospital, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Background: In addition to *ERBB2* amplification/protein overexpression, activating *ERBB2* alterations have been increasingly discovered in diverse human cancers with varying incidence. *ERBB2*ΔEx16 is an alternatively spliced isoform of *ERBB2*, lacking the entire exon 16 which encodes a small extracellular domain. *ERBB2*ΔEx16 was recently reported to lead to oncogenic activation of ERBB2 and osimertinib resistance in *EGFR* T790M+ non-small cell lung cancer (NSCLC). **Methods:** A total of 38,680 Chinese cancer patients whose tumor specimen or circulating cell-free DNA underwent genomic profiling by targeted next-generation sequencing of cancer-related genes were retrospectively reviewed. Clinicopathological features and treatment history of *ERBB2*ΔEx16+ patients were evaluated. RNA sequencing was performed to validate the presence of exon-16-skipping *ERBB2* at the transcriptional level. **Results:** A total of eighteen *ERBB2*ΔEx16+ patients (11 NSCLC, 2 colorectal cancer, 2 gastric cancer, and 3 others) were identified (0.047%, 18/38,680). *ERBB2* exon 16 skipping may result from large fragment deletion spanning the whole or partial region of exon 16 (72.2%, 13/18), base substitution at the splice acceptor site (16.7%, 3/18) and deletion of the splice donor site (11.1%, 2/18). *ERBB2* exon 16 skipping, including large fragment deletion and splice site deletion, was validated at the RNA level by RNA sequencing in 3 patients with available samples. Co-occurrence of *ERBB2* amplification and *ERBB2* mutations were found in 83.3% (15/18) and 50% (9/18) of cases, respectively. Concurrent copy number variations were prevalent in *CDK12* (55.6%, 10/18), *CDKN2B* (44.4%, 8/18), *NKX2.1* (38.9%, 7/18) and *PTPRD* (33.3%, 6/18). Among the 11 cases of *ERBB2*ΔEx16+ NSCLC, 9 had coexisting activating *EGFR* mutations (exon 19 deletions, exon 21 L858R) and received prior treatment with EGFR tyrosine kinase inhibitors (TKIs), with 2 harboring acquired *EGFR* T790M mutation and 1 *EGFR* copy number gain. Further analysis of the matched pretreatment samples in 3 *EGFR*-mutated NSCLC patients confirmed that *ERBB2*ΔEx16 was acquired during EGFR TKI therapy. In the 7 cases of other cancers, 4 to 31 non-*ERBB2* mutations were identified in each sample, with *TP53* being the most frequently mutated gene. **Conclusions:** Our data suggest that *ERBB2*ΔEx16 may be a general mechanism of EGFR TKI resistance in a subset of *EGFR*-mutated NSCLC patients, in addition to being an oncogenic driver as reported in some solid malignancies including colorectal, gastric and ovarian cancers. Research Sponsor: None.

9529 Poster Session (Board #295), Fri, 8:00 AM-11:00 AM

A model comparing the value of broad next-gen sequencing (NGS)-based testing to single gene testing (SGT) in patients with nonsquamous non-small cell lung cancer (NSCLC) in the United States. *First Author: Nathan A. Pennell, Cleveland Clinic Foundation, Cleveland, OH*

Background: Patients (pts) with nonsquamous (ns) NSCLC should be tested for actionable driver oncogenes (ADOs), and highly effective treatments (tx) may be available for these pts. Although EGFR and ALK single gene testing (SGT) is relatively common (>80%) in the US, testing for less common ADOs is rare. Unidentified pts with ADOs have survival comparable to pts without alterations. We interrogate plausible testing configurations and discuss their implications for the US population. **Methods:** Simulation was used to evaluate various levels of testing with SGT or NGS on the basis of life years gained (LYG) as well as cost per LYG. Expected prevalence of ADOs among nsNSCLC pts as well as the survival distribution of pts in the presence versus absence of an ADO tx strategy were calibrated based on current literature. Survival duration for each simulated pt was generated from Weibull distributions fit to statistical estimates of median and 5-year survival. With appropriate match between ADO and targeted tx, the Weibull distribution offered a median additional 2 years of life. ADOs included in NGS: EGFR, ALK, ROS1, BRAF, RET, MET, NTRK. SGT: EGFR and ALK. **Results:** Each incremental 10% increase in NGS instead of SGT produces 2630 additional LYG and a cost savings per LYG between -$49 to -$109. At the current 80% testing rate, replacing SGT with NGS would result in an additional 21,019 LYG with reduced cost per LYG of -$599. Increasing testing from 80% to 100% of eligible pts would increase LYG by 15,017 over the current state. If 100% of eligible pts were tested with NGS and every identified pt received tx, the cost per LYG of this strategy would be $16,641.57. **Conclusions:** In a hypothetical model where highly effective tx is available to all identified pts with ADOs, broad NGS testing compared to SGT for EGFR/ALK leads to large gains in life years at reduced cost per LYG compared to SGT, supporting universal NGS testing of all advanced nsNSCLC pts. Conversely, lower levels of testing or only testing for common ADOs (as is the current state) result in large numbers of pts being unidentified and not experiencing these benefits. Research Sponsor: None.

Eligible nsNSCLC pts for testing in US annually.	89,000
Estimated pts with ADOs (EGFR/ALK/ROS1/BRAF/RET/MET/NTRK)	26,300
CMS reimbursement for NGS	$627.50
CMS reimbursement for SGTs (EGFR+ALK)	$732.30
Cost of treatment for 2 years	$10K/year = $20,000
Estimated median and 5-year survival of pt with ADO with highly-effective tx	39 months and 25%
Estimated median and 5-year survival of pt with ADO who goes unidentified	14 months and 5%

9530 Poster Session (Board #296), Fri, 8:00 AM-11:00 AM

Impact of SWI/SNF complex mutations in patients with non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors: Immuno-oncology biomarker study in LC-SCRUM-Japan (LC-SCRUM-IBIS). *First Author: Kiyotaka Yoh, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The SWI/SNF chromatin remodeling complex is reported to be involved in sensitivity and resistance to immune checkpoint inhibitor (ICI). However, their role in non-small cell lung cancer (NSCLC) remains unclear. We examined the relationship between SWI/SNF complex mutations and clinical outcomes of ICI in patients with NSCLC. **Methods:** Of 1017 lung cancer patients enrolled in LC-SCRUM-IBIS, 350 patients were analyzable for whole-exome sequencing (WES). WES data were used to analyze the presence of mutations in 29 major subunits of the SWI/SNF complexes. ARID1A and SMARCA4 mutations were also evaluated in a targeted NGS panel (Oncomine comprehensive assay, OCA). PD-L1 expression by 22C3, tissue tumor mutational burden (tTMB) by WES, STK11 and KEAP1 mutations by WES or OCA were also assessed. Durable clinical benefit (DCB) including CR, PR and SD > 6 mos to ICI, progression-free survival (PFS) and overall survival (OS) were compared in status of each of SWI/SNF complex mutations and other factors. **Results:** At least one mutation in any subunits of the SWI/SNF complex was present in 28% of NSCLC patients. The most common mutated subcomplexes were SMARCA4 (12%), BAF (7%: ARID1A, 4%), non-canonical BAF (3%), PBAF (3%), and SMARCA2 (2%). Of 101 NSCLC patients treated with PD-1/PD-L1 inhibitors, SMARCA4 mutations tended to be associated with lower DCB (16 vs 31%) and shorter median PFS (1.9 vs 3.6 m) and OS (7.4 vs 18.1m). Patients with ARID1A mutations tended to have better clinical outcomes (DCB, 40 vs 28%) compared to those without mutations. No significant associations were found between PD-L1 expression and SMARCA4 or ARID1A mutations. Patients with STK11/KEAP1 mutations had lower rate of PD-L1 expression (TPS > 50%) (18% vs 48%, $P = 0.03$) and worse clinical outcomes (DCB, 6 vs 33%) compared to those without mutations. There was no significant association between a tTMB status and clinical outcome. **Conclusions:** SMARCA4 and ARID1A mutations appear to affect clinical outcomes of ICI in NSCLC patients. These findings indicate that SWI/SNF complex mutations may serve as a predictive biomarker for ICI in NSCLC patients. Research Sponsor: AstraZeneca, Bristol-Myers Squibb, Chugai, Ono.

9531 Poster Session (Board #297), Fri, 8:00 AM-11:00 AM

Identification and in silico structural insights of rare recurrent *EGFR* mutations as resistance mechanisms to osimertinib in *EGFR*-mutated lung cancer. *First Author: N/a Zhoutong, Department of Medical Oncology, Changzhou Cancer Hospital of Soochow University, Changzhou, China*

Background: Inevitable progression on 3rd-generation EGFR-tyrosine kinase inhibitor (TKI) osimertinib of *EGFR*-mutated lung cancer patients represents a great challenge in clinic. Previous studies have revealed that one-third of the resistant mechanisms are due to acquired *EGFR* secondary mutations, mainly on C797, L718 and L792 residues. Our study aims to gain insights into novel mechanisms of acquired resistance to osimertinib. **Methods:** We performed genomic profiling on a total of 1,058 *EGFR*-mutated lung cancer patients with progressed disease on osimertinib, and a cohort of 1,803 patients who received only 1st-generation EGFR TKIs upon progression. Recurrent *EGFR* mutations with a significant enrichment in the osimertinib group were identified. We further established and applied molecular dynamic simulation-based computational model of the mutant EGFR protein to predict its sensitivity to osimertinib. **Results:** As expected, compared with 1st-TKIs alone group, *EGFR* mutations, including C797S/G (22.1% vs. 0.5%), L718Q/V (6.2% vs. 0.3%), L792F/H (4.4% vs. 0.3%), were significantly more enriched in the osimertinib cohort. Our computational model has also successfully predicted their sensitivities to osimertinib: WT (-35.19 kcal/mol) > L792F (-34.10 kcal/mol) > L718Q (-30.33kcal/mol) > C797S (-28.02 kcal/mol), which are consistent with our previous *in vitro* validations. Importantly, a total of 14 low-frequency *EGFR* mutations were exclusively observed in the osimertinib group, seven of which, including *EGFR* G796S(n = 6), V802F(n = 3), T725M(n = 2), Q791L/H(n = 2), P794S/R(n = 2), were predicted to dramatically reduce the binding affinity of osimertinib to EGFR. Of note, analysis of the pretreatment samples of two patients supported that *EGFR* V802F and Q791L/H were acquired during osimertinib treatment. Interestingly, *EGFR* G796S was predicted to be sensitive to gefitinib, suggesting the possibility of administration of gefitinib in patients with acquired *EGFR* G796S to first-line osimertinib treatment. Further *in vitro* functional validations are currently ongoing. **Conclusions:** Our study represents the largest *EGFR*-mutated lung cancer cohort so far to investigate osimertinib resistance in a real-world setting, and has uncovered a list of recurrent low-frequency *EGFR* mutations that may confer acquired resistance to osimertinib. Our *in silico* structural model was proved to be powerful and robust in the prediction of osimertinib sensitivity of EGFR mutants. Research Sponsor: None.

9532 Poster Session (Board #298), Fri, 8:00 AM-11:00 AM

Residual circulating tumor DNA (ctDNA) after two months of therapy to predict progression-free and overall survival in patients treated on S1403 with afatinib +/- cetuximab. *First Author: Philip C. Mack, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: ctDNA from patient plasma has demonstrated diagnostic utility in non-small cell lung cancer (NSCLC). Longitudinal changes in mutant allele frequency (MAF) have great potential to refine clinical management on targeted therapies. **Methods:** S1403 was a first-line phase II study of afatinib w or w/o cetuximab in pts with EGFR-mutant NSCLC. Between March, 2015 and April, 2018, 174 pts were randomized with 168 determined to be eligible. The study closed early due to futility. Plasma specimens were prospectively collected at baseline, Cycle 3 Day 1 (C3D1; 8 weeks) and at progression, and processed for batch analysis of ctDNA by next-generation sequencing (Guardant 360). A complete case analysis approach was used. The Kaplan-Meier method was used to estimate survival distributions, a Cox model to estimate hazard ratios and confidence bounds, and the log-rank test to compare distributions. A landmark analysis was used to assess predictive value of ctDNA clearance at C3D1. **Results:** 104 patients (62%) had analyzable baseline plasma specimens available, with *EGFR* mutations detected in 83 (80%). PFS was significantly shorter for pts with *EGFR* ctDNA positivity at baseline (p = 0.03) (Table) compared to those with no detectable ctDNA, likely a prognostic effect. Kinetic changes in ctDNA MAFs were analyzed in 79 pts with matching baseline and C3D1 specimens. Of 62 cases with detectable ctDNA at baseline, 68% (42/62) became undetectable at C3D1 ("ctDNA clearance"); ctDNA clearance relative to residual ctDNA was associated with significantly longer PFS (p = 0.00001) and OS (0.003) (Table). To date, 29 pts had matching *at-progression* samples. T790M mutations were observed at progression in 6/29 (24%) cases. Other putative emergent resistance factors include: a *TACC3-FGFR3* and an *EML4-ALK* fusion, *MET* exon 14 skipping, multiple *MET* amplifications and *NF1* frameshift mutations. **Conclusions:** Clearance of *EGFR* ctDNA after 60 days of therapy was associated with a substantial and statistically significant improvement in subsequent PFS and OS. Incorporation of ctDNA kinetics into routine clinical care represents a promising platform to identify patients with inferior outcomes on TKIs and detect targetable emergent resistance mechanisms. Research Sponsor: Boehringer Ingelheim; Eli Lilly, U.S. National Institutes of Health.

Effect of performance status on survival with pembrolizumab monotherapy in advanced non-small cell lung cancer (NSCLC). *First Author: Kartik Sehgal, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Pembrolizumab (P) is now widely used as standard of care (SOC) in advanced NSCLC. We sought to identify prognostic factors influencing survival with it in a real-world setting. **Methods:** We conducted a retrospective cohort study of with advanced NSCLC patients who initiated treatment with SOC P monotherapy at our center from 2/11/16 to 10/15/19 (data cutoff 1/15/20). Patient demographic, clinicopathologic, therapeutic and outcomes data were extracted. Survival time was defined from start of P. Cox proportional hazards and logistic regression were utilized. **Results:** Of 74 patients with median follow up of 83.9 weeks, 30 (40.5%) were alive at cutoff. Patient characteristics at start of therapy were: 36 (48.6%) female, median age 68.5 yr (range 33-87), 10 (13.5%) with symptomatic brain metastases; 54 (72.9%) treatment-naïve, 29 (39.2%) with ECOG performance status (PS) ≥2. Tumor characteristics were: 53 (71.6%) with PD-L1 tumor proportion score (TPS) ≥50%, median PD-L1 TPS 75% (range 1-100), tumor mutational burden (TMB) tested in only 37 (50%) patients, median TMB 8 mut/mB (range 1-62). Any grade immune-related adverse events (irAE) occurred in 33 (44.6%) patients, while 16 (21.6%) received systemic steroids. Median survival was 43.3 wks (95% CI 29-104.1). Multivariable regression showed ECOG PS of ≥2 as the strongest risk factor for death (Table). We next evaluated differences in characteristics of patients who were alive vs dead within 12 wks of starting P, by which initial response assessments are completed in routine practice. ECOG PS was the only significantly different baseline variable, even after multivariable adjustment (p = 0.002). **Conclusions:** ECOG PS of ≥2 is a poor prognostic risk factor associated with P monotherapy in advanced NSCLC. Though comprising a clinically significant subset of patients in real-world, they were not included in landmark trials (KEYNOTE-024 & 042). Prospective evaluation is warranted. Research Sponsor: U.S. National Institutes of Health.

	Univariate Hazard ratio for death (95% CI)	p	Multivariable Hazard ratio for death (95% CI)	p
ECOG PS ≥2 / 0-1	3.72 (1.99 – 6.95)	< 0.001	3.63 (1.80 – 7.31)	< 0.001
Any grade irAE, No / Yes	3.36 (1.72 – 6.58)	< 0.001	3.16 (1.59 – 6.28)	0.001
Symptomatic brain metastases, Yes / No	1.83 (0.84 – 3.9)	0.13	1.70 (0.74 – 3.95)	0.21
Age	1.02 (0.99 – 1.06)	0.11	1.01 (0.97 – 1.04)	0.78
PD-L1 TPS	0.99 (0.99 – 1.01)	0.56	1.01 (0.99 – 1.02)	0.25

Distinct genomic instability landscape of lung adenocarcinoma associated with treatment and metastasis. *First Author: Chuanxin Wu, Department of Medical Oncology, Cancer hospital of Guangzhou Medical University, Guangzhou, China*

Background: Lung adenocarcinoma (LUAD) is the most common subtype of non-small cell lung cancer (NSCLC). Genomic instability, defined as genome-wide copy number alterations, is a key pathogenic signature which occurs at the early stage of most cancers and is associated with an increased risk of recurrence or death. We examined the pattern of genomic instability in primary and metastatic LUAD. **Methods:** We performed deep targeted sequencing (425 genes) of 3395 tissue samples and whole exome sequencing (WES) of 60 tissue samples from LUAD patients. Whole-genome doubling (WGD) and arm level aneuploidy were analyzed to uncover correlation with clinical phenotypes and other genomic alterations including driver mutations, tumor mutation burden (TMB), and microsatellite instability (MSI). **Results:** Overall, targeted sequencing revealed that WGD occurred in 64.33% LUAD samples, which was comparable with WES results. Compared to primary site, metastasis exhibited higher proportion of WGD (1.14 fold). Specifically, liver metastasis has the highest WGD percentage among metastasis sites (~87.5%; 1.40 fold increase compared to primary). Interestingly, patients who received tyrosine kinase inhibitors (TKI) had higher frequency of WGD than patients without TKI treatment. In addition, TMB was higher in WGD^+ patients but MSI status was not significantly different between groups. Arm-level aneuploidy was prevalent in this cohort. The most common amplification events were 7p gain (62%), 5p gain (54%), and 8q gain (53%); top deletion events were 19p loss (47%), 15q loss (42%), and 10 q loss (41%). Patients with EGFR or TP53 mutation were more likely to have aneuploidy compared to wildtypes. Subgroup analysis showed distinct patterns of aneuploidy among metastasis sites, suggesting organ-specific alterations. Evolution analysis showed 7p gain was an early event common in primary tumor whereas metastatic tumor had multiple distinct evolutionary trajectories following 7p gain. Several copy number signatures were associated with specific TKI and chemotherapies. For example, TKI-naïve tumors lacked 7p gain but had 19p loss as the most common alteration. **Conclusions:** The genomic landscape of LUAD was characterized by widespread large-scale copy number alterations including WGD and chromosomal aneuploidy. Metastasis had elevated level of aneuploidy compared to primary tumors which were specific to metastatic site. Copy number signature associated with different treatments may contribute to distinct long-term survival and side effects among patients. Research Sponsor: None.

Prediction of the molecular status in non-small cell lung cancer based on metastatic pattern: A free webtool powered by artificial intelligence. *First Author: Benjamin Besse, Gustave Roussy Université Paris Sud, Villejuif, France*

Background: Molecular characterization of metastatic lung adenocarcinomas is mandatory but might be hampered by the quantity of tissue, restricted access to molecular platforms or limited economical resources. Our aim was to develop a tool supported by the hypothesis that radiological patterns of pts could help predict the rate of positivity of the most common oncogenic drivers. **Methods:** We defined an algorithm based on a molecularly defined cohort of 656 pts with stage IV lung adenocarcinoma. Two radiologists centrally reviewed the baseline imaging. Clinical data were retrospectively collected. There were 135 *EGFR* mutations, 81 *ALK* fusions, 47 *BRAF* mutations, 141 *KRAS* mutations, and 146 pan-negative tumors for these 4 oncogenic drivers. Univariate correlation analyses were performed to define an algorithm predicting the molecular testing positivity based on the metastatic pattern. Subsequently, an online tool was developed. This study was approved by our institutional review board. **Results:** Metastatic patterns correlated with the genomic drivers when compared to the pan-negative group. In the *EGFR* group, pleural metastases were more frequent (32% vs. 20%; p = 0.021), whereas adrenal and node metastases less frequent (6% vs.23%; p < 0.001 and 11% vs. 23% respectively; p = 0.011). In the *ALK* group, there were more brain and lung metastases (respectively 42% vs. 29%; p = 0.043 and 37% vs. 24% respectively; p = 0.037). In the *BRAF* group, pleural and pericardial metastases were more common (47% vs. 20%; p < 0.001 and 11% vs. 3% respectively; p = 0.04) and bone metastases less common (21% vs. 42%; p = 0.011). Lymphangitis was more frequent in *EGFR*, *ALK* and *BRAF* groups (6%, 7% and 15% vs. 1%; p = 0,016, p = 0,009 and p < 0,001 respectively). A free online access to the algorithm is now available after registration at http//tactic-ct.fr. Physicians enter age, sex, smoking status and the sites of metastases at diagnosis (present/absent/unknown). A mutation score is calculated, reflecting the % of chance to find an oncogenic driver. On the website, contributors can also enter new cases and an artificial intelligence will refine the algorithm and expand the number of oncogenic drivers. **Conclusions:** Our free access tool allows establishing a hierarchy in the molecular testing based on simple clinical and radiological information. Continual learning from new cases entered in the database will increase the sensitivity of the tool. This tool might save time, tumor tissue, economical resources and accelerate access to personalized treatment. Interaction between CAF and CD8+ T cells in non-small cell lung cancer affects prognosis and efficacy of immunotherapy. *First Author: Xinlong Zheng, Fujian University of Traditional Chinese Medicine, Fuzhou, China*

Background: Cancer-related fibroblasts (CAFs) are important components of the tumor microenvironment (TME) and play a key role in tumor progression. There is growing evidence that CAF levels in tumors are highly correlated with treatment response and prognosis. However, the effect of CAFs on immunotherapy response remains unknown. **Methods:** RNA-seq and clinical data were downloaded from TCGA and GEO. The SVA package *ComBat* function was used to remove batch effects. The ssGSEA algorithm was used to assess the level of cell infiltration in each sample. OS (overall survival) and DFS (disease free survival) were analyzed using the Kaplan–Meier method. GO enrichment analysis was used to assess the biological processes of subgroup differential genes. The Tumor Immune Dysfunction and Exclusion (TIDE) algorithm and subclass mapping were used to predict the clinical response to immune checkpoint blockade. **Results:** We evaluated the infiltration abundance of 24 types of immune cells and fibroblasts in 1768 NSCLC samples and found that almost all IMFRs (immune cells / fibroblasts) are beneficial to the prognosis. This phenomenon is called "CAFs-mediated immune resistance pattern (CMIRP)". We evaluated the infiltration abundance of 24 types of immune cells and fibroblasts in 1768 NSCLC samples and found that almost all IMFRs (immune cells / fibroblasts) are beneficial to the prognosis. This phenomenon is called "CAFs-mediated immune resistance pattern (CMIRP)". The prognosis according to CD8+ T cells was not strong, but CD8+ T cells / fibroblasts (CFR) were significant protective prognostic factors [n = 1588; hazard ratio (HR), 0.66; 95% confidence interval (CI), 0.56–0.78; P < 0.001]. Multivariate analysis revealed that the CFR was an independent prognostic biomarker. The TCGA pan-cancer cohort confirmed the widespread presence of CMIRP in cancer. We further defined the CFR high and CFR low subgroups. CFR high samples were enriched with immune activation pathways including T cell activation, cytolysis, and antigen presentation, while CFR low was associated with immunosuppression including activation of transforming growth factor β, epithelial-mesenchymal transition, and angiogenesis pathways. Finally, we combined TIDE and submap to speculate that CFR is a potential prognostic marker of immunotherapy for NSCLC. **Conclusions:** We proposed the term "CMIRP" to shed light on a more accurate assessment of immune status. CFR is a potential marker for prognosis and predictive efficacy of immunotherapy in NSCLC. Research Sponsor: None.

Brigatinib in Japanese ALK positive NSCLC patients previously treated with ALK tyrosine kinase inhibitors: J-ALTA. *First Author: Tatsuya Yoshida, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Brigatinib is an ALK inhibitor with demonstrated activity against ALK resistance mutations. To evaluate efficacy and safety in Japanese patients with ALK-positive non-small cell lung cancer (NSCLC), a prospective, single-arm, phase 2 study was conducted. We report the efficacy and safety of brigatinib in patients who have progressed on alectinib with or without prior crizotinib and of those who previously received up to two ALK tyrosine kinase inhibitors (TKIs) with or without prior chemotherapy. **Methods:** A safety evaluation lead-in was followed by an expansion stage of an ALK TKI-naïve and two ALK TKI-refractory cohorts. The refractory cohorts included patients with stage IIIB, IIIC, or IV NSCLC with ALK rearrangements. This report describes efficacy results from the post-alectinib patients in the expansion cohort and safety results from all refractory patients. The primary endpoint was confirmed objective response rate (ORR) assessed by IRC, secondary endpoints included duration of response (DoR), progression-free survival (PFS), disease control rate (DCR), and intracranial ORR (iORR). Brigatinib was administered at 180 mg QD with 90 mg QD lead-in for the first 7 days, and efficacy was evaluated every 8 weeks. **Results:** A total of 72 patients were enrolled in 28 sites, including a cohort of 47 patients with prior alectinib, with/without crizotinib between January 2018 and September 2019. The primary analysis of brigatinib in this cohort (data cut-off date 26 September 2019) demonstrated an IRC-assessed, confirmed ORR of 30% and a median DoR of 6.1 months. The median PFS was 7.3 months. Clinically meaningful intracranial efficacy was also observed (see table). Grade ≥3 TEAEs included blood creatine phosphokinase increase (18.1%), lipase increase (13.9%), hypertension (11.1%), amylase increase (4.2%), and pneumonitis (1.4%). Brigatinib also showed anti-tumor activity in patients with refractory secondary mutations in the ALK kinase domain, including G1202R, I1171N, V1180L, and L1196M. **Conclusions:** Brigatinib showed clinically meaningful efficacy in Japanese patients refractory to prior alectinib (first line or post crizotinib), regardless of prior chemotherapy. The safety profile of brigatinib was consistent with prior studies and no new safety findings were identified. Clinical trial information: NCT03410108. Research Sponsor: Takeda Pharmaceutical Company Ltd.

Endpoint	Value, 95% CI
ORR	30.6%, 16.530, 44.165
DCR	78.7%, 64.336, 89.297
DoR, median	6.1 months, 3.8, not reached
PFS, median	7.3 months, 3.7, not reached
iORR	25.0%, 3.185, 65.086

9538 Poster Session (Board #304), Fri, 8:00 AM-11:00 AM

Early pulmonary function changes associated with brigatinib initiation. *First Author: Terry L. Ng, Division of Medical Oncology, University of Colorado, Anschutz Medical Campus, Aurora, CO*

Background: Phase I-III studies reported symptomatic pulmonary toxicity within the first week of initiating brigatinib in 6% patients post-crizotinib and 3% in TKI naive patients with standard dosing (90mg QD for 7 days then 180mg QD as tolerated). A prospective observational study of pulmonary function testing (PFT) on initiating brigatinib was conducted. **Methods:** Patients PS≤2, with resting O2 sats on RA ≥90% and Hg ≥10 g/dL, without significant heart/lung disease or steroid use initiating brigatinib 90 mg QD were eligible. PFT with DLCO, Borg dyspnea and 6-minute walk tests were performed at baseline (prior to brigatinib), and on day 2 (D2), 8 (D8), and 15 (D15) of brigatinib. D15 analyses were initially as clinically indicated but became mandatory if DLCO had not returned to baseline by D8. Peripheral blood was collected at baseline, D2 and D8 for CyTOF analysis. The primary endpoint was the incidence of Early Onset Pulmonary Events (EOPEs), defined as a DLCO reduction of ≥ 20% from baseline. An interim analysis was performed on the first 10 patients due to a higher than expected incidence of DLCO reduction. **Results:** D2 and D8 measurements were captured in all 10 patients, D15 in 7 patients. Ninety percent (9/10) of patients experienced DLCO reduction with nadir occurring on D2 in 4/9 and on D8 in 5/9 patients. Median DLCO nadir was −13.33% from baseline (range: −34.44 to −5.00). Three patients (30%) met EOPE criteria, all on D8, all without symptoms. Brigatinib was not held and all 10 patients escalated to 180mg on D8. Despite continued dosing, 4/9 patients recovered DLCO to baseline or above by D15 (2/3 EOPEs cases), 2/9 recovered above nadir but below baseline by D15 (1/3 EOPE case), and 3/9 did not have improvement from nadir values but no D15 assessment was performed. Dyspnea and 6-minute walk test did not correlate with DLCO changes. Patients who experienced an EOPE had significantly higher levels of activated neutrophils (pERKhi) at baseline. On the day of the EOPE event, patients who met EOPE criteria had significantly higher levels of activated neutrophils and fewer activated CD4+ effector memory T cells. **Conclusions:** Modest DLCO reduction occurred in 90% (9/10) patients during the first 8 days of brigatinib-dosing without associated symptoms. When rechecked on D15, DLCO improved in 100% patients (6/6) despite continued dosing and standard dose escalation at D8. Patients unlikely to tolerate even this modest, short-lived change should consider shallower step-up dosing or alternative drugs. CyTOF analysis suggests levels of pretreatment neutrophils may be a biomarker for developing EOPEs. Clinical trial information: NCT03389399. Research Sponsor: Takeda Oncology.

PD-L1 tumor proportion score and clinical benefit from first-line pembrolizumab in patients with advanced nonsquamous versus squamous non-small cell lung cancer (NSCLC). *First Author: Deborah Blythe Doroshow, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The predictive value of PD-L1 tumor proportion score (TPS) on NSCLC tumor cells as a biomarker for response to PD-(L)1 inhibitors is well established. However, its histology specific value in advanced (a) squamous (Sq) versus nonsquamous (NS) cancers remains unclear. Here, we used real world data to assess the differential value of PD-L1 TPS as a predictive biomarker for overall survival (OS) after first-line pembrolizumab (P) in patients (pts) with Sq versus NS NSCLC. **Methods:** Inclusion criteria for this analysis of the Flatiron Health EHR-derived de-identified database required that pts were diagnosed with aNSCLC, tested for PD-L1 TPS and received a numerical result, had no alteration in *EGFR*, *ALK*, or *ROS*, and received first-line, single agent P. The primary endpoint was overall survival (OS) from the first dose of P in patients with TPS ≥ 50% (H) compared to patients with TPS < 50% (L). Due to the violation of the proportional hazards assumption, a generalized gamma model of OS was used, adjusting for demographic variables and estimated median OS and their confidence intervals with the bootstrap method. The PD-L1-histology interaction was examined by comparing the differences in median OS (H vs. L) between Sq and NS patients. **Results:** Of 1560 pts with NSCLC treated from 1/2011 – 5/2019, 1055 had NS and 405 Sq. No meaningful differences in age, gender, or smoking history were seen between PD-L1 H and L pts with either histology. Among NS pts, H had significantly longer OS than L, with unadjusted hazard ratio (HR) of 0.71 (95% CI: 0.53 - 0.94; p = 0.018). Among Sq pts, H was not associated with longer OS than L, with unadjusted HR 0.89 (95% CI: 0.64 - 1.25; p = 0.514). Based on the generalized gamma model, PD-L1 H in Sq patients was associated with a 0.19 year improvement in median OS (95% CI: -0.22-0.49, P = 0.283), whereas PD-L1 H in the NS group was associated with a 0.70 year improvement in OS (95% CI: 0.34-1.05, P < 0.001). The median improvements between the Sq and NS patients were significantly different (P = 0.034), after adjusting for demographic variables. **Conclusions:** PD-L1 TPS of ≥ 50% predicted longer OS in pts with NS NSCLC treated with first-line P compared to pts whose tumors had a TPS of < 50%. However, no relationship between PD-L1 TPS and OS after first-line P was seen in patients with Sq NSCLC. These data suggest that PD-L1 may not be an appropriate predictive biomarker for checkpoint inhibitor use in NSCLC with squamous histology. Research Sponsor: None.

9540 Poster Session (Board #306), Fri, 8:00 AM-11:00 AM

SRC-homology 2 domain-containing phosphatase 2 (SHP2) in epidermal growth factor receptor (EGFR)-mutant lung adenocarcinoma (LUAD). *First Author: Rafael Rosell, Catalan Institute of Oncology, Barcelona, Spain*

Background: Epidermal growth factor (EGFR)-mutant lung adenocarcinomas (LUADs) display impaired phosphorylation of extracellular signal-regulated kinase (ERK) and SRC-homology 2 domain-containing phosphatase 2 (SHP2) in comparison with EGFR wild-type LUADs. However, the function of SHP2 in early EGFR-mutant LUADs and EGFR wild-type LUADs has not been reported. We posit that SHP2 mRNA expression could be a predictive marker in resected EGFR-mutant LUADs versus EGFR wild-type patients (pts). **Methods:** We examined 267 resected LUADs from Japan and Spain. mRNA expression levels of AXL, MET, CDCP1, STAT3, YAP1 and SHP2 were analyzed by quantitative reverse transcriptase polymerase chain reaction (PCR). EGFR mutant cell lines were investigated for their activity of SHP2. **Results:** Among the 267 enrolled pts, 100 (37.3%) were EGFR-mutant LUADs. Five-year recurrence-free survival (RFS) and overall survival (OS) were lower for EGFR-mutant LUADs with high SHP2 mRNA levels (hazard ratio = 1.83 and 2.28, respectively. p = 0.03 and p = 0.04). However, SHP2 was not associated with RFS nor OS in the 167 wild-type EGFR LUADs. In EGFR-mutant cells, RMC-4550 (SHP2 inhibitor) plus erlotinib showed synergism via inhibition of AKT (S473) and ERK1/2 (T202/Y204). While erlotinib translocates SHP2 (Y542) into the nucleus, either RMC-4550 alone, or in combination with erlotinib, relocalizes SHP2 into the cytoplasm membrane, limiting AKT and ERK activation. **Conclusions:** High SHP2 mRNA is related to shorter RFS and OS in EGFR-mutant LUADs, but not in EGFR wild-type LUADs. The findings indicate that the addition of SHP2 inhibitors could improve adjuvant therapy in EGFR-mutant LUADs. Research Sponsor: None.

9541 Poster Session (Board #307), Fri, 8:00 AM-11:00 AM

An FDA analysis of the association of tumor growth rate and overall and progression-free survival in metastatic non-small cell lung cancer (NSCLC) patients. *First Author: Yutao Gong, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Previous studies have suggested that tumor growth rate (g), estimated using prostate-specific antigen values, is associated with overall survival (OS) in prostate cancer (Wilkerson, 2016). We performed a retrospective pooled analysis in non-small cell lung cancer (NSCLC) to investigate the extent to which g values estimated using radiological tumor measurements in clinical trials are associated with survival. **Methods:** We identified 24 randomized clinical trials submitted to FDA between 2013 and 2019 investigating either immune checkpoint inhibitor (ICI) or targeted therapy (TT) in pts with metastatic NSCLC. Of 9934 patients (pts) enrolled, 5532 pts (2401, 1189, and 1942 pts treated with ICI, TT, and chemotherapy respectively) had sufficient data to derive a valid g. The g was evaluated by both type and line of therapy. Pts were then grouped according to quartiles of g, with Q1 being the lowest. We calculated OS and progression-free survival (PFS) for each group via the Kaplan-Meier method, and used the Cox model for group comparison. **Results:** Median g was 9.7E-4, 1.4E-3, and 2.2E-3/day, and median OS was 34.2, 21.3, and 15.3 months (mo), in pts treated with TT, ICI, and chemotherapy, respectively, regardless of lines of therapy. When treated with the same type of therapy, pts receiving 2nd line therapy had a higher median g than those receiving 1st line. The median survival and log-rank hazard ratios for pts treated with 1st line ICI monotherapy are shown in the Table. **Conclusions:** TT is associated with the lowest median g, followed by ICI, and then chemotherapy, perhaps due to patient selection, better inherent biology/natural history, or favorable results of TT on selected tumors. Regardless, we found that g is inversely associated with survival, across treatment types. This relationship is also observed in pts treated with the same type and line of therapy (for example, 1st line ICI), where Q1 has the longest survival, followed by Q2, Q3, and then Q4. In summary, our exploratory analysis suggests that g derived from radiological tumor measurements in NSCLC may relate to survival. Prospective studies are needed to evaluate if g might be an earlier endpoint compared to classical response criteria. Research Sponsor: None.

		OS		PFS

ctDNA levels before treatment predict survival in non-small cell lung cancer patients treated with a tyrosine kinase inhibitor. *First Author: Mariano Provencio-Pulla, Department of Medical Oncology, University Hospital Puerta de Hierro-Majadahonda, Madrid, Spain*

Background: Currently there is an intense debate concerning therapeutic strategies in EGFR positive NSCLC patients with advance disease. Osimertinib is superior to standard EGFR Tyrosine Kinase Inhibitors (TKIs) as first line treatment. However, it is yet unclear whether this option is superior to sequential treatment of a 1st or 2nd generation TKI followed by osimertinib. In order to clarify this issue it is important to identify which patients are at high risk of progression disease. **Methods:** This is a prospective, multicentre, cross-sectional study promoted by Spanish Lung Cancer Group. 698 plasma samples from 196 advanced NSCLC patients with tumors harboring an EGFR activating mutation and treated with a first line TKI (afatinib, gefitinib, erlotinib or osimertinib) were analyzed. Plasma samples were prospectively collected before treatment (T0), after 3 months of treatment (T3), after 6 months of treatment (T6) and at first disease progression. EGFR mutations were analyzed by dPCR. Multivariate Cox proportional hazards analysis was used to determine the significance of ctDNA in the prediction of prognosis. **Results:** The median follow up was 19.8 months. At baseline patients with plasma EGFR sensitizing mutations at allele frequency (AF) $\geq$ 10% had worse OS and PFS than patients in which the opposite occurred (HR = 1.86; 95 %CI: 1.09-3.17, and HR = 1.65; 95 %CI: 1.07-2.58, respectively). Noteworthy, median OS and PFS time were 18.6 and 8.8 months respectively, in patients with plasma AF$\geq$10% before treatment initiation compared to 37.9 and 12.4 months for patients with plasma AF $<$ 10%. Similar results were obtained when a cutoff of AF$\geq$ 5% was used (HR = 1.73; 95%CI: 1.02-2.94 for OS, and HR = 1.72; 95%CI: 1.13-2.61 for PFS). Patients who remained ctDNA-positive after 3 months of treatment exhibited also poorer outcomes (HR = 3.24; 95%CI: 1.77-5.94 for OS, and HR = 3.1; 95%CI: 1.91-5.03 for PFS). In the same way, detectable levels of ctDNA after 6 months of treatment predicted shorter OS and PFS (HR = 3.3; 95%CI: 1.53-7.13 and HR = 2.62; 95%CI: 1.62-4.25, respectively). **Conclusions:** ctDNA levels significantly predict survival. Moreover, ctDNA levels before treatment initiation can be useful to assess patient's progression risk which is not possible to assess otherwise facilitating treatment decision making. Research Sponsor: Boehringer Ingelheim.

9543 Poster Session (Board #309), Fri, 8:00 AM-11:00 AM

Racial diversity of genomic alterations in lung adenocarcinomas. *First Author: Huashan Shi, Mayo Clinic, Jacksonville, FL*

Background: Lung cancer is the leading cause of cancer related death in the United States in all racial groups. However, the overall death rate from lung cancer is different among white, black and Asian. Although differences in socioeconomic status and treatments received might be the contributing factors, the biology, particularly genomic alteration of cancer might also have an important impact. To date, the differences of genomic alterations among all racial patients are poorly understood. **Methods:** The American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE, version 7.0) database was analyzed. A total of 8908 patients with lung adenocarcinoma (LUAD) were identified. Among them, 5652 patients who had comprehensive sequencing results (gene panel $\geq$ 275) were selected for further analysis. Patients with unknown race, undefined and Pacific Island (only 3 patients) were excluded. Finally, 5360 patients were included in the study. The prevalence and distribution of genomic alteration cross all racial groups were analyzed. **Results:** Overall 5951 samples from 5360 patients were collected (85.7% white, 7.9% Asian, 4.7% black, 0.2% Native American and 1.4% other). Most patients have only one sample. The median mutation counts in white, black, Asian, Native American and others are 7, 6, 5, 5, 7 respectively (Kruskal–Wallis test, $P<$ 0.001). Asian have significantly higher rates of insertion and deletions than other races (14.8% of Asian versus 9.8% of white, 10.7% of black, 10.4% of Native American, 11.1% of other; Pearson's chi-square test, $<$0.001). TP53, EGFR, KRAS and STK11 are the most frequent alterations in white, black and other. EGFR, TP53, KRAS and APC are the most frequent alterations in Asian. STK11 mutations are rare in both Asian and Native American. Native Americans have more alterations of LRP1B, ARID2 and ATM, although the patients' number remains small. ATM and KEAP1 mutations are also common in white and black. EGFR is the highest discrepancy gene in racial distribution. 78.9% Asian, 47.7% black, 36.4% of native American had EGFR alteration in comparison to 29.6% in white (Fisher's exact test, $P < 0.001$). KRAS is the second highest discrepancy gene in racial distribution. 11.6% Asian, 26.3% black, 27.3% of Native American had KRAS alteration in comparison to 36.1% in white (Fisher's exact test, $P<$ 0.001). **Conclusions:** Our study demonstrated the potential diversity of genomic alterations across all racial groups with potential impact on therapeutic decisions. Research Sponsor: Paul Calabresi Career Development Award for Clinical Oncology (K12) - National Cancer Institute Awardee: Yanyan Lou.

9544 Poster Session (Board #310), Fri, 8:00 AM-11:00 AM

Characterization of KRAS mutations (mt) in non-small cell lung cancer (NSCLC). *First Author: Stephen V. Liu, Georgetown University, Washington, DC*

Background: KRAS is the most commonly mutated oncogene in NSCLC and the development of direct KRAS inhibitors has renewed interest in this molecular subtype. However, there are several different KRAS mts, representing unique biology and different prognostic and therapeutic impact. A more comprehensive understanding of the genomic landscape relative to each KRAS mt subset will help guide therapeutic development. **Methods:** Molecular profiles of 17,113 NSCLC specimens were obtained using next-generation sequencing of 592 genes (Caris Life Sciences) and classified based on presence and types of KRAS mt. Incidence of KRAS mts was noted across the cohort and by histology. Co-occurring genomic alterations, tumor mutational burden (TMB) and PD-L1 IHC (22C3, TPS score) were analyzed by KRAS mt type. **Results:** Across the entire cohort, 4706 (27%) of samples harbored a KRAS mt (Table). The most common was G12C (40%), followed by G12V (19%) and G12D (15%). The prevalence of KRAS mt was 37.2% among adenocarcinoma and only 4.4% in squamous. High TMB, defined by $>$ 10 mts/Mb, varied across the different KRAS mt types, most common in G13X (68.3%) and least common in G12D (43.2%). PD-L1 expression also varied. G12C was the most likely to be PD-L1 positive, with 65.5% TPS $>$ 1%, and the most likely to be PD-L1 high, with 41.3% TPS $>$ 50%. STK11 was mutated in 8.6% of KRAS wild type NSCLC but more frequently noted in every KRAS subtype, with the highest rate in G13X (36.2%) and the lowest in G12D(14.2%). TP53 mts were more frequent in KRAS wild type NSCLC (73.6%), with the highest rate among KRAS mutants at 55.4% (G12other) and the lowest at 36.8% (Q61X). NF1 was noted to be mutated in 21.4% of KRAS G13X cases, while all other KRAS mts had a lower frequency of NF1 mts than KRAS wild type (11.5%). **Conclusions:** KRAS mts are relatively common in lung adenocarcinoma and KRAS G12C is the most common variant. The different KRAS mts have different co-occurring mutations and a different genomic landscape. KRAS G12C was associated with the highest rate of PD-L1 expression. The clinical relevance of these differences in the context of therapeutic intervention warrants investigation. Research Sponsor: None.

9545 Poster Session (Board #311), Fri, 8:00 AM-11:00 AM

Real-world performance of blood-based host immune profiling in first-line immunotherapy treatment in advanced-stage non-small cell lung cancer. *First Author: R. Brian Mitchell, Virginia Cancer Inst, Midlothian, VA*

Background: Immune checkpoint inhibition (ICI) has improved outcomes for many treatment-naïve advanced non-small cell lung cancer (NSCLC) patients. However, better biomarkers are needed to predict patient response and guide treatment decisions considering added toxicity and higher cost of combination treatments. A prospectively designed, observational study assessed the ability of a clinically validated, blood-based, host immune classifier (HIC) to predict ICI therapy outcomes. **Methods:** The study (NCT03289780) includes 33 US sites having enrolled over 3,000 NSCLC patients at any stage and line of therapy. All enrolled patients are tested and designated HIC-Hot (HIC-H) or HIC-Cold (HIC-C) prior to therapy initiation. An interim analysis of secondary and exploratory endpoints was performed after 12- 18 months (mo) follow-up with the first 2,000 enrolled patients. We report the overall survival (OS) of HIC-defined subgroups comprising advanced stage (IIIB and higher) NSCLC patients treated with first-line regimens (284 ICI containing treatments, 877 total first-line patients). **Results:** In a real-world clinical setting, OS of advanced stage NSCLC treatment-naïve patients receiving platinum-based chemotherapy (n = 392) did not differ significantly from patients receiving any type of ICI containing regimen (n = 284); 11.7 mo vs. 14.4 mo; hazard ratio (HR) = 0.94 [95% confidence interval (CI): 0.76–1.17], p = 0.59. HIC-H patients experienced longer survival than HIC-C across multiple regimens, including ICI. For all ICI, median OS (mOS) was not reached for HIC-H (n = 196, CI: 15.4 mo–undefined) vs. 5.0 mo (n = 88, CI: 2.9 mo–6.4 mo) for HIC-C patients (HR = 0.38 [CI: 0.27–0.53], p $<$ 0.0001). Similar results were seen in the ICI only (16.8 mo vs. 2.8 mo; n = 117, HR = 0.36 [CI: 0.22–0.58], p $<$ 0.0001) and ICI/chemotherapy combination subgroups (unreached vs. 6.4 mo; n = 161, HR = 0.41 [CI: 0.26–0.67], p = 0.0003). In the PD-L1 high cohort (PD-L1 $\geq$50%), mOS for HIC-H was not reached (n = 81, CI: 13.9 mo–undefined) vs. 3.9 mo (n = 41, CI: 2.1 mo–7.8 mo) for HIC-C (HR: 0.39 [CI: 0.24-0.66], p = 0.0003). HIC results were independent of PD-L1 score (p = 0.81) and remained predictive of OS in first-line ICI-treated patients when adjusted for PD-L1 and other covariates by multivariate analysis (HR = 0.40 [CI: 0.28-0.58], p $<$ 0.0001). **Conclusions:** Blood-based host immune profiling may provide clinically meaningful information for selecting NSCLC patients for two common ICI containing regimens independent of and complementary to PD-L1 score. Research Sponsor: Biodesix, Inc.

9546 Poster Session (Board #312), Fri, 8:00 AM-11:00 AM

Tumor antigen expression and survival of patients with previously treated advanced non-small cell lung cancer (NSCLC) receiving viagenpumatucel-L (HS-110) plus nivolumab. *First Author: Daniel Morgensztern, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Viagenpumatucel-L (HS-110) is an allogeneic cellular vaccine derived from a human lung adenocarcinoma cell line transfected with gp96-Ig fusion protein. Gp96-Ig functions as an antigen chaperone for dendritic cell activation and direct CD8+T cell expansion via cross presentation. DURGA is a multi-cohort study evaluating HS-110 plus anti-PD-1 mAbs in patients (pts) with advanced NSCLC. We report on Cohort A, which enrolled previously-treated pts who had not received an anti-PD(L)1 prior to study entry. **Methods:** Primary objectives were safety and objective response rate (ORR). Overall Survival (OS) was a secondary endpoint. Pts received 1 X 10^7 HS-110 cells intradermally every week for 18 wks and nivolumab until tumor progression. To determine cancer testis antigen (CTA) overexpression from baseline pt tumor samples, hybrid-capture RNA-seq libraries were prepared from macrodissected formalin fixed paraffin embedded tumor tissue and sequenced on an Illumina NovaSeq 6000. Gene-level transcripts were quantified using the Salmon software package. **Results:** 47 pts were enrolled into Cohort A. ORR and clinical benefit rate (CR + PR + SD) were 21% and 43%, respectively, with a 17.2 month median duration of response. Median OS was 28.7 months (mos), with a median follow up of 15.7 mos. One and 2-year survival were 57% and 36%, respectively. A prespecified exploratory analysis of CTA expression level in baseline pt tumor tissue was performed. 50% of pts shared at least 8 of the 39 total antigens overexpressed by HS110. Although there was no difference in ORR between these groups, mOS was higher in pts with tumors that shared $\geq$ 8 antigens with HS-110 (not reached (NR) [95%CI: 10.3 mos, NR] vs 6.7 mos [95%CI: 1.4 mos, NR]), p = 0.028. Pts whose tumors expressed the ZNF492 antigen also had improved OS (NR [95%CI: 11.6 mos, NR] vs 7.2 mos [95%CI: 1.6 mos, NR]), p = 0.03. All pts experienced at least one adverse event (AE), and the most common AEs were fatigue (28%), arthralgia (19%) and cough (17%). There were 2 grade 5 AEs not related to treatment. **Conclusions:** The combination of HS-110 and nivolumab appears safe and well tolerated. OS was improved in pts whose tumors express $\geq$ 8 shared antigens with HS110, as well as in those who specifically expressed ZNF492. Further exploration of antigen expression as a predictor for treatment outcome with HS110 plus nivolumab is ongoing. Clinical trial information: NCT02439450. Research Sponsor: Heat Biologics.

9547 Poster Session (Board #313), Fri, 8:00 AM-11:00 AM

Circulating and tumor-associated neutrophil subtypes discriminate hyper-progressive disease (HPD) from conventional progression (PD) upon immune checkpoint inhibitors (ICI) in advanced non-small cell lung cancer (NSCLC) patients (pts) and in vivo models. *First Author: Roberto Ferrara, Medical OnIstituto Nazionale Dei Tumori di Milano, Milan, Italy*

Background: HPD occurs in $\simeq$10-25% of NSCLC pts upon single-agent ICI and correlates with poor prognosis. High circulating neutrophil count and neutrophils/lymphocytes ratio have been associated with shorter survival and HPD in NSCLC pts. In mouse lung cancer models, interleukin-17 (IL-17) promoted tumour growth upon ICI increasing intratumoral neutrophils. The role of specific circulating and/or tumour-associated neutrophils in driving HPD is currently unknown. **Methods:** NSCLC pts treated with single agent ICI were assessed for HPD and circulating neutrophils' phenotype. Conventional PD was defined by RECIST 1.1. HPD required 3 tumour assessments (2 before ICI, 1 upon ICI) and was defined as delta tumour growth rate (TGR) (TGR upon ICI – TGR before ICI) $>$ 50% and/or TGR ratio (TGR upon ICI/ TGR before ICI) $\geq$2. Correlations with continuous variables were performed by Mann-Whitney test. Circulating low density neutrophils (LDNs) subtypes were assessed by flow cytometry (FC) on peripheral blood mononuclear cells (PBMCs) from fresh blood samples. LDNs were defined as $CD66b^+CD15^+$ cells among $CD11b^+$ PBMCs. Immature subtypes were defined as $CD10^-$ and $CD10^-CD16^-$ LDNs. The occurrence of HPD upon anti-PD-1 treatment was tested in C57BL/6 immune competent mice bearing Lewis Lung Carcinoma and treated with anti-murine PD-1. Tumour associated neutrophils' phenotype was assessed by FC. **Results:** Of 52 NSCLC, 65% were $>$ 65 years, 83% had stage IV, 25% PD-L1 on tumour cells $\geq$50%, 67% received 1st line ICI. PD and HPD occurred in 21 (40%) and 5 (10%) pts, respectively. Before ICI start, HPD pts had higher circulating immature neutrophils measured as median percentage of $CD10^-$ LDNs [41.9 (min 26.7; max 83.5) vs 10.1 (min 0.69; max 79.3), p = 0.01] and of $CD16^-$ cells among $CD10^-$ LDNs [93 (min 89.5; max 98.4) vs 86.3 (min 24.2; max 99), p = 0.03] compared to conventional PD pts. PD and HPD occurred in 17 (71%) and 3 (12.5%) of 24 immune competent mice treated with anti-murine PD-1. The median percentage of IL-17^+ tumour associated neutrophils ($Gr1^{high}Ly6C^{low}$) was significantly higher in HPD compared to PD mice [0.25 (min 0.14; max 0.63) vs 0.06 (min 0.02; max 0.32), p = 0.02]. **Conclusions:** Circulating immature ($CD10^-$ and $CD10^-$ $CD16^-$) LDNs and IL-17^+ tumour associated neutrophils discriminate HPD from conventional PD upon ICI in NSCLC pts and in vivo models, respectively. Functional characterization of specific neutrophil subsets is ongoing. Research Sponsor: IASLC Young Investigator Award 2019 and ASCO Merit Award 2019.

9548 Poster Session (Board #314), Fri, 8:00 AM-11:00 AM

Radiotherapy to augment pembrolizumab responses and outcomes in metastatic non-small cell lung cancer: Pooled analysis of two randomized trials. *First Author: James William Welsh, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In metastatic non-small cell lung cancer (mNSCLC), the clinical trials NCT02492568 and NCT02444741 are the only known randomized comparisons of pembrolizumab alone versus pembrolizumab combined with radiation therapy (RT). When the trials were analyzed individually, some potential benefit was observed in the combination therapy group, but the relatively small sample size of each trial limited the detection of potential differences in response rates and outcomes. Hence, we perform a pooled analysis of these two randomized trials to validate and explore whether RT improves mNSCLC patient responses to immunotherapy. **Methods:** This was a pooled analysis of two randomized trials (NCT02492568 and NCT02444741) of pembrolizumab with or without RT for mNSCLC. Endpoints included the out-of-field overall response rate (ORR) and disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and subgroup analysis of the different RT schemes. **Results:** In all, 131 patients were analyzed (n = 66 pembrolizumab; n = 65 pembrolizumab/RT (iRT)). ORR was 21% in the pembrolizumab arm vs. 38% in the iRT arm (p = 0.01); DCR was 53% in the pembrolizumab arm vs. 67% in the iRT arm (p = 0.0009); PFS was 4.4 m vs 8.3 m (p = 0.046); and OS was 9.2 m vs 19.2 m (HR 0.66; p = 0.040). Ablative RT (24Gy/3 fractions and 50Gy/4 fractions) had better ORRs of 48% and 54%, respectively, compared to 18% for non-ablative RT (45Gy/15 fractions) and 20% for pembrolizumab alone (p $<$ 0.05, respectively). **Conclusions:** The addition of RT to immunotherapy significantly increased the ORR of unirradiated lesions and was additionally associated with significant improvements in PFS and OS. Ablative RT was associated with response rates significantly higher than those of non-ablative RT, possibly due to a detrimental effect of non-ablative RT on ALC. These hypothesis-generating findings require dedicated, large-volume, and randomized studies for corroboration. Clinical trial information: NCT02492568 and NCT02444741. Research Sponsor: Merck Sharp & Dohme.

9549 Poster Session (Board #315), Fri, 8:00 AM-11:00 AM

Long-term responders to PD-1 blockade in patients with advanced non-small cell lung cancer (NSCLC). *First Author: Jia Luo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Long-term response – the plateau of the survival curve – is the transcendent benefit from PD-1 blockade. However, only a subset of responses achieve substantial durability. The frequency, characteristics, and predictors of long-term responders (LTR) to PD-1 blockade are not well known and may differ from short-term responders (STR). **Methods:** Patients with advanced NSCLC treated with anti-PD-1/PD-L1 therapy from two institutions (MSK and DFCI) were examined. Responses were assessed by RECIST. LTR was defined as PR/CR lasting $\geq$ 24 months. STR was defined as PR/CR lasting $<$ 12 months. Comparisons were also made to patients with progressive disease (PD). PD-L1 expression was assessed by IHC. TMB was assessed by targeted NGS; high TMB was defined as $\geq$ median of the cohort. A subset had detailed molecular profiling by MSK-IMPACT. Fisher's exact and Mann-Whitney U tests were used to compare features, and the log-rank test was used to compare survival. **Results:** Of 2318 patients (MSK n = 1536, DFCI n = 782), 126 (5.4%, 95% CI 4.6-6.4%) achieved LTR, with similar rates in both cohorts. STR occurred in 139 (6%). Overall survival was longer in LTR compared to STR (median NR vs 19.6 months, HR 0.07, $p <$ 0.001). LTR had deeper responses compared to STR (median best overall response -69% vs -46%, $p < 0.001$). Patients with LTR were younger ($<$ 65 years old) and had increased TMB ($\geq$ median mut/Mb) compared to both STR and PD ($p = 0.006$, $p = 0.03$; $p < 0.001$, $p < 0.001$). The rate of LTR was enriched among patients with both high TMB/high PD-L1 compared to those with low TMB/low PD-L1 (9% vs 1%, OR 9.2, $p < 0.001$), while STR was similar in both groups (7% vs 6%). 2% of patients with sensitizing EGFR mutations (n = 243) achieved LTR. Loss of function variants in ARID1A (14% vs 2%), PTEN (8% vs 0%), and KEAP1 (12% vs 2%) were enriched in LTR compared to STR ($p < 0.05$ for each). Among patients with KRAS mutations, the rate of LTR was higher in those with co-mutation with TP53 compared to STK11 (11% vs 2%, $p = 0.01$). **Conclusions:** Long-term response (LTR, ongoing response $\geq$ 24 months) to PD-1 blockade is an uncommon but profound clinical outcome in metastatic lung cancers. Younger age and high TMB correlate with LTR; the combination of high TMB/high PD-L1 enriches for LTR but not STR. Features predicting long term response may be distinct from those predicting initial response. Research Sponsor: T32-CA009207, NIH-T32, Investigational Cancer Therapeutics Training Program Grant.

9552 Poster Session (Board #318), Fri, 8:00 AM-11:00 AM

Comparative efficacy of chemoimmunotherapy versus immunotherapy alone in the front-line treatment of advanced non-small cell lung cancer: A systematic review and network meta-analysis. *First Author: Ranjan Pathak, Section of Medical Oncology, Yale School of Medicine, New Haven, CT*

Background: Immune checkpoint inhibitors (ICI) and combination chemotherapy (chemo) plus ICI (Chemo-ICI) have been shown in RCTs to have improved OS compared to chemo in the 1L treatment of advanced NSCLC. However, the benefit of chemo-ICI compared with ICI alone is unknown. **Methods:** Systematic review using MEDLINE, Embase and Cochrane CENTRAL was done to identify relevant studies up to December 2019. Phase 3 RCTs that evaluated the efficacy of 1L ICI or chemo-ICI and reported outcomes stratified by PD-L1 status ($<$1%, 1-49%, $\geq$50%) were included. ICI was defined as single-agent PD-1 axis inhibitor or dual checkpoint blockade with PD-1 axis inhibitor plus CTLA-4 inhibitor. Comparison for PD-L1$<$1% included chemo-ICI vs ipi/nivo and for PD-L1 1-49% and PD-L1$>$50% included chemo-ICI vs ipi/nivo or single-agent ICI. OS, PFS, and ORR were extracted. Network meta-analysis (NMA) was done in Bayesian random-effects regression models. **Results:** Ten phase 3 RCTs (7971 screened) involving 7,218 patients assigned to ICI (pembro or atezo or ipi/nivo) or chemo-ICI (platinum-doublet + atezo, pembro, or nivo) were included. In PD-L1 $<$1% patients, NMA comparing chemo-ICI with ipi/nivo failed to show a statistically significant difference in OS, PFS or ORR. In PD-L1 1-49% patients, there was no significant difference between chemo-ICI vs ICI in OS or ORR; PFS could not be analyzed due to lack of available data. In PD-L1 $>$50% patients, chemo-ICI was associated with improved PFS and ORR compared to ICI alone, but without any OS difference (Table). **Conclusions:** Although the addition of chemo to ICI appears to improve ORR and PFS in PD-L1 $\geq$50% patients when compared to ICI alone, chemo-ICI does not confer an OS benefit in the 1L treatment of NSCLC patients regardless of PD-L1 status. Prospective trials comparing chemo-ICI, ICI monotherapy, and combination ICI are needed to confirm these findings. OS, PFS and ORR with chemo-ICI vs ICI. Research Sponsor: None.

PD-L1 status	Comparison	OS (HR, 95% CrI)	PFS	ORR (OR, 95% CrI)
PD-L1 <1%	Chemo-ICI vs ipi/nivo	1.23 (0.74-1.99)	0.94 (0.53-1.60)	1.38 (0.40-5.05)
PD-L1 1-49%	Chemo-ICI vs ICI overall	0.83 (0.44-1.50)	NA	2.40 (0.66-9.10)
	Chemo-ICI vs ipi/nivo	0.82 (0.34-1.92)	NA	NA
	Chemo-ICI vs ICI monotherapy	0.84 (0.34-2.00)	NA	2.30 (0.65-8.20)
PD-L1 ≥50%	Chemo-ICI vs ICI overall	0.92 (0.66-1.30)	0.64 (0.47-0.88)	2.10 (1.20-3.50)
	Chemo-ICI vs ipi/nivo	0.88 (0.53-1.49)	0.66 (0.39-1.15)	2.27 (0.91-5.31)
	Chemo-ICI vs ICI monotherapy	0.95 (0.64-1.40)	0.63 (0.44-0.96)	2.00 (1.10-3.80)

9553 Poster Session (Board #319), Fri, 8:00 AM-11:00 AM

Clinical performance of a comprehensive novel liquid biopsy test for identifying non-small cell lung cancer (NSCLC) patients for treatment with osimertinib. *First Author: Jhanelle Elaine Gray, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Genotyping is required to identify cancer patients (pts) eligible for targeted therapy; however, many do not receive biomarker testing, in part due to limitations associated with tissue-only genotyping practices and the growing list of biomarkers recommended to be tested. Liquid biopsy overcomes many of these limitations but is not yet fully adopted. We report here the clinical performance of a comprehensive liquid biopsy test based on next generation sequencing (NGS) of circulating tumor DNA (ctDNA) for the identification of NSCLC patients with *EGFR* exon 19 deletions (ex19del) or L858R mutations (*EGFR*m) or *EGFR* T790M, eligible for treatment with osimertinib. **Methods:** 441 (79%) of 556 pts randomized in FLAURA (NCT02296125; first-line osimertinib vs comparator EGFR TKI in *EGFR*m NSCLC) and 300 (72%) of 419 pts from AURA3 (NCT012151981; osimertinib vs chemotherapy in NSCLC pts with T790M at progression on EGFR TKI) were retrospectively tested with Guardant360 (G360), a 74-gene ctDNA NGS assay assessing single nucleotide variants, insertion-deletions, amplifications, and fusions in genes relevant to targeted therapy selection as well as microsatellite instability. Progression-free survival (PFS) of pts with *EGFR*m or T790M detected by G360 was compared to pts detected by the cobas EGFR Mutation Test (cobas) using tissue or plasma with an unadjusted cox model. **Results:** Treatment with osimertinib was associated with a significant PFS benefit relative to control therapy in NSCLC pts with *EGFR*m (FLAURA) and T790M (AURA3) detected using G360 (Table). Observed clinical benefit for pts with *EGFR*m or T790M detected by G360 was similar to that for pts with *EGFR*m or T790M identified by cobas using tissue or plasma specimens. **Conclusions:** This analysis demonstrates that G360 accurately identifies pts for osimertinib therapy while simultaneously providing comprehensive genotyping for other therapeutic molecular targets. The application of NGS liquid biopsy has the potential to increase rates of pts genotyped and access to precision medicine. Research Sponsor: AstraZeneca.

Pivotal study (*EGFR* mutations)	PFS Hazard Ratio (95% CI)	p-value
FLAURA (ex19del/L858R)		
G360	0.42 (0.31, 0.55)	< 0.0001
cobas plasma	0.45 (0.35, 0.58)	< 0.0001
cobas tissue	0.43 (0.34, 0.54)	< 0.001
AURA3 (T790M)		
G360	0.39 (0.28, 0.57)	< 0.0001
cobas plasma	0.42 (0.28, 0.62)	< 0.0001
cobas tissue	0.37 (0.29, 0.48)	< 0.0001

9554 Poster Session (Board #320), Fri, 8:00 AM-11:00 AM

Phase III study of tislelizumab plus chemotherapy vs chemotherapy alone as first-line (1L) treatment for advanced squamous non-small cell lung cancer (sq NSCLC). *First Author: Jie Wang, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Tislelizumab is an anti-PD-1 antibody engineered to minimize binding to FcγR on macrophages to abrogate antibody-dependent phagocytosis. Tislelizumab in combination with chemotherapy has demonstrated a manageable tolerability profile and preliminary efficacy as 1L treatment for NSCLC. **Methods:** In this open-label phase 3 study (NCT03594747), Chinese pts with histologically confirmed stage IIIB or IV sq NSCLC were randomized (1:1:1) to receive IV Q3W: tislelizumab (200 mg, D1) + paclitaxel (P; 175 mg/m^2, D1) and carboplatin (carb; AUC 5, D1) (*Arm A*); tislelizumab + *nab*-P (100 mg/m^2; D1, 8, and 15) and carb (AUC 5, D1) (*Arm B*); or P (175 mg/m^2, D1) and carb (AUC 5, D1) (*Arm C*). Chemotherapy was administered for 4-6 cycles followed by tislelizumab. Patients were stratified by tumor stage and PD-L1 expression. The primary endpoint, PFS per RECIST v1.1, was assessed by Independent Review Committee; key secondary endpoints included OS, ORR, DoR, and safety/tolerability. **Results:** Across 360 pts, median PFS was significantly improved with tislelizumab plus chemotherapy (*Arms A* and *B*) compared with chemotherapy alone (*Arm C*) (Table). As of 6 Dec 2019, ORRs were higher and median DoRs were longer in *Arms A* and *B* vs *Arm C*. Across all arms, median OS was not reached and median number of treatment cycles were comparable. Adverse events (AEs) leading to discontinuation of any treatment were reported in 12.5%, 29.7%, and 15.4% of pts in *Arms A*, *B*, and *C*, respectively. The most commonly reported grade $\geq$3 AEs were hematologic in nature (eg, neutropenia) and consistent with known chemotherapy AEs. Serious treatment-related AEs (TRAEs) were reported in 72 pts (37.5% [*A*]; 38.9% [*B*]; 23.6% [*C*]); TRAEs leading to death were reported in 6 pts (n=1 [*A*]; n=2 [*B*]; n=3 [*C*]), none of which were solely attributed to tislelizumab. **Conclusions:** As 1L treatment for advanced sq NSCLC, addition of tislelizumab to P/carb or *nab*-P/carb chemotherapy significantly improved PFS and showed higher ORR and longer DoR than chemotherapy alone. The safety profile is in line with the known profiles of tislelizumab, chemotherapy, and underlying NSCLC; no new safety signals were identified with addition of tislelizumab to chemotherapy. Clinical trial information: NCT03594747. Research Sponsor: BeiGene, Ltd.

9556 Poster Session (Board #322), Fri, 8:00 AM-11:00 AM

Primary efficacy and biomarker analyses from the VISION study of tepotinib in patients (pts) with non-small cell lung cancer (NSCLC) with *MET*ex14 skipping. *First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Preliminary tepotinib data showed durable activity in pts with NSCLC with *MET*ex14 skipping prospectively identified by liquid (L+) or tissue (T+) biopsy. Having met target enrollment of ≥60 L+ pts & ≥60 T+ pts, we report primary data. **Methods:** VISION Cohort A enrolled pts with advanced *EGFR/ALK* wt, *MET*ex14 skipping NSCLC (asymptomatic brain metastases [BM] allowed), who received oral tepotinib 500 mg QD. On-study treatment decisions were based on investigator assessment (INV) of response. Primary endpoint was objective response rate (ORR) by independent review committee (IRC) analyzed in 3 primary ITT sets: L+ and/or T+, L+, T+. 2ary endpoints included ORR by INV, duration of response (DOR), disease control rate (DCR), PFS, OS, & safety. Preplanned analyses were performed in pts with BM at baseline (BL). BL/on-treatment ctDNA plasma samples (L+) were analyzed using a 73-gene NGS panel (Guardant360). Deep molecular responses (MR), defined as > 75% depletion of *MET*ex14, were compared with objective responses (OR). **Results:** By data cut-off (1 Oct 19) 151 pts received tepotinib (safety set); 99 L+/T+, 66 L+, 60 T+ pts comprised the 3 ITT sets with ≥6-month [m] allowed-up. Across treatment lines (n = 44 1L, n = 55 ≥2L), primary ORR & mPFS [95% CI] in 99 L+/T+ pts were 43% [34–54] & 8.6 m [6.9–11.0] by IRC and 56% [45–66] & 9.5 m [6.7–13.5] by INV. ORR was similar in L+ or T+ pts (table) or in T+L− pts (n = 25): 40% [21–61] by IRC and 48% [28–69] by INV. Only 2 pts were T−L+. Outcomes were also comparable in pts with BM (n = 11): IRC ORR 55% [23–83] & mPFS 10.9 m [8.0–ne]. 34/51 pts (67%) with matched BL/on-treatment L+ samples had deep MR strongly associated with clinical response: 32/34 pts (94%) with MR had disease control (INV), including 29/34 pts (85%) with OR; 2/34 pts had progressive disease. Further biomarker data will be presented. Grade ≥3 treatment-related adverse events (TRAEs) were reported by 37/151 pts (25%). 13 pts (9%) discontinued due to TRAEs. **Conclusions:** Tepotinib is a promising targeted therapy with durable clinical activity and manageable toxicity in pts with *MET*ex14 skipping NSCLC L+ or T+, including pts with BM. High ORR & DCR in pts with ctDNA molecular responses support that MET inhibition in *MET*ex14+ tumor cells can lead to clinical benefit. Clinical trial information: NCT02864992. 9557 Poster Session (Board #323), Fri, 8:00 AM-11:00 AM

Genetic profiling and the response to RET inhibitors in RET fusion positive non-small cell lung cancer (NSCLC) identified by international genomic screening project (LC-SCRUM-Asia). *First Author: Kaname Nosaki, National Cancer Center Hospital East, Kashiwa, Japan*

Background: *RET* fusions are targetable oncogenic drivers in 1 – 2 % of NSCLC, yet no RET inhibitors are approved. Selective RET inhibitors, such as LOXO-292 and BLU-667, are currently in development. The impact of co-occurring mutation on outcome in RET-TKI therapy remains largely unknown. **Methods:** In an international genome screening project in Asia (LC-SCRUM-Asia), 161 cancer-related genes have been analyzed by a next-generation sequencing (NGS) system, Oncomine™ Comprehensive Assay. The therapeutic efficacy and survival of *RET* fusion+ NSCLC were evaluated using a large-scale clinicogenomic database in the LC-SCRUM-Japan. **Results:** From Feb 2013 to Dec 2019, a total of 7177 patients with non-squamous NSCLC were enrolled. *RET* fusion were detected in 167 patients (2.3 %). Median age was 61 years (range: 29 - 85), 60 % were female, 61 % were never-smokers, 99 % had adenocarcinoma, and 78 % had stage IIIB/IV disease. Based on our database, the median overall survival was 37 months. 62 patients received RET inhibitor therapy. *RET* fusions was identified by NGS assay (KIF5B-RET: 75, CCDC6-RET: 30, Others: 2) in 107 patients. Co-occurring genomic alterations were detected in 62 (58 %) patients, the median number of co-mutations was 1 (range 0 - 4). The most common co-occurring mutations in tumor involved *TP53* (31; 29 %), *STK11* (6; 6 %), *CDKN2A* (5; 5 %) and *TSC2* (5; 5 %). In 23 patients treated with RET inhibitor (unapproved drugs), there was a strong association between co-occurring mutation and time to treatment discontinuation (TTD) in RET inhibitor therapy; HR 2.75 (95%CI 1.71 - 15.6, P = 0.0096). **Conclusions:** *RET* rearrangements continue to represent a rare but high unmet need disease. Co-occurring mutation was significantly associated with shorter TTD. Our data is the largest cohort of advanced-stage *RET* fusion+ NSCLC profiled by NGS to date. Co-occurring mutation should be evaluated in the development of novel targeted therapies for *RET* fusion+ NSCLC. Research Sponsor: None.

9558 Poster Session (Board #324), Fri, 8:00 AM-11:00 AM

Two-year follow-up of bintrafusp alfa, a bifunctional fusion protein targeting TGF-β and PD-L1, for second-line (2L) treatment of non-small cell lung cancer (NSCLC). *First Author: Byoung Chul Cho, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Bintrafusp alfa (M7824) is a first-in-class bifunctional fusion protein composed of the extracellular domain of the TGF-βRII receptor (a TGF-β "trap") fused to a human IgG1 mAb blocking PD-L1. Interim analysis of a global phase 1 study (NCT02517398) found an objective response rate (ORR) of 27.5% and a manageable safety profile in patients with NSCLC who received bintrafusp alfa 1200 mg in the 2L setting; median overall survival (OS) was not reached. Here we present the longest efficacy and safety follow-up in a cohort receiving bintrafusp alfa. **Methods:** Patients with advanced NSCLC unselected for PD-L1 expression level who progressed after first-line standard treatment (no prior immunotherapy) were randomized to receive bintrafusp alfa 500 or 1200 mg (n = 40 each) Q2W until disease progression, unacceptable toxicity or trial withdrawal. The primary objective was best overall response (BOR) per RECIST 1.1; secondary and exploratory objectives include safety and OS, respectively. **Results:** As of October 15, 2019, a total of 40 patients received bintrafusp alfa at the recommended phase 2 dose of 1200 mg Q2W for a median of 17 (range, 2-136) weeks, with a median follow-up of 128 weeks; 18 patients were still alive, 3 patients had an ongoing response, and 1 patient remained on treatment. Results for the 1200 mg dose cohort showed an ORR of 27.5%, and a median duration of response of 18 months. The 18- and 24-month progression-free survival and OS rates were 18.4% and 11.0%, and 49.7% and 39.7%, respectively. Duration of response rates at 18 and 24 months were 42.4% and 21.2%, respectively. Median OS in patients with positive (≥1%) PD-L1 expression was 21.7 months; 6 of 7 patients with high (≥80% with Ab clone 73-10, which is equivalent to ≥50% with 22C3) PD-L1 expression were still alive. The overall safety profile has remained consistent since the interim analysis, with no new safety signals or deaths and 1 additional treatment-related discontinuation (blood alkaline phosphatase increased). **Conclusions:** After two years of follow-up, bintrafusp alfa continues to show manageable safety with durable responses and encouraging long-term survival, especially in patients with high PD-L1 expression. A study evaluating bintrafusp alfa vs pembrolizumab as first-line treatment for NSCLC is ongoing in patients with high PD-L1 expression (NCT03631706). Clinical trial information: NCT02517398. Research Sponsor: Merck KGaA, Darmstadt, Germany, Pharmaceutical/Biotech Company.

9560 Poster Session (Board #326), Fri, 8:00 AM-11:00 AM

Nivolumab (NIVO) plus ipilimumab (IPI) with two cycles of chemotherapy (chemo) in first-line metastatic non-small cell lung cancer (NSCLC): CheckMate 568 Part 2. *First Author: Justin F. Gainor, Massachusetts General Hospital, Boston, MA*

Background: In Part 1 of the phase II CheckMate 568 study (NCT02659059), NIVO + IPI was active and tolerable in patients (pts) with advanced NSCLC. The addition of chemo to dual immune checkpoint inhibitor therapy may further improve initial disease control. We report results from Part 2 of CheckMate 568, which evaluates NIVO + IPI combined with 2 cycles of chemo in pts with advanced treatment-naive NSCLC. **Methods:** Adult pts with untreated stage IV NSCLC received NIVO 360 mg Q3W + IPI 1 mg/kg Q6W combined with 2 cycles of histology-based platinum-doublet chemo, followed by NIVO + IPI without chemo until disease progression/unacceptable toxicity for ≤ 2 years. The primary endpoints were dose-limiting toxicity (DLT) within the first 9 weeks and safety/tolerability. Treatment was considered safe if ≤ 25% of at least 22 evaluable pts had a DLT. DLTs included but were not limited to: uncontrolled grade 3 non-skin treatment-related adverse events (TRAEs), grade 4 TRAEs, grade 2 treatment-related pneumonitis not resolved within 14 days, and treatment-related hepatic function abnormalities. **Results:** In total, 36 pts received treatment; 97% of pts completed 2 cycles of chemo combined with NIVO + IPI. Three pts discontinued IPI while continuing NIVO. Minimum follow-up was 14.9 months. Only 1 (3%) pt experienced a DLT (transient, asymptomatic grade 3 AST and ALT elevation) within the first 9 weeks. The elevation occurred on cycle 1, day 21 and resolved 2 weeks later with discontinuation of IPI, delay of NIVO, and treatment with prednisone; chemo was continued throughout and NIVO was restarted thereafter without recurrent toxicity. Grade 3–4 TRAEs occurred in 21 (58%) pts. Eight (22%) pts experienced a TRAE leading to discontinuation, most commonly colitis, encephalopathy, pneumonitis, and arthralgia (each in 2 [6%] pts); these events occurred outside of the 9-week window for DLT assessment. The most common select TRAEs (defined as AEs of potential immunologic causes) were skin related (18 [50%] pts); the most common grade 3–4 select TRAEs were endocrine (3 [8%] pts), skin related, gastrointestinal, and pulmonary (each in 2 [6%] pts). No treatment-related deaths occurred. Updated safety in addition to efficacy data will be presented. **Conclusions:** In pts with untreated advanced NSCLC, the addition of 2 cycles of platinum-doublet chemo to NIVO + tumor-optimized IPI was tolerable. No unexpected safety signals were observed. Clinical trial information: NCT02659059. Research Sponsor: Bristol-Myers Squibb.

9561 Poster Session (Board #327), Fri, 8:00 AM-11:00 AM

Soluble BTN2A1 as a potential predictive biomarker of immune checkpoint inhibitor efficacy in advanced non-small cell lung cancer (NSCLC). *First Author: Philippe Rochigneux, Institut Paoli-Calmettes, CRCM U1068, Marseille, France*

Background: Medical treatment of lung cancer has irreversibly changed since the development of immune checkpoint inhibitors (ICI). However, immune biomarkers of efficacy are still lacking. Preliminary data in leukemia and pancreatic cancer showed that soluble immune checkpoints are associated with a reduced overall survival (OS). This led us to explore the prognostic and predictive value of soluble immune checkpoints in non-small cell lung cancer (NSCLC) patients treated with chemotherapy or ICI. **Methods:** We analyzed 90 advanced NSCLC patients. The pilot cohort (Rennes University Hospital, France), included 48 patients treated with platinum doublets (n = 33) or ICI (n = 15) (LOC/11-16 protocol). The confirmation cohort (Paoli-Calmettes Institute) included 42 patients treated with ICI (nivolumab or pembrolizumab) in a longitudinal prospective setting (Immunosup trial, NCT03595813). In both cohorts, enzyme-linked immunosorbent assays (ELISA) were performed in baseline plasma samples for soluble forms of PD-1, PD-L1, global BTN3, BTLA, BTN3-A1 and BTN2A1. Soluble ICI levels were linked to clinical data using Kaplan-Meier, log-rank and Cox proportional-hazards models. Cut-points were determined using maxstat package for survival, R software R 3.6.2. **Results:** Five soluble immune checkpoints correlated and clustered together in unsupervised analysis (PD-1, PD-L1, global BTN3, BTLA, BTN3-A1), but were not associated with ICI efficacy. In patients treated with ICI, in the pilot and confirmation cohort, a high baseline plasmatic concentration of soluble BTN2A1 was significantly associated with an improved OS (confirmation cohort with a BTN2A1 cut-point of 3.55 ng/ml: HR = 0.30, 95%CI = 0.12-0.74, p = 0.0057, median OS in $BTN2A1^{low}$ = 7.6 months and median OS in $BTN2A1^{hi}$ = 19.5 months). On the contrary, in patients treated with chemotherapy, soluble BTN2A1 concentration was not associated with overall survival. **Conclusions:** In advanced NSCLC patients, a high baseline plasmatic concentration of soluble BTN2A1 was correlated with improved outcomes for ICI, but not for chemotherapy, suggesting that baseline soluble BTN2A1 level is a potential predictive biomarker of ICI efficacy. Additional studies are ongoing to confirm this finding. Research Sponsor: Institut Paoli Calmettes and Rennes University Hospital.

9562 Poster Session (Board #328), Fri, 8:00 AM-11:00 AM

A phase Ib study of abemaciclib in combination with pembrolizumab for patients (pts) with stage IV Kirsten rat sarcoma mutant (KRAS-mut) or squamous non-small cell lung cancer (NSCLC) (NCT02779751): Interim results. *First Author: Jean-Louis Pujol, Centre Hospitalier Universitaire, Maladies Respiratoires, Montpellier, France*

Background: Abemaciclib is an orally administered, selective small molecule cyclin-dependent kinase 4 and 6 inhibitor. In preclinical models, abemaciclib induced intratumor immune inflammation and synergized with PD-1 blockade to enhance antitumor efficacy in anti-PD-L1 refractory disease. Here, we report the safety and antitumor activity of abemaciclib plus the approved NSCLC treatment pembrolizumab in 2 cohorts for pts with nonsquamous and squamous NSCLC. **Methods:** Eligible pts for this non-randomized, open-label, multicohort, phase 1b study were either chemotherapy-naive with ≥ 1% tumor cell (TC) PD-L1 staining, *KRAS*-mut nonsquamous NSCLC (Cohort A) or had a squamous subtype and received ≤ 1 prior platinum-containing chemotherapy regimen (Cohort B) for metastatic NSCLC. Primary endpoint was safety; secondary objectives included objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Results:** Twenty-five pts with NSCLC were enrolled in each cohort. Most pts (68%) in Cohort B had received 1 prior line of chemotherapy. Safety profiles observed in both cohorts were largely consistent with previous reports for abemaciclib and pembrolizumab monotherapy. Grades 3/4 AEs in Cohorts A and B, respectively, included ALT increase (6 pts [24%]/ 0 pts), diarrhea (3 pts [12%]/ 0 pts), neutropenia (3 pts [12%]/ 0 pts), and pneumonitis (3 pts [12%]/ 1 pt [4%]). Six pts in Cohort A (24%) and 2 pts in Cohort B (8%) had a confirmed partial response for a disease control rate (CR+PR+SD) of 52% and 64%, respectively. In Cohort A, the ORR in pts with strong (≥50% TC) PD-L1 staining (n = 13) was 31% vs. 17% in pts with weak (1-49% TC) PD-L1 expression (n = 12). Median PFS and OS were 7.6 months (95% CI: 1.6, NR) and 22.0 months (95% CI: 9.9, NR) in Cohort A and 3.3 months (95% CI: 1.4, 5.2) and 6.0 months (95% CI: 3.7, 13.1) in Cohort B, respectively. **Conclusions:** Abemaciclib plus pembrolizumab resulted in a numerical higher rate of transaminase elevations and pneumonitis. Antitumor activity was remarkable in the *KRAS*-mut nonsquamous NSCLC but not noticeably higher as compared to historical data for pembrolizumab monotherapy. Clinical trial information: NCT02779751. Research Sponsor: Eli Lilly and Company.

9563 Poster Session (Board #329), Fri, 8:00 AM-11:00 AM

Randomized phase II study of pembrolizumab (P) alone versus pegilodecakin (PEG) in combination with P as first-line (1L) therapy in patients (pts) with stage IV non-small cell lung cancer (NSCLC) with high PD-L1 expression (CYPRESS 1). *First Author: David R. Spigel, Sarah Cannon Research Institute, Nashville, TN*

Background: Pembrolizumab (P) is an immune checkpoint inhibitor (CPI) approved to treat 1L advanced NSCLC pts with high PD-L1 expression. PEG + CPI has demonstrated promising efficacy in NSCLC pts in a phase I trial (IVY; NCT02009449; Naing et al., 2019 *Lancet Oncol*), providing rationale for this randomized phase II trial (CYPRESS 1; NCT03382899). **Methods:** CYPRESS 1 was an open label phase II trial, for treatment-naïve, ECOG 0-1, PD-L1 high (22C3 clone TPS ≥ 50%), Stage IV NSCLC pts, without known EGFR/ALK mutations. Pts were randomized 1:1 to arm P (received 200mg IV on day 1 of a 21-day cycle) v. arm PEG+P (received P as above + PEG daily of 0.8 mg if weight ≤80kg and 1.6mg if weight> 80 kg up to 35 cycles in each arm). Pts were stratified by tumor histology and must have no prior history of cancer or prior CPI therapy. Primary endpoint was ORR (per RECIST v1.1 by investigator) Secondary endpoints included PFS, OS, and safety. Exploratory endpoints included ORR and PFS by blinded independent central review (BICR). Immune activation biomarkers (baseline and change from baseline) were assessed by serum immunoassay, IHC, and sequencing. **Results:** As of Dec 6, 2019, 101 pts were randomized to PEG+P (n=51) or P (n=50). Median follow-up time was 10.0 months (95% CI [8.4, 11.1]). Results for PEG+P versus P were: ORR per investigator was 47% v. 44% (p=0.76), ORR per BICR was 53% v. 46%(p=0.78), mPFS per investigator was 6.3 v. 6.1 months with HR = 0.94 (95% CI [0.54, 1.63];p=0.82), mPFS per BICR was 6.4 v. 7.2 months with HR = 1.10 (95%CI [0.62, 1.96]; p=0.74), and mOS was 16.3 months v. not reached with HR = 1.36 (95% CI [0.66, 2.77]; p-value=0.40). Gr ≥3 treatment related adverse events (TRAEs) were 62% for PEG+P versus 19% for P. Gr ≥3 TRAEs with ≥10% incidence included anemia (20% vs. 0%) and thrombocytopenia (12% vs. 2%). Biomarker data on immunostimulatory signals of the IL-10R pathway will be included. **Conclusions:** Adding PEG to P did not lead to improvement in ORR, PFS, or OS, in 1L advanced NSCLC with high PD-L1 expression. PEG+P arm demonstrated expected safety profile but overall higher toxicity compared to pembrolizumab alone. Clinical trial information: NCT03382899. Research Sponsor: Eli Lilly and Company.

9564 Poster Session (Board #330), Fri, 8:00 AM-11:00 AM

RELAY+: Exploratory study of ramucirumab plus gefitinib in untreated patients (pts) with *epidermal growth factor receptor* (*EGFR*)-mutated metastatic non-small cell lung cancer (NSCLC). *First Author: Makoto Nishio, Thoracic Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: The phase III randomized part of the RELAY study (Part B; RELAY; NCT02411448) showed a significant improvement in progression-free survival (PFS) for ramucirumab (RAM) plus erlotinib (ERL) vs placebo plus ERL in 449 untreated pts with *EGFR*-mutated metastatic NSCLC (median PFS: 19.4 vs 12.4 months; stratified hazard ratio: 0.59, 95% CI: 0.46–0.76, p<0.0001; 1-year PFS rate: 71.9% vs 50.7%). Here we report initial results from RELAY+ (additional cohort of RELAY; Part C), an open-label, single-arm, exploratory study evaluating RAM plus gefitinib (GEF) in East Asian pts. **Methods:** Previously untreated East Asian pts with metastatic NSCLC and *EGFR* exon 19 deletions (Ex19del) or exon 21 substitution mutation (Ex21.L858R) received RAM (10 mg/kg Q2W) plus GEF (250 mg/day) until disease progression or unacceptable toxicity. The 1-year PFS rate (primary endpoint, assuming a 1-year PFS rate of 55% for RAM+GEF), tumor response, biomarkers, and safety were assessed. *EGFR* T790M status (baseline/30-day follow-up) was assessed in liquid biopsy samples by Guardant360 NGS. **Results:** In total, 82 pts were enrolled (Japan: 68; Taiwan: 8; Korea: 6); 65.9% were female, 65.9% were never-smokers, and 43.9% had Ex19del. With median follow-up of 13.8 months (range: 2.6–20.2; censoring rate: 58.5%), the overall 1-year PFS rate (95% CI) was 65.0% (52.4–75.1), 67.2% (48.6–80.3) in pts with Ex19del (n=36), and 63.4% (45.0–77.1) in pts with Ex21.L858R (n=46). The objective response rate was 70.7% (95% CI: 59.6–80.3), disease control rate was 98.8% (95% CI: 93.4–100.0), and duration of response was immature at this point in time with a censoring rate of 56.9% where the median point estimate was 13.6 months (95% CI: 11.1–18.2). Post-progression *EGFR* T790M was seen in 7 of 9 (78%; 95% CI: 45.3–93.7) pts with 30-day follow-up NGS results in which *EGFR* activating mutation was detected. Grade ≥3 treatment-emergent adverse events reported in >5% of pts were ALT increased (23.2%), hypertension (22.0%), and AST increased (12.2%). **Conclusions:** With a 1-year PFS rate of 65.0%, the primary endpoint of RELAY+ was met. The efficacy of RAM+GEF in RELAY+ was similar to that of RAM+ERL in RELAY, and the safety profile of the combination was similar to that of the individual drugs. Clinical trial information: NCT02411448. Research Sponsor: Eli Lilly and Company.

9566 Poster Session (Board #332), Fri, 8:00 AM-11:00 AM

Phase Ib study of BI 836880, a VEGF/Ang2-blocking nanobody, in combination with BI 754091, an anti-PD-1 antibody: Initial results in patients (pts) with advanced non-small cell lung cancer (NSCLC). *First Author: Nicolas Girard, Institut Curie, Institut du Thorax Curie-Montsouris, Paris, France*

Background: Preclinical studies show that combining anti-VEGF/Ang2 with anti-PD-1 therapy promotes an immunopermissive state supportive of T-cell-mediated tumor cell destruction. BI 836880 is a humanized bispecific nanobody that targets VEGF and Ang2, and BI 754091 is an anti-PD-1 antibody. Each has shown manageable safety and preliminary activity as monotherapy. Here, we report initial results from a Phase Ib study assessing BI 836880 in combination with BI 754091. **Methods:** In Part 1 (dose escalation), pts with locally advanced or metastatic (m) non-squamous NSCLC who progressed during/after completion of ≥2 cycles of platinum-based chemotherapy (CT) ± a checkpoint inhibitor (CPI) were enrolled. Pts received BI 836880 (cohorts of 360, 500 and 720 mg intravenously [iv] 3-weekly [q3w]) plus fixed-dose BI 754091 (240 mg iv q3w). Dose escalation was guided by Bayesian logistic regression models with overdose control. Primary endpoint in Part 1 was maximum tolerated dose (MTD)/recommended phase 2 dose (RP2D), based on dose-limiting toxicities (DLTs) in Cycle 1. Initial safety and efficacy results of Part 1 are reported here. Part 2 will assess safety and efficacy in 6 expansion cohorts: mNSCLC after CPI monotherapy; mNSCLC after CT + CPI; mSCLC after CT ± CPI; immunotherapy-resistant m-melanoma; recurrent glioblastoma after 1st-line CT; and hepatocellular carcinoma after prior sorafenib or lenvatinib ± subsequent CPI. **Results:** 12 pts received BI 836880 plus BI 754091 (8 male; median age 59.5 years; 8 had received prior CPI). 4 pts remain on treatment (including 1 treated for 15 cycles). 1 pt had a DLT during Cycle 1 (360 mg; G3 pulmonary embolism). All pts experienced an adverse event (AE; any-cause; safety data cut-off Nov 2019), most commonly (all%/G3%) hypertension (58/25), vomiting (42/0), nausea (33/0), and asthenia (33/0). Hypertension was transient. No G4 AEs were reported; one G5 AE occurred (general physical health deterioration). 5 pts had immune-related AEs (G2 hypothyroidism in 2 pts; G2 pruritus, G1 papular rash, and G2 vomiting). To date (Jan 2020), 2 pts have achieved partial response; 1 pt (500 mg dose; CPI-naïve) had 58% target lesion reduction, and 1 (720 mg; prior CPI) had 35% target lesion reduction. 8 pts had stable disease. **Conclusions:** MTD/RP2D was BI 836880 720 mg plus BI 754091 240 mg q3w. The combination had a manageable safety profile, and preliminary anti-tumor activity was observed. Expansion cohorts are ongoing. Equal contribution: JA and BH Clinical trial information: NCT03468426. Research Sponsor: Boehringer Ingelheim.

Phase II randomized trial of first-line pembrolizumab and vorinostat in patients with metastatic NSCLC (mNSCLC). *First Author: Andreas Nicholas Saltos, Department of Thoracic Oncology, Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Histone deacetylase inhibitors may enhance tumor immunogenicity through various mechanisms including induced expression of T cell chemokines. A previous phase I trial demonstrated the combination of pembrolizumab (P) with vorinostat (V) in mNSCLC was well tolerated with signals of activity in ICI-pretreated pts. We initiated a randomized trial in the first-line setting with the primary objective to determine if the combination had superior ORR compared to pembrolizumab monotherapy. **Methods:** Pts with treatment-naïve mNSCLC and PD-L1 expression ≥ 1% were eligible. Pts were randomized open-label 1:1 to receive P 200 mg IV q3 wk as monotherapy [Arm A] or P 200 mg IV q3 wk plus V 400 mg PO daily [Arm B]. The primary endpoint was overall response rate (ORR). Secondary endpoints included DOR, PFS and OS. Tumor biopsies were collected both pre- and on-treatment (day 15-21) for analysis of CD8+ TIL, scored using a 0-3 scale in tumor beds. Here we report results after a preplanned interim analysis for efficacy, with accrual ongoing to a planned total of 39 patients per arm. **Results:** Between 7/2017 – 1/2019, 49 pts were enrolled, with 47 pts evaluable for response (24 in Arm A and 23 in Arm B). Median age was 69 (range 47 - 87), 49% female, ECOG PS 0/1 in 11%/89%. PD-L1 TPS was ≥50% in 13/24 (54%) of pts in Arm A, and in 13/23 (57%) of pts in Arm B. The most common TRAEs in Arm A included diarrhea (13%), fatigue (8%), and pruritus (8%). 3 pts in Arm A experienced grade ≥ 3 irAEs (including 1 each of grade 3 hepatitis, pneumonitis, and rash). The most common TRAEs in Arm B included anorexia (43%), fatigue (43%), nausea (35%) and increased creatinine (35%). 1 pt in Arm B experienced grade ≥ 3 irAE (1 grade 3 pneumonitis). Pre-treatment CD8+ TIL were not significantly different between Arm A and Arm B (p = 0.85) with the majority of tumors in both arms having a low TIL score of 1 (65% Arm A and 73.7% Arm B). A significant increase from pre-treatment to on-treatment TIL scores was seen in both Arm A (p = 0.001) and Arm B (p = 0.002). The ORR in Arm B pts with low pre-treatment TIL (score = 1) pts was substantially higher (66.7%) than in Arm A (33.3%), suggesting the combination may be especially beneficial against low TIL tumors. **Conclusions:** The combination arm had a considerably higher ORR compared to pembrolizumab monotherapy, with a manageable toxicity profile. The combination of pembrolizumab plus vorinostat in mNSCLC warrants further investigation. Clinical trial information: NCT02638090. Research Sponsor: Merck, Other Government Agency.

Best response:	Arm A N = 24	Arm B N = 23	P value
PR	6 (25%)	11 (48%)	p = 0.135
SD	8 (33%)	10 (43%)	
PD	10 (42%)	2 (9%)	
DCR	14 (58%)	21 (91%)	p = 0.017

Outcomes to first-line pembrolizumab in patients with PD-L1-high (≥50%) non-small-cell lung cancer and a poor performance status. *First Author: Joao Victor Machado Alessi, Hospital Sírio-Libanês, São Paulo, Brazil*

Background: Patients with non-small cell lung cancer (NSCLC) and a poor Eastern Cooperative Oncology Group performance status (ECOG PS) have been excluded from immunotherapy clinical trials. We sought to evaluate clinical outcomes to first-line pembrolizumab in patients with advanced NSCLC, a PD-L1 tumor proportion score (TPS) of ≥50%, and an ECOG PS of 2. **Methods:** We performed a multicenter retrospective analysis of patients with metastatic NSCLC and a PD-L1 tumor proportion score (TPS) of ≥50% (negative for genomic alterations in *EGFR* and *ALK*) who received treatment with first-line commercial pembrolizumab. Clinical outcomes were compared in patients based on ECOG PS. **Results:** Among 234 patients, 83.3% (N = 195) had an ECOG PS of 0 or 1, and 16.7% (N = 39) had an ECOG PS of 2. The baseline clinicopathological characteristics were balanced between the ECOG PS 0-1 vs 2 groups in terms of age, sex, tobacco use, histology, *KRAS* mutation status, presence of other potentially targetable driver mutations (*BRAF*, *MET*, *HER2*, *RET*), history of central nervous system (CNS) disease, and PD-L1 TPS distribution. Compared to patients with an ECOG PS of 0-1, patients with an ECOG PS of 2 had a significantly lower objective response rate (ORR 43.1% vs 25.6%; P = 0.04), a numerically shorter median progression free survival (mPFS 6.6 months vs 4.0 months; P = 0.09), and a significantly shorter median overall survival (mOS 20.3 months vs 7.4 months; P < 0.001). Upon disease progression, patients with an ECOG PS of 2 were significantly less likely to receive second-line systemic therapy compared to patients with an ECOG PS of 0-1 (55.5% vs 14.3%, P < 0.001). **Conclusions:** Although a subset of patients with an ECOG PS of 2 can respond first-line pembrolizumab, clinical outcomes in this population are poor, and use of second-line systemic therapy is infrequent. Research Sponsor: None.

9569 Poster Session (Board #335), Fri, 8:00 AM-11:00 AM

Angiogenesis inhibitor plus erlotinib versus erlotinib alone as first-line for advanced non-small cell lung-cancer harboring EGFR mutation. *First Author: Thierry Landre, UCOG-HUPSSD-APHP, Paris, France*

Background: Erlotinib is indicated in first line treatment for patients with Non-Small-Cell-Lung cancer (NSCLC) harbouring EGFR mutation. Addition of anti-VEGF in combination with erlotinib in this setting is controversial. **Methods:** We performed a meta-analysis of randomized trials comparing VEGF inhibitor plus erlotinib with erlotinib alone in first line treatment for advanced NSCLC harbouring EGFR mutation. The outcomes included overall survival (OS), progression-free survival (PFS) objective response rate (ORR), and median duration of response (DOR). A fixed-effect model was used. **Results:** Four studies evaluated bevacizumab + erlotinib (ARTEMIS, NEJ026, J025667, Stinchcombe et al), and one study evaluated ramucirumab + erlotinib (RELAY). These five eligible studies included 1230 non-squamous NSCLC patients (654 with Ex19del and 568 with Leu858Arg);. Most of the patients were women (63%), Asian (85%) and non-smokers (60%), with a median age of 64 years. The combination (anti-VEGF + erlotinib) was significantly associated with improvement of PFS (hazards ratio [HR]: 0.59, 95%CI: 0.51-0.69, p < 0.00001). Improvement in PFS was seen across all subgroups analyzed. Interim analysis of OS (HR: 0.90, 95%CI; 0.68-1.19, p = 0.45) and ORR (odds ratio [OR], 1.19, 0.91-1.55, p = 0.21) were not statistically significant. DOR was statistically longer with combination (p < 0.005). **Conclusions:** For patients with untreated advanced NSCLC with EGFR mutation, the anti-VEGF combination with erlotinib, compared with erlotinib alone, is associated with significantly improved PFS and DOR, but mature data for OS are needed to confirm the benefit of this strategy. Research Sponsor: None.

9570 Poster Session (Board #336), Fri, 8:00 AM-11:00 AM

Osimertinib in non-small cell lung cancer (NSCLC) with atypical EGFR activating mutations: A retrospective multicenter study. *First Author: Jingran Ji, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Osimertinib (osi) is a 3rd generation EGFR tyrosine kinase inhibitor (TKI) approved for first line (1L) treatment of metastatic NSCLC harboring EGFR Exon 19 del and L858R (representing > 80% of EGFR activating mutations) or in NSCLC with $EGFR^{T790M}$ (the most common resistance mutation to 1st or 2nd generation TKI). However, it has not been well-studied in EGFR-mutant NSCLC harboring less common EGFR activating mutations such as G719X, L861Q, S768I, and exon 20 insertion (ins), among others. **Methods:** We conducted a multi-institution, retrospective study approved on institutional IRB protocols in a series of patients (pts.) with metastatic NSCLC treated with osi who harbored at least one atypical EGFR mutation, excluding those with concurrent L858R, Exon 19 del, or T790M. Kaplan-Meier analyses were generated with SPSS, v25 (IBM Corp., USA). Response was assessed by RECIST 1.1 in evaluable pts. Time on osi was employed as a surrogate endpoint for clinical benefit in this retrospective analysis. **Results:** Fifty-one NSCLC pts with uncommon EGFR mutations were identified among six US institutions. Pt characteristics: 72.5% women, median age 65 yo (44-83 yo), 82.3% ECOG PS 0-1, 43.1% never smoker, 100% lung adenocarcinoma, 58.8% Caucasian, 25.5% Asian, 3.9% Black, 2.0% Hispanic, and 9.8% Other. The most frequent mutations were L861Q (35.3%, N = 18), G719X (27.5%, N = 14), and Exon 20 ins (15.7%, N = 8). Osi was used in the 1L setting in 39.2% (N = 20). Median time on osi was 7.1 months (mo.) in the overall cohort (95% CI, 5.4 to 8.8 mo.) and 8.9 mo. (95% CI, 7.0 to 10.8 mo.) in pts receiving 1L osi. Patients harboring G719X (N = 4) and L861Q (N = 10) mutations had a median time on 1L osimertinib of 5.8 mo. and 19.3 mo., respectively. One patient's tumor had an EGFR exon 19 ins and was on 1L osi with a partial response for 16.8 months. Two patients with Exon 20 ins were on 1L osi for 9.3 mo. and 8 mo., respectively. **Conclusions:** In this largest known clinically annotated dataset of patients with atypical EGFR-mutations treated with osi, activity was noted, though 1L clinical benefit on osi appears lower in this multicenter US cohort than in E19del or L858R. These results are comparable to the recently published prospective phase II trial (*Cho et al*, 2019) conducted in Korea. Patients with L861Q and Exon 19 insertion appeared to benefit the most from osi in this time on treatment retrospective analysis. More detailed analysis of this cohort is planned and further prospective studies are warranted to determine clinical benefit of osi amongst diverse atypical EGFR-mutations. Research Sponsor: None.

9571 Poster Session (Board #337), Fri, 8:00 AM-11:00 AM

Intracranial anti-tumor activity of lazertinib in patients with advanced NSCLC who progressed after prior EGFR TKI therapy: Data from a phase I/II study. *First Author: Sang-We Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Lazertinib (YH25448) is a highly mutant-selective, irreversible 3rd-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) that targets the activating EGFR mutations (Del19 and L858R), as well as the T790M mutation, while sparing wild type. Brain metastasis (BM) are common in patients (pts) with advanced NSCLC. Lazertinib showed a high blood-brain barrier penetration profile in pre-clinical studies. We report intracranial response data in pts with advanced NSCLC from a Phase I/II study of lazertinib (NCT03046992). **Methods:** Pts with advanced NSCLC, who had progressed after prior EGFR-TKI therapy, were enrolled in an open-label, multicenter, phase I/II study with dose-escalation, dose-expansion and dose-extension phases. Brain MRI was done in all pts at baseline. Pts with asymptomatic BM were eligible for enrollment. Intracranial anti-tumor activity of lazertinib was analysed in pts with BM present on baseline brain scan. Pre-defined intracranial endpoints included objective intracranial response rate (OIRR) and intracranial progression-free survival (IPFS) by independent central review (ICR). The brain metastasis full analysis population included pts with measurable and/or non-measurable BM lesion present on baseline brain scan; the brain metastasis population evaluable for response included only pts with measurable BM lesion. **Results:** As of 30 Sep 2019, a total of 181 pts received at least one dose of lazertinib 20-320 mg across 7 dose levels. Of those, 64 pts (56% female, median age 63, 86% T790M mutation positive by central testing) were included in the brain metastasis full analysis population; Intracranial disease control rate (IDCR) was 90.6% (58/64; 95% CI 83.5, 97.8) and median IPFS was not reached (95% CI 14.0, NR). In the brain metastasis population evaluable for response, a total of 22 pts were included; OIRR and IDCR were 54.5% (12/22; 95% CI 33.7, 75.4) and 90.9% (20/22; 95% CI 78.9, 100), respectively. In 13 pts (7.2%) out of 181 pts, brain was the first site of disease progression by existing and/or new lesions. **Conclusions:** Lazertinib demonstrated clinically meaningful activity against BM, aligned with preclinical data. Clinical trial information: NCT03046992. Research Sponsor: Yuhan Corporation, Other Government Agency.

9572 Poster Session (Board #338), Fri, 8:00 AM-11:00 AM

Efficacy and safety of lazertinib 240 mg as the clinical dose in patients with EGFR T790M mutant NSCLC: Data from a phase I/II study. *First Author: Ki Hyeong Lee, Division of Medical Oncology, Department of Medicine, Chungbuk National University Hospital, Chungbuk National University College of Medicine, Cheongju, South Korea*

Background: Lazertinib (YH25448) is a highly mutant-selective, irreversible 3rd-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) that targets the activating EGFR mutations (Del19 and L858R), as well as the T790M mutation, while sparing wild type. We report the efficacy and safety results of lazertinib 240 mg as recommended phase 2 dose (RP2D) from a phase I/II study of lazertinib (NCT03046992). **Methods:** Patients (pts) with advanced NSCLC, who had progressed after prior EGFR-TKI therapy were enrolled in an open-label, multicenter, phase I/II study with dose-escalation (20-320 mg), dose-expansion (40-240 mg) and dose-extension phases. Pts were assessed for safety, tolerability, pharmacokinetics and efficacy. For dose-expansion and extension phases, tumors had to be T790M mutation-positive (T790M+). Of all 78 pts assigned to lazertinib 240 mg dose level across all phases, 76 pts with centrally confirmed T790M+ were included for efficacy analysis. **Results:** As of 30 Sep 2019, a total of 78 pts (49% female, median age 62) received at least one dose of lazertinib 240 mg. The median duration of follow-up was 9.6 months and 44 pts were ongoing at data cut-off. Of 78 pts, 76 pts with centrally confirmed T790M+ showed the objective response rate (ORR) 57.9% (95% CI 46.8, 69.0), the disease control rate (DCR) 89.5% (95% CI 82.6, 96.4), the median progression-free survival (PFS) 11.0 months (95% CI 5.6, 16.4) and the median duration of response (DoR) 13.8 months (95% CI 9.6, NR) by independent central review (ICR), respectively. Two pts (3%) experienced a confirmed complete response. The investigator-assessed ORR, DCR, median PFS and median DoR were 72.4% (95% CI 62.3, 82.4), 94.7% (95% CI 89.7, 99.8), 13.2 months (95% CI 9.6, not reached) and 11.8 months (95% CI 8.4, not reached), respectively. The most common treatment-emergent adverse events (TEAEs) at the 240 mg dose regardless of its causality were rash (35%), pruritus (33%) and paraesthesia (32%), which were mostly mild (Grade ≥3 rash: 1%; no Grade ≥3 pruritus or paraesthesia). TEAEs leading to dose reduction and dose discontinuation were observed in 13% (10/78) and 8% (4/78), respectively. Drug related TEAEs of grade ≥3 were observed in 6% (5/78). **Conclusions:** Lazertinib 240 mg has a favorable safety profile, and exhibits promising anti-tumor activity in pts with EGFR T790M+ NSCLC. Clinical trial information: NCT03046992. Research Sponsor: Yuhan Corporation, Other Government Agency.

9573 Poster Session (Board #339), Fri, 8:00 AM-11:00 AM

Study of anlotinib combined with icotinib as the first-line treatment in non-small cell lung cancer (NSCLC) patients harboring activating EGFR mutations (ALTER-L004). *First Author: Dingzhi Huang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Anti-angiogenic monoclonal antibodies plus EGFR TKIs have previously shown to prolong PFS in patients with EGFR-mutated NSCLC (JO25567 and NEJ026). Unlike bevacizumab, anlotinib is more convenient with orally administered and can inhibit more targets. Monotherapy using anlotinib has significantly prolonged median PFS and OS compared with the placebo values for third-line treatment or beyond in advanced NSCLC. We conducted a study to investigate the activity of anlotinb combined with icotinib, an oral EGFR TKI. **Methods:** This is a prospective, single-arm, multicenter clinical trial. Patients with locally advanced and/or metastatic IIIB, IIIC or IV non-squamous NSCLC are enrolled. Patients with EGFR exon 19 deletion and/or exon 21 L858R mutation who have not received prior therapies are eligible. The regimen consists of anlotinib (12 mg p.o, qd, day 1 to 14 every 21-day cycle) and icotinib (125mg p.o, tid). The primary endpoint is PFS. Secondary endpoints are OS, ORR, DCR and safety. **Results:** Between Jul 2018 and Dec 2019, 35 patients were enrolled in five centers and treated with anlotinb and icotinib. At data cutoff (Jan 7, 2020), patients were followed up for a median of 6.01 months.32 tumors were analyzed with 30 evaluable. Preliminary efficacy results: ORR was 59% (0 CR, 19 PR), DCR was 88% (0 CR, 19 PR, 9 SD). 26 patients are still receiving treatment and the longest exposure was 14 cycles. 10 (67%) of 15 patients with exon 19 deletions and 9 (53%) of 17 patients with L858R mutations achieved an objective response. 18 patients harbored aberrations in additional oncogenic drivers (PIK3CA or AKT1) and/or tumor suppressors (TP53, RB1, and PTEN) with an ORR of 72%. Upon analyses, AEs were observed in 97% (34/35) of patients. No Gr 5 AEs were reported. The most common Grade 3 AEs were hypertension (6 [17%]), hypertriglyceridemia (2 [6%]), diarrhea (1 [3%]), hyperuricemia (1 [3%]), hand and foot skin reaction (1 [3%]), asthenia (1 [3%]), and acute coronary syndrome (1 [3%]). Hypertriglyceridemia was the only grade 4 AE (2 [6%]). Three patients had to adjust treatment dosage. **Conclusions:** The strategy of anlotinib plus icotinib showed encouraging efficacy for previously untreated, EGFR-mutated advanced NSCLC patients. The combination was well tolerated and the AEs were manageable. The follow-up time is not sufficient and the PFS and OS outcomes need further evaluation. Clinical trial information: NCT03736837. Research Sponsor: None.

9574 Poster Session (Board #340), Fri, 8:00 AM-11:00 AM

Nazartinib (EGF816) in patients with treatment-naïve *EGFR*-mutant non-small cell lung cancer (NSCLC): Updated phase II results. *First Author: Daniel Shao-Weng Tan, National Cancer Centre Singapore, Singapore, Singapore*

Background: Prior data from a phase I/II study showed durable responses, including efficacy in brain lesions, and a tolerable safety profile with nazartinib in treatment (tx)-naïve patients (pts) with *EGFR*-mutant (mut), locally advanced (adv)/metastatic NSCLC. Here we report updated phase II results, including overall survival (OS). **Methods:** Tx-naïve adult pts with activating *EGFR*-mut (L858R or ex19del), stage IIIB/IV adv NSCLC with neurologically stable and controlled brain metastasis (BM) received oral nazartinib 150 mg once daily (continuous schedule). Primary endpoint: overall response rate (ORR) by BIRC per RECIST v1.1; secondary endpoints: disease control rate (DCR), duration of response (DOR), time to response, progression-free survival (PFS), OS, and safety. **Results:** At data cut-off (Nov 1, 2019), 45 pts were enrolled (median [range] age: 64 [28–83] years; 26 pts [58%] ECOG PS 1; 18 pts [40%] had baseline BM). *EGFR* mutations: 56% ex19del, 40% L858R, 4% other. 26/45 pts (58%) discontinued tx, with the primary reason being progressive disease in 19 pts (42%); 2 pts (4%) discontinued tx due to AEs. Median (range) follow-up for OS: 25 (0–33) months (mo); and for PFS: 17 (0–33) mo. ORR by BIRC: 69%; median PFS by BIRC: 18 mo; median OS was NE and at 33 mo, 56% of pts were alive (Table). BIRC results by baseline BM are shown in the Table. Median (range) duration of exposure: 24 (0–34) mo. Most frequent AEs (≥20% all grade, all causality): diarrhea (47%), maculopapular rash (38%), pyrexia (29%), cough and stomatitis (27% each), decreased appetite and pruritus (24% each), and dermatitis acneiform (22%). Most frequent grade 3/4 AEs (≥10%, all causality): maculopapular rash (5 pts [11%]; all grade 3) and increased lipase (5 pts [11%]; 1 pt with grade 4; no clinical pancreatitis AE was observed). **Conclusions:** After additional follow-up, median OS was still not reached and the safety profile was manageable. Nazartinib is a promising 3rd generation EGFR TKI for tx-naïve pts with adv *EGFR*-mut NSCLC, including pts with baseline BM. Clinical trial information: NCT02108964. Research Sponsor: Novartis Pharmaceuticals.

9575 Poster Session (Board #341), Fri, 8:00 AM-11:00 AM

Tepotinib in patients (pts) with NSCLC with *MET* exon 14 (*MET*ex14) skipping: Health-related quality of life (HRQoL). *First Author: Paul K. Paik, Thoracic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the phase II VISION study (NCT02864992) tepotinib had promising efficacy (response rate of 40–50% & median duration of response >1 y) and tolerable safety in pts with advanced NSCLC with *MET*ex14 skipping (3–4% of NSCLC), who are typically elderly with poor prognosis. Pt reported outcomes (PROs) of HRQoL are described here. **Methods:** Pts with advanced NSCLC positive for *MET*ex14 skipping by tissue or liquid biopsy received oral tepotinib 500 mg once daily; PROs were assessed using QLQ-LC13 (lung cancer symptoms), EORTC QLQ-C30 (Global health status [GHS] & 5 functional scales), and EQ-5D-5L (VAS). Questionnaires were completed at baseline (BL) and every 6 weeks (Wk); results were scored from 0–100 (minimal clinically important difference [MCID] ≥10 points). Mean change from BL was analyzed at Wk 12 (predefined analyses). **Results:** By 19 Jul 19 cut-off, 130 pts across treatment lines were enrolled (median age 74.2 y), with PROs available for 129. Questionnaire completion rates were 90.1% at Wk 12. Symptom burden at BL was moderate for advanced NSCLC; mean change from BL for PROs are shown in the table (better functioning: lower QLQ-LC13 or higher QLQ-C30 scores). For the QLQ-LC13 symptoms, mean changes from BL indicated a meaningful improvement in coughing, with a median time to improvement (2.8 months) paralleling the onset of objective response (within first 3 months), and a numerical improvement in dyspnea (–2.3 at Wk 12) and chest pain (–4.2 at Wk 12). QLQ-C30 values remained stable over treatment as did EQ-5D-5L scores (higher=better): mean (standard deviation, SD) change from BL score (60 [20.4]) was 6 (18.6) at Wk 6 and 5 (20.9) at Wk 12. **Conclusions:** In this first analysis of PROs in pts with advanced NSCLC with *MET*ex14 skipping with a moderate symptom burden, treatment with tepotinib led to a clinically meaningful improvement in coughing symptoms, while maintaining HRQoL. Coupled with the efficacy and safety profile, the predefined HRQoL analysis from the VISION study supports tepotinib as a promising treatment option for this elderly population with *MET*ex14+ NSCLC. Clinical trial information: NCT02864992. Research Sponsor: Merck KGaA.

			Mean change (SD):	
MCID: ≥10 points		**BL mean (SD)**	**Wk 6**	**Wk 12**

Lung-MAP (SWOG S1400): Design, implementation, and lessons learned from a biomarker-driven master protocol (BDMP) for previously-treated squamous lung cancer (sqNSCLC). *First Author: Mary Weber Redman, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: S1400, a BDMP, was designed to address an unmet need in sqNSCLC, run within the National Clinical Trials Network of the National Cancer Institute using a public-private partnership (PPP). The goal of was to establish an infrastructure for biomarker-screening and rapid evaluation of targeted therapies in biomarker-defined groups leading to regulatory approval. **Methods:** S1400 included a screening part using the FoundationOne assay and a clinical trial part with biomarker-driven studies (BDS) and "non-match" studies (NMS) for patients not eligible for any BDS. Patients could be screened (SaP) at progression or pre-screened (PreS). **Results:** Between June 2014 and January 2019, 1864 patients enrolled (711 PreS, 1079 SaP), 1674 with biomarker results, and 653 registered to a study with 217 to BDS and 436 to NMS. Six BDS and 3 NMS were initiated in small subsets with all BDS and 2 NMS completed within 2-3 years (see Table). Completed BDS have not demonstrated activity with 0-2 responses. On S1400I, Nivolumab and ipilimumab did not improve survival. Response with durvalumab (S1400A) was 16%. **Conclusions:** Lung-MAP met its goal to quickly answer targeted and other novel therapy questions in rare sqNSCLC subpopulations, answering questions that likely would not have been otherwise feasible, thereby demonstrating value. Activated just prior to the success of PD-(L)1 therapies in sqNSCLC, the trial had to undergo major design changes. Lessons learned include the need to update based on new science and that the PPP collaboration was essential to success. Lung-MAP continues now with new BDS and NMS in all NSCLC as of January 2019. Clinical trial information: NCT02154490. Research Sponsor: U.S. National Institutes of Health, Public-private partnership through Foundation for the NIH.

9577 Poster Session (Board #343), Fri, 8:00 AM-11:00 AM

Clinicopathologic characteristics and immunotherapy outcomes in SMARCA4-mutant (mut) non-small cell lung cancer (NSCLC). *First Author: Joao Victor Machado Alessi, Dana-Farber Cancer Institute, Boston, MA*

Background: The catalytic unit of the SWI/SNF chromatin remodeling complex is encoded by the SMARCA4 gene, which is mutated in ~10% of NSCLCs. We sought to characterize the clinicopathologic characteristics and outcomes to immune checkpoint inhibition in SMARCA4-mutant NSCLC. **Methods:** We collected clinicopathologic and genomic data from patients with NSCLC that had undergone targeted next generation sequencing (NGS) by OncoPanel at the Dana-Farber Cancer Institute. SMARCA4 frameshift, nonsense, and splice-site mutations were considered pathogenic, as were missense mutations if predicted to be pathogenic by Mutation Assessor and Polyphen-2. Clinical outcomes to immune checkpoint inhibition among SMARCA4-mutant NSCLCs were retrospectively assessed. **Results:** Of 2690 patients with NSCLC, 8% (N = 211) harbored SMARCA4 mutations. Clinicopathological characteristics were balanced between SMARCA4 mut and SMARCA4 wild-type (wt) in terms of age, histology, and PD-L1 expression. We observed a male predominance (P = 0.03), greater use of tobacco (P < 0.001), a higher tumor mutational burden (TMB) (P < 0.001), a higher prevalence of advanced disease (P < 0.001), and a lower prevalence of concurrent targetable driver mutations (P < 0.001) in SMARCA4mut vs SMARCA4wt NSCLCs. Among 513 patients with nonsquamous NSCLC who received immune checkpoint inhibitors, 11% (N = 57) harbored SMARCA4 mutations. From the start of immunotherapy, we observed no difference in overall response rate (ORR 21.5% vs 19.3%; P = 0.3), median progression free survival (mPFS 3.2 months vs 2.1 months; P = 0.4), or median overall survival (mOS 12.0 months vs 8.2 months; P = 0.09) in SMARCA4wt vs SMARCA4mut NSCLC, respectively. However, among KRASmut NSCLC, a concurrent SMARCA4 mut conferred a significantly lower ORR (23.1% vs 0.0%; P = 0.02), a significantly shorter mPFS (4.8 months vs 1.7 month; HR: 0.31 [95% CI: 0.15-0.61]; P < 0.001), and a significantly shorter mOS (15.6 months vs 2.7 months; HR: 0.25 [95%CI: 0.12-0.49]; P < 0.001). The deleterious effect of SMARCA4 mut on immunotherapy outcomes in KRAS mut NSCLC was maintained when controlling for concurrent STK11 mut. **Conclusions:** SMARCA4 mutations define a genomic subset of NSCLC with unique clinicopathologic characteristics, and confer worse outcomes to immunotherapy in KRAS mut NSCLC. Research Sponsor: None.

9578 Poster Session (Board #344), Fri, 8:00 AM-11:00 AM

***FOXO3* polymorphisms were correlated with gefitinib-induced hepatotoxicity in patients with non-small cell lung cancer.** *First Author: Shaoxing Guan, Laboratory of Drug Metabolism and Pharmacokinetics, School of Pharmaceutical Sciences, Sun Yat-sen University, Guangzhou, China*

Background: Drug-induced liver injury (DILI) is one of the most safety concern in drug development and clinical therapy. Severe hepatotoxicity of gefitinib often leads to acute/chronic liver injury, drug discontinuation and further treatment failure, however, the mechanism of gefitinib-induced hepatotoxicity remains unclear. *AKT1/FOXO3* regulates expression of genes involved in multiple biological/pathological processes in liver cells, including apoptosis, oxidative stress, and cell-cycle transition, as well as expression of autophagy-related (Atg) genes. Therefore, we investigated the correlation between single nucleotide polymorphisms (SNP) in *AKT1/FOXO3* and gefitinib-induced hepatotoxicity in patients with advanced non-small cell lung cancer (NSCLC). **Methods:** A total of 172 advanced NSCLC patients with activating *EGFR* mutations were enrolled and administered with gefitinib 250mg daily. 22 tag SNPs in *AKT1/FOXO3* were selected by Heploview 4.2 and sequenced by Agena MassARRAY System. The associations between polymorphisms of *AKT1/FOXO3* and gefitinib-induced hepatotoxicity were analyzed by Chi square test. This study was approved by the ethical committee of Sun Yat-Sen University Cancer Center. **Results:** *FOXO3* rs4946935 and *FOXO3* rs75544369 were found to be associated with gefitinib-induced hepatotoxicity in NSCLC patients. *FOXO3* rs4946935 AA carriers have higher risk of developing gefitinib-induced hepatotoxicity than those with *FOXO3* rs4946935 AG/GG. ($P = 0.018$, OR = 12.414, 95%CI (1.53-100.711)). Patients with *FOXO3* rs75544369 GA have higher risk of developing hepatotoxicity with *P* of 0.0002 (OR = 5.241, CI%(1.85-14.851)), or developing severe hepatotoxicity with *P* of 0.033 (OR = 2.963, 95%CI (1.090-8.059)), than those with *FOXO3* rs75544369 GG. **Conclusions:** *FOXO3* rs4946935 and *FOXO3* rs75544369 are predictive biomarkers for gefitinib-induced hepatotoxicity in NSCLC patients. The mechanism underlying the association between *FOXO3* polymorphisms and gefitinib-induced hepatotoxicity are worth investigating in further studies. Clinical trial information: NCT01994057. 9579 Poster Session (Board #345), Fri, 8:00 AM-11:00 AM

Is checkpoint inhibitor pneumonitis underreported in patients with advanced non-small cell lung cancer (NSCLC) on PD-1 inhibitor monotherapy? *First Author: Benjamin Oren Spieler, University of Miami Miller School of Medicine, Miami, FL*

Background: For patients with advanced non-small cell lung cancer (NSCLC), immunotherapy (ImT) has led to improvements in survival and quality of life. Checkpoint inhibitor pneumonitis (CIP) is an uncommon but sometimes life-threatening adverse event. While CIP is a diagnosis of exclusion, many oncologists believe the incidence of CIP is underreported. Radiomics, an image analysis technique that can extract imperceptible information from radiographic images, has been incorporated into predictive models for many cancers. Recent studies suggest that radiomic analysis of pre-ImT imaging can predict CIP. We hypothesized that for patients with advanced NSCLC treated with Nivolumab monotherapy, the rate of CIP is underreported and radiomics features can identify CIP that was clinically misclassified. **Methods:** From an IRB-approved database (DB) of 159 patients with advanced NSCLC treated with Nivolumab, chart review identified 8 patients diagnosed with CIP of any grade (5%). 42 additional patients from the same DB without diagnosis of CIP were randomly selected for analysis. For all 50 patients, uninvolved lung in the last pre-ImT CT imaging study was segmented, delineated, and analyzed for radiomics features associated with CIP. A logistic regression model incorporating radiomics assigned a CIP probability score to every patient. **Results:** Six radiomics features correlated with CIP (*p*-values range from 0.02 to 0.03). Each feature had an AUC of ~0.79 (range 0.789 to 0.794) showing large effect size, with odds ratios greater than 3.50 (4 features) or less than 0.3 (2 features). The radiomics-based probability model assigned 7/42 patients (17.5%) without clinical diagnosis of CIP a greater than 50% probability of CIP. Chart review revealed that 6/7 "misclassified" patients exhibited symptoms or radiographic features highly suggestive of CIP within 5 months of initial immunotherapy treatment. These indications originally had been attributed to disease progression, overshadowed by more severe symptoms or simply mislabeled (e.g. a case of recall pneumonitis was described as "radiation pneumonitis"). **Conclusions:** For patients with advanced NSCLC treated with nivolumab, the incidence of checkpoint-inhibitor pneumonitis (CIP) is underreported and radiomics features can help identify CIP that has been clinically misclassified. Future directions include expansion of this study across the full database, correlation of radiomics features with blood biomarkers, and the inclusion of tumor burden as an additional covariate in the analysis. Indirect comparison of TAK-788 vs real-world data outcomes in refractory non-small cell lung cancer (NSCLC) with *EGFR* exon 20 insertions. *First Author: Leora Horn, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Currently approved epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are ineffective in patients (pts) with *EGFR* exon 20 insertion NSCLC. TAK-788 is an EGFR TKI with potent and selective preclinical inhibitory activity against *EGFR* exon 20 insertions, and has demonstrated preliminary efficacy in a single-arm phase 1/2 clinical trial (NCT02716116). We performed an indirect comparison of real-world outcomes with clinical trial data for this subset of pts to determine whether TAK-788 provides superior efficacy over standard treatment options. **Methods:** We compared efficacy in pts with refractory NSCLC with *EGFR* exon 20 insertions treated with TAK-788 160 mg qd (1–7 prior lines) from the ongoing clinical trial (data cut Mar 1, 2019) vs real-world data (RWD) in the second-line setting from the US Flatiron Health electronic health record–derived database (Jan 2011–Jun 2018). This analysis was conducted using an unadjusted data set, as well as by applying propensity score modeling with inverse probability of treatment weighting (IPTW) to adjust for group differences in key baseline characteristics. Progression-free survival (PFS) and objective response rate (ORR) were compared between groups. **Results:** A total of 99 pts were included, n=28 TAK-788 and n=71 RWD; mean age 62/65 y; male 25%/46%; Asian 18%/10%; former smoker 39%/45%; brain metastases 43%/34%. In the RWD, there was no consistent regimen for second-line treatment (including 29.6% immuno-oncologic agents, 25.4% EGFR TKI, 10% docetaxel). Baseline characteristics were comparable after weighting. PFS and ORR showed statistically significant improvements with TAK-788 vs RWD (Table). Specifically, after weighting, median PFS for TAK-788 vs RWD is 7.3 vs 3.5 mo, and ORR is 43% vs 13%. **Conclusions:** Despite a more heavily pretreated pt population, the efficacy of TAK-788 in pts with refractory NSCLC with *EGFR* exon 20 insertions appears better than other second-line treatment options used in the real-world setting. Clinical trial information: NCT02716116. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

9581 Poster Session (Board #347), Fri, 8:00 AM-11:00 AM

SPRING: A Worldwide Innovative Network (WIN) Consortium phase I study of triple therapy (avelumab, axitinib, and palbociclib) in advanced non-small cell lung cancer (NSCLC) with genomic and transcriptomic correlates. *First Author: Benjamin Maurice Solomon, Avera Cancer Institute, Sioux Falls, SD*

Background: The Worldwide Innovative Network (WIN) Consortium has developed the Simplified Interventional Mapping System (SIMS) algorithm in order to predict treatment response by comparing tumor and normal tissue biopsies on both genomic and transcriptomic platforms. SPRING is the first trial to assess a SIMS-based tri-therapy regimen in advanced non-small cell lung cancer (NSCLC). **Methods:** Patients with advanced NSCLC (no *EGFR* or *ALK* alterations; no *ROS1* alterations if tested; PD-L1 unrestricted; $\leq$2 prior therapy lines) were treated with avelumab, axitinib, and palbociclib (3+3 dose escalation design). Tumor and normal endobronchial mucosal biopsies were obtained on all patients for retrospective SIMS algorithm validation. **Results:** Fifteen patients were treated: 6 at dose level 1 (DL1); 6, dose level 2 (DL2); 3, dose level 3 (DL3). Three dose-limiting toxicities (DLTs) at least possibly drug-related occurred: 1 DLT at DL2 (Grade 3 (G3) infusion reaction); 2 patients with DLTs at DL3 (1 with G3 hand/foot syndrome and G3 fatigue and 1 with G5 respiratory failure). Among 14 evaluable patients, the partial response (PR) rate was 28.6% (4/14 patients including 2/6 patients at DL1; two PRs in patients who failed prior pembrolizumab; two PRs in patients with PD-L1 $<$ 1%). The maximum tolerated dose was avelumab 10 mg/kg IV q2weeks, axitinib 5 mg PO BID continuous, palbociclib 75 mg PO daily on days 8-28 of a 28 day cycle (DL2). DL2 was above the recommended phase II dose (RP2D), since 5/6 patients treated at DL2 required later treatment delays and/or dose reductions, mostly due to neutropenia. To further evaluate DL1, 3 patients were added to this cohort (total of 6). Since no DLTs were seen at DL1, and 5 of 6 patients did not require dose reduction, DL1 (avelumab 10 mg/kg IV q2weeks, axitinib 3 mg PO BID continuous, palbociclib 75 mg PO daily on days 8-28 of a 28 day cycle) is the RP2D. **Conclusions:** The RP2D was determined to be dose level 1. This triplet showed antitumor activity in patients with NSCLC, including those progressing on prior pembrolizumab. SIMS algorithm correlates of response are being assessed. Clinical trial information: NCT03386929. Research Sponsor: ARC Foundation for cancer research, Villejuif, France, Pharmaceutical/Biotech Company.

9582 Poster Session (Board #348), Fri, 8:00 AM-11:00 AM

Final analysis of KEYNOTE-189: Pemetrexed-platinum chemotherapy (chemo) with or without pembrolizumab (pembro) in patients (pts) with previously untreated metastatic nonsquamous non-small cell lung cancer (NSCLC). *First Author: Delvys Rodriguez-Abreu, Complejo Hospitalario Universitario Insular Materno-Infantil de Gran Canaria, Universidad de Las Palmas de Gran Canaria, Las Palmas De Gran Canaria, Spain*

Background: The phase III KEYNOTE-189 study (NCT02578680), showed significant improvements in OS and PFS with pembro + chemo vs placebo + chemo in pts with previously untreated metastatic nonsquamous NSCLC without sensitizing *EGFR/ALK* mutations. We report the protocol-specified final analysis of KEYNOTE-189. **Methods:** Pts were randomized 2:1 to receive 35 cycles of pembro 200 mg Q3W (n = 410) or placebo Q3W (n = 206) plus 4 cycles of pemetrexed (pem) and carboplatin/cisplatin followed by maintenance pem. Pts in the placebo + chemo arm could crossover to pembro upon PD. PFS and OS were primary endpoints; ORR was a secondary endpoint. PFS2 (time from randomization to objective tumor progression on next-line treatment/death), was an exploratory endpoint. **Results:** At data cutoff (May 20, 2019), median (range) time from randomization to data cutoff was 31.0 (26.5–38.8) mo. 17 pts in the pembro + chemo arm and 1 pt in the placebo + chemo arm were receiving initially assigned treatment; 84 pts crossed over to pembro. Median (95% CI) OS (22.0 [19.5–24.5] vs 10.6 [8.7–13.6] mo; HR 0.56 [95% CI, 0.46–0.69]) and PFS (9.0 [8.1–10.4] vs 4.9 [4.7–5.5] mo; HR 0.49 [95% CI, 0.41–0.59]) were longer with pembro + chemo vs placebo + chemo (Table). The 2-y OS rate was 45.7% vs 27.3% and the 2-y PFS rate was 22.0% vs 3.4%. ORR was 48.3% with pembro + chemo vs 19.9% with placebo + chemo. 56 pts in the pembro + chemo arm completed 35 cycles of pembro among whom ORR was 85.7% (4 CR, 44 PR, 8 SD) and median OS was not reached. 292 (72.1%) pts in the pembro + chemo arm and 135 (66.8%) pts in the placebo + chemo arm had grade 3–5 AEs. **Conclusions:** Pembro + chemo continued to show improved outcomes in OS, PFS, ORR and PFS2 compared with placebo + chemo, with manageable toxicity. These findings support first-line pembro + chemo in pts with previously untreated metastatic nonsquamous NSCLC. Clinical trial information: NCT02578680. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

9583 Poster Session (Board #349), Fri, 8:00 AM-11:00 AM

A phase Ib study of a novel c-MET, AXL and VEGFR-2 inhibitor ningetinib and gefitinib combination therapy in Chinese EGFR-TKI resistant NSCLC with T790M negative. *First Author: Hongyun Zhao, Department of Medical Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, China*

Background: Ningetinib is a novel tyrosine kinase inhibitor, targeted at c-Met, Axl, VEGFR-2, Mer and Flt3. This phase Ib trial (NCT03758287) evaluated the safety, determined the recommended phase II dose (RP2D), and further explored the pharmacokinetic and efficacy of Ningetinib + Gefitinib in EGFR-TKIs acquired resistant NSCLC patients (pts) with T790M negative. **Methods:** Chinese Pts with advanced or metastatic NSCLC, acquired resistant to at least one EGFR-TKI, T790M negative were enrolled. Pts received Ningetinib 30, 40, 60 mg + Gefitinib 250mg orally once daily in dose-escalation (n = 12) by a Fibonacci 3+3 design. Expansion phase (n = 74, enrollment is ongoing) started at tolerated dosage. Safety, RP2D were primary endpoints; PK, antitumor activity were secondary endpoints. Non-mandatory tumor samples at baseline were collected for exploratory objectives. **Results:** Totally, 86 eligible pts were enrolled between Nov 2016 and Dec 2019, and received treatment (Ningetinib 30 mg, n = 36; 40 mg, n = 46; 60 mg, n = 4), with median age 56.7 years, 36% with baseline brain metastasis, 66%/33%/1% prior 1/2/3 lines EGFR-TKI treatment, respectively. Treatment-related adverse events (TRAEs) occurred in 82 (95%) pts, grade 3/4 in 32 pts (37%). Most common TRAEs (≥30%) were myocardial enzyme elevation (all grade 74.4%; grade 3-4 0%), transaminase elevation (73.3%; 2.3%), skin rash (60.5%; 3.5%), albuminuria (44.2%; 0%), coagulation abnormalities (mostly asymptomatic Fbp decrease; 37.2%; 15.1%), diarrhea (33.7%; 2.3%) and hypertension (32.6%; 11.6%). Two Dose limited toxicities were observed at 60 mg dosage (both were grade 3 Fbg decrease), RP2D was decided at 40 mg. Of 84 efficacy evaluable pts, ORR was 19.1% (16 PR), DCR was 91.7% (61 SD, 7 PD). Totally, 65 (75.6%) progression events occurred at data cut-off (9 Jan 2020), the median PFS for all pts was 4.4 months (95%CI 3.7-4.6). No PFS differences were found between pts grouped by 3rd TKIs history or brain metastasis. C-Met gene amplification by FISH was conducted in 72 pts (83.7%). Pts with higher gene copy number (GCN) responded better in treatment, ORR in the GCN ≥6 (n = 11), GCN ≥5 (n = 16) and GCN ≥3 (n = 37) subgroups was 36.4%, 25.0% and 21.6% respectively. **Conclusions:** Ningetinib was well tolerated at 30 mg and 40 mg dosage with Gefitinib 250 mg, the RP2D for Ningetinb was 40 mg. This combination therapy showed promising anti-tumor activity in prior EGFR-TKIs acquired resistant NSCLC pts with T790M negative. C-Met GCN was the potential efficacy biomarker. Clinical trial information: NCT03758287. Research Sponsor: HEC R&D Center, Sunshine Lake Pharma Co., Ltd.

9584 Poster Session (Board #350), Fri, 8:00 AM-11:00 AM

Genomic characterization of metastatic lung cancers. *First Author: Hui Yu, Department of Medical Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: Lung carcinomas are most often diagnosed at stage IV, with metastases, which contribute to 90% of deaths of patients. Enormous efforts have been made in previous studies in seek of underlying mechanisms and treatments that prevent or cure metastases. However, few comprehensive conclusions have been drawn on organ-specific genomic landscapes and molecular dependencies of lung cancer metastases, largely due to limited sample sizes. **Methods:** We employed massive targeted next generation sequencing (NGS) with a panel covering 425 cancer-related genes on 10409 samples from 8619 patients with lung cancer, including 8479 from primary tumors and 1930 from metastases to the brain, liver, pleura, bones, and lymph nodes. We investigated single nucleotide variants (SNVs), copy number variants (CNVs), structural variations (SVs), mutational signatures, and other genomic characteristics at all primary and metastatic sites. With data of primary-metastatic tumor pairs, we also examined genomic evolutionary patterns. **Results:** Our data revealed that metastases harbored more instable and complicated genomes. Most SNVs (5/6), CNVs (41/47), and SVs (2/3) that showed significant differences of prevalence between primary tumors (PTs) and metastases (MTs) were MT-enriched. Among them, we identified a novel MT-enriched event, *PTK2* amplification (2.33 folds), as well as known ones including mutations of *TP53*, *ARID1A*, and *BRCA1* (1.23, 1.74, and 2.29 folds), and amplifications of *MYC*, *RICTOR*, and *EGFR* (2.04, 2.15, and 1.59 folds). In addition, almost all actionable CNV alterations (6/7) showed higher frequencies in MTs. *ALK* fusions and *EGFR* mutations, which indicate distinct target therapies, exhibited opposite preference in MTs and PTs, respectively. We also identified MT site-specificity of alterations, such as *NF2*, *TSC2*, and *LRP1B* mutations enriched in the brain, *BRAF* and *GNAS* mutations absent in the liver, and APOBEC-associated mutational signatures enriched in lymph nodes. Moreover, we unraveled organ-specific patterns of genomic evolutionary trajectories in metastatic diseases. **Conclusions:** The genomic profile and evolutionary pattern of metastatic lung cancer differed from that of primary tumors. The identification of site-specific characteristics that may have empowered directional metastasis, such as *NF2*, *TSC2*, and *LRP1B* mutations in the brain and APOBEC-associated mutational signatures in lymph nodes, may guide personalized disease management, design of clinical trials, and/or discovery of therapeutic targets for metastatic lung cancer at different body regions. 9585 Poster Session (Board #351), Fri, 8:00 AM-11:00 AM

A phase I, dose-escalation and expansion study of TQ-B3139, a novel ALK TKI, in Chinese ALK or ROS1 positive advanced non-small cell lung cancer (NSCLC). *First Author: Yuxiang Ma, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: TQ-B3139 is a novel ALK inhibitor with activity 3-7 folds higher than Crizotinib against a broad range of ALK mutations. This phase I study (NCT03099330) is to investigate the safety, and determine the recommended phase II dose (RP2D), and pharmacokinetic (PK), clinical efficacy of TQ-B3139 in Chinese NSCLC patients. **Methods:** Patients with advanced NSCLC and failed at least one systemic anti-cancer treatment were enrolled. TQ-B3139 was administered orally from 50mg~100mg qd and 200, 300, 400, 500, 600 and 800mg bid, using a PK-guided modified Fibonacci 3+3 dose escalation design. The dose-escalation evaluated patients in 28-day cycles, dose limited toxicities (DLTs) was observed at first cycle. Dose-expansion phase started at dose level which objective response occurs. Treatment was continued until disease progression, death or unacceptable toxicity. **Results:** Between July 2017 and May 2019, totally 63 patients (59 ALK+, 4 ROS1+) were enrolled. Sixteen patients had prior ALK inhibitor therapy (11 Crizotinib, 5 Ensartinib), and 23 (36.5%) with baseline brain metastasis. Totally, 62 (98.4%) patients experienced treatment-related adverse events (TRAEs), grade 3-4 TRAEs were observed in 21 (33.3%) patients. One DLT occurred in the 800mg bid dose cohort (grade 3 nausea and vomiting). Top 3 common TRAEs were nausea (all grade 87.3%; grade 3-4 3.2%), diarrhea (84.1%, 6.4%), transaminase elevation (65.1%, 4.8%). AUC and C_{trough} at steady state increased proportionally from 200mg to 600mg bid. Absorption saturation was observed in 800mg bid. Base on the safety and PK results, PR2D was decided at 600mg bid. Overall ORR was 73.0% (2 CR, 44 PR); DCR was 85.7% (8 SD). Objective response was observed from dose level 200mg bid cohort, ORR and DCR at ≥200mg bid was 78.0% and 89.8%. For ALK TKI-naïve and -resistant patients, the ORR was 78.7% (37/47) and 56.3% (9/16) respectively. For patients with measurable baseline brain metastasis, the ORR for brain lesions was 80.0% (8/10). At data cut-off (23 Jan 2020), 32 events (50.8%) occurred, the median PFS for all patients was 12.1 months (95%CI 8.5-15.6), for patients at ≥200mg bid dose was 12.2 months. The median PFS was not reached for -naive patients (6 months PFS rate 74.5%, 95%CI 68.1-80.9), and 5.6months (95%CI 1.6-9.5) for ALK TKI-resistant patients. **Conclusions:** TQ-B3139 was well tolerated in Chinese NSCLC patients with high antitumor activity. RP2D was established at 600mg bid. A randomized phase III trial of TQ-B3139 versus Crizotinib in advanced ALK-TKI naïve NSCLC patients is underway. Clinical trial information: NCT03099330. 9586 Poster Session (Board #352), Fri, 8:00 AM-11:00 AM

High-dose osimertinib for CNS progression in EGFR+ non-small cell lung cancer (NSCLC): A multi-institutional experience. *First Author: Andrew Piper-Vallillo, Beth Israel Deaconess Medical Center, Boston, MA*

Background: High-dose osimertinib 160 mg QD (osi160) has activity in osi-naïve, EGFR+ NSCLC pts with CNS or leptomeningeal disease (LMD) per the BLOOM trial, but the role of dose-escalation for CNS progression (PD) and/or LMD that develops while on 80 mg QD (osi80) is unclear. We describe here our multi-institutional experience with osi160. **Methods:** 105 pts from 8 institutions with advanced EGFR+ NSCLC treated with osi160 were retrospectively reviewed. To assess the CNS efficacy of dose escalation for CNS PD, we focused on pts who escalated from osi80 to osi160 for CNS PD without the addition of chemo and/or RT during dose escalation (cohort A, 24 pts). We also examined osi escalation for CNS PD while receiving chemo and/or RT (cohort B, 34 pts) and those who started on osi160 for CNS PD as the initial osi dose without overlapping therapies (cohort C, 11 pts). Radiographic responses were clinically assessed via chart review of scan reports. Kaplan-Meier analysis was used for time-to-event endpoints. We defined median duration of CNS disease control (MedDurCNSCon) on osi160 as time from the start of osi160 to CNS PD or discontinuation of osi160. **Results:** Among the 105 pts, 69 (26M, 43F; median age 57) EGFR+ NSCLC pts (29 del19, 31 L858R, 9 other) received osi160 for CNS PD between 10/2013 and 1/2020. Median lines of therapy pre-osi was 1 (range 0-8). While all 69 pts had CNS PD at the start of osi160, 61 (90%) had isolated CNS/LMD PD, without systemic PD. In cohort A, osi160 monotherapy had a MedDurCNSCon of 3.8 mos (95% CI, 1.7 – 5.8). Cohort A pts with isolated LMD (11) had MedDurCNSCon 5.8 mos (95% CI, 1.7 – 9) while those with parenchymal mets only (11) had MedDurCNSCon of 2 mos (95% CI, 1 - 4.9). In cohort B, osi160 in combination with RT (22) and/or chemo (14), had a MedDurCNSCon of 5.1 mos (95% CI, 3.1 – 6.5). In cohort C, osi160 monotherapy had a MedDurCNSCon of 4.2 mos (95% CI, 1.6 – NA). Pts on osi160 had no severe or life-threatening side effects. **Conclusions:** In this real-world cohort of EGFR+ NSCLC pts with CNS and/or LMD PD on osi80, dose escalation to 160 provided modest benefit with median 3.8 mos added CNS disease control. Dose escalation appeared more effective in pts with LMD versus parenchymal disease (MedDurCNSCon of 5.8 vs 2 mos). Treatment intensification with osi escalation plus RT and/or chemo appeared to confer about 1 month additional CNS disease control (power for comparison limited). Osi naïve pts started at 160 for CNS PD derived similar benefit. While limited by small numbers and retrospective design, this study suggests we need improved strategies to optimally manage CNS PD arising on osi80. Research Sponsor: None.

9587 Poster Session (Board #353), Fri, 8:00 AM-11:00 AM

IMpower150: Exploratory analysis of brain metastases development. *First Author: Federico Cappuzzo, Azienda Unità Sanitaria Locale della Romagna, Ravenna, Italy*

Background: In the global phase III IMpower150 study (NCT02366143), atezolizumab (atezo) + bevacizumab (bev) + chemo (carboplatin + paclitaxel [CP] (ABCP) showed significant improvements in PFS and OS vs BCP in patients with chemotherapy-naive metastatic NSCLC (Socinski et al. *N Engl J Med* 2018). Because bev has been shown to delay or prevent brain metastases progression in NSCLC (Fu et al. *J Chemother* 2016; Ilhan-Mutlu et al. *Mol Can Ther* 2016), exploratory analyses were conducted to assess the development of brain metastases in patients treated with ABCP, BCP and atezo + CP (ACP) in IMpower150. **Methods:** A total of 1202 patients (intention-to-treat [ITT] population) were randomized 1:1:1 to receive ABCP, ACP or BCP. Doses were given every 3 weeks: atezo 1200 mg, bev 15 mg/kg, carboplatin AUC 6 mg/mL/min and paclitaxel 200 mg/m^2. Co-primary endpoints were investigator-assessed PFS and OS in ITT–wild-type (no *EGFR* or *ALK* alterations) patients. Exploratory analyses included the rate and time to development (TTD) of new brain metastases in the ITT population, regardless of the presence of baseline brain metastases, as well as safety. Brain scans were performed as clinically indicated, and analyses were based on investigator assessments. **Results:** With a minimum follow-up of 32.4 months in the ITT population (data cutoff: September 13, 2019), 100 patients had developed brain metastases, with the highest rate of new brain lesions seen in the ACP (11.9%) vs the ABCP (7.0%) and BCP (6.0%) arms (table). Median TTD was not reached in any arm; a trend toward delayed TTD was seen in the ABCP vs BCP arm (HR, 0.68 [95% CI: 0.39, 1.19]). Among patients with and without brain metastases, 17 (35.4%) and 155 (44.0%) in the ACP arm, 18 (64.3%) and 207 (56.7%) in the ABCP arm and 10 (41.7%) and 183 (49.5%) in the BCP arm had Grade 3-4 treatment-related adverse events, respectively. **Conclusions:** The ACP arm had the highest rate of new brain lesions, whereas the ABCP and BCP arms had similar, lower rates. Taken together with the trend toward delayed development of new brain lesions with ABCP, the data suggest that adding atezo to BCP may not reduce the rate of new brain lesion development but may delay the time to new lesion development. No new safety signals were observed in this exploratory analysis. Clinical trial information: NCT02366143. Research Sponsor: F. Hoffmann-La Roche, Ltd.

Plasma-derived cfDNA to reveal potential biomarkers of response prediction and monitoring in non-small cell lung cancer (NSCLC) patients on immunotherapy. *First Author: Francesco Vallania, Freenome, South San Francisco, CA*

Background: Immune checkpoint inhibitors have shown promising results in many advanced cancers, but the response rate remains low. Various molecular and cellular biomarkers, such as elevated tumor-infiltrating cytotoxic T cells and Natural Killer (NK) cells at baseline, are associated with response. Blood-based biomarkers to predict or monitor response remain challenging to develop. Here we investigate the potential of cell-free DNA (cfDNA) biomarkers to predict response to the PD-1 immune checkpoint inhibitor nivolumab in patients with refractory metastatic non-small cell lung cancer (NSCLC). **Methods:** Plasma from stage IV NSCLC patients enrolled in ALCINA (NCT02866149) was collected before (baseline, BL, n = 30) and at week 8 (W8, n = 17) of nivolumab therapy. Response was determined using RECIST 1.1 (responders n = 5; non-responders n = 25). Whole-genome sequencing was performed to characterize cfDNA fragments. Tumor fraction (TF) was assessed using ichorCNA. Cellular composition was estimated by deconvolution of cfDNA co-fragmentation patterns, and transcription factor activity was estimated by measuring binding site accessibility across the genome. **Results:** Although estimated TF at baseline did not predict response to nivolumab, NK cell levels estimated by cell-mixture deconvolution were significantly higher in responders at BL ($p < 0.05$). Furthermore, estimated monocyte levels at W8 strongly correlated with overall survival ($r = 0.75$, $p < 0.0005$, HR = 2.71) and were significantly higher in responders ($p < 0.05$). By evaluating changes in transcription factor binding activity, we identified factors with greater accessibility in non-responders at baseline (DEAF1, THAP11) and W8 (DUX4, PDX-1). **Conclusions:** Plasma cfDNA signatures may be useful for response prediction and monitoring in NSCLC patients on immunotherapy. Our results suggest that changes in the immune system, as reflected by cellular composition and transcriptional activity inferred from cfDNA, may provide biological insights beyond TF alone that may benefit biomarker discovery and drug target identification. Research Sponsor: None.

9589 Poster Session (Board #355), Fri, 8:00 AM-11:00 AM

Therapeutic impact of mutation subtypes and concomitant *STK11* mutations in *KRAS*–mutated non-small cell lung cancer (NSCLC): A result of nationwide genomic screening project (LC-SCRUM-Japan). *First Author: Yutaro Tamiya, National Cancer Center Hospital East, Kashiwa, Japan*

Background: *KRAS* mutations are one of the common oncogene drivers in non-small cell lung cancer (NSCLC), and the development of several targeted drugs for *KRAS*-mutated NSCLC is now ongoing. However, the clinical impact of *KRAS* mutation subtypes or concomitant other gene mutations in NSCLC patients (pts) remains unclear. **Methods:** In a nationwide genomic screening project (LC-SCRUM-Japan), we have prospectively analyzed lung cancer pts for genetic alterations and tumor mutation burden (TMB) by next-generation sequencing system, and for PD-L1 expression by immunohistochemistry (22C3 antibody). The therapeutic efficacy and survival of *KRAS*-mutated non-squamous (non-sq) NSCLC pts were evaluated using a clinico-genomic database of the LC-SCRUM-Japan. **Results:** A total of 5166 non-sq NSCLC pts enrolled from 2015 to 2019. *KRAS* mutations were detected in 794 pts (15%; G12C/G12D/G12V/G12A/G13X/others = 232/186/165/66/61/84). Among the 794 pts, TMB and PD-L1 expression were analyzed in 128 and 79, respectively, and 218 received PD-1/PD-L1 inhibitors (IO) after 1st-line chemotherapy. The median age was 66 years (range, 29-89). 142 pts (65%) were male and 172 (78%) were smokers. Concomitant *STK11* mutations were detected in 33 pts (15%) with no difference in the mutation frequency among *KRAS* mutation subtypes. *KRAS* G12C was significantly associated with high TMB (≥ 10 mut/Mb) ($p = 0.03$), and *KRAS* G12C or G12V with high PD-L1 expression (≥ 50%) ($p = 0.02$). In pts who received IO, median progression-free survival (mPFS) was significantly longer in pts with *KRAS* G12C or G12V than in those with other *KRAS* mutations (4.7 vs 2.0 months, hazard ratio (HR) 0.58 [95%CI 0.43-0.78], $p < 0.01$). Among pts with *KRAS* G12C or G12V, mPFS of IO was significantly shorter in pts with concomitant *STK11* mutations than in those without (1.8 vs. 5.7 months, HR 1.97 [95%CI 1.06-3.41], $p = 0.02$). These correlations were not observed in platinum-containing chemotherapy (Plt-CTx). There were also no significant differences in IO and Plt-CTx efficacies between with and without other concomitant mutations, such as *TP53*, *RB1*, *CDKN2A* and *PTEN* mutations. **Conclusions:** Non-sq NSCLC pts with *KRAS* G12C/V were more sensitive to IO therapies than those with other *KRAS* mutations, but *KRAS* G12C/V-positive pts with concomitant *STK11* mutations were less sensitive than those without. These results could be highly informative in the development of novel targeted therapies for *KRAS*-mutated NSCLC. Research Sponsor: Japan Agency for Medical Research and Development.

9590 Poster Session (Board #356), Fri, 8:00 AM-11:00 AM

Large scale clinico-genomic analyses among patients with BRAF-mutated non-small cell lung cancers (NSCLC) identified by nationwide genomic screening project (LC-SCRUM-Japan). *First Author: Tetsuya Sakai, National Cancer Center Hospital East, Kashiwa-Shi Chiba, Japan*

Background: *BRAF* mutations are functionally classified into three groups, comprisingV600-mutant kinase-activating monomers (class I), kinase-activating dimers (class II), kinase-inactivating heterodimers (class III). The difference of clinical outcomes and concomitant genetic alterations among the three classes in non-small cell lung cancers (NSCLC) are unclear. **Methods:** We have prospectively analyzed NSCLC patients (pts) for cancer-related genes by a next-generation sequencing system, Oncomine™ Comprehensive Assay, in a large-scale genome screening project in Japan (LC-SCRUM-Japan). The clinical characteristics and outcomes of pts with *BRAF*-mutated non-squamous (non-sq) NSCLC were comparatively evaluated among the three classes of *BRAF* mutations. **Results:** A total of 5166 non-sq NSCLC pts were enrolled into the LC-SCRUM-Japan from 2015 to 2019. *BRAF* mutations were detected in 176 pts (3%). Among the 176 pts, 153 (87%) were classified into the three classes according to the mutation variants, including 65 (42%) into class I, 52 (34%) into class II and 36 (24%) into class III. The remaining 23 were not classified into any of the three classes. Compared with class I, class II or class III was significantly associated with smoking ($P = 0.02$ and < 0.01, respectively). Concomitant *RAS* mutations were significantly more frequent in class II and class III than in class I ($P < 0.01$ and $= 0.04$, respectively). The frequency of concomitant *STK11* mutations was significantly higher in class III than in others ($P < 0.01$, respectively). There was no significant difference in the frequency of other oncogene and tumor suppressor gene mutations among the three classes. In the 1st-line platinum-containing chemotherapies for advanced or recurrent cases, median progression-free survival (mPFS) of class III pts was shorter than class I or class II pts (4.2, 11.5 and 4.8 months, I vs III; $P < 0.01$, II vs III; $P = 0.06$). In the treatment with 2nd-4th line PD-1/PD-L1 inhibitors, mPFS was not significantly different among the three classes. Overall survival of class III pts was significantly shorter than class I pts (11.9 vs 35.2 months, $P = 0.03$). **Conclusions:** Concomitant gene mutations and clinical features are largely different among the *BRAF* mutation classes. Especially in class III, concomitant *RAS* and *STK11* mutations are more frequent and clinical outcomes were significantly less favorable. These results suggest the need of novel therapeutic strategy based on the mutation class for *BRAF*-mutated lung cancers. Research Sponsor: None.

9591 Poster Session (Board #357), Fri, 8:00 AM-11:00 AM

Real-world (RW) outcomes for advanced non-small cell lung cancer (aNSCLC) patients (pts) with *EGFR* exon 19 deletions (x19del) stratified by deletion size. *First Author: Sai-Hong Ignatius Ou, Chao Family Comprehensive Cancer Center, University of California Irvine, Orange, CA*

Background: *EGFR* x19dels are well-established targetable drivers in NSCLC. Historically x19dels have been treated as a single group, but it's unclear whether responses vary for distinct subtypes. We compared demographic, clinical and genomic characteristics as well as outcomes to EGFR tyrosine kinase inhibitors (TKIs) for aNSCLC pts with x19dels of varying lengths using a RW Clinico-Genomic Database (CGDB). **Methods:** Eligible pts had a diagnosis of aNSCLC, received care within the Flatiron Health network between 1/2011-9/2019, and had comprehensive genomic profiling (CGP) by Foundation Medicine. Clinical characteristics, treatment history and RW progression were obtained via technology-enabled abstraction as previously described (Singal G, JAMA 2019). x19del length was evaluated for association with overall survival (OS) and RW progression-free survival (rwPFS) with Kaplan-Meier analysis and unadjusted/adjusted (practice type, gender, age at TKI start, EGFR TKI type, race) hazard ratios (HR/aHR) from Cox proportional hazards models adjusted for survival bias. **Results:** Among 6,577 aNSCLC pts, *EGFR* x19dels were detected in 336 cases (5%). E746_A750del was the most frequent (214; 64%) and generally 5 amino acid (aa) deletions (x19del-5) were the most common (241; 72%). Other deletions (x19del-other) of 6 (61; 18%), 3 (20; 6%), 4 (11; 3%) or 8 aa (3; 1%) were also observed. Among pts treated with 1st-line EGFR TKI monotherapy after CGP, the x19del-5 ($n = 70$) cohort was more frequently female compared to x19del-other ($n = 27$) (90% vs 59%, $p = 0.001$). No statistically significant differences in the frequency of co-occurring alterations were observed, specifically for genes associated with response to EGFR TKI response such as *CTNNB1* (14% vs 19%) and *PIK3CA* (10% vs 15%). 1st line EGFR TKIs used were similar for x19del-5 vs x19del-other (43% vs 41% osimertinib, 30% vs 37% erlotinib, 24% vs 22% afatinib, 3% vs 0% gefitinib). x19del-5 pts had similar median rwPFS (10.6 vs 10.6 months, HR: 0.73 [0.41-1.28], aHR:0.78 [0.38-1.59]) and median OS (29.2 vs 24.9 months, HR: 0.64 [0.32- 1.29], aHR: 0.75 [0.32-1.75]) compared to x19del-other. **Conclusions:** In a RW CGDB of 336 aNSCLC pts with *EGFR* x19dels**,** 5 aa x19dels were most common (71%) and 29% of cases had 3, 4, 6 or 8 aa x19dels . For pts included in the treatment cohort, no significant differences in rwPFS or OS were observed. These results suggest that x19del length does not significantly impact clinical outcomes to 1st-line EGFR TKIs. Research Sponsor: None.

9592 Poster Session (Board #358), Fri, 8:00 AM-11:00 AM

Genomic testing among patients (pts) with newly diagnosed advanced non-small cell lung cancer (aNSCLC) in the United States: A contemporary clinical practice patterns study. *First Author: Adam Gondos, F. Hoffmann-La Roche Ltd, Pharmaceutical Division, Personalized Healthcare Center of Excellence, Basel, Switzerland*

Background: We describe contemporary clinical patterns of guideline-mandated genomic testing in newly diagnosed US pts with aNSCLC. **Methods:** From the Flatiron Health electronic health record-derived de-identified database, we included pts with newly diagnosed advanced non-squamous cell carcinoma of the lung between 1.1.2018–6.30.2019 who had received first-line (1L) therapy. We defined inadequate testing as no successful test for at least one of four examined genes: *ALK*, *BRAF*, *EGFR*, and *ROS1*. We grouped pts according to testing received into users of next-generation sequencing (NGS) testing, including a subgroup using comprehensive genomic profiling (CGP, exemplified by Foundation Medicine, Inc.), users of non-NGS testing, and no testing. We describe the following aspects of genomic testing before the start of 1L therapy: occurrence of testing, patterns of use of testing technologies, occurrence of inadequate testing, test failures, percentage of pts with potentially missed targeted therapy with US Food and Drug Administration approval (no positive test and <4 successful tests), and recent trends in genomic testing. **Results:** Among 2971 included pts, 690 (23.2%) had no genomic testing before 1L treatment. Among pts who had a test (n=2281), 59.4% (n=1355) received NGS (CGP: 18.8%, n=429), while 40.6% (n=926) received non-NGS tests only. In the CGP user group, 79.7% of pts received no other type of test, compared with 29.8% of pts in the other NGS group. Inadequate testing was recorded in 13.4% of NGS-tested pts (CGP: 4.9%), compared with 52.5% of pts tested by non-NGS only. Test failures contributed to unsuccessful testing in 4.2% of pts tested by NGS (CGP: 1.2%) and in 6.8% of pts who received non-NGS tests. In the NGS group, 10.1% (CGP: 3.0%) of patients potentially missed a targeted therapy option, compared with 40.3% in the non-NGS group. *EGFR* and *ALK* testing were performed in $\geq$95% of pts, regardless of the testing group; however, only 83.6% and 55.7% of pts received tests for *ROS1* and *BRAF*, respectively, in the non-NGS group. In the latter group, for the first 6 months of 2019, 88.4% and 58.2% of pts were tested for *ROS1* and *BRAF* mutations, respectively. **Conclusions:** Not performing any, or performing only inadequate genomic testing in pts with newly diagnosed aNSCLC remains a concern in clinical practice. The use of NGS, particularly CGP, may help to avoid suboptimal testing, minimize test failures, and improve uptake of testing for newly introduced biomarkers, enabling individualized, targeted therapy. Research Sponsor: F. Hoffmann-La Roche Ltd, Basel, Switzerland.

9593 Poster Session (Board #359), Fri, 8:00 AM-11:00 AM

Updated overall survival (OS) and genomic analysis from a single-arm phase II study of dabrafenib (D) + trametinib (T) in patients (pts) with *BRAF* V600E mutant (Mut) metastatic non-small cell lung cancer (NSCLC). *First Author: David Planchard, Institut Gustave Roussy, Thoracic Team, Villejuif, France*

Background: The phase II multicenter, open label study, which evaluated efficacy and safety of D+T in pretreated (cohort B) and treatment (tx)-naive (cohort C) pts with *BRAF* V600E mut metastatic NSCLC. The results of the primary analysis have been reported. Here, we present an updated survival and genomic analysis data for cohorts B and C. **Methods:** Tx-naïve (n=36) and pretreated (n=57) pts received D 150 mg twice daily + T 2 mg daily. Primary objective: ORR, secondary objectives: PFS, DOR, OS, safety, tolerability and PK of D+T. Tumor samples were centrally tested using a NGS cancer targeted panel (Oncomine Dx Target test, ThermoFisher Scientific). KM curves and Cox regression models were used to evaluate potential associations between baseline genomic landscape and pt efficacy endpoints. **Results:** As of June 22, 2019, median (m) follow-up was 16.3 mo in tx-naïve pts and 16.6 mo in pretreated pts. mOS was 17.3 mo (95% CI: 12.3, 40.2; 3 yr OS: 40%) and 18.2 mo (95% CI: 14.3, 28.6; 3 yr OS: 33%) with 14/36 and 11/57 pts alive in tx naïve and pretreated pts respectively. Detailed efficacy results are presented in table. 57/62 tumor samples retrieved from 93 pts were centrally confirmed to have *BRAF V600E* mut; 5 non-confirmed BRAF tumors (3 pts had PR) were positive for *c-MET* T1010I, *KRAS* G12V, *ALK* fusion and 2 *JAK3* S493C with mPFS of 13.8 mo while OS was NE due to limited data points. Eleven pts (18%) had concomitant somatic mutations and/or genetic alterations in addition to *BRAF* V600E mut: 4 had alterations within PI3K pathway4 had concomitant mutations at *IDH1* R132X, and 3 pts had additional mutations at *BRAF* G466V, *KRAS* G13C and a *cMET* exon 14 skipping, respectively. Pts whose tumors had concomitant genetic alterations, particularly in PI3K pathway, showed a trend towards decreased PFS and OS. Safety profile was similar to previous reported results. **Conclusions:** This update of BRF113928 study reported improved and durable OS rates with combination D+T in *BRAF* V600E mut NSCLC pts. Co-occurring genetic alterations might influence clinical outcomes of such pts. Further validation is ongoing to corroborate current genomic findings. Clinical trial information: NCT01336634. Research Sponsor: Novartis Pharmaceuticals Corporation.

9594 Poster Session (Board #360), Fri, 8:00 AM-11:00 AM

Patient-reported outcomes (PROs) in the randomized, phase III IMpower110 study of atezolizumab (atezo) vs chemotherapy in 1L metastatic NSCLC. *First Author: Filippo de Marinis, Istituto Europeo di Oncologia IRCCS, Milan, Italy*

Background: IMpower110 (NCT02409342) evaluated atezo (anti–PD-L1) monotherapy as 1L treatment in PD-L1–selected patients (pts) with metastatic NSCLC and met its primary endpoint with statistically significant and clinically meaningful OS benefit in TC3 or IC3 wild-type (WT; *EGFR/ALK*-negative) pts. PROs were prespecified endpoints to assess pt perspectives on overall clinical benefit. **Methods:** Pts were randomized 1:1 to receive atezo 1200 mg IV q3w (Arm A) or platinum-based chemo (Arm B; 4 or 6 21-day cycles). Arm B non-squamous pts received cisplatin (cis) 75 mg/m^2 or carboplatin (carbo) AUC 6 + pemetrexed 500 mg/m^2 IV q3w; Arm B squamous pts received cis 75 mg/m^2 + gemcitabine (gem) 1250 mg/m^2 or carbo AUC 5 + gem 1000 mg/m^2 IV q3w. PROs were assessed by the EORTC Quality of Life Questionnaire Core 30 (QLQ-C30) and lung cancer module QLQ-LC13. Time to confirmed deterioration (TTD) in QLQ-LC13 lung cancer symptoms (secondary endpoint) and change from baseline (BL) in global health status (GHS), functioning and lung cancer symptoms (exploratory endpoints) were analyzed in TC3 or IC3-WT pts. Clinically meaningful change was defined as a $\geq$10-point deterioration from BL. **Results:** Completion rates at BL (atezo, n = 107; chemo, n = 98) were high in both arms for the QLC-C30 (90% atezo, 86% chemo) and the QLC-LC13 (89% atezo, 85% chemo), and remained $>$ 80% at most visits. Mean BL scores for GHS, physical functioning, and role functioning were moderate, symptom burden was low, and all were similar in both arms. No differences in TTD were seen between arms for cough (HR, 0.98; 95% CI: 0.48, 2.03), chest pain (HR, 1.02; 95% CI: 0.47, 2.22), dyspnea (HR, 0.96, 95% CI: 0.57, 1.60), and 3-symptom composite score (HR, 0.92; 95% CI: 0.59, 1.44). Mean change in physical function from BL to wk 42 was modestly improved with atezo and greater than or similar to chemo. No clinically meaningful worsening in dyspnea, cough or chest pain was seen with atezo vs chemo. Mean change in cough and chest pain from BL numerically improved immediately after start of treatment and was maintained to wk 48 with atezo. Fatigue and nausea/vomiting scores numerically improved immediately with atezo and were maintained to wk 48. **Conclusions:** QLQ-C30 and QLQ-LC13 completion rates were high at BL and most study visits. TTD of lung cancer-related symptoms was similar in both arms, indicating pts' low BL symptom burden was maintained for a similar duration. Pts receiving atezo vs chemo sustained numerical improvements in physical function and no worsening in lung cancer-related symptoms. Clinical trial information: NCT02409342. Research Sponsor: F. Hoffmann-La Roche, Ltd.

9595 Poster Session (Board #361), Fri, 8:00 AM-11:00 AM

A phase II study of lorlatinib in patients (pts) with ALK-positive (ALK+) lung cancer with brain-only progression. *First Author: Ibiayi Dagogo-Jack, Massachusetts General Hospital, Boston, MA*

Background: Lorlatinib is a 3rd-generation ALK tyrosine kinase inhibitor (TKI) developed to penetrate the central nervous system (CNS) and overcome resistance to 2nd-generation (2nd-gen) ALK TKIs. In a phase II study, lorlatinib demonstrated significant intracranial (IC) activity after failure of 2nd-gen TKIs. As treatment discontinuation for extracranial (EC) progression can confound assessment of durability of IC response, we performed a phase II study (NCT02927340) to selectively evaluate lorlatinib activity in ALK+ pts with CNS-only disease. **Methods:** Between 11/2016 and 1/2019, 22 pts with IC progression on an ALK TKI with no other sites of measurable disease were enrolled at 2 institutions. Pts received lorlatinib at a starting dose of 100 mg QD. The primary endpoint was the IC disease control rate (DCR) at 12 weeks per modified RECIST v1.1. Secondary endpoints were IC objective response rate (ORR), duration of response (DOR), and progression-free survival (PFS). **Results:** Of the 22 pts enrolled, 21 (95%) had progressed on a 2nd-gen ALK TKI and 14 (64%) had previously received CNS radiation (median 21.1 months between radiation and lorlatinib). Median number of prior ALK TKIs was 2 (range 1-4). As of the data cutoff of 12/15/19, median follow-up was 14 months. At 12 weeks, the IC-DCR was 95%, including 8 pts with stable disease. Best IC ORR was 59% with 6 complete and 7 partial responses. Nine (41%) pts relapsed on study, including 3 IC-only, 5 EC-only, and 1 combined relapse. Four pts continued treatment beyond EC-only progression. Although median IC DOR and PFS were not estimable due to few progression events, the IC progression-free rate at 12 months was 81% (95% CI: 53%-94%). Twelve pts have discontinued study treatment due to progression (n = 6), edema (n = 1), pulmonary hypertension (n = 1), or transition to commercial lorlatinib (n = 4). **Conclusions:** Lorlatinib induces durable intracranial responses in pts with CNS-only progression on 2nd-gen ALK TKIs, suggesting that CNS-specific relapses are primarily driven by ALK-dependent mechanisms. Further studies are needed to characterize the molecular basis of sensitivity to lorlatinib in this unique subgroup of pts with ALK+ lung cancer. Clinical trial information: NCT02927340. Research Sponsor: Pfizer.

9596 Poster Session (Board #362), Fri, 8:00 AM-11:00 AM

Clinical characteristics and anti-PD-(L)1 treatment outcomes of KRAS-G12C mutant lung cancer compared to other molecular subtypes of KRAS-mutant lung cancer. *First Author: Kathryn Cecilia Arbour, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *KRAS* mutations are identified in approximately 30% of NSCLC. There are no FDA approved targeted therapies for patients with KRAS-mutant non-small cell lung cancer (NSCLC) but novel direct inhibitors of KRAS G12C have shown some activity in early phase clinical trials. We hypothesized that patients with *KRAS*-G12C mutations may have distinct clinical characteristics and responses to systemic therapies compared to patients with non-G12C subtypes. **Methods:** We identified patients with KRAS-mutant lung cancers who underwent next-generation sequencing with MSK-IMPACT, between January 2014 and December 2018. Baseline characteristics were compared with the Chi-square and Fisher's exact test for categorical data and Wilcoxon rank-rum test for continuous data. Overall survival was calculated from time of diagnosis of metastatic/recurrent disease to date of death or last follow up, with left truncation to account for time of MSK-IMPACT. Overall survival was compared between groups using the Cox proportional-hazards model. Response evaluations where performed by independent thoracic radiologists according to RECIST 1. and compared between group with the Fisher's exact test. **Results:** We identified 1194 patients with KRAS-mutant NSCLC, 772 with recurrent or metastatic disease. Of patients with advanced disease, 46% (352/772) had mutations in *KRAS*-G12C and 54% harbored non-G12C mutations (15% G12D, 16% G12V, 8% G12A, 4% G13D). Co-mutation patterns were similar with respect to KEAP1 (p=0.9) and STK11 (p=1.0). Patients with non-G12C mutations had a higher proportion of never smokers (10% vs 1.4% p$<$0.001). The median OS from diagnosis was 13 months for G12C and non-G12C patients (p=0.99). 45% (347/772) received 1L or 2L line treatment with PD-(L)1 inhibitor. RECIST measurements were available for 290/347 cases (84%). ORR with anti-PD-(L)1 treatment was 24% vs 28% in G12C vs non-G12C patients (p=0.5). In patients with PD-L1 50% (n=103), ORR was 39% for G12C vs 58% non-G12C patients (p=0.06). **Conclusions:** KRAS G12C mutations are present in 12% of patients with NSCLC and represent a relevant subtype of NSCLC given KRAS G12C inhibitors now in clinical development. Baseline characteristics including co-mutation patterns are similar between patients with G12C and non-G12C, except for smoking history. The efficacy of KRAS G12C direct inhibitors will need to be compared to other available therapies for KRAS mutant NSCLC (chemotherapy and PD-(L)1 inhibitors) to identify most effective therapeutic strategy. Research Sponsor: None.

9597 Poster Session (Board #363), Fri, 8:00 AM-11:00 AM

A phase II study of osimertinib for patients with radiotherapy-naïve CNS metastasis of non-small cell lung cancer harboring EGFR mutations: The OCEAN study (LOGIK 1603/WJOG 9116L). *First Author: Kazushige Wakuda, Division of Thoracic Oncology, Shizuoka Cancer Center, Sunto-Gun, Shizuoka Prefecture, Japan*

Background: Approximately 15%–30% of patients treated with EGFR-TKIs experience central nervous system (CNS) progression. Although radiotherapy is a standard treatment for CNS metastasis, the efficacy of radiotherapy against CNS is poor. The aim of OCEAN study was to assess the efficacy of osimertinib for patients with radiotherapy-naïve CNS metastasis of NSCLC harboring EGFR mutations. **Methods:** OCEAN study was two-cohort phase II trial, 65 patients (T790M cohort; 40 patients and first-line cohort; 25 patients) with radiotherapy-naïve CNS metastasis of EGFR mutation-positive NSCLC was included. Patients were treated with osimertinib 80 mg once daily. The primary endpoint was the response rate of brain metastasis (BMRR) assessed by the PAREXEL criteria. We set a threshold value of 50% and an expected value of 70% based on the overall response rate (ORR) of AURA trial. Based on one-sided alpha = 0.05 and power = 0.8, the sample size of T790M cohort was calculated to be 40. Key secondary endpoints were progression-free survival (PFS), and ORR, BMRR assessed by the RECIST criteria. We are exploratorily assessing the blood concentration of osimertinib at day 22, which considered to represent steady state. In this report, we present the results of T790M cohort. **Results:** Between October 2016 to July 2019, 40 participants were recruited in the T790M cohort. The median age was 66.5 with 30.0% male. Eight patients had symptomatic CNS metastasis and most patient had multiple CNS metastasis (77.5%). BMRR assessed by PAREXEL criteria was 66.7% (95%CI: 54.3 – 79.1%) and BMRR assessed by RECIST was 70.0% (95%CI, 49.9 – 90.1%). Median PFS was 7.1 months (95%CI, 3.4 – 13.6 months) and ORR assessed by RECIST was 40.5% (95%CI, 24.7 – 57.9%). Treatment related pneumonitis was observed in 4 patients (10.0%). There was no grade 3 or higher toxicities that were found in more than 10%. **Conclusions:** This first study assessed the efficacy of osimertinib for patients with radiotherapy-naïve CNS metastasis of EGFR T790M mutation-positive NSCLC. The OCEAN study met primary endpoint. The results of this study suggested that patients with brain metastasis harboring EGFR T790M mutations had better to receive osimertinib prior to brain radiotherapy. Clinical trial information: 071180017. Research Sponsor: AstraZeneca.

9598 Poster Session (Board #364), Fri, 8:00 AM-11:00 AM

Blood serum amyloid A as potential biomarker of pembrolizumab efficacy for patients affected by advanced non-small cell lung cancer (NSCLC) over-expressing PD-L1: Early results of the FoRECATT Study. *First Author: Vincenzo Di Noia, Medical Oncology, Cliniche Humanitas Gavazzeni, Bergamo, Oncological Sciences, Catholic University of the Sacred Heart, Rome, Italy*

Background: Identifying the patients who may benefit the most from immune checkpoints inhibitors remains a great challenge for clinicians. The tumor-derived Serum Amyloid A (SAA) inhibits the immune-response in melanoma patients. Here we present the early results of FoRECATT study investigating on blood SAA as biomarker of response to upfront pembrolizumab in patients with advanced non-small-cell lung cancer (NSCLC). **Methods:** In this prospective study, patients with PD-L1 $\geq$ 50% receiving upfront pembrolizumab (P cohort) and with PD-L1 0-49% treated with chemotherapy (CT cohort), were evaluated for blood SAA and radiological response at baseline and every 9 weeks. Primary endpoint was response rate (RR) according to Response Evaluation Criteria in Solid Tumors 1.1; secondary endpoints were progression-free (PFS) and overall survival (OS). The most accurate SAA cut-off to predict response was established with ROC-analysis in the P cohort. **Results:** In the P Cohort (n = 42), the overall RR was 38%. After a median follow-up of 18.5 months (mo), baseline SAA $\leq$ the ROC-derived cut-off (29.9 mg/L; n = 14/42, 33%) was significantly associated with higher RR (53.6 *versus* 7.1%; OR 15, 95%CI 1.72-130.7, *P*= 0.009), longer PFS (17.4 *versus* 2.1 mo; *P*< 0.0001) and OS (not reached *versus* 7.2 mo; *P*< 0.0001) compared with SAA > 29.9 mg/L. In multivariate analysis, low SAA positively affects PFS (*P*= 0.001) and OS (*P*= 0.048) irrespective of ECOG PS, number of metastatic sites and pleural effusion. SAA monitoring (n = 40) was also significantly associated with survival endpoints: median PFS 17.4 *versus* 2.1 mo and median OS not reached *versus* 7.2 mo when SAA remained low (n = 14) and high (n = 12), respectively. In the CT Cohort (n = 30), RR was not significantly affected by SAA level, while low SAA at baseline (n = 17) was associated with better PFS (HR = 0.42, 95%CI 0.16-1.10, *P*= 0.02) and OS (HR = 0.16, 95% CI 0.04-0.55, *P*= 0.0004). **Conclusions:** Low SAA predicts a higher likelihood of response to upfront pembrolizumab only and good survival outcomes irrespective of treatment in advanced NSCLC patients. Therefore, a simple blood test might be useful to identify patients likely to derive better outcomes from immunotherapy. A further study (FoRECATT-2) is ongoing to confirm the results in a larger validation cohort and to assess the potential effect of SAA on immune response in vitro assays. Research Sponsor: None.

9599 Poster Session (Board #365), Fri, 8:00 AM-11:00 AM

Outcomes in patients with metastatic non-small cell lung cancer (mNSCLC) with brain metastases treated with pembrolizumab-based therapy. *First Author: Lova Sun, UPHS, Philadelphia, PA*

Background: Patients (pts) with mNSCLC with active brain metastases (BM) are often excluded from clinical trials; data on efficacy and safety of immunotherapy in this population are limited. We compared outcomes of pts with mNSCLC with and without BM who received pembrolizumab-based therapy. **Methods:** We conducted a retrospective single-center study of pts with mNSCLC treated with pembrolizumab (P) with or without chemotherapy. Progression-free survival (PFS) and overall survival (OS) were determined by Kaplan-Meier methodology and compared using multivariable Cox regression and log rank testing. **Results:** We identified 587 consecutive pts with mNSCLC who began P-based therapy between 8/2013 and 12/2018: 306 (52%) female, median age 67 years (range 32-98), 437 (74%) adenocarcinoma, and 508 (87%) former/current smokers. 388 (66%) patients received P in first line therapy, and 334 (57%) received single-agent P. 131 pts (22%) had detectable BM at baseline (start of P-based therapy). Pts with BM were younger (median 65 y vs 68 y, p < 0.01) and more likely to have adenocarcinoma (86% vs. 71%, p < 0.01) and baseline steroid use (22% vs 1%, p < 0.01). Presence of BM did not differ by race, sex, line of therapy, treatment regimen, or PD-L1 status. Of the 131 patients with detectable BM on pre-treatment brain MRI, 55 (42%) had stable BM as a result of prior local therapy, while 76 (58%) had active (new or growing) BM on pre-treatment imaging. Most patients with active BM underwent radiation therapy (RT) in either the 30 days before (n = 46) or 30 days after (n = 17) P start; of the remaining 13 treated with P-based therapy alone, intracranial responses included 2 CR, 2 PR, 3 SD, and 4 PD. As of 1/1/2020, with 15-month median follow up, there was no difference in mPFS (9.2 vs 7.3 months, p = 0.41) or mOS (18.3 vs 18.0 mo, p = 0.67) between pts with and without BM in our P-treated cohort. On multivariable analysis, female sex, ECOG 0-1, adenocarcinoma histology, and P as first line therapy were associated with improved PFS and OS. Presence of BM, baseline steroid use, and timing of local RT (before vs. after P) were not associated with inferior survival. **Conclusions:** In our single-center experience of pts with mNSCLC treated with P, pts with and without BM had similar PFS and OS. We observed several intracranial responses to P-based therapy alone, but most pts with active BM underwent local RT. mNSCLC pts with BM should be considered for P-based therapy; BM may be treated with RT immediately before or even after P with similar survival outcomes. Research Sponsor: None.

9600 Poster Session (Board #366), Fri, 8:00 AM-11:00 AM

Physiologic colonic uptake of ^{18}F-FDG on PET/CT predicts immunotherapy response and gut microbiome diversity in patients with advanced non-small cell lung cancer (NSCLC). *First Author: Lena Cvetkovic, Centre de recherche du Centre hospitalier de l'Université de Montréal (CRCHUM), Montréal, QC, Canada*

Background: Immune checkpoint inhibitors (ICI) represent the backbone treatment of advanced non-small cell lung cancer (aNSCLC) patients. Emerging evidence suggests increased gut microbiome (GM) diversity is associated with favorable response. Conversely, antibiotic-induced dysbiosis may be associated with deleterious outcomes in patients receiving ICI in multiple retrospective studies and one prospective study. ^{18}F-FDG physiologic colonic uptake on PET/CT increases following treatment with antibiotics and could be a surrogate marker for GM diversity and therefore clinical response. The aim of this study was to determine if ^{18}F-FDG physiologic colonic uptake prior to ICI initiation correlates with outcomes and GM metagenomics in patients with advanced NSCLC. **Methods:** 71 patients with aNSCLC who underwent PET/CT prior to ICI were identified. For each patient, the colon was manually contoured, SUVmax was measured in each segment of the colon by a nuclear medicine specialist and average SUVmax was calculated for the whole colon. Patients were stratified in two groups according to median colon SUVmax (low vs high uptake). ^{18}F-FDG physiologic colonic uptake was then compared to overall survival (OS), objective response (ORR), and progression-free survival (PFS). For patients with available stool samples (n = 10), GM composition was defined using metagenomics sequencing. **Results:** 71 patients (54% men, median age: 68 years) with aNSCLC were included in the study and ICI was the first line of therapy in 38% of those patients. The mean colon SUV for the low and high uptake groups were 1.41 (CI 95% 1.35-1.47) and 2.18 (CI 95% 1.90-2.46) respectively. The high uptake group had a higher proportion of non-responders (p = 0.033) and significant shorter PFS (4.1 months vs 11.3 months, p = 0.005). In the caecum, high uptake also correlated with numerically shorter OS (10.82 vs 27.56 months, p = 0.058) compared to low uptake group. Despite the low number of samples, metagenomics sequencing revealed that PLS-DA (Partial Least Squares Discriminant Analysis) for diversity was lower in the high SUV group (p = 0.008). **Conclusions:** Higher colon SUVmax on pre-ICI FDG PET/CT is associated with worse clinical outcomes and lower baseline GM diversity in patients with advanced NSCLC. Here, we propose that ^{18}F-FDG physiologic colonic uptake on PET/CT could serve as a surrogate marker of GM diversity and predicts clinical outcomes. Research Sponsor: None.

9601 Poster Session (Board #367), Fri, 8:00 AM-11:00 AM

ctDNA resistance landscape of lazertinib, a third-generation EGFR tyrosine kinase inhibitor (TKI). *First Author: Ji-Youn Han, Center for Lung Cancer, Research Institute and Hospital, National Cancer Center, Goyang, South Korea*

Background: While *EGFR* mutant (*EGFRm*) non-small cell lung cancer (NSCLC) patients usually experience improved clinical benefit with EGFR TKIs, most eventually progress. Understanding mechanisms of resistance (MoR) may allow for more personalized treatment. Lazertinib is an irreversible third generation EGFR TKI for which MoR are unknown. Obtaining sufficient tumor tissue for genotyping at progression is often difficult. Therefore, we utilized plasma ctDNA from patients treated with lazertinib to explore MoR. **Methods:** Plasma samples from 47 NSCLC patients in the phase 2 trial of lazertinib (NCT03046992) were collected at screening and progressive disease (PD) and underwent ctDNA NGS of 74 genes using Guarant360. All patients were positive for an *EGFR* Ex19del or L858R (*EGFRm*) and T790M by tissue testing at screening. Acquired, nonsynonymous, characterized mutations detected in a PD sample but not in the screening sample from the respective patient were considered putative MoR, excluding aneuploidy. Patients with detectable plasma *EGFRm* and/or T790M at screening were evaluable. **Results:** ctDNA was detected in 47 (100%) screening samples and 43/45 (96%) PD samples (two failed sequencing). An *EGFRm* was detected in 85% of patients at screening (n = 40), 38 of which had PD ctDNA results and were included in analysis. T790M was detected in 30 patients at screening and subsequently not detected at PD in 21 of these patients, 55% of all 38 included patients. Among the ten patients with T790M detected at PD, on-target MoR were detected in 7 (18% of all included patients) including *EGFR* C797S (n = 3, 8%), *EGFR* amplification (n = 3, 8%), and *EGFR* T854A (n = 1, 3%). All C797S were in cis with T790M. No on-target MoR were detected in patients without T790M detected at PD. Off-target MoR were seen in 34% of patients (13/38) including mutations in *PIK3CA* (13%; 2 E545K, 2 E542K, 1 E81K), *ERBB2* (5%; 1 D769H, 1 V777L), *KRAS* (3%; 1 G12C), and *BRAF* (3%; 1 G469A). Gene amplifications were detected in *CCND1* (n = 1, 3%), *CCNE1* (n = 2, 5%), *ERBB2* (n = 1, 3%), *FGFR1* (n = 1, 3%), *MET* (n = 4, 11%), and *PIK3CA* (n = 1, 3%), with some patients having multiple MoR. **Conclusions:** The spectrum of MoR identified in this cohort of patients treated with lazertinib is similar to that reported in other third generation EGFR TKIs, but with some differences in frequencies. The most common resistance mechanisms are T790M loss and *PIK3CA* alterations which may address the mechanism of action. Our findings suggest putative MoR of lazertinib and show that ctDNA NGS is an effective way to identify MoR in patients progressing on targeted therapy. Clinical trial information: NCT03046992. Research Sponsor: Yuhan Corporation, Other Government Agency.

9602 Poster Session (Board #368), Fri, 8:00 AM-11:00 AM

Efficacy and safety of alflutinib (AST2818) in patients with T790M mutation-positive NSCLC: A phase IIb multicenter single-arm study. *First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: Alflutinib (AST2818) is a third generation EGFR-TKI. This phase IIb, multicenter, single arm study (ALSC003, NCT03452592) aimed to assess the efficacyand safety of Alflutinib in patients with EGFR T790M mutated non-small cell lung cancer (NSCLC). **Methods:** Patients with locally advanced or metastatic EGFR T790M mutated NSCLC who progressed after first/second-generation EGFR-TKIs therapy or primary EGFR T790M mutation positive received 80 mg Alflutinib orally once daily. Tumor tissue samples underwent central laboratory testing for EGFR T790M mutation. The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS) and safety. Efficacy was assessed by independent radiological review committee per RECIST 1.1. Safety was assessed by NCI CTCAE version 4.03. **Results:** From Jun 4, 2018 to Dec 8, 2018, 220 patients were enrolled with a median age of 61.0 (range 29 to 80) years. According to the AJCC version 8 staging system, 212 (96.4%) cases were in stage IV, and 8 (3.6%) cases in stage III. All patients had EGFR T790M mutation. By April 12, 2019, the ORR was 73.6% (95% CI 67.3–79.3). The DCR estimated at 6 and 12 weeks were 87.3% (95%CI 82.1-91.4) and 82.3% (95%CI 76.6-87.1), respectively. The median PFS was 7.6 months (95% CI 7.0–NA). Median OS and DoR have not been reached. 209 (95.0%) patients had at least one adverse events (AEs), which were mostly grade 1 or 2 and well tolerable. The most common AEs were increased aspartate aminotransferase (33 [15.0%]), upper respiratory tract infection (33 [15.0%]), and cough (33 [15.0%]). Grade 3 to 5 AEs occurred in 42 (19.1%) patients. The most common one was elevated γ-glutamyltransferase (n = 4). There were 3 deaths patients, 2 of which possibly not be related to the study drug, and 1 could not be determined. No interstitial pneumonia was reported. **Conclusions:** Alflutinib has promising efficacy and acceptable safety profile for the treatment of EGFR T790M mutated NSCLC patients. Clinical trial information: NCT 03452592. Research Sponsor: Shanghai Allist Pharmaceuticals co. ltd., China National Major Project for New Drug Innovation (2017ZX09304015, 2018ZX09301014009 and 2019ZX09201-002) and CAMS Innovation Fund for Medical Sciences (CIFMS) (2016-I2M-1-001).

9603 Poster Session (Board #369), Fri, 8:00 AM-11:00 AM

Longitudinal monitoring by next generation sequencing of plasma cell-free DNA in ALK-rearranged non-small cell lung cancer (NSCLC) patients treated with ALK tyrosine kinase inhibitors. *First Author: Minsuk Kwon, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Patients with anaplastic lymphoma kinase-rearranged (ALK+) NSCLC inevitably acquire resistance to ALK inhibitors. We hypothesized that longitudinal monitoring of cell-free plasma DNA (cfDNA) next generation sequencing (NGS) could predict the response and resistance of TKI therapy in ALK+NSCLC **Methods:** Patients with ALK+ advanced NSCLC determined by standard tissue testing and planned for TKI therapy were prospectively recruited. Plasma was collected before therapy (n = 92), two months post-therapy (n = 58), and at progression (n = 35). Plasma DNA NGS analysis was done retrospectively by Guardant360. **Results:** From April 2015 to July 2019, 92 patients enrolled; 81 (88.0%) received *ALK* TKI as first-line (crizotinib, n = 59; alectinib, n = 22), 10 (10.9%) received TKI as second-line (alectinib, n = 6; crizotinib, n = 2; ceritinib, n = 1; brigatinib, n = 1), and 1 (1.1%) was treated in third-line (lorlatinib). At the cut-off date of January 28, 2020, 56 of 92 patients had disease progression. Circulating tumor DNA (ctDNA) was detected in 69 baseline samples (75%); among these were 43 *ALK* fusions (62.3%) and 1 *ALK* G1202R without fusion (1.4%). Fusions included *EML4-ALK* v1 (n = 19), *EML4-ALK* v3 (n = 14), *CLTC-ALK* (n = 1), *TPM3-ALK* (n = 1), *GCC2-ALK/CLIP4-ALK* (n = 1), and other *EML4-ALK* fusions (n = 7). Eight patients developed *ALK* resistance mutations after crizotinib therapy: L1196M (n = 5), G1269A (n = 1), G1202R (n = 1), and co-occurring F1174L, G1202R, and G1269A (n = 1). Two patients developed *ALK* resistance mutations after ceritinib: G1202R (n = 1), and co-occurring G1202R and T1151R (n = 1). The absence of detectable ctDNA at baseline was associated with longer progression-free survival (PFS; median 36.1 vs 11.6 months, HR 0.432, p = 0.004) and overall survival (OS; median not reached vs 27.9 months, HR 0.418, p = 0.034). Patients with clearance of ctDNA at two months (n = 29) had significantly longer PFS (median 25.4 vs 13.9 months, HR 0.343, p = 0.030) and OS (median not reached vs 25.7 months, HR 0.173, p = 0.035) than those without clearance (n = 22). Patients with co-occurring *TP53* alterations and *ALK* fusions at baseline (n = 9) showed shorter PFS (median 7.0 vs 12.5 months, HR 3.596, p = 0.0154) than those without *TP53* alterations (n = 35). **Conclusions:** NGS of cell-free plasma DNA is useful not only for the detection of *ALK* fusions and resistance mutations but also for assessing prognosis and monitoring the dynamic changes of genomic alterations in *ALK*+ NSCLC treated with ALK TKI. 9604 Poster Session (Board #370), Fri, 8:00 AM-11:00 AM

Nintedanib + docetaxel in lung adenocarcinoma patients (pts) following treatment with immune checkpoint inhibitors (ICIs): Updated efficacy and safety results of the ongoing non-interventional study (NIS) VARGADO (NCT02392455). *First Author: Christian Grohé, Department of Pneumology, ELK Berlin, Berlin, Germany*

Background: Nintedanib (Vargatef) is an oral triple angiokinase inhibitor targeting VEGF-, PDGF- and FGF receptor pathways. It is approved in the EU and other countries in combination with docetaxel for treatment of locally advanced, metastatic or locally recurrent NSCLC of adenocarcinoma histology after 1st line chemotherapy. ICI +/- chemotherapy has changed the standard of care for 1st line treatment of metastatic non-mutated NSCLC. However, currently, only limited clinical data are available to help guide treatment decisions after prior ICI therapy in subsequent lines. **Methods:** This updated analysis is part of the ongoing NIS VARGADO (cohort B), a prospective non-interventional study of nintedanib + docetaxel after 1st line chemotherapy for adenocarcinoma NSCLC. The analysis includes 57 pts who had previously received both chemotherapy and ICI treatment. **Results:** Median age was 61 years (range: 45 – 80), 32/57 pts (56.1%) were men, and 41/57 pts (71.9%) were ECOG PS 0/1. 12/57 pts (21.1%) had brain metastases, and 46/57 pts (80.7 %) were current or former smokers. 1st line chemotherapy treatments included pemetrexed (36/57 pts, 63.2%), cisplatin (29/57 pts, 50.9%), carboplatin (33/57 pts, 57.9%), bevacizumab (14/57 pts, 24.6%), vinorelbine (13/57 pts, 22.8%), paclitaxel (8/57 pts, 14.0%), and docetaxel (1/57 pts, 1.8%). 2nd line treatments included nivolumab (34/57 pts, 59.7%), pembrolizumab (14/57 pts, 24.6%), and atezolizumab (7/57 pts, 12.3%). Under nintedanib and docetaxel, ORR was 50% (20/40 pts); DCR was 85.0% (34/40 pts). Median PFS was 6.5 months (95%CI 4.8 – 8.7), median OS was 12.4 months (95%CI 11.4 – 14.1). Treatment emergent adverse events (TEAEs) grade ≥3, serious TEAEs, and TEAEs leading to discontinuation were observed in 30/57 pts (52.6%), 30/57 pts (52.6%), and 17/57 pts (29.8%), respectively. **Conclusions:** This updated analysis of the VARGADO study continues to show the clinical benefit and manageable safety profile of nintedanib plus docetaxel in patients who had previously received both chemotherapy and ICI treatment. These data add to the real-world evidence that can inform clinical decision-making after prior ICI therapy. Clinical trial information: NCT02392455. Research Sponsor: Boehringer Ingelheim Pharma GmbH & Co. KG.

9605 Poster Session (Board #371), Fri, 8:00 AM-11:00 AM

Establishment of the first international large-scale, genomic screening platform to identify patients with rare oncogene drivers in non-small cell lung cancer (NSCLC) in East Asia. *First Author: Shingo Matsumoto, National Cancer Center Hospital East, Kashiwa, Japan*

Background: A rapidly increasing number of oncogenic drivers have been identified in non-small cell lung cancer (NSCLC), and most of them occur in less than 5% of patients. Large-scale genomic screening to identify patients with rare driver alterations is thus necessary to enable precision medicine and to support the development of novel targeted therapies and companion diagnostics (CDx). **Methods:** A lung cancer genomic screening project (LC-SCRUM-Asia) capturing clinical outcome was established in 2013 with 206 institutions in Japan and 5 in Taiwan currently participating. A separate genomic screening project with similar structure was established in China (LC-IRICA-China) in collaboration with LC-SCRUM-Asia in 2019 (3 institutions enrolling, 17 about to open, 63 undergoing review). Samples are analyzed by a multi-gene PCR panel and targeted next-generation sequencing. The target is to enroll 70000 NSCLC patients (20000 from LC-SCRUM-Asia and 50000 from LC-IRICA-China) by 2022. **Results:** From March 2013, a total of 9383 lung cancer patients were enrolled in LC-SCRUM-Asia, and from October 2019, 1649 pts were included in LC-IRICA-China (January 2020). The rates of genomic alterations in LC-SCRUM-Asia: *EGFR* (17%) of which ex20ins (2%), *KRAS* (13%) of which G12C (4%), *ALK* fusions (2%), *ROS1* fusions (2%), *RET* fusions (2%), *HER2* ex20ins (3%), *MET* ex14skip (2%), *BRAF* V600E (1%), *NRG1* fusions (0.2%) and *NTRK3* fusions (0.03%). Corresponding rates in the initial 243 pts in LC-IRICA China: *EGFR* (45%) of which ex20ins (2%), *KRAS* (8%), *ALK* (5%), *ROS1* (2%), *RET* (1%), *HER2* (2%), *MET* ex14skip (1%), *BRAF*V600E (1%). Through the screening, 266 patients from Japan and Taiwan were enrolled into genotype-matched clinical trials of unapproved targeted drugs. In Japan, ROS1-, BRAF- and TRK-targeted therapies were successfully approved based on these clinical trials, and a NGS-based multigene CDx for EGFR/ALK/ROS1/BRAF targeted-therapies was approved based a concordance study using archival samples from the project. **Conclusions:** An East Asian international genomic screening platform has been established to enable precision medicine for patients, accelerate drug and diagnostic development in patients with very rare alterations and to help provide a deeper understanding of the underlying biology of NSCLC in East Asian patients. The screening network will be further expanded to other countries in East Asia in the near future. 9606 Poster Session (Board #372), Fri, 8:00 AM-11:00 AM

Outcomes in patients with advanced non-small cell lung cancer (aNSCLC) and high PD-L1 expression treated with immune checkpoint inhibitor monotherapy: An FDA-pooled analysis. *First Author: Sujay Yogesh Shah, Food & Drug Administration, Silver Spring, MD*

Background: Higher PD-L1 score ≥ 50% predicts for greater benefit to immune checkpoint inhibitor (ICI) therapy in first line (1L) treatment of aNSCLC. It has recently been reported that PD-L1 score ≥ 90% predicts for even greater benefit to 1L ICI monotherapy (Aguilar et al., 2019). We examined pooled clinical trial databases to examine the relationship between high PD-L1 expression across multiple ICI monotherapies in 1L and second line (2L) treatment of aNSCLC. **Methods:** Data was pooled from trials (five 1L and five 2L) of ICI for the treatment of patients with aNSCLC. We defined PD-L1 score as the proportion of tumor cell stained by the assay (total of four assays identified) and included patients in the analysis with PD-L1 score ≥ 50%. Tumor-infiltrating immune cell staining was not considered. Progression-free survival (PFS) and overall survival (OS) by line of therapy for patients with PD-L1 score ≥ 90% and patients with PD-L1 score 50-89% was analyzed. **Results:** A total of 1320 patients treated with ICI monotherapy were identified, 873 in 1L and 447 in 2L. Median follow-up was 9.6 months in 2L patients and 13.3 months in 1L patients. Patients receiving 2L ICI therapy with PD-L1 score ≥ 90% (N = 208) had longer PFS and OS compared to patients with PD-L1 score 50-89% (N = 239), with mPFS 7.1 vs. 4.2 months (HR = 0.66 [95% CI: 0.52-0.83]) and mOS NR vs. 15.8 months (HR = 0.66 [95% CI: 0.49-0.89]). 1L ICI therapy analysis revealed similar trends, as patients with PD-L1 score ≥ 90% (N = 405) had longer PFS and OS compared to patients with a PD-L1 score 50-89% (N = 468), with mPFS 8.3 vs. 5.4 months (HR = 0.78 [95% CI: 0.66-0.92]) and mOS 22.9 vs. 16.4 months (HR = 0.74 [95% CI: 0.61-0.90]). **Conclusions:** This analysis showed the potential of an enhanced clinical benefit in patients with aNSCLC and PD-L1 score ≥90% across ICI monotherapies in both the 1L and 2L treatment setting. These data will be further analyzed in real world populations. Research Sponsor: Food & Drug Administration.

9607 Poster Session (Board #373), Fri, 8:00 AM-11:00 AM

Phase II study of TAK228 in patients with advanced non-small cell lung cancer (NSCLC) harboring NFE2L2 and KEAP1 mutations. *First Author: Paul K. Paik, Thoracic Oncology Service, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: Despite past efforts, no targeted therapies exist for squamous cell lung cancer (LUSC) pts. We identified a heretofore untargeted oncogene (NFE2L2)/tumor suppressor (KEAP1) pair, each mutated in ~15% of LUSCs. NFE2L2 encodes NRF2, a transcription factor involved in the oxidative stress response and targeted for degradation by KEAP1. *NFE2L2* mutations (mut) occur only in an exon 2 hotspot (Neh2 domain), which is the binding site for KEAP1. Mutations in this region disrupt KEAP1 binding, leading to NRF2 nuclear translocation and increased mTOR signaling via RagD. We report translational studies and results from a phase 2 trial of the oral TORC1/2 inhibitor TAK228 in biomarker-selected pts. **Methods:** Cell line and xenograft experiments were performed using LK-2 LUSC (NFE2L2 E79K mut), A549 ADCL (KRAS G12S + KEAP1 loss), and SK-MES-1 LUSC cells (NFE2L2/KEAP1 WT) treated with TAK-228, everolimus, rapamycin, or deforolimus. Pts with stage IV LUSC harboring NFE2L2 or KEAP1 mut and ADCL harboring KRAS + KEAP1 co-mut were treated on an NCI CTEP phase 2 study of TAK228 3mg po qd (NCT02417701). Primary endpoint: ORR. Secondary endpoint: PFS. The study used a Simon 2-stage design for each cohort with H0 = 5% (N≥1/5 responses), HA = 40% (N≥2/10 responses). **Results:** TAK228 exhibited differential anti-tumor activity over TORC1 rapalogs in LK-2 and A549 cells. TAK228 alone was cytotoxic at sub-[μM] (IC50 68nM) in LK-2 cells; all other rapalogs had IC50s > 10μM. This was associated with marked decrease in TORC1/2 & MAPK signaling (decreased pS6, pAKT, pERK). Anti-tumor response was seen in LK-2 and A549 xenografts treated with TAK228. No anti-tumor/growth inhibitory responses were seen with any other rapalog. N = 21 evaluable pts have been treated (10 *NFE2L2*, 6 *KEAP1*, 5 *KRAS+NFE2L2/KEAP1*). Median age = 70; median prior lines tx = 2, smokers = 100%, median pack yrs = 39. Most common AEs included hyperglycemia (72%), fatigue (32%), diarrhea (32%), decreased appetite (32%). In *NFE2L2* mut LUSC pts, ORR = 20% (2/10 confirmed PR), DCR = 100% with median PFS = 8.9mos (95%CI 7-NR). In *KEAP1* mut LUSC pts, ORR = 17% (1/6 confirmed PR), DCR = 67% with PFS range = 1.8-8.6 mos. In *KRAS + NFE2L2/KEAP1* mut ADCL pts, ORR = 0% and DCR = 0%. **Conclusions:** TAK228 is tolerable with differential activity in *NFE2L2* (primary endpoint met) and *KEAP1* mutant LUSC. A randomized phase 2 trial of TAK228 + docetaxel vs. SoC chemotherapy in advanced LUSC pts with *NFE2L2/KEAP1* mut is in development (LungMAP S1900D) as is an NCI CTEP phase 1/1b trial of TAK228 + CB-839 in advanced NSCLC patients with *NFE2L2/KEAP1* mut (NCI #10327). Clinical trial information: NCT02417701. Research Sponsor: Druckenmiller Center for Lung Cancer Research Grant.

9609 Poster Session (Board #375), Fri, 8:00 AM-11:00 AM

Biomarker utilization in non-small cell lung cancer, are we treating after testing? *First Author: Elias Makhoul, Cedars-Sinai Medical Center, West Hollywood, CA*

Background: Targeted therapy in EGFR and ALK mutated non-small cell lung cancer (NSCLC) has been the standard of care for nearly a decade with subsequent FDA approvals for ROS1 and BRAF V600 mutated NSCLC occurring in 2016 and 2017. However, recent studies have shown suboptimal utilization of genomic profiling results in these patients. In 1 recent study of community oncologists, ~70% of EGFR/ALK+ patients received appropriate targeted therapy, while patients with other gene mutations (including BRAF and ROS1) only received targeted therapy ~30% of the time. Left unanswered was what patients were receiving instead and why. Additionally, it is unknown if this finding is generalizable to the academic setting. We aimed to investigate whether in our patient population, NSCLC patients with actionable mutations received associated FDA approved therapies and if not why. **Methods:** The pathology database was queried for all NSCLC with molecular testing (including qPCR, FISH and NGS) from 2009 to 2019. Patients with sensitizing EGFR, ALK, ROS1 or BRAF mutations that were detected after the first FDA approval for their respective targeted therapies were included for analysis with those lost to follow up subsequently excluded. Basic demographic and clinical variables were collected as well as treatment records. **Results:** 2160 NSCLC patients were evaluated (2160 EGFR, 1417 ALK, 810 ROS1, 589 BRAF). 468 patients were identified with targetable mutations (411 EGFR, 46 ALK, 5 ROS1, 6 BRAF). No patient had more than 1 targetable mutation. Of those patients, 248 were at an advanced stage and had clinical follow up (202 EGFR, 37 ALK, 4 ROS1, 5 BRAF). Of those patients 197/202 (97.5%), 33/37 (89.2%), 3/4 (75%) and 1/5 (20%) received EGFR, ALK, ROS1 or BRAF targeted therapy respectively. Across biomarkers 14/248 patients (5.6%) did not receive subsequent targeted therapy. 10 patients (5 EGFR, 3 ALK, 1 ROS1 and 1 BRAF) passed away before targeted therapy could be initiated. Physician choice and missed findings accounted for the remaining four cases. **Conclusions:** The vast majority of advanced NSCLC patients analyzed in this study received appropriate targeted therapy matched to genomic findings. The main reason (~4% of total cases) that patients did not receive therapy was due to rapidly progressive disease and death before it could be initiated. These findings are at odds with those published from the community setting. This may be due to multiple factors, including clinician education, ease of access to targeted therapies across patient populations and incomplete data in the previous study populations. Research Sponsor: None.

9610 Poster Session (Board #376), Fri, 8:00 AM-11:00 AM

Cabozantinib in combination with atezolizumab in non-small cell lung cancer (NSCLC) patients previously treated with an immune checkpoint inhibitor: Results from cohort 7 of the COSMIC-021 study. *First Author: Joel W. Neal, Stanford Cancer Institute, Stanford, CA*

Background: First-line immunotherapy with/without chemotherapy is standard of care for patients (pts) with advanced NSCLC; however, there is a need for effective treatment options after progression on a prior immune checkpoint inhibitor (ICI). Cabozantinib (C) may augment response to ICI by inhibiting kinases implicated in suppressing immune cell responses and has shown encouraging clinical activity in combination with ICI in other tumor types including RCC and HCC. COSMIC-021, a multicenter phase 1b study, is evaluating the combination of C with atezolizumab (A) in various solid tumors (NCT03170960). We report results from cohort 7 in NSCLC pts after prior ICI therapy. **Methods:** Eligible pts had ECOG performance status (PS) 0-1 and radiographic progression after one prior anti-PD-1/PD-L1 ICI given alone or in combination with chemotherapy for metastatic nonsquamous NSCLC. Up to 2 lines of prior systemic anticancer therapies were permitted. Pts received C 40 mg PO QD and A 1200 mg IV Q3W. CT/MRI scans were performed Q6W for the first year and Q12W thereafter. Primary endpoint is ORR per RECIST 1.1 by investigator. Other endpoints include safety, duration of response (DOR), progression-free survival, and overall survival. **Results:** Thirty pts with advanced NSCLC were enrolled. Median age was 67 yrs (range 41, 81), 43% were male, 57% had ECOG PS 1, and 23% had liver metastases. Median duration of prior ICI therapy was 4.8 months (mo; range 0.8, 29), and 15 (50%) pts were refractory to prior ICI (progressive disease as best response). As of December 20, 2019, the median follow-up was 8.9 mo (range 5, 20) with 9 (30%) pts continuing study treatment. The most common treatment related adverse events (TRAEs) of any grade were diarrhea (53%), fatigue (37%), nausea (23%), decreased appetite (20%), palmar-plantar erythrodysesthesia (20%) and vomiting (20%). Grade 3/4 TRAEs occurred in 14 (47%) pts, and 1 (3.3%) had grade 5 TRAEs of myocarditis and pneumonitis. Confirmed ORR per RECIST 1.1 was 23% (7 of 30 pts; all partial responses including 3 pts refractory to prior ICI). Time to response was 1.4 mo (range 1, 3), and median DOR was 5.6 mo (range 2.6, 6.9). DCR (CR+PR+SD) was 83%. **Conclusions:** The combination of C and A had an acceptable safety profile and showed encouraging clinical activity in pts with advanced NSCLC who had progressed after prior ICI therapy. The response rate was greater than previously observed with C monotherapy. Due to the promising data, enrollment in this cohort has been expanded and is ongoing. Clinical trial information: NCT03170960. Research Sponsor: Exelixis Inc.

9611 Poster Session (Board #377), Fri, 8:00 AM-11:00 AM

Resistance to lorlatinib in *ROS1* fusion-positive non-small cell lung cancer. *First Author: Jessica Jiyeong Lin, Massachusetts General Hospital, Boston, MA*

Background: Lorlatinib is a potent, brain-penetrant ROS1/ALK tyrosine kinase inhibitor (TKI), which has demonstrated efficacy in advanced *ROS1* fusion-positive (ROS1+) non-small cell lung cancer (NSCLC), including in patients (pts) previously treated with crizotinib. Despite initial benefit, however, most pts experience disease progression on lorlatinib. Mechanisms of resistance to lorlatinib in ROS1+ NSCLC are poorly understood. **Methods:** We analyzed repeat tumor biopsies derived from advanced ROS1+ lung cancer pts progressing on lorlatinib. Next-generation sequencing (NGS, n = 17) or whole exome sequencing (n = 1) was performed to detect mutations, indels, and copy number alterations. **Results:** Sixteen pts underwent a total of 18 repeat tumor biopsies after progression on lorlatinib. Fourteen had received prior crizotinib; two received prior crizotinib and entrectinib. Median duration of therapy on lorlatinib was 13.5 months (95% CI, 8.3-18.4). Among the 18 cases analyzed by sequencing, 7 (38.9%) harbored a *ROS1* resistance mutation, including G2032R (4/18, 22.2%), S1986F/L2000V (1/18, 5.6%), L2086F (1/18, 5.6%), and G2032R/S1986F/L2086F (1/18, 5.6%). Of note, ROS1 L2086F was a novel resistance mutation not previously reported in the literature, but analogous to ALK L1256F (a lorlatinib-resistant *ALK* mutation). Structural modeling studies showed that ROS1 L2086F causes steric interference with binding of lorlatinib, as well as crizotinib and entrectinib. In addition to ROS1 kinase domain mutations, NGS analyses also identified *MET* copy number gain in a lorlatinib-resistant case, validated by fluorescence in situ hybridization as high-level focal *MET* amplification (MET/CEP7 copy number ratio 6.3) without a concomitant *ROS1* resistance mutation. Duration of therapy on lorlatinib was significantly shorter in pts with a post-lorlatinib *ROS1* resistance mutation compared to those without (8.3 vs 18.1 months; p = 0.005). **Conclusions:** *ROS1* resistance mutations are observed in over one-third of cases progressing on lorlatinib, including the solvent front mutation G2032R and a novel L2086F mutation. These findings underscore the importance of developing next-generation ROS1 TKIs with activity against *ROS1* mutations, and the need to elucidate ROS1-independent resistance mechanisms. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

9613 Poster Session (Board #379), Fri, 8:00 AM-11:00 AM

Clinical and genomic analysis of non-small cell lung cancer (NSCLC) patients with MET exon14 skipping (METex14) mutations and responses to anti-MET therapy. *First Author: Andrew McKenzie, Sarah Cannon Research Institute, Nashville, TN*

Background: *MET* is a validated oncogene for molecular targeted therapy in non-small-cell lung cancer (NSCLC), and METex14 mutations result in *MET* overexpression. Studies with MET-targeting therapies have demonstrated high objective response rates and prolonged disease control. There are few clinical and genomic analyses of patients with METex14-positive NSCLC in the community setting. We herein characterize key clinical and genomic findings for patients harboring METex14 mutations. **Methods:** Sarah Cannon provides clinical research to partnering medical oncology practices who order broad-based NGS, from both tissue and blood, as a part of standard of care. Genospace, a clinico-genomic software tool, was used for identification of patients for clinical trials and analysis of clinical and genomic data. **Results:** Of 6521 lung cancer patients with NGS results, 66 (1.01%) harbored METex14 mutations (45.5% from blood and 54.5% from in tissue). The mean age at diagnosis was 75.7 and 21.2% developed brain metastases. Of the 66 patients with METex14 mutations, 69.5% are current/former smokers. Nineteen percent of former/current smokers and 7.6% of never smokers had PD-L1 scores of $>50\%$, respectively. The majority of METex14-positive patients either received standard of care (66.7%) or were unable to take (19.7%) 1st-line therapy. Patients who received chemotherapy (Chemo), immunotherapy (IO), and Chemo/IO in the first and second line settings responded to SOC treatment, and patients receiving anti-MET therapy benefited from therapy even after front-line SOC (table). Genomic analysis revealed the most common co-occurring mutations to be *EGFR, MET, NF1, KRAS,* and *BRCA2* (Freq = 8.7%, 8.7%, 8.7%, and 7.6%, respectively). **Conclusions:** Genospace enables real-time patient identification of METex14-positive NSCLC cases and analysis of these cases indicates that anti-MET therapy may be effective at any line of treatment. Genospace's clinico-genomic database was used to analyze treatment history, clinical correlates, and co-occurring mutations that may reveal novel treatment combination strategies or resistance mechanisms. Research Sponsor: Sarah Cannon.

9614 Poster Session (Board #380), Fri, 8:00 AM-11:00 AM

Effect of genomic and transcriptional alterations in first-line chemotherapy on subsequent immunotherapy in non-small cell lung cancer (NSCLC) patients. *First Author: Yayi He, Division of Medical Oncology, Department of Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: Recent studies have demonstrated that first-line immunotherapy has better therapeutic response than second-line immunotherapy in NSCLC patients. However, the mechanism behind this observation has not been elucidated. The aim of this study is to investigate the mechanism of unfavorable influence that the first-line chemotherapy exerts on subsequent immunotherapy. **Methods:** 29 NSCLC patients without tyrosine kinase inhibitor (TKI)-related driver gene (EGFR, ALK, ROS1, RET, BRAF, C-MET) mutations were enrolled in this study. Paired cancer tissues before and after chemotherapy were collected, and NGS-based WES and mRNA sequencing were performed. Sequencing data were analyzed with R packages and statistics analysis was performed with SPSS 20 software. $P \leq 0.05$ was regarded as statistically significant. **Results:** We found that the total number of SNV/INDEL mutations and the tumor mutational burden (TMB) decreased significantly following chemotherapy. The decrease of mutation burden correlated well with therapeutic response: patients with partial response (PR) exhibited significant decrease while patients with stable disease (SD) or progression of disease (PD) did not. Meanwhile, a sharp decrease in common mutations before and after chemotherapy was observed in PR and PD patients, but not SD patients, suggesting that mutational change reflected the therapeutic response. The change in copy number variations (CNVs) exhibited similar trends and correlation with therapeutic response. Subsequent analysis on mRNA levels revealed a sharp decrease in the expression levels of genes related to antigen processing and presentation as well as other factors relevant to immunotherapy response. Pathway enrichment analysis showed that the genes with decreased expression mainly represented immune-related signaling pathways or biological processes. **Conclusions:** Our study revealed a possible mechanism underlying unsatisfactory multiple-line immunotherapy following chemotherapy, and indicated that first-line chemotherapy may influence the tumor microenvironment to exert unfavorable influence on subsequent immunotherapy. 9615 Poster Session (Board #381), Fri, 8:00 AM-11:00 AM

Lorlatinib for advanced ALK and ROS1+ non-small cell lung cancer (NSCLC): Efficacy and treatment sequences in the IFCT-1803 LORLATU expanded access program (EAP) cohort. *First Author: Simon Baldacci, Thoracic Oncology Department, Lille University Hospital, Lille, France*

Background: Lorlatinib, a third-generation tyrosine kinase inhibitor targeting ALK and ROS1, has been made available in France starting October 2015 through an EAP for advanced, refractory, ALK+ NSCLC after the failure of chemotherapy and TKIs. Besides the landmark, multi-cohort phase II trial that assessed lorlatinib in ALK+ NSCLC, real-life evidence regarding the efficacy and safety, as well as treatment sequences including lorlatinib, is lacking. **Methods:** We report the cohort of consecutive patients with advanced, refractory, ALK or ROS1+ NSCLC enrolled in the French EAP of lorlatinib from October 2015 to October 2019. Data were collected from medical records by French Cooperative Thoracic Intergroup (IFCT) research study assistants on site. Primary endpoint was progression-free survival. **Results:** 200 patients were included: 143 (71.5%) ALK+, 57 (28.5%) ROS1+, 87 (44%) men, 127 (66%) never-smokers, and 167 (85%) stage IV disease. Mean age was 59 years. At the time of initiation of lorlatinib, 146 (74%) patients had Central Nervous System (CNS) disease (78 % for ALK+, 63% for ROS1+), 131 (76%) were PS 0/1. Lorlatinib was delivered as 2nd/3rd/4th/5th+ line in 3%/17%/27%/53%of ALK+ patients and in 30%/30%/16%/24%of ROS1+ patients, respectively. 150 (75%), 185 (93%), 138 (69%), and 80 (40%) patients had received prior chemotherapy, crizotinib, 2nd generation TKIs, and brain radiotherapy, respectively. Median PFS and OS from the initiation of lorlatinib were 11.8 (95% CI 7.3-14.6) months and NR (95% CI 18.6-NR) months, respectively for ALK+ patients and 7.6 (95% CI 6.2-10.2) months and 20.9 (95% CI 10.0-NR) months, respectively for ROS1+ patients. ORR and DCR were 46.2% (95% CI 37.6-54.7) and 86.2% (95% CI 80.2-92.1), respectively for ALK+ patients and 47.1% (95% CI 33.4-60.8) and 88.2% (95% CI 79.4-97.1), respectively for ROS1+ patients. CNS ORR was 41.7% (95% CI 33.3-50.1) and 37.7% (95% CI 24.7-50.8), respectively. With a median follow-up of 15.6 (95% CI 14.0-17.6) months, progression under lorlatinib treatment was observed in 71 (50%) ALK+ patients and 35 (61%) ROS1+ patients, and CNS progression in 24 (34%) and 8 (23%) patients, respectively. The safety profile of lorlatinib was consistent with published data. **Conclusions:** These real-life results confirmed lorlatinib as a major treatment option for patients with advanced refractory ALK or ROS1+ NSCLC. 9616 Poster Session (Board #382), Fri, 8:00 AM-11:00 AM

Randomized phase I trial to evaluate *C*oncurrent *or S*equential *I*pilimumab, *N*ivolumab, and stereotactic body *R*adiotherapy in patients with stage IV non-small cell lung cancer (*COSINR Study*). *First Author: Jyoti D. Patel, Lurie Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Stereotactic body radiotherapy (SBRT) provides high rates of treated metastasis control, stimulates innate and adaptive immune pathways, and is safe in patients treated with anti-PD1 monotherapy following SBRT. We hypothesize that SBRT may improve outcomes for patients receiving immunotherapy through both direct cytoreduction and increased immunogenicity. Within this context, we conducted a phase 1 trial designed to evaluate the safety of combination immune checkpoint blockade with nivolumab and ipilimumab(N/Ip) plus sequential (Seq) or concurrent (Con) multisite SBRT (mSBRT) in patients with stage IV NSCLC. **Methods:** Treatment naïve patients (EGFR/ALK WT) with advanced NSCLC received SBRT to 1 to 4 metastases. Not all metastases were targeted, and metastases >65 mL were partially irradiated. Brain metastases were allowed on protocol, and those >3mm were treated prior to enrollment. SBRT dose varied by anatomic site and ranged from 45 to 50 Gy in 3 to 5 fractions with predefined dose de-escalation if excess dose-limiting toxicities were observed. Patients on Seq arm received N/Ip between 1-7 days after completion of SBRT. Patients in Con arm received N/Ip prior to completion of SBRT. N/Ip continued until progression, development of toxicity, or up to 2 years. Patients underwent pre- and post-treatment biopsy of one irradiated lesion. **Results:** A total of 35 patients (Seq/Con 19/16) were enrolled and evaluable for toxicity analysis (SBRT and at least 1 cycle N/Ip). Brain metastases were present in 27%. PD-L1 expression: 0% (16), 1-49% (10), >50% (9). Median number of metastases treated with SBRT was 3.2. 6 patients experienced DLT (4 pneumonitis), resulting in dose reduction in central lung Seq cohort of the organs at risk (OAR) by 20%. Median PFS by RECIST (total/Seq/Con) was 5.9 mo, 95% CI: 4.9-13.1/ 6.2 mo, 95% CI: 3.5-12.6/ 5.9 mo, 95% CI: 3.1-18.0. RECIST best response was 11% CR, 57% PR, 6% SD, and 26% PD. Treatment past first progression was allowed, and time to second line therapy (chemotherapy) by arm (Seq/Con) was NR/17.5 months. Median OS has not been reached with median follow up of 15mo. PDL1 status did not impact PFS ($p = 0.64$) nor OS ($p = 0.77$). **Conclusions:** Multisite SBRT and concurrent N/Ip was well tolerated. Responses appear durable as median OS was not reached. Multimodality therapy with mSBRT and dual checkpoint inhibitor therapy resulted in impressive tumor control and clinical benefit with promising efficacy. Clinical trial information: NCT03223155. Research Sponsor: BMS.

9618 Poster Session (Board #384), Fri, 8:00 AM-11:00 AM

FLT3 ligand (CDX-301) and stereotactic radiotherapy for advanced non-small cell lung cancer. *First Author: Nitin Ohri, Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY*

Background: In a murine non-small cell lung cancer (NSCLC) model, we demonstrated synergy between localized radiotherapy and the dendritic cell growth factor fms-like tyrosine kinase 3 (FLT3) ligand. We now present results from a phase II study testing this combination in patients with advanced and treatment-refractory NSCLC. **Methods:** Advanced NSCLC patients with multi-focal active disease after at least one line of systemic therapy and ECOG performance status 0-2 received 5 daily subcutaneous injections of CDX-301 (75 μg/kg) concurrent with stereotactic body radiotherapy (SBRT, 30-54 Gy in 1-5 fractions based on target size and location) directed at a single site of disease. Additional "cycles" of SBRT and CDX-301 could be administered at least four months after the initial study treatment, at the discretion of the treating physicians. The primary endpoint was progression-free survival four months after treatment initiation (PFS4), with a hypothesis that the PFS4 rate would exceed 40%. Secondary endpoints included overall survival (OS) duration, responses on PET (PERCIST criteria) and CT (RECIST criteria), and dose-limiting toxicities (grade $\geq$3 adverse events within 30 days). Lesions targeted with SBRT were excluded from response assessments. The intended sample size was 29 subjects. Blood samples were obtained for flow cytometry and other analyses of immune activation. **Results:** Twenty-nine subjects received study therapy between October 2016 and January 2020. Subjects received a median of 3 lines (range: 1-5) of systemic therapy prior to study enrollment, including immune checkpoint inhibitors targeting the PD-1/PD-L1 axis in 26 subjects (90%). At the time of this analysis, the actuarial PFS4 rate is 60%, which exceeds our pre-specified efficacy objective. With a median follow-up duration for living patients of 12 months, the actuarial 12-month OS rate is 55%. Partial response of lesions not targeted with SBRT ("abscopal effect") was observed in 9 subjects (31%) using PET criteria and in 4 subjects (14%) using CT criteria. Seven subjects (24%) received a second course of SBRT and CDX-301 after initial study therapy. No dose-limiting toxicities have been observed. Only six subjects (21%) have received additional chemotherapy or immunotherapy after study treatment. **Conclusions:** The combination of CDX-301 and SBRT is well-tolerated and has activity as systemic therapy for advanced NSCLC. Additional studies to maximize the efficacy of this *in situ* vaccination approach with the addition of an agonist anti-CD40 antibody (CDX-1140) are planned. Clinical trial information: NCT02839265. Research Sponsor: U.S. National Institutes of Health.

9619 Poster Session (Board #385), Fri, 8:00 AM-11:00 AM

Dose escalation and expansion from the phase I study of DS-1062, a trophoblast cell-surface antigen 2 (TROP2) antibody drug conjugate (ADC), in patients (pts) with advanced non-small cell lung cancer (NSCLC). *First Author: Aaron Elliott Lisberg, Department of Medicine, Division of Hematology/Oncology, UCLA, Los Angeles, CA*

Background: TROP2 is an intracellular calcium signaling transducer overexpressed in NSCLC, portending poor survival. DS-1062 is a TROP2-targeting ADC with a novel topoisomerase 1 inhibitor (exatecan derivative, DXd) and promising preclinical antitumor activity. Updated results inclusive of 24 additional dose escalation pts and 32 dose expansion pts from an ongoing phase 1 study of DS-1062 in advanced/metastatic NSCLC are reported (NCT03401385/J101). **Methods:** Pts aged $\geq$18 (US) or $\geq$20 (Japan) with unresectable NSCLC refractory to/relapsed from standard treatment with measurable disease (RECIST v1.1) and available tumor for retrospective TROP2 evaluation were eligible. Primary objectives include maximum tolerated dose (MTD) identification, safety, and tolerability and secondary objectives include efficacy, pharmacokinetics, and incidence of anti-drug antibodies against DS-1062. Pts were eligible regardless of TROP2 level. **Results:** As of November 16, 2019, 95 pts were treated with $\geq$1 dose of DS-1062. 63 pts were treated during escalation at 0.27 (n = 4), 0.5 (n = 5), 1.0 (n = 7), 2.0 (n = 6), 4.0 (n = 6), 6.0 (n = 19), 8.0 (n = 8), and 10.0 (n = 8) mg/kg and 32 pts were treated in expansion at the MTD of DS-1062, 8 mg/kg. 59 pts (62%) discontinued (25 [42%] due to progressive disease per RECIST v1.1). Pts were exposed to a median of 3 treatment cycles (range, 1-19). In 88 response-evaluable pts, 22 had partial response (1 PR/6 pts at 2.0 mg/kg, 2 PR/6 pts at 4.0 mg/kg, 5 PR/18 pts at 6.0 mg/kg, 13 PR/34 pts at 8.0 mg/kg, and 1 PR/8 pts at 10.0 mg/kg; 14 PRs were confirmed and 8 PRs are awaiting confirmation). Treatment emergent adverse events (TEAEs) regardless of causality were reported in 91 of 95 pts (96%; 44 pts [46%] experienced $\geq$grade 3, 30 pts [32%] had serious events). Treatment-related TEAES were reported in 76 of 95 pts (80%; 17 pts [18%] experienced $\geq$grade 3, 8 pts [8%]) had serious events). Potential interstitial lung disease (ILD) occurred in 8 pts (8%; 2 at 6.0 mg/kg and 6 at 8.0 mg/kg); 6/8 with potential ILDs adjudicated as treatment-related (1 at 6.0 mg/kg [grade 2] and 5 at 8.0 mg/kg [1 grade 1, 2 grade 2, 1 grade 3, and 1 grade 5]). 14 escalation pts and 22 expansion pts remain on trial. Updated trial details/results will be presented. **Conclusions:** In this first-in-human study of DS-1062, treatment was well tolerated up to 8 mg/kg, and a dose effect on antitumor activity was observed over 2.0-10.0 mg/kg in heavily pretreated pts with prior progression on standard treatment. Clinical trial information: NCT03401385. Research Sponsor: Daiichi Sankyo.

9620 Poster Session (Board #386), Fri, 8:00 AM-11:00 AM

Genomic characterization and outcome evaluation of kinome fusions in a large non-small cell lung cancer population. *First Author: Fengying Wu, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Lung cancer is the leading cause of cancer death worldwide. Kinase fusion represents an important type of somatic alterations which promote oncogenesis and serve as a diagnostic marker in lung cancer. This study aims to identify the landscape of kinase fusions in lung cancer and expand our understanding of druggable fusions, together providing valuable information for therapeutics decision making. **Methods:** We performed genomic profiling of tumor/plasma biopsies of a total of 18,839 Chinese lung cancer patients using next generation sequencing (NGS) by targeting 425 cancer-relevant genes. Patients' clinical characteristics and treatment history were retrospectively studied. **Results:** A total of 1,048 patients (5.56%, 1,048/18,839) were identified with kinase fusions, including 815 adenocarcinomas (ADCs) and 34 squamous cell carcinomas (SCCs). Briefly, a total of 198 unique gene fusion events have been observed, including 37 recurrent fusions and 114 novel fusions which have previously not been documented. ADC patients with kinase fusions were relatively younger than SCC patients (median: 53 vs 61 years old, $p< 0.01$). The most frequently observed fusion was *EML4-ALK* for both ADCs (50.0%) and SCCs (32.4%), followed by *FGFR3-TACC3* (29.4%) in SCCs and *KIF5B-RET* (11.8%), *CD74-ROS1* (9.2%), *CCDC6-RET* (3.9%) and *SLC34A2-ROS1* (2.3%) in ADCs, retrospectively. A total of 14 recurrent fusions including *FN1-ALK*, *MEMO1-ALK, CUX1-ALK*, *KIF13A-RET* and *PHF20-NTRK1* were also identified at low frequencies. Of note, *EML4-* or *STRN-ALK* fusion events mainly rearranged in the intron 19 of *ALK*, but the breakpoints of *VCL-ALK* were mostly located upstream of *ALK* exon 18. Meanwhile, *CD74-*, *SLC34A2-* and *TPM3- ROS1* rearrangement mainly occurred in the *ROS1* introns 31, 33 and 34. In addition, among patients with novel fusions, *RORB-ALK* and *AFF2-RET* may potentially function as oncogenic drivers in lung cancer and have demonstrated clinical benefit from crizotinib treatment. **Conclusions:** Our data have depicted a comprehensive overview of the landscape of kinase fusions in lung cancer, which helps recognize potentially druggable fusions and translate into therapeutic applications. Research Sponsor: None.

9621 Poster Session (Board #387), Fri, 8:00 AM-11:00 AM

Acquired resistance to PD-1 blockade in NSCLC. *First Author: Adam Jacob Schoenfeld, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Although durability is the trademark characteristic of response to PD-1 blockade, acquired resistance can occur. The frequency, patterns, and survival outcomes of patients with acquired resistance to PD-1 blockade are unknown. **Methods:** All patients with NSCLC treated with PD-1 blockade at MSKCC were examined. Acquired resistance was defined as initial CR/PR (by RECIST) followed by progression/death. Oligo vs systemic patterns of acquired resistance were defined as progression in ≤ 2 sites of disease or ≥ 3 sites of disease, respectively. **Results:** Of 1201 patients treated with PD-1 blockade, 243 (20%) achieved initial response and 189 (78%, 95% CI 72-83%) eventually developed acquired resistance (AR). Onset of AR was variable and decreased with longer duration of response (53% within 1 year, 37% 1-2 years, 10% $>$ 2 years). Patients with PD-L1 expression $<$ 50% and TMB $<$ 8mut/Mb were more likely to develop resistance compared those with PD-L1 expression $\geq$50% and TMB $\geq$8mut/Mb (OR 5.5, p = 0.02). Unlike organ sites of primary refractory disease, AR commonly occurred in lymph nodes (41%) and infrequently in the liver (6%). Patterns of AR were most commonly oligo rather than systemic (79/141 [56%], 39/141 [28%]); some patients died without radiographic progression (23/141 [16%]). Oligo-AR occurred later (median onset 13 vs 5.6 mo) and associated with improved post-progression survival (median OS 55.2 vs 9.2 mo, HR 6.0, p $<$ 0.001) compared to systemic-AR. Post-progression survival was highest in patients with AR compared to those with initial SD or PD to PD-1 blockade (median 18.9 vs 12.5 vs 4.4, p $<$ 0.001). Of 49 patients treated initially with locally-directed therapy for AR, 28 (57%) remain alive and systemic therapy-free. **Conclusions:** Acquired resistance to PD-1 blockade is common in NSCLC. Risk of acquired resistance is lower in biomarker-enriched patients and with increased duration of response. Patterns of acquired resistance is commonly oligo in nature, which is amenable to locally-directed therapy and can be associated with improved survival. Differences in organ-site distribution and post-progression survival suggest distinct biology associated with acquired resistance vs primary refractory disease. 9622 Poster Session (Board #388), Fri, 8:00 AM-11:00 AM

Progression-free survival estimates in non-small cell lung cancer when RECIST is unavailable: Project GENIE's integration of genomic, therapeutic and phenomic data. *First Author: Jessica A. Lavery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Molecular tumor profiling has become an integral component of oncology practice but linked genomic-phenomic data remain scarce. Recurrence, treatment response and progression are not structured consistently in medical records and this deficit has been a roadblock to discovery of biomarkers that are associated with favorable outcomes. **Methods:** The Genomics Evidence Neoplasia Information Exchange (GENIE) consortium is an AACR sponsored project to link and share genomic and phenomic data to promote discovery in precision medicine. 3 cancer centers that routinely perform somatic tumor profiling for advanced cancers agreed to curate anti-neoplastic treatment exposures and outcomes including recurrence, progression, response and survival using a standard method. 6 cancer types (lung, colorectal, breast, prostate, pancreas and bladder) were selected and a REDCAP database captures anti-neoplastic treatments, and specific elements from pathology, radiology and oncology reports. Curators abstract data using data fields that rely on the PRISSMM standard. "Real world" progression free survival (PFS) was identified based on curation of: 1) the text of radiologists' reports for CT, PET/CT, PET and MRI scans (PFS_I) and 2) medical oncologists' notes (PFS_M). PFS_I and PFS_M were estimated from the start of 1st line anti-neoplastic systemic therapy until progression or death for all patients with molecularly characterized non-small cell lung cancer (NSCLC). **Results:** Genomic sequencing was performed between 2015 and 2017 for 748 patients with NSCLC treated at three major cancer centers. Median age at diagnosis was 66 years (interquartile range 58, 73) and 43% were male. As shown in the table, when RECIST assessments are unavailable, estimates of PFS vary based on whether they are derived from radiologists' or oncologists' interpretations. **Conclusions:** Radiologists' reports and oncologists' reports provide different PFS estimates. Cohort studies should specify the method used to define "real world" endpoints. Project GENIE will have 1800 NSCLC patients with curated endpoints by the ASCO meeting. Research Sponsor: American Association for Cancer Research.

"Real World" PFS from 1st line treatment for NSCLC: estimates based on radiologists' reports (PFS_I) and oncologists' notes (PFS_M).

Regimen	N	PFS_I (months; 95% CI)	PFS_M (months; 95% CI)
Any therapy	468	7.6 (6.4, 9.2)	10.7 (9.9, 12.4)
Immunotherapy	45	3.7 (1.5, 6.0)	7.0 (4.4, 10.1)
Cytotoxic therapy	370	9.0 (7.4, 10.5)	11.5 (9.9, 14.0)
Targeted therapy	53	7.3 (4.9, 14.1)	11.1 (8.9, 24.4)

9623 Poster Session (Board #389), Fri, 8:00 AM-11:00 AM

SWOG S1400F (NCT03373760): A phase II study of durvalumab plus tremelimumab for previously treated patients with acquired resistance to PD-1 checkpoint inhibitor therapy and stage IV squamous cell lung cancer (Lung-MAP Sub-study). *First Author: Natasha B. Leighl, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The Lung Cancer Master Protocol (Lung-MAP) is designed to evaluate novel targeted therapies in patients with advanced squamous lung carcinoma. In the S1400F sub-study (non-match), we tested whether combined CTLA-4 and PD-1 inhibition with durvalumab plus tremelimumab (D+T) could overcome primary or acquired resistance to anti-PD-(L)1 therapy. Response, progression-free (PFS) and overall survival, and safety in the acquired resistance cohort are reported herein. **Methods:** Patients with previously treated squamous lung carcinoma, performance status (PS) 0-1, and adequate organ function that developed disease progression after $\geq$24 weeks of anti-PD-(L)1 monotherapy were eligible. Prior severe immune-related toxicities, intervening systemic therapy and combination chemo-immunotherapy were not permitted. Patients received D1500 mg + T75 mg IV q28 days for 4 cycles then D maintenance until disease progression. The primary endpoint was best objective response (RECIST 1.1). Interim analysis for futility was planned after 20 patients evaluable for response were enrolled. If no responses were observed, the cohort would stop enrolment. **Results:** 30 eligible patients were accrued to the acquired resistance cohort. Median age was 68 years, 60% of patients were male, 33% PS 0 and had received a median of 2 prior lines of therapy (maximum 4). Best response to prior anti-PD-(L)1 therapy was CR/PR/SD in 3/7/20 patients, with a median duration of anti-PD-(L)1 therapy of 8.6 months (5.2-30.4). No objective responses were seen with D+T; 47% had SD as best response. Median PFS was 2.0 months (95% CI 1.6-2.9) and survival 7.5 months (95% CI 5.3-8.7). Among the 14 patients with SD as best response, the median PFS calculated from first disease assessment is 2.8 months (95% CI: 1.4-3.9). Grade$\geq$3 adverse events at least possibly related to protocol therapy were seen in 10/30 patients. These include 1 treatment-related death due to pneumonitis and 1 death not otherwise specified. Other adverse events include grade 3 confusion (1), dehydration (2), diarrhea (3), encephalopathy (1), weakness (1), hyperglycemia (1), hypoxia (1), lymphopenia (1), nausea, (1), neutropenia (1), thrombocytopenia (1), rash (1), vomiting (1), grade 4 dyspnea (1), leucopenia (1) and lymphopenia (1). **Conclusions:** D+T did not demonstrate activity in patients with acquired resistance to PD-1 checkpoint inhibitors and pretreated advanced squamous lung carcinoma. Clinical trial information: NCT03373760. Research Sponsor: U.S. National Institutes of Health, Lung-MAP trial supported in part by NIH/NCI grants CA180888, CA180819, CA180820, CA180821, CA180863, CA180868, and by AbbVie Inc., Amgen, AstraZeneca, Bristol-Myers Squibb Company, Genentech and Pfizer through the Foundation for the National Institutes of Health, in partnership with Friends of Cancer Research.

9624 Poster Session (Board #390), Fri, 8:00 AM-11:00 AM

BRIGHTSTAR: A pilot trial of local consolidative therapy (LCT) with brigatinib in tyrosine kinase inhibitor (TKI)-naïve ALK-rearranged advanced NSCLC. *First Author: Yasir Elamin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Approximately, 95% of patients who have an initial response to ALK-TKIs exhibit an incomplete response resulting in residual disease that enables the emergence of acquired resistance. Eliminating residual disease using LCT may delay resistance emergence and improve clinical outcomes. **Methods:** This is a single center investigator-initiated trial that assesses the safety, feasibility and efficacy of brigatinib with LCT. Eligible patients have TKI-naïve ALK rearranged advanced NSCLC with any number of metastases. Patients treated with brigatinib for an induction period of 8 weeks followed by LCT with radiation and/or surgery. **Results:** Between 12/2018 and 01/2020, 17 out of 24 planned patients were enrolled. Median age 55 (range 33-73). At study entry, 15 patients had polymetastatic disease ($>$ 3 sites) while 2 had oligometastatic disease. As of February 1, 2020, 16 patients were evaluated for response and completed LCT while 1 patient remained on induction brigatinib. The disease control rate was 100% with an objective response rate of 94% (n = 15). Median follow up was 8 months (range 3-13) with no patients with disease progression to date. LCT used was radiation (n = 11), surgery (n = 3), surgery and radiation (n = 2). Among 5 patients who had surgery, 4 had lobectomy and mediastinal lymph node dissection (MLND), 1 had wedge resection with MLND, and 1 had adrenalectomy. Of these, 2 had complete pathological response and 1 had complete pathological response at the primary tumor. There were no grade $\geq$2 adverse events (AEs) related to LCT, including in 7 patients treated with concurrent brigatinib and radiation, and 6 patients treated with radiation while brigatinib was held. All patients continued brigatinib after LCT. Brigatinib-related severe AEs included grade 3: increased blood levels of creatine kinase, lipase, alanine aminotransferase, amylase (n = 1 each) and nausea (n = 1). One patient had grade 2 pneumonitis after 2 weeks of starting brigatinib, this resolved with steroids and brigatinib was resumed at a lower dose. **Conclusions:** Brigatinib with LCT is safe and feasible in patients with ALK-rearranged advanced NSCLC irrespective of number of metastatic sites. Brigatinib and LCT may be an effective therapeutic strategy in this subset of NSCLC patients. Clinical trial information: NCT03707938. Research Sponsor: Takeda.

TPS9625 **Poster Session (Board #391), Fri, 8:00 AM-11:00 AM**

Phase III trial comparing antibody-drug conjugate (ADC) SAR408701 with docetaxel in patients with metastatic non-squamous non-small cell lung cancer (NSQ NSCLC) failing chemotherapy and immunotherapy. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: Despite recent advances in the treatment of NSQ NSCLC, including the integration of immune checkpoint inhibitors (ICI) into first-line treatment of all patients, novel therapies are necessary at disease progression. Carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5), a cell-surface glycoprotein, is overexpressed in several tumor types, including NSQ NSCLC; ~20% of patients express high CEACAM5 levels. SAR408701 is an ADC combining a humanized antibody targeting CEACAM5 with the potent cytotoxic maytansinoid derivative DM4 and is expected to selectively deliver DM4 to CEACAM5-expressing cancer cells. In an interim analysis of a first-in-human study (NCT02187848) in patients with NSQ NSCLC and CEACAM5 expression in ≥50% of tumor cells, SAR408701 administered 100 mg/m^2 every 2 weeks showed an objective response rate (ORR) of 23% and a favorable safety profile (Gazzah A et al *J Clin Oncol*. 2019;37:15, 9072). **Methods:** In this randomized, open-label, phase 3 trial, patients receive either SAR408701 100 mg/m^2 IV every 2 weeks or the standard of care treatment docetaxel 75 mg/m^2 IV every 3 weeks. Randomization is stratified on ECOG performance status (PS), previous ICI treatment (sequential vs combination), and geographical region. Patients are ≥18 years with metastatic NSQ NSCLC after platinum-based chemotherapy and ICI treatment (anti-PD-1/PD-L1 monoclonal antibody), express CEACAM5 in ≥50% of tumor cells at ≥2+ intensity (central testing), and have ECOG PS 0–1. Exclusion criteria include untreated brain metastases, history of corneal disorders, and prior treatment with docetaxel, maytansinoid derivatives, or CEACAM5-targeting drugs. Tumor imaging occurs at baseline and every 8 weeks until disease progression. Primary endpoints are progression-free survival (PFS; RECIST v1.1 by independent blinded review committee) and overall survival (OS), both analyzed by Kaplan-Meier method, stratified log-rank test, and stratified Cox proportional hazard model. Study success is defined either on PFS or OS, with a strong type-I error control for multiple hypotheses. Secondary endpoints are ORR and duration of response (RECIST v1.1), health related quality of life (EORTC QLQ-C30 and EORTC QLQ-LC13), and safety (adverse events graded by NCI CTCAE v5). Approximately 554 randomized patients (277 per arm) is adequate to reach both PFS and OS events. The study opened in Nov 2019, and as of Feb 7, 2020, 20 sites in 8 countries are activated. Clinical trial information: NCT04154956. Research Sponsor: Sanofi.

TPS9626 **Poster Session (Board #392), Fri, 8:00 AM-11:00 AM**

Randomized phase II study of canakinumab (CAN) or pembrolizumab (PEM) as monotherapy or in combination as neoadjuvant therapy in patients (Pts) with surgically resected (Stage IB-IIIA) non-small cell lung cancer (NSCLC): CANOPY-N. *First Author: Tony S. K. Mok, The Chinese University of Hong Kong, Hong Kong, China*

Background: Complete surgical resection is the standard treatment (tx) for pts with stage I-IIIA NSCLC. 5-year survival rates range from 19-50%, with most pts dying from distant recurrence. Neoadjuvant or adjuvant chemotherapy improves overall survival (OS) by only 5% in pts with NSCLC, and new tx options are needed. Preliminary data with PD-1 or PD-L1 inhibitors as neoadjuvant therapy has shown major pathologic responses (MPR) or pathologic complete responses (pCR) in pts with early stage NSCLC. CANTOS study demonstrated reduced incidence of NSCLC and decreased lung cancer-related mortality with CAN (IL-1β inhibitor) versus placebo, in a dose-dependent manner for pts with atherosclerosis. In pre-clinical NSCLC humanized models, tx with CAN±anti PD-1 inhibitor could lead to anti-tumor activity. Combination of CAN and PEM is expected to enhance the efficacy of PD-1 inhibition by inhibiting dysregulated inflammation in tumor microenvironment. Based on available evidence, CANOPY-N study was designed to evaluate effect of CAN and PEM as monotherapy or in combination as neoadjuvant tx for pts with resectable NSCLC. **Methods:** CANOPY-N (NCT03968419) is a phase II, randomized, open-label study evaluating effect of CAN or PEM monotherapy or in combination as neoadjuvant tx in resectable NSCLC pts. Histologically confirmed stage IB-IIIA, tx-naive, ECOG PS 0-1 NSCLC pts eligible for surgery and with a planned surgical resection in approximately 4-6 weeks (after 1st dose of study tx), are eligible to participate. An archival (if obtained up to 6 months before 1st day of tx) or new biopsy is required. Approximately 110 pts will be randomized in 2:2:1 ratio (stratified by histology [squamous/non-squamous]) to one of the tx arms to receive a total of 2 doses (200 mg Q3w) of CAN alone (n = 44) or in combination with PEM (n = 44) or PEM (n = 22) with safety follow-up up to 130 days from last study drug dose. Primary endpoint is to determine MPR rate (≤10% of residual viable tumor cells at time of surgery), secondary endpoints include determination of ORR, MPR rate based on local review, surgical feasibility rates, anti-drug antibodies incidence and PK parameters. Clinical trial information: NCT03968419. Research Sponsor: Novartis Pharmaceuticals Corporation.

TPS9627 **Poster Session (Board #393), Fri, 8:00 AM-11:00 AM**

A phase II randomized study of telaglenastat, a glutaminase (GLS) inhibitor, versus placebo, in combination with pembrolizumab (Pembro) and chemotherapy as first-line treatment for KEAP1/NRF2-mutated non-squamous metastatic non-small cell lung cancer (mNSCLC). *First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mutational activation of the KEAP1/NRF2 pathway occurs in >20% of NSCLC patients (pts). KEAP1/NRF2 activation protects tumor cells from diverse forms of oxidative stress and promotes tumor growth and survival. In pts w/ advanced NSCLC, mutation of the KEAP1/NRF2 pathway is associated w/ dramatically reduced survival and poor outcomes following standard-of-care therapy. These tumors have increased dependence on GLS-mediated conversion of glutamine to glutamate due to upregulation of NRF2 target genes involved in glutamine metabolism. Telaglenastat (CB-839), an investigational, first-in-class, potent, oral GLS inhibitor, has demonstrated preclinical activity in KEAP1/NRF2-mutated NSCLC cell lines and xenograft models. This study will evaluate the safety and efficacy of telaglenastat + standard-of-care pembro and chemotherapy as 1L therapy for KEAP1/NRF2-mutated non-squamous mNSCLC (NCT04265534). **Methods:** This phase II, randomized, multicenter, double-blind study will enroll ~120 pts with histologically or cytologically documented stage IV non-squamous NSCLC w/ KEAP1 or NRF2 mutation, no prior systemic therapy for mNSCLC, measurable disease (RECIST v1.1), ECOG PS 0-1, and no EGFR, ALK, ROS, or other actionable mutation w/ available approved therapy in 1L setting. KEAP1 or NRF2 mutations will be determined by next generation sequencing (NGS), and study-provided liquid biopsy NGS will be available. Pts will be randomized 1:1 to receive telaglenastat (800 mg BID PO) or placebo, in combination with pembro, carboplatin, and pemetrexed at standard doses on day 1 of each 21-day cycle. Pts will be stratified by STK11/LKB1 mutational status and M stage of cancer (M1a-b vs M1c). The study will include an initial safety run-in period (n=12; 1 cycle). Co-primary endpoints are safety and investigator-assessed progression-free survival (RECIST v1.1). Secondary endpoints include overall response rate, duration of response, overall survival, and efficacy analysis in the subgroup of pts w/ biochemical confirmation of KEAP1/NRF2 pathway activation. Findings of this novel NGS biomarker-selected study will inform the efficacy and safety profile of telaglenastat + standard-of-care chemoimmunotherapy for 1L treatment of KEAP1/NRF2-mutated, non-squamous mNSCLC. Clinical trial information: NCT04265534. Research Sponsor: Calithera Biosciences, Inc.

TPS9628 **Poster Session (Board #394), Fri, 8:00 AM-11:00 AM**

A phase I/II study of REGN5093, a MET x MET bispecific antibody, in patients with MET-altered advanced non-small cell lung cancer (NSCLC). *First Author: Tracey Rowlands, Regeneron Pharmaceuticals, Inc., Tarrytown, NY*

Background: Mesenchymal-epithelial transition (MET) factor is a transmembrane tyrosine kinase receptor activated by hepatocyte growth factor (HGF). Aberrant activation of MET via gene amplification or gene mutations, as well as MET protein overexpression, has been reported in NSCLC and other cancer types and can promote tumorigenesis. REGN5093 is a human bispecific antibody that binds to two distinct epitopes of MET, blocking HGF binding and inducing internalization and degradation of MET. REGN5093 prevents MET-mediated signaling and inhibits growth of MET-driven tumor cells without inducing MET-driven biological responses (DaSilva et al, *CCR*, 2019; PMID: 31848185). **Methods:** This Phase I/II, first-in-human, multicenter study is investigating the safety, tolerability, pharmacokinetics (PK), and efficacy of REGN5093 in patients with MET-altered advanced NSCLC who have received all available approved therapies (NCT04077099). Key eligibility criteria include age ≥18 years, Eastern Cooperative Oncology Group performance status of ≤1, and documented presence of either *MET* exon 14 gene mutation and/or *MET* gene amplification and/or elevated MET protein expression. Patients are required to provide a biopsy during screening for assessment of MET biomarkers. Key exclusion criteria include prior MET-targeted biologic therapy (expansion cohorts only). Prior therapy with tyrosine kinase inhibitors are not exclusionary in any part of the study. For each patient, the study comprises a screening period of up to 28 days, followed by 3-week cycles of REGN5093 monotherapy. Study treatment will continue until confirmed disease progression or other protocol-defined reason for discontinuation. The study has two parts: dose escalation and dose expansion. Dose escalation will proceed via 4+3 design until a maximum-tolerated dose is reached or a recommended Phase II dose selected. The primary objective of the dose escalation part is to assess safety (incidence and severity of adverse events and Grade ≥3 laboratory abnormalities), tolerability (incidence of dose-limiting toxicities), and PK of REGN5093. During the expansion phase, patients will be allocated to cohorts according to the type(s) of documented biomarkers of MET-altered disease. Anti-tumor activity based on objective response rate per Response Evaluation Criteria in Solid Tumors version 1.1, determined by CT or MRI, will be the primary endpoint in the expansion cohorts. The study is currently open for enrollment. Clinical trial information: NCT04077099. Research Sponsor: Regeneron Pharmaceutical, Inc.

TPS9629 **Poster Session (Board #395), Fri, 8:00 AM-11:00 AM**

Phase II randomized trial of carboplatin + pemetrexed + bevacizumab, +/- atezolizumab in stage IV non-squamous non-small lung cancer (NSCLC) patients who harbor a sensitizing EGFR mutation or have never smoked. *First Author: Joseph Nicholas Bodor, Fox Chase Cancer Center, Philadelphia, PA*

Background: Stage IV NSCLC patients who are never-smokers or with EGFR-mutated tumors generally do not benefit from single-agent immunotherapy. Retrospective subgroup analyses from recent phase III trials suggest that immunotherapy-chemotherapy +/- VEGF inhibition may overcome resistance to PD-L1 inhibitors in these patients, however prospective research on this is needed. This trial will examine a patient population with stage IV non-squamous disease who either have tumors that possess an EGFR exon 19 or 21 mutation or who are never-smoker wild-types, to determine whether the PD-L1 inhibitor atezolizumab in combination with pemetrexed, carboplatin, and bevacizumab can improve outcomes. **Methods:** This is a randomized, phase II, multi-center, open-label trial to assess pemetrexed/carboplatin and bevacizumab +/- atezolizumab in 117 subjects with stage IV non-squamous NSCLC. Randomization will be 2:1 favoring the + atezolizumab arm. Patients are stratified by EGFR mutation status (i.e. EGFR exon 19 or 21 vs. never-smoker wild-type). Never-smoker wild-type is defined as smoking $<$ 100 cigarettes in a lifetime and without any EGFR mutation or ALK or ROS1 rearrangement. Patients with EGFR exon 19 or 21 mutated tumors must have progression of disease or intolerance of treatment with one or more prior TKIs. Primary endpoint is progression-free survival (PFS). Secondary endpoints include overall survival (OS), overall response rate, duration of response, and time to response. Primary objective is to compare PFS between arms. Secondary objectives include a safety analysis in all treated subjects, and comparisons of PFS and OS between arms for the patient subset with EGFR-mutated tumors. Correlative studies include interrogating flow cytometry-based peripheral blood biomarkers, examining the role of desmoplasia in local tumor immunosuppression, and assessing the contribution of estrogen metabolites to tumorigenesis. This study opened in August 2019 with 2 patients enrolled at the time of submission. Twenty U.S. sites through the NCCN are participating. This study was approved and funded by the National Comprehensive Cancer Network (NCCN) Oncology Research Program from general research support provided by Genentech, Inc. Clinical trial information: NCT03786692. Research Sponsor: F. Hoffmann-La Roche Ltd./Genentech.

TPS9630 **Poster Session (Board #396), Fri, 8:00 AM-11:00 AM**

Phase IIa study of marrow infiltrating lymphocytes (MILs), an adoptive T cell therapy, alone or in combination with nivolumab in non-small cell lung cancer (NSCLC). *First Author: Martin Edelman, Fox Chase Cancer Center, Philadelphia, PA*

Background: Primary or secondary resistance to anti-PD-1 may be due to loss of T cell function. Persistent antigen stimulation can lead to impaired CD8+ T cell function, which often results in acquired resistance to PD-1 inhibition. It is unclear whether reinvigoration of tumor infiltrating cells or recruitment of novel T cells impart the activity of anti-PD-1 therapy. The bone marrow is a reservoir for antigen experienced memory T cells. We have previously shown that MILs can be generated for patients with hematologic malignancies and solid tumors including patients with NSCLC. MILs are the product of the activation and expansion of bone marrow T cells with a polyantigenic memory phenotype that recognize tumor antigens, are cytotoxic to autologous tumor and are able to persist over a long period of time. In a pre-clinical study of NSCLC, MILs were able to be expanded in all patients tested. Furthermore, all of the NSCLC products tested showed specificity to shared NSCLC antigens. The combination of adoptive cell therapy (ACT) with checkpoint inhibitors (CPIs) has distinctive positive effects on CD8 and CD4 T cell subsets, with the possibility for complete tumor control. We hypothesize that patients with NSCLC who have relapsed on anti-PD-1 treatment could benefit from an infusion of non-exhausted, central memory-enhanced, antigen specific T cells i.e. MILs which can delay the induction of tumor-associated anergy and augment the overall effectiveness of immunotherapy. **Methods:** Patients with advanced NSCLC who have progressed following prior anti-PD-1 therapy, with sufficient bone marrow reserve and an ECOG 0-1 are eligible. In eligible patients, bone marrow (200 mL) will be harvested and processed. Patients will undergo lymphodepletion (fludarabine 300 mg/m^2/day and cyclophosphamide 30 mg/m^2/day on days -5,-4,-3) followed by infusion of MILs on day 0. In Part 1, up to 6 patients will be administered MILs alone on day 0. In Part 2, approximately 20 subjects will be administered MILs on day 0 followed by NIVO 480 mg Q4W starting on day 1. The objectives of the study are to assess safety of MILs alone and in combination with NIVO, as well as efficacy. The first patient was treated in December 2019. Clinical trial information: NCT04069936. Research Sponsor: None.

TPS9631 **Poster Session (Board #397), Fri, 8:00 AM-11:00 AM**

A phase II trial of durvalumab (MEDI4736) and tremelimumab with chemotherapy in metastatic EGFR mutant non-squamous non-small cell lung cancer (NSCLC) following progression on EGFR tyrosine kinase inhibitors (TKIs) (ILLUMINATE). *First Author: Chee Khoon Lee, St George Hospital, Kogarah, Australia*

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have proven remarkably effective in the treatment of advanced EGFR mutant non-small cell lung cancer (NSCLC). However, drug resistance is inevitable and outcomes with subsequent platinum-pemetrexed chemotherapy are poor. The role of immune-checkpoint inhibitor monotherapy in EGFR mutant NSCLC remains uncertain with trials demonstrating inferior survival outcomes compared to chemotherapy. However, a recent randomised study with combination checkpoint inhibitor-chemotherapy demonstrated improved survival over chemotherapy alone in this patient population. This study aims to evaluate the efficacy and tolerability of combination dual immune-checkpoint blockade, durvalumab and tremelimumab, with platinum-pemetrexed chemotherapy in metastatic EGFR mutant NSCLC following progression on EGFR-TKIs. **Methods:** This international phase II cohort study will recruit 100 participants from Australia and Taiwan with advanced EGFR mutant NSCLC following disease progression with EGFR-TKIs [Cohort 1 (n=50): T790M mutation negative on tissue and plasma; Cohort 2 (n=50): T790M mutation positive on tissue and/or plasma, and progression on3rd generation TKIs]. Participants will receive 4 cycles of induction durvalumab 1500mg and tremelimumab 75mg with platinum-pemetrexed chemotherapy every 3 weeks, followed by maintenance durvalumab 1500mg and pemetrexed 500mg/m2 every 4 weeks until disease progression. Response will be assessed at 6 and 12 weeks, then 8-weekly during the first year, and 12-weekly thereafter. Major endpoints include objective tumour response rate (OTRR; RECIST1.1; primary), disease control rate, OTRR (iRECIST), progression-free survival, overall survival, and adverse events. Correlative studies include biomarker assessment as potential predictive/prognostic factors. ILLUMINATE is a collaboration between the Australasian Lung Cancer Trials Group, National Health Research Institutes (Taiwan) and the NHMRC Clinical Trials Centre, University of Sydney. As of 6/2/2020, 11 of planned 100 participants have been recruited. Clinical trial information: NCT03994393. Research Sponsor: AstraZeneca.

TPS9632 **Poster Session (Board #398), Fri, 8:00 AM-11:00 AM**

Randomized phase III study of first-line pembrolizumab plus pemetrexed/platinum followed by pembrolizumab and maintenance olaparib versus pemetrexed in patients with metastatic nonsquamous non-small cell lung cancer (NSCLC): KEYLYNK-006. *First Author: Jhanelle Elaine Gray, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: First-line treatment with pembrolizumab + pemetrexed/platinum improved clinical outcomes in patients with advanced non-squamous NSCLC in KEYNOTE-021 and KEYNOTE-189. Poly(ADP-ribose) polymerase inhibitors (PARPi), including olaparib, have been shown to upregulate PD-L1 expression in preclinical studies, and preliminary evidence suggests potential therapeutic benefit and acceptable safety with PARPi plus anti–PD-(L)1 therapy. KEYLYNK-006 (NCT03976323) evaluates first-line pembrolizumab + pemetrexed/platinum followed by pembrolizumab + olaparib vs pembrolizumab + pemetrexed in patients with metastatic nonsquamous NSCLC. **Methods:** This phase III, randomized, open-label trial enrolls patients aged $\geq$18 years with histologically/cytologically confirmed treatment-naive, metastatic, nonsquamous NSCLC. Patients (target n = 792) receive induction pembrolizumab 200 mg + pemetrexed 500 mg/m^2 + carboplatin AUC 5 mg/mL/min or cisplatin 75 mg/m^2 Q3W for 4 cycles. Patients with PR/CR or SD are randomized (target n = 618) 1:1 to pembrolizumab 200 mg Q3W (31 cycles) + maintenance olaparib 300 mg twice daily or pembrolizumab + pemetrexed 500 mg/m^2 Q3W stratified by ECOG PS (0 vs 1), PD-L1 tumor proportion score ($<$50% vs $\geq$50%), and response (CR/PR vs SD). Tumor imaging per RECIST version 1.1 ($\leq$5 per organ; maximum 10 total lesions) by central review (BICR) is performed at baseline and Q6W until 60 weeks after randomization, then Q9W until disease progression, start of new cancer therapy, study withdrawal, or death. Primary endpoints are PFS (RECIST 1.1 by BICR) and OS estimated by the Kaplan-Meier method, stratified log-rank test, and Cox proportional hazard model with Efron's method of tie handling. Secondary endpoints are safety and quality of life; ORR and duration of response are exploratory endpoints. AEs are monitored throughout the study until 30 days after the last dose of treatment (90 days for serious AEs) and graded using NCI CTCAE, version 4.0. The study began enrolling in June 2019. Clinical trial information: NCT03976323. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS9633 Poster Session (Board #399), Fri, 8:00 AM-11:00 AM

AcceleRET Lung: A phase III study of first-line pralsetinib in patients (pts) with RET-fusion+ advanced/metastatic non-small cell lung cancer (NSCLC). *First Author: Benjamin Besse, Gustave Roussy Université Paris Sud, Villejuif, France*

Background: RET gene fusions have been identified as oncogenic drivers in multiple tumor types, including 1-2% of NSCLC, but no selective RET inhibitors are approved for use. The investigational RET inhibitor, pralsetinib, potently and selectively targets oncogenic RET alterations, including those that confer resistance to multikinase inhibitors. In the registration-enabling phase 1/2 study (ARROW; NCT03037385), pts with RET-fusion+ NSCLC treated with 400 mg once daily (QD) of pralsetinib (N = 80) after platinum-based chemotherapy achieved an overall response rate (ORR) of 61% (95% CI 50, 72; 2 responses pending confirmation) per independent central review. In addition, a promising ORR of 73% (all centrally confirmed responses) was attained in the treatment naïve cohort (N = 26). Most treatment-related adverse events were grade 1-2 across the entire safety population treated at 400 mg QD (N = 354). AcceleRET Lung, an international, open-label, randomized, phase 3 study, will evaluate the efficacy and safety of pralsetinib versus standard of care (SOC) for first-line treatment of advanced/metastatic RET fusion+ NSCLC (NCT04222972). **Methods:** Approximately 250 pts with metastatic RET-fusion+ NSCLC will be randomized 1:1 to oral pralsetinib (400 mg QD) or SOC (non-squamous histology: platinum/pemetrexed ± pembrolizumab followed by maintenance pemetrexed ± pembrolizumab; squamous histology: platinum/gemcitabine). Stratification factors include intended use of pembrolizumab, history of brain metastases, and ECOG PS. Key eligibility criteria include no prior systemic treatment for metastatic disease; RET-fusion+ tumor by local or central assessment; no additional actionable oncogenic drivers; no prior selective RET inhibitor; measurable disease per RECIST v1.1. Pts randomized to SOC will be permitted to cross-over to receive pralsetinib upon disease progression. The primary endpoint is progression-free survival (blinded independent central review; RECIST v1.1). Secondary endpoints include ORR, overall survival, duration of response, disease control rate, clinical benefit rate, time to intracranial progression, intracranial ORR, safety/tolerability and quality of life evaluations. Recruitment has begun with sites (active or planned) in North America, Europe and Asia. Clinical trial information: NCT04222972. Research Sponsor: Blueprint Medicines.

TPS9635 Poster Session (Board #401), Fri, 8:00 AM-11:00 AM

Phase III trial of sitravatinib plus nivolumab vs. docetaxel for treatment of NSCLC after platinum-based chemotherapy and immunotherapy (SAPPHIRE). *First Author: Ivor John Percent, Florida Cancer Specialists South/Sarah Cannon Research Institute, Port Charlotte, FL*

Background: Sitravatinib is an oral spectrum-selective tyrosine kinase inhibitor that targets the TAM (TYRO3/AXL/MERTK) and split (VEGFR2/KIT) family receptor tyrosine kinases (RTKs), as well as MET. Inhibition of TAM RTKs may promote the depletion of myeloid-derived suppressor cells (MDSCs) in the tumor microenvironment (TME) and repolarize tumor associated macrophages towards the pro-inflammatory M1 phenotype. Inhibition of the split RTKs may reduce immunosuppressive regulatory T cells in addition to MDSCs within the TME. Given these pleiotropic immune-stimulating effects, sitravatinib may reverse resistance to checkpoint inhibitor therapy (CIT) and augment the antitumor immune response of nivolumab in patients (pts) with non-small cell lung cancer (NSCLC). An ongoing Phase 2 study (MRTX-500) demonstrates clinical activity of this combination in pts with metastatic non-squamous NSCLC after progression on or after CIT. **Methods:** Global, randomized, open-label, Phase 3 study of sitravatinib in combination with nivolumab vs docetaxel in pts with advanced non-squamous NSCLC who have progressed on or after CIT. Pts must have also received platinum-based chemotherapy either in combination with CIT or prior to CIT. Pts are randomized (1:1) to receive oral sitravatinib 120 mg once daily in continuous 28-day cycles combined with nivolumab IV 240 mg every 2 weeks or 480 mg every 4 weeks vs treatment with docetaxel 75 mg/m^2 IV every 3 weeks. Patients are stratified based on number of prior treatment regimens in the advanced setting, ECOG performance status, and presence of brain metastases. Key eligibility criteria include duration of treatment of CIT of at least 4 months, discontinuation of prior treatment with CIT $<$ 90 days prior to the date of randomization, and absence of symptomatic or uncontrolled brain metastases. The primary endpoint is overall survival (OS). Key secondary endpoints include safety and tolerability, ORR, PFS, PROs, and PK. OS will be analyzed using Kaplan-Meier methods and the stratified log-rank test to estimate and compare the median OS between the two treatment arms with 95% CI. An IDMC will review safety at regular intervals and efficacy at a planned interim analysis based on OS. Enrollment is ongoing. Clinical trial information: NCT03906071. Research Sponsor: Mirati Therapeutics, Inc.

TPS9636 Poster Session (Board #402), Fri, 8:00 AM-11:00 AM

A phase III, open-label, randomized study of atezolizumab in combination with carboplatin + paclitaxel + bevacizumab compared with pemetrexed + cisplatin or carboplatin with stage IV non-squamous non-small cell lung cancer (NSCLC) with activating EGFR mutation or ALK translocation (ATLAS Trial). *First Author: Sehhoon Park, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: In patients with activating EGFR mutations and ALK fusion, target specific tyrosine kinase inhibitor (TKI) showed significant survival improvement compared to the cytotoxic chemotherapy. However, the questions remain which combination strategy will be the best option for the patients who have failed from TKI. Especially, the role of an immune checkpoint inhibitor (ICI) in this population is still unclear. This study is designed and conducted based on the recent subgroup analyses from the IMpower 150 study which showed the positive clinical outcomes of atezolizumab combined with VEGF inhibitor and conventional cytotoxic chemotherapy in EGFR mutation and ALK translocation. **Methods:** This study is the phase III, open-label, multicenter study of atezolizumab in combination with bevacizumab + carboplatin + paclitaxel (ABCP, Arm A) compared with pemetrexed + cisplatin or carboplatin (Arm B). The study population will be randomized to either Arm A (n = 152) or Arm B (n = 72) based on two stratification factors, EGFR vs. ALK and presence of brain metastases. In Arm A, patients will be treated with 4 or 6 cycles of ABCP followed by maintenance atezolizumab and bevacizumab every three weeks. In Arm B, pemetrexed maintenance therapy will be applied every three weeks after 4 or 6 cycles of pemetrexed + cisplatin or carboplatin. As key inclusion criteria, the patients must be diagnosed with stage IV non-squamous non-small cell lung cancer with either activating EGFR mutation or ALK translocation. All the patients need to be cytotoxic chemotherapy naïve and must have experienced disease progression to treatment with at least one EGFR or ALK TKI. If the patients have T790M mutation after 1st or 2nd generation EGFR TKI, second line 3rd generation EGFR TKI treatment is mandatory. The number of T790M positive patients is restricted to under 30% of the entire study population. The primary endpoint is progression-free survival and the major secondary endpoints are overall survival, objective response rate and duration of response. A total of 228 subjects will be enrolled to detect a hazard ratio of 0.67. The first subject received treatment in Aug. 2019 and 19 patients receive the treatment. This study is opened in 3 sites and expected to be opened at 18 sites in South Korea. The time point for the primary analyses is Q3. 2022. Clinical trial information: NCT03991403. Research Sponsor: Roche/Genentech.

TPS9637 Poster Session (Board #403), Fri, 8:00 AM-11:00 AM

TRIDENT-1: A global, multicenter, open-label Phase II study investigating the activity of repotrectinib in advanced solid tumors harboring *ROS1* or *NTRK1-3* rearrangements. *First Author: Robert Charles Doebele, University of Colorado, Aurora, CO*

Background: Repotrectinib is a next-generation ROS1/TRK inhibitor with $>$ 90-fold greater potency than crizotinib against ROS1 and $>$ 100-fold greater potency than larotrectinib against TRK. Preclinical studies demonstrated inhibitory activity of repotrectinib against ROS1 resistance mutations, including the solvent-front mutation (SFM) G2032R. In the phase 1 portion of the study, repotrectinib was found to be well tolerated with encouraging antitumor activity including a 91% confirmed overall response (cORR) in TKI-naïve *ROS1+* NSCLC pts. In *ROS1+* NSCLC pts who received 1 prior chemo and 1 prior TKI, the cORR was 57% at the clinical dose of 160 mg QD or above. Intra-cranial (IC) activity was observed in *ROS1+* NSCLC pts with measurable CNS disease (100% IC-ORR in TKI-naïve and 75% IC-ORR in patients with 1 prior TKI). Encouraging antitumor activity was observed in pts with NTRK+ solid tumors. **Methods:** A global phase 2 study was initiated and is actively enrolling. The primary endpoint for the Phase 2 study is cORR assessed by BICR (Blinded Independent Central Review) using RECIST v1.1, in each expansion cohort in pts with advanced solid tumors that harbor a ROS1 or NTRK1/2/3 gene fusion. Secondary endpoints include duration of response (DOR), progression-free survival (PFS), overall survival (OS), IC-ORR, IC-PFS, and quality of life assessments. All pts need to have RECIST 1.1 measurable disease confirmed by BICR and ECOG performance score $\leq$1. Repotrectinib is administered at 160 mg QD for 14 days and, if tolerated, the dose can be increased to 160 mg BID. Approximately 320 pts ($\geq$12 years old) will be enrolled into 6 defined expansion cohorts, depending on the status of previous treatment with TKIs and cancer types (see table below). Clinical trial information: NCT03093116. Research Sponsor: Turning Point Therapeutics Inc.

Cohort #	Tumor Type	Prior Treatment	Sample Size (pts)
1	*ROS1*+NSCLC	*ROS1* TKI-naive	55
2		1 Prior *ROS1* TKI AND 1 Platinum-based Chemo	100
3		2 Prior *ROS1* TKIs AND 1 Platinum-based Chemo	40
4		1 Prior *ROS1* TKI and NO Prior Chemo OR Immunotherapy	Up to 30
5	*NTRK*+solid tumors	*TRK* TKI-naïve	55
6		*TRK* TKI-pretreated (up to 2 prior TKIs)	40

TPS9638 Poster Session (Board #404), Fri, 8:00 AM-11:00 AM

A phase II study of atezolizumab and cobimetinib in PD-1/PD-L1 inhibitor resistant or refractory non-small cell lung cancer: ETCTN #10166. *First Author: Stephen V. Liu, Georgetown University, Washington, DC*

Background: Use of checkpoint inhibitors, alone or with chemotherapy, has emerged as the preferred standard treatment for patients with advanced, driver-negative non-small cell lung cancer (NSCLC). While outcomes are superior to chemotherapy alone, only a subset of patients achieve durable response and long term survival. One potential mechanism of primary resistance to checkpoint inhibitors is the lack of tumor-infiltrating lymphocytes. Inhibition of mitogen-activated protein kinase (MAPK) kinase (MEK) increases the number of CD8+ T-cell within a tumor and has shown synergy with anti-programmed death-ligand 1 (PD-L1) antibodies. The combination of the MEK inhibitor cobimetinib and the PD-L1 antibody atezolizumab has led to limited responses in colorectal cancer, a tumor typically non-responsive to checkpoint inhibition. This phase II trial explores the combination of cobimetinib and atezolizumab in patients with PD(L)1-refractory NSCLC. **Methods:** This phase II study is being conducted through the Experimental Therapeutics Clinical Trials Network (ETCTN #10166). Eligible patients have advanced NSCLC with primary resistance to anti-PD(L)1 therapy (defined as progression noted within 6 months of initiating therapy) and tumor amenable to serial core biopsy. Patients will receive atezolizumab 840mg intravenously every 2 weeks and cobimetinib 60mg orally for 21 days in 28-day cycles. Two cohorts will enroll in parallel, defined by presence or absence of a KRAS mutation. Each cohort will employ a Simon two-stage design to test a null rate of 5% vs. 25% (power = 0.90, □ = 0.10). If > 1 of 9 patients in stage 1 achieve a partial response, an additional 15 patients are enrolled and if > 3 patients achieve a durable response, the combination will be worthy of further investigation. The primary endpoint is durable (> 6 months) response rate. Secondary endpoints are overall response rate, progression free survival, overall survival, duration of response and adverse events. Biopsies performed at baseline and after 3 weeks of therapy will assess the change in the density of tumoral CD8+ T-cells. Whole exome sequencing and immune cell profiling will also be performed on serial samples. Enrollment was initially limited to KRAS-mutant NSCLC. Prespecified activity goal for the first stage of accrual has been met; second stage accrual began in September 2019. Enrollment to the KRAS wild-type cohort will commence. Clinical trial information: NCT03600701. Research Sponsor: U.S. National Institutes of Health.

10000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Pembrolizumab versus placebo after complete resection of high-risk stage III melanoma: New recurrence-free survival results from the EORTC 1325-MG/Keynote 054 double-blinded phase III trial at three-year median follow-up. *First Author: Alexander M. Eggermont, Princess Máxima Center, Utrecht, Netherlands*

Background: We conducted the phase 3 double-blind EORTC 1325/KEYNOTE-054 trial to evaluate pembrolizumab vs placebo in patients (pts) with resected high-risk stage III melanoma. Based on 351 recurrence-free survival (RFS) events and at a median follow-up of 1.25 years (yrs), pembrolizumab improved RFS (hazard ratio (HR) 0.57, P<0.0001) as compared to placebo (Eggermont, NEJM 2018). This led to the approval of pembrolizumab adjuvant treatment by EMA and FDA. **Methods:** Eligible pts included those ≥18 yrs of age with complete resection of cutaneous melanoma metastatic to lymph node(s), classified as AJCC-7 stage IIIA (at least one lymph node metastasis >1 mm), IIIB or IIIC (without in-transit metastasis). A total of 1019 pts were randomized (stratification by stage and region) to pembrolizumab at a flat dose of 200 mg (N=514) or placebo (N=505) every 3 weeks for a total of 18 doses (~1 year) or until disease recurrence or unacceptable toxicity. The 2 co-primary endpoints were RFS in the intention-to-treat overall population and in pts with PD-L1-positive tumors. Here, we report an updated RFS analysis based on a longer follow-up. **Results:** Overall, 15%/46%/39% of pts had stage IIIA/IIIB/IIIC. At 3.05-yr median follow-up, pembrolizumab (190 RFS events) compared with placebo (283 RFS events) prolonged RFS, in the overall population and in the PD-L1 positive tumor subgroup (see Table). RFS was consistently prolonged across subgroups, in particular according to AJCC-7 staging, BRAF-V600 E/K mutation status. **Conclusions:** Pembrolizumab, administered at 200 mg every 3 weeks for up to 1 year as adjuvant therapy, provided, at a 3-yr median follow-up, a sustained improvement in RFS, which was clinically meaningful, in resected high-risk stage III melanoma. This improvement was consistent across subgroups. In the overall population, the 3-yr cumulative incidence of distant metastasis being the first recurrence was 22.3% (pembrolizumab group) vs 37.3% (placebo group) (HR 0.55, 95% CI 0.44-0.69). Clinical trial information: NCT02362594. Research Sponsor: Merck.

		3-yr RFS rate		Stratified by stage at randomization	
	N pts	Pembrolizumab	Placebo	HR	CI (HR)*
Overall population	1019	64%	44%	0.56	0.47-0.68
PD-L1 positive	853	65%	46%	0.57	0.43-0.74
PD-L1 negative	116	57%	33%	0.45	0.23-0.90
Stage IIIA	152	81%	66%	0.50	0.22-1.16
Stage IIIB	472	66%	47%	0.56	0.39-0.81
Stage IIIC	395	54%	32%	0.57	0.40-0.81
BRAF-mutated	440	62%	37%	0.51	0.36-0.73
BRAF-WT	448	62%	47%	0.66	0.46-0.95

10001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Long-term benefit of adjuvant dabrafenib + trametinib (D+T) in patients (pts) with resected stage III *BRAF* V600–mutant melanoma: Five-year analysis of COMBI-AD. *First Author: Axel Hauschild, University Hospital Schleswig-Holstein, Kiel, Germany*

Background: Previous results of the COMBI-AD trial (NCT01682083) showed a significant relapse-free survival (RFS) benefit with 12 mo of adjuvant D+T vs placebo (PBO) in pts with high-risk resected stage III *BRAF* V600E/K–mutant melanoma. In the primary analysis, 3-year RFS rates with D+T vs PBO were 58% vs 39% (hazard ratio [HR], 0.47 [95% CI, 0.39-0.58]; $P < .001$). An interim analysis of overall survival (OS) yielded 3-year OS rates of 86% with D+T vs 77% with PBO (HR, 0.57 [95% CI, 0.42-0.79]). Here we report data from 5-year analyses including long-term RFS and an updated cure rate model. **Methods:** COMBI-AD is a randomized, Phase III trial evaluating 12 mo of adjuvant D 150 mg twice daily + T 2 mg once daily vs 2 matched PBOs in pts with resected stage III *BRAF* V600E/K–mutant melanoma. Pts were stratified by *BRAF* status and disease stage (per AJCC 7 criteria). The primary endpoint is RFS; secondary endpoints include OS and distant metastasis–free survival (DMFS). A Weibull mixture cure rate model was applied to estimate the fraction of pts who will remain relapse free in the long term. As all patients had completed treatment by the time of the primary analysis, updated safety analyses were not performed. **Results:** This analysis represents a median follow-up of 60 mo for the D+T arm and 59 mo for the PBO arm. As of the data cutoff (Nov 8, 2019), 190 of 438 pts in the D+T arm and 262 of 432 pts in the PBO arm had an RFS event. Median RFS was not reached (NR; 95% CI, 47.9 mo-NR) with D+T vs 16.6 mo (95% CI, 12.7-22.1 mo) with PBO (HR, 0.51 [95% CI, 0.42-0.61]). The 4- and 5-year RFS rates were 55% (95% CI, 50%-60%) and 52% (95% CI, 48%-58%) with D+T vs 38% (95% CI, 34%-43%) and 36% (95% CI, 32%-41%) with PBO. These findings match those estimated by the cure rate model. The RFS benefit with D+T was evident across all AJCC 7 substages (HR [95% CI]: IIIA, 0.61 [0.35-1.07]; IIIB, 0.50 [0.37-0.67]; IIIC, 0.48 [0.36-0.64]). Median DMFS was NR in either arm but favored D+T (HR, 0.55 [95% CI, 0.44-0.70]). OS was not updated at this data cutoff as the prespecified number of events for the final OS analysis had not yet occurred. **Conclusions:** This 5-year analysis confirms the long-term benefit of adjuvant D+T in pts with resected stage III *BRAF* V600E/K–mutant melanoma. Clinical trial information: NCT01682083. Research Sponsor: Novartis Pharmaceuticals Corporation.

10002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

First safety and efficacy results of PRADO: A phase II study of personalized response-driven surgery and adjuvant therapy after neoadjuvant ipilimumab (IPI) and nivolumab (NIVO) in resectable stage III melanoma. *First Author: Christian U. Blank, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: OpACIN-neo tested 3 dosing schemes of neoadjuvant (neoadj) IPI+NIVO and identified 2 cycles of IPI 1mg/kg + NIVO 3mg/kg (I1N3) as the most favorable with a pathologic (path) response rate (pRR) of 77% and 20% grade 3-4 irAEs. After 17.6 months median FU, 1/64 (2%) patients (pts) with path response vs 13/21 (62%) of the non-responders (> 50% viable tumor cells; pNR) had relapsed. We hypothesized that therapeutic lymph node dissection (TLND) could be omitted in pts achieving a complete or near-complete path response (≤10% viable tumor cells; major path response, MPR) in the index node (largest LN metastasis: ILN), whereas additional adjuvant (adj) therapy might improve the outcome of pNR pts. **Methods:** PRADO is an extension cohort of the multi-center phase 2 OpACIN-neo study that aims to confirm the pRR and safety of neoadj I1N3 and to test response-driven subsequent therapy. Pts with RECIST 1.1 measurable clinical stage III melanoma were included to receive 2 cycles of neoadj I1N3 after marker placement in the ILN. ILN resection was planned at wk 6. Pts that achieved MPR in the ILN did not undergo TLND; pts with pPR (> 10 – ≤50% viable tumor cells) underwent TLND; and pts with pNR underwent TLND and received adj NIVO or targeted therapy (TT) for 52 wks +/- radiotherapy (RT). Primary endpoints were pRR in the ILN and 24-month RFS. Estimated toxicity rates at wk 12 were calculated using a Kaplan Meier based method. **Results:** Between Nov 16, 2018 and Jan 3, 2020, 99 of 114 screened pts were eligible and enrolled. So far, 86 pts had ≥12 wks FU. 70/99 pts achieved a path response in the ILN (pRR 71%, 95% CI 61% - 79%); 60 (61%) had MPR. TLND was omitted in 58 (97%) of the MPR pts. There were 28 non-responders; 7 developed distant metastasis before ILN resection. To date, 8 of the 21 pNR pts had adj NIVO, 7 had adj TT and 7 had adj RT. The estimated grade 3-4 irAE rate at wk 12 was 24%. Due to toxicity, 10 pts (10%) received only 1 cycle I1N3 and in 3 pts ILN resection was not performed: 2 of these pts underwent TLND at wk 9 and one pt was not evaluated for path response. At data cutoff, the surgery-related grade 1,2 and 3 AE rates were 29%, 10% and 0% in pts who underwent ILN resection only vs 21%, 30% and 9% in pts who underwent subsequent TLND (p = 0.004). At ASCO 2020 all pts will have reached ≥12 wks FU. **Conclusions:** Neoadj I1N3 treatment induced a high pRR with tolerable toxicity. TLND was omitted in a major subset of pts, reducing surgical morbidity. Longer FU is needed to report safety and RFS when TLND is omitted in MPR pts. Clinical trial information: NCT02977052. Research Sponsor: BMS.

10003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase II study to evaluate the need for > two doses of nivolumab + ipilimumab combination (combo) immunotherapy. *First Author: Michael A. Postow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Standard of care nivolumab (nivo) + ipilimumab (ipi) combo immunotherapy is given for 4 doses in patients (pts) with unresectable stage III/IV melanoma. Whether 4 doses are needed is questionable as retrospective data suggest pts treated with <4 doses of combo due to toxicity can have durable benefit. No prospective trials have evaluated the efficacy of intentionally giving <4 doses of combo in unresectable stage III/IV melanoma. **Methods:** In this phase 2, multicenter clinical trial (n=60), pts with unresectable stage III/IV melanoma received 2 doses of nivo (1mg/kg) + ipi (3mg/kg) followed by a CT scan at week 6. Pts with complete (CR) or partial responses (PR) by RECIST 1.1 or stable disease without an increase in total measurable tumor burden had protocol defined early favorable anti-tumor effect (FATE) and ceased combo, transitioning to maintenance nivo. Pts without FATE at week 6 received the standard third and fourth doses of combo followed by maintenance nivo. The primary endpoint was response rate by RECIST 1.1 at week 12. Secondary endpoints included additional efficacy assessments and safety. **Results:** 41 pts (68%) had FATE at week 6. The best overall response rates (CR + PR) by RECIST at week 12 or any time afterwards were 48% (95% CI: 35.2-61.6%) and 53% (95% CI: 40.0-66.3%), respectively. 18%, 58%, 12%, 10% had 1, 2, 3, 4 doses of combo, respectively. With a median follow-up of 11 months, any grade treatment-related toxicity occurred in 100% (57% grade 3-4) of pts. Three pts died due to treatment-related toxicity (2 myocarditis, 1 possible adrenal insufficiency). Among the 19 pts without FATE at week 6 and not selected to de-escalate combo after dose 2, no pts ultimately responded with ongoing combo dosing. **Conclusions:** The first 2 doses of nivo + ipi appear to drive combo's response efficacy and toxicity. Early radiographic imaging at week 6 may be able to identify pts who do not respond to combo dosing beyond dose 2. Randomized studies are planned to evaluate 1 dose of combo to see if efficacy is maintained with reduced toxicity. Clinical trial information: NCT03122522. Research Sponsor: Bristol Myers-Squibb.

10004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Significant antitumor activity for low-dose ipilimumab (IPI) with pembrolizumab (PEMBRO) immediately following progression on PD1 Ab in melanoma (MEL) in a phase II trial. *First Author: Daniel Olson, University of Chicago Comprehensive Cancer Center, Chicago, IL*

Background: Combination PD1 + CTLA4 antibodies (Abs) shows greater response rate (RR) versus PD1 Ab alone in MEL, but RR after initial PD1 Ab progression awaits robust investigation. CTLA4 Ab alone after PD1 Ab progression has a historical RR of 13%. We report final results of the first prospective clinical trial evaluating IPI 1mg/kg + PEMBRO immediately following progression on PD1 Ab (NCT02743819). **Methods:** Patients (pts) with advanced MEL, no prior CTLA4 Ab for metastatic disease, and who had progressed on PD1 Ab as immediately prior therapy (or non-CTLA4 Ab combination) were eligible. Pts received PEMBRO 200 mg + IPI 1 mg/kg Q3W for 4 doses, then PEMBRO alone for up to two years. The primary endpoint was RR by irRECIST. After 35 pts, the study met its primary endpoint with 10/22 evaluable pts achieving a response. The trial was expanded to enroll a total of 70 pts in open-label accrual to further describe the RR for this regimen in an exploratory fashion. The data analysis cutoff was January 30, 2020. **Results:** 67/70 accrued patients were evaluable for treatment response. Prior treatments included 60 on PD1 Ab alone and 10 on PD1 Ab-based combinations. Of these, 10 pts had progressed in the adjuvant setting. Median length of treatment on prior PD1 Ab was 4.8 months. Response assessments included 4 CR, 17 PR and 16 SD for a RR of 31% (21/67) in evaluable pts, and 30% (21/70) in all enrolled pts. 4 pts with a PR and 6 with SD had unconfirmed responses making the irRECIST response rate 25% (17/67) and 24% (17/70) among evaluable and enrolled pts, respectively. Median progression free survival (PFS) was 4.7 mo (95% CI: 2.8-8.3) and PFS at six months was 45% (95% CI: 33%-57%). 15/70 (21%) pts experienced ≥ grade 3-4 drug-related AEs, the most common being diarrhea, rash and transaminase elevation. PD-L1 positive vs negative status from historical tumor specimens did not associate with RR. **Conclusions:** This is the largest prospective study of IPI 1mg/kg + PEMBRO, demonstrating significant antitumor activity and tolerability in MEL post-PD1 Ab. Clinical trial information: NCT02743819. Research Sponsor: Merck via Investigator Sponsored Trial.

10005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Ipilimumab (IPI) alone or in combination with anti-PD-1 (IPI+PD1) in patients (pts) with metastatic melanoma (MM) resistant to PD1 monotherapy. *First Author: Ines Pires Da Silva, Melanoma Institute Australia, Sydney, Australia*

Background: PD1 induces long-term responses in approximately 30% of MM pts, however 2/3 are resistant (innate or acquired) and will require further treatment. A subset of these pts will benefit from IPI or IPI+PD1, but these pts are yet to be identified. We sought to determine; i) response rate (RR) and survival to IPI+/-PD1 after PD1 progression, and ii) clinical predictors of response and survival to IPI+/-PD1. **Methods:** MM pts resistant to PD1 and then treated with IPI+/-PD1 were studied. Demographics, disease characteristics and baseline blood parameters were examined. Univariate, multivariate and backward elimination technique analyses were performed to create predictive models of response and overall survival (OS). **Results:** Of 330 MM pts resistant to PD1 (median time to prog 2.9 months [0.5 – 42.3], 12% adjuvant, 88% metastatic; 70% innate, 30% acquired), 161 (49%) had subsequent IPI and 169 (51%) had IPI+PD1. Characteristics at start of IPI+/-PD1 were similar in IPI vs IPI+PD1 groups (stage M1D 27% vs 34%; elevated LDH 38% vs 40%), except IPI group had more ECOG ≥1 (60% vs 34%) and less BRAF mutation (mut) (21% vs 37%). Median follow-up from start of IPI+/-PD1 was 22.3 months (19.8 - 25.8); RR was 22%, higher in IPI+PD1 (31%) vs IPI (12%) ($p < 0.01$). PFS and OS at 1 year were 20% and 48%, respectively; better with IPI+PD1 (27%/57%) vs IPI (13%/38%) ($p < 0.01$). PD1 setting (adjuvant/metastatic) and response did not impact response to IPI+/-PD1. Most pts progressing on adjuvant PD1 had IPI+PD1 (88%) and RR was 33%. Neither the interval between PD1 and IPI+/-PD1 nor use of other drugs affected response to IPI+/-PD1. RR was similar in BRAF WT (23%) vs BRAF mut (RR 21%) pts. In BRAF WT pts, RR was higher with IPI+PD1 vs IPI (38% vs 9%, $p < 0.01$), while RR was similar with IPI (24%) or IPI+PD1 (19%) in BRAF mut pts. One third of BRAF mut pts had BRAF inhibitors (BRAFi) prior to IPI+/-PD1 and lower RR (13%) vs those without BRAFi (RR = 25%, $p > 0.05$). High grade (≥G3) toxicity (tox) was similar with IPI+PD1 (30%) or IPI (34%, $p = 0.48$), and was not associated with response. Stage III/M1A/M1B, normal LDH and treatment with IPI+PD1 were the best predictors of response (AUC = 0.69). These factors, in addition to sex (male), ECOG PS = 0, BRAF mut, progressed/recurred > 3 months on PD1, and absence of bone mets were the best predictors of longer OS (AUC = 0.74). **Conclusions:** In pts resistant to PD1, IPI+PD1 has higher RR, longer survival, yet similar high grade tox than IPI alone. Predictive models of response & survival will help select pts for IPI+/-PD1 after progressing on PD1. Research Sponsor: None.

10006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Long-term follow up of lifileucel (LN-144) cryopreserved autologous tumor infiltrating lymphocyte therapy in patients with advanced melanoma progressed on multiple prior therapies. *First Author: Amod Sarnaik, Moffitt Cancer Center, Tampa, FL*

Background: Treatment options are limited for patients with advanced melanoma who have progressed on checkpoint inhibitors and targeted therapies. Adoptive cell therapy using tumor-infiltrating lymphocytes (TIL) leverages and enhances the body's natural defense against cancer and has shown durable responses in heavily pretreated melanoma patients. **Methods:** C-144-01 is a global Phase 2 open-label, multicenter study of efficacy & safety of lifileucel in patients with unresectable metastatic melanoma who have progressed on checkpoint inhibitors and BRAF/MEK inhibitors, if $BRAF^{V600}$ mutant. We report on Cohort 2 (N = 66) patients who have received TIL. Tumors were resected at local institutions, processed in central GMP facilities for TIL production, manufactured, cryopreserved & shipped back to sites in a 22-day process. Therapy consisted of one week of lymphodepletion, a single lifileucel infusion, and up to 6 IL-2 doses. ORR was based on RECIST v1.1 by investigator assessment. Data cutoff was Feb 2, 2020. **Results:** Baseline characteristics: 3.3 mean prior therapies (anti-PD1 100%; anti-CTLA-4 80%; BRAF/MEK inhibitor 23%), high baseline tumor burden (106 mm mean target lesion sum of diameters), 44% liver/brain lesions, 40.9% LDH > ULN. ORR by investigator was 36.4% (2 CR, 22 PR) and DCR was 80.3%. Mean time to response was 1.9 months (range: 1.3-5.6). After a median study follow-up of 17.0 months, median DOR (mDOR) was still not reached. Six responders have progressed, 2 have died and 2 started other anti-cancer therapy without progression. The adverse event profile was consistent with the underlying advanced disease and the lymphodepletion and IL-2 regimens. Additional follow-up data will be available for presentation. **Conclusions:** Lifileucel treatment results in a 36.4% ORR and mDOR was not reached at 17.0 months of median study follow up in a heavily pretreated metastatic melanoma patients with high baseline disease burden who progressed on multiple prior therapies, including anti-PD1 and BRAF/MEK inhibitors, if $BRAF^{V600}$ mutant. Clinical trial information: NCT02360579. Research Sponsor: Iovance Biotherapeutics, Inc.

10007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Overall survival and biomarker analysis of a phase Ib combination study of toripalimab, a humanized IgG4 mAb against programmed death-1 (PD-1) with axitinib in patients with metastatic mucosal melanoma. *First Author: Xinan Sheng, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Metastatic mucosal melanoma responds poorly to PD-1 blockade therapy in comparison with cutaneous melanoma. Vascular endothelial growth factor (VEGF) is indicated to play an important immunosuppressive role in mucosal melanoma. Combination of VEGF inhibition with PD-1 blockade might provide therapeutic opportunities. Toripalimab was approved as a second-line treatment for metastasis melanoma in Dec 2018. This study is to evaluate the safety and clinical efficacy of toripalimab combined with axitinib for the treatment of metastatic mucosal melanoma. (Clinical trial ID: NCT03086174). **Methods:** Patients with metastatic melanoma receive 1 or 3 mg/kg toripalimab Q2W in combination with 5 mg axitinib BID until disease progression, unacceptable toxicity, or voluntary withdrawal. Clinical response is assessed every 8 weeks according to RECISTv1.1. Tumor PD-L1 expression, tumor mutational burden (TMB), and gene expression profile (GEP) will be evaluated for correlation with clinical response. **Results:** From April 2017 to April 2018, 33 patients were enrolled in the study. No DLT or treatment related death was observed. 97% patients experienced treatment related AE (TRAE) and 39.4% patients experienced Grade 3-4 TRAEs. Most common TRAEs include diarrhea, proteinuria, hand and foot syndrome and hypothyroidism. Only one patient discontinued treatment due to TRAE. Among 29 treatment naïve mucosal melanoma patients, 14 PR and 11 SD were observed for an ORR of 48.3% and a DCR of 86.2%. The median DOR was 13.7 months. The median PFS was 7.5 months and the median OS was 20.7 months. PD-L1 expression or TMB had no significant differences in responders versus non-responders. In contrast, GEP scores of eight selected immune-related and four angiogenesis-related genes showed strong correlation with clinical response, whereas previous published immune related signature or angiogenesis signature alone had no correlation. **Conclusions:** Toripalimab combined with axitinib is a promising treatment option for metastatic mucosal melanoma. GEP scores of selected immune-related and angiogenesis-related genes might predict the response to the combination. A randomized 3-arm Phase 2 trial has been initiated to compare toripalimab plus axitinib with toripalimab or axitinib alone. Clinical trial information: NCT03086174. Research Sponsor: Shanghai Junshi Bioscience Co., LTD.

10008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Single-center phase I/Ib study of concurrent intrathecal (IT) and intravenous (IV) nivolumab (N) for metastatic melanoma (MM) patients (pts) with leptomeningeal disease (LMD). *First Author: Isabella Claudia Glitza, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MM pts with LMD have a dismal prognosis, with a median overall survival (OS) < 3 months and no approved therapies. IT administration of interleukin-2 (IL2) achieves survival in ~15% of MM LMD pts, but at cost of severe toxicities. Given the favorable clinical activity and safety of systemic anti-PD1, we hypothesized that IT N administration is safe and can achieve clinical benefit in pts with LMD. **Methods:** The primary objectives of this first-in-human study (NCT03025256) were to determine the safety and the maximum tolerated dose (MTD) of IT N given with IV N in MM pts with LMD. Eligible pts had MM, ECOG PS < / = 2, and evidence of LMD by MRI and/or CSF cytology. Dexamethasone < / = 4mg/daily was allowed. For cycle 1, IT N is administered via intraventricular reservoir on day (D) 1; Blood and CSF is collected at multiple time points for translational research. For subsequent cycles (every 14 days), pts receive IT N on D1, followed by IV N 240 mg on D2. IT N doses evaluated were 5, 10, and 20 mg. Bayesian mTPI methodology was used to define the MTD. The study was recently amended to allow for concurrent BRAF/MEK inhibitor(i) treatment. **Results:** To date, 15 pts have been treated: two at 5, three at 10, and 10 at 20 mg IT N. Median age at LMD diagnosis was 41.8 (30.9-73.2) years; 6 pts are male. All pts had radiographic evidence of LMD and neurological symptoms; 8 pts had positive CSF cytology. 12 pts received prior therapies for their MM: anti-PD1 (n = 11), BRAFi/MEKi (n = 9), chemo (n = 2), IT IL2 (n = 4) other (n = 2). 11 pts had prior XRT, including whole brain RT (n = 7). 1 pt was treatment-naïve. The median numbers of IT N doses was 4 (1-42). No grade (Gr) 4-5 AEs were attributed to IT N or IV N; only 4 events (Gr 1, n = 2; Gr2, n = 2) were possibly related to the IT N. With a median follow-up of 18.7 weeks (1-83.3 wks), the median OS is 46.1 weeks (0.1-83.3). Clinical response data, translational research endpoints, including changes in CSF cytokines and cfDNA, will be reported. **Conclusions:** The trial demonstrates the feasibility of prospective clinical trials in MM patients with LMD. The combination of IT/ IV N was safe and well-tolerated, with no unexpected systemic or neurological toxicity. Final presentation will include results of LMD composite response assessment, comparative analysis of longitudinal CSF/blood samples to assess immunologic effects. Finally, the interim OS of the patients is encouraging, and supports further evaluation of IT administration of immunotherapy agents for pts with MM and LMD. Clinical trial information: NCT03025256. Research Sponsor: Bristol- Myers Squibb.

10009 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Integrative tumor and immune cell multi-omic analyses to predict melanoma response to immune checkpoint blockade. *First Author: Valsamo Anagnostou, Bloomberg~Kimmel Institute for Cancer Immunotherapy, Baltimore, MD*

Background: The complex crosstalk between tumor and immune cells during immune checkpoint blockade mandates the development of integrated models to interpret the antitumor immune response and predict clinical outcome. **Methods:** We performed comprehensive genomic, transcriptomic and T cell repertoire analyses on tumor biopsies from 64 patients with advanced melanoma receiving nivolumab +/- ipilimumab on CheckMate-038 (NCT01621490). Tumor biopsies were obtained at baseline and 2-4 weeks on therapy. Machine learning and Cox proportional hazards regression analyses were employed to integrate multi-omics features in predictive models of response, defined by RECISTv1.1 as complete and partial response, and survival (PFS and OS). **Results:** Responding patients had a higher tumor mutation burden (TMB) than non-responders. Expressed TMB more accurately predicted overall survival than genomic TMB (log rank p = 0.028 vs 0.078). High tumor aneuploidy was associated with worse prognosis especially for the patients in the nivolumab + ipilimumab group (log rank p = 0.01). TCR sequencing of paired tumors before and on-treatment revealed that responders had a significantly higher number of unique TCR clones at baseline and more clonotypic shifts on-treatment (p = 0.0018). Gene rearrangement analyses using transcriptome data identified a higher number of rearrangements involving immunoglobulin (Ig) genes in baseline tumors from responders. Deconvolution of transcriptomic data confirmed an enrichment in tumor associated B cells in baseline tumors of responders, suggesting that pre-existing B cell infiltration is a predictor of clinical outcome. Random forests were utilized to integrate Ig rearrangements, expressed TMB and tumor aneuploidy, into a predictive model of response that was superior to TMB (AUC = 0.89 and 0.65 respectively). Multivariate Cox proportional hazards analysis incorporating the same features was utilized to generate a risk score for each patient; those with high risk scores had a significantly shorter PFS compared to low risk patients (median PFS 1.45 months vs 29.01 months, log rank p = 3.4e-06, HR = 9.18, 95% CI: 3.14-26.85). **Conclusions:** Our findings highlight the multi-faceted interactions between the tumor and the immune system and the importance of pre-existing T and B cell immunity in driving clinical response and PFS after immune checkpoint blockade, laying the groundwork for integration of genomic and immune features into predictive models that may ultimately optimize therapeutic decisions. Research Sponsor: Bristol Myers Squibb.

Using machine learning to predict immunotherapy response in advanced melanoma. *First Author: Paul Johannet, NYU School of Medicine, New York, NY*

Background: Several predictors of response to checkpoint inhibitors show potential, but use pathological assays and/or molecular characterization, which limits their clinical utility outside of the academic setting. We aimed to develop a streamlined approach by leveraging information immediately available through standard care. Here, we present a computational method that integrates deep learning on histology specimens with clinicodemographic variables to predict treatment outcomes in advanced melanoma. **Methods:** We used hematoxylin and eosin (H&E) sections from 72 patients (*n*= 153 slides) from New York University (NYU) to build a Segmentation Classifier that distinguishes tumor, lymphocyte, and connective tissue. Using pre-treatment H&E slides from 121 NYU patients (*n* =302 slides), we trained a Response Classifier to predict response by selectively analyzing tumor regions. We then developed a logistic regression classifier that combines neural network output with clinicodemographic variables. The classifiers were tested on an independent cohort of 32 patients from Vanderbilt University (*n* =42 slides). Area under the curve (AUC) was calculated as a measure of prediction accuracy. **Results:** The Segmentation Classifier distinguished tumor, lymphocyte, and connective tissue with AUCs 0.886-0.984. For the Response Classifier, optimal learning conditions were identified through training on NYU patients and testing on Vanderbilt patients (AUCs 0.685 and 0.728, respectively). The fully trained Response Classifier performed with AUC 0.711 on Vanderbilt patients. The logistic regression model performed with enhanced prediction accuracy with AUC 0.803 on NYU patients and AUC 0.793 on Vanderbilt patients. **Conclusions:** Histology slides and patients' clinicodemographic characteristics are readily available through routine standard of care and have the potential to predict immunotherapy response. Our approach is time-efficient, reproducible, and requires minimal resource allocation, thus overcoming multiple common barriers to generalizability for contemporary biomarkers. Autoantibodies as predictors for survival and immune-related adverse events in checkpoint inhibition therapy of metastasized melanoma. *First Author: Jessica Cecile Hassel, Department of Dermatology and National Center for Tumor Diseases (NCT), Heidelberg University Hospital, Heidelberg, Germany*

Background: Increasing evidence suggests that the B cell response in cancer patients is an important component of anti-tumour immunity. Autoantibodies targeting tumour and self-antigens may serve as biomarkers of anti-tumour and auto-immunity. As they can be measured in patient' sera, they have great potential as clinical routine biomarkers. The objective of this study was to explore if autoantibodies are associated with survival and immune related adverse events (irAE) in patients with metastatic melanoma under checkpoint inhitibor (CPI) therapy. **Methods:** Pre-treatment serum samples from 333 metastatic melanoma patients receiving CPI therapy at 5 European centers were retrospectively used to identify autoantibody signatures for survival and irAE. We designed a cancer immunotherapy antigen array comprising 832 autoimmune and tumour antigens as well as immune and cancer pathway proteins. Statistical tests were separately performed for patients treated with anti-CTLA4 (alone or in combination) and with anti-PD1 antibody monotherapy. Cox-regression analysis and univariate statistical tests were applied for biomarker discovery. Progression free and overall survival was measured from treatment initiation to tumor progression or death date. irAE were recorded including onset date and grade (CTC-AE). **Results:** For each therapy group we identified a set of autoantibody reactivities in untreated melanoma patients that were associated with the development of irAEs and/or survival. The identified autoantibodies target a diverse set of antigens comprising neoantigens (p53), cancer testis antigens (MAGEB4), paraneoplastic antigens (gephyrin), autoantigens (ribosomal proteins, Nor-90) and FGFR1. Autoantigens that correlated with irAE and survival were e.g. anti-MAGEB4 and anti-FGFR1. Elevated anti-MAGEB4 pre-treatment levels were associated with longer overall survival (p = 0.002, HR = 0.77) and the development of irAEs (p = 0.002, HR = 1.27) in ipilimumab +/- nivolumab treated patients. Higher pre-treatment anti-FGFR1 antibodies were associated with shorter survival (p = 0.008, HR = 1.27) and a lower a lower frequency of irAEs (p = 0.04, HR = 0.69) in these patients. **Conclusions:** We identified autoantibody targets suggesting a diverse B cell response to antigens expressed in tumours and those associated with autoimmunity. Depending on the specific antigen, the immune response towards those antigens may be associated with anti-tumour or pro-tumour responses. Research Sponsor: Oncimmune Germany GmbH.

Update on overall survival in COLUMBUS: A randomized phase III trial of encorafenib (ENCO) plus binimetinib (BINI) versus vemurafenib (VEM) or ENCO in patients with *BRAF* V600-mutant melanoma. *First Author: Helen Gogas, First Department of Medicine, National and Kapodistrian University of Athens School of Medicine, Athens, Greece*

Background: Treatment of patients with *BRAF* V600–mutant melanoma includes BRAF/MEK-inhibitor combinations based on demonstrated benefits on progression-free survival (PFS) and overall survival (OS). To better understand the proportion of patients who derive long-lived benefit and their characteristics, we performed an updated analysis of OS and other endpoints from the COLUMBUS trial. **Methods:** In Part 1 of COLUMBUS, 577 patients with advanced/metastatic *BRAF* V600–mutant melanoma, untreated or progressed after first-line immunotherapy, were randomized 1:1:1 to ENCO 450 mg QD + BINI 45 mg BID (COMBO450) vs VEM 960 mg BID (VEM) or ENCO 300 mg QD (ENCO300). An updated analysis including PFS, OS, objective response rate (ORR), and safety was conducted after an additional 24 months' follow-up from the initial analysis. The study is ongoing. **Results:** At data cutoff (November 2019, as-is data), events had occurred in 65%, 59%, and 75% of patients in the COMBO450, ENCO300, and VEM treatment arms, respectively. Across arms, median follow-up for OS was 60.6 months (mo), with median OS of 33.6 mo (95% CI, 24.4–39.2) for COMBO450, 23.5 mo (95% CI, 19.6–33.6) for ENCO300, and 16.9 mo (95% CI, 14.0–24.5) for VEM. Compared to VEM, COMBO450 decreased the risk of death by 38% (HR, 0.62 [95% CI, 0.49–0.79]). Updated median PFS was COMBO450, 14.9 mo (95% CI, 11.0–20.2), ENCO300, 9.6 mo (95% CI, 7.4–14.8), and VEM, 7.3 mo (95% CI, 5.6–7.9). PFS was longer for COMBO450 vs VEM (HR, 0.52 [95% CI, 0.40–0.67]). A landmark analysis showed a higher rate of OS for COMBO450 at each year analyzed, with OS rates at 4 years of 39%, 37%, and 26% COMBO450, ENCO300, and VEM, respectively. Updated safety analysis confirmed the beneficial long-term tolerability of COMBO450. **Conclusions:** In the COLUMBUS trial, results for updated PFS and OS with COMBO450 continue to demonstrate long-term benefits in patients with *BRAF* V600–mutated melanoma. Clinical trial information: NCT01909453. Research Sponsor: Pfizer Inc.

Long-term survival from pembrolizumab (pembro) completion and pembro retreatment: Phase III KEYNOTE-006 in advanced melanoma. *First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, Royal North Shore Hospital, Mater Hospital, Sydney, Australia*

Background: 5-year follow-up of the phase 3 KEYNOTE-006 study (NCT01866319) showed pembro improved OS vs ipilimumab (ipi) in patients (pts) with advanced melanoma. 3-y OS rate from pembro completion for pts who completed 2 y of pembro was 93.8%. Results with 8 mo of additional follow-up are presented to inform clinical care. **Methods:** Eligible pts with ipi-naive advanced melanoma, ≤1 prior therapy for *BRAF*-mutant disease, and ECOG PS 0 or 1 were randomized to pembro 10 mg/kg Q2W or Q3W for ≤2 y or ipi 3 mg/kg Q3W for 4 doses. Pts discontinuing pembro with CR, PR, or SD after ≥94 weeks were considered pts with 2-y pembro. Pts who stopped pembro with SD, PR or CR could receive ≤12 mo of additional pembro (2nd course) upon disease progression if still eligible. ORR was assessed per immune-related response criteria by investigator review. OS was estimated using the Kaplan-Meier method. Pembro arm data were pooled. Post hoc ITT efficacy analyses are shown. **Results:** Median follow-up from randomization to data cutoff (Jul 31, 2019) was 66.7 mo in the pembro and 66.9 mo in the ipi arms. OS outcomes are shown in Table. For the 103 pts with 2-y pembro (30 CR, 63 PR, 10 SD), median follow-up from completion was 42.9 mo (95% CI, 39.9-46.3).Median DOR was not reached. 36-mo OS from pembro completion was 100% (95% CI, 100.0-100.0) for pts with CR, 94.8% (95% CI, 84.7-98.3) for pts with PR, and 66.7% (95% CI, 28.2-87.8) for pts with SD. 15 pts received 2nd-course pembro; BOR in 1st course was 6 CR, 6 PR, and 3 SD. Median time from end of 1st course to start of 2nd course was 24.5 mo (range, 4.9-41.4). Median follow-up in pts who received 2nd-course pembro was 25.3 mo (range, 3.5-39.4). Median duration of 2nd-course pembro was 8.3 mo (range, 1.4-12.6). BOR on 2nd course was 3 CR, 5 PR (ongoing responses, 7 pts), 3 SD (ongoing, 2 pts), and 2 PD (1 death); 2 pts pending. **Conclusions:** Pembro improves the long-term survival vs ipi in pts with advanced melanoma, with all pts who completed therapy in CR still alive at 5 years. Retreatment with pembro at progression in pts who stopped at SD or better can provide additional clinical benefit in a majority of pts. Clinical trial information: NCT01866319. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

	Deaths (additional since last data cutoff Dec 3, 2019), n	Median OS (95% CI), mo	HR	5-Y OS rate (95% CI), %

The nature and management of acquired resistance to PD1-based therapy in melanoma. *First Author: Adriana Hepner, Melanoma Institute Australia, Sydney, Australia*

Background: Anti-PD1 therapy (PD1), either alone or in combination with anti-CTLA4, has high initial response rates, but 20% of patients (pts) with complete response (CR) and 60% with partial response (PR) experience disease progression by 5 years. The nature and best management of this acquired resistance (AR) remains unknown. **Methods:** Consecutive pts from 16 centers who achieved CR or PR to PD1-based therapy and who later progressed were examined. Demographics, disease characteristics, nature of progression and subsequent treatments were examined. **Results:** 300 pts were identified, median age was 64y, 133 (44%) BRAF mutant and 55 (18%) had target therapy (TT) prior to PD1-based therapy. 173 (58%) received PD1 alone, 114 (38%) PD1+CTLA4 and 13 (4%) PD1 + an investigational drug. 89 (30%) pts had CR, 210 (70%) pts had PR. Median time to AR was 12.6 mo (95% CI, 11.3, 14.2) and 142 (47%) progressed while still on drug. Most pts (N = 194, 65%) progressed in a single organ site, and in a solitary lesion (N = 154, 51%). 38 (25%) progressed in the brain only. AR was in new lesion in 136 (45%), existing lesions in 106 (35%), and both new and existing lesions in 58 (19%). For those with solitary lesion progression, 51 (33%) had local (L) treatment alone, 54 (35%) had local and systemic (L+ST), 46 (30%) had systemic therapy alone (ST) and 3 (2%) had no further treatment (BSC). If progression was non-solitary, 89 (61%) had ST, 33 (23%) L+ST, 17 (12%) L alone and 7 (5%) BSC. For those who received ST after AR, first ST (ST1) was PD1 alone in 130 (51%) [53, 41% continuation, 77, 59% reinduction], PD1+CTLA4 in 31 (12%), CTLA4 alone in 15 (6%), targeted therapy in 49 (19%) and investigational drugs in 29 (11%). Median follow-up from AR was 20 mo (95% CI 18-22). The ORR to ST1 was 46% for PD1 alone (56% continuation, 42% reinduction), 56% for PD1+ CTLA4, 0% for CTLA4 alone, 20% for investigational drugs and 67% for TT. Median OS from AR was 38 mo (95% CI, 34.6-NR). 2y-OS was 69% in those with solitary progression compared to 55% for the pts that had a non-solitary progression ($p < 0.001$). There was no difference in OS by ST1 class. Detailed analyses including nature and management of AR while on PD1 or after discontinuation will be presented, as will site-specific AR outcomes. **Conclusions:** Acquired resistance to PD1-based therapy in melanoma is usually oligometastatic, occurring approximately one year after PD1 start. Most pts with isolated progression have local therapy, and the most frequent subsequent systemic therapy is PD1-alone. Patients with AR can have meaningful survival, with median OS over 3 years from AR. Research Sponsor: None.

10015 Poster Discussion Session; Displayed in Poster Session (Board #364), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Twenty-four months RFS and updated toxicity data from OpACIN-neo: A study to identify the optimal dosing schedule of neoadjuvant ipilimumab (IPI) and nivolumab (NIVO) in stage III melanoma. *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Early results of the OpACIN-neo study testing 3 different dosing schedules of neoadjuvant IPI + NIVO demonstrated that 2 cycles IPI 1mg/kg + NIVO 3mg/kg (IPI1NIVO3, arm B) was the most favorable schedule with 20% grade 3-4 immunotherapy-related adverse events (irAEs) and a pathologic response rate (pRR) of 77%. After a median follow-up (FU) of 8.3 months, none of the 64 patients (pts) with a pathologic (path) response (< 50% viable tumor cells) versus 9/21 (43%) without a path response had relapsed. Here, we present the updated 2-year RFS, EFS and long-term toxicity data. **Methods:** In the phase 2 multi-center OpACIN-neo trial, 86 stage III melanoma pts with resectable and RECIST 1.1 measurable lymph node metastasis were randomized between 3 different dosing schedules of neoadjuvant IPI + NIVO: arm A: 2x IPI3+NIVO1 Q3W (n = 30), arm B: 2x IPI1+NIVO3 Q3W (n = 30), and arm C: 2x IPI3 Q3W followed by 2x NIVO3 Q2W (n = 26). Lymph node dissection was scheduled at week 6. Primary endpoints were toxicity, radiologic RR and pRR; RFS and EFS were secondary endpoints. **Results:** After a median FU of 24.6 months, the median RFS and EFS was not reached in any of the 3 arms. In total, 2 pts progressed before surgery, 12 pts relapsed (11 pts without path response and 1 pt with pCR) and 5 pts died (4 due to melanoma and one pt due to toxicity). Estimated 24-months RFS was 84% (95% CI 76-92%) for the total population, 97% (95% CI 93-100%) for pts with a path response and 36% (95% CI 17-74%) for pts without a path response. Estimated 24-months EFS for the total population was 82% (95% CI 74-91%). RFS and EFS did not differ between the arms. Of the 81 pts alive, 55 (68%) have ongoing irAEs; only 2 (3%) pts have ≥ grade 3 irAEs. Most frequent ongoing irAEs were vitiligo (35%), fatigue (14%), sicca syndrome (11%), rash (10%), arthralgia (7%) and endocrine toxicities (20%). 17 pts need hormone replacement therapy: 11 (14%) thyroid hormone and 7 (9%) hydrocortisone. No difference between treatment arms was observed. Ongoing surgery-related AEs were observed in 31 (38%) pts of which lymphedema was seen most frequently (17 pts; 21%). **Conclusions:** Extended follow-up data shows that 2 cycles of neoadjuvant IPI + NIVO without adjuvant therapy induces durable RFS. While almost no ongoing high-grade irAEs were observed, the majority of pts have low-grade ongoing toxicities. These outcomes strongly support the need to test 2 cycles of neoadjuvant IPI1+NIVO3 versus adjuvant anti-PD-1 in a randomized phase 3 trial. Clinical trial information: NCT02977052. Research Sponsor: BMS.

Melanoma recurrence after adjuvant targeted therapy: A multicenter analysis. *First Author: Prachi Bhave, Alfred Health, Melbourne, VIC, Australia*

Background: Adjuvant targeted therapy (TT) improves relapse free survival (RFS) in patients (pts) with BRAF mutant stage 3 melanoma. The outcomes and optimal management of pts who relapse after adjuvant TT is unknown. **Methods:** Pts from 21 centres with recurrent melanoma after adjuvant TT were included. Disease characteristics, adjuvant therapy, recurrence, treatment at relapse and outcomes were examined. **Results:** 87 pts developed recurrent melanoma; 21 (24%) during and 66 (76%) after cessation of adjuvant TT. Median time to 1st recurrence was 16.3 months with median follow up after 1st recurrence of 31 months. 30 (34%) pts recurred locoregionally, 51 (59%) pts developed distant recurrence and 6 (7%) pts had both. Of those who recurred locoregionally, 23/30 (77%) pts underwent surgery to no evidence of disease, only 3 (13%) of which received adjuvant anti-PD1 therapy, and 15/30 (50%) subsequently developed distant disease. 29 (33.3%) pts have died. 75 (86%) pts received systemic therapy at either 1st or subsequent recurrence. 40 (46%) pts received 1st line anti-PD1 based therapy (single agent anti-PD1, anti-PD1 with ipilimumab or anti-PD1 with investigational agent), 12 (14%) pts received ipilimumab monotherapy, 18 (21%) pts received retreatment with combination BRAF/MEK inhibitors and 5 (6%) pts received other agents (chemotherapy, TVEC). 57 (66%) pts had disease that was assessable for response rate (RR). RR after relapse was 69.7% (23/33) to 1st line anti-PD-1 based therapy, 46% (6/13) to TT and 9% (1/11) to ipilimumab monotherapy (Table). Median overall survival (OS) from date of 1st recurrence for all pts was not reached. OS varied by drug class received as 1st line systemic therapy after relapse. 3 year OS was 79% for anti-PD-1 based therapy, 55% for TT and 25% for ipilimumab. **Conclusions:** This study demonstrates that pts who relapse after adjuvant TT may respond to subsequent immunotherapy at similar rates to the treatment naïve setting. Research Sponsor: None.

Response rate to first-line systemic therapy after recurrence.

Final analysis of relapse-free survival in a multicenter, double-blind, placebo-controlled trial of seviprotimut-L polyvalent melanoma vaccine after resection of high-risk melanoma. *First Author: Craig L. Slingluff, University of Virginia School of Medicine, Charlottesville, VA*

Background: Seviprotimut-L is a vaccine prepared from antigens of 3 human melanoma cell lines, administered with alum. Prior formulations induced T cell and antibody responses and improved survival in a small phase II clinical trial. Part B1 of MAVIS (Melanoma Antigen Vaccine Immunotherapy Study, a three part, Phase III clinical program), was a multicenter, double-blind, placebo-controlled trial to assess efficacy of seviprotimut-L, with the primary endpoint of relapse-free survival (RFS). The goal of Part B1 was to guide design of the pivotal Part B2. **Methods:** Patients with AJCC v7 stage IIB-III cutaneous melanoma, after surgical resection, age 18-75, ECOG PS 0-1, were randomized 2:1 to seviprotimut-L 40 mcg or placebo, injected subcutaneously every 2 weeks x 5, then monthly x 4, then every 3 months x 9. Patients were stratified by stage (IIB/C, IIIA, IIIB/C). Target enrollment was 325. The study was powered for assessment of RFS, with target hazard ratio (HR) of 0.625, one-sided alpha of 0.10, and power 80%. Final data are presented. **Results:** 347 patients were randomized. Arms were well-balanced. Treatment-related adverse events (AEs) led to discontinuation in 0.4% and 0%, respectively, for vaccine and placebo arms. There were no treatment-related SAEs. By intent-to-treat (ITT) analysis, RFS was not significantly longer for seviprotimut-L in the full study population but trended toward benefit (HR 0.88). Subgroup analysis based on planned stratification revealed the hazard ratio (HR) for the Stage IIB/IIC subset (randomization stratum, n=111) to be 0.65 (95% CI [0.37, 1.17]), favoring seviprotimut-L. Age can decrease immune competence: RFS was longer with vaccine for patients age <60 overall (N = 191, HR = 0.64 [0.38, 1.08]) and among Stage IIB/C patients (N = 52, HR = 0.32 [0.12, 0.86]). The effect modification interaction p value for age for stage IIB/IIC patients was 0.056. In a multivariable RFS model, for IIB/IIC patients <60 with ulceration (n=38), HR = 0.209 [0.07,0.61]. For overall survival, for patients < 60, HR = 0.41 [0.33,1.14] (n=191, 19 deaths) and for those ≥60, HR = 0.92 [0.39,2.12] (n = 156, 24 deaths). **Conclusions:** Seviprotimut-L is very well-tolerated. Subgroup efficacy analyses identified populations who may benefit from Seviprotimut-L: those with Stage IIB/IIC melanoma and those under age 60. These data support design of the definitive part B2 of the MAVIS phase III trial to test seviprotimut-L for stage IIB/C patients, with stratification by age and ulceration. Clinical trial information: NCT01546571. Research Sponsor: Polynoma.

Phase II study of cemiplimab in patients (pts) with advanced cutaneous squamous cell carcinoma (CSCC): Longer follow-up. *First Author: Danny Rischin, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Cemiplimab monotherapy achieves clinically meaningful activity in pts with advanced CSCC (metastatic [mCSCC] or locally advanced [laCSCC] not amenable to curative surgery or curative radiation) and has a safety profile consistent with other anti–PD-1 agents. Based on initial data (median follow-up of 9.4 months in the pivotal study, NCT02760498), cemiplimab (cemiplimab-rwlc in the US) was approved for the treatment of pts with advanced CSCC. Historical data shows median overall survival (OS) of approximately 15 months with conventional chemotherapy or EGFR inhibitors (ASCO 2019, e21033). We present ~1-year additional follow-up from the largest prospective data set in advanced CSCC. **Methods:** Pts received cemiplimab 3 mg/kg Q2W (Group [Gp] 1; mCSCC; Gp 2, laCSCC) or cemiplimab 350 mg Q3W (Gp 3, mCSCC). The primary endpoint was objective response rate (ORR; complete response + partial response) per independent central review (ICR). Data presented here are per investigator review (INV); ICR data will be available at the meeting. **Results:** 193 pts were enrolled (Gp 1, n = 59; Gp 2, n = 78; Gp 3, n = 56). 128 pts had received no prior anti-cancer systemic therapy, 65 pts were previously treated. As of Oct 11, 2019 (data cut-off), median duration of follow-up was 15.7 months (range: 0.6–36.1) among all pts; 18.5 months (range: 1.1–36.1) for Gp 1, 15.5 months (range: 0.8–35.0) for Gp 2, and 17.3 months (range: 0.6–26.3) for Gp 3. ORR per INV was 54.4% (95% CI: 47.1–61.6) for all pts; 50.8% (95% CI: 37.5–64.1) for Gp 1, 56.4% (95% CI: 44.7–67.6) for Gp 2, and 55.4% (95% CI: 41.5–68.7) for Gp 3. ORR per INV was 57.8% (95% CI: 48.8–66.5) among treatment-naïve pts and 47.7% (95% CI: 35.1–60.5) among previously treated pts. Median duration of response (DOR) has not been reached (observed DOR range: 1.8–34.2 months). In responding pts, estimated proportion of pts with ongoing response at 24 months was 76.0% (95% CI: 64.1–84.4). Median OS has not been reached. Estimated OS at 24 months was 73.3% (95% CI: 66.1–79.2). The most common treatment-emergent adverse events (TEAEs) by any grade were fatigue (34.7%), diarrhea (27.5%), and nausea (23.8%). The most common grade ≥3 TEAEs were hypertension (4.7%) and anemia and cellulitis (each 4.1%). **Conclusions:** For pts with advanced CSCC, cemiplimab achieves ORRs, DOR and survival superior to what has been reported with other agents. Clinical trial information: NCT02760498. Research Sponsor: Regeneron Pharmaceuticals, Inc. and Sanofi.

CheckMate 067: Long-term outcomes in patients with mucosal melanoma. *First Author: Alexander Noor Shoushtari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Mucosal melanoma is a rare but aggressive malignancy with a poor prognosis. Here we report 5-y outcomes in a subgroup of patients with mucosal melanoma treated in CheckMate 067 with nivolumab plus ipilimumab (NIVO+IPI), NIVO alone, or IPI alone. **Methods:** Patients with previously untreated stage III or IV melanoma were randomized 1:1:1 to receive NIVO 1 mg/kg + IPI 3 mg/kg for 4 doses Q3W followed by NIVO 3 mg/kg Q2W, NIVO 3 mg/kg Q2W + placebo, or IPI 3 mg/kg Q3W for 4 doses + placebo until progression or unacceptable toxicity. Mucosal histology was not a stratification factor, and patients with mucosal melanoma were identified by local investigators in the study. Descriptive subgroup analyses were performed to evaluate efficacy (objective response rate [ORR], progression-free survival [PFS], overall survival [OS]), and safety. **Results:** A total of 79 patients with mucosal melanoma were treated. With a minimum follow-up of 60 mo, NIVO+IPI treatment was associated with the highest 5-y ORR (43% [vs 30% with NIVO and 7% with IPI]), PFS (29% [vs 14% and 0%, respectively]), and OS (36% [vs 17% and 7%, respectively]; Table), consistent with trends in the intent-to-treat (ITT) population; however, efficacy outcomes were generally less favorable overall relative to the ITT population. Complete response rates were higher with NIVO+IPI (14%) relative to monotherapy (NIVO, 4%; IPI, 0%) in patients with mucosal melanoma. Safety outcomes, including the grade 3/4 treatment-related adverse event rates of 54%, 26%, and 25%, respectively, were similar to the ITT population. **Conclusions:** This 5-y analysis showed that patients with mucosal melanoma in CheckMate 067 had similar safety outcomes but poorer long-term efficacy vs the ITT population. Patients with mucosal melanoma treated with NIVO+IPI appeared to have more favorable survival outcomes than those treated with NIVO or IPI alone. Novel therapies are needed to further improve long-term benefit in patients with mucosal melanoma. Clinical trial information: NCT01844505. Research Sponsor: Bristol-Myers Squibb, Grant (P30CA008748, to Dr. Wolchok) from the National Cancer Institute, and a grant (to Dr. Larkin) from the National Institute for Health Research Royal Marsden–Institute of Cancer Research Biomedical Research Centre.

Heterogeneous response and irAE patterns in advanced melanoma patients treated with anti-PD-1 monotherapy from different ethnic groups: Subtype distribution discrepancy and beyond. *First Author: Xue Bai, Department of Renal Cancer & Melanoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Programmed cell death receptor-1 (PD-1) monotherapy is the standard first line therapy for advanced cutaneous melanoma, with efficacy, toxicity, and their correlations well established. Yet these remain poorly characterized for non-Caucasians and for certain rarer melanoma subtypes. **Methods:** Clinical data from melanoma patients treated with anti-PD-1 monotherapy between 2009 and 2018 was collected retrospectively from three independent institutions from the US and China. Tumor response, survival outcome, and organ/system-specific immune-related adverse effects (irAEs) were directly compared between different subgroups. **Results:** Among 626 patients, 411 were Caucasian, 214 non-Caucasian; 369 had cutaneous melanoma, and 257 other subtypes. Both ethnicity and melanoma subtype were independently associated with benefit and irAEs. In multivariate analyses, Caucasians had significantly higher objective response rate (ORR) (OR 2.0, 95% CI 1.1-3.5), but this did not translate into a survival advantage (PFS, HR 0.8, 95% CI 0.6-1.1; OS, HR 1.0, 95% CI 0.7-1.4); melanoma of unknown primary shared similar response and survival profile with cutaneous, while acral (ORR, OR 0.4, 95% CI 0.2-0.9; PFS, HR 1.6, 95% CI 1.1-2.2; OS, HR 1.3, 95% CI 0.8-1.9), mucosal (ORR, OR 0.4, 95% CI 0.2-0.9; PFS, HR 1.4, 95% CI 1.0-2.0; OS, HR 1.7, 95% CI 1.1-2.6) and ocular (ORR, OR 0.1, 95% CI 0-0.6; PFS, HR 2.3, 95% CI 1.4-3.6; OS, HR 2.2, 95% CI 1.3-3.6) melanomas had inferior outcomes. Non-Caucasian cutaneous patients had a significantly worse ORR than Caucasians with cutaneous melanoma ($P < .01$). Distinct irAE patterns were observed, exemplified by lower incidence of most irAEs (although more frequent pneumonitis) in Caucasians, and higher and lower liver irAE incidence in ocular and mucosal melanomas, respectively. Endocrine, musculoskeletal and skin irAEs were associated with improved PFS and OS across ethnicities and nearly all melanoma subtypes, whereas heterogeneity existed for other irAE types. **Conclusions:** Ethnicity and melanoma subtype are associated with distinct response patterns, survival outcomes, and irAE profiles in the setting of anti-PD-1 monotherapy. More research is needed to elucidate the molecular and immunologic determinants of these variable outcomes. Research Sponsor: None.

The IMPemBra trial, a phase II study comparing pembrolizumab with intermittent/short-term dual MAPK pathway inhibition plus pembrolizumab in melanoma patients harboring the BRAFV600 mutation. *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Continuous combination of MAPK inhibition (MAPKi) and anti-PD-(L)1 has been investigated by several trials to improve outcome of BRAFV600 mutated melanoma patients. A major obstacle for continuous combination is the high frequency (~60%) of grade 3-4 treatment-related adverse events (TRAE) for which many patients need to discontinue (~40%). In a preclinical model we showed that short-time MAPKi induces T cell infiltration and is synergistic with anti-PD-1. In patients T cell infiltration increased after short-term MAPKi, while after > 2 weeks this was often diminished. The aim of this phase 2b study was to identify the optimal duration of MAPKi with dabrafenib (BRAFi) + trametinib (MEKi) in combination with pembrolizumab (anti-PD-1) in terms of safety, feasibility and immune-activating capacity. **Methods:** Treatment-naïve BRAFV600E/K mutant advanced melanoma patients started pembrolizumab (PEM) 200mg Q3W and were randomized in week 6 to continue PEM only (cohort 1) or to receive in addition intermittent dabrafenib (D) 150 mg BID + trametinib (T) 2mg QD for 2 x 1 week (cohort 2), 2 x 2 weeks (cohort 3), or continuous for 6 weeks (cohort 4). All cohorts continued PEM for up to 2 years. Primary endpoints were safety and treatment-adherence. Secondary endpoints were objective response rate (ORR, RECIST 1.1) at week 6, 12, 18 compared to baseline and PFS. **Results:** Between June 2016 and August 2018, 32 patients have been included; 56% were male, 50% had M1c disease and the majority had a BRAFV600E mutation (81%) and a baseline LDH level > ULN (87%). Grade 3-4 TRAE were observed in 12%, 12%, 50%, and 62% of patients in cohort 1, 2, 3, and 4, respectively. All planned D+T was given in 88%, 63%, and 38% of patients in cohort 2, 3, and 4. Most patients needed to interrupt or discontinue D+T due to fever or elevated liver enzymes. ORR at week 6, week 12, and week 18 were 38%, 62%, and 62% in cohort 1, 25%, 62%, and 75% in cohort 2, 25%, 50%, and 75% in cohort 3 and 0%, 62%, and 50% in cohort 4. After a median follow-up of 17.4 months, the median PFS of patients treated with PEM monotherapy was 10.6 months compared to 27.0 months for patients treated with PEM and short-term/intermittent D+T ($p = 0.13$). **Conclusions:** Combination of PEM plus intermittent D+T seems more feasible and tolerable than continuous triple therapy. Intermittent short-time combination therapy might be equally effective, enables therapy with MAPKi as a second line, and therefore warrants further investigation in a larger patient cohort. Clinical trial information: NCT02625337. Research Sponsor: MSD.

A phase II, multicenter study of encorafenib/binimetinib followed by a rational triple-combination after progression in patients with advanced BRAF V600-mutated melanoma (LOGIC2). *First Author: Reinhard Dummer, Skin Cancer Center in the Department of Dermatology at University Hospital Zürich, Zürich, Switzerland*

Background: LOGIC2 evaluates the benefit of a 3rd agent added to encorafenib (enco)/binimetinib (bini), selected at progression based on the genetic tumor evolution. **Methods:** In part I/run-In, pts were treated with enco/bini until disease progression (as defined per RECIST v1.1). Foundation One NGS was applied on a baseline sample and on a PD sample. Based on the genetic evolution between the biopsy at inclusion (bxI) and at progression (bxPD) and clinical considerations, pts entered part II and received one of four 3rd agent additions to enco/bini combinations: A. LEE011 (CDK4/6 inhibitor), B. BKM120 (PI3K inhibitor), C. INC280 (c-Met inhibitor), or D. BGJ398 (FGFR inhibitor). An adaptive Bayesian logistic regression model (BLRM) guided by the escalation with overdose control (EWOC) principle was used to make dose escalation decisions. Assessments include objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), and safety. Data cutoff for this analysis was May 12, 2019. Data is as is. Part 1 of study is ongoing. Part 2 of study is closed to enrollment. **Results:** 58 pts enrolled into part II (group A=38; B=6; C=13; D=1). 29 pts were assigned to treatment based on bxPD results (Table). In groups A, B, and C, the confirmed ORR was 5.3%, 0%, and 0%, and the DCR was 26.3%, 16.7%, and 15.4%, with median PFS of 2.1, 1.6, and 2.2 months, respectively. Safety was consistent with known profiles of the individual agents. **Conclusions:** Triple therapy is feasible when a 3rd agent is added to enco/bini at progression based on genetic alterations, although activity observed was low. Further exploration to identify patterns of resistance susceptible to the addition of a 3rd agent is needed. Gene alterations for enrollment into part 2. Clinical trial information: NCT02159066. Research Sponsor: Pfizer Inc.

Time to central nervous system (CNS) metastases (mets) with atezolizumab (A) or placebo (P) combined with cobimetinib (C) + vemurafenib (V) in the phase III IMspire150 study. *First Author: Paolo Antonio Ascierto, Fondazione IRCCS-Istituto Nazionale dei Tumori, Naples, Italy*

Background: The phase 3 IMspire150 study (NCT02908672) demonstrated improved progression-free survival with first-line combination treatment with A+C+V vs P+C+V in patients (pts) with previously untreated *BRAF*^{V600} mutation–positive advanced melanoma. Here we report incidence and time to development of CNS mets with A+C+V vs P+C+V in the IMspire150 study. **Methods:** Eligible pts were randomized 1:1 to receive A+C+V or P+C+V. A or P were given on day 1 and 15 of each 28-day cycle after an initial cycle of C+V. Incidence and time to development of CNS mets were evaluated in pts with no history of CNS mets at baseline confirmed by magnetic resonance imaging/computed tomography (MRI/CT). On study MRI/CT assessments were performed as clinically indicated. Time-to-event outcomes were estimated using the Kaplan-Meier method and competing risks analysis. Sensitivity analyses were conducted using landmark analysis at time of initiation of A or P. **Results:** 514 pts were randomized to receive A+C+V (n = 256) or P+C+V (n = 258); 244 and 247 pts, respectively, had no history of CNS mets at baseline. After a median follow-up of 18.9 months, CNS mets had developed in 52/244 pts (21%) in the A+C+V arm and 62/247 pts (25%) in the P+C+V arm. In both arms, pts with CNS mets were more likely to have other known unfavorable prognostic factors: elevated LDH, presence of liver mets, and/or higher tumor burden. Cumulative incidence of CNS mets as first site of progressive disease with A+C+V vs P+C+V was 8% vs 9%, 16% vs 19%, 20% vs 24%, and 23% vs 26% at 6, 12, 18, and 24 months, respectively (hazard ratio [HR] 0.87; 95% CI 0.60-1.26). Estimated CNS mets-free survival rates for A+C+V vs P+C+V were 91% vs 90%, 81% vs 75%, 74% vs 66%, and 69% vs 62% at 6, 12, 18, and 24 months, respectively, with a trend for improved CNS mets-free survival with A+C+V (HR 0.79; 95% CI 0.55-1.14). Results of landmark analyses for CNS mets-free survival and cumulative incidence of CNS mets were similar to those in the overall analysis. **Conclusions:** The addition of anti–programmed death-ligand 1 to C+V is associated with numerically lower rates of interval development of CNS mets, consistent with the overall benefit observed for A+C+V in the study. This finding requires further follow-up to fully assess the magnitude of benefit of A+C+V on CNS mets-free survival. Clinical trial information: NCT02908672. Research Sponsor: F. Hoffmann-La Roche Ltd.

10024 Poster Session (Board #373), Fri, 8:00 AM-11:00 AM

The impact of BRAF mutation status on clinical outcomes with single-agent PD-1 inhibitor versus combination ipilimumab/nivolumab. *First Author: Vincent The-Luc Ma, University of Michigan, Ann Arbor, MI*

Background: Nearly half of all metastatic melanoma patients possess the BRAF V600 mutation. Several therapies are approved for BRAF mutant metastatic melanoma, but it is unclear if there is a differential outcome to various immunotherapy regimens. Our aim was to better assess if BRAF mutation status has any impact on survival to combination ipilimumab/nivolumab (I/N) versus single-agent PD-1 inhibitor (PD-1i). **Methods:** We performed a single center, retrospective analysis on a cohort of patients diagnosed with metastatic or unresectable melanoma from 2012 to 2019 at the University of Michigan who were treated with standard I/N or PD-1i (nivolumab or pembrolizumab). A univariate analysis of progression free survival (PFS) and overall survival (OS) was stratified by treatment type and BRAF mutation status. A multivariate Cox regression of survival was used to compare the effects of the treatment groups adjusted by BRAF status, age, gender, pre-treatment LDH level, prior treatment status, and brain metastases status. **Results:** 323 patients were identified. 132 had BRAF V600 mutation and 191 had BRAF wildtype (WT) status. 138 patients received I/N and 185 patients received PD-1i. In our univariate analysis, there was no difference in PFS [HR: 0.72, 95% CI, 0.46 – 1.13] or OS [HR: 0.78, 0.44 – 1.38] with I/N versus PD-1i in the BRAF mutant cohort, but there was improved PFS [HR: 0.55, 0.35 – 0.88) and OS [HR: 0.52, 0.28 – 0.95] with I/N compared to PD-1i in the BRAF WT group. In the multivariate analysis, the BRAF WT group continued to show PFS benefit with I/N compared to PD-1i [HR: 0.57, 95% CI, 0.35 – 0.95], but the OS benefit no longer achieved statistical significance [HR: 0.54, 0.28 – 1.03]. **Conclusions:** Our study results were discordant with the observation in the landmark CheckMate 067 trial, which noted improved PFS and OS with I/N compared to nivolumab alone in the BRAF mutant group and no difference in the BRAF WT group. In our real-world retrospective analysis, I/N over PD-1i should be considered as initial immunotherapy for metastatic melanoma patients regardless of BRAF mutation status, but even more favorably in BRAF WT. Research Sponsor: None.

10025 Poster Session (Board #374), Fri, 8:00 AM-11:00 AM

Initial report of treatment of uveal melanoma with hepatic metastases with yttrium90 internal radiation followed by ipilimumab and nivolumab. *First Author: David R. Minor, California Pacific Medical Center Research Institute, San Francisco, CA*

Background: Hepatic metastases from uveal melanoma have no established therapy, with a median survival of only 6-12 months. To date therapy with checkpoint inhibitors has yielded minimal results. To take advantage of possible synergy between radiation and immunotherapy we treated patients with yttrium90 internal radiation followed by immunotherapy. **Methods:** Patients received yttrium90 (Sir-Spheres) via hepatic artery infusion in two treatments, one to each lobe 3-4 weeks apart, followed in 3-6 weeks by ipilimumab and nivolumab for 4 doses, then nivolumab maintenance. **Results:** We are presenting interim results because of the excessive toxicity seen when these FDA-approved modalities were used in sequence with the FDA-approved dosages. Initially dosing of yttrium90 (Y90) followed the package insert "BSA method" but after 8 patients we had 5 cases of grade 3-4 hepatic toxicity; in 4 cases the toxicity was observed after just the Y90. One case of cirrhosis occurred in a patient whose liver received 40-45Gy; her cirrhosis was felt most likely due to the Y90. Y90 dosing was then reduced to limit dosage to normal liver to 35Gy, and none of the next 5 patients have had more than grade 2 hepatic toxicity. Dosage to the normal liver is approximated by the MIRD formula: Actual delivered liver dose [Gy] = 50 * Administered activity [GBq] * (1 – Lung shunt fraction) / kg of treated liver. If calculated dose was $>$ 35GY, dosage in GBq is reduced proportionally. Toxicity in the first 5 patients to receive immunotherapy included one grade 4, two grade 3 and two grade 2 hepatic toxicities, and only 3 of the 5 patients received more than one dose of ipilimumab. We then reduced dosing of ipilimumab from 3mg/kg x 4 to 1mg/kg x 4 because of this excessive autoimmune toxicity. Of 13 patients, 10 received both Y90 and immunotherapy, and 3 had responses (1 CR, 2 PR) with 3 patients stable $>$ 5months. Median progression-free survival for all patients is 27 weeks and median overall survival is greater than 48 weeks. Treatment with Y90 produced an over 50% fall in peripheral blood lymphocytes which was reversed in most patients by the immunotherapy. **Conclusions:** With dose modifications this therapy appears feasible and objective tumor responses were seen. Sequential therapy with Y90 and immunotherapy appears tolerable if radiation to normal liver is limited to 35Gy and ipilimumab dose is 1mg/kg. Clinical trial information: NCT02913417. Research Sponsor: California Pacific Medical Foundation.

10026 Poster Session (Board #375), Fri, 8:00 AM-11:00 AM

Combination anti-PD-1 and ipilimumab (ipi) therapy in patients with advanced melanoma and pre-existing autoimmune disorders (AD). *First Author: Lauren Julia Brown, Crown Princess Mary Cancer Care Centre, Westmead, NSW, Australia*

Background: Clinical trials of immunotherapy exclude patients (pts) with pre-existing AD. While retrospective data exist regarding the efficacy and safety of single agent ipi and anti-PD1 antibodies (PD1) in pts with AD, no data are available regarding the safety and efficacy of combination therapy in pts with AD, which has a higher toxicity risk. **Methods:** Pts with melanoma and pre-existing AD treated with combination ipi/PD1 were retrospectively identified from 10 international centres. Data regarding AD, treatment, toxicity and outcomes were examined. **Results:** Fifty-five pts were included, 46 were treated with ipi/nivolumab and 9 with ipi/pembrolizumab. 40 had an ipi dose of 3mg/kg while 15 had a lower dose regimen. 9 pts received prior PD1 therapy; 3 suffered moderate immune-related adverse events (irAE) with no flares of AD on single agent PD1. Pre-existing AD included inflammatory bowel disease (IBD), thyroiditis, rheumatoid arthritis (RA), multiple sclerosis and psoriasis. 10 pts had active symptoms of AD and 13 were immunosuppressed at commencement of ipi/PD1. Eighteen pts (33%) experienced a flare of their AD including 4/7 with RA, 3/6 with psoriasis, 5/9 with IBD, 3/18 with thyroiditis, 1/1 with Sjogren's syndrome, 1/1 with polymyalgia, 1/1 with Behcet's syndrome. Median time to flare was 19 days (range 4 – 167). 13 pts were managed with steroids, 5 required additional immunosuppressants. 7 pts were hospitalised for management of flare (5 with IBD, 2 with RA). 2 pts required intensive care and vasopressors for severe IBD flare, quiescent prior to ipi/PD1. One for diarrhoea and shock and one for duodenal perforation. 8 pts ceased treatment due to flare (3 with IBD, 2 with RA, 1 with Behcet's, 1 with Sjogren's). Thirty-seven pts (67%), experienced an irAE unrelated to their AD, 38% G3 or G4. The most frequent irAEs were colitis (n = 16), hepatitis (n = 12), endocrinopathies (n = 12), with 13 pts experiencing an irAE in $\geq$ 2 organs. 9 pts experienced both AD flare and an irAE. 20 pts (36%) ceased immunotherapy due to irAEs. ORR was 55% (54% in PD1 naive pts), at a median follow up of 14 months, 77% of responses ongoing. ORR in pts who had a flare of their AD was 44% and in pts on immunosuppression was 46%. Median PFS was shorter in pts who had a flare of AD compared with those who did not (2.6 vs 9 months; P-value 0.047). **Conclusions:** Combination ipi/PD1 shows efficacy comparable to clinical trial populations in pts with pre-existing AD and advanced melanoma. Whilst there was a substantial risk of flare of AD, no increased frequency of irAE's was observed. Research Sponsor: None.

10028 Poster Session (Board #377), Fri, 8:00 AM-11:00 AM

The anti–PD-1 antibody spartalizumab in combination with dabrafenib and trametinib in advanced *BRAF* V600–mutant melanoma: Efficacy and safety findings from parts 1 and 2 of the Phase III COMBI-i trial. *First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, and Royal North Shore and Mater Hospitals, Sydney, NSW, Australia*

Background: Treatment (tx) with checkpoint inhibitors or targeted therapy improves outcomes in patients (pts) with *BRAF* V600–mutant advanced melanoma; however, many pts subsequently progress and die. Preliminary evidence suggests that targeted therapy may enhance the impact of checkpoint inhibitors and improve efficacy compared with either treatment alone. **Methods:** COMBI-i is investigating first-line spartalizumab 400 mg every 4 wk + dabrafenib 150 mg twice daily + trametinib 2 mg once daily in pts with unresectable or metastatic *BRAF* V600–mutant melanoma (NCT02967692). We report efficacy and safety data from parts 1 (run-in cohort) and 2 (biomarker cohort), with a median follow-up of 24.3 mo. Response was assessed per RECIST v1.1. The randomized part 3 is ongoing. **Results:** 36 pts were enrolled (part 1: n = 9; part 2: n = 27); 20 (56%) had stage IV M1c disease and 15 (42%) had elevated lactate dehydrogenase (LDH) levels ($\geq$ upper limit of normal). At the data cutoff (August 19, 2019), tx was ongoing in 10 pts (28%). The confirmed investigator-assessed objective response rate (ORR) was 78% (n = 28), with 16 complete responses (CRs; 44%) and 12 partial responses (33%). Median duration of response (DOR; 10/28 responders with events) was not reached (NR); 24-mo DOR rate was 53.4% (95% CI, 29%-73%). Median progression-free survival (PFS) was 22.7 mo; 24-mo PFS rate was 41.4% (95% CI, 23%-59%). At the cutoff, median overall survival (OS) was NR, with a 24-mo OS rate of 74.1% (95% CI, 56%-86%). In pts with elevated LDH, ORR was 67%, with 4 CRs (27%); median PFS was 10.7 mo (95% CI, 4.6-19.1 mo), and median OS was NR. The estimated 24-mo PFS and OS rates in these pts were 26.7% and 52.5%, respectively. All pts had $\geq$ 1 tx-related adverse event (TRAEs); 26 (72%) had grade $\geq$ 3 TRAEs. The most common grade $\geq$ 3 TRAEs were pyrexia (17%), increased lipase (11%), neutropenia (11%), increased blood creatine phosphokinase (8%), and increased γ-glutamyltransferase (8%). AEs leading to discontinuation of all 3 study drugs occurred in 6 pts (17%). All-causality grade $\geq$ 3 AEs requiring immunosuppressive medication occurred in 19 pts (53%). One pt died of cardiac arrest that was not considered tx related. **Conclusions:** The combination of spartalizumab + dabrafenib + trametinib resulted in high ORR and CR rates, with a high frequency of durable responses, including in patients with poor prognostic factors. Clinical trial information: NCT02967692. Research Sponsor: Novartis Pharmaceuticals Corporation.

10029 Poster Session (Board #378), Fri, 8:00 AM-11:00 AM

Association between complete response and survival in advanced melanoma treated with talimogene laherparepvec (T-VEC) plus ipilimumab (ipi). *First Author: Jason Alan Chesney, James Graham Brown Cancer Center, University of Louisville, Louisville, KY*

Background: This is the first randomized trial testing the addition of an oncolytic virus to an immune checkpoint inhibitor for advanced melanoma. At the 3-year (yr) follow-up, the combination (combo) of T-VEC and ipi demonstrated durable and statistically superior objective response rate (ORR) over ipi alone (36.7% vs. 16.0%; odds ratio, 3.0; 95% CI, 1.6–6.0; $P = 0.002$). Complete response (CR) rate was 21.4% with the combo and 6.0% with ipi. Median overall survival (OS) was not reached in either arm. In this post hoc analysis, we utilized the 3-yr landmark data to explore the relationship between CR and OS in the combo arm. **Methods:** Pts with unresectable, stage IIIB-IV melanoma were randomized 1:1 to receive combo or ipi alone. T-VEC was administered intratumorally on day 1 of week (wk) 1 at 10^6 plaque-forming units (PFU)/mL followed by subsequent doses at 10^8 PFU/mL on day 1 of wk 4, and every 2 wks thereafter. Ipi (3 mg/kg) was given every 3 wks starting on day 1 of wk 6 for up to 4 doses. Response was assessed by investigators per immune-related response criteria every 12 wks until disease progression. The primary endpoint was ORR; key secondary endpoints were OS, progression-free survival, and safety. **Results:** 198 pts were randomized (98 to combo; 100 to ipi). As of February 25, 2019, the median follow-up time was 40.0 mos (range: 0.2–63.7) for the combo arm. Among 98 pts who received combo, 21 (21.4%) had a best overall response of CR including 8 who converted from an initial partial response (PR), 15 (15.3%) had PR, 19 (19.4%) had stable disease, 30 (30.6%) had progressive disease, and 13 (13.2%) were unevaluable. Of 21 pts achieving CR, 17 (81%) had ECOG status of 0, 16 (76.2%) had stage IIIB-IVM1a disease, and 16 (76.2%) had no visceral metastases. Median duration of CR was not reached (range: 5.4[+]–58.2[+] mos); 19 of 21 CRs lasted more than 6 months. The baseline tumor burden was lower in pts with CR than in those with non-CR. Median OS was not reached in pts with CR (range: 25.1[+]–63.7[+] mos) and was 47.6 mos (range: 0.2[+]– 63.7[+] mos) in pts with non-CR (Log-rank $P = 0.0005$). The Kaplan–Meier estimated 3-year OS rate was 100.0% for patients with CR and 52.3% for those with non-CR. **Conclusions:** CR rate was higher with T-VEC plus ipi than with ipi alone in pts with advanced melanoma (21.4% vs. 6.0%). In the combo arm, CR was associated with prolonged OS, and pts with CR tended to have better ECOG performance status, earlier-stage disease, and lower baseline tumor burden, as compared with those with non-CR. Clinical trial information: NCT01740297. Research Sponsor: Amgen Inc.

10030 Poster Session (Board #379), Fri, 8:00 AM-11:00 AM

Surrogate endpoints for overall survival in anti-programmed death-1 and anti-programmed death ligand 1 trials of advanced melanoma. *First Author: Run-Cong Nie, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: The mechanisms of action of anti-PD-1/PD-L1 agents are markedly distinct from those of cytotoxic agents, thus a critical issue that is under investigation is what is the optimal endpoint and how should tumor response be evaluated in anti-PD-1/PD-L1 trials for metastatic melanoma. Here, we assessed surrogacy of objective response rate (ORR), disease control rate (DCR) and progression-free survival (PFS) for overall survival (OS) in anti-PD-1/PD-L1 trials of metastatic melanoma through a meta-analysis of randomized controlled trials (RCTs). **Methods:** PubMed and EMBASE were searched for phase 2/3 RCTs till June 2019 investigating anti-PD-1/PD-L1 agents. Treatment effect (hazard ratio or odds ratio) on potential surrogates (ORR/DCR/PFS) and OS were collected. At trial level, we assessed the correlation between treatment effect on potential surrogates and OS, weighted by sample size, fixed and random effect models, and calculated the surrogate threshold effect (STE). Sensitivity analyses and leave-one-out cross-validation approach were performed to evaluate the robustness of our findings. **Results:** We included 8 RCTs (4,110 patients; 11 comparisons). We did not identify strong correlations between ORR (coefficient of determination [R^2]: 0.09 to 0.25), DCR (0.41 to 0.57) and OS. However, we noted a strong correlation between PFS and OS, with R^2 of 0.82 in sample size, 0.75 in fixed effect, and 0.72 in random effect model weighting, the robustness of which was further verified by leave-one-out cross-validation approach. Sensitivity analyses with restriction to trials with less than 50% crossover (R^2: 0.94-0.94), phase 3 trials (R^2: 0.94-0.95), large trials (R^2: 0.78-0.86) and first-line trials (R^2: 0.83-0.91) strengthened the correlation. The STE for PFS was 0.78. **Conclusions:** PFS may be the appropriate surrogate for OS in anti-PD-1/PD-L1 trials of metastatic melanoma. A future anti-PD-1/PD-L1 trial would need less than 0.78 for PFS of the upper limit of confidence interval to predict an OS benefit. Research Sponsor: None.

Does body mass index really predict the response to systemic therapies in metastatic melanoma: A multicenter study from the MelBase French National Cohort? *First Author: Yoann Di Filippo, Dermatology Department, Nice Hospital,, Nice, France*

Background: Obesity is an established risk factor for several cancers and higher body mass index (BMI) is associated with poor prognosis. These data are still debated in melanoma. Furthermore, recently the concept of "obesity paradox" has emerged. In a large cohort published by *McQuade JL et al*, higher BMI was associated with better survival in patients with metastatic melanoma (MM) especially for those treated with targeted therapy (TT) and immune checkpoint inhibitors (ICI). We studied the association between BMI and progression-free survival (PFS) and overall survival (OS) in patients with MM treated with systemic therapies. **Methods:** This study was conducted from the prospective MelBase cohort (NCT02828202). Patients with MM treated with first-line ICI, TT, or CT were included. BMI was categorized by WHO criteria. Underweight patients were excluded. The co-primary outcomes were the associations between BMI and PFS or OS, stratified by treatment, sex and age. Multivariate analyses were performed. **Results:** A total of 1214 patients were analyzed. The majority of them were treated with ICI, followed by TT. Obese patients represented 22% of cohort (Table). Median follow-up was 13.5 months. The patients who were overweight or obese did not have different PFS ($p = 0.88$) or OS ($p = 0.25$) than patients with normal BMI. Stratifying this cohort by treatment received, age, sex and others parameters (such as LDH, number of metastatic site) did not revealed any difference. Multivariate analysis did not change the results. **Conclusions:** BMI was not associated with clinical outcomes in our cohort, especially in ICI and TT groups. Thus, we did not confirm the results presented by *McQuade JI et al.* with a cohort quite similar in term of size. Because BMI is too simplistic and then an imperfect measure of body composition, the published data are not reproducible. We caution the oncologists, about BMI as valuable predictive marker of survival for melanoma patients. Research Sponsor: None.

Surgery for unresectable stage IIIC and IV melanoma in the era of new systemic therapy. *First Author: Stephanie Blankenstein, Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Over the past decade opportunities for surgical treatment in metastatic melanoma patients have re-emerged due to the development of novel systemic therapies. However, selecting patients who will benefit from surgery after systemic therapy is still difficult. The aim of this study is to present data on outcomes of surgery in patients with unresectable stage III and IV melanoma, who have previously been treated with immune checkpoint inhibitors (ICI) or targeted therapy, to provide insight in which patients may benefit from surgery. **Methods:** Data was extracted from the prospectively collected, nationwide, Dutch Melanoma Treatment Registry (DMTR) onunresectable stage IIIC or advanced/metastatic stage IV melanomapatients who obtained disease control with systemic therapy and underwent subsequent surgery. Disease control was defined as a complete response (CR), partial response (PR) or stable disease (SD). After disease control was achieved with systemic therapy, progressive disease (PD) was allowed as a most recent status of disease prior to surgery, to avoid excluding patients with oligoprogression. Major exclusion criteria were non-cutaneous melanoma and brain metastases. **Results:** Of 3959 patients in the DMTR database, 154 patients met our inclusion criteria. Of these patients, 79 (51%) were treated with ICI, 61 (40%) with targeted therapy and 9.1% with study or other treatments before surgery. The best response to systemic therapy was a CR in 5.2%, PR in 46.1% and SD in 44.2% of patients. At a median follow-up of 10.0 months (IQR 4-22) after surgery, the median overall survival (OS) had not been reached in our cohort and median progression free survival (PFS) was 9.0 months (95% CI 6.3-11.7). A multivariate cox regression analysis showed that when surgery led to CR or PR, the PFS and OS were better than if surgery led to SD or PD ($p < 001$). Also, ICI seemed to be more favorable than targeted therapy in both PFS (median of 15 versus 7 months) and OS (median not reached versus 32 months) ($p = 0.026$ and $p = 0.003$). **Conclusions:** We conclude that selected unresectable stage IIIC or stage IV melanoma patients might benefit from surgery after achieving disease control with systemic therapy. Expected residual tumor after surgery could be an important selection criterion. Especially patients undergoing surgery after initial tumor response on ICI have a chance of long-term survival. 10033 Poster Session (Board #382), Fri, 8:00 AM-11:00 AM

Health-related quality of life (HRQL) in patients with advanced cutaneous squamous cell carcinoma (CSCC) treated with cemiplimab: Post hoc exploratory analyses of a phase II clinical trial. *First Author: Michael Robert Migden, Departments of Dermatology and Head and Neck Surgery, University of Texas, MD Anderson Cancer Center, Houston, TX*

Background: Cemiplimab-rwlc (cemiplimab), a PD-1 Inhibitor, showed a robust clinical response in patients (pts) with metastatic (mCSCC) or locally advanced (laCSCC) CSCC not eligible for curative surgery/radiation. This post hoc exploratory analysis examined data from the EORTC cancer specific 30-item HRQL questionnaire (QLQ-C30) for pts participating in a cemiplimab phase 2 clinical trial (clinicaltrials.gov NCT02760498). **Methods:** Adults (N = 193) with invasive CSCC, ≥1 lesion and ECOG performance status ≤1 received IV cemiplimab 3mg/kg q2w (mCSCC n = 59; laCSCC n = 78) or 350mg q3w (mCSCC n = 56). At baseline (BL) and day 1 of each treatment cycle, pts were administered the QLQ-C30. Mixed effects repeated measures (MMRM) models were used to estimate mean change from BL to cycle 5 (C5) for domains/items of the QLQ-C30. For pts with data from BL to C5, the proportion who reported clinically meaningful improvement or worsening (≥10 points) or maintenance (those who did not have ≥10 point change) on each domain was determined for combined and individual treatment groups. **Results:** BL scores indicated moderate to high levels of functioning and low symptom burden. From BL to C5, a clinically meaningful improvement in pain score was observed (least squares [LS] mean [standard error] change -12.1 [2.1]; $P < .0001$); other domains/items remained stable or showed a trend towards improvement (LS mean changes < 10 points). By C5, the majority of pts experienced clinically meaningful improvement or remained stable across key domains (Table). Similar findings were observed on individual symptoms (85%-94% for dyspnea, nausea/vomiting, diarrhea, constipation, appetite loss) and in each treatment group. **Conclusions:** Cemiplimab-treated patients achieved a clinically meaningful reduction in pain and most pts either improved or maintained their HRQL, function with low symptom burden. Clinical trial information: NCT02760498. Research Sponsor: Regeneron Pharmaceuticals, Inc. and Sanofi.

Difference from baseline at C5 on key QLQ-C30 domains (all combined groups).

10034 Poster Session (Board #383), Fri, 8:00 AM-11:00 AM

Effect of first-line spartalizumab + dabrafenib + trametinib on immunosuppressive features detected in peripheral blood and clinical outcome in patients (pts) with advanced BRAF V600–mutant melanoma. *First Author: Reinhard Dummer, University Hospital Zürich Skin Cancer Center, Zürich, Switzerland*

Background: Spartalizumab + dabrafenib + trametinib has previously shown a high response rate of 78% (28 of 36 pts), with a complete response (CR) rate of 42%. A correlative analysis of gene expression signatures (GES)/pathways using whole-transcriptome RNA-seq data from tissue showed that pts with a CR had significantly lower expression levels of immunosuppressive factors in the tumor microenvironment (TME) at baseline (BL). Here we analyze BL peripheral blood markers in the same cohort of pts to assess whether liquid markers can also predict response and clinical outcome to spartalizumab + dabrafenib + trametinib. **Methods:** The Phase III COMBI-i study (NCT02967692) is evaluating spartalizumab + dabrafenib + trametinib in pts with previously untreated *BRAF* V600–mutant unresectable or metastatic melanoma. In parts 1 (safety run-in; n = 9) and 2 (biomarker cohort; n = 27), blood and tissue samples were collected at BL, on treatment after 2-3 wk and 8-12 wk, and at disease progression. Lactate dehydrogenase (LDH) and other blood-based markers (including cytokine profiling [n = 45] and blood RNA-seq [114 signatures]) were assessed in all 36 pts. Pts were divided into 2 groups of 24 and 12 pts based on progression-free survival (PFS) of > 1 or < 1 y. **Results:** In addition to LDH, previously described blood markers such as neutrophil to lymphocyte ratio (NLR) and plasma IL-8 were identified among other neutrophil and immunosuppressive features as top candidates associated with PFS > 1 y. Low plasma IL-8 levels were also associated with CR, and multivariate models suggested that IL-8 may add independent predictive value to LDH and NLR for PFS > 1 y and CR. Pts with high IL-8 levels in the circulation were characterized by high neutrophil chemokine signaling ($\rho = 0.553$) and high neutrophil markers ($\rho = 0.466$) in the tumor as measured by RNA-seq GES levels. We observed a decrease in plasma IL-8 levels from BL upon treatment with spartalizumab + dabrafenib + trametinib. **Conclusions:** Our peripheral blood marker analysis confirmed recent findings from tissue samples that intratumoral immunosuppressive features may preclude a CR and are associated with poor outcomes. High BL plasma IL-8 levels may be associated with an immunosuppressive TME. Further validation is warranted; the randomized placebo-controlled part 3 of COMBI-i is ongoing. Clinical trial information: NCT02967692. Research Sponsor: Novartis Pharmaceuticals Corporation.

10035 Poster Session (Board #384), Fri, 8:00 AM-11:00 AM

Phase I trial of autologous cMET-directed CAR-t cells administered intravenously in patients with melanoma & breast carcinoma. *First Author: Payal D Shah, Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA*

Background: Advanced relapsed/refractory melanoma and metastatic triple-negative breast cancer are lethal diseases for which effective therapies are limited. We conducted a pilot phase I clinical trial (NCT03060356) to establish the safety and feasibility of intravenous autologous chimeric antigen receptor (CAR) T cell immunotherapy targeting cMET, a cell-surface antigen that is highly expressed in these cancers. **Methods:** Subjects had metastatic or unresectable melanoma (Mel) or triple-negative breast cancer (BC) with ≥30% expression of cMET on archival tissue or screening biopsy. Eligible subjects had measurable disease and progression on at least 1 prior therapy. Patients (pts) received up to 6 doses ($1x10^8$ total T-cells per dose) of RNA electroporated anti-cMET CAR T cells over a 2-week period without antecedent lymphodepleting chemotherapy. Subjects underwent pre- and post-infusion biopsies. The primary objective was to determine feasibility and safety of treatment. **Results:** 77 subjects (39 mel, 38 BC) were prescreened for tumor cMET expression and 37 (17 mel, 20 BC) met the eligibility threshold. Seven pts (4 BC, 3 Mel) received cMET-directed CAR T infusions on study. Mean age was 50 years (35-64); median (M) ECOG 0 (0-1); M prior lines of chemotherapy/immunotherapy were 4/0 for BC pts and 1/3 for Mel pts. 6 of 7 pts received all planned CAR T cell infusions, and 1 received 5 infusions. 5 pts experienced grade (G) 1 or G 2 toxicity that was possibly or definitely related to study. Toxicities occurring in ≥1 pt included: anemia (n = 3), fatigue (n = 2), and malaise (n = 2). No G ≥3 toxicities or cytokine release syndrome were observed. No pts discontinued therapy due to toxicity. Best response was stable disease in 4 pts (2 BC, 2 Mel) and PD in 3 pts (2 BC, 1 Mel). Messenger RNA signals corresponding to CAR T cells were detected by RT-PCR in the peripheral blood of all pts during the infusion period and in 2 pts after the infusion period. 6 pts underwent baseline biopsy and 4 pts underwent post-infusion biopsy. Immunohistochemical stains of CD3, CD4, CD8, CD163, L26, PD1, PDL1, Foxp3, Ki67, Granzyme B and Phospho-S6 were performed on pre- and post-treatment tissue biopsies and are being evaluated. **Conclusions:** Intravenous administration of RNA-electroporated cMET-directed CAR T cells was safe and feasible. Future directions include examination of this target using a lentiviral construct in combination with lymphodepleting chemotherapy. Clinical trial information: NCT03060356. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

10036 Poster Session (Board #385), Fri, 8:00 AM-11:00 AM

A phase II study of ERK inhibition by ulixertinib (BVD-523) in metastatic uveal melanoma. *First Author: Elizabeth Iannotti Buchbinder, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Uveal melanoma is a rare and aggressive subset of melanoma that is minimally responsive to traditional therapies. Greater than 80% of uveal melanomas have a mutation in GNAQ or GNA11 which lead to downstream signaling through the MAPK pathway. This has led to efforts to treat uveal melanoma with MEK inhibition with mixed results. Ulixertinib (BVD-523) is a potent and reversible small molecule ATP-competitive inhibitor of both ERK1 and ERK2 protein kinases which has undergone phase I testing. **Methods:** We performed a phase II study to determine the efficacy and safety of BVD-523 in patients with metastatic uveal melanoma. This was conducted as a Simon two-stage design with a total sample size of 25 patients (pts) and an initial evaluation of efficacy after 13 pts. Two responses were required to continue to the second stage. **Results:** From April 2018 to April 2019 thirteen pts were enrolled. Pts were predominantly female (69%) with a median age of 64 yrs. (34 -76). Sites of metastasis included liver (84.6%) and lung (30.8%). Grade 3 and 4 toxicities associated with therapy were consistent with BVD-523 and other ERK inhibitors and included LFT elevation, hyponatremia, pruritis, amylase elevation, anemia and rash. The best response, per RECIST 1.1, was stable disease (SD) in 4 pts, and disease progression (PD) in 7 patients. Two patients were unevaluable for response due to withdrawing themselves from the study. Median time to progression was 2.0 months (90% CI: 1.8 – 3.6 mos.). There were eight deaths due to disease progression with a median survival time of 6.9 months (90%CI: 3.2 to 8.3 mos.). Analysis of correlative data from pre- and on-treatment biopsies exploring the change in expression of key signaling proteins relating to treatment is underway. **Conclusions:** ERK inhibition with ulixertinib (BVD-523) did not demonstrate activity in patients with metastatic uveal melanoma. The toxicities observed on study were consistent with what would be expected with MAPK pathway inhibition. Clinical trial information: NCT03417739. Research Sponsor: BioMed Valley Discoveries, Inc.

10037 Poster Session (Board #386), Fri, 8:00 AM-11:00 AM

A proteomic biomarker discovery platform for predicting clinical benefit of immunotherapy in advanced melanoma. *First Author: Yuval Shaked, Technion, Haifa, Israel*

Background: Immune checkpoint inhibitor-based immunotherapies that target CTLA-4 and the PD-1/PD-L1 axis have revolutionized the treatment of advanced melanoma due to their remarkable clinical benefit. However, only a limited number of patients respond to treatment. Therefore, biomarkers to identify appropriate candidates who will benefit from such therapy are needed. Our previous studies have identified therapy-induced, host-mediated mechanisms that drive resistance to a variety of cancer treatment modalities. Here, we explored whether assessing the systemic host-mediated response to immunotherapy can serve as a basis for predicting clinical outcome in melanoma patients. **Methods:** The cohort consisted of 34 advanced melanoma patients receiving anti-PD-1 monotherapy or anti-PD-1 and anti-CTLA-4 combination therapy. Clinical benefit was assessed. Plasma samples were obtained from patients at baseline and 2-4 weeks after a single treatment. Proteomic profiling of plasma samples was performed using ELISA-based protein arrays. A generalized linear model (GLM) was applied to a subset of the cohort (n = 13) to identify a proteomic signature that can predict clinical response to treatment. The predictive signature was then tested on the entire cohort (n = 33), excluding one patient with stable disease. **Results:** We identified a 10-protein signature that accurately distinguishes between responders and non-responders with an area under the curve (AUC) of 0.84 (confidence interval: 0.69-0.99, p-value 5.56E-04), and sensitivity and specificity of 0.94 and 0.79, respectively. These results are currently being validated in a larger cohort in an ongoing prospective study (PROPHETIC trial, NCT04056247). To explore the biological basis of resistance to immunotherapy, we performed a pathway enrichment analysis. Multiple mechanisms of resistance were identified in the non-responder group, including signaling pathways associated with immunosuppression and inflammation. Comparison between the two treatment modalities revealed pathways unique to each treatment, implying important differences between the two regimens. **Conclusions:** Our study provides insights into mechanisms of resistance to immunotherapy and paves the way towards the discovery of novel predictive biomarkers for patient stratification in melanoma. Research Sponsor: OncoHost.

10038 Poster Session (Board #387), Fri, 8:00 AM-11:00 AM

Spatial proximity of CD8 T cells to tumor cells as an independent biomarker for response to anti-PD-1 therapy. *First Author: Maarten Slagter, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Only a subset of advanced melanoma patients respond to anti-PD-1 (aPD1) monotherapy. Upfront identification of (non-)responsiveness would help guide first-line treatment decisions, prevent overtreatment and unnecessary risk for toxicities. T cell density and expression of T cell related genes have been associated with response to aPD1, but are imperfect predictors. We investigated whether spatial proximity of CD8 T cells to tumor cells improves upon the predictive value of T cell density alone. **Methods:** Pretreatment tumor specimens from melanoma patients treated with aPD1 in the Netherlands Cancer Institute were stained for DAPI, SOX10/Melan-A, CD4, CD8, FOXP3 and PD-1 by multiplex immunofluorescence. Sections were imaged on Vectra and analyzed using HALO to optimize marker thresholds and demarcate tumor and stroma. T cell proximity to tumor cells was evaluated as difference in area under the curve between i) a spatial G-function quantifying T cell density around tumor cells in tumor areas and ii) analogous null distributions obtained by random permutation of cell labels. This assessment of co-clustering is independent of cell density and heterogeneity therein and does not reflect repulsion of T cells to stromal/marginal areas. Clinical characteristics, RECIST response and survival were collected from patient records. Associations between T cell density, T cell proximity to Sox10/Melan-A^{+} tumor cells, other clinical biomarkers (LDH, M stage and WHO performance status) and response were examined in a Bayesian hierarchical logistic regression. **Results:** Tumor specimens of 98 patients were included, of whom 45 were treated with aPD1 as first-line therapy and 33 had an objective response. CD8 T cell proximity to tumor cells was associated with response in an independent, comparatively strong, and tissue dependent manner (cutaneous tissue: 2.78 [2.45, 3.17], visceral: 2.30 [1.95, 2.72], lymphoid: 2.12 [1.88, 2.40], format: maximal posteriori odds ratio [89% equal-tailed credibility interval]), in a multivariate model correcting for CD8 T cell density (1.74 [1.62, 1.88]), LDH (1.93 [1.72, 2.16]), M stage (0.92 [0.87, 0.98]) and WHO performance status (0.79 [0.72, 0.88]). Our model achieved an area under the ROC curve of 77.7%, whereas an analogous model omitting the proximity variable achieved 73.1%. **Conclusions:** Our analyses show that spatial proximity of CD8 T cells to tumor cells functions as an independent biomarker for response to aPD1 and suggests that preexisting CD8 T cell tumor reactivity is reflected by this spatial proximity. Research Sponsor: None.

10039 Poster Session (Board #388), Fri, 8:00 AM-11:00 AM

Association of prior immune checkpoint blockade (ICB) with longer progression-free survival (PFS) in patients treated with intermittent versus continuous dabrafenib and trametinib: A post-hoc analysis of S1320. *First Author: Alain Patrick Algazi, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: S1320 is a phase 2 randomized clinical trial presented at the 2020 AACR Annual Meeting in April demonstrating that continuous dosing of dabrafenib and trametinib yields longer PFS than intermittent dosing of these agents in patients with BRAF$^{V600E/K}$ melanoma. Here we look at the association between prior exposure to ICB and PFS in patients randomized to either intermittent or continuous dosing on S1320. **Methods:** Patients without disease progression after 8 weeks of dabrafenib and trametinib were randomized 1:1 to proceed with intermittent therapy (3-week-off, 5-week-on) or to stay on the continuous daily dosing schedule. The design called for 206 randomized patients with the primary outcome of PFS. Response assessments were made using RECIST v1.1 at 8-week intervals. A post-hoc analysis assessed differences in PFS in the pool of all randomized patients based on prior exposure to anti-PD1 antibodies, a randomization stratification factor. Kaplan-Meier estimates and multivariable Cox regression models (controlling for pre-randomization age, Zubrod performance status, LDH, unknown primary, M-Stage) were used to evaluate the association between this stratification factor and PFS. **Results:** Of 242 patients treated on study, 105 were randomized to continuous dosing, 101 to intermittent dosing, and 36 were not randomized due to disease progression at 8 weeks or other factors. 37% of the 242 enrolled and 37% of the 206 randomized patients had previously been treated with ICB. Among all randomized patients, there were no differences in baseline characteristics comparing patients with and without prior immune checkpoint inhibitor exposure: age median 62 vs 59, LDH elevation 37% vs 39%,, stage IVB/C 73% vs 64%, Zubrod performance status 0, 57% vs 58%. PFS was longer in patients with prior ICB exposure (hazard ratio = 0.60, 95% confidence interval 0.41,-0.98, median = 6 vs 9 months from randomization, 8 vs 11 months from starting treatment). There was no difference in the association between prior ICB exposure and PFS between arms (interaction p-value = 0.62). **Conclusions:** In patients without early progression on dabrafenib and trametinib, PFS was longer with prior to exposure to ICB . Although the groups had similar baseline characteristics and rates of randomization, these results could still be influenced by non-controlled factors influencing clinicians' decisions to start a patient on immune versus targeted therapy. Clinical trial information: NCT02196181. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

10040 Poster Session (Board #389), Fri, 8:00 AM-11:00 AM

A phase II study of vorolanib (CM082) in combination with toripalimab (JS001) in patients with advanced mucosal melanoma. *First Author: Lu Si, Department of Renal Cancer & Melanoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Vorolanib (CM082) is a multi-target tyrosine kinase inhibitor including VEGF, PDGF, c-kit, and Flt-3. Toripalimab (JS001) is a humanized IgG4 mAb against programmed death-1 (PD-1) with clinical activity in metastasis melanoma but not in its mucosal subtype. In this phase II study (NCT03602547), we investigated the safety and efficacy of CM082 in combination with JS001 in patients (pts) with advanced mucosal melanoma. **Methods:** The study enrolled pts from 18 to 75 years-old with histologically confirmed metastatic mucosal melanoma, ECOG PS 0-1, no prior systemic anti-cancer treatment. Eligible pts were treated with CM082 tablet (150 or 200 mg once daily) combined with JS001 (240mg every 2 weeks, IV, Q2W) until confirmed disease progression or unacceptable toxicity. Clinical response was evaluated every 8 week. The primary endpoint was overall response rate (ORR) using RECIST v1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), duration of remission (DOR), and time to first remission (TTR) according to RECIST v1.1 and iRECIST. The safety was also assessed. **Results:** Between July 2018 and April 12, 2019, 40 pts (19 pts in 150mg group; 21 pts in 200mg group) were enrolled and 38 pts were evaluable for tumor response (150mg n = 18, 200mg n = 20), with 4 (22.2%) confirmed partial response (PR), 6 (33.3%) stable disease (SD) and 8 (44.4%) progression disease (PD) in the 150mg CM082 group; 3 (15%) PRs (including 2 unconfirmed), 10 (50%) SD, and 7 (35%) PD were reported in the 200mg CM082 group. Tumors shrank in 10 pts (56%) in the 150mg group and 10 pts (50%) in the 200mg group. At data cut-off (November 28, 2019), 29 pts had PFS events (150mg n = 12; 200mg n = 17). The median PFS was 5.7 (95% CI 2.0, NE) months and 5.6 (1.9, 7.7) months in the two groups, respectively. The most common treatment-related adverse events (AEs) were grade 1 or 2, including leukopenia, elevated LDH, increased ALT, neutropenia, increased AST, and elevated GGT. Common grade 3 or higher adverse events ($>$ 10%) were increased ALT (12 pts, 30%), increased AST (11 pts, 27.5%), neutropenia (6 pts, 15%) and elevated GGT (6 pts, 15%). Eight pts had 9 serious AEs (SAEs). The study is still ongoing and more data will be presented in the future. **Conclusions:** PFS benefit was observed in both 150mg and 200mg subgroups. This study demonstrated potentially improved efficacy with predictable toxicities of CM082 in combination with JS001 therapy, which may be an effective treatment option for pts with advanced mucosal melanoma. Clinical trial information: NCT03602547. Research Sponsor: Betta Pharmaceuticals Co.,Ltd.

10041 Poster Session (Board #390), Fri, 8:00 AM-11:00 AM

FDG-PET metabolic tumor volume in advanced melanoma treated with ipilimumab and nivolumab (ipi/nivo). *First Author: Amir Iravani, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Predictors of outcomes of immune checkpoint inhibitors (ICI) are desirable. We aim to investigate the prognostic value of ^{18}F-fluorodeoxyglucose-PET/CT (FDG-PET) parameters at baseline and response monitoring of patients (pts) with advanced melanoma receiving ipi/nivo. **Methods:** From 2016-2019, melanoma pts who received ipi/nivo and had PET Response Criteria In Solid Tumors (PERCIST) measurable lesions on baseline FDG-PET were included. Baseline whole-body metabolic tumor volume (wbMTV), tumor stage, mutational status, ECOG performance score, lactate dehydrogenase (LDH) and treatment-line were correlated with overall survival (OS) in univariate and multivariate Cox-regression analysis. Response were assessed for a subset of pts with post-treatment FDG-PET based on PERCIST. **Results:** Of 162 pts receiving ipi/nivo, 122 pts (median age: 61; male: 73%; ECOG 0: 78%; raised LDH: 52%; M1c: 39%, M1d: 45% and BRAF$^{V600E/K}$mutation: 45%) met eligibility criteria. Forty percent received ipi/nivo as first-line treatment, 48% as second-line (25% post BRAF inhibitor(i)/MEKi and 23% post single-agent ICI) and 12% as third-line. At median follow-up of 21 months (mths), median OS was 20 mths (95% CI 11-not reached [NR]). Pts with above the median wbMTV had shorter OS than those with below the median wbMTV (NR vs 10 mths, 95% CI 8-NR; HR 2.0, 95% CI 1.2-3.4, p = 0.009). In multivariate analysis, wbMTV, ECOG and treatment-line were independently associated with OS. In 106 pts with post-treatment FDG-PET, 24 mths OS rate was higher for those with objective response (OR): 91% (95% CI 82-100%) vs stable disease:55% (27-100%) vs progressive disease:17% (8-35%) as best response, p < 0.001. OR was higher in first-line compared to second or third-line treatment, 75% vs 29-33% vs 23%, respectively, p = 0.0012. **Conclusions:** Increased baseline FDG-PET wbMTV is an independent prognostic biomarker in pts with advanced melanoma receiving ipi/nivo. FDG-PET response accurately predicts outcome. Research Sponsor: Peter MacCallum Cancer Centre Foundation.

10042 Poster Session (Board #391), Fri, 8:00 AM-11:00 AM

Real-world outcomes of advanced melanoma patients not represented in phase III trials. *First Author: Rawa Ismail, Dutch Institute for Clinical Auditing, Leiden, Netherlands*

Background: A large proportion of patients with advanced melanoma is not represented in phase III clinical trials, due to ineligibility. Real-world efficacy evidence of immune- and targeted therapies in these patients is lacking. We aimed to provide insight in survival outcomes of systemically treated patients who were not represented in the phase III trials in order to support clinical decision-making. **Methods:** Systemically treated ineligible patients with advanced melanoma diagnosed between 2014-2017 were analyzed. Prognostic importance of factors associated with overall survival (OS) was assessed by Kaplan Meier method, Cox regression models, predicted OS probabilities of prognostic subgroups and a conditional inference survival (decision) tree. **Results:** Of 2,536 systemically treated patients with advanced melanoma, 1,004 (40%) patients were ineligible for phase IIII trials. Ineligible patients had a poorer median OS (mOS) compared to eligible patients (8.8 vs 23 months). Eligibility criteria most strongly correlated with survival in ineligible systemically treated patients with ECOG Performance Score (PS) ≥2 vs PS 0-1 (HR 1.95 (95%CI: 1.52-2.5)), symptomatic brain metastases (BM) vs absent BM (HR 1.71 (95%CI: 1.34-2.18)) and LDH > 500 U/l vs normal (HR 1.89 (95%CI: 1.49-2.41)). All other factors for ineligibility were not associated with OS. By combining ECOG PS, BM and LDH, 18 subgroups were created. The 3-year survival probability of patients with ECOG PS ≤1, asymptomatic BM and normal LDH was 35.1%. Patients with ECOG PS of ≥2 with or without symptomatic BM had a mOS of 6.5 and 11.3 months and a 3-year survival probability of 9.3% and 23.6% respectively. In the decision tree, the covariate with the strongest predictive distinctive character for survival was LDH, followed by ECOG PS. Prognosis of LDH of > 500 U/L is infaust, although still long-term survival is possible (3-year survival probability of 15.3%). The decision tree showed the prognosis of patients with symptomatic BM can be good if ECOG PS is 0 and patients are aged ≤55 years (mOS of 22.3 months). **Conclusions:** Patients with advanced melanoma not represented in phase III trials treated with systemic therapy can achieve long term survival. LDH was the strongest predictive factor associated with survival, followed by ECOG PS and symptomatic BM. Other factors for ineligibility were not associated with OS. These results, together with the decision tree, can be used to provide insight in outcomes to facilitate the shared decision-making process when comparative studies are not available. Research Sponsor: None.

10043 Poster Session (Board #392), Fri, 8:00 AM-11:00 AM

Estimating treatment-free survival (TFS) over extended follow-up in patients (pts) with advanced melanoma (MEL) treated with immune-checkpoint inhibitors (ICIs): Five-year follow-up of CheckMate 067. *First Author: Meredith M. Regan, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: We previously defined a novel outcome, TFS, to characterize the time between ICI therapy cessation and subsequent therapy initiation/death. TFS is part of an integrated analysis to comprehensively describe how pts spend overall survival (OS) time, on and off treatment, with/without treatment-related toxicity. We reported survival states, including TFS, in ICI-treated pts with MEL in the phase 3 CheckMate 067 trial (NCT01844505) over the 36-mo period since randomization (Regan. *J Clin Oncol.* 2019); 60-mo results are presented here. **Methods:** Data were analyzed for 937 pts with MEL who started treatment with nivolumab (NIVO) plus ipilimumab (IPI), NIVO, or IPI in CheckMate 067. TFS was defined as the area between the Kaplan–Meier (KM) curves for 2 conventional time-to-event endpoints defined from randomization: time to protocol therapy cessation and time to subsequent therapy/death. TFS was also divided into TFS with/without grade ≥3 treatment-related adverse events (TRAEs), and OS was estimated. The area under each KM curve was estimated by the 60-mo restricted mean (r-mean) time to event and expressed as a percentage of the 60-mo period. Bootstrapped 95% CIs were calculated for differences. **Results:** Over the 60-mo period, pts spent an average of 33%, 17%, and 20% of time free of treatment after receiving NIVO+IPI, NIVO, and IPI, respectively (r-mean TFS, 19.7, 9.9, and 11.9 mo; Table). NIVO+IPI-treated pts had r-mean TFS that was 9.8 mo longer than NIVO-treated pts (95% CI, 6.7–12.8) and 7.8 mo longer than IPI-treated pts (95% CI, 4.6–11.0). Mean TFS with grade ≥3 TRAEs remained a small proportion of the 60-mo period at 3%, 2%, and < 1% with NIVO+IPI, NIVO, and IPI, respectively. **Conclusions:** With extended follow-up, average TFS with/without toxicity represented greater percentages of the 60-mo vs 36-mo period for NIVO+IPI and NIVO, but not for IPI. Pts treated with NIVO+IPI continued to have TFS twice as long as those treated with NIVO alone, due to earlier therapy cessation for toxicity without disease progression and subsequent resolution of many of those toxicities. The majority of TFS time was spent without grade ≥3 TRAEs across all arms. Research Sponsor: Bristol-Myers Squibb.

Estimated r-mean TFS time and survival states over 60-mo follow-up.

	r-mean time (mo)		
Survival state	**NIVO+IPI**	**NIVO**	**IPI**
Time on protocol therapy	12.3	16.9	2.6
TFS	19.7	9.9	11.9
TFS without grade ≥3 TRAEs	18.1	9.0	11.7
TFS with grade ≥3 TRAEs	1.6	0.9	0.2
Survival after subsequent therapy initiation	6.6	9.3	13.9
OS	38.6	36.1	28.4

10044 Poster Session (Board #393), Fri, 8:00 AM-11:00 AM

CA209-9JC: A phase II study of first-line nivolumab (NIVO) in patients (pts) with locally advanced or metastatic cutaneous squamous cell carcinoma. *First Author: Rodrigo Ramella Munhoz, Hospital Sírio Libanês, São Paulo, Brazil*

Background: Cutaneous squamous cell carcinoma (cSCC) is among the most frequent malignancies worldwide, and an increasing incidence has been documented over the past decades. For those not amenable to treatment with curative intent, immune checkpoint blockade (ICP) with anti-PD-1 monoclonal antibodies emerged as a novel therapeutic option, supported by evidences of high mutational burden and expression of PD-L1. In this single-arm study, we sought in investigate the activity of NIVO in pts with advanced cSCC (AcSCC). **Methods:** We conducted a Simon two-stage, open-label, phase II study to evaluate the safety/efficacy of NIVO for up to 24 systemic-treatment-naïve pts with metastatic and/or locally advanced cSCC. NIVO at 3mg/kg was administered intravenously every 2 weeks (w) until disease progression, unacceptable toxicity or 12 months of treatment. The primary endpoint was the best objective response rate (bORR) at 24w as per RECIST criteria. Tumor measurements were performed every 12w. Secondary endpoints included safety/tolerability, progression-free survival (PFS) and overall survival (OS). **Results:** Between October 2018 and October 2019, 24 pts with AcSCC were enrolled, with a median age of 74 years (range 48-93) and a male/female ratio of 1.4:1. Most frequent primary sites were head/neck (42%), trunk (29%) and extremities (25%); identified risk factors included chronic sun exposure or burn scars in 66 % and 12.5 %, respectively. Upon enrolment, the proportions of patients with locally advanced, locoregional (regional lymph node involvement) and metastatic disease were 16.6%, 66.6% and 16.6%, respectively. At data cut off (median number of doses of NIVO: 15), 15 pts (62.5%) remain on treatment and 6 pts have progressed and/or died. Three pts completed 12 months of treatment and entered surveillance. Among 22 pts evaluable for response (n = 2 have not reached 12w of treatment), the bORR was 54.5% (12/22), and disease control (stable disease or objective response) was achieved in 77% (17/22). Median duration of response, PFS and OS have not been reached. Grade ≥3 treatment-related adverse events occurred in 21% of the pts, and 1 patient discontinued NIVO due to toxicities. **Conclusions:** NIVO resulted in robust antitumor activity and good tolerability in systemic treatment-naïve pts with AcSCC. There were no new safety signals, despite the inclusion of individuals at advanced ages. These data provide further evidence to support the use of ICP as the standard treatment option for pts with AcSCC. Clinical trial information: NCT03834233. Research Sponsor: BMS.

10045 Poster Session (Board #394), Fri, 8:00 AM-11:00 AM

Response to immune checkpoint inhibitor (ICI) rechallenge after high-grade immune related adverse events (irAE) in patients (pts) with metastatic melanoma (MM). *First Author: Payal Shah, New York University Langone Medical Center, New York, NY*

Background: ICIs have transformed MM mortality. Pts receiving ICIs may experience high-grade irAEs that limit continuation of treatment per current guidelines. We aimed to evaluate the safety and response rate of ICI rechallenge. **Methods:** 551 MM pts treated with ICI were retrospectively reviewed from Jan 2014 to Jan 2020 after IRB approval. The incidence of a recurrent irAE in pts with ICI rechallenge within the same drug class after an initial high-grade (Grade III/IV) irAE was evaluated. Age, gender, irAEs, and outcomes were descriptively analyzed within the rechallenged cohort. **Results:** 32.7% of pts (180/551) experienced a high-grade irAE. 60.0% of these (108/180) pts were on combination therapy with at least one ICI. 50.6% (91/180) of pts were rechallenged with ICI within the same drug class. The rechallenged cohort had a median age of 63.8 [range: 28-86] years and 48.4% was female. The cohort's initial irAE occurred at a median of 7.6 weeks from treatment onset with Grade 3/4 severity of 60.0% /40.0% (91). Toxicities included colitis 27.5% (25/91), hepatitis 23.1% (21/91), skin toxicity 22.0% (20/91), adrenal insufficiency 5.5% (5/91) hypophysitis 5.5% (5/91), neurological abnormality 4.4% (4/91), pancreatitis 3.3% (3/91), hematological abnormality 3.3% (3/91), arthralgia 3.3% (3/91), myalgia 3.3% (3/91), pneumonitis 2.2% (2/91), insulin dependent diabetes 1.1% (1/91), fatigue 1.1% (1/91), vasculitis 1.1% (1/91), and hyponatremia 1.1% (1/91). ICI rechallenge occurred at a median of 9.7 weeks from the first Grade 3/4 irAE. 51.8% (29/56) pts initially treated with combo were rechallenged with combo, while 48.2% (27/56) were rechallenged with single agent ICI. Of pts initially treated with single ICI, 60% (21/35) were rechallenged with single agent ICI and 40% (14/35) with combo. With a median follow-up of 21.1 months after rechallenge, irAEs occurred in 75.8% (69/91), with 44.9% of irAEs (31/69) presenting as a different type from the initial event and 31.9% (22/69) as high-grade events. There were no rechallenge irAE-related deaths. Within the rechallenge cohort, 39.6% (36/91) of pts had disease progression. Clinical benefit was achieved in 60.4% (55/91) of pts: 40.7% (37/91) complete response, 11.0% (10/91) partial response and 8.8% (8/91) stable disease. **Conclusions:** ICI rechallenge can be safely administered in pts with MM after recovery from an initial high-grade irAE. Rechallenge irAE's did not always reflect initial irAE's. Close monitoring for any type or grade of IRAE is recommended. Research Sponsor: None.

10046 Poster Session (Board #395), Fri, 8:00 AM-11:00 AM

Discordant response comparing 18F-FDG PET/CT with response assessment by RECIST in patients with advanced melanoma treated with immune checkpoint blockade. *First Author: Milton Jos De Barros E Silva, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: Immune checkpoint blockade (ICB) has changed the natural history advanced melanoma (AM). Based on phase III trial, which used RECIST criteria, the complete response (CR) rate with anti-PD1 therapy is around 20%. In daily practice, PET/CT is a useful tool to evaluate response to treatment in melanoma patients. Little is known about the number of patients who achieve metabolic CR by PET/CT but with anatomic residual disease and their prognosis. **Methods:** We conducted a retrospective analysis of patients with AM treated with ICB who achieved metabolic CR by PET/CT but with residual disease on tomography and compared to patients with RECIST CR in a high-volume cancer center. Progression-free (PFS) and overall survival (OS) were obtained by Kaplan Meier method and log-rank test. **Results:** One hundred seventy pts with AM treated with anti-PD1 (79%) or anti-PD1 + anti- CTLA4 (21%) betweenSeptember 2013 and December 2019 were analyzed. At a median follow-up of 23.6 months, seventy-five (44%) pts achieved CR. RECIST criteria: 22 pts (29.3%) and metabolic CR: 53 pts (70.7%). All patients with metabolic CR had RECIST partial response. The median total time on treatment was 14.8m (95%CI:0.9-42.3). The median time to reach CR was 5.4m (95%CI: 3-39). The median time of treatment after CR was 6.8m (95%CI: 0-21.4). The rate of CR patients off treatment at the moment of this analysis was 69%. The median follow-up after discontinuing treatment was 5.2m. There was no difference in PFS (36 month-rate: 84.4% vs 74%, p:0.64) and OS (36 month-rate: 100% vs 86.3%, p:0.14) between pts with CR based on RECIST or PET-CT, respectively. Median time for PFS and OS have not been reached until the date cut-off. Nine pts have relapsed (12%). Seven of them had residual disease on tomography but with no metabolic active lesion(s) at the time of the end of treatment. **Conclusions:** Twice more patients achieve complete response considering only metabolic parameters on PET/CT compared to RECIST criteria and they seem to have comparable prognosis. Research Sponsor: None.

10047 Poster Session (Board #396), Fri, 8:00 AM-11:00 AM

A first-in-human phase I/II study of HL-085, a MEK Inhibitor, in Chinese patients with NRASm advanced melanoma. *First Author: Xuan Wang, Peking University Cancer Hospital and Institute, Beijing, China*

Background: MEK inhibitors have confirmed effects on malignant tumors, especially for those induced by RAS/RAF dysfunction. There is no effective drug in clinic for NRASm advanced melanoma. HL-085 is a selective MEK inhibitor, showing good safety and efficacy in preclinical studies. This study is a phase I/II study to evaluate the safety, tolerability, pharmacokinetic and preliminary anti-cancer activity of HL-085 in patients(pts) with NRASm advanced Melanoma. **Methods:** The phase I/II study is conducted using a "3+3" regimen for dose escalation. The pts are treated with HL-085 at a starting dose of 0.5mg BID to 18mg BID. Adverse events (AEs) are reported per NCI CTCAE version 5.0. Preliminary anti-cancer activity is evaluated by ORR, DCR, PFS and DoR. **Results:** Total 33 pts were enrolled in the study. The histologic types were acral (51.4%), mucosal (27.2%) and other (21.2%). The NRAS mutation types were Q61 (72.7%), G12 (18.2%) with half for G12D, and G13 (9.1%). Most AEs were G1 or G2, and the most common drug-related AEs were rash, increased creatine phosphokinase, peripheral edema, increased alanine aminotransferase and aspartate aminotransferase. No dose-limited toxicity was observed. PK analysis was shown linear PK profile with no obvious accumulation. Among 12 evaluable pts over 9 mg, 4 pts were at the stage of M1c with 1 liver metastasis. Average targeted tumor size was 74.6mm with the largest 184 mm. 10 pts achieved tumor shrinkage [60% with Q61, 20% with G12D, 10% each with G12S and G13R]. 4 pts (2 acral, 1 mucosal and 1 other, each pt has mutaiton type of Q61R,Q61L, Q61K and G12S respectively) had confirmed partial response(PR) [median treatment duration 26.6 weeks (wks) with longest 47.6 wks]). 6 pts achieved stable disease (SD) (median treatment duration 15.72 wks with longest 24 wks), and 66.7% were over 14 wks . The median PFS was 17.4 wks, and confirmed best ORR was 33.3% with DCR 83.3% . **Conclusions:** Our data demonstrated that HL-085 is well tolerated, with manageable side-effects and promising anti-cancer activity in pts with NRASm advanced melanoma. Clinical trial information: NCT 03973151. Research Sponsor: Shanghai KeChow Pharma.

10048 Poster Session (Board #397), Fri, 8:00 AM-11:00 AM

Clinical outcomes with early-elective discontinuation of PD-1 inhibitors (PDi) at one year in patients (pts) with metastatic melanoma (MM). *First Author: Rebecca Pokorny, Department of Pharmacy, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Randomized trials of PDi in MM permitted treatment for 2 years (pembrolizumab) or more (nivolumab). However, the optimal treatment duration is unknown, and shorter courses may be effective. We reviewed clinical outcomes of pts who electively discontinued PDi at 1 year at our institution. **Methods:** We performed a real-world, observational cohort study of pts with MM treated with single-agent PDi from 1/1/2015 to 12/31/2018 at Huntsman Cancer Institute. This was a continuous series of pts who made the joint decision with their provider to electively discontinue PDi at 1 year ($>$ 6 mos and $<$ 18 mos) in the setting of ongoing treatment response or disease stability. Exclusion criteria: PDi with other systemic therapy, discontinuation due to disease progression or immune-related adverse event, and PDi in neoadjuvant, adjuvant, or clinical trial settings. Local therapies, as in real-world, were allowed. Best objective response (BOR) per RECIST 1.1 at PDi discontinuation, progression-free survival (PFS) and retreatment characteristics were analyzed. **Results:** Of 485 pts who received PDi, 52 met inclusion criteria. Median age was 60.5 years and 26.9% were female. Median duration of PDi from first to last dose was 11.1 mos (95% CI 10.5 - 11.4). BOR was complete response in 13 (25%), partial response in 28 (53.8%), and stable disease in 11 (21.2%) pts. After median follow-up of 20.5 mos (range 3 - 49.2) from treatment discontinuation, 39 (75%) pts remained without disease progression (median PFS not reached). Only 13 (25%) pts progressed. Median time to progression after treatment discontinuation was 3.9 mos (range 0.7-30.9). Of the 13 pts, 7 immediately underwent successful localized treatment to the solitary site of progression (3 SRS/SBRT, 4 resection; followed by PDi in 2), 5 were retreated with PDi and 1 received BRAF/MEK followed by PDi. Retreatment with PDi controlled disease in all 5 pts. All pts except 1 were alive at data cut-off. **Conclusions:** In the largest continuous series of pts with MM who electively discontinued PDi after 1 year of treatment, the majority remained without progression on follow-up. Risk of disease progression even in pts with residual disease on imaging was low, and retreatment was effective. Strengths of our study include real-world cohort and treatment pattern analysis. Limitations include single-institution, retrospective design. After prospective validation, elective PDi discontinuation at 1 year may reduce financial and PDi-related toxicity without sacrificing outcomes. Research Sponsor: None.

10049 Poster Session (Board #398), Fri, 8:00 AM-11:00 AM

Activity and safety of third-line BRAF-targeted therapy (TT) following first-line TT and second-line immunotherapy (IT) in advanced melanoma. *First Author: Victoria Atkinson, University of Queensland, Brisbane, Australia*

Background: Patients with advanced melanoma who progress on 1st line TT and 2nd line IT have limited treatment options. We explored the safety and efficacy of re-treatment with 3rd line TT. **Methods:** was pooled from 6 centers in Australia from 2009-2018. Eligible patients with BRAF V600 mutant melanoma had 1st line therapy with a BRAF/MEK inhibitor, 2nd line IO and were re-challenged with a BRAF/MEK inhibitor. **Results:** 90 patients were included; median age 61 years, 78% BRAF V600E, 89% ECOG 0-1 at baseline. 1st line TT was combination BRAF/MEK inhibitors in 80%, predominately dabrafenib/trametinib. Response to 1st line therapy was CR 20%, PR 41%, SD 17% and PD 13% and median duration of therapy was 7.2 months (0-33 months). 70% stopped for progressive disease, 9% toxicity and 16% had a planned switch to immunotherapy. For 2nd line IT, 49% had PD-1 alone, 33% had PD-1+CTLA-4, 14% had CTLA-4 alone. Only median duration on IT was 67 days (0-23 months), 81% ceased for PD, 14% for toxicity. Of patients who had a planned switch to IO before 1st line TT progression, one patient responded to second line IO with SD as BORR, there were no other responses to 2nd line IO in the planned switch group. At 3rd line TT re-challenge, 54% were AJCC stage IVd, 34% IVc, 51% had elevated LDH, 59% ECOG 0-1. 47% were re-challenged with dabrafenib/trametinib, 33% vemurafenib/cobimetinib, 11% encorafenib/binimetinib. BORR was 28%, with median duration on 3rd line TT 81 days. The OS was 1.7 years, with 34% alive at time of analysis. **Conclusions:** Despite progression on 1st line TT and 2nd line IT, patients may experience meaningful response and on re-challenge TT. Research Sponsor: None.

Circulating tumor DNA (ctDNA) using Guardant360 to predict response in BRAF V600 WT metastatic melanoma (MM) patients (pts) receiving immune checkpoint inhibitors (ICI). *First Author: Jenny HJ Lee, Westmead Hospital Cancer Care, Sydney, Australia*

Background: ctDNA detected by ddPCR predicts ICI response in MM, although its utility is limited to pts with known recurring mutations eg. *BRAF*, *NRAS*, *KIT*. We sought to overcome this limitation by using a next generation sequencing approach in *BRAF V600* wild type (WT) MM pts. **Methods:** Plasma was collected at baseline and Week (wk) 6 in 35 *BRAF V600* WT MM pts treated with ICI. Cell free (cf)DNA was analyzed using Guardant360 and only somatic non-synonymous and promoter variants were considered. Pts who failed cfDNA extraction at baseline were excluded (n = 3). Favorable ctDNA was defined as undetectable ctDNA at wk 6 and unfavorable ctDNA defined as detectable ctDNA at wk6. Response was according to RECIST at first restaging. **Results:** Of the evaluable 32 pts (64 plasma samples), median baseline cfDNA quantity was 33ng (range 4-657ng) and ctDNA was detected in 29/32 pts (91%). All 3 pts with undetectable baseline ctDNA had less than 10ng cfDNA compared to only 1/29 pts with detectable baseline ctDNA. Number of mutations identified in the 29 ctDNA-positive pts was 4 per pt (range 1-22). Response assessment was performed on 30 evaluable pts. Candidate driver mutation(s) in *BRAF*, *NF1*, or *N/K/HRAS* were identified in 26/30 pts. These mutations were often detected with other established mutations involved in tumorigenesis (eg. *TERT* promoter), or passenger mutations (eg. clonal hematopoiesis). Analysis of driver mutations revealed a sensitivity and specificity in predicting treatment failure of 92% and 93%, respectively (table). When all mutations identified were evaluated for treatment response, 9/18 responding pts retained some ctDNA at wk 6, although this never included *TERT* variants. The resulting sensitivity and specificity in predicting treatment failure changed to 100% and 50%, respectively, when all cfDNA variants were included. **Conclusions:** The extensive coverage of Guardant360 improves ctDNA detection in *BRAF V600* WT MM pts, allowing non-invasive, rapid, and longitudinal assessment of response in a broader population. The expanded coverage also identifies passenger variants of potential non-MM origin, eg. clonal hematopoiesis, and with significant overlap with ctDNA, it is not possible to distinguish between the two in the circulation. We therefore recommend identification and monitoring of known cancer driver mutations only. Research Sponsor: National Health and Medical Research Council.

Preclinical and clinical studies of a class I/IV HDAC inhibitor, mocetinostat, in melanoma. *First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: Mocetinostat is a class I/IV HDAC inhibitor with HDAC1/2/3/11 activity. Preclinical murine data suggest that HDAC inhibition has immune activity and may augment the clinical benefit of checkpoint inhibition. Several trials are assessing the effects of adding HDAC inhibition to PD-1 blockade. **Methods:** Patients with therapy-naive metastatic melanoma were treated in a pilot phase Ib trial with nivolumab at 3 mg/kg/ipilimumab at 1 mg/kg every three weeks four times and a starting dose of mocetinostat at 70 mg orally three times a week in a 12-week induction cycle followed by 12-week maintenance cycles of nivolumab 240 mg every 2 weeks and mocetinostat at the same dose and schedule as induction. Endpoints were toxicity, definition of a recommended phase 2 dose and preliminary assessment of response as well as correlative marker determination. Peripheral blood mononuclear blood cells from patients were tested *in vitro* at varying concentrations of mocetinostat, and its impact on T, regulatory T and myeloid-derived suppressor cell phenotypes were assessed by flow cytometry, as well as cytokine production by Luminex. **Results:** In the mocetinostat, nivolumab and ipilimumab phase I trial, 10 patients were treated, including 5 males and 5 females with a median age of 59. There were 2 complete and 5 partial responses confirmed; 6 of 7 are maintained at a median of 16 months of follow up. Three patients had progressive disease. Seven patients had grade 3-4 immune related adverse events; in 3 they were multiple. No patients died. *In vitro*, mocetinostat at doses from 125 to 500 nM increased relative percentage of CD4/CD8 central memory T cells, and decreased IL-6 levels while increasing interferon-gamma production ($p = 0.005$). Percentages of regulatory T and monocytic myeloid-derived suppressor cells were decreased by mocetinostat ($p = 0.005$), which also down-modulated regulatory T cell function by reducing FOXP3, HELIOS and GARP ($p = 0.001$). **Conclusions:** *In vitro*, mocetinostat promoted accumulation of central memory CD8 and CD4 T cells from melanoma patients, and decreased percentages and suppressive activity of T regulatory cells and myeloid-derived suppressor cells. In a pilot clinical trial, mocetinostat combined with nivolumab and ipilimumab in treatment-naïve metastatic melanoma patients exhibited a response rate of 70% with long duration of response but all ten patients treated had at least one grade 3 or 4 immune-related toxicity. De-escalation of the mocetinostat dose to 50 mg three times a week was felt to be indicated due to the toxicity of the triple regimen. Clinical trial information: NCT03565406. Research Sponsor: Mirati Pharmaceuticals.

10053 Poster Session (Board #402), Fri, 8:00 AM-11:00 AM

Risk of disease progression (PD) following discontinuation of BRAF±MEK targeted therapies for reasons other than PD in patients (pts) with metastatic or unresectable melanoma. *First Author: Francesca Corti, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In pts with metastatic melanoma bearing BRAF V600E/K mutations BRAF V600±MEK inhibitors are administered until PD/unacceptable toxicity. In patients achieving durable responses, outcomes following discontinuation for reasons other than PD are largely unknown. **Methods:** We identified all patients who interrupted BRAF±MEK inhibitors for reasons other than PD after complete (CR) or partial response (PR) from a clinical dataset of patients with *BRAF* mutated metastatic/unresectable melanoma treated with targeted therapy at a single Institution. **Results:** We included 24 pts. Fifteen (62.5%) and 9 (37.5%) pts were treated respectively with BRAF inhibitor monotherapy and BRAF+MEK inhibitor combination. All pts had normal baseline LDH and ECOG PS0, 2 (8%) pts had brain metastases and 15 (62.5%) had multi-organ metastatic involvement. Dose reduction was required for 12 (50%) pts. Median treatment duration was 59 (12-88) months. Causes of discontinuation were unacceptable toxicity (19 pts-79%) and consent withdrawal (5 pts-21%). At the time of discontinuation, 17 (71%) and 7 (29%) pts had achieved respectively CR and PR. At a median follow up of 31 (8-59) months after treatment discontinuation, 9 (37.5%) pts had experienced PD. Median time to PD after treatment discontinuation was 9 (3-16) months. At time of PD, 2 (22%) pts displayed involvement of new organ sites. Risk of PD following discontinuation was respectively 31% and 45% at 12 and 24 months. Neither baseline characteristics nor treatment duration and time to best response influenced risk of PD; we found a non-significant trend towards higher risk of relapse for patients interrupting treatment with residual disease compared to those who interrupted treatment after achieving CR [HR 3.3; 95%CI (0.8–14.1); log-rank $p = 0.081$]. After PD, 6 pts received BRAF+MEK inhibitors with a response rate of 100% and 3/6 pts achieving CR. **Conclusions:** In a subset of patients with favorable prognostic characteristics and retained sensitivity to BRAF±MEK inhibitors, treatment discontinuation was associated with relevant risk of relapse with about one third of pts experiencing PD within one year. Biomarker studies are needed to identify pts who might safely discontinue therapy due to sustained toxicity, especially after achieving CR. Research Sponsor: None.

10054 Poster Session (Board #403), Fri, 8:00 AM-11:00 AM

Landmark analysis of immunotherapy duration and disease free survival in advanced melanoma patients with a complete response. *First Author: Grayce N. Selig, Department of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Checkpoint blockade improves survival in patients with melanoma, with durable complete responses (CR) after stopping therapy. Based on data from KEYNOTE-001, immunotherapy is often continued for 24 months in patients with confirmed CR. Outcomes with treatment of less than 24 months hav not been adequately evaluated and reported. If equally efficacious, shorter courses would potentially reduce health care costs and toxicity. **Methods:** 45 patients with locally advanced stage III and IV melanoma who received immunotherapy (pembrolizumab, nivolumab or ipilimumab/nivolumab) as 1st line or subsequent therapy, achieved a CR, and stopped therapy were identified under an IRB approved protocol at Penn. Disease Free Survival (DFS) was defined as time from declaration of CR until recurrence or date of analysis (1/15/20). Landmark DFS from time of CR was analyzed based on duration of therapy (less than or greater than 7 months, based on early trial requirements to treat patients with confirmed CR for at least 6 months). Rationale for stopping (toxicity or CR) was also analyzed. **Results:** Of 45 patients with CR, 27 (60%) were treated less then 7 months (median 4.8, range 1 day to 6.7 months) and 18 (40%) were treated for greater than 7 months (median 12.4, range 7.5 to 24.2 months). Patients who were treated for less than 7 months had a median DFS from time of CR of 30.4 months (95% CI 23.7 to 37.2, range 2.9 to 65.7 months). Patients treated for greater than 7 months had a median DFS of 28.0 months (95% CI 18.9 to 37, range 8.5 to 73.7 months). Patients who stopped due to toxicity (N = 17, 40%) had a median treatment duration of 3.7 months. Their median DFS from time of CR was 30.4 months (95% CI 20.7 to 40.1, range of 2.9 to 65.7 months). Patients who stopped due to CR (N = 28, 60%) had a median treatment duration of 8.5 months. Their median DFS was 27.6 months (95% CI 21.2 to 34 range 7.2 to 73.7 months). Two of 27 (7.4%) patients treated for less then 7 months and 3 out of 18 (16%) patients treated greater than 7 months recurred after stopping. One out of 17 (5.8%) recurred after stopping for toxicity vs. 4/28 (14.3%) who stopped after CR. **Conclusions:** Patients who stop therapy at less than 7 months have CRs that are equally durable as those treated longer than 7 months, without reduction in landmark DFS. Patients who stopped therapy due to toxicity and then achieved a CR had no difference in DFS compared to patients treated until CR. There was no significant difference in recurrence after achieving a complete response in patients treated for a longer vs shorter treatment course. Research Sponsor: None.

10057 Poster Session (Board #406), Fri, 8:00 AM-11:00 AM

Long-term immune-related adverse events under PD-1 inhibitors: a multicenter prospective cohort study (MELBASE). *First Author: Charlee Nardin, Dermatology, CHU de Besançon, Besançon, France*

Background: PD-1 inhibitors (anti-PD1) are frequently associated with immune-related adverse events (IRAE). Since melanoma patients included in clinical trials were frequently treated during two years, data on IRAE occurring after 2 years of treatment are lacking. This study aimed to describe IRAE in melanoma patients treated with anti-PD1 for longer than 2 years in a real-life setting. **Methods:** Patients were screened from MelBase, a French multicentric biobank dedicated to the prospective follow-up of unresectable stage III or IV melanoma. All patients who received anti-PD1 for at least 2 years between January 2013 and November 2019 were included. Among them, patients who experienced IRAE and long-term IRAE defined as IRAE occurring after 2 years of anti-PD1 were identified. **Results:** Among 1849 patients with advanced melanoma included in Melbase, 119 patients received anti-PD1 monotherapy during at least 2 years, from January 2013 to November 2019, with a median follow-up of 41.7 months (25.2-57.5). Patients characteristics at treatment initiation were: male gender (61%), mean age of 63 years old, past history of autoimmune disease (11%), BRAF WT (72%), AJCC stage IV (84%), brain metastases (22%), ECOG 0-1 (88%) and normal LDH (56%). Patients were treated with Nivolumab (n = 53) or Pembrolizumab (n = 66). IRAE occurred in 99 patients (83%) with a median time of 13.3 months (0-53.9), including severe IRAE (grade 3 or 4) in 30 patients (30%). Long-term IRAE, mostly grades 1-2, occurred in 52 patients (43%). Long-term IRAE led to 5 hospitalizations (4%) of which 4 were grades 3-4. Among patients with long-term IRAE, 45 patients (87%) previously experienced IRAE within the first 2 years of anti-PD1 and 29 patients (56%) experienced multiple IRAE. **Conclusions:** Our data demonstrate that long-term IRAE are frequent especially in patients who already experienced IRAE within the first two years of treatment. These data should be taken into account to establish formal recommendations on the duration of anti-PD1 therapy. Research Sponsor: BMS, MSD, Novartis, Roche.

10059 Poster Session (Board #408), Fri, 8:00 AM-11:00 AM

Clinical outcomes in patients with $BRAF^{V600}$ mutant melanoma and undetectable circulating tumor DNA treated with dabrafenib and trametinib. *First Author: Alain Patrick Algazi, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: Circulating tumor DNA (ctDNA) analysis has been promoted as a less-invasive surrogate assay for tumor-tissue based tumor oncogene analysis. Here, we associate detection of BRAF mutant ctDNA with PFS and OS in patients with tissue-confirmed $BRAF^{V600}$ mutant melanoma enrolled in S1320, a randomized phase 2 clinical trial of continuous versus intermittent dosing of dabrafenib and trametinib. **Methods:** Patients with $BRAF^{V600}$ melanoma received continuous therapy with dabrafenib and trametinib for 8 weeks after which patients were randomized 1:1 to proceed with intermittent treatment on a 3-week-off, 5-week-on schedule or to continue with continuous therapy. Pre-treatment blood samples were interrogated using the Guardant 360 ctDNA assay for all exons of 30 known oncogenes including BRAF and for all exons with known oncogenic mutations in the COSMIC database in 40 additional oncogenes. Clinical responses were assessed at 8-week intervals by RECIST v1.1 and PFS and OS estimates were compared using log-rank test in patients with detectable versus undetectable $BRAF^{V600}$ mutant ctDNA,. **Results:** Somatic $BRAF^{V600E}$ or $BRAF^{V600K}$ ctDNA was detected in 34 of 50 patients with baseline (before lead-in cycle 1) blood samples available for analysis including 16 of 23 (70%) patients randomized to continuous dosing, 15 of 21 (71%) randomized to intermittent dosing, and 3 of 6 (50%) who were not randomized due to disease progression at 8 weeks or other factors. Four additional patients had other detectable somatic mutations but no detectable $BRAF^{V600}$ ctDNA at baseline, and 12 patients had no detectable somatic ctDNA mutations at baseline. Detection of $BRAF^{V600}$ ctDNA was associated with baseline disease stage (p = 0.008). There was no difference in the overall response rate based on baseline ctDNA detection. Detection of ctDNA at baseline was associated with worse PFS (median $BRAF^{V600}$ ctDNA positive = 5.8; 95% CI: 4.2-9.6 months, $BRAF^{V600}$ ctDNA negative = 21.4 mos; 95% CI 10.4-NA; measured from registration to lead-in cycle 1, p = 0.001) and OS ($BRAF^{V600}$ ctDNA positive = 17.8 mos; 95% CI 9.76-NA, $BRAF^{V600}$ ctDNA negative = not reached; 95% CI NA-NA, p = 0.0021). **Conclusions:** The absence of detectable $BRAF^{V600}$ ctDNA at baseline is associated with improved PFS and OS in patients receiving treatment with dabrafenib and trametinib. Clinical trial information: NCT02196181. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

10060 Poster Session (Board #409), Fri, 8:00 AM-11:00 AM

Association of pathogenic germline variant KDR Q472H with angiogenesis and resistance to treatment in melanoma. *First Author: Margaret Chou, The Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York, NY*

Background: Preclinical data suggest that melanoma angiogenesis promotes resistance to MAPK-pathway (MAPKi) and immune checkpoint inhibitors (ICIs). However, phase II clinical trials of anti-angiogenic therapy in melanoma were disappointing. We previously identified a pathogenic germline variant Q472H in the kinase insert domain receptor [KDR Q472H; vascular endothelial growth factor receptor-2 (VEGFR-2)] in 35% of primary melanoma patients. We hypothesize that KDR Q472H promotes resistance to MAPKi or ICIs, and that combined MAPKi or ICI and VEGF pathway inhibition may improve outcomes in patients harboring the variant. **Methods:** Metastatic melanoma (MM) patient clinical data and biospecimens enrolled in the NYU Langone Medical Center Melanoma program were studied. KDR status was determined by TaqMan assays. Tumor microvessel density (MVD) was assessed by CD34 immunohistochemistry. The impact of KDR Q472H on the tumor microenvironment was determined by RNA-seq and Nanostring. Synergy between BRAF (dabrafenib) and VEGFR-2 (lenvatinib) inhibitors in KDR-genotyped MM cell lines was assessed using cell proliferation assays and the Chou-Talalay method. Synergy between ICIs and anti-VEGFR-2 was evaluated *in vivo* using a B16 melanoma model. **Results:** We studied 221 MM patients (38% KDR Q472H variants). KDR Q472H variant was significantly associated with higher tumor MVD (P = 0.002). Among the MAPKi-treated patients, KDR Q472H homozygotes had shorter median progression-free survival (PFS, 3.3 vs 9.7 months, P = 0.009) than KDR wild type (WT). In patients treated with anti-PD-1-based therapies, response rates were lower in KDR Q472H variant patients compared to WT (P = 0.012), with shorter median PFS (8.4 months vs not reached, P = 0.0443). Transcriptomic analyses identified an immunosuppressive phenotype in KDR Q472H tumors, with reduced expression of genes associated with chemotaxis, inflammation, T cell activity, and antigen presentation. Consistent with this finding, VEGFR-2 blockade in a KDR Q472H B16 mouse melanoma model augmented the anti-melanoma immune response. KDR Q472H cell lines displayed synergistic cytotoxicity with dabrafenib and lenvatinib, compared to KDR WT cells. **Conclusions:** Our data demonstrate that melanoma patients with pathogenic germline variant KDR Q472H may be more resistant to both ICIs and MAPKi. Anti-angiogenic therapy should be reconsidered within this specific subset of patients in prospective clinical trials. Research Sponsor: P50 CA225450 NYU Melanoma SPORE, P30 CA016087 Cancer Center Support Grant.

10061 Poster Session (Board #410), Fri, 8:00 AM-11:00 AM

Integrated biomarker study of neoadjuvant pepinemab and nivolumab in patients with resectable metastatic melanoma. *First Author: Michael C. Lowe, Department of Surgery, Emory University, Atlanta, GA*

Background: SEMA4D has broad immunomodulatory effects in the tumor microenvironment (TME); blocking SEMA4D in combination with checkpoint inhibitors (CI) promotes immune infiltration, reduces recruitment of myeloid cells, enhances T cell activity, and promotes tumor regression. We hypothesized that adding pepinemab (VX15/2503), which targets SEMA4D, to CI would increase immunomodulatory effects and augment response in melanoma (NCT03769155). **Methods:** Patients with resectable stage IIIB/C/D melanoma were enrolled to control (no neoadjuvant therapy) or treatment cohorts (n = 8 in four cohorts of pepinemab plus nivolumab, ipilimumab, nivolumab/ipilimumab or alone). Here we report results from patients receiving two doses of nivolumab (360mg) and pepinemab (15mg/kg) every three weeks followed by surgery. Primary endpoint was T cell infiltration into the TME; secondary endpoints include pathologic response rates, peripheral immune profile, and safety. **Results:** Ten patients are reported: two were controls, eight received neoadjuvant therapy. Two patients had pathologic complete response, one had a near-complete pathologic response ($<$ 1% viable tumor), one had a partial response (41% viable tumor) and four had stable disease (73-90% viable tumor). All neoadjuvant patients underwent surgery without delay; one patient experienced grade 3 post-operative cellulitis. There were two treatment-related grade 3 adverse events (weakness and arthralgia). Pharmacodynamic studies confirmed saturation of PD-1 and SEMA4D in peripheral and tumor-infiltrating T cells. T/B cell ($CD8^+/CD20^+$) ratios, a surrogate for T cell infiltration, were higher in post-treatment tumors compared to pre-treatment and were higher in the tumor bed compared to normal adjacent tissue. Flow cytometric evaluation identified an increase in $CD26^{hi}$ $CD4^+$ and $CD8^+$ tumor-infiltrating effectors in treated patients compared to controls and an increase in peripheral frequencies of the PD-1-responsive effector HLA-$DR^+CD38^+Ki67^+$ $CD4^+$ and $CD8^+$ T cells following treatment. Treatment increased infiltration of myeloid populations into the TME, increased expression of PD-L1 on TME myeloid populations, and increased expression of the SEMA4D receptor Plexin-B2 on the surface of TME $CD45^-$ and M2 macrophages and MDSC. **Conclusions:** Neoadjuvant nivolumab and pepinemab results in increased T cell infiltration with excellent major response rate (38%) and expected safety profile. We continue to enroll patients using other rational combinations of pepinemab and CI. Clinical trial information: NCT03769155. Research Sponsor: Vaccinex, Inc.

10062 Poster Session (Board #411), Fri, 8:00 AM-11:00 AM

The use of plasma proteomic markers to understand the biology of immunotherapy response. *First Author: Arnav Mehta, Dana–Farber Cancer Institute, Boston, MA*

Background: Despite recent successes with immune checkpoint blockade (ICB) in melanoma, the prognosis for most patients remains dire. Whereas small fraction of patients are able to achieve disease control, most do not respond or are limited by immune-related toxicities. Robust non-invasive predictors of ICB response have the potential to guide clinical decision and alter management of patients, however, no such predictors currently exist. **Methods:** We applied a highly-multiplex Proximity Extension Assay to simultaneously detect $>$ 1000 proteins in the plasma of anti-PD-1 treated melanoma patients. Our cohort comprised 116 patients, 66 responders (R) and 50 non-responders (NR). Additional 65 patients comprised a validation cohort with 30 R and 35 NR, and included 50 patients who developed treatment-related toxicities. Plasma samples were collected at baseline, 6-weeks and 6-months after starting the treatment. A subset of patients had single-cell RNA-seq performed on tumor tissue. Group differences and treatment effects were evaluated by linear model with maximum likelihood estimation for model parameters and Benjamini and Hochberg multiple hypothesis correction. **Results:** At baseline, 6 significantly differentially expressed (DE) proteins were identified between R and NR. Elevated expression of ST2 and IL-6, two key immunoregulatory proteins were found in NR. At 6-weeks, more dynamic changes occurred and 79 significantly DE proteins were identified between R and NR, including proteins implicated in primary or acquired resistance as IL-8, MIA, TNFR1 and potential novel targets as MCP-4/CCL13, ICOSLG and VEGF. Proteomic changes identified at baseline and 6-weeks were more profound at 6-months, and moreover 238 proteins were confirmed significant between R and NR. Importantly, we were able to leverage these differences to build classifiers of R and NR subsets. We compared mRNA expression of DE proteins within the tumor microenvironment by leveraging scRNAseq data from a subset of these patients. Enriched expression of these genes was uncovered in certain myeloid and exhausted T cell subsets, thus shedding insight into the potential role of these cell subsets in ICB response. **Conclusions:** Plasma proteomic profiling of anti-PD1 treated patients identified important tumor and immune changes associated with response. Non-invasive means discovery of circulatory protein biomarkers may predict sensitivity to immunotherapy and uncover biological insights underlying primary resistance. Research Sponsor: Olink proteomics.

10063 Poster Session (Board #412), Fri, 8:00 AM-11:00 AM

Survival analysis between narrower surgical margins and guideline-recommended margins for excision of cutaneous squamous cell carcinoma: A multicenter, retrospective study of 1,204 Japanese cases. *First Author: Natsuki Baba, Saitama Medical University International Medical Center, Saitama, Japan*

Background: Controversy exists regarding the optimal surgical margin for cutaneous squamous cell carcinoma (cSCC). Current NCCN Guidelines recommend excision with a 4–6-mm clinical margin for low-risk cSCC and wider ($>$ 6-mm) clinical margin for high-risk cSCC tumors. However, adherence to this guideline is often difficult, as high-risk cSCCs frequently occur on the faces of elderly patients. Thus, we aim to investigate the correlation between different surgical margins and prognosis in patients with cSCC. **Methods:** Patients with cSCC who had undergone surgical excision of the primary site between 2011 and 2019 at 11 Japanese institutions were included in this study. Patients were divided into two groups: the standard margin group (SMG) with excisions adhering to the guideline-recommended margins, and narrower margin group (NMG) with excisions with narrower margins than are guideline-recommended. Local recurrence-free survival (LRFS), relapse-free survival (RFS), and overall survival (OS) were estimated using Kaplan–Meier analysis and compared between the two groups. **Results:** A total of 1204 patients with cSCC (SMG, 637; NMG, 567) were included in this study. RFS was significantly lower in SMG than in NMG (5-year RFS 72% vs 79%; P = 0.03); however, no statistically significant differences were observed between the two groups in LRFS (5-year LRFS 80% vs 82%; P = 0.41) or OS (5-year OS 84% vs 83%; P = 0.90). Due to striking statistical significance in several characteristics of patients between the two groups, subgroup analyses, focusing on the cohort of head and neck cSCCs, were also performed. The patient characteristics were similar between SMG and NMG in both the T1-sized tumor ($<$ 2 cm, SMG, 182; NMG, 250) and T2-sized tumor (2 cm $\leq$ tumor $<$ 4 cm, SMG, 130; NMG, 136) cohorts, based on AJCC-TNM staging (8th edition). There were also no significant differences between the SMG and NMG in LRFS (5-year LRFS, T1: 80% vs 86%; P = 0.59; T2: 85% vs 84%; P = 0.84), RFS (5-year RFS, T1: 80% vs 81%; P = 0.84; T2: 77% vs 76%; P = 0.99), or OS (5-year OS, T1: 82% vs 87%; P = 0.42; T2: 88% vs 85%; P = 0.68). Furthermore, when the NMG was divided into the two margin groups (margins reduced by $<$ 3 mm or $\geq$3 mm from the standard margin), no significant difference was observed in LRFS, RFS, and OS. **Conclusions:** This study did not reveal a significant impact of the size of clinical excision margins on survival in patients with cSCCs. Strikingly, the narrower margins may be more appropriate for $<$ 4 cm-sized head and neck cSCCs. Research Sponsor: National Cancer Center Research and Development Fund.

10064 Poster Session (Board #413), Fri, 8:00 AM-11:00 AM

Health-related quality of life in stage III melanoma patients treated with neoadjuvant ipilimumab and nivolumab followed by index lymph node excision only, compared to therapeutic lymph node dissection: First results of the PRADO trial. *First Author: Noëlle Milena Jane Van den Heuvel, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant ipilimumab and nivolumab induces high pathologic response rates of 74-78% (OpACIN and OpACIN-neo trial), thus the role of Therapeutic Lymph Node Dissections (TLND) in patients with major pathologic responses (MPR: pathological (near) complete response) is now unclear. In the PRADO trial, TLND was omitted in patients with MPR in their index lymph node ((ILN), the largest LN marked prior to neoadjuvant therapy). We sought to determine if less extensive surgery is associated with better Health Related Quality of Life (HRQoL). These are the first results of the comparison of HRQoL between patients undergoing a TLND or less extensive ILN excision. **Methods:** HRQoL was assessed with the European Organisation for Research and Treatment of Cancer QoL questionnaire-C30 (QLQ-C30). A generalized estimation equation was used to assess the difference in HRQoL outcomes between patients who underwent TLND (pathological non- and partial-responders, pNR/pPR) versus those who did not (pathological (near)complete responders, pNCR/pCR). Differences were adjusted for age, gender and follow-up (FU, in weeks), but not for pathological responses (pNR, pPR, pNCR & pCR). Differences in QLQ-C30 scores were classified as clinically important according to published guidelines. **Results:** A total of 49 patients from the PRADO study had reached at least 24 weeks FU, and were included in the first explorative analysis. The median age of this study population was 58 years (range, 22-84). Questionnaire completion rates were high: 94% at baseline, 100%, 90%, 88% at week 6, 12 and 24, respectively. Sixteen (33%) patients underwent TLND versus 33 (67%) who had ILN excision only. Over a FU period of 24 weeks, patients who underwent TLND scored significantly lower on global (68 vs 78, adjusted difference (diff) = -9.53, p = .005), physical (84 vs 94 diff = -11.1, p = $<$ .001), emotional (69 vs 83, diff = -11.7, p = .001), role (70 vs 85, diff = -13, p = .004), and social functioning (81 vs 91, diff = -8.9, p = .016) and had a higher symptom burden of fatigue (35 vs 23, diff = 11.1, p = .004), insomnia (38 vs 18, diff = 16.6, p = .002) and financial impact (12 vs 4, diff = 7.9, p = .027) than patients undergoing ILN excision only. These differences were indicated as clinically relevant. **Conclusions:** First results from PRADO suggest that reducing the extent of surgery following neoadjuvant immunotherapy might result in better HRQoL of high-risk stage III melanoma patients. Clinical trial information: NCT02977052. Research Sponsor: Bristol Myers Squibb.

10065 Poster Session (Board #414), Fri, 8:00 AM-11:00 AM

Cemiplimab as first intervention for patients with locally advanced cutaneous squamous cell carcinoma. *First Author: Jennifer Lynn Atlas, Levine Cancer Institute-Atrium Health, Charlotte, NC*

Cemiplimab as First Intervention for Patients with Locally Advanced Cutaneous Squamous Cell Carcinoma (cSCC) **Background:** Cutaneous squamous cell carcinoma is the second most common non-melanoma skin cancer. Early stage disease is managed with local intervention in the form of surgery or radiation and translates into cure for greater than 95% of the patients. Patients with high risk disease who have large primary lesions, neural, or nodal involvement are usually not amenable to cure with local intervention and may experience significant morbidity, disfigurement, or functional deficits. These patients had no effective systemic treatment options until recent approval of cemiplimab. We report the outcomes for upfront treatment with cemiplimab in locally advanced cSCC. **Methods:** This is a single institution retrospective study of patients with locally advanced cSCC defined as those requiring more than simple excision and/or complex repair or regional disease with nodal involvement who received at least two doses of cemiplimab between January 1, 2018 through January 17, 2020. Patients with radiologically measurable disease had response evaluated per RECIST criteria. Patients who had no measurable disease had their clinical response (complete resolution or healing of primary lesion) assessed per treating physician and need or lack of local intervention documented. Adverse events were assessed and graded per CTCAE criteria. The primary end point was to ascertain the need for local intervention. **Results:** Thirty six patients were eligible. Twenty-two (61%) patients treated with upfront cemiplimab were able to avoid local intervention with surgery and/or radiation; four patients progressed or died on treatment. Three (8%) patients received local intervention. Eleven (31%) patients are still receiving cemiplimab and local intervention decision is pending. The overall response rate was 69% and the clinical benefit rate was 92%. The median treatment duration was six months and the median number of doses received was six. Adverse events occurred in 31% of patients; the most common adverse event was dermatitis. **Conclusions:** Upfront treatment with cemiplimab in patients with locally advanced cSCC obviated need for disfiguring/complex surgery or radiation in majority of patients. Cemiplimab was tolerated well; no new safety signals were observed. Neo-adjuvant phase II study is in development. Research Sponsor: None.

10066 Poster Session (Board #415), Fri, 8:00 AM-11:00 AM

Using digital-image analysis of tumor-infiltrating lymphocytes to predict survival outcomes in primary melanoma. *First Author: Margaret Chou, The Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York, NY*

Background: Inclusion of tumor-infiltrating lymphocytes (TIL) into AJCC staging criteria has been proposed due to evidence suggesting its prognostic significance. However, subjective inter-observer discordance prevents adoption of semi-quantitative TIL grading (e.g. absent, non-brisk, brisk) into clinical practice. We hypothesize that digital-image analysis (DIA) of TIL can provide a standardized, quantitative scoring system that more accurately predicts survival compared to currently used semi-quantitative grading methods. **Methods:** Clinical data and tumor specimens were analyzed from prospectively enrolled primary melanoma patients in the New York University Interdisciplinary Melanoma Cooperative Group with median follow-up of 5 years. H&E-stained slides were digitized using an Aperio ScanScope at 20X magnification. QuPath software was used for automated TIL quantification. Cox regression analysis was used to assess the improved prognostic value of TIL on recurrence-free (RFS) and overall survival (OS). Patients were separated into high- and low-TIL groups using a score threshold determined by the Youden Index. **Results:** 453 patients (18% stage I, 42% stage II, 40% stage III) were scored using automated TIL assessment and scores were significantly correlated with better RFS and OS per 10% increase in TIL (stage adjusted hazard ratio [aHR] = 0.92 [0.84-1.00] for RFS and aHR = 0.90 [0.83-0.99] for OS). A model combining TIL score with stage increased prognostic ability for both RFS (0.68 to 0.70, P = 0.02) and OS (0.62 to 0.64, P = 0.01), as assessed by concordance indices (C-index). Kaplan-Meier curves of high- ($>$ 16.6%) versus low-TIL ($\leq$16.6%) patients showed clear separation in RFS and OS (median RFS = 155 vs 48 months, P $<$ 0.001; median OS = 155 vs 89 months, P = 0.002). For comparison, a subset of the cohort (n = 250) was semi-quantitatively graded (absent, non-brisk, brisk) by an attending melanoma pathologist; however, this did not significantly differentiate RFS between groups (P $>$ 0.05). **Conclusions:** A standardized, quantitative TIL scoring system significantly improved prediction of RFS and OS in primary melanoma patients compared with semi-quantitative TIL grading. Incorporation of quantitative TIL scoring into prognostic algorithms, such as AJCC criteria, should be considered. Research Sponsor: P50 CA225450 NYU Melanoma SPORE, Other Foundation, P30 CA016087 Cancer Center Support Grant.

10067 Poster Session (Board #416), Fri, 8:00 AM-11:00 AM

Radiomic signatures to predict response to targeted therapy and immune checkpoint blockade in melanoma patients (pts) on neoadjuvant therapy. *First Author: Rivka R. Colen, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Metastatic melanoma pt outcomes have been revolutionized by targeted therapy (TT) and immune checkpoint blockade (ICB), which are now being evaluated in the neoadjuvant (neoadj) setting. While tumor-based biomarkers may help predict response, predictors of response obtained by less invasive strategies could greatly benefit pt care and allow real-time treatment response monitoring. Radiomic signatures derived from computerized tomography (CT) images have recently been shown to predict response to ICB in stage IV pts. However, the association of radiomic features with pathological response following neoadj therapy has not been assessed. We sought to determine if radiomic assessment predicts pCR in pts receiving neoadj TT and ICB. **Methods:** We collected data for a cohort of melanoma pts with locoregional metastases who were treated with neoadj TT (n = 33) or ICB (n = 30). Pts received systemic therapy for 8-10 weeks prior to planned surgical resection. Responses were evaluated radiographically (RECIST 1.1) and via pathological assessment (evaluating for pathologic complete response; (pCR) versus $<$ pCR). Thirty two pts (19 ICB; 13 TT) were included in the radiomics analysis based on the availability of appropriate CT imaging. A total of 310 unique radiomic features (10 histogram-based and 300 second-order texture features) were calculated from each extracted volume of interest (VOI). Feature extraction was performed on baseline and initial on-treatment pre-operative CT scans. Features associated with pCR were assessed using a feature selection approach based on Least Absolute Shrinkage and Selection Operator (LASSO). Selected features were used to build a classification model for prediction of pCR to ICB or TT. Leave-One-Out Cross-Validation was performed to evaluate the robustness of the estimates. **Results:** Out of 310 radiomic features, three features measured at baseline were able to predict a pCR to neoadj ICB or TT with sensitivity, specificity and accuracy of 100%, though these signatures were non-overlapping. In the on-treatment pre-operative scans, 3 distinct features (also non-overlapping and distinct from the predictive pre-treatment signatures) also predicted pCR to ICB and TT with 100% sensitivity, specificity and accuracy. **Conclusions:** Radiomic signatures in baseline and on-treatment CT scans accurately predict pCR in melanoma pts with locoregional metastases treated with neoadj TT or ICB. These provocative findings warrant further investigation in larger, independent cohorts. Research Sponsor: None.

10068 Poster Session (Board #417), Fri, 8:00 AM-11:00 AM

Using a clinicopathologic and gene expression model to identify melanoma patients at high risk for disease relapse. *First Author: Alexander M. Eggermont, Princess Máxima Center, Utrecht, Netherlands*

Background: The identification of early stage melanoma patients at high risk for relapse is still difficult. Roughly 50% of melanoma deaths occur in patients who were initially diagnosed with nonmetastatic melanoma. Therefore, a strong clinical need has emerged for diagnostic tools that can identify melanoma patients at high risk for relapse. Here, we assessed the performance of a recently developed model (Bellomo et al., JCO Precis Oncol. 2020: in press), combining clinicopathologic and gene expression variables (CP-GEP), in identifying melanoma patients that have a high risk for disease relapse. **Methods:** We assessed the prognostic performance of the CP-GEP model in a cohort of 837 consecutive melanoma patients from Mayo Clinic who had a sentinel lymph node biopsy (SLNb) performed within 90 days of their diagnosis. The CP-GEP model combines Breslow thickness and patient age, with the expression of 8 genes in the primary tumor, to stratify patients according to their risk of relapse: CP-GEP High Risk or CP-GEP Low Risk. The main clinical endpoint of this study was five-year relapse free survival (RFS). **Results:** Patients were stratified based on SLNb status and CP-GEP classification. 76% of the patients were SLNb negative and had an RFS of 79% versus 52% for SLNb positive patients; HR, 3.21; P $<$ 0.0001. 60% of the patients were identified as CP-GEP High Risk and had an RFS of 62% versus 87% for CP-GEP Low Risk patients; HR, 4.12; P $<$ 0.0001. Within the SLNb negative group (637 patients of which 65% stage I), 51% of patients were classified as CP-GEP High Risk. Here, RFS was 70% for CP-GEP High Risk patients versus 89% for CP-GEP Low Risk patients; HR, 3.61; P $<$ 0.0001. The prognosis of these CP-GEP High Risk patients is similar to stage IIC/IIIA patients with reported RFS ranging from 63% to 77%. This confirms the heterogeneity in prognosis among patients with stage I/II melanoma disease. **Conclusions:** The CP-GEP model can be successfully used to stratify patients based on their risk for relapse. In particular, it can be used to identify SLNb negative patients with a high risk for disease relapse who may benefit from therapeutic interventions. Independent validation studies are ongoing to validate the CP-GEP model in various patient populations. Research Sponsor: Mayo Clinic, U.S. National Institutes of Health.

	Stratification	Number of patients	RFS	DMFS	MSS
837 cohort	None	837	73%	80%	91%
	SLNb negative	637	79%	86%	93%
	SLNb positive	200	52%	64%	85%
	CP-GEP Low Risk	337	87%	92%	96%
	CP-GEP High Risk	500	62%	72%	88%
637 SLNb negative	CP-GEP Low Risk	310	89%	94%	97%
	CP-GEP High Risk	327	70%	78%	89%

10069 Poster Session (Board #418), Fri, 8:00 AM-11:00 AM

Vismodegib (V) for organ preservation for locally advanced (LA) orbital/periocular basal cell carcinoma (BCC). *First Author: Francis P. Worden, University of Michigan, Ann Arbor, MI*

Background: LA BCC of the eye/lacrimal drainage system most often requires disfiguring radical surgery, possibly including exenteration. As an alternative to radical surgery, we evaluated ophthalmologic outcomes following treatment with V using a novel Visual Assessment Weighted Score (VAWS) in patients (pts) with locally advanced periocular BCC. **Methods:** In this open label, non-randomized trial, pts with globe- and lacrimal-threatening orbital/periocular BCC were scored with VAWS prior to treatment with 150 mg of V daily. Pts were evaluated by ophthalmic exam (OE) every 3 mo & with MRI/CT at 5-9 mo. Pts with progressive disease (PD) were offered salvage surgery. Tumor response was assessed by RECIST v1.1. Responders (CR, PR, SD) continued V if tolerating therapy. Pts with intolerable side effects stopped V & were offered surgery of their residual tumor. Post-surgical specimens were assessed for histologic presence of BCC by a dermatopathologist. The primary endpoint, maintenance of visual function, was evaluated by VAWS at final post treatment assessment (FPTA), 1 yr after the start of V or 2 mo post-surgery. A VAWS of 21/50 was considered successful, representing preservation of a functional eye. **Results:** 50 pts were planned for enrollment, but the study was stopped early for benefit. From 06/25/2015 to 05/16/2019, 35 pts signed consent; 1 was a screen failure; 34 (97%) received V & 35 were evaluable for analysis by ITT; 1 died from aspiration pneumonia. The median time on study was 261 days. Average treatment with V was 223 days. 32 (91%) underwent OE & 27 (77%) had an MRI/CT. 27 (77%) underwent surgery & 33 (94%) attained organ preservation. Overall response rate (ORR) on OE was 84% (0%-PD,6%-SD,29%-PR,54%-CR, 11% not assessed(NA)). ORR by MRI/CT was 72% (0%-PD,6%-SD, 26%-PR,46%-CR,22% NA). 31 (89%) were scored with VAWS at 3 mo & 30 (86%) at FPTA. The mean VAWS at baseline was 44/50, 46/50 at 3 mo, & 47/50 at FPTA. Of the 35 pts scored at baseline by VAWS, 1 (3%) had a major decline during follow up, 5 (14%) a minor decline, 27 (77%) stable/improved, & 2 (6%) NA. No pts experienced grade 3-5 events. Of the 27 post-surgical pathologic specimens evaluated for histological response, 67% had NED, 22% had clear margins, & 11% had BCC to the margin. Two pts have recurred & underwent Mohs surgery. **Conclusions:** Treatment with V led to organ preservation for pts with LA periocular BCC, with preservation of visual function. Vismodegib is practice changing as neoadjuvant therapy for LA BCC of the eye/lacrimal drainage system in which surgery would result in unacceptable morbidity. Clinical trial information: NCT02436408. Research Sponsor: Genetech, institutional funding from the University of Michigan.

10070 Poster Session (Board #419), Fri, 8:00 AM-11:00 AM

Checkpoint inhibitor treatment in patients with isolated in-transit melanoma metastases. *First Author: Lucy Storey, Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: In the context of multiple in-transit melanoma metastases without nodal involvement, a variety of treatment modalities have historically been employed including surgery, laser, isolated limb perfusion/infusion, intralesional interleukin-2, T-VEC and electrochemotherapy. Unfortunately, most patients treated with these modalities experience subsequent disease progression. While checkpoint inhibitors (CPI) are a standard of care for bulky unresectable stage III and for stage IV melanoma, patients with isolated in-transit metastases were rarely included in registration studies. There are anecdotal reports of lower response rates in these patients despite them having disease characteristics that would usually be associated with a good response. **Methods:** We report data from 11 retrospective patient cohorts treated at cancer centres across Europe who received CPI between 2016 and April 2019. All patients had multiple in-transit metastases without clinical or radiological evidence of nodal or distant disease. Disease response was assessed using CT, PET-CT or MRI depending on clinical indication. All patients had at least one prior resection of loco-regional relapsed disease and were deemed not curable by further surgery. **Results:** Sixty three patients meeting criteria were identified, 40 females and 23 males. Median age was 72 years and 54 (86%) patients had a normal lactate dehydrogenase (LDH). 19 (30%) patients had a BRAF mutation. At treatment initiation, the majority 55 (87.3%) received single agent PD-1 inhibitor, 7 (11.1%) combination ipilimumab + nivolumab and 1 (1.6%) received single agent anti-CTLA 4. The overall response rate was 62% for the full population. The response rate with anti-PD1 monotherapy was 59%. With a median FU of 23 months, the median PFS was 26 months, median OS not reached. OS estimates with 95% CI: 12 month - 93% (87-100%), 24 month - 88% (80-98%), 36 month - 80% (67-95%). **Conclusions:** The results show a high response rate to CPI in patients with in-transit metastases and support early treatment with CPI following identification of in-transit metastases not curable with surgery whilst disease characteristics remain favourable. Research Sponsor: None.

10072 Poster Session (Board #421), Fri, 8:00 AM-11:00 AM

KRT-232, a first-in-class, murine double minute 2 inhibitor (MDM2i), for TP53 wild-type ($p53^{WT}$) Merkel cell carcinoma (MCC) after anti–PD-1/L1 immunotherapy. *First Author: Michael K.K. Wong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MCC is an aggressive neuroendocrine skin cancer with very poor prognosis. Immune checkpoint inhibition was recently shown to benefit some patients (pts). There are few effective treatments (tx) and no standard of care for those who relapse on or are refractory to anti-PD-1/L1 agents (R/R). In $p53^{WT}$ MCC, oncoproteins from the Merkel cell polyomavirus can inhibit p53 tumor suppressor functions via L-MYC/EP400-dependent activation of MDM2. KRT-232, a potent, selective, orally available MDM2i, is being evaluated in pts with $p53^{WT}$MCC who are R/R to anti-PD-1/L1 tx. **Methods:** In stage 1 of this open-label, multicenter, phase 2 study (NCT03787602) pts initially received KRT-232 240mg QD days 1-7 of a 21 day (d) cycle (cy). This cohort was closed due to Grade (Gr) 3/4 cytopenias and pts were moved to 240mg QD days 1-5 of a 28d cy to allow for hematologic recovery. Two new arms were opened: 240mg and 180mg QD days 1-5 of a 28d cy. The primary endpoint is objective response rate (ORR) by RECIST 1.1. Secondary endpoints include duration of response, progression-free survival, overall survival, and safety and tolerability of KRT-232. **Results:** At the time of this analysis, 11 pts were treated with KRT-232: 6 on the 240mg 7/21d, 3 on the 240mg 5/28d and 2 on the 180mg 5/28d schedules. Median age was 66; 46% of pts had ECOG 1 (range 0-1), the median prior lines of systemic therapy was 3 (range 1-4) and 82% had prior radiation tx. Treatment-emergent adverse events (AEs), regardless of grade or causality, were reported in all pts: 55% had Gr 3-4 AEs and 36% had serious AEs (SAEs). The most common AEs included neutropenia (55%), anemia, leukopenia and thrombocytopenia (each 45%), diarrhea, nausea and fatigue (each 36%), and lymphopenia, hypomagnesaemia, lipase increase and sinus tachycardia (each 27%). SAEs were mainly due to cytopenias. One Gr 5 AE of respiratory failure/ascites was attributed to progression. Median time on study was 11.3 wks (range 1.3-20.9). Two of 11 pts on active tx have not yet reached the first response assessment (wk 6). Of the 9 pts who have reached wk 6, 2 PRs and 1 SD (converted to PR at wk 12) were reported. At the second response assessment (wk 12), 2 PRs were reported; one of the PRs at wk 6 has not yet reached wk 12. The ORR was 33% (3/9 pts). **Conclusions:** KRT-232 demonstrates promising monotherapy activity in MCC $p53^{WT}$ pts who failed anti-PD-1/L1 tx. This is the first clinical proof-of-concept for inhibiting the MDM2 pathway in MCC. Safety and efficacy continue to inform KRT-232 dose and schedule optimization. Clinical trial information: NCT03787602. Research Sponsor: Kartos Therapeutics, Redwood City, CA, USA.

10073 Poster Session (Board #422), Fri, 8:00 AM-11:00 AM

Patient-reported outcomes (PROs) from the phase III IMspire150 trial of atezolizumab (A) + cobimetinib (C) + vemurafenib (V) in patients (pts) with *BRAF*$^{V600+}$melanoma. *First Author: Karl D. Lewis, University of Colorado Comprehensive Cancer Center, Aurora, CO*

Background: In IMspire150, A+C+V significantly improved investigator-assessed progression-free survival vs placebo (Pbo)+C+V in previously untreated pts with unresectable stage IIIc/IV *BRAF*$^{V600+}$melanoma. PRO data from this trial are now reported. **Methods:** 514pts were randomized 1:1 to 28-day cycles of A+C+V or Pbo+C+V. Pts received C+V in cycle 1; A or Pbo was added on days 1 and 15 from cycle 2 onward. Pts completed the EORTC QLQ-C30 questionnaire on day 1 of cycle 1 (baseline), days 1 and 15 of cycle 2 and cycle 3, day 1 from cycle 4 onward, within 28-d of treatment discontinuation, and ≤6 months post-treatment. Prespecified secondary PRO endpoints were time to confirmed deterioration (TTCD; defined as time from randomization to first ≥10-point decrease from baseline held for 2 consecutive assessments, or 1 assessment followed by death on treatment) in quality of life (QoL) and physical functioning (PF). Prespecified exploratory endpoints were TTCD in role functioning (RF); mean change from baseline and percentage of pts with a clinically meaningful change (≥10 points from baseline) in QoL, PF, and RF. **Results:** Questionnaire completion rates were > 80% for most of the treatment period. At baseline, mean QoL, PF, and RF scores were moderate to high (Table). At week 6 (cycle 2), following initiation of A, QoL, PF, and RF scores declined, but returned to near-baseline levels at week 10 (cycle 3) and were largely maintained until week 36 (cycle 10), when < 50% of pts contributed data. In this time, ≥56% pts in both arms did not experience a clinically meaningful deterioration in QoL, PF, and RF. TTCD on QoL (hazard ratio [HR] 1.23; 95% CI 0.90-1.67), PF (HR 1.27; 95% CI 0.93-1.74), and RF (HR 1.15; 95% CI 0.86-1.55) favored Pbo, but only one-third of pts overall experienced a confirmed deterioration. **Conclusions:** PRO data showed that A+C+V did not worsen QoL, PF, and RF in pts with advanced *BRAF*$^{V600+}$melanoma, thus supporting its use as a treatment option. Clinical trial information: NCT02908672. Research Sponsor: F. Hoffmann-La Roche Ltd.

	Mean (SD) score, baseline	Mean (SD) change from baseline, week 6	Mean (SD) change from baseline, week 10
A+C+V (QoL)	70.6 (21.4)	-9.10 (22.9)	-2.07 (20.4)
Pbo+C+V (QoL)	70.8 (23.0)	4.11 (21.6)	1.43 (19.6)
A+C+V (PF)	84.0 (20.8)	-6.55 (19.4)	0.26 (16.7)
Pbo+C+V (PF)	85.3 (19.0)	1.96 (17.3)	-0.12 (15.4)
A+C+V (RF)	79.8 (28.4)	-12.0 (30.9)	-3.63 (25.1)
Pbo+C+V (RF)	80.1 (28.0)	0.11 (31.0)	-0.94 (26.5)

10074 Poster Session (Board #423), Fri, 8:00 AM-11:00 AM

Efficacy of imiquimod in the management of lentigo maligna. *First Author: Brigitte Dréno, Department of Dermatology-Oncology, Nantes University, CHU Nantes, CIC1413, CRCINA, Nantes, France*

Background: Lentigo maligna (LM), a melanocytic proliferation occurring on photoexposed skin, might progress to LM melanoma. Surgery is recommended as first-line treatment. However, the main challenge is the size of the excision inducing often-aesthetic injuries on the face and thus often refused by patients. The excision margins of 5 to 10 mm remain without international consensus. Several studies have shown that imiquimod induced LM regression, acting *by enhancing IFN-*γ production and effector function of T cells. The main goal of this study is to investigate the effect of imiquimod versus placebo in neoadjuvant setting to decrease the excision size as from the first surgical procedure. **Methods:** We performed a prospective, randomized, open, multicenter, phase III clinical study (NCT01720407). The health authority and ethics committee approvals were obtained and all subjects signed an informed consent. The primary endpoint was to demonstrate that in neoadjuvant situation, imiquimod could reduce the surgical excision size of LM with a healthy tissue margin of 5 mm. The main inclusion criteria were: Patients $>$ 18 years fit for surgery. LM of the head histologically confirmed and not previously treated. Surface lesion $\geq$ to 1cm^2 and $\leq$ to 20cm^2. The two treatment arms were imiquimod or placebo followed by LM excision. Imiquimod or placebo were applied once daily, 5 days/week for 4 weeks followed by 5 mm margin surgery performed four weeks after the last treatment application. For sample size, 268 patients were expected to demonstrate a difference of 15% between the two arms in a bilateral situation with an alpha risk of 5% and a beta risk of 20%. **Results:** The trial involved 273 patients, 238 (105 men (44%) and 133 women (56%), mean age of 71 $\pm$ 10.2 years, were analyzed in modified ITT. Statistical analysis was performed on 122 patients in the imiquimod arm and 116 patients in the placebo arm. For the primary endpoint, the first extralesionnal excision has been achieved for 112 (91.8%) patients in the imiquimod arm and for 98 (84.5%) placebo patients group. There was no significant difference (p value = 0.1067) between the two arms. However, regarding the surface of LM, imiquimod allowed a highly significant reduction (4.2 cm^2 $\pm$ 4.6 to 2.3 cm^2 $\pm$ 3.3) compared to LM treated by placebo (4.0 cm^2 $\pm$ 3.5 to 4.0 cm^2 $\pm$3.3; p $<$ 0.0001). **Conclusions:** This randomized prospective study shows that imiquimod reduces the LM area (-50%) after one month of treatment. Reducing the surface of LM with imiquimod is not associated with a higher risk of intralesional excision (marge 5mm), with a significant esthetic result (less excised surface). Clinical trial information: NCT01720407. Research Sponsor: French Hospital Clinical Research Program in Cancer.

Adjuvant crizotinib in high-risk uveal melanoma following definitive therapy. *First Author: Shaheer Khan, Columbia University Irving Medical Center, New York, NY*

Background: Uveal melanomas (UM) measuring at least 12mm in base diameter with a class 2 signature as defined by gene expression profiling (DecisionDx-UM) are characterized by high metastatic risk, with a median time to recurrence of 32 months. No therapy has been shown to reduce this risk. The growth factor receptor Met is highly expressed in UM. We have previously shown that crizotinib, an inhibitor of Met, is an effective adjuvant therapy in preclinical models *(Surriga et al, Mol Cancer Ther 2013).* We therefore conducted a phase II study of adjuvant crizotinib in high-risk UM. **Methods:** Eligibility included: primary lesion $\geq$12mm in base diameter; class 2 by DecisionDx-UM testing; definitive therapy within 120 days before starting crizotinib; and, no evidence of metastatic disease. Patients (pts) received 12 four-week cycles of crizotinib (250 mg twice daily). Surveillance imaging (chest CT and MRI abdomen/pelvis) were performed q3 months. The primary endpoint was distant relapse-free survival (RFS). Secondary endpoints were overall survival (OS) and toxicity. We hypothesized that the addition of crizotinib would increase the 32 month RFS from 50% to 75% (α = 0.05; β = 0.11). **Results:** As of 1/31/2020, 34 pts had enrolled and received at least one dose of study drug with median age of 60 (range, 26-86); 41% female; and median ECOG PS 0 (range, 0-1). 2 pts could not be evaluated for the primary endpoint due to early withdrawal and loss to follow-up. The median time from primary treatment to crizotinib initiation was 60 days (range, 0-106). All pts experienced a treatment-related adverse event (AE) of any grade. 11/34 (32%) experienced a grade 3 or 4 AE, the most common being transaminase elevation (n = 8/11). 9 pts (28%) did not complete the full 48-week treatment course due to disease recurrence (n = 5) or toxicity (n = 4). An additional 5 pts required dose reduction due to hepatic toxicity or diarrhea. 15/32 evaluable pts developed distant disease relapse, with 14 developing relapse within 32 months. With a median duration of follow up of 28.7 months, the median RFS was 30.6 months (95% CI: 27.8-58.5%). The median OS was not reached. **Conclusions:** The use of adjuvant crizotinib in patients with high-risk UM did not reduce rates of relapse in this multicenter, single arm trial. 9/32 (28%) pts required dose modification or discontinuation due to AE which may have limited efficacy. Further investigations of adjuvant treatment options are warranted. Clinical trial information: NCT02223819. Research Sponsor: Pfizer Inc., Columbia University

Effect of automated TIL quantification in early-stage melanoma on accuracy of standard T staging using AJCC guidelines. *First Author: Michael Moore, Columbia University Medical Center, New York, NY*

Background: Patients diagnosed with early stage melanoma are at risk of recurrence and death. Adjuvant therapy decreases risk but incurs toxicity and expense. While tumor-infiltrating lymphocytes (TILs) improve prognosis, studies have shown conflicting results due, at least in part, to inter-observer variability. Thus, TILs are not included in standard American Joint Committee on Cancer (AJCC) staging. Here, we quantitatively analyze TILs in hematoxylin and eosin (H&E) melanoma images using two machine learning algorithms. **Methods:** H&E images were evaluated by two methods for patients with resectable stage I-III melanoma from Columbia (N = 81) and validated using samples from Geisinger and Moffitt (N = 128). For both methods, H&E images were manually annotated using open source software, QuPath, to specify tumor regions. For Method A, images were divided into patches and, for each patch, a probability was generated to detect lymphocytes. Patches above a set threshold were considered to be "TIL positive". Ratio of TIL positive patches to total patches was assessed for every image. For Method B, a classifier was manually trained in QuPath and then applied on each image to determine the ratio of the areas of all immune cells to all tumor cells as previously published. Cutoff values to define high and low risk groups were established based on a test set and then validated in an independent cohort. **Results:** Both methods distinguished patients with visceral recurrence from those without for the Columbia training set (Method A p = .0015, Method B p = .043). Using Method A, Kaplan-Meier curve at the selected cutoff also correlated significantly with disease specific survival (DSS) for Columbia (p = .022) and was validated in the Geisinger/Moffitt (p = .046) cohort. Cox analysis using Method A showed that TIL status predicted DSS in the validation set (p = .047) and added significantly to depth and ulceration (HR = 3.43, CI: 1.047-11.257, p = .042). **Conclusions:** Both open source machine learning algorithms find significantly higher TILs in patients who do not develop metastasis. Notably, Method A may add to standard predictors, such as depth and ulceration. These results demonstrate the promise of computational algorithms to enhance visual grading, and suggest that digital TIL evaluation may add to current AJCC staging. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Melanoma Research Alliance.

Multivariable Cox table for validation cohort using Method A.

	Hazard Ratio	95% CI	*P*
TIL Score	3.43	1.047 to 11.257	0.042
Depth	1.09	1.010 to 1.183	0.028
Ulceration	2.66	1.420 to 4.973	0.002

10077 Poster Session (Board #426), Fri, 8:00 AM-11:00 AM

Incidence and trends of skin cancer in the United States, 1999-2016. *First Author: Hoa Van Le, BMS, Princeton, NJ*

Background: Cutaneous skin cancer is among the most common malignancies in US. While Surveillance, Epidemiology and End Results (SEER) data are vital to estimate its incidence, delays and under-reporting remained major limitations. Surveillance is hindered due to exclusion from states' reportable diseases and possible outpatient diagnoses' omission from registries. Thus, exact incidence has not been known. This study determined skin cancer incidence and trends from 1999 to 2016 in a nationally representative sample. **Methods:** New melanoma, non-melanoma and other skin cancer cases among adults aged $\geq$20 years were identified in the National Health and Nutrition Examination Survey (NHANES), 1999-2016. Crude and age-adjusted incidences and 95% CIs were estimated by survey year cohorts (1999-2008 and 2009-2016) based on the 2000 US standard population. Sex and age-stratified longitudinal trends were examined in age and sex-adjusted regression models. Statistical analyses accounted for complex survey design with examination sample weight and adjusted for nonresponse. Sensitivity analyses included unadjusted, sex- and age- adjusted modeling. Statistical significance was determined by 2-sided *p*-value of .05. **Results:** Among 47,172 adults and 21,192 non-Hispanic whites from 1999-2016, the overall age-standardized incidences of skin cancer per 100000 persons were 390.9 (95% CI: 312-469.7) and 519 (95% CI: 413.8-624.3), respectively. The median age at first diagnosis was 72.2 (mean = 69.8, IQR = 57.5-79.5 years). The incidence was higher in men than women (474.7 vs 313.8 per 100000 persons, $p<$ .001) and increased with older age ($p<$ .001). Between 1999-2008 and 2009-2016, the incidence was significantly higher in those older than 70, 75 and 80 ($p \leq$.01). Rising incidence was also observed in overall population, women, and by approximately 90% among those older than 70. Sensitivity analyses showed similar trends. **Conclusions:** Our incidence rates for skin cancer were high, particularly in the elderly. From 1999 to 2016, the incidence increased in women and those 70 and older, a concerning observation given the aging population. As understanding susceptible groups has public health implications, our study provided an updated depiction of skin cancer incidence and trends in US. Research Sponsor: None.

Trends in incidence of skin cancer per 100000 persons among US adults 20 Years and older by sex and age group, 1999-2016.

	1999-2008	2009-2016	p for trend
Overall	299.4	491.1	0.02
Men	382.9	574.7	0.12
Women	222.9	414.0	0.03
≥ 70 y	1278.1	2424.9	$<$ 0.01
≥ 75 y	1481.2	3592.6	$<$ 0.01
≥ 80 y	2200.3	5403.2	$<$ 0.01

10078 Poster Session (Board #427), Fri, 8:00 AM-11:00 AM

Exploring the clinical efficacy of the total body skin exam. *First Author: Tanner Harding, University of Central Florida College of Medicine, Orlando, FL*

Background: The clinical efficacy of the total body skin exam has long been the subject of debate. A 2016 report by the United States Preventative Services Task Force (USPSTF) found the current body of evidence was "insufficient to assess the balance of benefits and harms of visual skin examination by a clinician to screen for skin cancer in [asymptomatic] adults.'' However, the USPSTF based its recommendations on studies evaluating mainly the ability of primary care physicians to diagnose melanoma through total body skin exams (TBSE). This study seeks to address this insufficiency in the current literature by exploring the clinical efficacy of the dermatology provider performed TBSEs as a screening tool with respect to the detection of malignant melanoma (MM), squamous cell carcinoma (SCC), and basal cell carcinoma (BCC). **Methods:** A search was performed within the electronic medical record of a large multi-state dermatology group practice for all instances of new and established patient office visits occurring from 1 January 2018 to 31 December 2019. Per practice policy, it is denoted whether each office visit includes a TBSE or partial skin exam (PSE). The number of MM, SCC, and BCC diagnoses made within the context of each class of skin exam was analyzed. **Results:** Of the 930,706 office visits analyzed, 438,027 TBSEs and 492,679 PSEs were performed. For each of the three types of skin cancer surveyed, the number of cancers diagnosed in the context of a TBSE was significantly greater than the number diagnosed in the context of a PSE. One MM was diagnosed per 161.0 TBSEs and 371.3 PSEs (X^2 ($df = 1$, $N = 930706$) = 662, $p < 0.001$). One SCC was diagnosed per 56.7 TBSEs and 108.4 PSEs (X^2 ($df = 1$, $N = 930706$) = 1258.5, $p < 0.001$). One BCC was diagnosed per 10.2 TBSEs and 17.8 PSEs (X^2 ($df = 1$, $N = 930706$) = 5884, $p < 0.001$). **Conclusions:** Skin cancer is detected at significantly higher rates in TBSEs than PSEs. The finding that one MM is detected in 161 TBSEs may be compared to one cervical cancer is detected in 3,776 Pap smears. Thus, a TBSE is 23.5 times more likely to identify a MM than a Pap smear is to identify a cervical cancer. This trend holds even when adjusted for prevalence. Further analysis will allow for the comparison of exam types with respect to patient age, staging, lesion size, and Breslow depth at time of cancer diagnosis. This continued analysis will allow for a more detailed risk benefit-analysis and insight into the clinical efficacy of the TBSE. Research Sponsor: None.

TPS10079 Poster Session (Board #428), Fri, 8:00 AM-11:00 AM

Design and rationale of MASTERKEY-115 phase II trial of talimogene laherparepvec (T-VEC) with pembrolizumab (pembro) in patients with advanced melanoma who progressed on prior anti-programmed cell death-1 (anti-PD-1) therapy. *First Author: Jason Alan Chesney, James Graham Brown Cancer Center, University of Louisville, Louisville, KY*

Background: Treatment options are limited for patients with advanced metastatic or unresectable melanoma, especially after anti-PD-1 failure. T-VEC is an intralesional oncolytic viral immunotherapy designed to selectively replicate in tumor cells and induce local and systemic antitumor response. Pembro promotes T cell activity by blocking PD-1 receptors. Combining T-VEC and pembro may produce robust antitumor activity by increasing T cell activation and blocking T cell inhibition, with a tolerable safety profile. The MASTERKEY-115 trial will evaluate safety and efficacy of T-VEC combined with pembro in patients with advanced melanoma who experienced progressive disease (PD) on prior anti-PD-1 therapy. **Methods:** NCT04068181 is a phase 2, open-label, single-arm, multicenter trial of T-VEC with pembro in patients with advanced melanoma and PD on prior anti-PD-1. The study is expected to enroll approximately 100 patients and comprises 4 cohorts. Cohorts 1 and 2 will receive anti-PD-1 in a locally recurrent or metastatic setting and experienced PD within 12 weeks of the last anti-PD-1 dose (Cohort 1: PD or stable disease prior to confirmed PD; Cohort 2: complete or partial response prior to confirmed PD). Cohorts 3 and 4 will receive adjuvant anti-PD-1 and were disease-free for $<$ 6 months (Cohort 3) or $\geq$ 6 months (Cohort 4) prior to confirmed PD. Enrollment criteria include adults with histologically confirmed unresectable or metastatic stage IIIB–IVM1d melanoma, measurable and injectable disease, ECOG PS 0-1, and prior anti-PD-1 ($\geq$ 2-3 consecutive cycles within 8 weeks, immediate prior treatment before enrollment). The primary endpoint is objective response rate per modified RECIST. Key secondary endpoints assess efficacy (objective response rate, best overall response, complete response rate, response duration, durable response rate, disease control rate, progression-free survival, overall survival), safety (incidence of treatment-emergent and treatment-related adverse events, abnormal laboratory tests), and time to subsequent anticancer therapy. The study began enrolling patients in January 2020 and enrollment is ongoing. Clinical trial information: NCT04068181. Research Sponsor: Amgen, Inc.

TPS10080 Poster Session (Board #429), Fri, 8:00 AM-11:00 AM

A phase I study of CX-4945 administered orally twice daily to patients with advanced basal cell carcinoma. *First Author: Zeynep Eroglu, Department of Cutaneous Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Smoothened inhibitors (SMOi) targeting the Hedgehog (Hh) pathway have been approved for the treatment of patients with locally advanced Basal Cell Carcinoma (laBCC) or metastatic BCC (mBCC). Unfortunately, resistance against SMO inhibitors (SMOi) can develop. Targeting the signaling cascade downstream of SMO, in this case via a novel small molecule inhibitor, could obviate this issue. Casein Kinase 2 (CK2) affects the terminal component of the Hh signaling pathway by promoting Gli2 stability and Gli2's interaction with target genes. Given the interplay between CK2 and GLI-2 and the importance of Hh signaling activation, CX-4945, a potent CK2 inhibitor, may provide benefits for the BCC patients with resistance or intolerance to SMOi. **Methods:** A phase I trial (NCT03897036) to explore various treatment durations of CX-4945 was designed for patients with laBCC or mBCC; with endpoints include safety (CTCAE v5) and objective response rate by RECIST 1.0 for mBCC and composite response for laBCC. Major eligibility criteria include progression or intolerability to SMO inhibitors; laBCC patients must not be surgical candidates and must have received prior radiation unless contraindicated, and basosquamous histology is excluded. The first phase of the trial uses a 3+3 design to test the tolerance of a CX-4945 dose of 1000 mg bid for a duration of 28 days continuously. If 2 out of 3, or 2 out of 6 patients experience a DLT, the regimen of 1000 mg bid for 21 days followed by 7 days off (already tested in prior CX-4945 Phase I trials in other tumor types) will be selected as the recommend phase 2 dose (RP2D). Upon determining the RP2D, a dose-expansion phase will further evaluateCX-4945 in two cohorts (laBCC & mBCC), with 10 patients enrolled in each. Currently, we are enrolling patients and collecting sufficient data for the determination of RP2D in this patient population; thus, further assessments are required to determine the safety, tolerability, and efficacy of CX-4945 in advanced BCC. Clinical trial information: NCT03897036. Research Sponsor: Senhwa Biosciences.

TPS10081 Poster Session (Board #430), Fri, 8:00 AM-11:00 AM

A phase II study evaluating atezolizumab (A), cobimetinib (C), and vemurafenib (V) in patients (pts) with BRAF-mutant melanoma and central nervous system (CNS) metastases (mets). *First Author: Paola Queirolo, Division of Medical Oncology for Melanoma, Sarcoma, and Rare Tumors, IEO, European Institute of Oncology IRCCS, Milan, Italy*

Background: CNS mets, a common complication of melanoma, are associated with poor survival prognosis (median of 4-5 months). The rationale for combining PD-L1 pathway blockade using atezolizumab (A) with the small molecule *BRAF* pathway–targeted inhibitors cobimetinib (C) and vemurafenib (V) for the treatment of $BRAF^{V600}$ mutation–positive melanoma is based on preclinical and translational evidence supporting the synergistic antitumoral effects of these approaches. Recently, the phase 3 IMspire150 study (NCT02908672) demonstrated improved progression-free survival outcomes with A + C + V vs C + V. **Methods:** This phase 2 study (NCT03625141) is currently evaluating A + C + V in pts with $BRAF^{V600}$ mutation–positive advanced melanoma and CNS mets. The study originally included a parallel cohort evaluating A + C in pts with $BRAF^{V600}$wild-type advanced melanoma and CNS mets. This cohort was closed at an enrollment of 15 pts after the primary analysis of the phase 3 IMspire170 study (NCT03273153), which showed no added benefit with A + C vs pembrolizumab in pts with $BRAF^{V600}$ wild-type disease. Eligible pts are aged $\geq$18 years with histologically confirmed melanoma and magnetic resonance imaging–confirmed brain mets $\geq$5 mm in at least 1 dimension. In addition, pts should not have received prior systemic treatment for metastatic disease; they were required to have ECOG performance status $\leq$2 and adequate hematologic and end organ function. Prior stereotactic or surgical therapy of $\leq$10 brain mets is allowed. The primary endpoint is intracranial objective response rate (ORR) with A + C + V in $BRAF^{V600}$mutation–positive melanoma as assessed by an independent review committee. Key secondary endpoints include investigator-assessed intracranial ORR, extracranial ORR, overall ORR, safety, and quality of life. Exploratory biomarker analyses are planned. The sample size for the cohort will be approximately 60 pts. No formal statistical hypothesis is being tested in this study. The primary study analysis and the analyses of all efficacy endpoints and safety summaries will be based on data collected $\leq$6 months after the last pt is enrolled. Clinical trial information: NCT03625141. Research Sponsor: F. Hoffmann-La Roche Ltd.

TPS10082 Poster Session (Board #431), Fri, 8:00 AM-11:00 AM

A phase II trial of nivolumab in combination with talazoparib in unresectable or metastatic melanoma patients with mutations in BRCA or BRCAness. *First Author: Tamara A. Sussman, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Melanoma has a response rate of 10-15% with anti-PD-1 re-challenge in the refractory setting. Newer targeted therapies in melanoma are needed, especially once patients progress on immune checkpoint inhibitor (ICI) therapy. Analysis of TCGA and the Cleveland Clinic's Gross Family Melanoma Registry reveals that a significant proportion (~40%) of melanoma patients possess somatic (31.6%) or germline (TCGA: 4.2%; Registry: 8.3%) mutations in homologous recombination repair genes, which may serve as a therapeutic target. PARP inhibitors, specifically talazoparib, have demonstrated synthetic lethality, potent PARP trapping activity, and increased immunogenicity of tumor cells by promoting T cell and NK cell infiltration *in vitro* and *in vivo*. Moreover, augmentation of the STING pathway via PARP inhibition modulates the tumor microenvironment, impacting PD-L1 expression and type I interferon production. Therefore, the use of talazoparib in combination with the ICI, nivolumab, may have a synergistic immunomodulatory and antitumor effect. **Methods:** This phase II, single arm, open label trial aims to enroll 37 primary or recurrent unresectable or metastatic melanoma patients harboring a somatic or germline mutation or deletion in *BRCA* or *BRCA*ness (genes including *ARID1A/B/2, ATM, ATR, BAP1, BARD1, BLM, BRCA1/2, BRIP1, CDK4/12, CHEK1/2, DSS1, EMSY, ERCC3, FANCA/D2, HDAC2, IDH1, LIG3/4, MDC1, MLH1/3, MRE11, NBN, PALB2, PRKDC, RAD50/51/54, XRCC6*) who have progressed on prior ICI therapy. Patients will be treated with nivolumab 480mg IV every 4 weeks and talazoparib 1mg PO daily. The primary objective is to determine clinical efficacy of the combination therapy, as measured by the objective response rate. The trial is designed to test the null hypothesis that ORR $\leq$ 10% and is powered to detect an effect size of ORR $\geq$ 30%. Secondary objectives include PFS, OS, immune-related objective response rate (irORR), irPFS, and treatment-related adverse events. Associations with clinical response will be assessed with correlative studies of PD-L1 expression, ctDNA, tumor mutational burden, copy number variation, and the phenotypic and functional characterization of circulating and tumor infiltrating immune cells. The study is currently open and enrolling patients. Clinical trial information: NCT04187833. Research Sponsor: Pfizer, Internal funding.

TPS10084 Poster Session (Board #433), Fri, 8:00 AM-11:00 AM

A phase III, randomized, double-blind study of adjuvant cemiplimab versus placebo post-surgery and radiation therapy (RT) in patients (pts) with high-risk cutaneous squamous cell carcinoma (CSCC). *First Author: Danny Rischin, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: CSCC is the second most common skin cancer. While the surgical cure rate for CSCC is $>$ 95%, a proportion of pts are considered to have high risk for recurrence as assessed by immune status, primary disease stage, extent of nodal involvement, presence of extracapsular extension, and prior treatment. Post-operative RT is recommended for pts with high-risk features, but relapse with locoregional recurrence or distant metastases may still occur. This study evaluates the efficacy of cemiplimab, a human anti–PD-1 monoclonal antibody, as an adjuvant therapy for pts with CSCC with high-risk features, after surgery and RT. **Methods:** This randomized, placebo-controlled, double-blind, multicenter, Phase 3 study will evaluate cemiplimab as an adjuvant treatment for pts with high-risk CSCC, based on surgical and clinicopathologic findings, who have completed surgery and post-operative RT (NCT03969004). Immunocompromised pts were excluded. The trial will enrol 412 pts from about 100 sites in North America, Europe, and Asia-Pacific regions. Pts with at least one of the following high-risk features are eligible: a) nodal disease with extracapsular extension b) in-transit metastases c) T4 lesion d) perineural invasion, and e) recurrent CSCC with at least one other risk factor. In Part 1 (blinded), pts will be randomized 1:1 to receive cemiplimab 350 mg or placebo intravenously every 3 weeks (Q3W) for up to 48 weeks. In optional Part 2 (unblinded), pts in the placebo arm who experience disease recurrence or pts in the cemiplimab arm who experience disease recurrence $\geq$3 months after completion of 48-week treatment in Part 1 will be eligible to receive open-label cemiplimab 350 mg Q3W for up to 96 weeks. Key objectives are to compare disease-free survival (primary) as well as overall survival, freedom from locoregional relapse, and distant relapse (secondary) of adjuvant cemiplimab vs placebo in pts with high-risk CSCC. This study is currently open for enrollment. Clinical trial information: NCT03969004. Research Sponsor: Regeneron Pharmaceutical, Inc. and Sanofi.

TPS10085 Poster Session (Board #434), Fri, 8:00 AM-11:00 AM

A phase II study of anti-PD1 monoclonal antibody (Nivolumab) administered in combination with anti-LAG3 monoclonal antibody (Relatlimab) in patients with metastatic melanoma naive to prior immunotherapy in the metastatic setting. *First Author: Anjali Rohatgi, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Novel checkpoint inhibitors are a promising treatment for advanced melanoma, as only a fraction of patients have durable responses to current FDA-approved immunotherapy. Lymphocyte activation gene 3 (LAG3) is an inhibitory checkpoint receptor on CD4+ and CD8+ T cells, where engagement results in suppression of T cell activation and proliferation. LAG3 and PD1 are co-expressed on T cells during T cell receptor signaling and are down-regulated after antigen clearance. Persistent stimulation leads to prolonged LAG3 and PD1 expression and to T cell exhaustion, a possible mechanism of resistance to immunotherapy. Both LAG3 and PD1 are expressed on tumor-infiltrating T cells in melanoma. Murine tumors treated with both anti-LAG3 and anti-PD1 have demonstrated increased tumor regression than tumors in mice treated with either single agent. Further, a phase I trial has demonstrated safety of combined anti-LAG3 monoclonal antibody, relatlimab and anti-PD1 monoclonal antibody, nivolumab. **Methods:** This phase II, single-center clinical trial is designed to enroll treatment naive patients with unresectable or metastatic melanoma to ultimately receive combined relatlimab and nivolumab after a lead-in arm where patients are randomized to receive relatlimab, nivolumab, or the combination for the first 4 week cycle. For the lead-in phase, patients will have baseline and post-treatment blood and tumor sampling. Disease assessment by imaging will occur after the lead-in phase at 4 weeks. After completion of the lead-in phase, all patients proceed to combination therapy with disease assessment at 12-week intervals. The primary endpoint for the lead-in phase is to evaluate changes in immune cell populations in peripheral blood and tumor with the single agents and combination treatment. The primary endpoint for the combination phase is best overall anti-tumor response. Secondary clinical endpoints include progression-free survival, overall survival, duration of response and toxicity. Exploratory endpoints are to determine the mechanistic effects of anti-LAG3 and anti-PD1 on the blood and tumor microenvironment, cytokine signatures, and correlation of these with clinical response. The study is currently accruing with enrollment of 9 out of 42 patients. Clinical trial information: NCT03743766. Research Sponsor: Bristol-Meyers-Squib.

TPS10086 Poster Session (Board #435), Fri, 8:00 AM-11:00 AM

A phase Ib study of endogenous SLC45A2-specific cytotoxic T cells for the treatment of patients with metastatic uveal melanoma. *First Author: Suzanne Phillips, MD Anderson Cancer Center, Houston, TX*

Background: Overall survival (OS) for patients (pts) with advanced uveal melanoma (UM) is poor with a median survival of approximately 12 months. Roughly half of all pts with UM will develop distant metastatic disease despite effective treatment of the primary site. Metastatic UM has a 90% prevalence of liver involvement. Currently, there are no specific FDA-approved treatments for metastatic UM and consensus guidelines recommend participation in a clinical trial. Modern treatments such as checkpoint inhibitors and targeted therapy have less impressive outcomes in UM. Our group has identified peptide epitopes of SLC45A2, a melanosomal transport protein, that is highly expressed in UM and present at very low levels in normal melanocytes. We demonstrated that cytotoxic T cells against SLC45A2 were able to kill HLA-matched UM cell lines. Through the use of enabling technologies, SLC45A2-specific cytotoxic T cells can be isolated and expanded ex-vivo from peripheral blood for use in endogenous T cell (ETC) therapy (a form of adoptive cellular therapy). These activated ETCs can then be infused to traffic to tumor sites. CTLA4 is a T-cell surface protein that binds to B7 with a higher affinity than the costimulatory receptor CD28, providing an inhibitory signal to T-cells. Anti-CTLA4 blockade can divert this inhibition and release the brake on antigen-specific T-cell activation of ETC. We hypothesize that antigen-specific ETCs infused via hepatic artery will be safe and tolerable for UM pts with liver metastasis. **Methods:** We are conducting a first-in-human clinical trial (NCT03068624) of ETC therapy targeting SLC45A2 in combination with anti-CTLA4 in pts with metastatic UM. Pts who express HLA-A*02:01 or A*24:02 undergo apheresis to collect T cells. Their cells then undergo ex vivo cloning and interleukin-21 primed expansion. Hepatic arterial infusion of ETCs will ensure direct localization to the target organ of interest. Conditioning with low-dose cyclophosphamide (300 mg/m2) occurs on Day -2. Hepatic arterial infusion of ETCs on Day 0 is followed by low dose subcutaneous interleukin-2 (IL-2) twice daily for 14 days. The initial dose escalation phase is a 3+3 design with a starting dose level of 3.3×10^9 cells/m^2 of ETCs alone. Once the maximum tolerated dose of ETCs is established, the dose expansion phase will include ETCs in combination with anti-CTLA4 (Ipilimumab). The primary objective is to evaluate the safety of this first in human T cell regimen. Secondary objectives are to evaluate the in vivo persistence and anti-tumor efficacy. Clinical trial information: NCT03068624. Research Sponsor: U.S. National Institutes of Health, Other Government Agency, NCI MD Anderson SPORE in Melanoma.

TPS10087 Poster Session (Board #436), Fri, 8:00 AM-11:00 AM

Personalized combination of neoadjuvant domatinostat, nivolumab and ipilimumab in macroscopic stage III melanoma patients stratified according to the interferon-gamma signature: The DONIMI study. *First Author: Irene L.M. Reijers, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Previous OpACIN and OpACIN-neo studies, investigating neoadjuvant ipilimumab (IPI) plus nivolumab (NIVO), demonstrated high pathologic response rates (74-78%) and favorable long-term outcomes in patients (pts) achieving pathologic response; at 36 and 18 months follow-up, respectively, only 1/71 (1.4%) pts with response has relapsed. In contrast, pts without pathologic response (pNR) have a poor prognosis; 15/23 (65.2%) have relapsed so far. This emphasizes the need for baseline biomarkers predictive of non-response and new neoadjuvant treatment combinations for these pts. In our previous studies, baseline interferon-gamma (IFN-γ) signature low pts were less likely to respond to neoadjuvant IPI plus NIVO. The DONIMI study tests the combination of NIVO +/- IPI with domatinostat (DOM), a class 1 histone deacetylase inhibitor, according to the IFN-γ signature in the tumor. Based on the signature previously described by Ayers et al. we have developed a neoadjuvant IFN-γ signature algorithm that will be used for the first time to classify pts in this prospective trial. **Methods:** The aim of this two-center investigator-initiated phase 1b study is to assess the safety and feasibility of neoadjuvant NIVO +/- DOM +/- IPI in 45 stage III melanoma pts with RECIST 1.1 measurable de-novo or recurrent disease. IFN-γ signature high pts (n = 20) will be randomized (stratified by center) to Arm A (2 cycles NIVO 240mg q3wk) or Arm B (2 cycles NIVO 240mg q3wk + DOM 200mg twice daily (BID), d1-14, q3wk). IFN-γ signature low pts (n = 25) will be randomized to Arm C (2 cycles NIVO 240mg q3wk + DOM 200mg BID, d1-14, q3wk) or Arm D (2 cycles NIVO 240mg q3wk + IPI 80mg q3wk + DOM 200mg once daily (OD), d1-14, q3wk). Based on safety data of the first 5 pts in arm D, the remaining pts will be treated with either a higher dosing scheme (200mg BID, d1-14, q3wks), a lower dosing scheme (100mg OD, d1-14, q3wks) or the same dosing scheme (200mg OD, d1-14, q3wks). The primary endpoint is safety and feasibility. A treatment arm will be declared as not feasible if 2/5 or 3/10 pts cannot adhere to the preplanned time of surgery (week 6 +/- 1week) due to treatment-related adverse events. Biopsies (week 0, 3), blood samples (week 0, 3, 6, 12) and feces (week 0, 3, 6) will be collected for translational research. The first patient was enrolled on January 23th, 2020. Clinical trial information: NCT04133948. Research Sponsor: 4SC.

TPS10088 Poster Session (Board #437), Fri, 8:00 AM-11:00 AM

A phase II study of neoadjuvant pembrolizumab and lenvatinib for resectable stage III melanoma: The neopele study. *First Author: Maria Gonzalez, Melanoma Institute Australia, North Sydney, Australia*

Background: Recent clinical trials of neoadjuvant (neo-adj) ipilimumab combined with nivolumab (OpACIN & OpACIN-neo) in resectable stage III melanoma show that a pathological response (< 50% viable tumour at the tumour bed as determined by histopathological analysis) is associated with a prolonged relapse-free survival compared to no pathological response. Furthermore, recurrences seldom occur in those who have a pathological response following neo-adj immunotherapy with only 1/71 pts (1.4%) having recurred. In contrast, 15/23 (65.2%) pts with no pathological response have relapsed to date. The NeoPeLe trial will test the hypothesis that the synergistic combination of PD-1 blockade (pembrolizumab) with anti-angiogenic/multiple RTK inhibitor (lenvatinib) will result in a high rate of pathological response in the resected surgical specimen with a low rate of toxicity. Tissue and blood biomarkers are drawn at several timepoints and correlated to clinical and pathological endpoints to explore mechanisms of response and resistance. We will compare pathological response rate, and other clinical outcomes in this study, with previously published neo-adj clinical trials to select the best schedules for larger-scale clinical testing. Across neo-adj studies, we will also analyse the tissue collected to explore determinants of the optimal therapy for individual pts, whilst minimising toxicity. **Methods:** Eligible pts with stage IIIB/C/D, resectable and measurable (RECIST 1.1) nodal metastatic melanoma will be enrolled to this phase II single-centre trial (n = 20). All pts undergo complete nodal resection (RES) at wk 6 following neo-adj therapy with pembrolizumab (200mg, IV, 3 wkly) and lenvatinib (20mg, oral, daily). Adjuvant therapy with pembrolizumab is given for 46 wks after RES. After 52 wks of the study treatment, pts will be followed for relapse and survival for 5 years. CT and FDG PET/CT are used to measure response and exclude progression in the neo-adj phase, and to monitor for recurrence during adj and post treatment phases. Blood and tumour samples are collected at baseline, day 8, RES and at relapse if feasible. Faecal samples are collected at baseline and before RES. The primary endpoint is the complete pathological response rate at RES following 6 wks of neo-adj therapy. Secondary endpoints include RECIST response, metabolic response, OS, RFS, safety/tolerability, surgical outcomes, quality of life, and biomarker analyses. Clinical trial information: NCTNCT04207086. Research Sponsor: Melanoma Institute Australia and Merck.

TPS10089 Poster Session (Board #438), Fri, 8:00 AM-11:00 AM

Phase II single-arm multi-center study of adjuvant ipilimumab in combination with nivolumab in subjects with high-risk ocular melanoma. *First Author: Suthee Rapisuwon, Georgetown University, Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Treatment of primary ocular melanoma is often very effective, with local recurrence rates of < 5%. However, distant recurrence is as high as 50% depending on features of the primary tumor. These data emphasize the need for effective adjuvant therapy for patients with locally treated ocular melanoma. Several adjuvant treatments have been developed for patients with high-risk cutaneous melanoma, including ipilimumab and nivolumab monotherapies and an ongoing trial is exploring the nivolumab/ipilimumab combination (CA209-915), but patients with high-risk ocular melanomas have been excluded from these trials. As yet there is no approved adjuvant treatment for high-risk ocular melanoma patients. **Methods:** We are conducting a Phase II single-arm multi-center study of adjuvant ipilimumab in combination with nivolumab in subjects with high-risk ocular melanoma. This study aims to generate efficacy and safety data for adjuvant this regimen in patients with locally treated high-risk ocular melanoma with 3-year risk of relapse > 50%. The primary endpoint is 3-year relapse-free survival rate. Secondary endpoints are median relapse-free survival, median overall survival, 3-year overall survival rate and safety. All patients will receive nivolumab 240mg IV every 2 weeks plus ipilimumab 1mg/kg IV every 6 weeks. Subjects may receive up to 25 doses of nivolumab and 8 doses of ipilimumab. The accrual goal is 50 patients across all participating institutions. Subjects treated in this study will be matched with controls selected from a contemporaneously collected OM registry, "contemporaneous control" in order to better assess efficacy. Control subjects will be from institutions not participating in this trial, will otherwise meet the trial eligibility criteria and will be further matched with trial participants for various demographic and risk factors to the extent possible. The study is enrolling in 6 comprehensive cancer centers in the US. Clinical trial information: NCT3528408. Research Sponsor: Bristol-Myers Squibb.

TPS10090 Poster Session (Board #439), Fri, 8:00 AM-11:00 AM

S1801: A randomized phase II trial of adjuvant versus neoadjuvant pembrolizumab (PEM) for melanoma. *First Author: Sapna Pradyuman Patel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although long term outcomes for most patients with early-stage melanoma is excellent following surgery, patients who have high-risk features such as lymph node involvement have poorer outcomes. Adjuvant therapy (AT) is currently considered for patients with stage III melanoma and selected patients with resected stage IV melanoma. Currently, AT for melanoma is anti-PD-1 or targeted therapy in the presence of a BRAF mutation. At this time we are not able to predict which patients will derive benefit from AT and experience cure. While curative surgery is the goal of early treatment of primary melanoma, some cases with bulky nodal involvement are at high risk of local or distant recurrence despite upfront surgery. Neoadjuvant treatment (NAT) offers the benefit of an early on-treatment pathological sample that can be profiled for biomarkers and correlated with survival. Treating with anti-PD1 while tumor transiently remains in the body may generate a stronger immune response from tumor-infiltrating lymphocytes against *in vivo* tumor antigens compared to the traditional adjuvant setting where antigen is presented by microscopic residual tumor burden. Pilot studies using NAT with have been initiated in melanoma. Multidisciplinary coordination in these cases is paramount. In these studies, an improvement in relapse-free survival and overall survival has been observed; additionally, pathologic response rates to NAT have been estimated in small studies. **Methods:** S1801 is a randomized phase II study of AT versus NAT with PEM (NCT03698019). Patients with measurable, clinically detectable and resectable cutaneous, acral, and mucosal melanomas without brain metastasis are eligible. Patients are randomized 1:1 to the AT or the NAT. Patients getting AT receive surgery first followed by 18 doses of PEM 200 mg IV every 3 weeks. Patients getting NAT receive 3 doses of pre-operative PEM followed by surgery and then 15 doses of adjuvant PEM. Radiation may be given on either arm after surgery, at the investigator's discretion. Primary endpoint is event-free survival measured from the date of randomization to the date of first documented progression that renders the patient unable to receive planned protocol surgery, failure to begin AT within 84 days of surgery, relapse after surgery, or death due to any cause. Safety monitoring is conducted with disease progression and toxicity thresholds. The key Translational Medicine objective of this trial is to determine the pathologic response rate to NAT with 3 doses of PEM. Enrollment is at 94 of a planned 500 patients. Clinical trial information: NCT03698019. Research Sponsor: U.S. National Institutes of Health.

10500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized phase II trial of MIBG versus MIBG/vincristine/irinotecan versus MIBG/vorinostat for relapsed/refractory neuroblastoma: A report from the New Approaches to Neuroblastoma Therapy Consortium. *First Author: Steven G. DuBois, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: ^{131}I-metaiodobenzylguanidine (MIBG) remains one of the most active agents for neuroblastoma. It is not clear if putative radiation sensitizers improve upon this activity. The primary aim of this trial was to identify the MIBG treatment regimen with highest response rate among: MIBG monotherapy (Arm A); MIBG/Vincristine/Irinotecan (Arm B); MIBG/Vorinostat (Arm C). The secondary aim was to compare toxicity across arms. **Methods:** We conducted a multicenter, randomized phase II trial. Patients 1-30 years with relapsed/refractory high-risk neuroblastoma were eligible with at least one MIBG-avid site and adequate autologous stem cells (ASCs). All patients received MIBG 18 mCi/kg on Day 1 and ASC on day 15. Patients on Arm A received only MIBG; patients on Arm B also received vincristine (2 mg/m^2) IV on Day 0 and irinotecan (50 mg/m^2) IV daily on Days 0-4; patients on Arm C also received vorinostat (180 mg/m^2) orally once daily on days -1 to 12. The primary endpoint was response after one course according to NANT response criteria. The trial was designed as a pick-the-winner study with a maximum of 105 eligible and evaluable patients to ensure an 80% chance that the arm with highest response rate is selected, if that response rate is at least 15% higher than the other arms. **Results:** 114 patients enrolled. Three patients were ineligible and 6 eligible patients never received MIBG, leaving 105 eligible and evaluable patients (36 Arm A; 35 Arm B; and 34 Arm C; 55 boys; median age 6.5 years). 9 patients had received prior MIBG monotherapy, 65 prior irinotecan, and 7 prior vorinostat. After one course, the response rates (Partial Response or better) on Arms A, B, and C were 17% (95% CI 7-33%), 14% (5-31%), and 32% (18-51%). An additional 4, 4, and 7 patients met NANT Minor Response criteria [partial response in one disease category (e.g., bone marrow) and stable disease in other categories] on Arms A, B, and C, respectively. On Arms A, B, and C, rates of any grade 3+ non-hematologic toxicity were 19%, 49% and 32%; rates of grade 3+ diarrhea were 0%, 11%, 0%; and rates of grade 3+ febrile neutropenia were 6%, 11%, and 0%. **Conclusions:** The combination of vorinostat/MIBG had the highest response rate, with manageable toxicity. Vincristine and irinotecan do not improve the response rate to MIBG and are associated with increased toxicity. These data provide response rates for MIBG monotherapy in a contemporary patient population assessed with current response criteria. Clinical trial information: NCT02035137. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

10501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized comparisons of bevacizumab (B) and irinotecan (I), added to temozolomide (T), in children with relapsed or refractory high-risk neuroblastoma (RR-HRNB): First survival results of the ITCC-SIOPEN BEACON-Neuroblastoma phase II trial. *First Author: Keith Wheatley, University of Birmingham, Birmingham, United Kingdom*

Background: BEACON is a randomized phase 2 trial assessing whether inhibiting angiogenesis with bevacizumab adds to the activity of chemotherapy and evaluating chemotherapy regimens for children with RR-HRNB. **Methods:** Patients with RR-HRNB were eligible. There were randomizations (rand), in a 3x2 factorial design, to: T, IT or topotecan (To)-T, +/- B. Toxicity and response were reported in 2019 (ASCO, ESMO). Survival outcomes – progression-free (PFS) and overall (OS) – for the I and B rands are reported here (To rand is still open). The B rand used a relaxed alpha (1-sided p=0.2) for PFS as its phase 2 success criterion; the I rand was Bayesian. Cox model hazard ratios (HR) <1.0 indicate benefit for I or B. Heterogeneity tests (HT) assessed interactions between B and I. Analysis was intention-to-treat. **Results:** From 2013-19, 160 patients were randomized to B v. no B, including 121 to I v. no I, with: median age 5.8 years; 113 and 47 measurable and evaluable disease; 67 and 93 refractory and relapsed disease; 35 had MYCN amplification. Median follow-up was 15.4 months. PFS and OS are shown in the table. In the main comparisons (I v. no I, B v. no B), I improved PFS and OS (98% probability that true HR<1.0 for both) and B just met its success criterion (PFS: 1p=0.20; OS: 1p=0.19). However, there was some, but not conclusive, evidence of a positive interaction between B and I for both PFS (HT: p=0.06) and OS (HT: p=0.12). If real, this would suggest that adding either I (IT) or B (BT) to T does not improve outcome, but adding both (BIT) does. Twice as many patients had serious adverse events with BIT (57%) than with T (26%) or IT (27%), with BT at 40%. **Conclusions:** The BEACON results show that single agent T is suboptimal. Statistical uncertainty about an interaction between I and B means two further interpretations are possible: 1) IT and possibly BT are better than T; 2) IT and BT are not better than T, but I and B together (BIT) are better. Hence, a definitive conclusion on the best combination(s) to take forward is not currently possible and further randomized evaluation is needed. Clinical trial information: ISRCTN40708286. Research Sponsor: Cancer Research UK.

PFS and OS by treatment arm.

		2-yr survival (%)

10502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Segmental chromosome aberrations and clinical response impact outcome of inss stage III patients ≥18 months with unfavorable histology and without MYCN amplification: A Children's Oncology Group (COG) report. *First Author: Navin R. Pinto, Seattle Children's Hospital, Seattle, WA*

Background: Patients with INSS stage III neuroblastoma represent a heterogeneous population with respect to disease presentation and prognosis and controversy exists regarding the most effective treatment algorithms. Patients ≥18 months of age with INSS Stage 3 tumors that are unfavorable histology (UH) and *MYCN*-non-amplified (*MYCN*-NA) represent a small cohort of patients with an outcome intermediate of those with favorable histology tumors and *MYCN* amplified tumors. The presence of Segmental Chromosome Aberrations (SCA) may predict outcome; however, their impact specifically in this cohort of patients has not been reported. **Methods:** Eligible patients enrolled on therapeutic protocols A3973 (n=34), ANBL0532 (n=27), and biology protocol ANBL00B1 (n=101 with 29 treated on A3973/ANBL0532) with stage III disease, *MYCN*–NA, UH and age ≥18 months at diagnosis were analyzed. Copy number alterations and loss of heterozygosity (LOH) for relevant loci were scored for gains/losses by two independent reviewers. **Results:** The 5-year EFS/OS for children ≥18 months with stage III, *MYCN*–NA, UH disease treated on A3973 and ANBL0532 was 73.0±8.1%/ 87.9±5.9% and 61.4±10.2%/ 73.0±9.2%, respectively, with no statistical differences in EFS or OS between the two cohorts (p=0.1286 and p=0.2180, respectively). In the combined cohort of patients enrolled on A3973 and ANBL0532, statistically significant differences were found (p(s) <0.0001) in patients with CR/VGPR (n=39) and PR (n=13) having better outcomes than <PR (n=5) (5-year EFS: 74.0±7.6% vs. 75.0±12.5% vs. 0%; 5-year OS: 84.4±6.2% vs. 100% vs. 20.0±17.9%). Subjects with chromosome 11q loss/LOH had an inferior outcome in comparison to those without 11q loss/LOH (10-year EFS: 44.4+/-24.1% vs. 78.1+/-9.4%, p=0.01; 10-year OS: 62.4+/-15.9% vs. 85.9+/-7.8%, p=0.02)). Patients with 1p loss/LOH and 2p gain also showed trend towards worse event-free survival (p=0.086 and p=0.088, not statistically significant) but not in overall survival. **Conclusions:** High-risk therapy that included single myeloablative therapy led to an 81.6±5.3%5-year OS in patients ≥18 months with UH and *MYCN*–NA stage III neuroblastoma. Response to therapy is a powerful predictor of survival and the presence of chromosome 11q loss/LOH is also associated with inferior outcomes. These patients should continue to be treated on high-risk clinical trials. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

LBA10503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

The pediatric precision oncology study INFORM: Clinical outcome and benefit for molecular subgroups. *First Author: Cornelis Martinus van Tilburg, Hopp Children's Cancer Center Heidelberg (KiTZ), German Cancer Research Center (DKFZ) and Heidelberg University Hospital, Heidelberg, Germany*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

10504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase I trial of lorlatinib in patients with ALK-driven refractory or relapsed neuroblastoma: A New Approaches to Neuroblastoma Consortium study. *First Author: Kelly C. Goldsmith, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Lorlatinib, a potent ALK inhibitor, exerts unprecedented activity against neuroblastoma (NB) derived xenografts harboring common crizotinib-resistant *ALK* mutations, leading to a first in child phase I study. **Methods:** R/R NB patients (pts) > 12 months, with *ALK* mutations/amplification and prior ALK inhibitor (ALKi) treatment were eligible. Lorlatinib was administered in 28-day courses (C). For pts < 18 years, 5 dose levels (DL) (45, 60, 75, 95, 115 mg/m^2/day) were assessed. DL5 (115 mg/m^2/day) expansion is enrolling (cohort A1). For patients > 18 years, two DL (DL3a the adult RP2D of 100 mg/day and DL4a at 150mg/day) were assessed (cohort A2). Primary endpoint was dose-limiting toxicity (DLT) during C1 and neurocognitive toxicity through C2. Blood samples for circulating tumor DNA (ctDNA) were matched to radiologic restaging. **Results:** From 9/2017 to 1/2019, 33 eligible patients enrolled (13 with prior ALKi therapy), with median age (range) 5.5 years (2-17) on A1, 21.5 years (15-50) on A2. In A1, 3 pts each enrolled onto DL1-3, with no DLT's. 5/10 pts enrolled on DL4, with no DLT's. 1/3 on DL5 had a DLT of grade 3 diarrhea, with expansion ongoing. In cohort A2, 5 patients enrolled at 100 mg/day with no DLT's; 6 enrolled at 150 mg/day, with one DLT (grade 4 reversible psychosis). Most common treatment-related adverse events were weight gain (90%, grade 1-3), hyperlipidemia (90%, grade 1-3), concentration/memory impairment (23%, grade 1-2), peripheral neuropathy (13%; grade 1-2, A2 only), and peripheral edema (10%; grade 1, A2 only). Lorlatinib steady state exposure at DL3 and DL4 was in the range of exposures seen in adult lung cancer patients at the 100 mg and 200 mg DLs. In A1, 1/18 had partial response (PR), 3/18 had minor responses (MR), and 4/18 had stable disease (SD). Of pts with MR, 2/3 had PR of soft tissue and 1/3 had complete response (CR) by MIBG. In A2 pts, 1/10 had CR, 3/10 PR, and 3/10 MR; Notably, 2/3 with PR had CR by MIBG. Of the pts with MR, one had PR and one CR by MIBG. Responses occurred across dose levels, ALK mutations, and in ALKi pre-treated pts with median courses of 2 (1-24) on A1 and 10.5 (2-28) on A2. Serial ctDNA results showed mutant *ALK* variant allele frequency trajectories that correlated with clinical response and emergence of novel *ALK* mutations in *cis* that corresponded with disease progression. **Conclusions:** Inhibition of ALK-driven NB with lorlatinib occurs with manageable toxicity and objective anti-tumor activity. Prospective ctDNA allows for monitoring of disease and evolution of resistance. Clinical trial information: NCT03107988. Research Sponsor: Pfizer.

10505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Final analysis of phase I study of ceritinib in pediatric patients with malignancies harboring activated anaplastic lymphoma kinase (ALK). *First Author: Johannes H Schulte, Charite Berlin Campus Virchow-Klinikum, Berlin, Germany*

Background: Activation of anaplastic lymphoma kinase has been detected in several pediatric malignancies, including anaplastic large-cell lymphoma (ALCL), inflammatory myofibroblastic tumor (IMT), neuroblastoma and others. Preliminary findings from this phase 1, multicenter, dose-escalation study (NCT01742286) indicated a Maximum Tolerated Dose (MTD)/Recommended Dose for Expansion (RDE) of the potent oral ALK inhibitor ceritinib to be 510 mg/m^2 (fasted) and 500 mg/m^2 (fed) in pediatric patients (pts). Here, we report final safety, pharmacokinetics (PK) and efficacy results. **Methods:** Children aged ≥1 to <18 years with advanced, mostly pretreated, ALK-aberrant malignancies were enrolled in this study. Dose escalation was conducted to determine the MTD/RDE of ceritinib (primary objective), in both fasted and fed states, following which pts entered an expansion phase to evaluate safety, tolerability, and efficacy at the MTD/RDE. Secondary objectives were evaluation of safety, PK, and efficacy (overall response rate [ORR], duration of response [DOR] and progression-free survival [PFS]). **Results:** A total of 83 pts (median age, 8 years) with *ALK*-aberrant malignancies were enrolled into dose-escalation (n = 40) and expansion (n = 43) study periods. Of these, 55 pts (neuroblastoma, n = 30; IMT, n = 10; ALCL, n = 8; others, n = 7) were treated with ceritinib at MTD/RDE (510 mg/m^2 [fasted], n = 13; 500 mg/m^2 [fed], n = 42). Systemic exposure of ceritinib between the two doses was comparable, so data were pooled for efficacy assessment. The ORRs (95% CI) were 75% (34.9-96.8) for pts with ALCL, 70% (34.8-93.3) for IMT and 20% (7.7-38.6) for neuroblastoma. The median DOR was 15 months (95% CI: 5.8, 22.2) for the 6/30 pts with neuroblastoma who had confirmed CR or PR treated at fasted/fed MTD/RDE. Median DOR was not reached for those with ALCL and IMT. Most common adverse events (AEs) (N = 83; all-grades, all-causality, ≥50% of pts): vomiting (86.7%), diarrhea (78.3%), increased ALT (65.1%), increased AST (59.0%), nausea (56.6%), and abdominal pain (50.6%). Grade 3/4 AEs were observed in 80.7% of pts (mostly transaminase elevations) and were manageable. Six pts (7.2%) were discontinued from ceritinib due to a grade 3/4 AE (mostly transaminase elevation). **Conclusions:** Substantial activity was observed with ceritinib at the RDE in pts with IMT, ALCL and heavily pretreated neuroblastoma. The toxicity profile of ceritinib in children was manageable and similar to that previously reported in adults. Clinical trial information: NCT01742286. Research Sponsor: Novartis Pharmaceuticals.

10506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Dabrafenib + trametinib combination therapy in pediatric patients with BRAF V600-mutant low-grade glioma: Safety and efficacy results. *First Author: Birgit Geoerger, Gustave Roussy Cancer Center, Université Paris-Saclay, Villejuif, France*

Background: Low-grade gliomas (LGGs) are the most common brain tumors among children. Pediatric LGGs are often not surgically resectable and tend to demonstrate relapsed/remitting courses with current standard chemotherapy regimens. Moreover, radiation is often avoided due to its associated neurocognitive and endocrinologic sequelae. However, in pediatric patients (pts) with *BRAF* V600-mutant LGG, dabrafenib monotherapy has demonstrated meaningful clinical activity and acceptable tolerability (Hargrave et al, *Clin Cancer Res.* 2019; NCT01677741). Here we report the efficacy and safety of dabrafenib + trametinib (D+T) combination therapy in pediatric pts with previously treated *BRAF* V600-mutant LGG. **Methods:** This is a 4-part, open-label, multicenter, phase I/II study (NCT02124772). The limited dose-escalation (ESC) portion evaluated the D+T combination in pediatric pts (< 18 y) with recurrent/refractory *BRAF* V600-mutated solid tumors that were naive to MAPK pathway–targeted therapy. This was followed by a tumor cohort expansion (EXP), and the D+T combination was evaluated in *BRAF* V600-mutant LGG pts at recommended dose levels. Efficacy was determined by both investigator and independent review using the RANO criteria (for gliomas). Adverse events (AEs) were assessed per NCI-CTCAE v4.03. **Results:** Overall, 36 pediatric pts with LGG received D+T combination therapy (ESC, n = 16; EXP, n = 20); pooled efficacy data were available for both ESC and EXP, while LGG-specific safety data were available for EXP. At interim analysis (Aug 2019), 17 of the 20 pts in EXP remained on protocol therapy. Three pts withdrew/discontinued treatment because of AEs. Skin toxicity (95%) and pyrexia (75%) were the frequent AEs reported. No on-treatment deaths were reported. Across both ESC and EXP, the objective response rate (ORR) was 25% (95% CI, 12%–42%) per independent review (1 complete response [CR], 8 partial response [PR], 24 stable disease [SD], 2 progressive disease [PD], 1 unknown [UNK]) and 50% (95% CI, 33%–67%) per investigator review (2 CR, 16 PR, 17 SD, 1 UNK). However, ORR + SD was similar, with 92% and 97% of pts having SD or better per independent and investigator review, respectively. **Conclusions:** In pediatric pts with pretreated *BRAF* V600-mutant LGG, D+T combination therapy demonstrated clinical activity, with 92% of pts having SD or better by independent review using the RANO criteria. Pyrexia and skin toxicity were the common AEs; majority of these were low-grade and manageable. Clinical trial information: NCT02124772. Research Sponsor: Novartis.

10507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase I study of regorafenib in combination with vincristine and irinotecan in pediatric patients with recurrent or refractory solid tumors. *First Author: Michela Casanova, Pediatric Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In pediatric patients with solid tumors, regorafenib demonstrated acceptable tolerability and preliminary anti-tumor activity. This phase 1 study evaluated regorafenib in combination with vincristine/irinotecan in pediatric patients with rhabdomyosarcoma (RMS) and other solid tumors. **Methods:** Patients with relapsed/refractory tumors received intravenous vincristine (1.5 mg/m^2, Days 1 and 8) and irinotecan (50 mg/m^2/day, Days 1–5) plus once-daily oral regorafenib (patients 6– < 24 months: 60 mg/m^2 escalating to 65 mg/m^2; patients 2– < 18 years: 72 mg/m^2 escalating to 82 mg/m^2) on either Days 1–14 (concomitant dosing) or Days 8–21 (sequential dosing) during each 21-day cycle. As per protocol, at least 50% of patients were required to have RMS. **Results:** At the time of the cut-off, of 21 treated patients (RMS, n = 12; Ewing sarcoma, n = 5; neuroblastoma, n = 3; Wilms tumor, n = 1), two had concomitant (72 mg/m^2) and 19 had sequential (72 mg/m^2, n = 6; 82 mg/m^2, n = 13) dosing. Median age was 10 years (1.5–17.0). Patients received a median of 3 cycles (1–17); dose reductions of irinotecan occurred in 62% of patients. Grade 3 dose-limiting toxicities were reported in both patients receiving concomitant dosing (peripheral neuropathy and liver injury; pain, vomiting, febrile aplasia) and one patient each in the sequential groups (rash and elevated AST; thrombocytopenia). Concomitant dosing was discontinued. The maximum tolerated dose and recommended phase 2 dose (RP2D) of regorafenib in the sequential combination was 82 mg/m^2. The most common grade ≥3 treatment-emergent adverse events were neutropenia (71%), thrombocytopenia (33%), leukopenia (29%), anemia (24%), and ALT increased (24%). The response rate was 38%, including 1 complete (RMS) and 7 partial responders (5 RMS, 2 Ewing sarcoma); 3 of whom had prior irinotecan. Six (4 with alveolar subtype) of 12 patients with RMS had a response. Nine patients (43%) had stable disease (maximum duration 17 cycles). After the cut-off, partial response was reported for two additional patients (1 RMS, 1 Ewing sarcoma). **Conclusions:** Regorafenib can be combined at its single agent RP2D of 82 mg/m^2 with standard-dose vincristine/irinotecan (with appropriate dose modifications) in pediatric patients with refractory/relapsed solid tumors in a sequential dosing schedule. Clinical activity was observed in patients with sarcoma. Clinical trial information: NCT02085148. Research Sponsor: Bayer.

10508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II study of antidisialoganglioside antibody, dinutuximab, in combination with GM-CSF in patients with recurrent osteosarcoma (AOST1421): A report from the Children's Oncology Group. *First Author: Pooja Hingorani, MD Anderson Cancer Center, Houston, TX*

Background: Treatment of patients with recurrent osteosarcoma (OS) is challenging and novel effective therapies are urgently needed. This study evaluated disease control rate (DCR) in patients with recurrent pulmonary OS, when treated with dinutuximab plus cytokine therapy as compared to a historical benchmark. The rationale for dinutuximab was the ubiquitous (> 95%) GD2 positivity in OS tumors and cell lines. **Methods:** AOST1421 was a single-arm phase 2 study. Patients with recurrent pulmonary OS in complete surgical remission were eligible. Patients received five cycles of dinutuximab 70mg/m^2/cycle with GM-CSF. Two different dinutuximab infusion schedules were used - 35mg/m^2/day over 20 hours (2-day) and 17.5mg/m^2/day over 10 hours (4-day) schedule. Primary end point was DCR, defined as proportion of patients event-free at 12 months from enrollment. Events were progressive disease or death within 12 months attributed to treatment or progression. The historical benchmark was AOST0221 with a 12-month DCR of 20% (95% CI 10-34%). Success was defined as ≥16/ 39 patients (> 40%) event-free at 12 months from enrollment. Secondary objectives included toxicity evaluation and dinutuximab pharmacokinetics (PK). **Results:** Forty-one patients were enrolled from Nov 2015 - Jan 2018. Thirty nine were eligible and evaluable (age 7-26 yr; median 15 yr). Data current to December 31, 2019 was used for analysis. Accrual rate was higher than expected (22.1 vs. 19.2 patients/ yr.) despite a concurrently open competing study. One of 136 administered therapy cycles met criteria for unacceptable toxicity when one patient receiving the 2-day schedule died after cycle 2 due to an unknown cause, attributed as probably related to protocol therapy. The protocol was revised to allow only the 4-day schedule. Other ≥ Grade 3 toxicities occurring in > 10 % participants were expected dinutuximab toxicities such as pain, diarrhea, hypoxia and hypotension. Dinutuximab did not demonstrate sufficient evidence of efficacy as 27/ 39 patients experienced an event for a DCR of 30.7% (95% CI 17- 47%). PK studies are pending and will be reported. **Conclusions:** Dinutuximab toxicity in adolescent and young adult OS patients was similar to younger patients. While GD2 remains a relevant target in OS, combination of dinutuximab with GM-CSF did not meet the targeted successful DCR in patients with completely resected tumor. Other strategies for targeting GD2 or dinituximab combination therapy may still be warranted. Clinical trial information: NCT02484443. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

10509 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Outcomes with reduced intensity therapy in a low-risk subset of children with National Cancer Institute (NCI) standard-risk (SR) B-lymphoblastic leukemia (B-ALL): A report from Children's Oncology Group (COG) AALL0932. *First Author: Reuven J. Schore, Children's National Health System and George Washington University School of Medicine and Health Sciences, Washington, DC*

Background: Post-hoc analysis of COG P9904 identified a low risk (LR) group of SR B-ALL patients aged 1-9.99 years with WBC < 50,000/μL, no CNS3, and either *ETV6/RUNX1* or double trisomies (DT) of chromosomes 4 and 10 with day 8 peripheral blood (PB) and day 29 marrow (BM) minimal residual disease (MRD) < 0.01% who had a 5-year event-free survival (EFS) of 97±2% and overall survival (OS) 98.8±0.8%. Outstanding results were also obtained for LR patients on COG AALL0331 using CCG-based ALL therapy. AALL0932 tested prospectively whether LR B-ALL patients could attain a 5-year EFS ≥95% with these regimens. **Methods:** Following a 3-drug induction, eligible AALL0932 LR patients had NCI SR B-ALL (no testicular leukemia, unfavorable genetics or Down syndrome) with DT or *ETV6/RUNX1* fusion, CNS1, no steroid pre-treatment, with Day 8 PB and Day 29 BM MRD < 0.01%. Between 2010-16, 603 LR patients were randomized to P9904-based regimen LR-M (n = 301) or CCG 1991/COG AALL0331-based regimen LR-C (n = 302). LR-M included 6 24-hour infusions of 1 gm/m^2 of methotrexate (MTX) with leucovorin rescue, but no anthracyclines or alkylating agents. Maintenance followed with daily 6-mercaptopurine (6-MP) and weekly oral MTX, and every 16 week 7-day pulses of dexamethasone (DEX) with vincristine (VCR) on days 1 and 8. Boys and girls were treated for 2.5 years from diagnosis. LR-C had no 24-hour MTX infusions, but included 2 Interim Maintenance (IM) phases with VCR and escalating IV MTX without leucovorin rescue given every 10 days for 5 doses, flanking an 8-week Delayed Intensification (DI) phase that included DEX, VCR, pegasparagase, doxorubicin (75 mg/m^2), cyclophosphamide (1 gm/m^2) and 8 doses of low-dose cytarabine (75 mg/m2/dose). LR-C Maintenance included daily 6-MP and weekly oral MTX with 5-day pulses of DEX and 1 dose of VCR given every 12 weeks. Girls received 2 years and boys 3 years of therapy from the start of IM I. **Results:** Both regimens achieved outstanding outcomes: 5-yr disease-free survival (±SE) 98.8%±0.8% for LR-M and 98.5%±0.9% for LR-C (p = 0.67). Both had 5-yr OS 100%. Therapies were well tolerated with higher rates of mucositis (12.9 vs 6.3%; p = 0.008) and allergic reactions (2.3% vs 0%; p = 0.02) on LR-C. **Conclusions:** AALL0932 demonstrated that application of stringent risk criteria can identify a favorable B-ALL subgroup almost certain to be cured with either LR-M or LR-C, allowing physicians and families to select the optimal treatment approach in the future. Clinical trial information: NCT01190930. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

10510 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Outcomes in children with Down syndrome (DS) and B-lymphoblastic leukemia (B-ALL): A Children's Oncology Group (COG) report. *First Author: Karen R. Rabin, Texas Children's Cancer Center, Houston, TX*

Background: Patients with DS and B-ALL experience increased rates of relapse and toxicities. Here, we report results from 4 COG trials (2003-2018). **Methods:** We analyzed clinical, and outcome data for DS (n = 743) and non-DS (n = 21,703) patients age 1-30 enrolled on standard-risk (SR) trials AALL0331 and AALL0932 and high-risk (HR) trials AALL0232 and AALL1131. Initially, DS-ALL patients on AALL0232/AALL0331 experienced excess mortality, prompting enhanced supportive care and omission of induction anthracycline except for slow responders on AALL1131. Other modifications included: non-random assignment to treatment strata without investigational agents; leucovorin rescue after intrathecal methotrexate (MTX); equal maintenance length for boys and girls; every 12-week maintenance vincristine/steroid pulses; and reduced anthracycline and intravenous MTX for HR patients. **Results:** Across all 4 trials, DS and non-DS patients did not differ significantly in age, sex, initial WBC, or CNS status. DS-ALL patients had significantly higher end of induction (EOI) minimal residual disease (MRD) vs non-DS patients on both AALL0932 and AALL1131, but the difference persisted at end of consolidation (EOC) only on AALL1131, with fewer EOI MRD+ DS patients achieving EOC MRD < 0.01% (76.1 vs 88.0%, p = 0.001). 5-year EFS and OS were significantly poorer for DS vs non-DS across all trials (EFS 79.6+2.1% vs 86.3+0.3%, p < 0.0001; OS 86.5+1.8% vs 93.1+0.2%, p < 0.0001), as well as on each individual trial. In Cox regression analysis for all DS patients, inferior EFS was associated with several known risk factors (age > 10, EOI MRD >0.01%) but not with cytogenetics or CRLF2 status Induction death was more frequent in DS patients (3.4% vs 0.8%, p < 0.0001) as was death in remission (4.8+0.8% vs 1.8+0.1%, p < 0.0001). For death in remission, the increased frequency occurred pre-maintenance and in patients taken off protocol therapy, but not during maintenance, in contrast to prior reports. Grade >3 mucositis, infections, and hyperglycemia were significantly more frequent in DS patients on all trials. Grade >3 seizures were significantly more frequent in DS patients on HR but not SR trials (4.1% vs 1.7%. p = 0.001) and occurred in all phases pre-maintenance. **Conclusions:** Patients with DS and B-ALL continue to have inferior outcomes compared to non-DS, with increased relapse and toxicities. Less toxic approaches such as immunotherapies and targeted therapies hold promise to improve outcomes in both these areas. Research Sponsor: U.S. National Institutes of Health.

10511 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

CD19-targeted chimeric antigen receptor (CAR) T cells in CNS relapsed acute lymphoblastic leukemia (ALL). *First Author: Haley Newman, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: CNS relapse of B-ALL is difficult to treat after cranial radiation or multiple relapses. Durable remissions of relapsed/refractory (r/r) B-ALL have been seen with CD19 CAR T cells; however, most trials excluded patients with active CNS disease. As we observed CAR trafficking into the CSF, we hypothesized that CD19 CAR T cells could control CNS B-ALL. **Methods:** We identified children and young adults with r/r CNS B-ALL treated on 4 clinical trials of CD19 CAR T cells, CTL019 or CTL119. NCT01626495 and NCT02435849 excluded active CNS disease, while the former in an amendment as well as NCT02374333 and NCT02906371 permitted active CNS disease controlled on therapy. All trials permitted CNS disease that cleared and excluded bulky intracranial disease that did not improve. We analyzed outcomes (CR, RFS) and safety. **Results:** We identified 65 patients 1-29y (median 10y) with r/r CNS B-ALL (CNS+) of 182 treated with CTL019/CTL119. There were no differences in age, sex, history of SCT or neurologic comorbidities in the CNS+ and CNS- cohorts. CNS+ patients were more likely to be in ≥2nd relapse (74% vs 46%, p < 0.01), to have received cranial radiation (58% vs 11%, p < 0.01), to have detectable CNS disease (p = 0.02) and less bone marrow disease pre-infusion (p < 0.01). At 1 mo post infusion, 62 (95%) CNS+ and 110 (94%) CNS- patients were in CR; 1 in each cohort died of sequelae of CRS and was inevaluable for response. All patients with CNS disease detected pre-infusion cleared by mo 3, including 9 in the CNS+ cohort [5 CNS2 (< 5 CSF WBC with blasts), 4 CNS3 (> 5 CSF WBC with blasts or exam/imaging evidence)] and 8 in the CNS- cohort (isolated CNS2 status pre-infusion). There was no difference in RFS (p = 0.28) in the CNS+ and CNS- cohorts [24-mo RFS: 61% (95% CI 46-73%) and 60% (95% CI 48-70%)]. There were 4 CNS relapses in the CNS+ cohort, and 1 in the CNS- cohort. Encephalopathy rate and grade was similar in the CNS+ and CNS- cohorts (52% vs 40% any grade; 12% vs 11% grade 3/4; p = 0.41). There were no deaths due to neurotoxicity (NT) and no statistically significant differences in incidence or severity of any NT or CRS in the CNS+ and CNS- cohorts. **Conclusions:** The CD19 CAR T cell therapies CTL019/CTL119 are effective at clearing CNS disease and inducing durable remissions in children and young adults with r/r CNS B-ALL. CNS relapse rates are low (< 3%). Most CD19 CAR T cell trials excluded patients with active CNS disease, primarily due to the risk of NT. We show that patients with r/r CNS B-ALL that is adequately controlled prior to infusion can be safely treated with CD19 CAR T cells, with no increased risk of NT. Clinical trial information: NCT01626495, NCT02435849, NCT02374333, NCT02906371. Research Sponsor: None.

10512 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Temsirolimus combined with etoposide and cyclophosphamide for relapsed/refractory acute lymphoblastic leukemia: Therapeutic advances in Childhood Leukemia Consortium (TACL 2014-001) trial. *First Author: Susan R. Rheingold, Children's Hospital of Philadelphia/Perelman School of Medicine, Philadelphia, PA*

Background: PI3K/mTOR signaling, a critical pathway in cell proliferation, metabolism, and apoptosis, is often dysregulated in acute lymphoblastic leukemia (ALL). A phase 1 trial of the mTOR inhibitor temsirolimus combined with etoposide and cyclophosphamide was performed in children with relapsed/refractory (r/r) ALL. **Methods:** Temsirolimus was administered intravenously (IV) on days 1 and 8 with cyclophosphamide 440 mg/m2 and etoposide 100 mg/m2 IV daily days 1-5. The starting dose level (DL) of temsirolimus was 7.5 mg/m^2 (DL1) with escalation to 10 mg/m^2 (DL2), 15 mg/m^2 (DL3), and 25 mg/m^2 (DL4). MRD was performed centrally. PI3K pathway inhibition was measured by phosphoflow cytometry (PFC) analysis of peripheral blood (PB) from treated patients (pts). **Results:** Sixteen heavily pretreated r/r ALL pts ages 2-19 years with marrow blasts $>$ 25% were enrolled; 15 were evaluable [10 B-ALL/5 T-ALL]. One dose-limiting toxicity (DLT) of grade (Gr) 4 pleural and pericardial effusions with pneumonitis/lung infection leading to Gr 5 cardiorespiratory arrest occurred in a pt treated at DL3. No further DLTs were seen in the DL3 expansion and DL4 cohorts. Gr 3/4 non-hematologic toxicities occurring in $\geq$ 3 pts included febrile neutropenia, elevated ALT, hypokalemia, mucositis, and tumor lysis syndrome and were independent of dose. Of 15 evaluable pts, 4 (27%; 2 B-ALL/2 T-ALL) had a complete response (CR) after cycle 1, comprised of 1 pt at each DL. Three had MRD $<$ 0.01%. Three pts (20%; 2 B-ALL/1 T-ALL) had partial response (PR). Overall response rate (CR+PR = ORR) was 47%. Pharmacodynamic PFC studies compared phosphoprotein levels pre (day 0) and post treatment (days 3-5) in 9 consenting pts with available PB. All tested pts showed basal activation of PI3K pathway signaling. Dose-dependent inhibition of mTOR targets phosphorylated (p) S6 and/or p4EBP1 was observed in 9/9 and 6/9 pts, respectively, following temsirolimus and chemotherapy treatment. Various patterns of compensatory upregulation of pPI3K, pmTOR, pAkt, and/or pERK was observed. **Conclusions:** Temsirolimus at 25 mg/m^2 combined with salvage etoposide and cyclophosphamide has an acceptable safety profile in high-risk pediatric patients with r/r ALL. Responses were observed at all DLs. mTOR target inhibition was achieved and appeared to correlate with dose level. Future testing of other PI3K/mTOR pathway inhibitors in combination with chemotherapy may be warranted with a goal of further increasing response in r/r ALL. Clinical trial information: NCT01614197. Research Sponsor: Pfizer IIB mechanism, Other Foundation.

10513 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Dexrazoxane and heart function among long-term childhood cancer survivors: A Children's Oncology Group study. *First Author: Eric Jessen Chow, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Dexrazoxane (DRZ) has cardioprotective effects among doxorubicin (DOX) treated childhood cancer survivors up to 5 years after therapy. However, longer-term data are lacking. **Methods:** P9404, P9425, P9426, and DFCI 95-01 were randomized trials of acute lymphoblastic leukemia and Hodgkin lymphoma, where patients were randomly assigned to DOX$\pm$DRZ. P9754 enrolled osteosarcoma patients who all received DOX+DRZ. In all studies, DRZ was given as an intravenous bolus before DOX (10:1mg ratio). DOX doses ranged from 100-600 mg/m^2 across these 5 trials. A subset of COG institutions prospectively assessed cardiac function in long-term survivors from these trials, plus a matched group of osteosarcoma survivors treated with DOX alone. Echocardiograms (left ventricular [LV] Biplane ejection fraction [EF], shortening fraction [SF]) and blood biomarkers (b-type natriuretic peptides [BNP], N-terminal [NT] proBNP) were all analyzed centrally, with DRZ status masked. Lower LV function was defined as EF$<$50% or SF$<$30%. T-test, rank-sum, and multivariate regression adjusted for sex, cancer diagnosis age, current age, DOX dose, and chest radiotherapy were used to examine differences and associations by DRZ status. **Results:** Among 173 participants assessed (52% DRZ+; 54% male; mean DOX 294$\pm$96 mg/m^2) 17.6$\pm$2.4y since cancer diagnosis, DRZ+ participants were slightly younger (27.8 vs 29.6y, p=0.02), but baseline characteristics otherwise did not differ significantly by DRZ status. DRZ status was associated with higher FS (34.7$\pm$3.6% vs 33.4$\pm$4.3%, p=0.04) and EF (63.4$\pm$5.4% vs 61.4$\pm$5.5%, p=0.01), and lower BNP (median 10.4 pg/mL [IQR 6.0-18.0] vs 13.0 [IQR 6.0-28.2], p=0.03) and NT-proBNP (median 30.8 pg/mL [IQR 18.9-58.2] vs 47.1 [IQR 23.0-83.1], p$<$0.01). In stratified analyses, the cardioprotective effects associated with DRZ tended to be more pronounced in females (vs males) and those who received DOX $\geq$300 mg/m^2 (vs $<$300mg/m^2). Results from multivariate models were similar: DRZ was associated with higher SF (1.4% [95% CI 0.2, 2.6]) and EF (2.7% [95% CI 0.8, 4.6]), and reduced BNP (-4.0 pg/mL [95% CI -7.6, -0.4]) and NT-proBNP (-20.7 pg/mL [95% CI -33.5, -7.9]). Overall, DRZ was associated with a reduced risk of having lower LV function (odds ratio 0.27 [95% CI 0.08-0.96]). **Conclusions:** After $>$17y, childhood cancer survivors treated with DOX+DRZ had better LV systolic function and less myocardial wall stress compared with those treated with DOX alone. DRZ may preferentially benefit females and those treated with greater DOX doses. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

10514 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Cardiomyopathy risk among childhood cancer survivors of African ancestry and its molecular mechanisms. *First Author: Yadav Sapkota, St. Jude Children's Research Hospital, Memphis, TN*

Background: Cardiomyopathy occurs at significantly higher rates in survivors of childhood cancer than the general population, but few studies have evaluated racial/ethnic disparities. Utilizing whole-genome sequencing data in the St. Jude Lifetime Cohort (SJLIFE), we previously identified two risk loci on chromosomes 1 (rs6689879) and 15 (rs9788776) for ejection fraction (EF) and cardiomyopathy in survivors of African ancestry. The rs6689879*C was associated with 4.2% reduction in EF and 21.6-fold risk of cardiomyopathy and the rs9788776*G was associated with 5.6% reduction in EF and 46.8-fold risk of cardiomyopathy. However, molecular mechanisms behind these genetic associations are unknown. **Methods:** We assessed the risk of clinically-assessed/graded (per the National Cancer Institute Common Terminology Criteria for Adverse Events) cardiomyopathy in childhood cancer survivors of African ancestry (n = 301) by comparing them with those of European ancestry (n = 1870), adjusting for known cardiovascular risk factors including hypertension, abnormal glucose metabolism, hypercholesteremia, hypertriglyceridemia, sedentary behavior, risky alcohol drinking and smoking. Molecular mechanisms underlying the chromosome 1 locus was investigated using DNA methylation data in 265 SJLIFE survivors of African ancestry and gene expression profiles in human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) of breast cancer patients. **Results:** Multivariable analysis showed survivors of African ancestry had 1.46-fold (P= 0.067) and 2.43-fold (P= 0.0039) higher risks of grade 2-4 and grade 3-4 cardiomyopathy. Results from DNA methylation data showed rs6689879*C was correlated with hypomethylation of a probe (cg16996019) located within the promoter region of *PHTF1* (β = -0.10; P= 0.0014). Notably, the cg16996019 was also hypomethylated in survivors with cardiomyopathy (β = -0.15; P= 0.0028). These observations were further supported by upregulation (β = 0.45; P= 0.028) of *PHTF1* in hiPSC-CMs samples derived from doxorubicin-exposed breast cancer patients with and without experiencing cardiotoxicity (n = 3 each). **Conclusions:** Childhood cancer survivors of African ancestry are at higher risk of cardiomyopathy than those of European ancestry. Dysregulation of *PHTF1* may represent the molecular mechanism underlying the rs6689879-cardiomyopathy association. These findings have potential implications for long-term cardiac surveillance as well as up front cancer care for patients of African descent. Research Sponsor: U.S. National Institutes of Health, the Leukemia and Lymphoma Society and the American Lebanese Syrian Associated Charities, Memphis, Tennessee.

10515 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Underdiagnosis and undertreament of modifiable cardiovascular risk factors: A Childhood Cancer Survivor Study (CCSS) report. *First Author: Eric Jessen Chow, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Survivors of childhood cancer exposed to cardiotoxic therapies are at increased risk of heart disease. Hypertension, dyslipidemia, and diabetes are modifiable cardiovascular risk factors (CVRFs) that synergistically increase this risk. Therefore, we aimed to determine the prevalence of and predictors associated with CVRF underdiagnosis and undertreatment in this population. **Methods:** CCSS participants at increased risk of heart disease due to prior cancer therapy were enrolled in an ongoing randomized intervention trial (NCT03104543) to improve CVRF identification and treatment. Participants completed a baseline survey (CVRF status, lifestyle habits, attitudes towards healthcare), anthropometry, and blood draw. Blood pressure, low density lipoprotein, triglyceride, glucose and Hgb A1c were measured and classified as normal/abnormal per standard clinical criteria. Multivariable logistic regression estimated odds ratios (OR [95% confidence intervals]) associated with predictors and risk of CVRF underdiagnosis and undertreatment. **Results:** As of January 2020, 522 participants (43% male) were available for analysis (47% response), with a median age 38y (range 20-65) and 28y (18-49) from original cancer treatment (75% anthracycline, 47% chest radiation). With mean measured BMI 27.3$\pm$6.5 kg/m^2, self-reported prevalence rates were hypertension 27%, dyslipidemia 33%, and diabetes 9%. While 90% of participants had a routine check-up $\leq$2y ago, 58% had a measured CVRF in the abnormal range. Specifically, among previously undiagnosed participants, we observed rates of abnormal blood pressure (26%), lipids (17%), and glucose tolerance (27%). Among those with pre-existing hypertension, dyslipidemia, and diabetes, 11%, 49%, and 54%, respectively, had measurements outside of the usual therapeutic target range. In multivariable analysis, BMI $\geq$25 kg/m^2 (vs $<$ 25) was associated with risk of underdiagnosis (OR 1.8 [1.2-2.8]). For undertreatment, significant adverse factors included older age ($>$ 35 vs $\leq$35y: OR 2.5 [1.2-5.1]), BMI $\geq$30 kg/m^2 (vs $<$ 25: OR 3.3 [1.7-6.4]), and greater perceived reliance on others for healthcare decisions (OR 1.7 [1.2-2.4]). Those with greater health-related self-efficacy were less likely to be undertreated (OR 0.5 [0.3-0.96]). **Conclusions:** CVRF underdiagnosis and undertreatment among childhood cancer survivors at increased risk of heart disease was common. Greater awareness among survivors and primary care providers and more aggressive control of CVRFs may mitigate this risk. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

10516 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Activity of front-line window therapy with temozolomide plus irinotecan in patients with primary multifocal Ewing sarcoma: ISG/AIEOP EW-2 protocol. *First Author: Asaftei Dorin Sebastian, Pediatric Onco-Hematology, A.O.U Città della Salute e della Scienza, University of Turin, Turin, Italy*

Background: The prognosis of patients with primary multifocal metastatic Ewing sarcoma (PMES) remains dismal. So far, combination with temozolomide and irinotecan (TEMIRI) was tested in patients with refractory or relapsed disease. This study evaluates the activity and the tolerability of TEMIRI as front-line treatment in PMES. **Methods:** In the study-period 2012-2018, a front-line window therapy with 2 courses TEMIRI (temozolomide 100 mg/sqm/day + irinotecan 50 mg/sqm/day for 5 days every three weeks) was introduced as amendment to the ISG/AIEOP EW-2 protocol *(EUDRACT#2009-011197-15,* Vers. 1.02*)* for patients with PMES. Main objective was to test the activity of TEMIRI evaluated by RECIST 1.1 criteria, with centralized revision of the radiological response. Secondary objectives included assessment of the toxicity profile and clinical benefit of the combination. A two-step study design by Simon was planned. **Results:** Thirty-four patients were enrolled. Median age at diagnosis was 19 years (range 3-55); males/females ratio was 2.4. Primary axial tumour was present in 24 (70%). After TEMIRI, RECIST response was as follows: partial response -20 (59%), stable disease -11 (32%), progression disease -3 (9%). After TEMIRI, amelioration in ECOG/Lansky score was achieved in 25/34 (73,5%), and reduction or disappearance of pain was observed in 31/34 patients (91%). TEMIRI toxicity was manageable: incidence of grade 3-4 nonhaematological and haematological toxicity was 3% and 3%, respectively (67/68 evaluable courses). At the time of the present analysis, 11 patients are alive; 7 of them are in complete remission and completed their treatment program (5-drug standard chemotherapy). With a median follow-up of 31 months (range 23-75), the 3-year survival estimate is 36,5%±0.09. **Conclusions:** Upfront TEMIRI x 2 courses showed an encouraging activity, with response rate 59% and deserves further evaluation combined with conventional treatments also in non-metastatic patients. In PMES new treatment strategies are urgently needed. Clinical trial information: NCT02727387. Research Sponsor: None.

10517 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Maintenance therapy with oral cyclophosphamide plus celecoxib in patients with metastatic Ewing sarcoma: Results of the Italian Sarcoma Group/AIEOP EW-2 study. *First Author: Nadia Puma, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The prognosis of patients with metastatic Ewing sarcoma remains poor. The primary aim of the ISG/AIEOP EW2 Study (EUDRACT#*2009-011197-15*) was to evaluate the feasibility and efficacy of maintenance therapy with oral cyclophosphamide plus celecoxib. **Methods:** From June 1st 2009 to Nov 22nd 2019, 112 patients with metastatic Ewing sarcoma at onset entered the ISG/AIEOP EW2 study, consisting of induction chemotherapy, radiotherapy and/or surgery at the site of the primary tumor, a consolidation phase with high-dose busulphan/melphalan + autologous stem cell rescue, whole-lung irradiation (12-15Gy), and a maintenance phase of 180 days with cyclophosphamide 50 mg daily (35 mg/mq daily if age $<$ 14 years) plus celecoxib 400 mg twice daily (250 mg/mq twice daily if age $<$ 14 years). Exclusion criteria from the maintenance phase were disease progression, cardiac or gastro-intestinal comorbidity. For CTCAE v4.0 grade 3-4 toxicities a temporary interruption was planned. **Results:** Seventy-one patients were eligible and entered the maintenance phase. Median age was 16 years (range 13-41); sites of metastases were lung or single bone (n = 56) and multicentric metastatic spread (n = 15). Sixty-one patients terminated the maintenance phase, 4 patients are still on treatment, 1 patient interrupted the treatment due to auto-immune thrombocytopenia at 4 months, 5 patients were withdrawn throughout maintenance due to disease progression/relapse. The duration of maintenance therapy was 89% of the scheduled days, with a median suspension length of 12 days (range 1-44 days). Causes of temporary suspension were hematological toxicity (19 episodes), infections (12 episodes), gastrointestinal disorders (9 episodes), fluid retention/distal oedema (3 episodes), renal disorders (3 episodes). Median follow-up was 42 months. The 3-year EFS of patients who entered the maintenance phase was 0.79 $\pm$ 0.09 for lung or single bone, and 0.19 $\pm$ 0.11 for those with multicentric metastatic spread. **Conclusions:** This schedule of maintenance phase is feasible, despite previous intensive treatment. A longer follow-up is needed to monitor side effects and to evaluate clinical outcome of patients with lung or single bone metastases, while the outcome remains dismal for multicentric metastatic Ewing sarcoma. Clinical trial information: NCT02727387. Research Sponsor: None.

Tisagenlecleucel (Tisa) for relapsed/refractory (r/r) acute lymphoblastic leukemia (ALL): B2001X study focusing on prior exposure to blinatumomab (BLINA) and inotuzumab (INO). *First Author: Joerg Krueger, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada*

Background: B2001X (NCT03123939) is a multicenter global study of tisa to provide access to patients (pts) with r/r ALL including prior anti-CD19 therapy after enrollment ended in the pivotal ELIANA (NCT02435849) study. We report clinical outcomes and cellular kinetics in B2001X including pts with prior BLINA exposure or INO as bridging therapy (BT). **Methods:** Eligible pts ≤21 y at diagnosis with ≥2 relapse, refractory or post allogeneic transplant (alloSCT) relapse were enrolled globally. **Results:** As of Nov 4, 2019, 73 pts were enrolled; 67 received tisa. 91% received lymphodepletion. Among 65 pts ≥3 mo follow up (FU) or discontinued earlier (efficacy analysis set [EAS]) median FU was 9.6 mo (range [R] 0.2-16.5). Median age 10 y (R 2-33); prior alloSCT 61%; 15 pts had prior BLINA and 9 pts had INO as BT. Efficacy is summarized in Table. 13/14 relapsed pts were medullary (isolated or combined with extramedullary [EM]) and 1 EM; 9 within 6 mo including 4/5 who were CD19(+). 64% had CRS (G 3/4 13%/15%; Penn scale); 24% had neurologic events (G 3/4 9%/2%; CTCAE v4.03). 4 deaths ≤30 d: 2 early ALL progression, 1 fatal CRS with refractory ALL, 1 infection with multiorgan failure. Transgene level in peripheral blood: limited to no in vivo expansion in nonresponders (n=8) vs responders (n=42). Median duration of persistence (T last) of tisa was 272 d (R 27-379) in responders. In pts with CR/CRi, C_{max} (geo-mean [CV%]) and median T last were 9260 (124) copies/µg DNA and 154 d (R 28-349), respectively, in pts who received INO as BT (n=6) vs 38,500 (215) and 273 d (R 27-379), respectively, in pts with no INO as BT (n=36). **Conclusions:** Outcomes in B2001X remain consistent with ELIANA. In pts with prior BLINA or INO as BT, a trend toward suboptimal outcomes was observed but should be interpreted with caution due to small n, short FU and potential confounding factors. Clinical trial information: NCT03123939. Research Sponsor: Novartis.

Efficacy summary.

10519 Poster Discussion Session; Displayed in Poster Session (Board #406), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Evaluation of CD22 modulation as a mechanism of resistance to inotuzumab ozogamicin (InO): Results from central CD22 testing on the Children's Oncology Group (COG) phase II trial of INO in children and young adults with CD22+ B-acute lymphoblastic leukemia (B-ALL). *First Author: Nirali N. Shah, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD*

Background: The COG AALL1621 phase 2 trial evaluated the efficacy of InO in children and young adults with relapsed/refractory CD22+ B-cell ALL. We report results of central surface CD22 expression on ALL and impact on response. **Methods:** Optional central CD22 testing was performed on bone marrow and/or peripheral blood at the NCI flow cytometry (FC) laboratory pre/post cycle 1. Percentage of blasts with CD22+ expression (CD22%) was measured by multiparameter FC and the BD Biosciences QuantiBRITE system quantified the CD22 site density by measuring CD22 antibody bound per cell (ABC). Comparison of ABC and CD22% between subgroups was based on Wilcoxon rank sum test or signed rank test as appropriate. Post-treatment CD22 assessments could only be performed on those with residual ALL. **Results:** Amongst 48 patients, 28 (58.3%) achieved a complete response (CR) or CR with incomplete count recovery. The median CD22 ABC, pre and post-cycle 1, was 2688 (range, 290-10715, n = 33) and 1098 (184-6822, n = 15) respectively. Amongst 27 subjects with paired pre/post samples, median pre-treatment CD22 ABC was lower in those with residual ALL (n = 13) than in those without residual ALL (ABC 1005 (290-8848) vs ABC 4123 (762-10715), p = 0.003). Baseline CD22% ranged more widely in those with residual ALL, median 99% (40-100%) vs. 99% (92.9-100%, no residual ALL) p = 0.025; and significant decreases in CD22% were seen compared to baseline in those with residual ALL, with median post-treatment CD22% 82% (1.4%-100%), p = 0.007. Amongst 3 subjects with baseline partial CD22% (40%, 79% and 83% partial CD22+ populations), post-cycle 1 evaluations revealed emergence of predominantly CD22 negative populations (6.5%, 34% and 48% CD22+, respectively), precluding eradication of minimal residual disease. Amongst those with *KMT2A* rearrangement, 2 of 4 had partial CD22 expression and 4 of 4 had low ABC ($<$ 1500). **Conclusions:** Baseline CD22 expression, specifically low CD22 ABC and partial CD22% were significantly associated with response to treatment, emerging as potential biomarkers for poor InO response. This is particularly relevant to patients with *KMT2A*rearrangement who may be predisposed to CD22 partial positivity and low ABC. Evolution of CD22 negative/dim disease post-therapy suggests CD22 modulation is a mechanism of resistance to InO. Response to InO monotherapy may be limited in those with baseline CD22 negative/dim populations. Clinical trial information: NCT02981628. Research Sponsor: Pfizer.

Comparison of chemotherapy dose intensity for AYAs on COG AALL1131 versus CALGB 10403. *First Author: Jennifer Lynn McNeer, University of Chicago, Chicago, IL*

Background: Outcomes for adolescents and young adults (AYAs) with acute lymphoblastic leukemia (ALL) are superior with pediatric-inspired therapy. CALGB 10403, the first US adult cooperative group prospective trial using a pediatric-inspired augmented BFM (ABFM)-based regimen, demonstrated feasibility and improved survival. We examined differences in drug delivery and targeted toxicities in AYAs who received the same therapy on C10403 vs the Children's Oncology Group (COG) study AALL1131. **Methods:** The proportion of AYAs receiving full dose (within 10% of protocol- specified) vincristine (VCR) and pegaspargase (PEG) during induction (IND), consolidation (CON), and delayed intensification (DI); the likelihood of selected grade ≥3 adverse events (AEs); and the impact of patient characteristics were compared in AYAs 16-30 years. Targeted AEs with analogous reporting requirements in both studies included hyperbilirubinemia, pancreatitis, sensory neuropathy, and GI/intracranial hemorrhage. Thrombosis, transaminitis and hyperglycemia were not comparably captured. Fisher's Exact test and logistic regression models were used for analyses. **Results:** After excluding AYAs removed from study after induction, 87 AALL1131 AYAs (accrued 2012-2016) and 188 C10403 AYAs (accrued 2007-2012) were analyzed with median ages of 17 (16-26) vs 22 (17-30) years, $p < 0.001$. There was no difference in the intensity of VCR delivery during IND, but in CON and DI, AALL1131 AYAs were more likely to receive all specified VCR (93.1% vs 81.9%, p = 0.02; 92.7% vs 72.1%, p = 0.01). Women were less likely to receive all specified VCR (OR 0.57, 95% CI 0.34-0.94, p = 0.03), and overweight/obese AYAs were somewhat less likely to receive all VCR compared to those considered normal weight (OR 0.88 and 0.59, p = 0.09). More C10403 AYAs were obese/overweight compared to AALL1131 AYAs (p = 0.04). There were no significant differences in dosing of PEG during IND/CON, but in DI AALL1131 AYAs were more likely to receive both doses (75.6% vs 57.1%, p = 0.03). No patient variables impacted delivery of PEG. There was no significant difference in grade ≥3 toxicities captured similarly on both studies. **Conclusions:** AYAs enrolled on AALL1131 were more likely to receive all protocol-specified VCR and PEG compared to those on C10403. Selected AE rates were comparable, suggesting that older AYAs do not tolerate doses of VCR and PEG for reasons other than toxicity, with body habitus as one potential variable. Further analyses to compare dose density, toxicities, and outcomes experienced by younger AYAs versus older are ongoing. Research Sponsor: U.S. National Institutes of Health, St. Baldrick's Foundation.

OSTPDL1: A phase II study of avelumab, a monoclonal antibody targeting programmed death-ligand 1 (PD-L1) in adolescent and young adult patients with recurrent or progressive osteosarcoma. *First Author: Michael William Bishop, St. Jude Children's Research Hospital, Memphis, TN*

Background: Outcomes for recurrent osteosarcoma are poor and novel therapies are needed. Osteosarcoma has a high mutational burden with overexpression of PD-L1 in metastatic lesions, providing a rationale for testing immune checkpoint inhibitors in this population. We therefore evaluated the activity of the PD-L1 inhibitor avelumab in patients with recurrent or progressive osteosarcoma. **Methods:** We conducted a single-arm, open-label phase 2 trial at 4 collaborating institutions. Eligible subjects were ages 12 to ≤50 years with recurrent or progressive osteosarcoma and radiographic evidence of measurable disease. Subjects received avelumab 10 mg/kg intravenously every 2 weeks of 28-day cycles until disease progression or unacceptable toxicity. Primary endpoints were objective response rate (CR + PR according to RECIST v.1.1), and progression-free survival (PFS) at 16 weeks. Kaplan-Meier methods were used to estimate PFS. Secondary endpoints included toxicity. Correlative objectives included measurement of subsets of peripheral blood mononuclear cells and serum markers of immune activation, and measures of cell proliferation, co-inhibitory receptor expression on CD8 T cells, T cell repertoire, and epigenetic programming of T cells. **Results:** Between February 2017 and October 2019, 18 eligible subjects [67% male, median age 16.8 years (12.8-22.9)] were enrolled. Subjects had received median 3 prior systemic therapies (range 1-5). Sites of disease included lung/pleura (94%), bone (56%), and soft tissue (28%). Subjects received a median of 2 cycles (range 1-4) of avelumab. Median PFS was 8 weeks (95% CI 6.7-9.1). No objective responses occurred (17 with progressive disease), and the 16-week PFS was 0%. The most common adverse events (AEs) were alanine aminotransferase (ALT) elevation (17%), aspartate aminotransferase (AST) elevation, dyspnea, hyponatremia, and pain (each 11%). Treatment-related serious AEs (≥Grade 3) included dyspnea (n = 2), ALT/ALT elevation, hyponatremia, pericardial effusion and anemia (n = 1). Immune-related AEs included pneumonitis, Hashimoto thyroiditis, and pericardial effusion (all n = 1). One patient discontinued therapy after 1 dose due to grade 4 ischemic stroke, unrelated to avelumab. One death occurred on study due to rapid disease progression. **Conclusions:** Avelumab did not demonstrate activity in recurrent osteosarcoma. Correlative biology studies are ongoing to elucidate mechanisms of resistance to this therapy. Clinical trial information: NCT03006848. Research Sponsor: Pfizer, Other Foundation, American Lebanese Syrian Associated Charities.

Outcomes and toxicities in patients (pts) non-randomly assigned to immunotherapy Children's Oncology Group (COG) ANBL0032. *First Author: Ami Vijay Desai, University of Chicago Medical Center, Chicago, IL*

Background: Immunotherapy with the anti-GD2 antibody dinutuximab plus sargramostim (GM-CSF), aldesleukin (IL-2) and isotretinoin following consolidation therapy improved outcome for high-risk neuroblastoma (HRNBL) pts enrolled on COG ANBL0032. Randomization was halted in 2009; subsequent pts were non-randomly assigned to immunotherapy. Toxicities and survival were evaluated. **Methods:** HRNBL pts < 31 years old with a pre-autologous stem cell transplant (ASCT) response of ≥ partial response (PR) were eligible. Demographics, INSS stage, tumor biology, 1993 INRC pre-ASCT response and toxicities were summarized using descriptive statistics. Five-year (yr) EFS and OS from time of study enrollment were estimated. **Results:** From 2009-2015, 1,183 pts were non-randomly assigned to immunotherapy. 96.7% (n = 1,144) were ≥18 months old and 83.1% (n = 765/921) had stage 4 disease. 45.1% (n = 363/805) of tumors with known biology were *MYCN* amplified, 94.5% (n = 749/793) had unfavorable histology, and 54.9% (n = 397/723) were diploid. Pre-ASCT, 352 (29.8%) pts had complete response (CR), 418 (35.3%) had very good partial response (VGPR), and 413 (34.9%) had PR. 1,042 (88.1%) pts underwent a single and 141 (11.9%) underwent tandem ASCT. For the entire cohort, 5-yr EFS was 61.1±1.9% and 5-yr OS was 71.9±1.7%. 5-yr EFS and OS for pts ≥18 months of age with stage 4 disease (n = 746) were 58.4±2.3% and 71.0±2.1%. 5-yr EFS and OS were 82.3±4.8% and 86.7±4.2% among pts with stage 3 disease (n = 110). EFS but not OS was superior for those with a CR/VGPR pre-ASCT vs. PR (5-yr EFS: 64.2±2.2% vs. 55.4±3.2%, p = 0.0133; OS: 72.7±2.1% vs. 70.5±2.9%, p = 0.3811). There was a trend toward improved OS for those treated with tandem vs. single transplant (5-yr EFS: 65.9±4.3% vs. 60.4±2.1%, p = 0.1282; OS: 76.5±3.8% vs. 71.2±1.9%, p = 0.0704). Grade ≥3 toxicities (> 10% of pts) during GM-CSF and IL-2-containing cycles, respectively, included pain (15.6/11.4%), fever (15.1/32.7%), anemia (18.9/21.7%), thrombocytopenia (13.9/17.4%), lymphopenia (12.3/16.0%), and hypokalemia (13.3/25.2%). Additional Grade ≥3 toxicities (> 10% of pts) included hypoxia (10.1%) during GM-CSF-containing cycles, and anaphylaxis (12.0%), neutropenia (16.1%), hyponatremia (16.5%), and hypotension (13.8%) during IL-2-containing cycles. **Conclusions:** In this large cohort of HRNBL pts treated with immunotherapy, 5-yr EFS was 61.1%. Superior EFS was observed for pts with stage 3 disease and for those with CR/VGPR pre-ASCT. IL-2-containing cycles were associated with increased toxicity. Clinical trial information: NCT00026312. Research Sponsor: U.S. National Institutes of Health.

The first report of pediatric patients with solid tumors treated with venetoclax. *First Author: Kelly C. Goldsmith, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Dependence on the prosurvival protein B-cell lymphoma 2 (BCL-2) occurs in certain pediatric solid tumors, resulting in tumorigenesis and resistance to therapies. Venetoclax (VEN), an orally administered BCL-2-selective inhibitor, has preclinical anticancer activity in human-derived neuroblastoma models. Reported here are preliminary results from pediatric patients (pts) with recurrent or refractory (R/R) solid tumors treated with VEN monotherapy or VEN with cyclophosphamide and topotecan (Cy-Topo). **Methods:** This phase 1 open-label, 2-part study (NCT03236857) enrolled pts < 25 yr old with R/R malignancies; we report only on pts with solid tumors. Following a dose ramp-up, pts received 800 mg VEN (age/weight-adjusted adult equivalent) once daily for the first 8 wk; Cy-Topo was added optionally after wk 8. Dose-limiting toxicities (DLTs) were assessed during the first 21 days of VEN therapy or cycle 1 of VEN-Cy-Topo. Objectives included safety, toxicity, and preliminary efficacy. **Results:** As of Dec 17, 2019, 11 solid tumor pts were enrolled: neuroblastoma (n = 6), rhabdomyosarcoma (n = 2), Wilms' tumor, Carney-Stratakis syndrome, and low-grade fibromyxoid sarcoma (n = 1 each). Median age was 11 yr (range 3–22); median time on study was 6.9 mo (range 1.2–17.8). All pts experienced ≥1 treatment-emergent adverse event (TEAE); vomiting (72%; all grades) was most common. Grade ≥3 TEAEs were reported in 82% of pts; febrile neutropenia (64%), decreased blood cell count, and neutropenia (36% each) were the most common. Seven pts received 800-mg monotherapy for 8 wk; 3 of these pts did not receive Cy-Topo after monotherapy. Of the 7 pts who received VEN-Cy-Topo, 3 pts received 400 mg VEN with Cy-Topo. DLTs of grade 4 neutropenia/thrombocytopenia with delayed count recovery occurred in 2 pts on 800 mg VEN-Cy-Topo, necessitating a dose de-escalation (to 400 mg VEN). Grade 4 neutropenia occurred in 2 pts on 400 mg VEN with Cy-Topo, leading to the addition of myeloid growth factor to the therapy regimen. The best response after 8 wk of VEN monotherapy was stable disease (SD). Six pts were evaluable for tumor response with VEN-Cy-Topo; 1 neuroblastoma pt had a complete response after 5 cycles of 400 mg VEN, 4 pts had SD (3 on 800 mg and 1 on 400 mg VEN) and 1 (800 mg VEN) had progressive disease as best response. **Conclusions:** Continuous dosing of VEN with Cy-Topo was not tolerated due to cytopenias in 4/7 pts with solid tumors. Discontinuous dosing of VEN with Cy-Topo is being explored. Clinical trial information: NCT03236857. Research Sponsor: AbbVie, Inc.

Phase I study of tazemetostat, an enhancer of zeste homolog-2 inhibitor, in pediatric pts with relapsed/refractory integrase interactor 1-negative tumors. *First Author: Susan N. Chi, Dana-Farber Cancer Institute, Boston, MA*

Background: Absence of integrase interactor 1 (INI1) expression is a defining molecular feature of rhabdoid tumors (RT), epithelioid sarcoma (ES), and chordomas, inducing dependence on enhancer of zeste homolog-2 (EZH2). Tazemetostat (TAZ) is a selective EZH2 inhibitor approved by the FDA for treatment of patients (pts) ≥16 yrs with metastatic or locally advanced ES ineligible for complete resection. Data from a Phase 1 (Ph1) pediatric dose-escalation study (Ph1a) of TAZ were previously reported; herein we report interim efficacy and safety from the Ph1 pediatric dose-expansion study (Ph1b). **Methods:** NCT02601937 is a Ph1, multicenter study in pts 6 months – 18 yrs evaluating TAZ administered BID at 1200 mg/m^2 in Ph1b, per Ph1a recommendation. Ph1b cohorts enrolled pts based on tumor type: Atypical teratoid RT (ATRT), RT, and other INI1-negative tumors (including ES and chordoma). The Ph1b primary endpoint was overall response rate (ORR). Secondary endpoints included safety/tolerability, duration of response (DOR), and survival. **Results:** Ph1b has enrolled 47 pts who received TAZ oral suspension. Across all tumor types, ORR was 17% (Table). Responses were observed in ATRT (4/21), chordoma (2/4), and ES (2/7); 1 pt dosed at 520mg/m^2 and 7pts at 1200mg/m^2. In the ATRT cohort, 19% of pts responded to TAZ with a median DOR of 6.5 months. The median DOR has not yet been reached in the other cohorts, with ongoing responses in 3 pts. TAZ was generally well tolerated with no drug-related deaths. Most common adverse events (AE) include vomiting, nausea, and cough. During Ph1b enrollment, 1 pt with chordoma (dosed at TAZ 900 mg/m^2 for 15 months in Ph1a) developed a secondary malignancy (T-cell lymphoblastic lymphoma). In response, the pediatric recommended Ph2 dose was revised to limit exposure in pts without CNS involvement to 520 mg/m^2 TAZ (maximum dosing of 1 yr after response, pts to go off-treatment until disease progression). **Conclusions:** Interim results indicate TAZ is generally well tolerated in children with an AE profile similar to adults. Pt enrollment in the non-ATRT, INI1-negative cohorts is ongoing. TAZ shows promising anti-tumor activity in a subset of pediatric tumors, including ATRT, chordoma, and ES. Clinical trial information: NCT02601937. Research Sponsor: Epizyme, Inc.

Phase I trial of pazopanib in combination with irinotecan and temozolomide (PAZIT) for children and young adults with advanced sarcoma. *First Author: Kieuhoa T. Vo, University of California, San Francisco, CA*

Background: Pro-angiogenic factors may represent therapeutic targets in sarcoma. Preclinical studies have demonstrated a potential additive or synergistic interaction between anti-angiogenic agents and chemotherapy. The purpose of this study was to determine the maximum tolerated dose (MTD), toxicities, pharmacokinetic (PK) and pharmacodynamics (PD) effects of PAZIT in patients with advanced sarcoma. **Methods:** Patients 6-30 years of age with relapsed/refractory sarcomas were eligible. In the initial dose escalation plan (A), patients received pazopanib PO (225-450 mg/m^2/dose) on Days 1-21 of 21-day cycles. Pazopanib was combined with fixed doses of irinotecan (IV 50 or PO 90 mg/m^2/dose) and temozolomide PO 100 mg/m^2/dose on Days 1-5. Due to DLTs, an amendment was made to the dose escalation plan (B) and patients received fixed doses of pazopanib PO (225 mg/m^2/dose) on Days 1-21 of 21-day cycles and reduced irinotecan doses (IV 25-37.5 or PO 45-67.5 mg/m^2/dose) and temozolomide PO 100 mg/m^2/dose on Days 1-5. Oral cephalosporin diarrhea prophylaxis was required. Dose escalation followed a 3+3 design. Correlative studies included PK (pazopanib, irinotecan) and PD (angiogenic factors, ctDNA) effects. **Results:** Sixteen patients were treated (median age 16 years, range 7-21). The dose levels in the table were evaluated. First cycle DLTs occurred at all dose levels (Table) and included diarrhea, pancreatitis, colitis, neutropenia, hypertension, deep vein thrombosis, and ALT increase. Due to excessive toxicity, an MTD could not be established. One patient with osteosarcoma had a partial response. Four patients had prolonged stable disease > 4 cycles, including 2 patients with Ewing sarcoma (5 and 6 cycles), rhabdomyosarcoma (9 cycles), and desmoplastic small round cell tumor (6 cycles). Mean±SD plasma exposures to pazopanib, irinotecan, and SN-38 in patients treated on dose level 1B (n = 4) on Day 4 were 601±83, 1.4±0.2 and 0.1±0.04 ug/mL*hr, respectively. Analyses of correlative studies are ongoing. **Conclusions:** Combination PAZIT therapy is not tolerable as evaluated at these doses/schedules. This study provides important toxicity data to inform future clinical trials using combination anti-angiogenic strategies in sarcoma. Clinical trial information: NCT03139331. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Dose Level (mg/m^2/dose)	# of Evaluable Patients	# of Evaluable Patients with Cycle 1 DLTs
1A: pazopanib PO 350, irinotecan IV 50 or PO 90, temozolomide PO 100	5	2
-1A: pazopanib PO 225, irinotecan IV 50 or PO 90, temozolomide PO 100	5	2
1B: pazopanib PO 225, irinotecan IV 25 or 45, temozolomide PO 100	5	2

A phase I/II study of lenvatinib (LEN) plus everolimus (EVE) in recurrent and refractory pediatric solid tumors, including CNS tumors. *First Author: Filemon S. Dela Cruz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Proangiogenic signaling pathways cooperate with mTOR-mediated regulation of cell growth and maintenance to drive development of many pediatric cancers. We report results of the phase 1 dose escalation for LEN + EVE in pediatric patients (pts) with recurrent solid and CNS tumors conducted by Children's Oncology Group. **Methods:** Dose escalation was conducted using a rolling-6 design. Pts received LEN + EVE orally once daily in continuous 28-day cycles. Dose determination was based on toxicity (CTCAE v4.03) during cycle 1. Pharmacokinetics (PK) of plasma LEN and EVE were monitored. **Results:** 17 pts were enrolled (9 male; 8 female). Median (range) age was 10 (3–21) years; 8 pts had CNS tumors. 17 were evaluable for dose-limiting toxicity (DLT). Enrollment started at dose level 1 (DL 1; LEN 11 mg/m^2 + EVE 3 mg/m^2) and, after treatment of 3 pts, was initially de-escalated to DL –1 (LEN 8 mg/m^2 + EVE 3 mg/m^2) due to DLT of proteinuria in 1 pt and self-resolving headache in another who, on review, did not meet the definition of DLT. No pts enrolled at DL –1 (n = 5) experienced DLT. Overall, DLTs were observed in 2 of the first 6 patients enrolled at DL 1: the initial pt with proteinuria and 1 more pt with hypertriglyceridemia and hypercholesteremia. Because 2 pts had reversible DLT of different categories not related to C_{max} or AUC, the DL 1 cohort was expanded to enroll an additional 6 pts, none of whom had DLT. Thus, 2/12 pts experienced DLT at DL 1. Overall, most common treatment-emergent adverse events (TEAEs; ≥ 50% of pts) were diarrhea, hypertension, hypertriglyceridemia, vomiting, abdominal pain, headache, and hypothyroidism. 47% of pts had ≥ 1 treatment-related TEAE grade ≥ 3; the most frequent was proteinuria (n = 2). On cycle 1 day 15, mean (SD) C_{max} (ng/mL) for LEN at DL –1 and DL 1, respectively, was 314 (150) and 359 (270), and mean (SD) $AUC_{0\text{-}8h}$ (hr • ng/mL) for LEN was 1570 (935) and 1780 (1100). Taking all toxicities and PK into account, no further dose escalation was recommended. Best overall response in pts with measurable disease was 2/11 stable disease, 7/11 progressive disease, and 2/11 not evaluable. **Conclusions:** The recommended phase 2 dose of LEN + EVE in children with solid and CNS tumors was LEN 11 mg/m^2 + EVE 3 mg/m^2, with maximum daily doses capped at 18 mg and 5 mg, respectively. The toxicity profile was no more than additive to single-agent therapy. PK exposure was comparable with children on single-agent LEN and to adults receiving LEN + EVE. Enrollment to the phase 2 portion (Ewing sarcoma, high-grade glioma, and rhabdomyosarcoma strata) is ongoing. Clinical trial information: NCT03245151. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co. Inc., Kenilworth, NJ, USA.

Assisted reproductive technology outcomes in childhood cancer survivors: A report from the Childhood Cancer Survivor Study. *First Author: Kimberly W. Keefe, Brigham and Women's Hospital, Boston, MA*

Background: Some treatment exposures for childhood cancer reduce ovarian reserve. Registry-based evaluation has not been conducted for assisted reproductive technology (ART) outcomes of female survivors. **Methods:** The Childhood Cancer Survivor Study, a retrospective cohort of five-year survivors and siblings, was linked to the Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SART CORS), which captures nationwide, CDC-required reporting of ART outcomes. We assessed live birth rate and relative risk (RR, 95% CI) as a function of treatment exposure, using generalized estimating equation to account for multiple ovarian stimulations per subject. **Results:** Among 9885 female survivors, 137 (1.4%; median age at diagnosis 10 years, range 0-20; 11 years of follow-up, 2-11) underwent 243 ART cycles (mean 1.8 cycles) and among 2419 siblings, 33 (1.4%) underwent 60 ART cycles (mean 1.8). Median age at autologous egg retrieval was 30 years (19-44) for survivors and 34 (24-43) for siblings. In the subset using autologous eggs (Table), 99 survivors underwent 155 ovarian stimulation cycles that resulted in 113 embryo transfers and 49 live births for a live birth rate of 32% per ovarian stimulation and 43% per transfer. Sibling live birth rate was 38% (p = 0.39 compared to survivors) per autologous ovarian stimulation and 53% (p = 0.33) per transfer. 38 survivors and 1 sibling underwent egg donor ovarian stimulation cycles. Two survivors used autologous eggs with gestational carriers and one cycle resulted in live birth. Cranial radiation therapy (RT) [RR 0.48 (0.27-0.87) p = 0.02] and pelvic RT [0.30 (0.14-0.66) p = 0.002], compared with no RT, resulted in lower RR of live birth in survivors. The likelihood of live birth after ART in survivors was not impacted by alkylator exposure [CED < 8000 mg/m2 vs. none: 1.14 (0.65-2.02); CED >8000 mg/m2 vs none: 1.07 (0.06-1.91)]. **Conclusions:** While live birth rates among survivors were lower compared with siblings, differences were not statistically significant. Pelvic and cranial RT were associated with a decreased likelihood of live birth, with no association with alkylator exposure identified. Research Sponsor: U.S. National Institutes of Health, Institutional funding from Brigham and Women's Hospital (Expanding the Boundaries Grant).

Obstetrical and perinatal complications in survivors of childhood, adolescent, and young adult cancer: A population-based study. *First Author: Alina Zgardau, University of Toronto, Toronto, ON, Canada*

Background: Women who survive cancer diagnosed in childhood, adolescence or young adulthood may develop long-term health issues. Data are lacking on adverse reproductive outcomes such as infertility and obstetrical and perinatal complications. **Methods:** Using linked Ontario provincial cancer and obstetrical registries, we assembled a cohort of female cancer survivors diagnosed before age 21 years from 1985-2012. We matched survivors by age and geographic region to females without a prior cancer diagnosis. Outcomes included i) any recognized and past 20 weeks' gestation pregnancy; ii) perinatal complications; and iii) obstetrical complications (including a broad composite of severe maternal morbidity [SMM]). Multivariable Cox proportional hazard and modified Poisson models compared survivors to a non-cancer group and assessed demographic, diagnostic and treatment risk factors in survivors. **Results:** 3,486 survivors were matched to 17,428 women without prior cancer. Median age at cancer diagnosis was 12 years (IQR 5-16) and median follow-up was 26 years (IQR 21-32). 599 (17.2%) survivors had at least one recognized pregnancy compared to 3,885 (22.3%) women without prior cancer (Hazard Ratio [HR] 0.79, 95% Confidence Interval [CI] 0.7-0.9, $p < .0001$). Among those who had a recognized pregnancy, 581 (97.0%) survivors carried a pregnancy $>$ 20 weeks' gestation vs. 3791 (97.6%) in the non-cancer group (Relative Risk [RR] 1.0, CI 0.98-1.04). Factors significantly associated with a decreased likelihood of achieving at least one recognized pregnancy among survivors included brain tumour, cranial radiation, exposure to an alkylating agent or hematopoietic stem cell transplantation (HSCT). Among women who had a livebirth or stillbirth, survivors had a RR of 2.3 (CI 1.5-3.6) for SMM and 3.2 (CI 1.6-6.6) for cardiac morbidity. Factors associated with SMM among survivors included brain tumour and pre-existing kidney disease. Among livebirth pregnancies, cancer survivors were at higher risk of preterm birth (RR 1.6, CI 1.2-2.0), especially those who received an alkylating agent or HSCT. **Conclusions:** Survivors of childhood, adolescence or young adulthood cancer are less likely to achieve a recognized pregnancy compared to women without prior cancer. Those who carry a pregnancy >20 weeks' gestation are at higher risk for SMM and preterm birth. Fertility planning and counseling can be informed by cancer diagnosis and treatment, and high-risk obstetrical care is recommended for survivors at elevated risk of an adverse pregnancy outcome. Individual prediction of non-adherence to oral mercaptopurine (6MP) in children with acute lymphoblastic leukemia (ALL): Results from COG AALL03N1 study. *First Author: Anna Lynn Hoppmann, University of Alabama at Birmingham, Birmingham, AL*

Background: Poor adherence to 6MP (measured electronically [MEMS]) increases relapse risk in children with ALL (Bhatia et al. *JAMA Oncol* 2015). Adherence is difficult to assess clinically and non-adherers are more likely to over-report 6MP intake (Landier et al. *Blood* 2017). Key sociodemographic/clinical factors (Bhatia et al. *JCO* 2012) and red cell methyl-mercaptopurine (MMP, a 6MP metabolite) levels (Hoppmann et al. ASCO 2017) are associated with non-adherence and could potentially identify non-adherers. **Methods:** We developed a prediction model for 6MP non-adherence (MEMS adherence rate $<$ 90%), using receiver operating characteristic (ROC) analyses in 407 children with ALL receiving 6MP (mean age 7.7$\pm$4.4y; 68% males; 35% Caucasians, 34% Hispanics, 16% African Americans, 15% Asians). The cohort was divided into a training set (n = 250) and test set (n = 157) using stratified random sampling (stratified by race/ethnicity, gender, age and 6MP non-adherence). We used logistic regression with backward variable elimination, guided by change in area under ROC (AUC), to create a prediction model in the training set, using only clinical and sociodemographic variables (Clinical Model). We then generated a model that added 6MP dose-intensity (6MPDI)-adjusted red cell MMP levels to the Clinical Model (Final Model). All models were validated in the test set. **Results:** Predictors retained in the Training Clinical Model included: age, race/ethnicity, absolute neutrophil count, 6MPDI, family structure, and taking 6MP at the same vs varied time of day (AUC = 0.79; 95%CI 0.72-0.85). The Training Final Model (adding 6MPDI-adjusted MMP to the Clinical Model) yielded an AUC = 0.79 (95%CI 0.72-0.86). The Test Final Model (AUC = 0.79, 95%CI 0.69-0.88) showed significantly superior discrimination compared to the Test Clinical Model (AUC = 0.74, 95%CI 0.63-0.85; P = 0.002). Using a binary classifier with predicted probability of non-adherence $\geq$0.5, the Test Final Model had an accuracy of 79%, and positive and negative predictive values of 71% and 80%, respectively. **Conclusions:** We created, validated, and compared 2 risk-prediction models for 6MP non-adherence in children undergoing maintenance chemotherapy. While inclusion of red cell MMP levels provided superior discrimination in identifying non-adherent patients, the Clinical Model (without MMP levels) performed adequately well, and could be used in the clinical setting. LAG-3 overexpression in pediatric Hodgkin lymphoma. *First Author: Scott Moerdler, Department of Pediatrics, Rutgers Cancer Institute of New Jersey, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: The role of the PD-1/PD-L1 axis in Hodgkin Lymphoma (HL) has led to FDA approval for use of inhibitors in chemotherapy-refractory HL. Numerous additional immune checkpoints may be useful targets, but have not yet been evaluated in HL. LAG-3, a related checkpoint, has been demonstrated to be overexpressed on tumor infiltrating lymphocytes (TILs) of a variety of cancers with associated poor outcomes. LAG-3 is known to inhibit T cell proliferation and activation, representing a possible therapeutic pathway for anti-tumor immunity. However, LAG-3 has yet to be evaluated in pediatric cancers. The purpose of this study is to characterize the expression pattern and clinical significance of LAG-3 in pediatric HL using immunohistochemistry. **Methods:** Patient tumor samples from prior Children's Oncology Group clinical trials (AHOD0031) with matched patient outcome data containing 200 patient samples were obtained. 95% confidence intervals were calculated based on a range of observed prevalence of immune checkpoint expression. Using immunohistochemistry, paraffin embedded samples were tested for the expression of LAG-3 and PD-L1. Samples were stained for CD30 to better delineate Reed Sternberg cells from the remainder of the tumor microenvironment. Immune checkpoint staining was compared to positive controls of normal tonsil tissue, and negative controls of 3T3 cells. Expression intensity was scored by a Pediatric Pathologist. **Results:** 115 unique HL patient cases with evaluable HL tissue and correlating clinical outcome data were analyzed. Samples from 73/115 patients (63%) demonstrated positive LAG-3 staining, defined as over 10% of TILs expressing LAG-3. No demographic data including gender, race/ethnicity, age, or stage were significantly associated with LAG-3 expression. While not statistically significant there was a numerical difference in event free survival (EFS) and patients with LAG-3 expression demonstrated worse EFS. In terms of degree of LAG-3 expression, patients with the lowest positive expression were found to have the worst EFS, and those with highest expression demonstrated the best EFS. 97% of patient cases were found to be PD-L1 positive. 71/73 (97%) of patients who expressed LAG3 were also PDL1+, and 71/106 (67%) of PDL1+ cases were also LAG3+. LAG-3 and PD-L1 were found to be independent (p = 0.09). **Conclusions:** This project is innovative in its characterization of LAG-3 as an immune checkpoint target in pediatric HL. We hope that the information from this project will be used to support new clinical trials for pediatric patients with Hodgkin lymphoma. Research Sponsor: Children's Oncology Group.

Change in cardiac function with CPX-351 in relapsed pediatric AML: A Children's Oncology Group (COG) report from AAML1421. *First Author: Kasey J. Leger, Seattle Children's Hospital, Seattle, WA*

Background: Anthracyclines (AC) are highly effective in treating acute myeloid leukemia (AML), but limited by cardiotoxicity (CTX). CPX-351, a liposomal preparation of daunorubicin (DNR) and cytarabine, may provide therapeutic benefit with less CTX. We evaluated acute changes in cardiovascular (CV) function and biomarkers after 1 cycle of CPX-351 in children with relapsed AML within the phase 1/2 study, AAML1421. **Methods:** Patients (pts) received 135 units/m^2/dose of CPX-351 on days 1, 3, and 5. Echocardiograms were centrally quantified at baseline (BL) and day 29 (end of cycle (EOC)). High sensitivity troponin (cTnT) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) were measured at BL and days 5, 8, 15, 22, and 29. Differences between BL and post-CPX-351 echo/biomarker measurements were analyzed using pre-specified Wilcoxon signed rank tests. The relationship between EOC ejection fraction (EF) and clinical variables was assessed using repeated measures linear regression. **Results:** In 32 included pts, the median AC exposure prior to study entry was 337 mg/m^2 DNR equivalents. At baseline, markers of CV function and stress were abnormal (Table). Over 1 cycle, there was a statistically significant decrease in EF and circumferential strain (Table). NT-proBNP and cTnT did not increase significantly over time. In multivariable analysis, only increasing body surface area was significantly associated with lower EOC EF (b:-5.9, 95% CI -10.8,-0.9). Cancer therapy–related cardiac dysfunction, defined as $\geq$10% decline in EF to $<$ 50%, occurred in 6/32 pts at EOC. **Conclusions:** In this single arm study of AC pre-treated children, baseline abnormalities in CV function were common. CPX-351 was associated with a statistically significant decline in CV function without a rise in cardiac biomarkers. Absent a comparator population, it is not known how these cardiac trends compare to non-liposomal AC or non-AC salvage regimens. The COG AAML1831 trial will determine if CPX-351 offers cardioprotection compared to standard AC in pts with de novo AML. Clinical trial information: NCT02642965. Research Sponsor: Seattle Children's Center for Clinical & Translational Research Clinical Research Scholar Award, Other Foundation.

Changes in CV Parameters Following CPX-351.

Parameter	Baseline (BL)	End of Cycle (EOC) Day 29	Median Change from BL at EOC	p-value

Trends in conditional survival and predictors of late death in neuroblastoma. *First Author: Hannah Olsen, Dana–Farber Cancer Institute, Boston, MA*

Background: Significant advances in the treatment of neuroblastoma have been made in the past several decades. There are scant data examining how these improvements have changed over time and differentially affected conditional survival among high- and non-high-risk patient groups. **Methods:** We conducted a retrospective cohort study using the Surveillance, Epidemiology, and End Results Database. We analyzed clinical characteristics and survival outcomes for 4717 neuroblastoma patients. Kaplan-Meier methods were used to estimate overall survival (OS) and conditional overall survival (COS) conditioned on having survived 1, 2, or 5 years from diagnosis, with estimates compared between groups using log-rank tests. **Results:** Five-year OS was 41.46% (95% CI 38.77-44.13) for the high-risk group and 91.13% (95% CI 89.49-92.53) for the non-high-risk group. Both groups saw significant improvements in OS by decade ($p<0.001$). Five-year COS among 1-year survivors was 52.69% (95% CI 38.77-44.13) for the high-risk group and 96.75% (95% CI 95.57-97.62) for the non-high-risk group. One-year survivors in the high-risk group showed a statistically significant improvement in COS over time. No difference in COS was observed among 5-year high-risk survivors. There were no statistically significant changes in COS over time for 1- and 5-year survivors in the non-high-risk group. In the high-risk and non-high-risk groups, 82% and 32% of late deaths (>5 years from diagnosis) were attributable to cancer, respectively. Statistically significant adverse prognostic factors for late death were age >1 year at diagnosis, metastatic disease, and non-thoracic primary site (p=0.001). **Conclusions:** Improvements in COS over time have largely benefited high-risk patients, though they are still at higher risk for late death due to cancer when compared to non-high-risk patients. Age, stage, and primary site, but not treatment decade, influence outcomes among 5-year survivors. Research Sponsor: U.S. National Institutes of Health, Alex's Lemonade Stand Foundation.

10535 Poster Session (Board #422), Fri, 8:00 AM-11:00 AM

A phase I/II study of eribulin mesilate (ERI) plus irinotecan (IRI) in children with refractory or recurrent solid tumors. *First Author: Michela Casanova, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: ERI is an inhibitor of microtubule dynamics. IRI is used to treat pediatric sarcomas. In the pediatric preclinical testing program, ERI was well tolerated and had promising activity compared with vincristine (a common chemotherapeutic for pediatric cancers) for various solid tumors (*in vivo* xenograft panels). **Methods:** Children with relapsed/refractory solid tumors (excluding active central nervous system tumors) were enrolled. Prior treatment with IRI was allowed. Dose escalation was conducted for 2 schedules with the primary objective (phase 1) of determining the maximum tolerated dose and the recommended phase 2 dose: (A) ERI 1.4 mg/m^2 IV infusion (Days 1 + 8 of 21-day cycle) + IRI 20 or 40 mg/m^2 IV infusion (Days 1–5 of 21-day cycle); (B) ERI 1.4 mg/m^2 IV infusion (Days 1 + 8 of 21-day cycle) + IRI 100 or 125 mg/m^2 IV infusion (Days 1 + 8 of 21-day cycle). Safety and pharmacokinetic parameters were assessed. **Results:** 13 patients (pts) were enrolled (median age: 9 years [range: 3–17]); 4 pts had rhabdomyosarcoma (RMS), 2 had non-RMS soft tissue sarcoma, 2 had Ewing sarcoma, 2 had hepatoblastoma, 2 had nephroblastoma, and 1 had neuroblastoma. Overall, 7 pts previously received IRI. No dose-limiting toxicities (DLTs) were reported for either schedule. At data cut-off (July 14, 2019), 4 pts (with Ewing sarcoma, neuroblastoma, RMS, or hepatoblastoma) continued treatment (A, n = 2; B, n = 2) and 9 pts discontinued treatment (primarily for radiographic progression, n = 7 [A, n = 4; B, n = 3]). All pts experienced ≥1 treatment-emergent adverse event (TEAE); the most common any grade TEAE was neutropenia (n = 10; A, n = 5; B, n = 5). 11 pts had grade ≥3 TEAEs (A, n = 6; B, n = 5); the most frequent grade ≥3 TEAE was neutropenia (n = 9; A, n = 5; B, n = 4). No pt withdrew ERI or IRI due to an AE; 3 pts had dose reductions for ERI (A, n = 1; B, n = 2) and 3 pts had dose interruption of ERI (A, n = 2; B, n = 1) due to AEs. No pt had dose reductions for IRI, and 3 pts had dose interruption of IRI (A, n = 2; B, n = 1) due to AEs. 3 deaths occurred; 2 deaths were the result of tumor progression (A, n = 1; B, n = 1), and the cause of 1 was unknown (B). 1 pt with neuroblastoma treated according to schedule A had a partial response. Systemic exposures of ERI, IRI, and SN-38 (IRI active metabolite) were similar between schedules and doses. **Conclusions:** No DLTs were observed. Toxicity was manageable. Administration of IRI treatment on Days 1–5 is widely used in pediatric cancers; enrollment for phase 2 is ongoing with treatment Schedule A (ERI 1.4 mg/m^2 Days 1 + 8 of 21-day cycle; IRI 40 mg/m^2 Days 1–5 of 21-day cycle). Clinical trial information: NCT03245450. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA.

10536 Poster Session (Board #423), Fri, 8:00 AM-11:00 AM

Risk factors in the HR-NBL-1/SIOPEN study in patients receiving dinutuximab beta (DB) based immunotherapy. *First Author: Ruth Lydia Ladenstein, St. Anna Children's Hospital and St. Anna Kinderkrebsforschung, Department of Paediatrics, Medical University Vienna, Vienna, Austria*

Background: We previously developed a risk factor model in HR-NBL1/SIOPEN patients treated without DB including age, LDH and metastatic site index (MSI). We tested if this score (Morgenstern, PBC 2018) would provide meaningful information in DB treated HR-NBL1/SIOPEN patients. **Methods:** High-risk patients (stage 4 ≥1yr.; stage 4 < 1yr. with MYCN amplification (MNA); stage 2, 3, 0-21y with MNA) received intensive induction, surgery, high dose therapy (HDT) and local radiotherapy (21Gy). Patients with a ≤9 months intervall till HDT/SCT, ≥ partial response prior and no progression received up to 5 cycles of 100mg/m^2 DB: as short-term (STI: 5 days) or long-term infusion (LTI: 10 days) ± 6 (STI) or 3 (LTI) x 10^6 IU/m^2 subcutaneous interleukin 2 (scIL2 over 2 x 5 days) followed by 2 weeks of 160mg/m^2 oral isotretinoin. **Results:** DB was used in 1018 patients [512 males; 89% Stage, 1% Stage 4s, 10% loc. MNA; 2.8 yrs median age at diagnosis] in 18 countries. STI was used in 61% patients, LTI in 39% and DB without scIL2 in 62% patients. 2-yrs. event-free (EFS)/overall survival (OS) was 0.65±0.02/0.78±0.01 and 5-yrs. EFS/OS of 0.56±0.02/0.63±0.02. 891/1018 patients were evaluable for risk factor analysis. EFS multivariate analysis included age, MSI, LDH ≥1250U/L, HDT typ, response prior DB, DB schedule and use of scIL2: only age > 1.5yrs.(p = 0.002) and MSI > 1 (p = 0.002) had independent prognostic prediction. If restricted to stage 4 only, LDH ≥1250U/L was also an independent factor (p = 0.049). Points were allocated in proportion to the log-cumulative hazard ratio (cHR): cHR for LDH > 1250U/L was 1.33 (score of 1), cHR for age > 5 years and metastatic site involvement (MSI) > 1 were 1.79 and 1.86 (scores of 2). Using the score (0 to 5) relevant risk groups can be identified: 5-yrs. EFS/OS for scores 0&1 are 0.80±0.06&0.77±0.04, score 2/3 are 0.58±0.03&0.57±0.04 and for scores 4/5 are 0.50±0.06&0.43±0.08. **Conclusions:** The score adds value in DB treatment groups as it differentiates prognostic subgroups facilitating decision making for future DB add on treatments. Clinical trial information: NCT01704716. Research Sponsor: EC grant No. QLRI-CT-2002-01768, Pharmaceutical/Biotech Company.

10537 Poster Session (Board #424), Fri, 8:00 AM-11:00 AM

Outcome in patients with refractory high-risk neuroblastoma. *First Author: Amir Bari Siddiqui, University of Chicago Medical Center, Chicago, IL*

Background: Outcome for high-risk neuroblastoma (HRNBL) patients (pts) with refractory disease at end of induction (EOI) is poor. The impact of therapies such as I-131-MIBG or irinotecan/temozolomide/dinutuximab (I/T/DIN) prior to autologous stem cell transplant (ASCT) on outcome is unknown. **Methods:** A multi-center, retrospective study of HRNBL pts diagnosed between 2008-2018 with refractory disease at EOI was conducted. Demographics, tumor biology, treatment response, and outcomes were abstracted. 3-year (yr) EFS and OS from time of diagnosis were estimated by the Kaplan-Meier method. **Results:** 3-yr EFS and OS were 54% and 79% for the 136 pts analyzed. 91 pts received no additional therapy prior to ASCT (Cohort 1); 32 pts received post-induction therapy prior to ASCT (Cohort 2); and 13 pts did not undergo ASCT (Cohort 3). The prevalence of metastatic disease in Cohort 1, 2, and 3 was 65%, 97%, and 85%. 3-yr EFS and OS were not statistically different between Cohort 1 (3-yr EFS and OS; 62% and 81%) and Cohort 2 [3-yr EFS and OS; 49% (p = 0.48) and 82% (p = 0.19)]. Outcome for Cohort 3 pts was significantly worse than Cohort 1 [3-yr EFS: 15% vs. 62% (p < .001); and 3-yr OS: 48% vs. 81% (p = 0.003)] and Cohort 2 [3-yr EFS: 15% vs. 49% (p < .001); and 3-yr OS 48% vs. 82% (p = 0.035)]. For Cohort 2 pts with metastatic disease, post-induction therapy included I/T/DIN (n = 12), MIBG (n = 16), MIBG plus I/T/DIN (n = 1), and other (n = 2). Metastatic disease response was observed in 10/12 (83%) pts who received I/T/DIN and 9/16 (56%) who received MIBG. MIBG plus I/T/DIN (n = 1) or MIBG with chemotherapy (n = 1) also induced response. Among the 21 pts with metastatic disease response, 3-yr EFS and OS were 69% and 94%; significantly better than Cohort 2 patients who did not respond to post-induction therapy [3-yr EFS and OS: 11% (p = 0.016) and 66% (p = 0.2)]. 6 Cohort 2 pts achieved a complete response (CR) in metastatic sites following I/T/DIN (n = 5) or MIBG (n = 1), and all are alive without relapse with median follow-up of 3.4 years (range 2.7-8.1). The single Cohort 3 patient who achieved a metastatic CR with I/T/DIN and did not undergo ASCT remains disease-free 2.4 years from diagnosis. **Conclusions:** Patient characteristics differed in the 3 Cohorts, reflecting the influence of refractory disease on treatment decisions. For Cohort 2 pts, outcome was better for those with metastatic disease at EOI who responded to post-induction therapy compared to those who did not. Pts who achieved a metastatic CR of refractory disease had excellent survival. Prospective studies testing the efficacy of I/T/DIN in pts with refractory metastatic disease at EOI are warranted. Research Sponsor: None.

10538 Poster Session (Board #425), Fri, 8:00 AM-11:00 AM

Rhabdomyosarcoma of the female genital tract: Long-term outcome and association with *DICER1* variation. *First Author: Rejin Kebudi, Istanbul University, Oncology Institute, Pediatric Hematology-Oncology, Istanbul, Turkey*

Background: Rhabdomyosarcoma (RMS) of the female genital tract is rare, accounting for 3.5% of cases of rhabdomyosarcomas. Germline *DICER1* mutations are associated with predisposition to pleuropulmonary blastoma and other tumors including sarcomas. Recently *DICER1*-associated RMS of the uterus/ovary has ben reported.. The aim of this study is to evaluate demographic characteristics, molecular pathogenesis, treatment and long term outcome of female genital tract rhabdomyosarcoma. **Methods:** Files of children with RMS of the female genital tract diagnosed at the Istanbul University, Oncology Institute during 1990-2019 were reviewed. Molecular genetic sequencing was performed by polymerase chain reaction amplification of genomic DNA extracted from the formalin-fixed, paraffin embedded tumors, followed by Sanger sequencing. Genetic testing for *DICER1* variants of the proband and family members was performed if *DICER1* mutation was detected in the tumor of the proband. **Results:** Of 210 RMS cases, 11 arose from the female genital tract. The median age at diagnosis was 52 months (10 months-15 years). Primary sites were vaginal (n = 5), uterus (n = 4), and ovary(n = 2). Presenting symptoms included vaginal mass (n = 6), vaginal bleeding (n = 5), and abdominal pain (n = 3). Four had group 1, five group 3, two group 2 disease and all received chemotherapy (vincristine, actinomycinD + cyclophosphamide).Three received radiotherapy; three underwent hysterectomy. *DICER1* mutation was detected in tumor tissue in three patients:[c.5113G > A (p.E1705K); c.5428G > T (p.D1810Y); c.1870C > T (p.Arg624Ter)] Genetic testing revealed germline *DICER1* pathogenic variation in two patients and their family members, one of whom had cystic nephroma in infancy and history of Wilms tumor in an uncle. They were referred for surveillance for the *DICER1* related diseases. A patient with metachronous bilateral ovarian RMS died. Two are married, one has children. The 5 year survival for RMS of the female genital tract was 85.7 % at a median follow-up of 34 (4-298) months. **Conclusions:** Rhabdomyosarcoma of the female genital tract is associated with a favorable prognosis, however some individuals undergo aggressive local therapies. Individuals with RMS of the female genital tract should be tested for *DICER1* pathogenic variation. The detection of a *DICER1* mutation in an individual or family members is important to facilitate surveillance for related tumors, so that they may be detected at the earliest possible stage, potentially increasing survival and decreasing risks of late effects. Research Sponsor: None.

10539 Poster Session (Board #426), Fri, 8:00 AM-11:00 AM

The role of autologous stem-cell transplantation in high-risk neuroblastoma consolidated by anti-GD2 immunotherapy: Results of 2 consecutive studies in a single referral institution. *First Author: Jaume Mora, Hospital Sant Joan de Déu de Barcelona, Barcelona, Spain*

Background: Treatment of high-risk NB within the major international cooperative groups (COG and SIOP) comprise intensive induction, consolidation with high dose chemotherapy and autologous stem cell rescue (ASCR) followed by anti-GD2 immunotherapy and isotretinoin as maintenance therapy. In the COG studies dinutuximab and cytokines (GM-CSF and IL-2) were used to treat patients in complete remission (CR) after ASCR whereas SIOPEN studies used dinutuximab-beta plus/minus IL-2 and included patients with responsive (no progression 109 days after ASCR) but refractory (skeletal metaiodobenzylguanidine positivity with three or fewer areas of abnormal uptake). **Methods:** Since December 2014, HR-NB patients referred to HSJD were eligible for consolidation with anti-GD2/GM-CSF immunotherapy in 2 consecutive studies (dinutuximab for EudraCT 2013-004864-69 and naxitamab for 017-001829-40) and naxitamab/GM-CSF compassionate use (CU) with or without prior ASCR. Patients were enrolled in 1st CR or with primary refractory bone/bone marrow (B/BM) disease. We accrued a study population of two groups whose consolidative therapy, aside from ASCR, was similar: anti-GD2 (dinutuximab or naxitamab) antibodies + GM-CSF and local radiotherapy. This is a retrospective analysis of their event-free survival (EFS) and overall survival (OS) calculated from study entry. **Results:** From Dec 14 til Dec 19, 67 study patients were treated with the COG (dinutuximab + GM-CSF+ IL-2 + RA) regimen (n = 21) in the HSJD-HRNB-Ch14.18 study or with Naxitamab and GM-CSF in the Ymabs study 201 (n = 12) or CU (n = 34). 23 patients were treated with primary refractory disease in the B/BM, and 44 in 1st CR. The 67 study patients included 13 (19%) treated following single ASCR and 54 following induction chemotherapy and surgery. Median follow-up for all surviving patients is 16.2 months. Two-year rates for ASCR and non-ASCR patients were, respectively: EFS 64% vs. 54% (p = 0.28), and OS 66.7% vs. 84% (p = 0.8). For the 44 pts in 1st CR, 2-year rates for ASCR and non-ASCR patients were, respectively: EFS 65% vs. 58% (p = 0.48), and OS 71% vs. 85% (p = 0.63). **Conclusions:** In this retrospective, single center study, ASCR did not provide survival benefit when anti-GD2 + GM-CSF based immunotherapy was used for consolidation after dose-intensive conventional chemotherapy. Research Sponsor: Ymabs Therapeutics and United Therapeutics, Institutional Funds.

10540 Poster Session (Board #427), Fri, 8:00 AM-11:00 AM

Tag-n-trak study: Preliminary analysis of an unselected biobank tumors with NTRK fusion transcript, the French SFCE society contribution. *First Author: Lauriane Lemelle, SIREDO Oncology Center (Care, Innovation and Research for Children and AYA with Cancer), Institut Curie, PSL University, Paris, France*

Background: *NTRK* (*Neurotrophic receptor tyrosine kinase)* fusion transcript was initially described in infantile fibrosarcoma (IFS) and is now known to be present in many other rare types of tumor with a lower incidence. The main objective of the study is to describe the presentation and outcome of unselected tumors with NTRK fusion transcript (NTRK-FTT) to better consider the role of TRK inhibitors (TRKi) in such entities. **Methods:** We selected patients (pts) from the Institut Curie biobank (adults and children) with NTRK-FTT and which were assessed by RT-qPCR then RNA sequencing in a prospective or retrospective process, between 2001 and 2019. **Results:** We identified 62 NTRK-FTT among 2119 screened tumors (2.2 cases/year with RT-qPCR and 6.9 cases/year with RNA seq after 2016), *NTRK3* (44 cases) (including 41 *NTRK3-ETV6*), *NTRK2* (9) or *NTRK1* (9). Most of pts had under 2 years (y) (74%) and only 7 pts were adults. We report preliminary analysis of clinical observation for the first 27 pts. Median age was 0.4 y [0-60.2]. Pathologic diagnosis was IFS (12 cases), various CNS tumors (4), atypical teratoid rhabdoid tumor (1), myofibroblastic inflammatory tumor (2), benign tumors (3), cellular congenital mesoblastic nephroma (2), lipofibromatosis like neural tumor, myxoïd liposarcoma, unclassifiable sarcoma (1 each). Two pts had metastatic tumors. Among all, 22 had surgery (1 mutilating), 15 chemotherapy, 4 radiotherapy, and 5 received TRKi, as second line treatment (2 pts) or ≥ third line (3 pts). After a median follow-up of 50 months [range, 1-155], 20/27 pts remained in complete remission, 3 had stable residue, and 4 had progressive disease (associated to 1 disease-related and 1 toxic deaths). Five-year OS is 88% [95%CI, 73.5-100] and 5y-EFS 59.5% [95%CI, 41.7-84.9]. **Conclusions:** This descriptive study showed that NTRK-FTT is rare (2.9%), encompasses a variety of different histotypes (n = 14). Systematic RNA sequencing allowed to depict 3.5 times more NTRK-FTT than targeted RT-qPCR. Overall outcome is favorable despite frequent tumor events. According to tumor type and the uncertainties regarding the long-term side effects of TRKi, the benefit/risk ratio must be carefully evaluated before using these drugs in first line. Research Sponsor: Bayer, Other Government Agency.

10541 Poster Session (Board #428), Fri, 8:00 AM-11:00 AM

A phase I study of simvastatin in combination with topotecan and cyclophosphamide in pediatric patients with relapsed and/or refractory solid and CNS tumors. *First Author: Thomas Cash, Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta; Department of Pediatrics, Emory University School of Medicine, Atlanta, GA*

Background: HMG-CoA reductase inhibitors (statins) can inhibit IL-6-mediated STAT3 activation, a critical pathway in pediatric CNS and solid tumors. Statins also inhibit tumor proliferation, angiogenesis, and restore apoptosis in preclinical pediatric solid tumor models. We therefore conducted a phase 1 trial of simvastatin in combination with topotecan and cyclophosphamide in children with relapsed/refractory (r/r) solid and CNS tumors. **Methods:** Eligible patients were 1-29 years of age with a r/r solid or CNS tumor. Simvastatin was administered orally twice daily on days 1-21, with topotecan 0.75 mg/m^2/dose IV and cyclophosphamide 250 mg/m^2/dose IV on days 1-5. Four dose levels (DLs) were planned: 140, 180, 225, 290 mg/m^2/dose. A 3+3 design was used to determine the maximum tolerated dose (MTD). Pharmacokinetic and pharmacodynamic analyses were performed. **Results:** The median (range) age of 14 eligible patients was 11.5 years (1 - 23). Diagnoses included neuroblastoma (N = 4), sarcoma (N = 7), and one each of malignant rhabdoid tumor of kidney, medulloblastoma, and Wilms tumor. Eleven DLT-evaluable patients received a median of 4 cycles (range: 1-6). There were 3 cycle 1 DLTs, grade 3 diarrhea and grade 4 creatine phosphokinase (CPK) increased at DL 1, and grade 4 CPK increased at DL 0 (100 mg/m2/dose). Grade 3/4 treatment-related cycle 1 adverse events occurring in ≥ 10% patients were neutropenia (100%), leukopenia (100%), thrombocytopenia (91%), lymphopenia (91%), anemia (55%), febrile neutropenia (55%) and CPK increased (18%). Best overall response was partial response in 1 patient and stable disease in four. Simvastatin and simvastatin acid C_{max} (geomean 82.5 and 12.6 ng/mL) and AUC_{0-6} (geomean 82.5 and 12.6 ng • h/mL) were comparable with reported pediatric literature values (C_{max} 3.5 and 0.4-2.1 ng/mL; AUC_{0-8} 10.7 and 3.8 ng • h/mL) after correction for the higher doses (3.77 vs 0.16 mg/kg) used in our study. Patient peripheral blood mononuclear cells showed maximum phospho-(p)STAT3 inhibition on Day 5, with recurrence by Day 21 despite continued simvastatin dosing. Plasma IL6 levels showed sustained IL6 inhibition with decrease to normal values by Day 21 in all patients, indicating potential on target effects. **Conclusions:** For this first-in-pediatrics trial of statins as anti-cancer therapy, the MTD of simvastatin with chemotherapy was 100 mg/m^2/dose. This combination was well-tolerated with predominantly hematologic toxicity and predictable DLTs related to simvastatin. Clinical trial information: NCT02390843. Research Sponsor: Pediatric Hematology Oncology Research Grant (PHORG), Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta.

10542 Poster Session (Board #429), Fri, 8:00 AM-11:00 AM

Phase II study of alisertib as a single agent in recurrent or progressive atypical teratoid rhabdoid tumors. *First Author: Santhosh Upadhyaya, St. Jude Children's Research Hospital, Memphis, TN*

Background: We conducted a Phase II study of alisertib, small-molecule inhibitor of Aurora A kinase, as single-agent treatment in patients < 22 y with recurrent or progressive atypical teratoid rhabdoid tumors (ATRT) (NCT02114229). **Methods:** Patients received alisertib once daily [80 mg/m^2 (enteric-coated tablets) or 60 mg/m^2 (liquid)] on Days 1–7 of a 21-day cycle for 2 y or until progressive disease (PD). Therapy was considered promising if $\geq$10 patients were without PD by MR imaging at 12 wk. Molecular groups were determined using Infinium Methylation EPIC BeadChips and the Heidelberg classifier. Alisertib plasma concentrations were measured in cycle 1, on Days 1 (single dose) and 7 (steady state) and analyzed using population-based modeling. **Results:** Data from 30 patients representing all 3 molecular groups [SHH (10/26), MYC (10/26), TYR (6/26), unknown (4/26)] was analyzed. One patient remains on therapy. The study did not meet the efficacy end point as only 8/29 patients were without PD after 12 wk, including 1 with partial response. Progression-free survival (PFS) was 31%$\pm$8.2% at 6 months and 15.8%$\pm$6.5% at 1 y. One- year overall survival (OS) was 42.1%$\pm$9.2%. One patient remained on treatment for $>$ 12 months, and another for $>$ 18 months. The median treatment duration was 44 days (range, 2–653 days). There was no difference in OS (p = 0.096) or PFS (p = 0.98) by molecular groups. Neutropenia was the most common adverse effect (77%). After single-dose alisertib, we observed higher mean maximum concentration (C_{max}) 10.1$\pm$3.0 μM and faster time to C_{max} (T_{max} = 1.2$\pm$0.7 h) in the 22 patients who received liquid formulation than those who received tablets (C_{max} = 5.7$\pm$2.4 μM, T_{max} = 3.4$\pm$1.4 h). Drug exposure did not differ between the formulations ($AUC_{0-\infty}$ = 58.6$\pm$25 h$\cdot\mu$M). Average apparent oral clearance was 2.32 L/h per m^2, which was about half that reported in adults. Serial CSF samples were collected in 2 patients; the CSF/plasma AUC ratios were 1.2%-2.7%. **Conclusions:** Although the study did not meet the efficacy end point, alisertib was well tolerated as a single agent in children with recurrent ATRT. A third of the patients demonstrated disease stabilization for $>$ 6 months. Treatment response beyond 1 y was seen in 2 patients Clinical trial information: NCT02114229. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

10543 Poster Session (Board #430), Fri, 8:00 AM-11:00 AM

Naxitamab, a new generation anti-GD2 monoclonal antibody (mAb) for treatment of relapsed/refractory high-risk neuroblastoma (HR-NB). *First Author: Jaume Mora, Pediatric Cancer Center Barcelona, Hospital Sant Joan de Déu, Barcelona, Spain*

Background: NB is a rare cancer but represents the most common extracranial solid tumor of childhood. Most HR-NB patients present with or develop metastatic disease typically in bone or bone marrow (BM). Despite advances in frontline multimodal therapy ~50% of patients relapse. Refractory or relapsed disease represents an unmet medical need. GD2 is an adhesion molecule abundantly expressed in NB. Naxitamab is a humanized anti-GD2 mAb with high receptor affinity. **Methods:** We evaluated naxitamab in HR-NB patients with disease in bone and/or BM, who were refractory to initial treatment(s) or who had insufficient response to therapy for progressive/relapsed disease. Patients were treated in an outpatient setting with naxitamab as a planned 30-minute i.v. infusion and s.c. granulocyte-macrophage colony-stimulating factor (GM-CSF). Patients received 3 infusions of naxitamab 3 mg/kg/dose during the first week of a treatment cycle repeated initially every 4 weeks. Patients were evaluated for safety (CTCAE V4.0) and efficacy (INRC, Park et al. 2017). **Results:** We report on 24 patients recruited from April 2018 with a data cut off in June 2019. At diagnosis, 21 patients were stage 4, 1 was stage 3, 2 were unknown. At study entry, 11 patients had metastases in bone, 1 in BM and 12 in both bone and BM. Overall objective response was 75% (18/24), with complete response (CR) in 67% (16/24) and partial response in 8% (2/24). Of the 13 patients with BM involvement at enrollment, 12 achieved CR in BM during trial therapy. 6 treatment-related SAEs were reported in 5 patients (anaphylactic reaction, pyrexia, and respiratory depression). **Conclusions:** Naxitamab is an anti-GD2 mAb under development for HR-NB. In addition to a high CR rate of 67% and an overall objective response rate of 75% in a high-risk patient population, naxitamab offers an unique option for treatment of patients in the outpatient setting. These data and convenience to patients are strongly supportive of further drug development. Clinical trial information: NCT03363373. Research Sponsor: Y-mAbs Therapeutics Inc.

10545 Poster Session (Board #432), Fri, 8:00 AM-11:00 AM

Deep learning for improved prediction of late-onset cardiomyopathy among childhood cancer survivors: A report from the St. Jude Lifetime Cohort (SJLIFE). *First Author: Fatma Gunturkun, University of Tennessee Health Science Center, Memphis, TN*

Background: Early identification of survivors at high risk for treatment-induced cardiomyopathy may allow for prevention and/or early intervention. We utilized deep learning methods using COG guideline-recommended baseline electrocardiography (ECG) to improve prediction of future cardiomyopathy. **Methods:** SJLIFE is a cohort of 5-year clinically assessed childhood cancer survivors including baseline ECG measurements. Development of cardiomyopathy was identified from clinical and echocardiographic measurement using CTCAE criteria (grade 3-4). We applied deep learning approaches to ECG, treatment exposure and demographic data obtained at baseline SJLIFE assessment. We trained a cascaded model combining a 12-layer 1D convolutional neural network to extract features from waveform ECG signals with a 2-layer dense neural network to embed features from other phenotypic data in tabular format to determine if use of deep learning with ECG data could improve prediction of cardiomyopathy. **Results:** Among 1,218 subjects (median age 31.7 years, range 18.4-66.4) without cardiomyopathy at baseline evaluation, 616 (51%) were male, 1,041 (85%) white, 157 (13%) African American and 792 (65%) were survivors of lymphoma/leukemia. Follow-up averaged 5 (0.5 to 9) years from baseline examination. Mean chest radiation dose was 1350 cGy (range 0 to 6,200 cGy) and mean cumulative anthracycline dose was 191 mg/m^2 (range o to 734 mg/m^2). A total of 114 (9.4%) survivors developed cardiomyopathy after baseline. A cascaded deep learning model built on a training set (N = 974 participants) classified cardiomyopathy in the test set (N = 244 participants) using both clinical and ECG data with a sensitivity of 70%, specificity of 73%, and AUC of 0.74 (95% CI 0.63-0.85), compared to a model using clinical data alone (sensitivity 61%, specificity 62%, and AUC 0.67, 95% CI 0.56-0.79). In subgroup analyses, models predicting cardiomyopathy within 0-4 years following baseline had a sensitivity, specificity, and AUC of 77%, 78%, and 0.78 (0.65-0.91), respectively. When predicting cardiomyopathy 5-9 years following baseline, model performance dropped to a sensitivity, specificity, and AUC of 70%, 70%, and 0.68 (0.50-0.87), respectively. **Conclusions:** Deep learning using ECG at baseline evaluation significantly improved prediction of cardiomyopathy in childhood cancer survivors at high risk for cardiomyopathy. Future directions will incorporate deep learning approaches to echocardiography to further improve prediction. Research Sponsor: None.

10546 Poster Session (Board #433), Fri, 8:00 AM-11:00 AM

Neuromuscular dysfunction and associated health/socioeconomic outcomes: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Rozalyn L Rodwin, Yale School of Medicine, New Haven, CT*

Background: Childhood cancer survivors are at risk for neuromuscular dysfunction. We estimated the prevalence and cumulative incidence of neuromuscular dysfunction in a cohort of childhood cancer survivors and examined associations with treatment exposures and health/socioeconomic outcomes. **Methods:** CCSS participants $\geq$5 years from cancer diagnosed between 1970-1999 (n = 25,583, 46.5% female, median [range] age 54.4 [15.1-57.6] years) and siblings (n = 5,044, 52.3% female, median [range] age 54.1 [32.5-57.0] years) were included. Neuromuscular dysfunction was identified by self-report of 1) motor dysfunction: impaired balance, tremor, or extremity weakness; 2) sensory dysfunction: impaired touch sensation. Multivariable analyses examined predictors of dysfunction by diagnosis. **Results:** Cumulative incidence of neuromuscular dysfunction was elevated at 20 years from diagnosis in survivors (24.3%, 95% CI 23.8-24.8; motor 18.2%, sensory 13.5%) versus siblings (8.9%, 95% CI 8.1-9.7). In survivors five years from diagnosis, motor dysfunction was associated with exposure to cytarabine (OR = 1.39, 95% CI 1.10-1.77) and spinal radiation (OR = 2.11, 95% CI 1.31-3.41) in acute lymphoblastic leukemia/non-hodgkin lymphoma (ALL/NHL), vinca alkaloids (OR 1.29, 95% CI 1.03-1.60) and brain radiation (OR = 1.58, 95% CI 1.35-1.85) in central nervous system tumors, and cytarabine (OR = 3.73, 95% CI 1.62-8.57) and non-brain/spine radiation (OR = 1.84, 95% CI 1.42-2.40) in bone/soft tissue tumors. Sensory dysfunction was associated with exposure to vinca alkaloids (OR = 3.45, 95% CI 1.06-11.22) in ALL/NHL, and platinum agents (OR = 1.31, 95% CI 1.03-1.67) and spinal radiation (OR = 3.71, 95% CI 1.24-11.11) in bone/soft tissue tumors. Survivors with neuromuscular dysfunction were at increased risk for adverse health/socioeconomic outcomes (Table). **Conclusions:** Neuromuscular dysfunction is a prevalent morbidity in childhood cancer survivors, associated with specific therapies within a particular diagnosis. Interventions are needed to identify and improve neuromuscular dysfunction given its association with adverse health/socioeconomic outcomes. Research Sponsor: None.

Health/socioeconomic outcomes in survivors with neuromuscular dysfunction compared with those without dysfunction.

Emotional distress, stress, and cardiovascular health in adult survivors of childhood cancer. *First Author: Margaret M. Lubas, St. Jude Children's Research Hospital, Memphis, TN*

Background: The contribution of emotional distress and stress to cardiac health in adult survivors of childhood cancer has not been reported, despite evidence of causal associations in the general population. **Methods:** Comprehensive medical assessments and standardized measures of depression, anxiety, post-traumatic stress disorder, and perceived stress were performed on 3,267 survivors in the St. Jude Lifetime Cohort (median [range] 29.9[18.0-64.5] years of age; 7.7[0-24.8] years at diagnosis; 49% female). Physical outcomes included hypertension, diabetes, dyslipidemia, cardiomyopathy, dysrhythmia (grades 2-4 per the NCI CTCAE criteria), myocardial infarction (grades 3-4), and metabolic syndrome (yes/no). Multivariable generalized linear models examined associations between these outcomes with any distress/stress, adjusted for demographics, cumulative anthracycline dose and thoracic radiation, physical activity, BMI, smoking, and alcohol intake. Unadjusted longitudinal associations between distress/stress and new onset cardiac conditions were examined among survivors who completed repeat medical assessment(s) (n = 1748; median follow-up = 3.9 years). New onset conditions were defined as a change from grade 0-1 at baseline to ≥ grade 2 at follow-up. **Results:** Survivor reported distress/stress (29% overall) was more prevalent in those with hypertension (28.2% vs 19.5%, $P< 0.001$), dyslipidemia (16.4% vs. 11.3%, $P< 0.001$), diabetes (9.4% vs. 6.9%, $P= 0.02$), and metabolic syndrome (32.2% vs. 23.2%, $P< 0.001$), but not among dysrhythmia, cardiomyopathy, and myocardial infarction. In separate multivariable models, distress/stress was associated with hypertension (RR = 1.24, 95% CI 1.07-1.43), dyslipidemia (RR = 1.29, 95% CI 1.03-1.61), and metabolic syndrome (RR = 1.35, 95% CI 1.17-1.54). Baseline distress/stress was associated with new onset hypertension (OR = 1.33, 95% CI 0.94-2.01), dyslipidemia (OR = 1.37, 95% CI 0.94-1.87), and dysrhythmia (OR = 2.78, 95% CI 1.12-6.91). **Conclusions:** Emotional distress/stress is associated with adverse cardiovascular health and may serve as an intervention target for improving cardiac health outcomes among survivors of childhood cancer. Prediabetes and progression to diabetes among adult survivors of childhood cancer in the St. Jude Lifetime Cohort. *First Author: Stephanie Dixon, St Jude Children's Research Hospital, Memphis, TN*

Background: Cardiac death among survivors of childhood cancer occurs at > 10 times the rate expected in the general population. Modifiable cardiovascular risk factors, including diabetes, increase risk for major cardiac events in a near multiplicative fashion. Thus, prevention of progression from prediabetes to diabetes could improve long-term cardiac morbidity and mortality. However, little is known about prediabetes in survivors. **Methods:** Prevalence of prediabetes (fasting glucose 100-125 mg/dL or HbA1c 5.7-6.4%) and diabetes were assessed in 3529 5+ year survivors ≥18 years of age and compared to 450 community controls stratified by age and matched for race/ethnicity, sex, and BMI using Chi-squared statistics. Logistic regression estimated risk factors for prediabetes and cox proportional hazards regression for progression from prediabetes to diabetes among survivors with multiple visits, reported as odds (OR) and hazard ratio (HR), respectively, with 95% confidence intervals (CI). **Results:** Among 3529 survivors (median age 30 years, range 18-65), the prevalence of prediabetes overall was 29.2% (95% CI 27.7-30.7) and diabetes was 6.5% (5.7-7.3). In each age strata, survivors had significantly higher prevalence of prediabetes and diabetes than controls with over 50% of middle-aged survivors (35-44 years) having prediabetes or diabetes (Table). In a multivariable model, therapy-related risk factors for prediabetes included high pancreatic tail dose (≥20 Gy: 2.9 [1.8-4.8]) and moderate prescribed cranial radiation dose (OR [95% CI] > 0- < 20 Gy: 1.4 [1.1-1.8], 20- < 30 Gy: 1.4 [1.0-1.9]) independent of age, sex, race/ethnicity and BMI. Among 695 survivors with prediabetes and longitudinal follow-up, median 5.1 years, 68 (10%) progressed to diabetes. After adjustment for age, sex, race/ethnicity and BMI, risk of progression from prediabetes to diabetes was increased by the presence of insulin resistance (HR 4.9 [95% CI 2.3-10.6]) or prior treatment with hematopoietic cell transplant (HR 2.9 [1.1-7.7]) or total body irradiation (HR 4.6 [1.6-13.5]). **Conclusions:** Survivors of childhood cancer have a high prevalence of prediabetes and high rates of progression to diabetes. Strategies that prevent progression to diabetes should be considered to decrease diabetes risk and subsequent cardiac morbidity and mortality in this high-risk population. Peripheral motor and sensory neuropathy in survivors of childhood central nervous system (CNS) tumors in the St. Jude Lifetime (SJLIFE) cohort. *First Author: Rozalyn L Rodwin, Yale School of Medicine, New Haven, CT*

Background: Survivors of CNS tumors are at risk for peripheral motor and sensory neuropathy. Chemotherapy's contribution to peripheral neuropathy has not been well studied in this population. We aimed to estimate the prevalence of peripheral neuropathy, and determine its association with tumor characteristics and treatment exposures. **Methods:** Within the SJLIFE cohort, survivors of CNS tumors (n = 363, median [range] age 24 [18-53] years, 43.3% female) ≥10 years from diagnosis and ≥ 18 years at evaluation completed in-person assessments for peripheral motor and sensory neuropathy (defined as abnormal motor or sensory subscales of the Modified Total Neuropathy Score). For comparison, matched community controls (n = 445, median [range] age 34 [18-70] years, 55.7% female) underwent the same assessment. Prevalence of ≥ grade 2 motor or sensory neuropathy was estimated by a modified Common Terminology Criteria for Adverse Events. Multivariable analyses adjusting for age, sex and race were used to identify associated disease and treatment characteristics. **Results:** Overall, 11.0% of survivors of CNS tumors versus 0.9% of controls had ≥grade 2 motor neuropathy ($p < 0.001$), and 15.7% of survivors of CNS tumors versus 2.3% of controls had ≥grade 2 sensory neuropathy ($p < 0.001$). Prevalence of motor and sensory neuropathy varied by diagnosis (Table). Vinca alkaloid exposure (OR 3.5, 95% CI 1.7-7.0) and infratentorial tumor location (OR 2.5, 95% CI 1.1-5.4, reference supratentorial location) were independent risk factors for sensory neuropathy. Infratentorial tumor location was also associated with an increased risk of motor neuropathy (OR 2.4, 95% CI 1.2-4.8). History of radiation and surgery were not significant independent risk factors for motor or sensory neuropathy. **Conclusions:** Prevalence of peripheral motor and sensory neuropathy was significantly higher in survivors of CNS tumors than in matched community controls. Survivors of CNS tumors would benefit from increased surveillance to identify and treat peripheral neuropathy, especially in those who received vinca alkaloids or had infratentorial tumors. Clinical and genetic risk factors for radiation-associated ototoxicity: A report from the childhood cancer survivor study and the St. Jude Lifetime Cohort. *First Author: Matthew R. Trendowski, The University of Chicago, Chicago, IL*

Background: Cranial radiation therapy (CRT) for pediatric cancer often results in ototoxicity in the form of hearing loss and tinnitus. We sought to identify clinical determinants and genetic risk factors for ototoxicity among adult survivors of pediatric cancer treated with cranial radiation. **Methods:** Relationships between age at last observation, sex, cumulative CRT dose and self-reported ototoxicity were evaluated for hearing loss and tinnitus among 1,991 (tinnitus) and 2,198 (hearing loss) survivors in the Childhood Cancer Survivor Study who received CRT. Logistic regression evaluated associations with non-genetic risk factors and comorbidities as well as SNP dosages in GWAS of CRT-related tinnitus (cases: 146; controls: 1,845) and hearing loss (cases: 270; controls: 1,928). **Results:** Males were more likely to report CRT-related tinnitus (9.4% vs. 5.4%; $p = 5.81\text{x}10^{-4}$) and hearing loss (14.0% vs. 10.7%; $p = 0.02$) than females after adjusting for dose and age at last observation. Survivors with tinnitus or hearing loss were more likely to experience persistent dizziness or vertigo (tinnitus: $p < 2.00\text{x}10^{-16}$; hearing loss: $p = 6.35\text{x}10^{-9}$), take antidepressants (tinnitus: $p = 0.02$; hearing loss: $p = 0.01$) and report poorer overall health (tinnitus: $p = 9.40\text{x}10^{-7}$; hearing loss: $p = 1.30\text{x}10^{-6}$) compared to survivors without tinnitus or hearing loss after age-adjustment. GWAS of CRT-related tinnitus revealed a prominent signal in chromosome 1 led by rs203248 ($p = 1.50\text{x}10^{-9}$), while GWAS of CRT-related hearing loss identified rs332013 ($p = 5.79\text{x}10^{-7}$) in chromosome 8 and rs67522722 ($p = 7.78\text{x}10^{-7}$) in chromosome 6 as approaching genome-wide significance. Replication analysis in an independent cohort of pediatric cancer survivors (SJLIFE) indicated that rs67522722, intronic to *ATXN1*, a gene associated with the neurodegenerative disorder spinocerebellar ataxia type 1, was significantly associated with CRT-related hearing loss ($p = 0.03$). Enrichment analysis and LD score regression with previous GWAS results of cisplatin-related hearing loss and tinnitus in testicular cancer survivors showed no detectable enrichment in genetic architecture with CRT-related hearing loss and tinnitus, respectively. **Conclusions:** Radiation-associated ototoxicity was associated with sex, several neuro-otological symptoms, increased antidepressant use and poorer self-reported health. GWAS of CRT-related hearing loss identified rs67522722 that was replicated in an independent cohort of pediatric cancer survivors. Research Sponsor: U.S. National Institutes of Health.

Lung cancer as a subsequent neoplasm: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Taumoha Ghosh, University of Minnesota, Minneapolis, MN*

Background: Lung cancer has been reported as a subsequent neoplasm (SN) in childhood cancer survivors. We aimed to assess the prevalence of and risk factors for lung cancer in the CCSS. **Methods:** Among 25,654 five-year survivors participating in the CCSS, lung cancer was self-reported and then confirmed by pathologic record review. Cancer treatment exposures were evaluated including chemotherapy and chest radiation by field size (none, small, large) and in a dose group (0-10 Gy, 10-30 Gy, 30-40 Gy, and $>$ 40 Gy). Standardized incidence ratios (SIR) were calculated using rates from the Surveillance, Epidemiology, and End Results program. Hazard ratios (HR) were estimated for demographic and treatment variables using Cox proportional-hazards models. **Results:** Forty-two survivors developed subsequent malignant lung cancer (SIR 4.0, 95% CI 2.9-5.4), including 25 carcinomas, 7 mesotheliomas and 10 others. Two additional benign neoplasms were also identified. The cumulative incidence of lung SNs was 0.18% at 30 years (95% CI 0.10-0.25). Median time from primary diagnosis was 28 years (range 11-46); median age at diagnosis was 45 years of age (range 15-65). A multivariable model, including all covariates with a p-value $<$ 0.2 in univariate analysis, showed significant associations between lung cancer and older age at diagnosis (HR 10.5, 95% CI 1.4-76.4, for 15-21 years vs. 0-4 years), as well as with primary diagnoses (relative to leukemia, HR 8.7, 95% CI 1.1-66.0, for Hodgkin lymphoma; HR 20.7, 95% CI 1.3-331.0 for neuroblastoma; and HR 21.4, 95% CI 2.3-202.7, for bone cancer). In a treatment model, maximum chest radiation dose (HR 4.1, 95% CI 1.4-11.7, for 30-40 Gy; and HR 8.1, 95% CI 3.0-22.2, for $>$ 40 Gy, relative to 0-10Gy), but not sex, smoking status, or chemotherapy exposures, was associated with lung cancer. Notably, six survivors who developed lung cancer received no radiation and of these, five had a primary bone cancer. At the end of follow-up, 65.9% of survivors with lung cancer were deceased vs. 14.1% of survivors without lung cancer ($p < 0.001$). **Conclusions:** Survivors of childhood cancer are at increased risk for developing lung cancer associated with exposure to high doses of chest radiotherapy. To our knowledge, this is the first study to describe associations with neuroblastoma and bone cancer. Future studies to understand additional treatment-related risk factors beyond chest radiotherapy dose are needed. Research Sponsor: None.

Treatment intensity and risk of chronic health conditions and late mortality among long-term survivors of Wilms tumor: A report from the Childhood Cancer Survivor Study. *First Author: Brent R Weil, Boston Children's Hospital, Boston, MA*

Background: Refinement in risk stratification has led to intensification of therapy for Wilms tumor (WT) patients with adverse prognostic factors. Chronic health conditions (CHCs) including cardiac conditions, subsequent malignant neoplasms (SMNs), and late mortality are known risks for WT survivors, however the impact of specific treatment regimens on these outcomes is largely unknown. **Methods:** Late mortality (all-cause and non-recurrence death $>$ 5 years from diagnosis), SMNs, and severity-graded CHCs (2 = moderate, 3 = severe, 4 = life-threatening, 5 = fatal) were assessed in 5-year WT survivors in the Childhood Cancer Survivor Study diagnosed from 1970-99. Survivors were categorized according to therapy received (Table). Cumulative incidence of mortality and standard mortality ratios (SMR) were estimated. Piecewise exponential models estimated rate ratios (RR) with 95% confidence intervals (CI). **Results:** Among 1507 survivors (median age at follow-up 26 yrs; range 6-55), 35-year cumulative incidence of all-cause mortality was 7.9% (SMR 2.9, CI 2.3-3.6) and 5.1% (SMR 1.9, CI 1.4-2.4) for non-recurrence mortality. RRs for developing any grade 2-5 CHC, grade 3-5 SMN, and grade 2-5 cardiac CHCs were higher for survivors compared to sibling controls (2.0, CI 1.8-2.3; 7.4, CI 5.0-10.8; 2.6, CI 2.2-3.1, respectively). Compared with VA and no RT, RR for non-recurrence late mortality and CHCs among survivors were higher for VAD + any RT, and for $\geq$ 4 drugs + any RT (Table). **Conclusions:** Administering increased-intensity therapy for WT is associated with increased late health consequences and non-recurrence late mortality, necessitating strategies to monitor and improve long-term health among survivors. Research Sponsor: National Institutes of Health.

***HAGHL* genetic variants increase first fracture risk (FFR) in female childhood cancer survivors: A report from the Childhood Cancer Survivor Study (CCSS) and St. Jude Lifetime Cohort Study (SJLIFE).** *First Author: Cindy Im, University of Alberta, Edmonton, AB, Canada*

Background: Recent genome-wide association studies (GWAS) have reported substantial sex differences in the genetic architectures of bone-related phenotypes. We investigated sex-specific genetic determinants of FFR in survivors of childhood cancer. **Methods:** We performed sex-combined and sex-stratified GWAS for FFR using Cox regression models fitted on follow-up age in 2,453 long-term ($\geq$5 years) survivors in CCSS with ~5.4 million imputed SNPs (minor allele frequency, MAF$\geq$5%), with self-reported FFR defined by first fracture at any site after diagnosis. Replication analyses were conducted in an independent sample of 1,417 SJLIFE survivors with whole-genome sequencing and clinician-assessed FFR. All models were adjusted for relevant genetic (e.g., ancestry) and clinical (e.g., height, weight, treatment) factors. **Results:** Sex-combined and male-specific analyses yielded no associations with $P < 10^{-7}$. Among female CCSS survivors (N = 1,289, 33% $\geq$1 fractures), we discovered 7 genome-wide significant ($P < 5x10^{-8}$) SNP-FFR associations with strong evidence of sex effect heterogeneity ($P < 7x10^{-6}$) across 2 independent loci with no known associations with bone phenotypes. We replicated these associations in SJLIFE ($P \leq 0.05$) for 3 coding SNPs in the *HAGHL* gene (16p13.3), among which rs1406815 showed the strongest association (MAF = 20%, meta-analysis HR = 1.43, $P = 8.2x10^{-9}$; N = 1,935 women, 35% $\geq$1 fractures). We observed increased *HAGHL* SNP effects on FFR that corresponded with increasing head/neck (HN) radiation therapy (RT) dose (Table). Public *omics* data show replicated SNPs are associated with differential *HAGHL* expression in sex gland and musculoskeletal tissues (GTEx) and in osteoblasts treated with dexamethasone or prostaglandins (GRASP), suggesting sex-/therapy-specific biological pathways involving *HAGHL* SNPs for fracture are plausible. **Conclusions:** Novel associations between *HAGHL* genetic variants and FFR potentially reveal new sex- and therapy-specific biological mechanisms underlying bone-related health conditions in survivors of childhood cancer. Research Sponsor: U.S. National Institutes of Health.

Frailty and neurocognitive decline in young adult survivors of childhood cancer: A longitudinal analysis from the St. Jude lifetime cohort. *First Author: AnnaLynn Williams, St. Jude Children's Research Hospital, Rochester, TN*

Background: Among young adult childhood cancer survivors, 8% meet the criteria for frailty, an aging phenotype associated with poor health. Frailty is associated with neurocognitive decline in the elderly general population, but this association has not been examined in young adult survivors of childhood cancer. **Methods:** Childhood cancer survivors (N = 845, mean [SD] age 30 [7] years, 22 [7] years post diagnosis, 52% male) were clinically evaluated for prefrailty/frailty (defined as $\geq$2/$\geq$3 of muscle wasting, muscle weakness, low energy expenditure, slow walking speed, exhaustion) and completed neuropsychological assessments at baseline and five years later. Linear regression models estimated mean differences in neurocognitive decline in prefrail/frail survivors *vs.* non-frail survivors adjusting for age, sex, race, CNS therapy (cranial radiation, intrathecal chemotherapy, neurosurgery), and baseline neurocognitive performance. *P*-values were adjusted for multiple comparisons using false discovery rate (FDR). **Results:** 18% and 6% of survivors were prefrail and frail at baseline. Baseline frailty was associated with declines in visual-motor processing speed, short-term memory, and sustained attention (Table). Prefrailty and frailty were associated with declines in focused attention and executive function (Table). No significant associations were observed between prefrailty or frailty and decline in global cognition, academics, motor processing speed, long-term memory, verbal learning, or verbal fluency despite significant baseline cross-sectional associations. **Conclusions:** Young adult prefrail and frail survivors had greater declines in attention and executive function compared to non-frail survivors, domains commonly associated with aging. These findings suggest that interventions designed to mitigate components of frailty may also mitigate or prevent neurocognitive decline. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Expression of the senescence biomarker *p16^{INK4a}* among childhood, adolescent, and young adult cancer survivors. *First Author: Andrew Brian Smitherman, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: The mechanism of accelerated aging among survivors of childhood, adolescent, and young adult cancer is not clearly understood. Cellular senescence may contribute to this process. We measured peripheral blood T lymphocyte *p16^{INK4a}* expression, a biomarker of cellular senescence and aging, among pediatric and young adult cancer survivors hypothesizing that *p16^{INK4a}* expression is higher due to chemotherapy exposure and among frail survivors. **Methods:** Two cohorts were enrolled from January 2018 to December 2019 at an academic medical center. One, a cross-sectional cohort of young adult cancer survivors and age-matched, cancer-free controls in whom we assessed *p16^{INK4a}* expression and clinical frailty. Frailty was measured with the modified Fried Frailty Index that evaluates skeletal muscle index, weakness, slowness, leisure energy expenditure, and exhaustion. A second cohort underwent prospective measurement of *p16^{INK4a}* expression before and after cancer chemotherapy. Eligibility among survivors and newly diagnosed patients required treatment with an alkylating agent, an anthracycline / anthracenedione, or both. Multivariable linear regression was used to model expression of *p16^{INK4a}* by patient age at assessment, treatment intensity, and frailty status. **Results:** The cross-sectional cohort enrolled 60 young adult survivors and 29 age-matched, cancer-free controls with median age 21 years and range 17-29 years for both groups. Survivors were a median of 5.5 years from end of treatment. The prospective cohort enrolled nine newly diagnosed patients (range 1-18 years). Expression of *p16^{INK4a}* was higher among young adult cancer survivors as compared to age-matched controls (9.6 v. 8.9 $\log_2$ p16 units, $p < 0.01$) representing a 25-year age acceleration in the survivors. Expression of *p16^{INK4a}* increased among newly diagnosed patients from matched pre- to post-treatment samples (7.3 to 8.9 $\log_2$ p16 units, $p = 0.002$). Nine survivors (16%) met criteria for being frail and had higher *p16^{INK4a}* expression as compared to robust survivors (10.5 [frail] v. 9.5 [robust] $\log_2$ p16 units, $p = 0.055$). **Conclusions:** Chemotherapy is associated with increased cellular senescence in pediatric and young adult cancer survivors as reflected in expression of *p16^{INK4a}* indicating an increase in molecular age following chemotherapy exposure. The large proportion of frail survivors in this study also exhibited higher levels of *p16^{INK4a}* suggesting that cellular senescence may be associated with early aging observed among these survivors. Research Sponsor: U.S. National Institutes of Health.

10557 Poster Session (Board #444), Fri, 8:00 AM-11:00 AM

Is it safe and worthwhile? A multi-site randomized clinical trial of FAmily CEntered (FACE) pediatric advance care planning for adolescents with cancer and their families. *First Author: Justin N. Baker, St. Jude Children's Research Hospital, Memphis, TN*

Background: Many clinicians express concern that pediatric ACP (pACP) is too distressful for families. We describe the effect of FAmily CEntered pACP for Teens with Cancer (FACE-TC) on families' self-reported experience. **Methods:** A 4-site, intent-to-treat, longitudinal, randomized clinical trial recruited adolescent/family dyads from hospital-based cancer-specialty clinics from 2016-2019. Adolescent/family dyads were screened/assented/consented/enrolled and randomized at a 2:1 ratio to either FACE-TC or Treatment as Usual control. FACE-TC is three weekly, 60-minute sessions with a certified facilitator (ACP survey; Next Steps: Respecting Choices Interview; Five Wishes advance directive). Satisfaction Questionnaire measured 7 positive (useful, helpful, load off my mind, satisfied, something I needed to do, courageous, worthwhile) and 6 emotional reactions (scared, hurtful, harmful, too much to handle, angry, sad). It was administered by a trained/blinded research assistant immediately following the Respecting Choices interview or 3 weeks post-baseline for controls. **Results:** Family participants were: primarily mothers (75%); mean age 46 years; 83% female; 82% white. Household income was ≤100% Federal poverty level for 26%; 58% had less than a Bachelor's degree. Attendance was 92% for three FACE sessions. FACE families (N = 116) compared to controls were more likely to report the study was "worthwhile" (97% vs. 86%, 0 = 0.0245); "useful" (97% vs. 83%, p = 0.0102); "helpful" (96% vs. 79%, p = 0.0079); and "something I needed to do" (84% vs. 55%, p = 0.0006). FACE families (Mean 28.1, SD 3.3) reported higher positive subscale scores than control families (Mean 24.9, SD 4.4) ($\beta = 2.98$, p = 0.0001). No significant differences were found for age, gender, race, household income, or adolescent on active treatment. There were no differences between FACE or control dyads on the 6 emotional reactions subscale score. **Conclusions:** Among a geographically, economically diverse families, FACE pACP was safe and worthwhile. Clinicians can be assured that a structured facilitated pACP intervention, although emotionally intense, did not unduly distress families who found the experience overwhelmingly worthwhile. Results fill the gap about how to successfully engage families in pACP with their adolescent child. Clinical trial information: NCT02693665. Research Sponsor: U.S. National Institutes of Health.

10558 Poster Session (Board #445), Fri, 8:00 AM-11:00 AM

Hospice use at end of life in children with cancer: The effect of insurance. *First Author: Emily E. Johnston, Stanford University Medical Center, Palo Alto, CA*

Background: The National Quality Forum has endorsed hospice care as a metric of high quality end-of-life (EOL) care for adults with cancer. Specific hospice-related quality metrics include hospice enrollment, hospice enrollment for ≥3d, and death outside of the acute care setting. These metrics have been examined extensively in adults and disparities related to a number of clinical and sociodemographic factors, including insurance, have been identified. However, for children with cancer, hospice utilization data is lacking. We addressed this gap by examining location of death and hospice utilization at EOL for children with cancer and determining whether these metrics varied with insurance status. **Methods:** We used national insurance claims data (Truven) to conduct a population-based analysis of patients with cancer who died between 2011 and 2017 at age 0-21y. The dataset was queried for hospice claims, inpatient claims, and location of death. The association between insurance (private vs. Medicaid) and 1) location of death, 2) hospice enrollment, and 3) days between first hospice claim and death was examined using multivariable regression analysis, adjusting for age at death, gender, and cancer diagnosis (hematologic malignancies vs. solid tumor). **Results:** A total of 1,492 children died at a mean age of 11y (SD: 6y); 56% were privately-insured, 56% were male, and 30% had hematologic malignancies. Overall, 58% died in the hospital (privately-insured: 54% vs. Medicaid: 63%). Forty-five percent enrolled in hospice (privately-insured: 46% vs. Medicaid: 43%) with 2% returning to the hospital to die after enrolling in hospice. The average time between first hospice claim and death was 3d (privately-insured: 10d vs. Medicaid: 2d, p = < 0.001). When compared to privately-insured children, children on Medicaid had similar likelihood of hospice enrollment (RR = 1.0, 95%CI = 0.6-1.8). However, children on Medicaid were more likely to die in the hospital (RR = 1.3, 95%CI = 1.1-1.4) and have fewer days between hospice enrollment and death if enrolled in hospice (IRR: 0.5, 95%CI = 0.3-0.8). **Conclusions:** In this first study to examine national hospice utilization in children with cancer, care varies significantly with insurance status. Children on Medicaid are more likely to die in the hospital and have shorter hospice enrollment duration than children with private insurance. Whether this variation represents EOL care preferences, provider biases, differences in quality and availability of hospice or home care to different insurers, or other barriers needs to be examined. Research Sponsor: Alex's Lemonade Stand and Leukemia Lymphoma Society.

10559 Poster Session (Board #446), Fri, 8:00 AM-11:00 AM

Prevalence and predictors of high-intensity end-of-life care among adolescents and young adults with cancer in Ontario: a population-based study using the IMPACT cohort. *First Author: Hallie Coltin, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: End-of-life (EOL) care in adolescents and young adults (AYA) with cancer is poorly characterized, though this group may be at risk of elevated rates of high-intensity (HI) care and consequently, increased EOL suffering. Few population-based studies exist, and are limited by incomplete clinical information. AYA care patterns can vary by locus of care (LOC – pediatric v. adult), but LOC disparities in AYA EOL care are unstudied. **Methods:** We conducted a retrospective decedent population-based cohort study of all Ontario AYA diagnosed between 15-21 years of age with 6 prevalent primary cancers between 1992-2012, who died ≤5 years from diagnosis. Chart-abstracted clinical data were linked to health services data. The primary composite outcome (HI-EOL care) included any of: intravenous chemotherapy ≤14 days from death; > 1 emergency department visit ≤30 days from death; or > 1 hospitalization or intensive care unit (ICU) admission ≤30 days from death. Secondary outcomes included measures of the most invasive (MI) EOL care: mechanical ventilation ≤14 days from death, and death in the ICU. Factors associated with HI-EOL were examined. **Results:** Of 483 patients, 292 (60.5%) experienced HI-EOL care, 98 (20.3%) were mechanically ventilated ≤14 days from death, and 110 (22.8%) died in the ICU. Patients with hematological malignancies (v. solid tumors) were at greatest risk of HI-EOL care (OR, 2.3; 95CI, 1.5-3.5, $p < 0.01$), mechanical ventilation (OR, 5.4; 95CI, 3.0-9.7, $p < 0.01$), and death in an ICU (OR, 4.9; 95CI, 2.8-8.5, $p < 0.01$). AYA who died in a pediatric center were substantially more likely to experience MI-EOL measures compared to those dying in adult centers (mechanical ventilation, OR 3.2, 95CI 1.3-7.6, p = 0.01). Assessment of interactions showed LOC-based disparities widening over the study period (ICU death in pediatric v. adult centres: early period OR 0.9, 95CI 0.3-2.9, p = 0.91; late period OR 3.3, 95CI 1.2-9.2, p = 0.02; interaction term p = 0.04). AYA living in rural areas were also at higher risk of experiencing mechanical ventilation (OR, 2.0; 95CI, 1.0-3.8, p = 0.04) and death in ICU (OR, 2.1; 95CI, 1.1-4.0, p = 0.02). **Conclusions:** AYA with cancer experience high rates of HI-EOL care, with patients in pediatric centers and those living in rural areas at highest risk of MI-EOL care. Our study is the first to identify LOC-based disparities in AYA EOL care. Future studies should explore mechanisms underlying these disparities, including potential differences in palliative care services. Research Sponsor: Canadian Institutes of Health Research (CIHR), Other Foundation, Other Government Agency.

TPS10560 Poster Session (Board #447), Fri, 8:00 AM-11:00 AM

A phase II study of larotrectinib for children with newly diagnosed solid tumors and relapsed acute leukemias harboring TRK fusions: Children's Oncology Group study ADVL1823. *First Author: Theodore Willis Laetsch, University of Texas Southwestern Medical Center and Children's Health, Dallas, TX*

Background: In children, fusions of the *NTRK1/2/3* genes (TRK fusions) occur in soft tissue sarcomas, including infantile fibrosarcoma (IFS), congenital mesoblastic nephroma, high- and low-grade gliomas, secretory breast carcinoma, and papillary thyroid cancer. Rarely, TRK fusions also occur in Ph-like acute lymphoblastic leukemia and acute myeloid leukemia. Larotrectinib is a selective TRK inhibitor FDA-approved for the treatment of TRK fusion solid tumors in patients with no satisfactory alternative treatments or whose cancer has progressed following initial treatment. In children, larotrectinib demonstrated a 94% overall response rate (ORR) with a 12-month progression free survival rate of 75% (1). **Methods:** Patients <30 years with any newly diagnosed unresectable solid tumor or relapsed/refractory acute leukemia with TRK fusions are eligible. TRK fusions must be locally identified in a CLIA/CAP laboratory and are confirmed centrally using a targeted RNA sequencing panel. Patients with high-grade gliomas are excluded. Patients receive larotrectinib 100 mg/m^2/dose BID (max of 100 mg/dose) continuously in 28-day cycles. Patients with solid tumors who achieve CR will discontinue larotrectinib at the completion of at least 12 total cycles of therapy and 6 cycles after achieving CR. Those whose tumors become surgically resectable may undergo on study resection and discontinue therapy if an R0/R1 (IFS) or R0 (other tumors) resection is obtained. All other patients will receive 26 cycles in the absence of unacceptable toxicity or progressive disease. The primary endpoint is the ORR to larotrectinib according to RECIST 1.1 in children with IFS. The study uses a Simon 2-stage minimax design, and the regimen will be considered of sufficient interest if 16 of 21 (76%) patients with IFS demonstrate response. Patients with other solid tumors and leukemias will be analyzed in separate cohorts as secondary objectives. Correlative studies include serial sampling of circulating tumor DNA and neurocognitive assessments. This is the first Children's Oncology Group study to assign frontline therapy based on the presence of a molecular marker independent of histology, and the first clinical trial to evaluate larotrectinib for the treatment of leukemia. Enrollment began in October 2019 (NCT03834961). 1. Tilburg CMv, DuBois SG, Albert CM, et al: Larotrectinib efficacy and safety in pediatric TRK fusion cancer patients. Journal of Clinical Oncology 37:10010-10010, 2019 Clinical trial information: NCT03834961. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS10561 Poster Session (Board #448), Fri, 8:00 AM-11:00 AM

A phase I study of Aurora kinase A inhibitor LY3295668 erbumine as a single agent and in combination in patients with relapsed/refractory neuroblastoma. *First Author: Steven G. DuBois, Dana-Farber/Boston Children's Cancer and Blood Disorders Center and Harvard Medical School, Boston, MA*

Background: Aurora kinase A (AurA) has been implicated in high-risk neuroblastoma, including roles stabilizing and increasing expression of MYCN protein. AurA impacts the function of MYCN in mediating transcription in a cell cycle dependent manner, suggesting that neuroblastoma and other *MYC/MYCN*-driven tumors may be sensitive to AurA inhibition. LY3295668 is a selective AurA inhibitor. The lack of AurB inhibitory activity is hypothesized to minimize on-target hematologic toxicity associated with AurB inhibition. The molecule's selectivity is intended to allow for continuous dosing at exposures associated with > 90% target inhibition at trough. In an analysis of LY3295668 antiproliferative effects in 560 cancer cell lines, neuroblastoma was among the most sensitive histologies tested. This screen also separately evaluated genomic predictors of response to LY3295668, with *MYC*/*MYCN* amplification identified as among the strongest predictors of sensitivity to this agent. LY3295668 is currently being evaluated in early phase adult trials. The current trial (J1O-MC-JZHD) was uniquely designed to hasten time to first-in-child oncology development for a rare unmet need of relapsed/refractory neuroblastoma patients. **Methods:** Study J1O-MC-JZHD (NCT04106219) is a multicenter, dual collaboration (NANT and ITCC), randomized, open-label, Phase 1 study of oral LY3295668 in children with relapsed/refractory neuroblastoma. A rolling 6 design will be followed for dose escalation in both a monotherapy cohort and a combination cohort testing LY3295668 together with cyclophosphamide and topotecan. The starting monotherapy dose will be equivalent to 80% of the adult maximum tolerated dose. Key eligibility criteria include recurrent/refractory neuroblastoma not amenable to curative treatment, age 2-21 years, mandatory archival tissue submission, ability to swallow capsules, and adequate hematologic and organ function. LY3295668 is administered in capsule form orally BID continuously. Primary objectives include assessments of safety and tolerability of study drug to identify RP2D as monotherapy and combination, and assess antitumor activity. Secondary objectives include assessment of the pharmacokinetic profile as monotherapy and in combination, and assessment of the relationship between study drug exposure and efficacy. Following determination of the RP2Ds, an expansion phase will randomize patients to monotherapy or to the combination arm. Enrollment began 16 Dec 2019 and is ongoing. Clinical trial information: NCT04106219. Research Sponsor: Eli Lilly & Co.

11000 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Trainee and workforce diversity in hematology and oncology: Ten years later what has changed? *First Author: Ana I. Velazquez Manana, University of California, San Francisco Medical Center, San Francisco, CA*

Background: The diversification of the healthcare workforce has been identified as a strategy to address health disparities and increase patient-physician trust. A prior review of diversity among oncology fellows up to 2010, showed an increase in female representation over 17 years, but no change in underrepresented minorities (URM). We aim to assess the changes in hematology and oncology (HO) fellowship diversity over the last decade and how this compares to our workforce. **Methods:** Publicly available registries were used to assess differences among female and URM HO fellows, HO fellowship applicants, internal medicine (IM) academic faculty, IM residents, medical school graduates (MSG), and the US population in 2019. These were compared to the 2016 HO practicing physicians. Changes in URM and female HO fellow representation from 2009 to 2019 were assessed. Data was analyzed using binomial tests and simple linear regression models. **Results:** Female representation among HO fellows (43.8%) was increased when compared with HO practicing physicians (+11.8%, $p < 0.0001$) and IM faculty (+3.2%, $p = 0.0079$); no difference from IM residents or HO applicants. Female HO fellows were underrepresented when compared with MSG (-4.0%, $p = 0.0014$) and US population ($P < 0.0001$). Hispanic HO fellows (6.1%) had increased representation when compared to IM faculty (+2.7%, $p < 0.0001$), but were underrepresented when compared to IM residents (-2.2%, $p = 0.0012$) and US population ($p < 0.0001$). The proportion of Hispanic HO fellows was no different when compared to HO practicing physicians, HO applicants, and MSG. African American (AA) fellows (3.8%) were underrepresented when compared to IM residents (-2.0%, $p = 0.0005$), HO applicants (-1.7%, $p = 0.0465$), MSG (-2.4%, $p = 0.0001$), and US population ($p < 0.0001$). AA fellows were increased when compared to HO practicing physicians (+1.5%, $p = 0.0002$), but no different than IM faculty. Asian HO fellows were increased when compared to IM residents, MSG, and US population. Over the last 10 years there has been no significant change in the proportion of AA or female HO fellow representation, with a decreasing trend in Hispanics (-0.14% per year, $p = 0.04$).**Conclusions:** The current state of diversity in HO workforce still requires attention. Despite ongoing efforts, females, AA, and Hispanics continue to be underrepresented. The decreasing trend in Hispanic representation and clear differences in diversity between HO fellowships and IM residencies calls for action among fellowship programs and national societies to increase URM engagement and recruitment. Research Sponsor: None.

11001 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

A comprehensive analysis of the demographics and citation-based productivity of radiation oncologists practicing at comprehensive cancer centers. *First Author: Shearwood McClelland, Indiana University School of Medicine, Indianapolis, IN*

Background: Academic radiation oncology represents a constantly changing landscape. We sought to determine the demographic makeup of the current academic radiation oncology workforce. **Methods:** Internet searches of the 51 National Cancer Institute-designated Comprehensive Cancer Centers were conducted in September 2019. The Scopus database was subsequently searched in December 2019 to ascertain the h-index for each radiation oncologist. H-indices were analyzed by faculty rank (junior faculty versus associate professor versus full professor) and gender. Variables were coalesced for statistical analysis using Fisher's exact test and two-tailed t-tests. **Results:** Analysis of 993 radiation oncologists revealed that 53.6% are junior faculty, 24.8% are associate professors, and 21.7% are full professors. The average radiation oncologist has been an MD for 19.6 years; 32.5% (232/993) are women, and less than 5% (47/993) are underrepresented minorities (URM). Of the 51 department chairs, 11.8% are women and 5.6% are underrepresented minorities. Women are significantly underrepresented among full professors (odds ratio = 1.78; $p = 0.010$) and departmental chairs (odds ratio = 3.80; $p = 0.0007$); there was no significant difference for assistant professorship ($p = 0.067$) nor associate professorship ($p = 0.348$). The overall mean h-index for all faculty was 17.64. Mean h-index was 8.21 for junior faculty, 18.46 for associate professors, and 40.05 for full professors; these differences were statistically significant ($p < 0.0001$). The overall mean h-index was 19.35 for men (n = 668) and 14.11 for women (n = 323); this difference was statistically significant ($p < 0.0001$). **Conclusions:** The majority of academic radiation oncologists are assistant professors; fewer than 5% are underrepresented minorities. Men comprise more than two-thirds of the workforce, and are significantly overrepresented at the full professor (by 78%) and departmental chair (by 280%) levels in academic radiation oncology. The average radiation oncologist at a comprehensive cancer center has published more than 17 manuscripts cited at least 17 times. Contrary to previous findings comparing male and female residents, the difference in academic productivity by gender among faculty was statistically significant. These findings provide objective data to assess the radiation oncology academic workforce and provide a useful benchmark to measure change going forward. Research Sponsor: None.

11002 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Caring for transgender cancer patients: Shortcomings of medical education. *First Author: Ernesto Gil Deza, Insituto Oncologico Henry Moore, Buenos Aires, Argentina*

Background: Caring for transgender patients requires specific knowledge and skills. Medical schools spend less than 5 hours on average training for treatment of LGBT patients (Obedin-Maliver, JAMA, 306 (9), 971). This paper assesses the knowledge on the topic and skills of postgraduate Oncology students from Universidad del Salvador at the Observational Standard Clinical Examination (OSCE) 2019 (JCO 34 (15), Abstract e18150, 2017). **Methods:** At one of the stations of OSCE 2019, students had thirty minutes to complete a clinical record of a simulated transman patient with ovarian cancer stage IIIC. Based on the real case of Robert Eads, actors were trained with the documentary on his life "Southern Comfort". Students were assessed on: A) knowledge of the transman condition, B) use of preferred gender pronoun by the patient, C) discontinuation of testosterone treatment, D) recommendation of genetic study, E) treatment of ovarian cancer according to NCCN guidelines, F) moral discomfort with LGBT patient care. All interviews were filmed or recorded by an observer. All films, recordings and clinical records were reviewed to rate the students' performance. **Results:** A total of 25 postgraduate Oncology students took the OSCE 2019. Assessment: A) 5/25 (20%) lacked knowledge of the transman condition, B) 3/25 (12%) did not use the patient's preferred gender pronoun, C) 17/25 (68%) discontinued testosterone, D) 23/25 (92%) requested genetic study, E) all students treated ovarian cancer according to NCCN guidelines, F) none expressed moral discomfort with LGBT patient care. **Conclusions:** 1) It is feasible to assess the knowledge and skills required for treatment of transgender patients in Oncology. 2) We found shortcomings of student's medical training regarding transgender patients: one in five did not understand the patient's condition, three did not use the patient´s preferred gender pronoun during the interview and more than half suspended the necessary hormone therapy for their condition. 3) This emphasizes the need to deepen our medical and communication skills in order to assist the transgender population and should be included in future ASCO-ASH milestones for specialty accreditation. Research Sponsor: None.

11003 Poster Discussion Session; Displayed in Poster Session (Board #260), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Social media use among NCI designated cancer centers: Where is the diversity? *First Author: Ana I. Velazquez Manana, University of California, San Francisco, San Francisco, CA*

Background: The NCI-Designated Cancer Centers (NCC) are recognized for their leadership, research, and education of health care professionals (HCP). NCC are required to study and improve cancer disparities in their communities. Since the introduction of social media (SM), online platforms have become a source of health information and peer support among patients with cancer, leading to its adoption by NCC across the nation. We aimed to analyze the use of SM among NCC and how the racial/ethnic (RE) diversity represented in their SM messaging compares to their communities. **Methods:** We reviewed all original SM posts from adult NCC-specific Facebook (FB) and Twitter (TW) pages between 1/1/2019 to 12/31/2019. Basic laboratory NCC pages and retweets were excluded. A 1-year time period was selected to account for variation during health campaigns months. We analyzed each post's language and content, and the gender and RE of individuals presented in images and videos (IV). Content was categorized into: screening, clinical trials, HCP, or patient story. Data was analyzed using chi-square and Wilcoxon signed-rank tests. **Results:** We reviewed the FB and TW pages of 56 NCC. The median account age was 10 years for FB and 9 years for TW with a median number of followers of 9,861 and 6,066, respectively. The median number of posts per NCC was 250 in FB and 332 in TW. Only 5 NCC posted in a non-English language (range 1 – 5 posts). Among SM IV, >60% of pages displayed females in ≥50% of their posts, African Americans (AA) were presented in 12-14% and Hispanics in 5%. When compared to their city demographics, Whites and Asians were significantly over-represented while Hispanics and AA were under-represented in NCC's SM messaging (Table). When compared to the US census, over-representation of Asians and under-representation of Hispanics persisted. Cities with ≥20% AA or Hispanics displayed a higher proportion of IV presenting the respective RE group ($p<0.05$). Content was not associated with RE makeup. **Conclusions:** By analyzing the IV posted by NCC on 2 SM platforms, we identified that Hispanics and AA were under-represented in NCC's SM messaging. Furthermore, SM outreach for non-English speakers was abysmal. Equitable visual representation of diverse RE in NCC's SM messaging has the potential to serve as a tangible means to demonstrate cultural competency and close the gap in cancer disparities. Research Sponsor: None.

	US census (%)	City demographics NCI CC (mean %)	Facebook (mean %)	p-value	Twitter (mean %)	p-value
White	60	43	62	< 0.0001	61	< 0.0001
AA	13	23	14	< 0.0001	12	< 0.0001

Feasibility of developing a Twitter journal club for hematology/oncology education. *First Author: Elizabeth Henry, Loyola University Medical Center, Maywood, IL*

Background: Medical trainees are increasingly utilizing social media platforms for professional development, networking and education. Twitter chats (TC) are a growing tool to engage health professionals in virtual multi-institutional, cross-discipline discussions. A meta-analysis of Twitter as a tool in residency education demonstrated high rates of satisfaction and concept retention. Despite rapid uptake, few studies address needs for social media use and implementation in graduate medical education. **Methods:** We created a Twitter account (@HOjournalclub) and registered a certified hashtag (#HOJournalClub) with healthcare symplur. For each monthly TC, a specific tumor type and relevant publication was selected. This information was disseminated and amplified to reach trainees on Twitter. A content expert was invited to each TC to provide additional commentary. During TCs, participants answer questions based on domains of critical journal appraisal. Qualitative and quantitative analysis was performed. Basic demographics and tracked hashtag use to measure impressions, participants, and tweets per TC were gathered. Responses were collated and general themes were assessed. Participants were surveyed on ease of participation, article accessibility, and prior use of social media for education. **Results:** Since inception, @HOJournalClub has grown to >650 followers. Most are US-based (83%) medical trainees or healthcare professionals. Additional followers are in South America, Africa, UK, Europe, Middle East, India, East Asia and Australia. Gender is evenly distributed (51% male, 49% female.) Five #HOJournalClub chats have been held to date. Each attracted a mean of 30 participants, generating a mean of 217 tweets. Chats garnered a mean of 270,000 impressions (221,000-319,000) in the 48h after TC. Most participants accessed the chat in real time, with a small subset responding at alternate times. This asynchronous use has enhanced international participation. In post-TC surveys, majority of respondents report being new (48%) or sporadic (48%) users of TCs. Survey participants reported TC participation increased interaction with others in the field, improved literature appraisal skills and led to changes in clinical practice. **Conclusions:** Implementation of a Twitter-based journal club is feasible and attracts participation from trainees, promoting engagement and networking. It represents a novel educational tool for engagement in multi-institutional, multi-national and cross-discipline discussion of relevant hematology/oncology literature. Research Sponsor: None.

Effect of video-based patient education on pancreatic cancer knowledge and behavior. *First Author: Wendy Turell, PlatformQ Health, LLC, Needham, MA*

Background: Treatment outcomes for pancreatic cancer are optimized when patients/caregivers are engaged, informed and supported participants in their care. However, challenges exist regarding care engagement, disease and treatment related education, and the attainment of adequate psychosocial support. To address these needs, we created video-based patient education activities with the National Pancreas Foundation to empower patients/care with information and resources on pancreatic cancer facts, diagnosis, medical management, and strategies to minimize side effects and maximize quality of life. **Methods:** One 1-hour patient education activity was broadcast live and online, followed by on-demand release, in 2018-2019 at CancerCoachLive.com and via Facebook Video for 12 months. Features included panel discussions, slides, live polling and Q&A, and video vignettes of real patient experiences. Knowledge-focused test questions were administered at 3 time points (pre-activity, immediate post-activity, and 2-mos [follow-up] post). Behavioral and communication-focused questions were also asked at follow-up. Data from these questions, live poll responses, and learner-submitted questions pre-event and during live Q&A were analyzed to determine engagement, lessons learned and continuing patient needs. **Results:** In total, 6,276 patients took part in the activity. Patient questions prior to and during the activity focused on basic knowledge about pancreas gland function, tumor development, disease escalation, and medical management. In-session polling results revealed that prognosis and life expectancy were the top concerns for participants. Two months post-education evaluation showed: 33% reported improved communication with their healthcare providers (HCPs) regarding pancreatic cancer; 46% reported improved feelings of being more "in-control" of health care decisions; 25% reported improved care behaviors for their health. Reports of improved HCP communication were specific to: side effect management, clinical trials availability, treatment option knowledge, and confidence related to engaging in discussions. Knowledge improvements were observed for 3 of 4 questions related to facts about the pancreas, pancreatic cancer, and treatment. **Conclusions:** Patient/caregiver education on pancreatic cancer yields gains in knowledge and behavior, improves patient/caregiver engagement, improves treatment decision-making, and maximizes quality of life. Research Sponsor: Celgene.

Innovation in resident oncology education: Switching from an inpatient ward rotation to a hybrid model of inpatient consultations and outpatient clinics. *First Author: Jennifer King, Indiana University School of Medicine, Indianapolis, IN*

Background: Interest in pursuing a career in oncology has decreased among internal medicine residents completing an inpatient oncology rotation. Over several years, our institutional data at Indiana University School of Medicine reflected lower resident satisfaction with the oncology inpatient ward rotation compared to other rotations. **Methods:** A hybrid model of inpatient consultations and outpatient clinics replaced the traditional inpatient oncology rotation at our institution. Over a six-month period preceding and following the change in format, residents completed anonymous rotation assessments and rated their experiences on a 5-point Likert scale (low 1 to high 5). Areas assessed included: patient load, educational value of patient mix, quality of didactics and teaching, quality of patient care delivery, adequacy of time for reading, and overall educational quality of the rotation. **Results:** The hybrid oncology rotation (8 respondents out of 10 residents approached) was rated as significantly superior to the traditional ward format (15 respondents out of 16 residents approached) in six out of eight areas. Improvements in the perceived quality of patient care delivery (p=0.139) and quality of didactics (p=0.058) were also observed without reaching statistical significance. The balance of inpatient and outpatient experiences with the hybrid rotation was highly rated (4.5 ± 0.5). **Conclusions:** The implementation of a hybrid oncology rotation was associated with perceived improvement in educational value, patient mix, and time for reflection and study without apparent compromise in the quality of patient care delivery. Research Sponsor: None.

Comparison of resident ratings of the oncology rotation before and after the implementation of a new hybrid format of inpatient consultations and outpatient clinics.

	6-month period preceding implementation of new format (n=15)	6-month period following implementation of new format (n=8)	*p-value*
Number of admissions/consultations /patient contacts	4.2 (0.5)	4.625 (0.5)	0.044*
Educational value of patient mix	3.73 (1.1)	4.5 (0.5)	0.018*
Inpatient/outpatient balance		4.5 (0.5)	
Adequacy of time for reading/study	3.67 (0.9)	4.625 (0.5)	0.003*
Overall quality of faculty teaching	3.93 (0.8)	4.75 (0.3)	0.003*
Quality of patient care delivery system	4.33 (0.7)	4.625 (0.5)	0.139
Relevance of material to learner	4.08 (1)	4.83 (0.4)	0.018*
Quality of didactic education (teaching sessions)	4.08 (1)	4.67 (0.5)	0.058
Overall rating of rotation	3.93 (0.7)	4.75 (0.3)	0.002*

Design-based bone marrow biopsy training. *First Author: Sam Brondfield, University of California, San Francisco, CA*

Background: Hematology/oncology fellows must achieve bone marrow biopsy proficiency. However, a cost-effective, high-fidelity system to practice these procedures has not been described. Other specialties utilize 3D printing to practice procedures. Using design thinking, we developed, implemented, and evaluated a bone marrow biopsy training session with 3D pelvis models. **Methods:** We printed two models using an NIH template and optimized them through iterative prototyping. We covered a hole at the intended biopsy site with a replaceable cap simulating cortical bone, used cork as medullary bone, and used sand and water as marrow. Caps of two densities simulated softer and harder bone. Fellows could lift silicone skin pads to view anatomy. A flat base minimized movement. In July 2019, we conducted a one-hour practice session ("3D session") with eight fellows during orientation. After an anatomy review, fellows practiced biopsies using the models with faculty feedback. Fellows also attended a one-hour session with a hematologist demonstrating a biopsy on a patient ("patient session"), the only session offered in previous years. We used a t-test to compare course ratings and pre/post-orientation self-assessed comfort with biopsies (5-point scales). Six months later, we surveyed attendings about fellow biopsy skill and success rate compared to prior years. S.B. conducted a content analysis of a focus group with four fellows and email feedback from one fellow. **Results:** Fellows rated the 3D and patient sessions highly (4.50 vs 4.75, p = 0.51). Procedural comfort improved significantly after orientation (2.13 to 3.63, p = 0.03). Attendings noted no difference between the 2019 fellows and prior years. Fellows called the 3D session "helpful" and "high-yield." They praised the opportunity to practice repeatedly with high-fidelity anatomy, rehearse mechanics, receive feedback, and internalize anatomy and muscle memory for later recall. Fellows noted that the model did not allow for patient positioning practice and that the denser cap was too hard. Fellows suggested incorporating a female pelvis and more soft tissue. **Conclusions:** We developed, implemented, and evaluated a design-based bone marrow biopsy training session. Though we did not find outcome differences compared to traditional training, 3D printing represents a feasible, cost-effective, and high-fidelity educational tool. 3D sessions, in conjunction with patient sessions, may augment understanding of anatomy and provide opportunities for practice and feedback. Future iterations should incorporate user feedback to optimize model fidelity and utility. Research Sponsor: None.

Enhancing cancer literacy among Appalachian Kentucky middle and high school students. *First Author: Lauren Hudson, University of Kentucky Markey Cancer Center, Lexington, KY*

Background: Kentucky has the highest rates of overall cancer incidence and mortality in the United States and the Appalachian region of the state experiences the highest burden of the disease. Poor health behaviors, poverty, poor health care access, low education levels, and low health literacy drive the cancer disparities in Kentucky. Inadequate health literacy is associated with lower participation in preventive measures, which can increase one's risk of developing cancer. Increasing cancer literacy among youth represents an opportunity to potentially decrease cancer disparities across Kentucky. In a recent study, we piloted a cancer education intervention in Kentucky middle and high schools to determine if such an intervention could enhance students' cancer literacy. Through the study, we documented a significant increase in students' short-term cancer literacy levels (Hudson L. et al. *Journal of Cancer Education*, in press). **Methods:** This quantitative survey research study aims to examine the long-term effects of the cancer education intervention on the cancer literacy of Kentucky middle and high school students. An online pretest cancer literacy survey consisting of 10 items was administered to a new set of 164 participants from six new schools, followed by the delivery of a cancer education presentation. Immediately following the presentation, participants took a posttest with identical items to the pretest. A follow-up identical test is being administered 3 months after the initial intervention to determine participants' longer-term knowledge retention. **Results:** Replicating our prior work, significant ($p < 0.0001$) increases in both average and median percent of correctly marked items (average: pretest = 50% versus posttest = 77%; median: pretest = 50% versus posttest = 80%) and scores on each individual question were observed immediately following the intervention. Additionally, the average rating as to how the intervention influenced students considerations toward encouraging a family member or friend to change their habits following the intervention was 8 (1 = extremely unlikely;10 = extremely likely). **Conclusions:** This work demonstrates an increase in cancer literacy levels after the educational intervention and indicates that the information motivates participants to share cancer prevention information with others. A follow-up survey will measure participants' longer term knowledge retention levels. These data may suggest that a school-based educational intervention can change behaviors that can lower cancer incidence and mortality rates. Research Sponsor: U.S. National Institutes of Health.

Burnout among oncology physician assistants (PAs) from 2015 to 2019. *First Author: Eric Daniel Tetzlaff, Fox Chase Cancer Center, Philadelphia, PA*

Background: Changes in the demand and delivery of healthcare have led to a significant increase in employment of PAs in Oncology (Onc). These changes may also increase PAs risk of burnout, a syndrome characterized by a high level of emotional exhaustion (EE) and/or depersonalization (DP). This study was initiated to explore temporal changes in burnout & the PA workforce. **Methods:** Using the same methods from 2015, a national survey of Onc PAs was conducted in 2019. Survey items (n = 74) examined personal and professional characteristics, collaborative practice (CP), team structure, organizational context (OC), and burnout. OC was assessed using Areas of Worklife Survey (AWS) domains: workload, control, reward, community, fairness, & values. Low AWS domain score indicated a workplace mismatch (WM). Burnout was assessed with the Maslach Burnout Inventory. Change in burnout was examined with repeated measures logistic regression. **Results:** 234 out of 917 PAs (25.5%) completed the full survey. Respondents were mostly female (86%), married/partnered (78%), in Med Onc (71%), and practicing in the outpatient setting (67%). Burnout increased from 34.8% in 2015 to 48.7% in 2019 [odds ratio for burnout, 2019 vs 2015 = 1.92 (95%CI 1.40-2.65), $p < .001$]. Adjustment for workforce variables did not explain the increase in burnout. Among 2019 respondents, increased hours worked ($p = .003$), sub-specialty ($P = .018$), less time (%) spent on direct patient care ($p = .007$), practicing below full extent of education and training ($p = .048$), dissatisfaction with CP ($p < .001$), and perceptions of poor collaborative physician leadership ($p < .001$) were associated with higher rates of burnout. No difference in burnout was seen for personal or team characteristics, practice setting, years in onc, or # of patient visits. AWS scores were lower for PAs with burnout vs. without burnout ($p < .001$). PAs with a WM had a higher rate of burnout for each AWS domain ($p < .001$); most common WMs were fairness (44%) and workload (43%). **Conclusions:** The rate of burnout for Onc PAs has significantly increased and is now at levels of nearly 50%. Burnout in Onc PAs related to WM in workload is common, significant, & not explained by patient volume alone. The causes of burnout are multifactorial and additional research is needed in this at risk group. Research Sponsor: Association of Physician Assistants in Oncology, U.S. National Institutes of Health.

Identifying burnout in young oncologists: The sooner the better. *First Author: Elena Elez, Medical Oncology Department, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Professional burnout is an important issue for the healthcare systems with potentially relevant consequences in the quality of patient care. Young oncologists are a special risk population, due to high workload, academic pressure and other specific factors related to cancer care. Work life and lifestyle factors are related with burnout levels and may define specific interventions to reduce and prevent burnout. **Methods:** A survey based on the validated Maslach Burnout Inventory Human Services Survey for Medical Personnel (MBI-HSS MP) was conducted. Additional questions to explore work life and lifestyle factors were included. We studied potential burnout amongst young Spanish oncologists (residents and oncologist in the first 5 years of professional performance). Statistical analyses, including linear regression, were carried out to test the relations between overall burnout score and work and lifestyle factors. **Results:** We obtained 243 responses to the survey. The sample was representative in terms of age, sex, geographic region, professional profile (residents and young oncologists) and a homogeneous distribution per year of residence (final participation rate was of 26.6%). Regarding 5 Burnout profiles, 32.1% of the participants were classified as Ineffective, 25.1% as Burnout, 21% as Engaged, 17.3% as Overextended and 4.5% as Disengaged. Percentage of Burnout profile is higher in medical oncology residents (28.24%) than in young oncologists (19.79%). The highest percentage of burnout profile was observed in the second-year residents (35,71%) and gradually decreases, in parallel to an increase in the engaged profile. The multivariable linear regression analysis showed a significant correlation between not having a good work life balance and adequate vacation time and the burnout score. **Conclusions:** Burnout affects a significant number of young oncologists with significantly different profiles and differences across regions. Adapted interventions to the most frequent profiles and at different stages of the training and professional career may be necessary particularly at the early beginning. Actions towards achieving a better work and personal life balance and stress management could be effective. These results are the basis for the prospective part of our study that aims to design an intervention and to assess its efficacy in this population. Research Sponsor: Spanish society of medical oncology.

Results of emotional burnout study among oncologists in Russia. *First Author: Tatiana Semiglazova, NMIC N.N.Petrov, St. Petersburg, Russian Federation*

Background: Emotional burnout (EB) is a syndrome caused by chronic work-related stress. This is a non-adaptive reaction to chronic stress resulting from professional activities and leading to the depletion of emotional and personal resources. Oncologists have high burnout risk, because involuntarily involved in the negative experiences of patients and get emotional stress. So it is important to develop measures to prevent EB for medical oncologists. Aim: The aim is to study the prevalence and severity of EB among oncologists and to develop preventive measures. **Methods:** A screening survey of the Russian Society of Clinical Oncology (RUSSCO) was conducted among 389 oncologists in various regions of Russia. The Maslach Burnout Inventory and online self-administered questionnaire were used. The questionnaire was sent out in November 2019. The questionnaire was based on a multi-factor model, which includes the following components: emotional exhaustion, depersonalization, reduction of professional achievements. **Results:** The average age of the respondents was 49.5 years, 61% of them were female. Chemotherapists made up 47.5%, 28% were surgeons, 8.5% were radiotherapists, 7% were diagnostic profile specialists, administrators made up 3%, 14.5% of the respondents had related specialties: clinical psychologists, pathologists, palliative care doctors. 30% of respondents had scientific degree. The results of the study were the following. 71.6% of specialists have expressed EB syndrome; 28% at EB formation stage, 1% have no signs of EB. There wasn't a significant difference in EB rates across oncologists of various specialties. All stages of EB were identified. Female specialists are more likely to have manifestations of EB. EB severity was the same for doctors of inpatient and outpatient care. The extreme mode of work did not show significant differences of EB among both male and female specialists. First 5 years and more than 15 years of professional activity are most vulnerable to development of EB. EB was least affected by specialists over 65 years old with extensive experience. **Conclusions:** Hight level of EB was revealed among oncologists. Study results should be used during EB prevention, development of psychotherapeutic assistance and in educational programs. Research Sponsor: None.

The Matilda effect: Under-representation of women in hematology and oncology awards. *First Author: Shruti R Patel, Mayo Clinic, Rochester, MN*

Background: The proportion of women in the field of hematology and oncology (H&O) has increased over recent decades, but representation by women in leadership positions remains a challenge. Our aim was to examine representation of winners of recognition awards by gender and race from the major international hematology and oncology societies. **Methods:** Published award recipients from the seven major H&O societies were reviewed, with 26 years of data included (1994-2019). Awardee demographics and academic rank were collected and included in the analysis. Gender was determined based on awardee full name and verified by public data. Chi-square and Cochran-Armitage tests were used to analyze the data. **Results:** Over the past 26 years, 942 awards were presented at the 7 major H&O societies. We excluded 27 gender specific awards from the analysis. Of the 915 awardees included in analysis, award recipients were overwhelmingly men (77.9%) and non-Hispanic white (84.7%). Gender breakdown by society is described in table. ESMO and ASTRO represented the lowest distribution of women at 9.1% and 11.1%, respectively. Women awardees received 30.3% of the awards categorized as humanistic and education-related, while only receiving 16.0% of awards in the basic sciences category ($p<0.01$). The Cochran-Armitage test demonstrated an upward trend in the number of women awardees, from 10% between 1994-1998 to 25.6% between 2014-2019 (p=0.0004). Over the past five years, the average proportion of women medical oncologists was 35.6% per the AAMC. In this time period, women oncologists have received only 24.0% of all awards, suggesting the awardees included in the study period do not represent the proportion women in the field (p=0.00424). Black, Hispanic, and Asian awardees represented 3.7%, 3.3%, and 6.8% of the total awardees, respectively. Of the 64 Black and Hispanic awardees, 60.9% of the awards were for investigating healthcare disparities and only 4.6% were given for basic science research. **Conclusions:** During our study period, women physicians and investigators were less likely to receive recognition awards from the seven major H&O societies compared to men. We also observed a considerable low proportion of minority awardees in all oncology subspecialties. While the proportion of women awardees has increased over time, significant underrepresentation remains. Research Sponsor: None.

Society	Women (%)	Men (%)
ASCO	54 (27.8)	140 (72.2)
ASTRO	7 (11.1)	56 (88.9)
AACR	50 (22.1)	176 (77.9)
ASH	44 (23.2)	146 (76.8)
EHA	8 (20.5)	31 (79.5)
ESMO	6 (9.1)	60 (90.1)

Gender differences in faculty rank and subspecialty choice in academic medical oncology. *First Author: Laura Graham, University of Washington, Seattle, WA*

Background: The gender gap in the United States healthcare field has been closing. In 2000 women made up 45% of medical school matriculants and by 2017 outnumbered men. Based on our personal observations at academic meetings, however, we hypothesized that gender differences persist in faculty rank and subspecialty choice in academic medical oncology. **Methods:** We created a database of medical oncologists at the top 15 cancer centers as ranked by the *U.S News and World Report* in 2019. We identified all medical oncology faculty in the subspecialty fields of breast, gastrointestinal (GI), genitourinary (GU) and thoracic oncology from institution websites (12/2019-1/2020). Faculty working only at satellite clinics (i.e. non-research appointments), and the few faculty in more than one subspecialty group, were excluded. Gender (determined by pictures), subspecialty and academic rank were recorded based on data from institution websites and professional social networking sites. Proportions of men and women in each subspecialty and at each faculty rank were calculated; odds ratios (OR) and χ^2 tests were used for comparisons. **Results:** 346 men and 244 women were identified as subspecialty medical oncologists, comprising 59% and 41% of faculty members, respectively. Gender representation by subspecialty and academic rank are shown in the Table. Breast oncology had more women oncologists than men (OR 2.9, $p < 0.001$); GU oncology had fewer women (OR 0.3, $p < 0.001$). The representation of women and men was comparable at the lower academic ranks (instructor, assistant and associate professors). But at the top rank of full professor, only 31% were women (OR 0.54, $p = 0.001$). Notably, even in breast oncology, the one subspecialty with a greater proportion of women, women still comprised a lower proportion of full professors than men. **Conclusions:** Gender differences persist in academic medical oncology. At the top 15 US cancer centers, gender differences are seen in subspecialty representation, with more men in GU oncology and more women in breast oncology. Fewer women than men achieve the rank of full professor, even in breast oncology. Additional research is needed to explore the causes of, and contributors to, these differences as well as their impact. Research Sponsor: U.S. National Institutes of Health.

Gender variation in clinical activity and Medicare payments among medical oncologists and hematologists. *First Author: Manojna Konda, The University of Arkansas for Medical Sciences, Little Rock, AR*

Background: While physician sex has been shown to impact salary even after adjusting for productivity, gender-based differences in clinical activity and reimbursement for oncologists and hematologists are not completely understood. We evaluated the differences in Medicare reimbursement for male and female physicians in medical oncology and hematology. **Methods:** A retrospective analysis using Centers for Medicare & Medicaid Services Physician and Other Supplier Public Use File (POSPUF) for the year 2017 was performed to identify charges and total payment information for individual oncologists and hematologists. Mean values were compared using two-sample t-test, and the medians were compared by Wilcoxon rank-sum test. **Results:** A total of 8553 oncologists and hematologists (2710 women and 5843 men) were included in the POSPUF in 2017. Female physicians submitted a mean of 16,754 fewer charges (95% CI, −19,696 to −13,812; $P < .0001$), collected a mean of $173,632 less in revenue (95% CI, −201,184 to −146,080; $P < .0001$), and submitted a mean of 5.65 fewer unique billing codes (95% CI, - 6.69 to - 4.61; $P < .0001$) compared to their male counterparts. Women represented 219 of the 1069 most highly productive oncologists and hematologists (20.4%) and collected a mean of $281,263 (95% CI, −417,517 to −145,008; $P < .0001$) less than similarly productive men. **Conclusions:** This study suggests that female oncologists and hematologists submit fewer Medicare charges and receive lower Medicare payments compared to male providers. Even among similarly productive hematologists and oncologists, women collected less revenue than men. Further research is required to explore causes for this difference. Research Sponsor: None.

11015 Poster Session (Board #272), Fri, 8:00 AM-11:00 AM

Stress related to electronic health record (EHR) use among oncology trainees: A quality improvement study to optimize information gathering. *First Author: Teja Ganta, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Poor EHR usability is associated with physician burnout [1]. Oncology providers are tasked with coordinating data from multiple sources/tabs within an EHR (biomarkers, genetic data, imaging, etc.) to make treatment plan decisions. It is hypothesized that oncology trainees will have decreased stress using an EHR tool to optimize data gathering. **Methods:** This single-institution quality improvement study aims to decrease the time and stress associated with navigating the EHR to review/document laboratory data among first-year clinical oncology fellows rotating on consult services at The Mount Sinai Hospital as measured by self-reported survey data. An EHR tool was built that pulls into the note a drop-down list of user-selectable laboratory panels grouped according to hematologic/oncologic disease presentations. A survey was sent to all fellows in the program to assess attitudes toward the EHR. All 1st-year fellows were given access to the EHR tool as they are the ones who primarily rotate on consult services. After 3 months, a follow-up survey was sent to 1st-year clinical fellows to assess satisfaction with the EHR intervention. **Results:** For the baseline survey, there are a total of 17 respondents (response rate 77%). 70.6% of fellows believe using the EHR increases their level of stress. The most prevalent reasons cited for frustrations with the EHR are "Hard to read other providers' notes" (82.4%), "Gathering information from multiple different pages" (76.5%), "Increased documentation requirements" (76.5%), "Inability to quickly navigate the system" (64.7%). For the follow-up survey targeting 1st-year fellows, there are a total of 6 respondents (response rate 100%). 5 fellows tried the EHR tool at least once. Of those 5 fellows, 100% use it daily in clinical practice while on consult services, believe it makes notes more legible, believe it saves time spent in chart review, and believe it decreases their stress associated with navigating the EHR. **Conclusions:** A majority of clinical oncology fellows believe that the EHR contributes to their stress. The reasons cited suggest that interventions that optimize note-writing and chart-reviewing may decrease stress. The majority of fellows who used this EHR tool believe the tool improved their efficiency and stress levels. This suggests more widespread use of this tool among oncology clinicians may contribute to wellness although further studies to increase utilization must be taken. Research Sponsor: None.

11016 Poster Session (Board #273), Fri, 8:00 AM-11:00 AM

Is burn-out-syndrome a problem among oncology workers? Incidence and effective tools to achieve improvement. *First Author: Alberto Jacobo Cunquero Tomas, Medical Oncology Department, Consorcio Hospital General Universitario de Valencia, Valencia, Spain*

Background: Burn-Out Syndrome (BOS) is defined by (1) emotional and physical exhaustion; (2) cynicism and depersonalization; and (3) no personal nor professional fulfillment. It affects up to 78% of oncology-related workers (doctors, nurses and nurse-assistants, among others). This may decrease quality in both patient assistance and institutional processes. However, there is lack of resources for its diagnosis and management. Our objective is to: (1) determine the incidence of BOS in our team; (2) analyze potential causes; and (3) decrease in 20% the percentage of BOS affected workers. **Methods:** From October 2018 to November 2019, 20 nurses and nurse-assistants participated. Process map and Ishikawa fish-bone diagram were design to analyze BOS potential causes and to design appropriate interventions after Priority/pay-off matrix description. To do so, participants were asked to fulfill a personal detail questionnaire at the beginning, and adapted versions for the GHQ-12 and Maslach Index questionnaires after each intervention. To track the improvement process, a PDSA cycle was fulfilled and re-evaluated overtime. Project developed through the ASCO Quality Training Program and the Fundación ECO support. **Results:** Population main characteristics: 87% women, 47-year-old median age. 12 nurses, 6 working in the clinic. 90% with more than 5 years of experience in Oncology. At baseline, 75% healthy (GHQ-12), BOS cause risk: exhaustion 70%, depersonalization 45%, fulfillment 55%. Two interventions developed to improve exhaustion BOS risk: (1) ergonomy tips; and (2) self-assessment and self-help tools. 9 subjects lost after 2nd intervention. After interventions, 34% exhaustion risk reduction and 100% healthy workers (GHQ-12). **Conclusions:** After two interventions, we have achieved an improvement of 34% lowering the risk of suffering BOS among our workers. Health perception improved to 100%. The loss of 9 subjects after the 2nd intervention may be a bias when interpreting the final results. Giving the appropriate tools to medical oncology workers helps reduce BOS risk significantly Research Sponsor: None.

11017 Poster Session (Board #274), Fri, 8:00 AM-11:00 AM

The experience of first-year hematology and oncology fellows after implementing a wellness chief fellow at an academic cancer center. *First Author: Sherise C. Rogers, Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Hematology & Oncology trainees are high risk for burnout. Risk factors include early stage in career, female gender and isolation. From previous assessment, the program discovered that the feeling of isolation was a problem experienced by our trainees. Our first-year fellows are challenged with multiple acclimations and the intense demands of inpatient service. As a result, we developed the leadership position of Wellness Chief Fellow to address the specific needs of this population during academic year 2019. **Methods:** The Wellness Chief (WC) is a third-year Hematology and Oncology Fellow with good communication skills and knowledge of resources at the academic cancer center. The WC gave a Wellness lecture during first-year orientation to emphasize the prioritization of personal wellbeing throughout fellowship. The WC developed a list of wellness resources within the hospital system and local community and shared these with the fellows. The WC also provided quarterly one-on-one confidential mentoring to first year fellows. These meetings were informal and semi-structured. Topics included adjusting to the academic center and their new fellowship role, moving to a new city, current support system, clinical and research mentorship, life challenges and self-care. Mid-year, the first-year fellows were surveyed regarding their experience. **Results:** Eight fellows participated in one-on-one mentoring and 5 completed a mid-year evaluation. 4/5 fellows were new to the city. All trainees felt that mentoring helped them adjust to fellowship. 4/5 stated that they found a clinical mentor and 3/5 have a research mentor and started a research project. 4/5 acknowledged that they have a friend in the fellowship program and 5/5 stated that they do have someone to go to if they were experiencing a challenging life event. All fellows reported gaining something valuable after each mentoring session. 3/5 subjectively experienced burnout within 6 months of the fellowship program. One person stated they experienced burnout once per week and 2 reported monthly burnout. **Conclusions:** A Wellness Chief Fellow can buffer the effects of isolation within the first-year fellowship experience by providing mentoring and resources during a challenging acclimation period. Research Sponsor: None.

11018 Poster Session (Board #275), Fri, 8:00 AM-11:00 AM

Storytelling as a means of improving community and decreasing burnout in a large academic cancer center. *First Author: Sherise C. Rogers, Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Burnout is highly experienced amongst physicians who care for patients with cancer. Workplace isolation is a risk factor for burnout. The field of oncology is growing at a rapid pace and many cancer centers are expanding to meet the demands of patient care and research. Prior assessments revealed that our hematology and oncology fellows were experiencing feelings of isolation and disconnection, which was likely reflected from our greater academic community. **Methods:** The traditional art of storytelling has been used to offer guidance, teaching, new perspective taking and understanding of self. The concept of "My Story", an interactive storytelling lecture series was developed to address the following objectives at a large academic cancer center: 1) Promote connection and decrease isolation amongst the cancer sub-specialties 2) Increase fellow-faculty interaction for mentorship, 3) provide an outlet to discuss sensitive topics such as burnout, grief, unexpected patient outcomes, medical errors, work- life balance, career transitions, personal struggles, and bias. A faculty member was identified to tell their unique story for a special lecture. Fellows and faculty members from hematology, oncology, radiation-oncology, neuro-oncology, gynecology-oncology, and surgical oncology were invited. All audience members were encouraged to ask questions and engage in discussion. A survey was distributed after the inaugural event for evaluation. **Results:** A total of 56 people attended the inaugural event. There were 14 fellows, 9 faculty members and 33 others, which included basic scientists and advance practice providers. 17 individuals completed our post survey, which included 6 faculty members, 4 fellows, 1 nurse practitioner, 1 student and 5 others. On a scale from 1-10 (mean scores reported), participants rated the experience 7.5 for enjoyment, 6.6 for sense of connection with the group, 6.0 for inspiring them to make new connections with others and 6.8 when asked if they left with new tools to assist with personal challenge. **Conclusions:** A lecture series that invites multidisciplinary cancer physicians and surgeons to discuss personal career and life challenges can be beneficial to addressing burnout, decreasing isolation and improving connection and community at a large academic cancer center. Research Sponsor: None.

11019 Poster Session (Board #276), Fri, 8:00 AM-11:00 AM

Reflection rounds to facilitate resilience in hematology/medical oncology fellows. *First Author: Erica C. Nakajima, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Given the prevalence of burnout among medical oncologists (40-60% in the literature), education on burnout risk factors, recovery, and prevention are needed urgently in training curricula for medical oncology fellows. Care of patients with cancer is increasingly complex, and often can seem overwhelming to new trainees. Debriefing as a resiliency skill to develop self-reflection and identify coping strategies may provide a durable way to navigate these complexities. Optimization of fellowship Reflection Rounds (RR) was selected as a fellow-led quality improvement (QI) project for the current academic year. **Methods:** A QI team including the APD and representatives from all levels of fellowship training was assembled. Feedback regarding previously unstructured, monthly, hour long faculty-facilitated RR for first year fellows was reviewed. Topics with associated readings were selected and paired with fellow-nominated faculty based on the most common recurring themes. The QI team administered the Stanford Professional Fulfillment Index (PFI) to all fellows at the midway point of the academic year. RR were re-structured to include a chaplain with trainee communication expertise and a chief fellow to participate the sessions to assess changes in trainee engagement. Repeat assessment of the Stanford PFI is planned for the end of the academic year. **Results:** Topics identified for discussion included handling bias, futile care, patient communication, end of life care, and work-life balance. 26 fellows completed the Stanford PFI including nine 1st year fellows, 13 2nd year fellows, and 6 3rd year fellows. Survey results revealed emotional and/or physical fatigue as areas of greatest need for improvement in fellow well-being with 27% of fellows reporting "moderate" emotional or physical exhaustion. **Conclusions:** RR provides a safe and effective forum to develop peer debriefing and self-refection as resiliency skills within hematology/medical oncology fellowship training. Optimization of RR will continue as fellows become more involved in planning and implementation of curricular improvements to promote resiliency and enhance wellness. Research Sponsor: None.

11020 Poster Session (Board #277), Fri, 8:00 AM-11:00 AM

Exploring glocalization in the construction and implementation of global curricula. *First Author: Meredith Elana Giuliani, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Despite proposed advantages of global oncology curricular harmonization including physician mobility and improving the quality of care the challenges and unintended consequences require greater study. The aim of this study was to problematize the concept and implementation of global oncology curricula and their relationship to local contexts of power and culture. **Methods:** Fourteen international participants involved in the development and implementation of global oncology curricula completed in-depth, one-on-one semi-structured interviews lasting 40-60 minutes. Snowball sampling was employed. The participant sample was representative of different geographic regions, genders and professional scopes of practice to ensure diverse perspectives were sought. Through iterative analyses, using an abductive approach, the study team discussed and reviewed the data and made revisions through collaborative analysis to enhance comprehensiveness and to improve credibility. In the final analysis the meaning and implication of the themes were discussed yielding a conceptual analysis. **Results:** Our data have articulated 5 key challenges for global curricula including 1) Ambiguous or conflicting perspectives on the purpose and scope of Global Oncology Curricula 2) Insufficient representation of diverse perspectives and realities in the creation of the final curricula 3) A rigid conceptualization of competency requirements 4) A mismatch between the curricular requirements and local context and 5) The influence of power relationships and decision makers. Leveraging the strengths of diversity including fostering representation, addressing power differentials and factoring local contexts may be an approach to mitigating these challenges. **Conclusions:** Global oncology curricula may serve important advocacy roles within the healthcare system. Leveraging diversity may positively impact the common challenges in the construction and implementation of global oncology curricula. Research Sponsor: None.

11021 Poster Session (Board #278), Fri, 8:00 AM-11:00 AM

Effect of participation in the annual Immuno-oncology Young Investigators' Forum (IOYIF) on the competency and performance of young researchers. *First Author: Joan B. Fowler, Creative Educational Concepts, Lexington, KY*

Background: Advancing the fight against cancer involves many types of research across different disciplines and professions, from PhD-trained scientists to medical oncology physicians. The IOYIF is a competitive academic research program where oncology junior faculty, clinical and post-doctoral fellows who are pursuing a career in academic research in IO are invited to submit an abstract of their unpublished, original research to a panel of expert judges for assessment. **Methods:** Performance and confidence change were objectively assessed by analyzing pre- and post-test results before and after the presentation of research. Statistical testing between pre- and post-participation were conducted via chi square analysis with a priori significance set at 0.05. **Results:** Participants experienced an improvement in mean abstract score following participation in the forum. The mean abstract score improvement was statistically significant for All Participants ($P< 0.001$) and all sub-groups ($P< 0.001$), with the sole exception of Clinician Scientists. Overall, PhD/Postdoctoral Research participants demonstrated the most improvement. The mean abstract score improvement was statistically significant for those who attended presentation coaching ($P< 0.001$) as well as for those that did not ($P= 0.001$); the magnitude of improvement was greater among those who attended coaching. Participant self-reported mean confidence scores increased with statistical significance from pre- to post-participation in the forum ($P< 0.001$); this increase was noted across all participants and all sub-groups, and was observed in relation to both presentation skills and research defense. Young Investigators reported that lack of experience with grant writing is the most significant barrier they face to obtaining grant funding; they also listed lack of mentorship/guidance in publishing as a prominent barrier. **Conclusions:** This analysis demonstrates that an IO research forum designed for young investigators can improve the performance and confidence of these scientists. These findings highlight the robust, multifaceted impact of the IOYIF on advancing the professional development of the next generation of IO researchers. Identification of barriers demonstrates the tangible value of the IOYIF in providing needed mentorship to further research efforts, deliver axioms of grant writing guidance, and bridge the gap young researchers face in obtaining funding and publishing their work. Research Sponsor: AstraZeneca.

11022 Poster Session (Board #279), Fri, 8:00 AM-11:00 AM

Introduction of a patient communication course to postgraduate oncology training in Russia. *First Author: Maxim Kotov, National Medical Research Center of Oncology N.N.Petrov, St. Petersburg, Russian Federation*

Background: Communication skills are an obligatory part of postgraduate oncology education in European and Western countries and its benefits for doctors, patients, and the healthcare system are well-known. However, teaching efficient patient communication is challenging in developing countries where the paternalistic model is still spread and medical professionals are unaware that these skills are lacking. We hypothesize that a short simulation-based course for oncology residents introduces communication skills and raises awareness about its value. **Methods:** A 2-day communication course based on the Calgary-Cambridge model was taught to a cohort of PGY2 oncology residents. Lectures, seminars, and clinical simulations emphasizing a patient-centered approach, including open questions, active listening, identifying patient concerns, empathy, summarizing, and bad news delivery were conducted by certified teacher. A simulation exam was administered to those who completed the communication course and those who did not complete the course. Scores (max. 130) from two clinical scenarios assessed by the examiner, actors, and participant were compared between groups. **Results:** Ten PGY2 residents completed the course and seven did not complete the course. Medians scores for the first scenario given by the examiner, actor and resident were 99 (IQR: 90 – 122), 125 (IQR: 122 – 127) and 102 (IQR: 91 – 108) for course participants and 15 (IQR: 7-35), 18 (IQR: 12-34) and 61 (IQR: 41-83) for non-participants, respectively. Medians scores for the second scenario were also higher in participant group: 113.5 (IQR: 100-117), 107 (IQR: 98-118) and 104 (IQR: 99-112) vs. 22 (IQR: 12-50), 18 (IQR: 10 - 44) and 66 (IQR: 43-81), respectively. Four (40%) course participants and seven (100%) non-participants evaluated themselves higher than the examiner and actor. **Conclusions:** A short patient communication course for young oncologists effectively improves communication skills and provider self-awareness in developing countries. Research Sponsor: None.

11023 Poster Session (Board #280), Fri, 8:00 AM-11:00 AM

Oncology fellows' survivorship clinic: An opportunity for education and multidisciplinary care delivery. *First Author: Hira Latif, Medstar Washington Hospital Center, Washington, DC*

Background: Cancer survivors in the U.S. are expected to exceed 20 million by 2026. Most fellows do not receive formal training in survivorship during oncology fellowship despite cancer survivorship comprising 2% of the American Board of Internal Medicine's Oncology examination and the recent accreditation standards related to survivorship care from the Commission on Cancer. **Methods:** We developed a survivorship curriculum and a multidisciplinary survivorship clinic staffed by a medical oncologist and physiatrist in September 2018. Oncology fellows rotated during their ambulatory block and completed surveys assessing skills and perceptions of competence at the beginning and end of the academic year. **Results:** 8 fellows completed the pre-survey and 6 of them completed the post-survey. While only a quarter had delivered a survivorship care plan/treatment summary prior to starting clinic, all fellows had delivered these (median=2, range=2-8) at the end of the year. Most fellows had seen survivors of breast, colorectal and hematologic malignancies prior to starting clinic; few had seen survivors with lung (12.5%), GU (0%) or head and neck (25%) cancer. These numbers increased, particularly with fellows' seeing survivors of GU (50%) and head and neck cancers (100%) at the end of the year. Prior to the rotation less than half the fellows had assisted with managing cancer survivors' treatment consequences or provided continuity of care through a multidisciplinary team. Similarly, only 25% had counseled cancer survivors with psychosocial concerns. On the post-survey, 100% of fellows reported practicing and feeling experienced in these domains. Post- survey showed improvement in self-reported competence levels in caring for cancer survivors (see Table). **Conclusions:** Participating in a survivorship clinic has a positive impact on oncology fellows' experience and competence in caring for cancer survivors. Future directions are geared toward expansion of fellows' skills to include areas related to cardiovascular and physical medicine. Research Sponsor: None.

Median scores for fellows' self-reported level of competence in caring for cancer survivors using a Likert scale of 1-5. (1: very unskilled to 5: very skilled).

	Pre-Survey	Post-Survey	P- Value
Provide current cancer information at the appropriate level	3	4	0.070
Provide a treatment summary and survivorship care plan	2	4	0.028
Identify people at high risk of cardiovascular complications due to their cancer treatment	3	4	0.064
Work with a multidisciplinary specialty team to provide continuity of care	2	4.5	0.038

11024 Poster Session (Board #281), Fri, 8:00 AM-11:00 AM

Student loan debt and visa status influence on career choices for hematology and medical oncology fellows in the United States. *First Author: Karam Al-Issa, Indiana University School of Medicine, Indianapolis, IN*

Background: There are multiple factors influencing future career plans for US hematology/oncology fellows. The objective of this study is to evaluate the effects of student loan debt and visa status as potential factors affecting their career choices. **Methods:** A total of 159 US hematology/oncology fellowship programs were contacted, program directors forwarded the survey to current hematology/oncology fellows and recent graduates (classes of 2019, 2018 and 2017). The survey consisted of 13 questions regarding their student loan debt and visa status, research experience, initial career plan, current career for graduates, the influence of student loan debt and visa status on their career decisions (academic, private practice, industry), and whether or not their training programs had resources or mentorship to help them deal with those factors. We used a scale of 1-5 to determine how much each factor affected career choice (1 = extremely unaffected, 5 = extremely affected). **Results:** A total of 220 physicians have participated, 177 (80.5%) fellows and 43 (19.5%) graduates. For graduates, 35% had student loans during fellowship, 40% of them thought that their loans affected their career choice with a score of 4-5. 93% of graduates with student loans answered that they weren't aware of resources/mentorship to address their loans effect on their career. 44% of graduates were on J1/H1 visa during training, 74% of them thought that their visa status affected their career choice with score of 4-5. 63% of graduates who were on visa answered that they weren't aware of resources/mentorship to address visa status as a factor influencing their career options. For current fellows, 51% have student loans, one third of them thought that their loans affected their career choice with score 4-5. 77% of fellows with student loans answered that they weren't aware of resources/mentorship to address their loans effect on their career. 16% of current fellows are on J1/H1 visa, 66% of them thought that their visa status is affecting their career choice with score 4-5. 62% of fellows who are on visa answered that they weren't aware of resources/mentorship to address visa status as a factor influencing their career options. **Conclusions:** Hematology/oncology fellows report that student loan debt and visa status are important factors affecting their career decisions. The majority of hematology/oncology fellows in this survey weren't aware of resources or mentorship to help deal with these factors. Mentors need to be aware of these factors to help fellows achieve their career goals. Research Sponsor: None.

11025 Poster Session (Board #282), Fri, 8:00 AM-11:00 AM

Just-in-Time Teaching (JiTT) screencasts for the resident inpatient oncology service: A pilot study evaluating feasibility and effectiveness. *First Author: Patrick Kuhlman, Wake Forest School of Medicine, Winston-Salem, NC*

Background: Just-in-Time Teaching (JiTT) screencasts have been viewed positively in some undergraduate and graduate medical settings. JiTT screencast effectiveness has not yet been evaluated for medical trainees in the inpatient adult hematology/oncology setting. Objectives: Our pilot study's goal was to identify relevant learning objectives, to assess feasibility of screencast development, and to optimize screencast delivery. **Methods:** To identify key clinical topics, a mixed methods approach first utilized institutional retrospective data (6/1/2018-6/30/2019) to determine the most common inpatient medical problems followed by qualitative interviews of teaching faculty and senior residents. The following six topics were identified for inclusion: 1. Metastatic disease to spine 2. Brain metastases 3. Oncologic emergencies 4. Cancer associated venous thromboembolism 5. Hematologic emergencies 6. Sickle cell disease: inpatient management For each topic, a literature review was performed to develop teaching points which were then refined with input from clinician experts. Each screencast went through several rounds of edits by faculty and trainees prior to submission to the instructional design team for final editing. Screencast length ranged from 13 – 25 minutes (mean of 18 minutes). Qualitative and quantitative feedback was obtained from residents by structured focus group session and online surveys. **Results:** All residents reported that educational content was "just right." The series of 6 screencasts was completed within 2 months of dedicated fellow research time. Preferred screencast length was 10-20 minutes and preferred viewing speed was 1.5x original speed (7/10). All residents reported that a screencast database would be a helpful resource for future clinical rotations. All residents (n = 10) reported that screencasts improved medical oncology knowledge base and will improve care provided to cancer patients. **Conclusions:** Creation of a screencast series was feasible for a hematology-oncology fellow. Systematic identification of key clinical topics led to materials which were confirmed by faculty and trainees to be important for internal medicine medical education on inpatient oncology services. This pilot data indicate that JiTT screencasts may be an effective educational intervention and directly informed a randomized educational research study which is currently enrolling participants. Research Sponsor: Wake Forest Comprehensive Cancer Center Pilot Funds.

11026 Poster Session (Board #283), Fri, 8:00 AM-11:00 AM

Optimizing management of glioblastoma: Educational impact on clinicians. *First Author: Michelle Arielle Worst, Medscape LLC, New York, NY*

Background: Glioblastoma multiforme (GBM) is a rare, malignant tumor of the central nervous system (CNS) with poor prognosis. Nearly all patients experience recurrence due to GBM's heterogeneity and there is currently no standard approach to treatment. Despite having few targeted agents with demonstrated efficacy, molecular testing is utilized due to its value in improving diagnostic accuracy and prognostic stratification. Moreover, recent data has shown an increase in promising data with regards to treating GBM using various mechanisms. Because of the clinical conundrum GBM poses and the lack of available treatment options, clinicians are challenged to stay current with new data and how best to integrate new agents into treatment paradigms. The objective of this study was to assess the changes in oncologists' and pathologists' knowledge through participation in education regarding optimal GBM treatment. **Methods:** The educational activity was a 30-minute online, video discussion segmented into 3 parts with synchronized slides and 2 faculty. Educational effect was assessed with a repeated pairs pre-/post-assessment study with a 3-item, multiple choice, knowledge questionnaire and one confidence assessment question. For all questions, each participant served as his/her own control. Pre- and post-assessment scores were compared to determine the relative changes in the proportion of correct responses. A chi-square test assessed statistical significance at the $P < 0.05$ level. The activity launched 26th June 2019; data were collected until 19th August 2019. **Results:** Overall significant improvements were seen after education for oncologists (N = 62, $P < .001$) and pathologists (N = 67, $P < .01$). The relative improvement was 67% for oncologists and 45% for pathologists (pre-/post-assessment average correct response rates were 30%/50% and 29%/42%, respectively). Following the activity, 55% of oncologists and 51% of pathologists had a measurable improvement in confidence in their ability to differentiate among late-stage investigational agents for GBM based on mechanism of action. **Conclusions:** Participation in an online, CME intervention consisting of a series of video discussions, totaling 30-minutes, resulted in statistically significant improvements in knowledge and confidence of oncologists and pathologists, that may lead to improvements in clinical care. As new data and agents emerge, new educational activities are necessary to reinforce knowledge, close persistent gaps, and increase oncologists' and pathologists' confidence in this clinical setting. Research Sponsor: Bayer.

11027 Poster Session (Board #284), Fri, 8:00 AM-11:00 AM

Lung cancer screening knowledge in four internal medicine university programs. *First Author: Samuel Urrutia Argueta, Indiana University, Indianapolis, IN*

Background: Low density CT (LDCT) screening reduces lung cancer specific and all-cause mortality in high risk populations. However, it remains underutilized. Screening discussions often start in primary care clinics of which nearly 30% are occupied by residents. Recognizing gaps in knowledge in early medical training may translate into a higher utilization of LDCT screening. **Methods:** To evaluate knowledge about lung cancer screening in Internal Medicine (IM) residents at 4 academic programs we distributed a survey to assess population at risk, mortality benefits, comparison between LDCT, colonoscopy and mammogram, and a knowledge self assessment. **Results:** 166 out of 360 (46%) IM residents at the 4 institutions participated, including 42% PGY-1, 30% PGY-2, and 28% PGY-3. Residents attained an average of 2.9 correct responses out of 7 (43.1%), without any statistically significant difference among programs. PGY-1 residents performed better than PGY-2 and PGY-3 (p=0.022). 36% correctly identified the appropriate population for screening. 90% correctly indicated that LDCT screening results in a cancer specific mortality reduction. 59% correctly indicated that LDCT results in all-cause mortality reduction. 7.7% answered that women stand to benefit the most from screening. 66% correctly answered that LDCT underperforms colonoscopy regarding mortality reduction. 22% answered correctly that LDCT outperforms mammography in reducing mortality. 65% of residents perceived their knowledge to be average or lower. **Conclusions:** LDCT knowledge is deficient among the residents studied. PGY-1 residents performed significantly better than their upper level peers. There were no significant differences among institutions. Research Sponsor: None.

Practice gaps and challenges integrating new immuno-oncology agents in the treatment of cancer patients in the United States: A mixed-method study. *First Author: Neal E. Ready, Duke University School of Medicine, Durham, NC*

Background: Previous research has indicated challenges integrating new immuno-oncology agents (IOAs) and predictive immune biomarkers into practice. Barriers, clinical gaps and underlying causalities explaining these challenges, however, are poorly understood. **Methods:** A mixed-methods educational needs assessment was conducted with physicians from 6 specialties (oncology, interventional radiology, pathology, pulmonology, emergency medicine and rheumatology), clinical pharmacists, physician assistants and advanced nurse practitioners involved in the care of cancer patients in the United States. Semi-structured interviews and discussion groups were thematically analyzed to identify challenges, barriers and underlying causalities. Qualitative findings subsequently informed the development of online surveys, which served to quantify findings. The following findings pertain to oncologists. **Results:** A total of 660 health care providers participated in the study, in which 17 interviews and 88 surveys were completed with oncologists. Seventy-two percent reported sub-optimal knowledge of the interactions between IOAs and the tumor's micro-environment, while 62% reported sub-optimal skills determining which IOA to select based on this information. Oncologists reported sub-optimal knowledge of best practices for using IOAs to treat cancer in presence of an autoimmune disease (74%-80% depending on condition), and sub-optimal skills weighing the risks and benefits of prescribing IOAs for these profiles (66%-77%). In addition, 50% of oncologists reported feeling overwhelmed by the volume of new IOAs being made available. Many oncologists expressed doubts regarding the clinical benefit (59%) and innovative nature (43%) of emerging IOAs. Finally, 46% reported limited skills identifying viable treatment options based on pharmacodiagnostic test reports. Barriers to having predictive biomarkers inform treatment decisions included sub-optimal communication between specialists regarding specimen requirements and desired biomarker information. **Conclusions:** This study demonstrates the need to further support healthcare professionals as they face challenges integrating new IOAs and predictive immune biomarkers into practice. Given the wide array of IOAs becoming available each year, addressing the knowledge, skills, confidence and attitude gaps identified in this study could help improve health care delivery and potentially optimize outcomes for cancer patients. Research Sponsor: Bristol-Myers Squibb Company.

11029 Poster Session (Board #286), Fri, 8:00 AM-11:00 AM

GI oncology molecular tumor board: Fostering collaboration and clinical education for personalized therapy. *First Author: Joseph Elan Grossman, Beth Israel Deaconess Medical Center, Boston, MA*

Background: In recent years, genomic profiling has become standard of care for several gastrointestinal (GI) cancers. In addition to standard of care indications, comprehensive genomic profiling has led to novel and expanded applications of targeted therapy, chemotherapy, and immunotherapy and facilitated identification of potential clinical trials. A GI molecular tumor board (MTB) was developed with a goal of improving understanding of the biological effects of genomic alterations and their therapeutic implications to enhance personalized therapy. **Methods:** Foundation Medicine (FM) collaborated with physicians in the GI oncology group of an academic medical center to develop a GI MTB starting March 2019. As of December 2019, 27 GI oncology cases were presented where FoundationOneCDx testing was performed and a clinical question was posed. Cases were discussed by faculty, fellows, research staff, and a clinical genomic scientist and oncologist from FM. Impacted signaling pathways and biomarkers were discussed for each case alongside clinical content so that physicians could consider therapeutic options and clinical trials. Presenting faculty were asked to complete a questionnaire for each case presented to assess the impact of the MTB discussion on clinician knowledge and patient-level treatment recommendations. **Results:** Of 27 questionnaires sent to 7 providers, 17 (63%) were completed. Respondents indicated that as a result of the MTB, the treatment plan was changed in 2 cases (12%), reinforced in 9 cases (53%) and in 6 cases (35%) there was no effect. On a Likert scale of 1-4 where 1 is "rare/poorly" and 4 is "great" mean scores were as follows: Did this MTB help you understand the biological effects of the main genomic alteration(s) reported in the case presented? 3.3. Did this MTB help you understand the possible therapeutic implications of the main genomic alterations in the case presented? 3.3. Did this MTB improve your understanding of the role of next generation sequencing and comprehensive genomic profiling in making treatment decisions? 3.4. **Conclusions:** The results of our questionnaire indicate that treatment decisions were changed in a minority of cases based on the MTB. In most cases, clinical decision making was reinforced and understanding of the biological effects of genomic alterations and their therapeutic implications were improved. Based on this feedback we will continue to refine and integrate the GI MTB into clinical care for patients with GI malignancies, and share our experience locally with other disease groups. Research Sponsor: None.

11030 Poster Session (Board #287), Fri, 8:00 AM-11:00 AM

Perceptions of research training in a hematology/oncology fellowship program. *First Author: Stephanie L Pritzl, University of Wisconsin Department of Medicine, Madison, WI*

Background: Current research training in Hematology/Oncology (Heme/Onc) fellowship is typically limited to mentoring relationships, which are highly variable due to the absence of standardized training for mentors and different perceptions of successful mentor-mentee relationships. Formal research productivity assessment is challenging and lacking in our current educational framework. **Methods:** Electronic surveys were developed to assess research training during fellowship at the University of Wisconsin (UW). Surveys were sent to current Heme/Onc fellows (n = 9), members of fellowship leadership (n = 4), and core research faculty (n = 5) with prior successful mentorship to trainees. **Results:** Surveys were completed by 6 fellows, 3 fellowship leadership, and 5 core research faculty. Both faculty and trainees recognized the research mentor-mentee relationship to be critical, with 5/6 (83%) fellows and 3/5 (60%) core research faculty identifying research mentors as the most meaningful training source. However, despite 5/6 (83%) fellows having a research mentor identified, there were large variations in the perceived level of proficiency in core research topics. While 3 fellows felt only slightly prepared in basics of clinical trial design, 1 fellow felt very prepared and 2 felt somewhat prepared. Furthermore, 2 fellows each felt very prepared, somewhat prepared, or not at all prepared in assembling grant components. There was also variable confidence reported by core research faculty in the ability of trainees to obtain funding and conduct independent research after fellowship, with 1 extremely confident, 2 somewhat confident, and 2 only a little confident. All individuals surveyed recognized manuscript publication, abstract presentation, and grant acquisition as important measures of research productivity. Beyond that, however, only 1/5 (20%) core research faculty and 0/3 (0%) fellowship leadership noted using rubrics for critical review of trainee academic progress despite 3/6 (50%) fellows believing that such rubrics were being used for their evaluation. **Conclusions:** The divergent experiences identified among research mentors and mentees and the lack of clearly defined metrics of research productivity highlights the need for a more standardized educational framework and formative evaluation tools. These identified needs have led to a pilot program at UW that intends to create a professional learning community for research mentors, define competencies for research training, and design a research training portfolio and accompanying assessment rubric. 11031 Poster Session (Board #288), Fri, 8:00 AM-11:00 AM

Assessing impact of inpatient rotations on resident interest in hematology-oncology. *First Author: Bilal Farooqi, Comprehensive Hematology Oncology, Brandon, FL*

Background: Working as a hematologist-oncologist is rewarding yet challenging. As cancer cases increase, there is a growing need to recruit more oncologists. It has been hypothesized that earlier exposure to oncology may improve resident interest in the field. This is often achieved by rotations on inpatient oncology wards, which represents only a small subset of the clinical work typical in hematology-oncology. We looked to assess whether early exposure to an inpatient oncology rotation impacts pursuit of this career path. **Methods:** Categorical interns in Internal Medicine at the University of Florida during year 2017-2018 were surveyed anonymously before and after their inpatient oncology rotation. Confidential identifiers were used to pair surveys. Similar surveys were used in the cardiology and gastroenterology rotations to allow for comparison. The survey included descriptor words to choose when describing the field. These words were categorized as either positive or negative. **Results:** Thirty-three interns were surveyed. Seventeen surveys were able to be paired (52% response rate) in oncology. Cardiology had 15 paired survey responses and gastroenterology had 13 paired responses. Using a 4-point Likert scale, interest in hematology-oncology decreased overall from 3.12 to 2.82 ($p = 0.059$) while interest in pursuing a fellowship remained the same. Stress levels were increased slightly from 2.30 to 2.05 ($p = 0.564$). Cardiology also saw a decrease in interest in the field from 3.53 to 2.93 ($p = 0.007$) but also an increase in pursuing fellowship from 2.20 to 2.60 ($p = 0.014$) and decreased stress from 3.13 to 2.67 ($p = 0.020$). Gastroenterology saw a decrease in interest in the field as well from 3.46 to 2.92 ($p = 0.020$). Interest in pursuing a fellowship and stress levels were not significantly different for gastroenterology. Field descriptors including "challenging," "scared," and "excited" decreased the most while "confident," "inspired," and "motivated" increased the most when describing hematology-oncology. **Conclusions:** While interest in this field was negatively impacted, stress levels associated with the field decreased. Furthermore, field descriptors were generally more positive and optimistic in the post-rotation setting. Though not statistically significant, these findings suggest that interns see oncology as less stressful and feel more capable after inpatient exposure during intern year. As much of hematology-oncology practice is outpatient, increasing intern exposure in this area may further improve perception and recruitment to the field. Research Sponsor: None.

11032 Poster Session (Board #289), Fri, 8:00 AM-11:00 AM

Delivery of cancer survivorship education to community health care professionals. *First Author: Ashley Pariser, Yale Smilow Cancer Center, New Haven, CT*

Background: Cancer survivorship care is an integral part of oncology care. Although oncologists overwhelmingly demonstrate a desire to be a part of their cancer survivors' care and management, only 60% of oncologists feel comfortable promoting healthy lifestyle behaviors, screening and prevention care. There is currently no standard of care for survivorship care education and data evaluating current educational models is limited. **Methods:** Project ECHO (Extension for Community Healthcare Outcomes) utilizes telehealth to promote long-distance learning and sharing of best practices. We utilized the Project ECHO model to deliver a survivorship curriculum in 6 hourly, bi-weekly sessions from October 2019 to December 2019. The curriculum was aligned with the 4 central tenets of survivorship care and was developed based on a needs assessment. Recruited participants included registered nurses (RN), registered dietitians (RD), advanced practice providers (APP), radiation oncologists and medical oncologists. Participants were enrolled in either a local ECHO curriculum or a national ECHO curriculum. Local Connecticut participants were invited to participate in semi-structured interviews to evaluate their experience. **Results:** Eight participants including 3 MDs, 1 APP, 1 SW and 3 RNs from 3 community oncology clinics in suburban Connecticut enrolled in the local ECHO curriculum. Twenty-eight participants including 17 RDs, 2 MDs, and 3 APPs from 13 hospital and community practices enrolled in the national ECHO curriculum. Four participants (50%) agreed to participate in semi-structured interviews. Motivations to participate included ease of participation and interest in survivorship. Participants described a positive experience, citing a well-structured curriculum and sense of community as highlights. Two participants described the sessions as empowering, leading to more discussions and engagement with survivors. All participants described an increased awareness of resources available for cancer survivors. Areas for improvement included greater assistance with technology and session time management. Concomitant patient care was the most cited barrier to participation. **Conclusions:** This pilot study is the first to demonstrate the feasibility of the Project ECHO model for delivering cancer survivorship education to community oncology providers. Further research evaluating the correlation between improved provider knowledge and survivorship care outcomes is needed. Research Sponsor: None.

11033 Poster Session (Board #290), Fri, 8:00 AM-11:00 AM

Use of oncology electronic learning resources to learn about geriatric oncology. *First Author: Tina Hsu, University of Ottawa, Ottawa, ON, Canada*

Background: Despite the aging population driving cancer growth, oncology trainees receive little training in geriatrics. While electronic resources, such as ASCO University, may help meet this gap, use of available geriatric oncology (GO) modules is low. We sought to understand why by exploring how oncology trainees currently learn about GO, their preferred methods for learning about GO, and their attitudes towards e-learning and geriatrics. **Methods:** Canadian medical oncology residents and recent graduates were electronically surveyed about the following domains: demographics, self-directed learning practices, use of electronic resources, perceived facilitators and barriers to e-learning, and geriatric oncology teaching. Descriptive statistics were used to analyze the data. **Results:** Respondents (n = 47) were mostly aged < 35 (66%). Respondents felt that learning about older adults was important (mean 4.3±1.0 out of 5) and generally felt comfortable caring for them (mean 3.9±0.9 out of 5) despite minimal training in geriatrics.Almost half (48.9%) received 0-2 hours of teaching in GO during residency, with the majority (59.6%) receiving teaching in clinic, 36.2% through lectures and 21.3% via seminars. Respondents also learned about GO through reading journal articles (42.6%), modelling in clinic (36.2%), reading a textbook (19.2%) or attending a conference (19.2%). Respondents preferred to learn about GO through on-site lectures (46.8%), dinner meetings (42.6%), case discussion (42.6%) and attending conferences (38.3%). Although overall respondents highly valued electronic learning (mean 4.3±0.75 out of 5), only a minority (8.5%) had received GO teaching electronically using e-modules and only 23.4% respondents were aware of e-learning resources in GO. In contrast most respondents (83%) had used an e-learning resource to learn about oncology. The most common oncology e-resources used were ASCO University (61.7%), Oncology Education (61.7%), and ASCO meeting videos (44.7%). **Conclusions:** Although oncology trainees value and commonly use e-learning resources, e-learning is not a common or preferred way to learn about GO, potentially due to lack of awareness about these resources. Future research will explore whether the current methods of educating oncology learners about older adults are appropriate and sufficient, as well as how trainees value and prioritize learning about topics that are not included in the formal curricula. Research Sponsor: Royal College Robert Maudsley Fellowship for Studies in Medical Education, Department of Innovation in Medical Education (DIME) Health Professions Education Research Grant.

11034 Poster Session (Board #291), Fri, 8:00 AM-11:00 AM

Setting focus on oncology in a German undergraduate medical training program: Our experience with a longitudinal elective *Interdisciplinary Oncology*. *First Author: Stefanie Zschaebitz, Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany*

Background: Compared to other academic disciplines such as social sciences and humanities, medical school curricula leave limited opportunities to meet individual interests of students. **Methods:** To allow students to set an individual focus in their MD education, and to promote a sound scientific basis, n = 11 longitudinal electives ("tracks") were introduced within the Heidelberg Curriculum Medicinale (HeiCuMed) in 2017. The volume of additional training consists of 2 weekly lectures hours for at least 1.5 years of training. Participation in the program has been on a voluntary basis until 2019 and now is obligatory for every student. **Results:** n = 141 students are currently enrolled within the track "Interdisciplinary Oncology (IO)". More than n = 50 optional courses are offered each semester covering oncologic subjects such as scientific methods in cancer research, ethical issues in research and clinical practice, communication and clinical skills training. The modular system of the IO elective allows for a wide selection of topics for participating students but also poses a challenge for graded assessments. **Conclusions:** Conducting a modular elective including graded assessments is feasible. The longitudinal track IO has a high voluntary participation rate and very positive feedback from students. This indicates that our teaching concept is very well suited to address the call for increased choice and specialization in medical curricula in Germany. Research Sponsor: None.

11035 Poster Session (Board #292), Fri, 8:00 AM-11:00 AM

Effect of live education targeted to genetic counselors on knowledge and competence. *First Author: Vanessa Carranza, Creative Educational Concepts, Lexington, KY*

Background: Rapid advancements in genomics and sequencing technologies have presented a growing need for experts in the field of genetics to translate results and optimize patient care. As knowledge regarding DNA mutations and the technology to properly detect them continuously advances, it will be vital that genetic counselors play a larger role in the oncology healthcare team. **Methods:** These activities were designed to target genetic counselors involved in the diagnosis, management and genetic counseling of patients who have or are at risk for DDR-mutated cancers, attending live symposia at the 2018 & 2019 American College of Medical Genetics & Genomics Annual Meeting. Learning and knowledge was objectively assessed by analyzing pre- and post-test results before and after the educational activities. To determine retention of knowledge over time, follow-up assessments were sent to participants after each live activity. Assessment questions in the form of case studies were utilized to gauge whether participants translated knowledge into practice at follow-up. Statistical testing between pre- and post-tests and from pre-test to follow-up were conducted via chi square analysis with a priori significance set at 0.05. **Results:** Evaluations were collected from N = 275 (onsite) participants. Improved learners, as determined by significant ($P < 0.05$) increases in correct responses, were observed in several specific topic areas: When to consider germline testing (2018 participants: 53.33% pre-test vs. 87.5% post-test; 2019 participants: 42.55% pre-test vs. 84.72% post-test). Patients most likely to benefit from a PARP inhibitor based on genetic testing results (2018 participants: 50% pre-test vs. 93.75% post-test; 2019 participants: 75.49% pre-test vs. 94.37% post-test). However not all improvement was sustained at follow-up: When it is appropriate to consider germline testing (2018 participants: 64.44% at follow-up – not significant ($P = 0.138$); 2019 participants: 85% at follow-up ($P < 0.001$). Patients most likely to benefit from a PARP inhibitor based on genetic testing results (2018 participants: 68.89% at follow-up – not significant ($P = 0.140$); 2019 participants: 65% at follow-up – not significant ($P = 0.329$). **Conclusions:** This analysis shows that live accredited education can significantly improve the knowledge and competence of genetic counselors in multiple areas surrounding the use of germline testing to guide treatment recommendations. Results also suggest that ongoing education in clinically appropriate scenarios is warranted. Research Sponsor: AstraZeneca.

11036 Poster Session (Board #293), Fri, 8:00 AM-11:00 AM

Micro-learning: A new approach to upskilling and professional development on the management of patients on immunotherapy. *First Author: Helen Winter, Bristol Cancer Institute, Bristol, United Kingdom*

Background: Advances in cancer management are rapidly evolving . The introduction of immunotherapy across many tumour types and the potential of effector T cell therapies for patients requires upskilling in the wider health care team. This requires developing learning aimed at understanding the new mechanisms of action, potential side effects and how we educate and manage our patients receiving these therapies. **Methods:** Five stand alone micro-learning sessions on Immunotherapy were designed aimed at the acquisition of new skills and knowledge in a concise and targeted way. These sessions covered the key areas identified by the Systemic Therapy Day and Acute Oncology Units. These topics developed covered: What is Immunotherapy (IO) (its not chemo); How to interpret thyroid function for patients on IO; Get to know your Cortisol levels and adrenal insufficiency in patients with IO; Proactive management of IO Colitis; Liver function for patients on IO. These were delivered and evaluated during the working day in brief bite-sized sessions. **Results:** Attendance at formal training sessions - including annual study days and monthly study sessions are not keeping pace with the requirements for upskilling of staff. We present the evaluation of micro-learning delivered within the working day in short sessions. **Conclusions:** In the era of precision medicine, immunotherapy and effector T cell therapies a new approach to learning and upskilling in the wider health care team is needed. An integrated approach to learning on-the -job with short micro-learning sessions may embed the acquisition of new skills. More importantly, vocational education seeks to change habits, behaviour and culture. This needs to be accessible and flexible to adapt to the current patterns of work. Research Sponsor: None.

11037 Poster Session (Board #294), Fri, 8:00 AM-11:00 AM

Developing South Asia's first structured head and neck surgery multicenter fellowship initiative. *First Author: Shamit Chopra, Patel Hospital, Jalandhar, India*

Background: Despite high head neck cancer incidence in South Asia, there exist few fellowship programs, which are limited by lack of structure, review processes and standard curricula. Our aim was a regionwide multicenter head and neck fellowship initiative to address the above limitations. **Methods:** A 10-member task force was constituted in January 2018 under the aegis of the Foundation for Head and Neck Oncology. First phase: Initial curriculum drafted by incorporating region-specific perspectives, aided by multiple source documents. Candidate eligibility criteria outlined, accommodating multiple pertinent disciplines and an international applicant base. Format for a structured entrance examination, and a mandatory/desirable rotation schedule were developed. Second Subcommittee(SC) phase: Creation of a web portal (www.fhnofellowship.org) by Outreach SC, approval of applicant centers by Accreditation SC, layout of exam structure by the Examination SC, and defining a rank order list-driven match process by the Match SC. Third phase: Development of standard documentation including suggested bibliography, log book format, recommended grand rounds topics, common minimum criteria for fellowship graduation. A common entrance exam was conducted in Feb 2019, which incorporated written screening, center-candidate interactions, objective interview, and the merit-based institution-fellow match. **Results:** Total number of applicants: 92, the majority Oral Maxillofacial Surgeons(83.7%). Seventeen fellows matched in the first cycle, the initial and 6-month program compliance 94.1% and 88.2% respectively. More eligible institutions accredited(36.8% increase) prior to the second cycle in Nov 2019, during which 19 fellows(11.8% increase) were matched. An interim review was done in Oct 2019, and periodic reviewing set at 6-month intervals. Planned fourth phase: Objective center/candidate feedback, surgical video repository, online training schedule, develop the fellowship exit examination, and expand outreach to other countries. **Conclusions:** Owing to high head neck cancer incidence in the subcontinent, anatomic complexity, need to balance outcomes/toxicities and requirement of expert multidisciplinary care; structured head neck fellowship training is imperative. Despite inherent challenges of concept and implementation in a diverse multicultural resource-limited setting, we foresee the application of region-relevant perspectives helping us achieve the objective of furthering subspecialty head neck training in South Asia. Research Sponsor: None.

11038 Poster Session (Board #295), Fri, 8:00 AM-11:00 AM

Customized social media-based oncology education. *First Author: Udaykumar Punukollu, Nizam's Institute of Medical Sciences, Hyderabad, India*

Background: Social media has profoundly impacted our professional lives. Quick access to reliable sources of information and engaging with like-minded experts certainly aids in professional development. The purpose of this study is to assess the perception of oncology experts towards social media based education and to develop a platform based on their feedbacks for constructive engagement of the professionals and to improve educational outcomes. **Methods:** Based on Kirkpatrick 4 level model, 15 questions were designed for oncology experts. We collected responses through online surveys and by distributing the questionnaires at oncology events. Based on the results obtained, we developed a customised social media application for oncologists in android version. User experience design was done in InVision Studio and Model View Presenter (MVP) design pattern was used in software development. Beta testing of the application was done with 50 experts and questionnaire was given to them at the end of beta testing period to compare the technical advantages of our mobile application with their currently preferred social media platform for oncology based education. **Results:** Among 311 responders, medical oncologists, radiation oncologists, surgical oncologists, hemato oncologists and oncopathologists constituted 45%, 29%, 16%, 7% and 3% respectively. Only 14% clearly denied that social media has improved educational outcomes. Eighty seven percent felt that they lack adequate knowledge in other areas of expertise and 67% of the oncologists were not well informed about the latest oncology updates. Only 60% could actively engage in interdiscliplinary collaboration due to reasons unspecified. When asked about the best way to learn a topic of interest, majority opined it through peer discussion with experts pertaining to that topic of interest. The two major problems faced by experts while seeking social media based education is academic discussions being unorganised and non-academic discussions unwelcomed. After considering these feedbacks, a mobile application in android version was developed. At the end of beta testing, 96% reported a technical advantage of our customised application over their preferred social media based oncology education. **Conclusions:** A minimum viable product has been developed after considering the feedbacks received from oncologists of various sub-specialities. Such a customised social media application is more appealing when easily applicable across low and middle income countries and in a manner that allows addition of local language options without changing the application software. Research Sponsor: None.

11039 Poster Session (Board #296), Fri, 8:00 AM-11:00 AM

Quality and reliability of online video information of breast cancer in Spanish. *First Author: Fernando Cristobal Diaz, University of Texas Rio Grande Valley, Harlingen, TX*

Background: Online health information is a central part of how patients learn about a cancer diagnosis. Involving patients in shared decision making is associated with better outcomes. Previous studies have identified a lack of high-quality, reliable online material related to cancer in English using validated tools. As the number of Spanish speaking people in the US, and globally, continues to grow, it is important that high-quality, reliable information is available in Spanish. No studies have evaluated online breast cancer informational videos in Spanish. **Methods:** A search using the phrase "cancer de mama" (translation: "breast cancer") was conducted on YouTube. The first 200 video URLs were included for study with duplicates, non-Spanish, and non-informational videos excluded. The videos were characterized by several variables, including year of upload, country of origin, content discussed, views, likes, dislikes, and typology group ("Personal", "Professional", "Health Portal", etc.). The quality and reliability of these videos were examined by measuring Global Quality Scale (GQS), a 5-point DISCERN score, and JAMA scores. **Results:** 173 videos met inclusion criteria in the study. The majority of the videos which discussed signs and symptoms were uploaded by a 'commercial' typology, risk factors mainly uploaded by 'health portals' (21%), and treatment options by 'professionals' (50%). Relatively few videos have discussed reconstruction, survivorship, and breast cancer in men. 57% of these videos were uploaded prior to 2017, 36% by different personnel followed by government/news agency (25%), and professionals (23%). There was no significant difference between number of views (p-value: 0.526) and likes (p-value: 0.122) among the five typology groups. Professional videos had the highest average GQS (2.55), DISCERN score (1.90), and JAMA score (2.05). Personal videos had the lowest average GQS (1.98) and DISCERN score (1.06). GQS, DISCERN, and JAMA scores were all statistically significantly different between each typology. **Conclusions:** The majority of online breast cancer videos in Spanish are older than 3 years and produced outside the US. They are generally of poor quality and reliability, although higher in professional videos. Given the lack of current, high-quality, and reliable informational videos available, needs assessments should be conducted to identify the most useful learning resources for Spanish-speaking patients. Specialists should consider uploading educational videos to improve the paucity of high-quality, reliable information online. Research Sponsor: None.

11040 Poster Session (Board #297), Fri, 8:00 AM-11:00 AM

Content analysis of pancreatic cancer conversations on Twitter: What matters most to users? *First Author: Udhayvir Singh Grewal, Louisiana State University Health Sciences Center, Shreveport, LA*

Background: Social media has an important role in addressing medical misinformation by connecting the global community of health care professional (HCP), cancer patients and advocates. We evaluated the content and dynamics of discussions around pancreatic cancer (PC) on Twitter to identify subtopics of greatest interest to these users. **Methods:** We used online analytical tool (CREATION Pinpoint) to quantify Twitter mentions (tweets and re-tweets) related to PC between 1/2018 to 12/2019. Keywords, hashtags, word combinations and phrases were used to query for PC mentions. HCP profiles were identified using machine learning and then human verified and remaining user profiles were classified as general public (GP). Data from conversations were analysed and stratified qualitatively (using e.g keywords/combinations/phrases) into 5 categories; 1) prevention (P), 2) survivorship (S), 3) treatment (T), 4) research (R), and 5) policy (Po). We analysed the impact of PC awareness month (PCAM) and celebrity PC diagnosis on the overall level of conversations. **Results:** Out of 1,258,028 mentions on PC, 313,668 unique mentions were classified into the 5 categories. We found that HCP discuss PC research more than the GP, while GP are more interested in treatment. PCAM did not increase mentions by HCP in any of 5 categories while GP mentions over 2 years, increased temporarily in all categories except prevention. HCP mentions did not increase with celebrity PC diagnosis. Alex Trebek's diagnosis increased GP mentions on survivorship, while Ruth Ginsburg's diagnosis increased conversations on treatment (Table). **Conclusions:** Twitter mentions between HCP and GP around PC are not aligned. The HCP conversation was mainly limited to research while GP were more interested in treatment. PCAM temporarily increased GP conversations around treatment, research, survivorship and policy but not prevention. Future studies should address which factors determine how celebrity diagnoses drive conversations. Research Sponsor: None.

11041 Poster Session (Board #298), Fri, 8:00 AM-11:00 AM

Patterns of Twitter use among trainees in hematology-oncology related areas. *First Author: Miguel Gonzalez Velez, Mayo Clinic Arizona, Phoenix, AZ*

Background: Twitter (TW) is an essential tool in the medical community. Few studies have examined the use of TW by medical trainees. We aimed to assess its utilization among trainees in hematology-oncology related areas (HORAs). **Methods:** 576 training programs in HORAs were obtained. We contacted a potential pool of 3,142 trainees. A 50 item survey was distributed between 2/2019-5/2019, focusing on: demographics, professional use, attitudes toward TW, and patient interactions. Responses were analyzed using parametric descriptive statistics. **Results:** 442 responses (14% response rate) were received; 203 (46%) used a TW account for professional activities. See table for demographics. The most common reasons for using TW were: continuous education (73%), dissemination of information (62%), and networking (62%). > 80% of users have positive views on using TW for: promoting academic discussions (92%), trainees education (89%), and conference networking (83%). 50 (25%) have used TW for collaborations, with abstracts and papers being the most common (20%). Most agreed or strongly agreed that TW: is a useful education tool (89%), and might be useful for career advancement (85%). The most common challenges were: the value of TW content can be decreased by irrelevant content and biased sources (64%), not peer-reviewed (51%), and difficulty searching information (50%). 68% considered that programs should promote the engagement of trainees, but only 21% reported instruction in the use of TW. 83% agree or strongly agree that TW is useful for physicians and patient interactions, but 82% have concerns about legal repercussions. **Conclusions:** Almost half of trainees in HORAs use TW for professional activities. The most common uses are for education, dissemination of information and networking. Most trainees that use TW have positive views regarding education and academic collaborations. Use of Twitter may strengthen trainees' education, provide mentorship opportunities, and promote career advancement. Challenges on TW use should continue to be addressed. Research Sponsor: None.

11042 Poster Session (Board #299), Fri, 8:00 AM-11:00 AM

Females as surgical oncologists in Taiwan: A nationwide population-based study. *First Author: Weiming Cheng, Taipei City Hospital, Taipei, Taiwan*

Background: Operations for malignancy are stereotypically viewed as the field of men, especially in eastern countries. In recent decades, more and more women devoted themselves to be surgical oncologists. However, they face many challenges, especially when they treating patients with sex organ-related malignancies. In the present study, we compared the disparities between female and male surgical oncologists in urology, general surgery, and gynecology by analyzing a nationwide, population-based database in Taiwan. **Methods:** National Health Insurance covers more than 99.6% of population in Taiwan. The system's claim data are released as the National Health Insurance Research Database. One of its database, the Longitudinal Health Insurance Database 2000, contains all the original data of one million randomly-selected beneficiaries enrolled in year 2000. We recruited the yearly inpatient and outpatient service volumes, oncological surgical volumes, revenue, and sex ratio of patients of each female and male attending general surgeons, gynecologists, and urologists with practice more than five years from 1995 to 2013. The differences of these factors between male and female physicians in each specialty were compared with Mann-Whitney U-test. $P < 0.05$ was viewed as statistically significant. **Results:** There are 13, 87, and 191 female urologists, general surgeons, and gynecologists included, accounting for 6.7%, 7.0%, and 51.3% of physicians in each specialty in Taiwan respectively. Female urologists and general surgeons had significantly more female patients ($p = 0.004$ and < 0.001 respectively). Female urologists had insignificantly less patient service numbers, oncological surgical volumes, and revenues ($p = 0.285$, 0.718, 0.077 respectively), while female general surgeons and gynecologists performed worse than corresponding male physicians (all p value < 0.001). Of noted, female general surgeons have significantly less patient service (66.0 ± 57.1 vs. 94.8 ± 98.9 patients, $p < 0.001$) and total surgical volumes (2.30 ± 2.50 vs. 3.28 ± 3.33 surgeries, $p = 0.001$) but more oncological surgeries (0.33 ± 0.64 vs. 0.17 ± 0.41 surgeries, $p = 0.003$); however, there is no differences after exclusion of surgeries for breast cancer (0.07 ± 0.22 vs. 0.12 ± 0.32 surgeries, $p = 0.057$). **Conclusions:** Patients tend to seek medical help from same-sex physicians in Taiwan. Females could have a comparable career with males in urology, while gender inequality remains significant in general surgery and gynecology. Female surgical oncologists may have advantages in breast cancer treatment. Research Sponsor: None.

TPS11043 Poster Session (Board #300), Fri, 8:00 AM-11:00 AM

Building resilient oncologists: A feasibility study of a resiliency curriculum for hematology oncology fellows. *First Author: Monica Sheila Chatwal, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Rates of burnout and career dissatisfaction have declined slightly, but remain high among oncologists (Berg, AMA 2020). As hematology oncology fellows prepare to join this workforce, the ACGME now mandates wellness be a part of their training curriculum. Yet, there are few, if any, structured and effective programs specifically for these trainees. Based on feedback from our prior mindfulness-based wellness curriculum, we created a more varied and comprehensive resiliency program with the use of our institutional resources to incorporate and evaluate as part of our fellowship curriculum (ASCO, Abstract 10508), and potentially expand to other fellowships. **Methods:** This is a single-center, non-randomized, pilot project to assess the feasibility, acceptability, and impact of a resiliency training program. All hematology oncology fellows at our institution were eligible for enrollment, and participation was voluntary. A total of seven monthly, 1 hour sessions were conducted through the academic year. Each session focused on a particular topic - alternative forms of wellness through art and music, self care, mindfulness and stretching, reflective writing, and healthy boundaries and work life integration - which have all been studied individually in wellness and burnout with positive results. Sessions were co-led by a peer and "expert" guest speakers from our training institution. Participants completed questionnaires pre and post-program, and feedback evaluations after each session. Questionnaires included the Perceived Stress Scale (PSS), Five Facet Mindfulness Questionnaire (FFMQ), Connor Davidson Resiliency Scale (CDRS-10), and modified Maslach Burnout Inventory (MBI), as well as demographics and open response questions. The primary aim was feasibility (enrollment, completion, and compliance rates), and the secondary aim was acceptability (usefulness of the intervention). Examination of stress, mindfulness, resiliency, and burnout were exploratory. Enrollment and data collection are complete, with 18 of 29 (62%) eligible participants consented. Data analysis is in process. Research Sponsor: University of South Florida Graduate Medical Education Grant, Moffitt Cancer Center Genitourinary Department Funding.

11500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Comparison of two chemotherapy regimens in Ewing sarcoma (ES): Overall and subgroup results of the Euro Ewing 2012 randomized trial (EE2012). *First Author: Bernadette Brennan, Royal Manchester Children's Hospital, Manchester, United Kingdom*

Background: In 2010, different chemotherapy regimens were standard in Europe and the USA for newly diagnosed ES. In the absence of novel agents to investigate, comparison of these two strategies was considered worthwhile. **Methods:** Newly diagnosed localised or metastatic ES patients aged 5-50 were eligible. Patients were randomized to receive either the European regimen (Arm A) of VIDE (vincristine [V], ifosfamide [I], doxorubicin [D] and etoposide [E]) induction and VAI or VAC (V, actinomycin D and I or cyclophosphamide [C]) consolidation or the USA regimen (Arm B) of compressed VDC/IE induction and IE/VC consolidation. The primary outcome measure was event-free survival (EFS); secondary outcomes included overall survival (OS) and toxicity. The design was Bayesian with interpretation based on posterior probabilities (with non-informative priors) – i.e. probability that true hazard ratio (HR) < 1.0 given the data [Pr(HR$<$1.0| data)], with 95% credible intervals (CrI) reported. HRs were obtained from Cox models adjusted for baseline stratification parameters. Heterogeneity tests (HT) were used to investigate whether the treatment effect differed according to baseline parameters. Analysis was intention-to-treat. **Results:** Between December 2013 and May 2019, 640 patients were randomised (320 to each arm) from 10 European countries. Baseline stratification factors were: sex (58% male; 42% female); age (41% $<$14 years; 59% 14+ years); disease type (74% localised, 17% lung/pleural metastasis, 9% other metastasis); tumour volume (56% $<$200 ml, 44% $>$200 ml); country (37% UK, 31% France, 32% other). Median follow-up was 1.7 years. The HRs (95% CrI) were 0.70 (0.51, 0.95) for EFS and 0.64 (0.42, 0.96) for OS in favour of Arm B, with posterior probabilities of 98% for both that Arm B was better. Subgroup analyses showed no evidence that this benefit differed depending the baseline features, with no HT being close to significance (table). There were no major differences in acute toxicity: 68% of patients in Arm A experienced serious adverse events and 67% in Arm B. **Conclusions:** VDC/IE chemotherapy is superior to VIDE for both EFS and OS, with no excess toxicity. This benefit is consistent across all baseline stratification parameters. Clinical trial information: ISRCTN92192408. Research Sponsor: Cancer Resaerch UK and European Union FP7 grant.

11501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Efficacy of add-on treosulfan and melphalan high-dose therapy in patients with high-risk metastatic Ewing sarcoma: Report from the International Ewing 2008R3 trial. *First Author: Uta Dirksen, Pediatrics III, West German Cancer Center, University Hospital Essen, German Cancer Consortium (DKTK), Essen, Germany*

Background: Ewing 2008R3 (EudraCT2008-003658-13) was conducted in 12 countries. It evaluated the effect of treosulfan and melphalan high dose chemotherapy followed by re-infusion of autologous hematopoietic stem cells (HDTreoMel) on event-free (EFS, primary endpoint) and overall survival (OS) in high-risk Ewing Sarcoma (EwS). **Methods:** Phase III, open label, prospective, multi-center, randomized controlled clinical trial. Eligible patients (pts) had disseminated EwS with metastases to bone and/or other sites, excluding pts with only pleuropulmonary metastases. Pts received 6 cycles of VIDE induction and 8 cycles of VAC consolidation therapy. Patients were randomized to receive additional HDTreoMel chemotherapy or no further treatment (control), They were further stratified by number of bone metastases (1, 2-5, $>$ 5). One-sided adaptive inverse-normal 4-stage design, changed after the 1st interim analysis via Müller-Schäfer method. Initial sample size 185 pts, type I error rate 2.5%, power 80%. **Results:** 109 pts were randomized between 2009 and 2018: 55 were randomized to HDTreoMel. With a median follow-up of 3.3 years, the primary endpoint EFS was not significantly different between HDTreoMel and control in the adaptive design (HR 0.85, 95% CI 0.55-1.32, intention-to-treat). 3-year (3y) EFS was 20.9 % (95% CI 11.5-37.9%) in HDTreoMel and 19.2 % (95% CI 10.8-34.4%) in control pts. Results were similar in the per protocol collective. Subgroup analyses showed that independent of treatment, male patients had a worse outcome than female patients: 3y EFS 13.3% (95% CI 5.7-31.1%) vs 25.2% (95% CI 15.5-40.8%); p = 0.07. Patients aged $<$ 14 had a better outcome when treated in the HDTreoMel group: 3y EFS 39.3% (95% CI 20.4-75.8%) vs 9% (95% CI 2.4-34%); p = 0.016; HR 0.40 (0.19-0.87). These effects were similar in the per protocol collective. Severe toxicities of hematology, gut, general condition and infection were more pronounced in the HDTreoMel group ($p < 0.05$). **Conclusions:** In patients with very high risk EwS, additional HDTreoMel was of no benefit for the entire cohort of patients. HDTreoMel may be of benefit for children age $<$ 14. This observation is supported by comparable results from a non-randomized trial EE99 R3 (Ladenstein et al. JCO, 2010). Clinical trial information: NCT00987636. Research Sponsor: German Cancer Aid.

11502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results of the second interim assessment of rEECur, an international randomized controlled trial of chemotherapy for the treatment of recurrent and primary refractory Ewing sarcoma (RR-ES). *First Author: Martin G. McCabe, University of Manchester, Manchester, United Kingdom*

Background: Five-year survival of RR-ES is about 15%. Several chemotherapy regimens are used, but without robust evidence. rEECur, the first randomised controlled trial in this setting, is defining a standard of care, balancing efficacy and toxicity. **Methods:** Patients aged 4 to 50 with RR-ES and fit to receive chemotherapy were randomised between topotecan & cyclophosphamide (TC), irinotecan & temolozomide (IT), gemcitabine & docetaxel (GD) or high-dose ifosfamide (IFOS). Primary outcome measure was objective response (OR) after 4 cycles by RECIST 1.1. Secondary outcomes included PFS, OS and toxicity. A probability-based Bayesian approach was used with multiple pairwise comparisons. At the first interim analysis patients allocated to GD had worse OR and PFS than the other arms and accrual to the GD arm was halted. The second interim assessment was planned to determine which arm should be closed when at least 75 evaluable patients had been recruited to the remaining arms and evaluated for the primary outcome measure. **Results:** 366 patients (87% RECIST-evaluable), recruited between 18/12/14 and 17/12/19, were randomised to TC (n=124), IT (118), GD (72) and IFOS (53). Median age was 20 years (range 4-49). Patients had: refractory disease (19%), first recurrence (66%), $>$ first recurrence (14%). Initial disease site was bone in (66%). Sites of progression were: primary site only (16%) pleuropulmonary only (32%), other metastatic (52%). At median follow up of 9.2 months, outcome in the IT arm was: response rate 20%, median PFS 4.7 months (95% CI: 3.4 to 5.7), median OS 13.9 months (95% CI: 10.6 to 18.1). The table shows, for each pairwise comparison of IT with the other open arms (randomly labelled A and B to maintain blinding), the probabilities that OR, PFS and OS were better for X than for each other arm (RR = risk ratio, HR = hazard ratio). For OR, PFS and OS, all comparisons favoured arms A and B. The main grade 3/4 adverse events (% patients with an event) for IT (left hand values) compared with A and B pooled were: vomiting (6% v 1%), nausea (6% v 0%), diarrhoea (17% v 0%), fatigue (3% v 1%) and febrile neutropenia (3% v 24%). **Conclusions:** The first randomised trial in RR-ES has shown that IT, used as a control arm in planned and ongoing randomised phase II studies in RR-ES, is less effective than A and B in achieving tumour shrinkage or prolonging PFS and OS. The remaining two arms are continuing to recruit patients. Clinical trial information: ISRCTN36453794. Research Sponsor: Cancer Research UK, European Commission, German Cancer Aid, Finnish Children's Cancer Foundation, Australia & New Zealand Children's Haematology & Oncology Group, Australia & New Zealand Sarcoma Association.

11503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Three versus one year of adjuvant imatinib for high-risk gastrointestinal stromal tumor (GIST): Survival analysis of a randomized trial after 10 years of follow-up. *First Author: Heikki Joensuu, Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland*

Background: Adjuvant imatinib improves recurrence-free survival (RFS) when administered after surgery to selected patients with operable gastrointestinal stromal tumor (GIST). It is uncertain whether overall survival (OS) improves, since imatinib improved OS in only one of the 3 large randomized trials conducted, and in this trial (the Scandinavian Sarcoma Group XVIII/German trial; SSGXVIII/AIO; NCT00116935) the statistical significance for OS remained borderline. The objective of the present analysis was to evaluate long-term OS of patients who participated in the SSGXVIII/AIO trial. **Methods:** SSGXVIII/AIO is an open-label, randomized (1:1), multicenter phase 3 trial. Four hundred patients who underwent macroscopically complete surgery for GIST with a high estimated risk for recurrence according to the modified National Institutes of Health Consensus Criteria were accrued between February 2004 and September 2008. Imatinib was scheduled to be administered 400 mg/day orally for either 12 months or 36 months after surgery. The patients were scheduled to be followed up for 10 years after study entry. Imaging of the abdomen was carried out periodically. The primary end point was RFS; the secondary objectives included OS and treatment safety. **Results:** The median follow-up time was 119 months. In the Intention-To-Treat Population 194 RFS events and 96 OS events were recorded. In the 36-month group, 5-year and 10-year RFS was 71.4% and 52.5%, and in the 12-month group, 53.0% and 41.8%, respectively (HR 0.66, 95% CI 0.49-0.87; P = .003). In the 36-month group, the 5-year and 10-year OS rates were 92.0% and 79.0%, and in the 12-month group, 85.5% and 65.3%, respectively (HR 0.55, 95% CI 0.37-0.83; P = .004). In the Efficacy Population, from which 15 patients who did not have GIST in central pathology review and 24 patients who had intra-abdominal metastases removed at surgery were excluded, 10-year OS was 81.6% in the 36-month group and 66.8% in the 12-month group (HR, 0.50, 95% CI 0.32-0.80; P = .003). No new safety signals were detected. **Conclusions:** About 50% of deaths can be avoided during the first decade of follow-up after surgery with 3-year imatinib treatment as compared to 1-year treatment. Clinical trial information: NCT00116935. Research Sponsor: Novartis.

11504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results of a randomized phase II/III study comparing perioperative adriamycin plus ifosfamide and gemcitabine plus docetaxel for high-grade soft tissue sarcomas: Japan Clinical Oncology Group study JCOG1306. *First Author: Kazuhiro Tanaka, Oita University Faculty of Medicine, Yufu, Oita, Japan*

Background: Our previous phase II study for high-grade soft tissue sarcomas (STS), JCOG0304, suggested long-term favorable effects of perioperative adriamycin plus ifosfamide (AI) on survival of STS patients. We have also reported in 2015 ASCO Annual Meeting that a phase II/III trial to confirm the non-inferiority of perioperative gemcitabine plus docetaxel (GD) to AI for high-grade STS (JCOG1306) had been started. We herein report the results of JCOG1306 at the early termination by the preplanned second interim analysis. **Methods:** Patients with operable, FNCLCC grade 2/3 STS primary tumor (T2bN0M0 or anyTN1M0, AJCC 7th edition) or first local recurrent tumor in the extremities or trunk were randomized to AI or GD. Chemotherapy consisted of adriamycin 60 mg/m^2 plus ifosfamide 10 g/m^2 for AI or gemcitabine 1,800 mg/m^2 plus docetaxel 70 mg/m^2 for GD. The treatments were repeated for 3 courses preoperatively and 2 courses postoperatively in a 3-week interval. The primary endpoint in phase III part was overall survival (OS). Planned sample size was 140 with a one-sided alpha of 0.1, power of 0.7 and a non-inferiority margin of 8% at 3-year OS, assuming 3-year OS of AI to be 85% and that of GD as 87%. The patient accrual has started in February 2014 and finished in September 2018. **Results:** A total of 143 patients were enrolled and included in the efficacy analysis. Seventy and 73 patients were assigned to AI and GD, respectively. At the second interim-analysis on December 2019, the estimated 2-year OS was 94.3 % (95% confidence interval (CI) 83.4–98.1) in AI and 91.6 % (80.9–96.4) in GD (hazard ratio (HR) 2.55, 95% CI 0.67–9.78). The estimated 2-year progression-free survival was 81.9 % (95% CI: 69.5–89.7) in AI and 64.0 % (51.1–74.4) in GD (HR 2.32, 95% CI 1.22–4.39). There were no treatment-related deaths in both groups. The most common Grade 3 or higher adverse events in AI were neutropenia (88.4%), anemia (49.3%), and febrile neutropenia (36.2%), whereas those in GD were neutropenia (79.5%), febrile neutropenia (17.8%), and alanine aminotransferase (9.6%). Based on the result of this analysis, the Data Monitoring and Safety Committee of JCOG recommended terminating the study since the point estimate of HR was above the prespecified allowable HR of 1.61. **Conclusions:** Although the toxicities were modest in GD, non-inferiority of GD to AI could not be confirmed. In the perioperative chemotherapy for high-grade STS in the extremities and trunk, AI remains the standard regimen. Clinical trial information: UMIN000013175. Research Sponsor: National Cancer Center Research and Development Fund [grant number 29-A-3], AMED [grant number JP18ck0106336].

11505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Preliminary results of a phase II study of neoadjuvant checkpoint blockade for surgically resectable undifferentiated pleomorphic sarcoma (UPS) and dedifferentiated liposarcoma (DDLPS). *First Author: Christina Lynn Roland, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: is a randomized, phase II non-comparative trial evaluating the efficacy of neoadjuvant checkpoint blockade [nivolumab (N) or ipilimumab/nivolumab (I/N)] in patients (pts) with surgically resectable retroperitoneal DDLPS or extremity/truncal UPS treated with concurrent neoadjuvant radiation therapy (RT, UPS only). **Methods:** Primary endpoint was pathologic (path) response. Secondary endpoints were safety, RECIST response, recurrence-free survival, overall survival and patient-reported outcomes. Biospecimens (tumor, blood, fecal microbiome) at baseline, on therapy, and at time of surgery were collected and will be assessed for immune-based prognostic biomarkers. We assessed correlation between radiographic and pathologic response by linear regression. Correlative analyses includes assessment of tumor PD-L1 expression, characterization of tumor immune infiltrates by multiplex immunohistochemistry, and transcriptomic and genomic analyses. **Results:** Of the 25 pts enrolled; 24 are evaluable for response (14 DDLPS, 9 UPS). Clinical activity was variable by histologic subtype and treatment with RT. Median path response in the UPS cohort was 95% [95% CI 85–99] and was similar between the N/RT and I/N/RT groups (Table). Median path response in the DDLPS cohort was 22.5% [95% CI 85–99; Table]. Median change in tumor size (radiographic response) was -4% and +9% in the UPS and DDLPS cohorts, respectively. There was no correlation between path response and radiographic response (R^2 0.0309; p = 0.43). Of 8 pts with path response $\geq$ 85%, there was 1 partial response, 5 stable disease and 2 progressive disease by RECIST criteria. There was 1 delay to surgery due to grade 3 hyperbilirubinemia (Arm B). There was no difference in toxicity between N/RT and I/N/RT. **Conclusions:** N/RT and I/N/RT have significant clinical activity in UPS; more than expected compared to historic controls. Toxicity profiles were as expected and the majority of patients underwent resection without delay. Larger studies evaluating N/RT in UPS are warranted given the significant path response in this cohort. RECIST was not associated with path response and better markers of on-treatment clinical activity are needed. Correlative analyses that may guide combination strategies are ongoing and will be presented at the meeting. Clinical trial information: NCT03307616. Research Sponsor: Bristol Myers Squibb.

11506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A single-arm multicenter phase II trial of doxorubicin (Doxo) in combination with trabectedin (Trab) given as first-line treatment to patients with metastatic/advanced uterine (U-LMS) and soft tissue leiomyosarcoma (ST-LMS): Final results of the LMS-02 study. *First Author: Patricia Pautier, Medical Oncology Department, Institut Gustave Roussy, Villejuif, France*

Background: U-LMS and ST-LMS are rare tumors with poor prognosis when locally advanced or metastatic, and with moderate chemosensitivity. Overall response rates (ORR) given in the 1st-line setting do not exceed 50% for U-LMS and 35% for ST-LMS with a mean response duration of 3- 6 months without impact on overall survival (OS). In 2015 we reported very encouraging results of the LMS-02 study (NCT02131480) with ORR of 59.6% in U-LMS, and 39.3% in ST-LMS with manageable toxicity (Pautier; Lancet oncol 2015). Herein, we report the updated results of progression-free survival (PFS) and final results of overall survival (OS). **Methods:** Patients (pts) received 60 mg/m^2 intravenous Doxo followed by trabectedin 1.1 mg/m^2 as a 3-hour infusion on Day 1 and pegfilgrastim on Day 2, repeated every 3 weeks for up to 6 cycles. Surgery for residual disease was permitted. Patients were stratified into U-LMS and ST-LMS groups. **Results:** Overall, 108 patients with LMS with a median age of 59 years and mostly metastatic disease (85%) were enrolled. Of those, 77 patients (71.3%) have received all 6 cycles of treatment, and 20 patients (18.5%) had metastasis resection. With a median follow-up of 7.2 years (95% CI: 6.9 - 8.2), the overall median PFS was 10.1 months (95% CI: 8.5 - 12.6), being 8.3 months (95 CI: 7.4 - 10.3) and 12.9 months (95% CI: 9.2 - 14.1) in U and ST group, respectively. Median OS was 34.4 months (95% CI: 26.9 - 42.7), being 27.5 months (95% CI: 17.9 - 38.2) in U-LMS and 38.7 months (95% CI: 31.0 - 52.9) in ST-LMS group. The median OS among the 20 pts with surgery was not reached vs 31.6 months in the population without surgery (95% IC: 23.9 - 35.4). **Conclusions:** The Doxo +Trab combination is an effective 1st-line therapy for pts with LMS, with promising PFS and OS results and an acceptable safety profile. Merely for comparison, the most recent results of Doxo alone in metastatic LMS, given in 1st-line setting in a phase III ANNOUNCE trial conducted during the same period, reported median PFS of 6.9 months, and median OS of 21.9 months (ASCO 2019 LBA3). Results of the LMS04 trial (NCT02997358), a randomized phase III study comparing this combination vs Doxo alone in 1st-line therapy in metastatic LMS are pending. Clinical trial information: NCT02131480. Research Sponsor: Pharmamar laboratory.

11507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A Ib/II study of the combination of lenvatinib (L) and eribulin (E) in advanced liposarcoma (LPS) and leiomyosarcoma (LMS) (LEADER). *First Author: Tom Wei-Wu Chen, National Taiwan University Hospital, Taipei City, Taiwan*

Background: For advanced LPS and LMS, the two most common histologies in soft tissue sarcoma, there are limited treatment options that readily balance efficacy and toxicity. Patients (pts) treated with E had an improved median overall survival (OS) in a phase III randomized study compared to dacarbazine but with an unsatisfactory 4% objective response rate (ORR). Early studies of L, a multi-targeted anti-angiogenic inhibitor, had suggested efficacy in sarcoma pts. We hypothesized that the combination of anti-angiogenic agent and chemotherapy could potentiate treatment benefit and aimed to explore the safety and efficacy of L + E in advanced LMS and LPS. **Methods:** LEADER was a single-arm phase Ib/II study for advanced adult LMS and LPS pts who had received no more than 2 lines of systemic chemotherapy. The phase Ib part (starting dose: L 18mg/day, E 1.1mg/m^2) had been reported and the recommended phase 2 dose (RP2D) was determined at L 14mg/day and E 1.1mg/m^2 D1, D8 every 21 days. The primary endpoint of the phase II part was ORR by RECIST 1.1, secondary endpoints included ORR by Choi criteria, progression-free survival (PFS), 6-month PFS rate, and OS. With $\alpha = 0.05$ and 80% power, the pts needed for stage I and total of the Simon 2-stage design was 13 and 27 pts, respectively. **Results:** As of Jan 22, 2020, 20 pts (F/M 13/7) had been treated with at least one cycle of L + E; 14 were LMS (5 uterine, 9 non-uterine) and 6 were LPS (4 dedifferentiated, 2 myxoid round cell). The median age was 51 (range 29-73); the median lines of treatment(s) received before enrollment was 1 (range 0-3). 18 pts were evaluable for primary endpoint: the ORR by RECIST 1.1 was 27 % (5/18) (95% CI 10-53%). The ORR by Choi criteria was 67 % (12/18) (95% CI 41-87%). With 8 PFS events, the median PFS and 6-month PFS rate was 56 weeks (95% CI 25-not reached) and 72%, respectively. There were no OS events. The ORRs by RECIST 1.1 between different L starting doses were not significantly different (18mg 33% (2/6) vs 14mg 25% (3/12), p = 0.7). 15 pts experienced at-least one grade (gr) 3 or 4 adverse event (AE); gr 3 or 4 AEs occurred in $>$ 1 pts included (% of phase Ib, % of phase II pts) hypertension (n = 4) (67%, 0%); hand-foot-syndrome (n = 4) (50%, 7%), proteinuria (n = 3) (0%, 25%), febrile neutropenia (n = 2) (17% vs 5%), neutropenia (n = 6) (50% vs 25%). The RP2D was associated with overall lower gr3/4 AEs except for proteinuria. **Conclusions:** L + E had shown promising efficacy in advanced LMS and LPS. L at 14mg/day had a better AE profile without compromising activity. The exploratory biomarker study of LEADER is ongoing. Clinical trial information: NCT03526679. Research Sponsor: Eisai.

11508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase II study of MEK162 (binimetinib [BINI]) in combination with imatinib in patients with untreated advanced gastrointestinal stromal tumor (GIST). *First Author: Ping Chi, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ETV1 and KIT are lineage-specific master transcriptional and signaling survival factors in GIST. In preclinical models, dual lineage targeting of ETV1 by MEK inhibition with BINI and KIT by imatinib are synergistic in suppressing GIST tumorigenesis and progression. This single-arm phase II study is designed to test the efficacy of the BINI+imatinib as a first-line treatment in patients (pts) with advanced GIST. **Methods:** Adult pts with untreated advanced GIST received imatinib (400mg daily) plus BINI (30mg twice daily), 28-day cycles. The primary endpoint (EP) was RECIST1.1 objective response rate (ORR) (complete response [CR]+partial response [PR]). The study was designed to detect a 20% improvement in the ORR of imatinib alone (unacceptable rate of 45%; acceptable rate of 65%). A sample size of 44 patients was required, using an exact binomial test, one-sided type I error of 0.08 and type II error of 0.1. Confirmed PR in $>$ 24 pts would be considered positive. Secondary EPs included RR by Choi and EORTC criteria, resectability conversion rate (RCR), progression free survival (PFS), overall survival (OS) and long-term AEs. Correlatives included characterization of tumor genomics by MSK-IMPACT, cfDNA by MSK-ACCESS, ETV1 protein levels and transcriptomes and signaling inhibition. **Results:** At data cutoff of Jan 31, 2020, 38/39 pts with advanced GIST of all genotypes, including 3 *KIT/PDGFRA*-wild type GIST pts, were evaluable for primary EP. Median age 60 (range 29-78), 29% female. 26/38 pts with confirmed PR; Best ORR was 68.4% (two-sided 95% CI, 51-83%; one-sided 90% CI, 57-100%). 8/9 pts became resectable after treatment; RCR was 88.9% (95% CI, 52-100%). 13 pts remain on trial (2-159 weeks [wks]). 9 pts discontinued trial due to disease progression (11-159 wks); one pt progressed within 3 months, indicating primary resistance. Grade 3/4 toxicity included CPK elevation (asymptomatic, 61%), neutrophil decrease (11%), maculopapular rash (8%), anemia (8%). No unexpected toxicities observed. Correlation of outcome with MSK-IMPACT, MSK-Access and paired tumor biopsies will be presented. **Conclusions:** This study met its primary endpoint. BINI plus imatinib is highly effective in treatment-naive advanced GIST, with expected and manageable long-term treatment-associated toxicities. The combination strategy warrants further evaluation in direct comparison with imatinib in the frontline treatment of GIST. Clinical trial information: NCT01991379. Research Sponsor: Both Array/Pfizer and NIH OPD/FDA.

A phase II multi-arm study of durvalumab and tremelimumab for advanced or metastatic sarcomas. *First Author: Neeta Somaiah, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The combination of durvalumab (D), (anti- PD-L1) and tremelimumab (T), (anti-CTLA-4), was evaluated to determine activity in specific sarcoma subtypes (NCT02815995). We report final results of the clinical efficacy, safety and correlatives. **Methods:** Pts $\geq$12 yrs, with advanced/metastatic sarcoma, were enrolled based on subtype: LPS, LMS, angiosarcoma (AS), UPS, synovial sarcoma, osteosarcoma, ASPS, chordoma, and other sarcomas. Pts received D 1500mg and T 75mg every 4 wks for 4 cycles followed by D alone every 4 wks for up to 12 months (mo) unless the patients experienced unacceptable toxicity or disease progression. Re-treatment was allowed if progression occurred after stopping therapy within the next 12 mo. The primary end-point was PFS at 12 wks (RECIST). Secondary objectives included safety, response rates (irRC and RECIST) and survival. Biopsies were collected at baseline and at 6 wks for flow, PD-L1, multiplex IHC staining and sequencing. **Results:** Baseline characteristics of the 57 pts who received treatment are listed in the Table. Median OS for all pts was 20.8 mo (95% CI: 11.7, NR), the 12-mo survival was 63% (95% CI: 52%, 78%) and the 24-mo survival was 45% (95%CI: 33%, 61%). The mPFS for all pts was 4.5 mo (95% CI: 2.8, 6.9). The PFS at 12 wks for all pts was 51% (95%CI: 37%, 63%), PFS at 12 mo was 28% (95% CI: 18%, 43%), and PFS at 24 mo was 25% (95% CI: 16%, 41%). The 12 wk PFS was lowest for the LPS cohort (6 pts) at 16% (95% CI: 1%, 52%), and highest for the ASPS cohort (10 pts) at 90% (95% CI: 47%, 99%). PRs by irRC were observed in ASPS (5/10), chordoma, (1/5), UPS (1/5), and cutaneous AS (1/1), and 14 pts completed 12 mo of therapy. 14 pts (24.6%) experienced grade $\geq$3 related AEs (colitis, nausea, cardiac dysfunction, thyroiditis, pneumonitis, hepatitis, myositis, anemia and fatigue). Clinical benefit correlated with tumors with an inflamed phenotype; based on higher than median density of 3 major categories of tumor infiltrating lymphocytes (TIL): CD3+, CD3+CD8+, CD3+CD8+GZB+, seen in the 36 paired biopsies. **Conclusions:** In addition to histology (ASPS, cutaneous AS, UPS, chordoma), a higher TIL immune score can help predict clinical benefit. Clinical trial information: NCT02815995. Research Sponsor: Medimmune- AstraZeneca.

Association of immune-related adverse events (irAEs) with improved clinical outcome in sarcoma patients treated with immune checkpoint blockade (ICB). *First Author: Evan Rosenbaum, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: IrAEs are associated with improved clinical outcomes after treatment with ICB in select epithelial malignancies. We hypothesized that sarcoma patients (pts) treated with ICB who developed an irAE would have improved outcomes compared to pts who had no irAE. **Methods:** Adverse events (AEs) from 3 sarcoma-specific ICB trials (nivolumab plus NKTR-214, pembrolizumab plus epacadostat, and pembrolizumab plus T-VEC) were reviewed. AEs probably or definitely related to ICB were classified as immune- or non-immune-related by the principal investigator. Endpoints of interest included best overall response (BOR) by RECIST 1.1 (complete response [CR]/partial response [PR]), durable clinical benefit (DCB; CR/PR/stable disease [SD] $\geq$ 16 weeks), and progression-free survival (PFS). Outcomes were stratified by the presence or absence of $\geq$ 1 irAE of any grade and by grade 1-2, grade 3-4, or no irAE (three-category comparison). **Results:** A total of 124 pts received ICB on these studies. Median pt age was 56 (range: 13-90); 53% were male; all but one pt had a performance status of $\leq$ 1. BOR was PR in 12 pts, SD in 41, and PD in 69. 2 pts were not evaluable. 40 pts (32%) had $\geq$ 1 irAE of any grade, 6 of whom had a grade 3-4 irAE. The most common irAEs ($\geq$ 5% of pts) were rash (15%), arthralgia (11%), myalgia (9%), pruritis (8%), and hypothyroidism (6%). The proportion of pts with a CR/PR was higher in pts with than without an irAE (18% vs. 6%, respectively; P = 0.058). A significantly higher proportion of pts with an irAE had DCB compared to those without (53% and 29%, respectively; P = 0.017). The median PFS of pts with an irAE was 16.6 months compared to 10.6 in those without (P = 0.013). The proportion of pts with a grade 3-4 irAE and a CR/PR was highest (33%) compared to pts with grade 1-2 (15%) or no irAE (6%) (P = 0.048). More pts with grade 3-4 irAE achieved DCB (67%) than grade 1-2 (50%) or no irAE (29%) (P = 0.027). Median PFS was 22.6, 15, and 10.6 weeks in the grade 3-4, grade 1-2, and no irAE groups, respectively (P = 0.047). **Conclusions:** Approximately one-third of advanced sarcoma pts with ICB-based immunotherapy developed an irAE. As reported previously in select carcinomas, sarcoma pts with irAEs were more likely to have clinical benefit than those without irAEs. Further research is needed to understand the mechanism behind this association and to validate these findings prospectively. Research Sponsor: None.

A multicenter phase II study of nivolumab +/- ipilimumab for patients with metastatic sarcoma (Alliance A091401): Results of expansion cohorts. *First Author: James Lin Chen, The Ohio State University, Columbus, OH*

Background: In the open-label multicenter phase II study, A091401, nivolumab (N) and nivolumab+ipilimumab (N+I) demonstrated a confirmed response rate (RR) of 5% and 16%, respectively in patients (pts) with advanced sarcoma (D'Angelo SP et al Lancet Oncology 2018). Responses occurred in undifferentiated pleomorphic sarcoma (UPS), myxofibrosarcoma, leiomyosarcoma, sarcoma not otherwise specified and alveolar soft part sarcoma. Here, we report efficacy of N and N+I, in each of 3 expansion cohorts [gastrointestinal stromal tumor (GIST), UPS and dedifferentiated liposarcoma (DDLS)]. **Methods:** Pts refractory to $\geq$ 1 regimen(s) were randomized (non-comparative) to receive either N [N (3 mg/kg q2W)] or N+I [N (3 mg/kg Q3W x4, then Q2W) plus I (3 mg/kg q3W x4)]. The primary endpoint was 6 month confirmed RR (RECIST v1.1). For UPS and DDLS, 2 confirmed responses in the 1st 12 evaluable pts was needed (85% power, 1-sided alpha=0.15, 5 v 25% RR). For GIST, a confirmed response in the 1st 9 evaluable pts expanded enrollment to 24 (80% power, 1-sided alpha=0.10, 5 v 20% RR). Other endpoints: adverse events (AEs, TRAEs), progression-free and overall survival (PFS, OS), and correlatives. **Results:** See table. **Conclusions:** Neither N or N+I lead to confirmed responses in GIST. In DDLS and UPS, the primary response endpoint was met with N+I but not with N alone (RR 14% for N+I vs. 7% and 8% for N alone). For the GIST cohort TRAE was higher with N+I, holding enrollment as required per protocol. There remains a pressing need to determine genomic and clinical biomarkers of response, resistance and toxicity. Correlative analyses (whole exome sequencing, multiplex IHC and RNAseq) are in progress. Support: U10CA180821, U10CA180882; ClinicalTrials.gov Identifier: NCT02500797. Research Sponsor: U.S. National Institutes of Health.

Survivin-responsive conditionally replicating adenovirus for patients with advanced sarcoma demonstrated potent and long-term efficacy and high safety in a phase I clinical trial. *First Author: Satoshi Nagano, Kagoshima University, Kagoshima, Japan*

Background: Whereas one of oncolytic viruses (OVs), inducing selective tumor killing and systemic anti-tumor immunity, was approved by FDA in 2015, the best OV that more safely and efficiently treats intractable cancers has not been successfully developed. By our platform technology to efficiently construct next-generation OVs, *i.e.*, "conditionally replicating adenoviruses (CRAs) that target and/or treat tumor cells with multiple factors" (m-CRAs), we identified that among candidates, survivin-responsive m-CRAs (Surv.m-CRAs) exhibited the most potent antitumor efficacy and cancer selectivity (*i.e.*, safety) in preclinical studies (*Cancer Res*, 2005 *et al.*). Here we present the data of First-In-Human phase I clinical trial of Surv.m-CRA-1 for musculoskeletal tumors (MST). **Methods:** This single-arm, open label study included 9 patients with unresectable and advanced MST. Patients underwent a single intratumoral injection of either 1×10^10 viral particle (vp) (low), 1×10^11 vp (mid) or 1×10^12 vp (high). The primary endpoints were safety and tolerability. The secondary endpoints included the local control of treated tumor at one month, defined by RECIST and Choi criteria, analysis of dissemination of Surv.m-CRA-1, serum cytokine and adenoviral antibody. Long-term follow-up was done in some patients. **Results:** Four patients (44.4%) had grade 3 or higher adverse events, including lymphopenia, leukocytopenia and mildly elevated liver transaminase in 2, 1 and 1 patient, respectively. Virus excretions, including second peak of viremia from viral replication in tumor, were observed in 1, 2 and 3 patients of low, mid and high dose, respectively. Out of 9 patients, 5 PR, 3 SD and 1 PD by Choi, and 8 SD and 1 PD by RECIST were observed. During follow-up, another 1 and 2 patients became PR by Choi and RECIST, respectively. Of note, long-term PR (over 2 years) after a single injection of Surv.m-CRA-1 was achieved in two chordoma cases in low dose. **Conclusions:** Surv.m-CRA-1 was well tolerated and showed antitumor activity for prolonged periods against advanced MST. We about to start Phase I/II study of multiple injections of Surv.m-CRA-1 for advanced solid tumors in two-arms for musculoskeletal tumors and pancreatic cancer. Clinical trial information: R000026464. Research Sponsor: Japan Agency for Medical Research and Development.

Defining the role of neoadjuvant systemic therapy in high-risk retroperitoneal sarcoma: A multi-institutional TARPSWG study. *First Author: William W. Tseng, Department of Surgery, Division of Breast, Endocrine and Soft Tissue Surgery, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Background: Surgery is the mainstay of treatment for patients with retroperitoneal sarcoma (RPS), but this can be challenging, and recurrence rates are high. Novel treatment approaches are needed. In this study, we sought to 1) determine the frequency and potential predictors of radiologic tumor response and 2) assess clinical outcomes in patients with primary high risk RPS who were treated at sarcoma referral centers with neoadjuvant systemic therapy followed by surgery. **Methods:** Clinicopathologic data was retrospectively collected for eligible patients treated from 2008-2018 at 13 institutions within the Transatlantic Australasian Retroperitoneal Sarcoma Working Group (TARPSWG). For each patient, preoperative objective response (RECIST1.1) was reported by each institution. Univariable and multivariable logistic models were performed to determine predictors of response. Kaplan-Meier plots were constructed for overall survival (OS) and cumulative incidences of local recurrence (LR) and distant metastasis (DM). **Results:** In total, 158 RPS patients were included in this study. A median of 3 cycles (IQ range 2-4) of neoadjuvant systemic therapy were given. No complete responses were observed. Partial response (PR) was seen in 37 patients (23%), stable disease (SD) in 88 (56%) and progressive disease (PD) in 33 (21%). Subtype-specific differences were seen including PR in 5 out of 11 (45%) patients with undifferentiated pleomorphic sarcoma. Overall, higher number of cycles given was positively associated with PR ($p = 0.005$). No other factors including receipt of neoadjuvant radiation therapy were predictive of PR. All patients underwent complete (R0/R1) resection with a major complication (Clavien-Dindo $\geq$3) rate of 23%. Differences in OS were observed based on preoperative response type ($p = 0.005$). In grade 3 dedifferentiated liposarcoma, patients who received adriamycin-ifosfamide versus another regimen had decreased LR and improved OS. In leiomyosarcoma, patients who received adriamycin-DTIC versus another regimen had a higher PR rate (37% vs. 16%), decreased LR, DM and improved OS. Limited by low numbers, these subtype-specific data did not reach statistical significance. **Conclusions:** In patients with high risk RPS, response to neoadjuvant systemic therapy is overall modest and may be regarded as an indicator of disease biology to predict survival after surgery. Subtype-specific regimens should be further validated and incorporated into prospective trials of neoadjuvant systemic therapy in RPS (e.g. STRASS2). Research Sponsor: None.

Trabectedin and radiotherapy in soft-tissue sarcoma (TRASTS) study: An international, prospective, phase II trial in localized myxoid liposarcoma—A collaborative Spanish (GEIS), Italian (ISG) and French (FSG) group study. *First Author: Alessandro Gronchi, Sarcoma Service, Department of Surgery, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Myxoid liposarcoma (ML) exhibits especial sensitivity to trabectedin (T). In prospective series, T showed responses in 44% of patients (pts) with ML. ML is also sensitive to radiation therapy (RT) and preclinical data suggested radiosensitizing properties of T. Preoperative short-course of T with concurrent low-dose RT was conducted in a multicenter, European, phase I/II trial. We present here the data from the phase II part in pts with centralized diagnosis of locally advanced, resectable ML. **Methods:** Pts received 3 cycles (C) of T in combination with RT (45 Gy) in 25 fractions (1.8Gy/fraction). The phase I part of the study had the classic 3+3 design. Dose Levels for T were: -1 (1.1 mg/m^2), 1 (1.3 mg/m^2) and 2 (1.5 mg/m^2) Results were already reported (EClincalMedicine 2019;9:35-43) and the dose selected for the phase 2 part was 1.5 mg/m2. RECIST responses were evaluated preoperatively at week 10. Surgical specimens were processed for histologic changes and residual tumor. **Results:** From July 2016 to September 2019, 47 pts (M/F 31/16) with median age 43y (18-77) and median tumor size 11 cm (3-25 cm), 20 low and 24 high grade (3 not available) were enrolled in the phase II part of the study. The major grade 3/4 toxicities were neutropenia (21.3%), ALT (14.9%), GGT (8.5%) and AST (8.5%) elevation. There were no deaths due to toxicity. 43/47 patients received the planned 3 preoperative T cycles. All pts completed RT. 1 patient started RT before the first cycle of T and was excluded from the analysis. All pts were evaluable for response: 14 achieved PR (30%), 32 SD (70%). All pts underwent surgery (37 [86%] R0/ 5 [12%] R1/ 1 [2%] R2/ 3 not available). Median viable residual tumor was 10% (0-90) with 23/43 pts (53%) with $\leq$ 10% viable remaining tumor. Of them 6/43 (14%) had complete responses. At a median FU of 18 months (3-41) one pt developed local recurrence and 2 distant metastases. No deaths were observed. The corresponding 2-yr disease-free survival and overall survival were 97% (95% confidence interval 95-100) and 100%. **Conclusions:** T in combination with RT was feasible and well tolerated in the preoperative setting. The activity of the combination compares favorably with the administration of T/RT alone. This regimen could potentially become an alternative to anthracycline+ifosfamide concurrent to RT in high risk localized ML. Clinical trial information: NCT02275286. Research Sponsor: PharmaMar.

11515 Poster Discussion Session; Displayed in Poster Session (Board #403), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

A randomized phase II study of gemcitabine (G) alone or with pazopanib (P) in refractory soft tissue sarcoma (STS). *First Author: Christopher W. Ryan, Oregon Health & Science University, Knight Cancer Institute, Portland, OR*

Background: Both G and P are active single-agents in the treatment of STS. We hypothesized that the anti-VEGF-R activity of P could augment the efficacy of G and conducted this study of G+P vs G+placebo (0). **Methods:** In this multi-center, double-blind study, eligibility included metastatic STS with receipt of 1–3 prior systemic regimens inclusive of an anthracycline. Patients (pts) were stratified by sarcoma subtype (liposarcoma (LPS) vs. other) and study site, then randomly assigned 1:1 to receive G 1000 mg/m2 IV over 30 minutes on days 1 and 8 every 21 days plus either P 800 mg PO or matching 0 daily. The primary endpoint was progression-free survival (PFS). **Results:** 54 pts were accrued from 2012–2019, Accrual was halted prior to the planned N of 80 due to withdrawal of funding. There were no differences in pt characteristics between the two arms including age (median = 60), sex (M/F 52/48%), histology (LPS 30%, leiomyosarcoma 26%, UPS 15%, synovial 11%, other 17%) and number of prior systemic therapies (median = 1). With a median follow-up of 19.1 months, PFS favored G+P and was significant using the Gehan-Wilcoxon test which favorably weighs earlier events (table). The response rate was 6.9% on the G+P arm and 8.0% on the G+0 arm; response rate was 22% for LPS treated with G+P. The most common grade $\geq$3 AEs (G+P v G+0) were: neutropenia (41% vs 40), hypertension (17% v 4), anemia (7% v 12). One patient died of hepatic failure on the G+P arm. **Conclusions:** This study demonstrated improved PFS with G+P as compared with G alone. Early termination limited statistical power. G+P is active in LPS, although P regulatory labeling currently limits use for LPS. Clinical trial information: NCT01532687. Research Sponsor: Novartis and Glaxo Smith Kline, U.S. National Institutes of Health.

Long-term follow-up for duration of response (DoR) after weekly *nab*-sirolimus in patients with advanced malignant perivascular epithelioid cell tumors (PEComa): Results from a registrational open-label phase II trial, AMPECT. *First Author: Andrew J. Wagner, Dana-Farber Cancer Institute, Boston, MA*

Background: Malignant PEComa is a rare, aggressive sarcoma, with no approved medical treatment. Cytotoxic chemotherapies have limited benefit for patients with advanced disease. The AMPECT trial measured the effects of *nab*-sirolimus (ABI-009) and is the first prospective study in advanced malignant PEComa. *nab*-Sirolimus is a nanoparticle albumin-bound mTOR inhibitor with significantly higher intratumoral drug levels, mTOR target suppression, and anti-tumor activity in animal models versus other mTOR inhibitors. This report presents long-term follow-up of DoR after the primary analysis. **Methods:** Patients (N=34) received *nab*-sirolimus (100mg/m^2 IV, weekly, 2/3 weeks) until progression or unacceptable toxicity. Primary endpoint: ORR by IRR. Key secondary endpoints included DoR, PFS6, OS, and safety. Exploratory endpoints included correlation of tumor genotype and outcome. The sample size of 30 efficacy-evaluable patients was based on an estimated ORR of 30% and the lower bound of the 95%CI of ORR to exclude values less than 14.7%. The primary analysis was conducted when all patients were treated ≥6 months (May 22, 2019). This report updates the primary response analysis and DoR with an additional 8.5-month of follow-up. **Results:** As of Feb 06, 2020, of the 31 efficacy-evaluable patients, the confirmed ORR by IRR was 39% (12/31, 95%CI: 21.8, 57.8), with 1 complete response (CR) and 11 partial responses (PR), 52% stable disease (SD, 16/31, with 10/16 SD ≥12 weeks), and 10% progressive disease (3/31); the disease control rate (CR+PR+SD ≥12 weeks) was 71%. PFS6 was 71% (95%CI: 47.7, 85.1). The majority of responses (67%) were reached at the first post-baseline scan at week 6, with a median time to response of 1.4 months (95%CI: 1.3 to 2.8). The median DoR by IRR was not yet reached (range 5.6-38.7+ months; calculated median 22.2+ months) with 8/12 (67%) responders still on treatment for >1 year and 5/12 (42%) >2 years. Mutational analysis available for 25 patients identified that TSC2 loss-of-function mutations significantly correlated with response; 8/9 (89%) patients with TSC2 had a confirmed response. **Conclusions:** Responses of advanced malignant PEComa to *nab*-sirolimus were highly durable and occurred in 39% of patients based on independent review. The high disease control rate with manageable toxicities suggest that *nab*-sirolimus is effective and represents an important new treatment option for these patients. Clinical trial information: NCT02494570. Research Sponsor: Aadi Bioscience, Other Government Agency.

A phase II study of oraxol in the treatment of unresectable cutaneous angiosarcoma. *First Author: Vinod Ravi, The University of Texas MD Anderson Cancer Center, Department of Sarcoma Medical Oncology, Houston, TX*

Background: Oraxol is a combination of oral paclitaxel and a novel oral P-glycoprotein inhibitor, HM30181A. Cutaneous angiosarcomas are highly aggressive malignant tumors with poor prognosis. Currently there is no FDA-approved treatment. **Methods:** This is an open label study evaluating the activity, safety and tolerability of Oraxol 205mg/m^2 administered orally, once daily, for 3 consecutive days per week. Planned treatment is for 25 weeks. Subjects included in this study had not received prior therapy with a taxane and did not have metastatic disease. Tumour response was evaluated at 6 weekly intervals using RECIST and photography. A Simon two stage design was used. **Results:** 18 of 24 enrolled patients (pts); male/female 11/7; median age 77 years (range 56-93), were evaluable at time of analysis. Subjects were recruited during an 18 month period, from Aug-2018 to Jan-2020. Best objective response rates were: CR 22% (n = 4), PR 11% (n = 2), SD 67% (n = 12), PD 0%. 42% of pts with SD had durability > 13 weeks (range 13-25). Median PFS was 38 weeks. All pts remain alive at time of reporting. Furthermore, 5 pts (28%) who had inoperable lesions were deemed operable after Oraxol and received surgical resection. Oraxol was generally well tolerated. Most common adverse events (AEs) G>3 were: diarrhea (n = 1), fatigue (n = 3), neutropenia (n = 9), leucopenia (n = 5), lymphopenia (n = 5). Serious AEs were G3 pneumonia in 2 subjects and G4 neutropenia in 2 subjects, one of which was febrile. All events fully resolved. Neuropathy was uncommon: n = 2 (G1 = 1 @ day 10, G2 = 1 @ day 64). Dose reductions were recorded in 7 subjects. 2 subjects discontinued treatment due to AEs; both asymptomatic pneumonitis seen on CT, which recovered after discontinuation. Following the initial positive results, the protocol has been amended to change the maximum recruitment of subjects from 25 to 43. **Conclusions:** Oraxol provides an orally administered treatment option for angiosarcoma, with a high and durable clinical benefit rate (CR + PR+ long SD). It is generally well tolerated even in an older patient population; particularly with respect to the the low incidence of neuropathy compared to IV paclitaxel. Recruitment is ongoing. Clinical trial information: NCT03544567. Research Sponsor: Athenex Inc.

A phase II single-arm study of nivolumab and ipilimumab (Nivo/Ipi) in previously treated classical Kaposi sarcoma (CKS). *First Author: Alona Zer, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: CKS is a mesenchymal neoplasm associated with HHV8 infection. Though recombinant INFa is approved for treatment of AIDS-related KS, data is limited regarding the role of immune modulation in CKS therapy. Based on favorable responses in viral-induced cancers, we hypothesized that CTLA-4 and PD-1 blockade can induce tumor regression in CKS. We present pre-planned interim analysis of a phase II study of Nivo/Ipi in previously treated progressive CKS. **Methods:** CKS pts with progressive disease after > 1 line of systemic therapy and measurable disease received nivolumab 240mg d1,15,28 and ipilimumab 1mg/kg d1 q42 days until progression or toxicity. The primary endpoint was overall response rate (ORR) evaluated clinically, radiologically (RECIST) and metabolically (FDG-PET). Secondary endpoints include 6-months progression free survival rate (PFS) and safety. Exploratory endpoints included PD-L1/MMR by IHC, DNAseq (596 genes)/RNAseq (whole transcriptome) of tumor and matched blood specimens to explore CKS genomic traits and IO correlates: TMB and MSI status, MMR and PD-L1 protein expression, and immune gene transcript expression (PD-1, PD-L1, CTLA-4, and others) (Tempus Labs, Chicago, IL, USA). **Results:** Fifteen patients were enrolled and evaluable (Apr18-Jan20). Median age 72.5 (61-81), all male. At a median FU of 15.7 mo ORR as per RECIST was 66% (9 pts PR, 1 pt CR, 2 pts SD, 3 pts NE). Clinical ORR was 87% and metabolic ORR was 60%. Median PFS was not reached, 6mo PFS rate was 85% and 1y PFS rate was 75%. The safety profile was as expected with all pts experiencing G1 toxicity, 3 pts with G2 toxicity (1 hepatic, 2 asymptomatic lipase increase) and 2 pts with G3 toxicity (1 colitis, 1 asymptomatic lipase increase). One SAE was reported (TIA considered not related to therapy) and treatment was discontinued in 3 pts. Correlative results are available for 8 pts showing a trend for copy number loss in genes with tumor-suppressive activity (FOXA1, ELF3), no PDL1 expression, low TMB, microsatellite stability, but marked overexpression of CTLA-4, PD-1, PDL-1, CD40, OX40 and LAG3 RNA immune transcripts. **Conclusions:** The interim analysis of this prospective phase II study of nivolumab and low-dose ipilimumab demonstrates promising activity in progressive CKS, with 66% ORR and a 6mo PFS rate of 85%. Toxicity profile is as expected in this class of drugs. Correlative studies are preliminary, but warrant further investigation into genomic traits and immune gene expression profiles. Clinical trial information: NCT03219671. Research Sponsor: BMS.

A pilot study evaluating the safety, tolerability, and efficacy of doxorubicin and pembrolizumab in patients with metastatic or unresectable soft tissue sarcoma. *First Author: Michael B. Livingston, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Doxorubicin has been the traditional standard therapy for treatment of advanced soft tissue sarcoma (STS). The addition of cytotoxic agents leads to increased toxicity with minimal improvement in efficacy. Pembrolizumab monotherapy has demonstrated activity and tolerability in previous study of advanced STS. This study combined pembrolizumab with doxorubicin to determine safety and efficacy in the frontline setting. **Methods:** This single-center, single-arm, phase 2 trial enrolled subjects with unresectable or metastatic STS and no prior anthracycline therapy. Subjects were treated with pembrolizumab 200 mg IV and doxorubicin 60 mg/m2 (75 mg/m2 dose escalation per investigator discretion) IV every 3 weeks. The primary endpoint of safety, based on Bayesian stopping rules, evaluated if the severe or life-threatening treatment emergent adverse event (TEAE) rate exceeded 0.55. Secondary endpoints included overall survival (OS), objective response rate (ORR), and progression free survival (PFS). Efficacy and safety were based on RECIST 1.1 and CTCAE v 4.0, respectively. Kaplan-Meier methods evaluated time to event outcomes. **Results:** From 4/2017 to 12/2019, 30 subjects (53% female, median age 61.5 years, 10 patients > 70 years (33%)) were enrolled in the study with 6 (20%) patients still on treatment and 27 evaluable for response. The most common histologic subtypes were leiomyosarcoma (33%) and liposarcoma (23%), and a majority of patients demonstrated high grade disease (60%). Current analysis shows a median follow-up of 9.9 months. One subject experienced a stopping rule event (grade 3 autoimmune disorder). ORR was 33% (95% CI 17-54%), with documented disease control in 78% (95% CI 57.7-91.4%) of patients. Eight (30%) patients achieved a partial response, one (4%) patient achieved a complete response and 12 (44%) patients had stable disease. Preliminary results demonstrate median PFS of 6.9 months (PFS-6 mo: 52%) and median OS of 15 months (OS-6 mo: 81%) compared to historical PFS-6mo of 4.6 months and OS of 12.8 months with doxorubicin alone.[1] Most common grade 3+ TEAEs included neutropenia (11 [37%]), febrile neutropenia (6 [20%]), anemia (5 [17%]), and nausea (4 [13%]). Molecular and biomarker analysis is currently in progress. **Conclusions:** The combination of pembrolizumab with doxorubicin has manageable toxicity and preliminary promising activity in the treatment of anthracycline-naive advanced soft tissue sarcomas. SAINT: Results of an expanded phase II study using safe amounts of ipilimumab (I), nivolumab (N), and trabectedin (T) as first-line treatment of advanced soft tissue sarcoma [NCT03138161]. *First Author: Erlinda Maria Gordon, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Sarcoma cells are most immunogenic earlier in the disease. Hypothesis: Immune checkpoint inhibitors would be most effective when given as first-line therapy. **Methods:** Eligible patients include previously untreated male or female patients, ≥ 18 years of age with locally advanced unresectable or metastatic soft tissue sarcoma (STS), with measurable disease by RECIST v1.1. Immune checkpoint inhibitors I (1 mg/kg i.v. q 12 weeks) and N (3 mg/kg i.v. q 2 weeks) were given with T (1.2 mg/m2 i.v. q 3 weeks), a tumoricidal agent that depletes growth-promoting macrophages in the tumor microenvironment. Primary endpoint: Objective response rate by RECIST v1.1; Secondary endpoints: (1) Progression-free survival (PFS) at 6 months, (2) Overall survival (OS) at 6, 9, 12, 24, and 48 months, and (3) Incidence of adverse events. **Results:** Efficacy analysis: There were forty-one evaluable subjects. Best overall response rate was 19.5%; disease control rate 87.8%. The median OS was >12.5 months; median PFS was >6.0 months (6-month OS rate: 75%; 6-month PFS rate: 50%). Safety analysis: Grade 3 TRAEs include fatigue (n = 5), increased TSH (n = 3), decreased TSH (n = 1), adrenal insufficiency (n = 1), hyperglycemia (n = 1), dehydration (n = 1), hyponatremia (n = 2), bipedal edema (n = 2), increased AST (n = 8), increased ALT (n = 19), increased ALP (n = 2), increased CPK (n = 3), port site infection (n = 2), psoriasis exacerbation (n = 1), anemia (n = 6), thrombocytopenia (n = 2), and neutropenia (n = 2). Grade 4 TRAES include neutropenia (n = 1), thrombocytopenia (n = 2), and increased CPK (n = 2). **Conclusions:** These data suggest that combinatorial therapy with Ipilimumab, Nivolumab and Trabectedin (1) may have synergistic activity in achieving disease control, and (2) is safe with manageable toxicity for patients with previously untreated STS. Clinical trial information: NCT03138161. Research Sponsor: Bristol-Myers-Squibb.

Differential genomic landscape of clinically advanced/metastatic chordomas (mChor) based on primary tumor site. *First Author: Jonathan Keith Killian, Foundation Medicine, Cambridge, MA*

Background: We queried whether comprehensive genomic profiling (CGP) could differentiate genomic alteration (GA) differences in mChor based on tumor site of origin **Methods:** 111 mChor FFPE tissues were sequenced using a hybrid-capture based CGP method to evaluate all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on up to 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined on 114 loci. **Results:** 27 clivus (Cliv), 12 cervical (Cerv), 10 thoracic (Thor) and 44 lumbosacral (Sacr) mChor were compared (Table). A separate set of 18 mChor were submitted as metastasis biopsies with no primary tumor site available (Unk). mChor was generally more common in men with Sacr tumors. Cliv patients were significantly younger (p = 0.00002). GA/tumor was highest in Sacr at 2.9 and lowest Thor at 1.5. All (100%) mChor were MSI stable and the TMB was low (< 5 mut/Mb) for all cases. *CDKN2A* and *CDKN2B* mutation frequencies were highest in Sacr (52% and 46%, p = 0.009 and 0.0109). Potentially actionable GA in *PTEN* were highest in Thor and Sacr. *PTCH1* GA were seen in Cliv and Cerv and *PBRM1* GA potentially associated with immune-oncology (IO) drug response were present in all groups. Additional noteworthy targets were seen in all groups but were found in less than 11% of cases throughout the study (Table). **Conclusions:** Genomic profiles of our mChor cohort differ based on the site of tumor origin in the axial spine. Sacr appear to have the highest frequency of GA and the greatest number of potentially targetable GA. Although MSI and TMB biomarker results do not predict responsiveness, a significant *PBRM1* GA frequency in all groups raises the possibility of IO drug benefit for some patients. IMMUNOSARC: a collaborative Spanish (GEIS) and Italian (ISG) sarcoma groups phase I/II trial of sunitinib and nivolumab in advanced soft tissue and bone sarcoma: Results from the phase II part, bone sarcoma cohort. *First Author: Emanuela Palmerini, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy*

Background: Herein, we present the results of the cohort on advanced bone sarcoma patients of the phase II part of the IMMUNOSARC study (NCT03277924), a European multicentre phase I-II trial aimed at investigating the activity of the combination of sunitinib (SU) and nivolumab (NI) in selected advanced sarcoma subtypes. **Methods:** Adult, pretreated, progressing patients, ECOG 0-1, with a diagnosis of osteosarcoma, high-grade bone sarcoma, Ewing sarcoma, chondrosarcoma or dedifferentiated chondrosarcoma were eligible. SU 37.5 mg/day as induction was given days 1-14 and then reduced to 25mg/day continuously. NI was administered at 3 mg/Kg every 2 weeks from week 3. SU-NI was maintained up to progression or intolerance. Primary end-point was progression-free survival rate (PFSR) at 6 months (H1: PFSR 6-months: 15%). Secondary end-points: overall survival (OS), objective response rate (ORR) by RECIST v 1.1 and toxicity. **Results:** From Nov 2017 to Dec 2018, 40 eligible patients were included: (M/F = 27/13), median age 47 years (range 21-74), ECOG 0 in 11 (27%) cases, 36 (90%) were metastatic, 4 (10%) locally advanced. Histology: 17 osteosarcomas (43%), 14 chondrosarcomas (35%) (4 dedifferentiated), 8 Ewing sarcomas (20%), 1 bone undifferentiated pleomorphic sarcoma (2%). PFSR at 6 months based on local evaluation was 32%. At a median FU of 12.5 months (2-26), median PFS was 3.7 months (95% IC 3.4-4) while median OS was 14.2 months (95%CI: 7.1-21.3). OS rate at 3 and 6 months were 87% and 73%, respectively. ORR by RECIST: 1 CR (2.5%) (1 patient with dedifferentiated chondrosarcoma, lasting 22 months and on going), 1 PR (2.5%) (1 patient with osteosarcoma, lasting 5.7 months), 22 SD (55%, lasting > 6 months in 45% of the cases) and 16 PD (40%). G3/5 toxicities are detailed in Table. **Conclusions:** The trial met its primary endpoint in the cohort of patients with advanced bone sarcoma, with > 30% of patients free from progression at 6 months. Preplanned tumor microenvironment genomic, exploratory analysis on pre and post-treatment tumor samples is on going. Clinical trial information: NCT03277924. Research Sponsor: Pfizer, Bristol-Myers Squibb, Matteo Amitrano Onlus.

Grade 3-5 side effects in 40 patients with bone sarcoma after sunitinib and nivolumab.

Efficacy of maintenance therapy with zoledronic acid in patients with localized Ewing sarcoma: Report from the international Ewing 2008 trial. *First Author: Uta Dirksen, Pediatrics III, West German Cancer Center, University Hospital Essen, German Cancer Consortium (DKTK), Essen, Germany*

Background: Ewing 2008R1 (EudraCT2008-003658-13, Sponsor UKM) was conducted in 12 countries. It evaluated the effect of zolendronic acid (ZOL) maintenance therapy on event-free (EFS, primary endpoint) and overall survival (OS) from randomization in standard risk Ewing Sarcoma (EwS). **Methods:** Phase III, open label, prospective, multi-center, randomized controlled clinical trial. Eligible patients (pts) had localized EwS with either good histological response to induction chemotherapy and/or small tumors (< 200ml). Pts received 6 cycles VIDE induction and 8 VAI (male) or 8 VAC consolidation (female) and were randomized to receive either 9 cycles of maintenance ZOL or no further treatment (control;ctrl). ZOL cycles started parallel to the 6^{th} consolidation cycle. Randomization was stratified by tumor site (pelvis/no pelvis). Two-sided adaptive inverse-normal 4-stage design, changed after the 1^{st} interim analysis via Müller-Schäfer method. Initial sample size 448 pts, type I error rate 5%, power 80%. **Results:** 284 pts were randomized between 2009 and 2018 (142 ZOL / 142 ctrl). With a median follow-up of 3.9 years, the primary endpoint EFS was not significantly different between the ZOL and ctrl group in the adaptive design (HR 0.74, 95% CI 0.43-1.28, intention to treat). 3-year (3y) EFS rates were 84.0% (95% CI 77.7-90.8%) for ZOL vs 81.7% (95% CI 75.2-88.8%) for ctrl. Results were similar in the per protocol collective. Cause-specific HR for local recurrence in ZOL was csHR 0.30 (95% CI 0.08 -1.09; p = 0.07), for metastatic progress/ new metastases csHR 1.0 (CI 0.5-2.2), for combined relapse/progress csHR 0.3 (95% CI 0.1-1.7), for second malignancies csHR 4.0 (95% CI 0.45-36.1) compared to ctrl. The 3y OS was 92.8% (95% CI 88.4-97.5%) for ZOL and 94.6% (95% CI 90.9-98.6%) for ctrl. For ZOL the 5y OS was 87.3% (95% CI 80.7-94.5%) and 89% (95% CI 83.7-95.9%) for ctrl. Noticeable more renal, neurological and gut toxicities were observed for ZOL ($p < 0.05$), with severe renal toxicities occurring more often in the ZOL arm (p = 0.003). **Conclusions:** In patients with standard risk localized Ewing Sarcoma there is no benefit from maintenance treatment with zoledronic acid, but significant side effects were observed. Clinical trial information: NCT00987636. Research Sponsor: German Cancer Aid.

11524 Poster Session (Board #412), Fri, 8:00 AM-11:00 AM

Correlation of response with progression-free (PFS) and overall (OS) survival in relapsed/refractory Ewing sarcoma (RR-ES): Results from the rEECur trial. *First Author: Keith Wheatley, University of Birmingham, Birmingham, United Kingdom*

Background: Survival for RR-ES at 5 years remains < 15%, so novel treatments are needed. Almost all Phase II trials for RR-ES use response as the primary outcome measure. It is unclear whether response is a valid surrogate for survival outcomes. **Methods:** Patients (pts) were eligible if they had RR-ES and were evaluable for imaging response (primary outcome) if they had measurable disease by RECIST 1.1. The randomization was initially between four chemotherapy regimens: topotecan-cyclophosphamide, irinotecan-temozolomide, gemcitabine-docetaxel (GD), high-dose ifosfamide. Response was assessed after 2, 4 (primary) and 6 cycles of therapy and was classified as complete response (CR), partial response (PR), stable disease (SD), progressive disease (PD). PFS and OS were secondary outcomes. Survival from each assessment point by response status was analyzed, by Cox models, with hazard ratios (HR) given for PR v. SD and CR+PR v. SD. **Results:** From 2015-19, 241 pts with response data were entered. The relationship between response status and PFS and OS is shown in the table (HR < 1.0 indicates better outcome for PR or CR+PR than SD). Both PFS and OS were similar for pts with PR or CR+PR compared to those with SD. OS was inferior for patients with PD (all $p < 0.01$) (PFS is by definition zero for patients with PD at that timepoint). Small numbers mean CR results are not reliable. Results were consistent across all treatments and between refractory and relapsed disease. At the first interim assessment the GD arm was dropped, with risk ratios for response compared to the other three arms (blinded as still open) of 0.3, 0.5 and 0.5. If a new outcome – disease control (CR+PR+SD) – is defined, the risk ratios are 0.7, 0.8 and 0.7; i.e. still inferior for GD, but less so. **Conclusions:** Response does not correlate with survival outcomes in RR-ES, so considering PR, or even CR, a success and SD a failure when evaluating treatments may be misleading. We propose PFS as a better primary outcome for future trials and it will be introduced as such in the rEECur trial. Clinical trial information: ISRCTN36453794. Research Sponsor: European Union FP7 grant.

A phase II study of anlotinib in treating patients with relapsed or metastatic primary malignant bone tumor. *First Author: Lina Tang, Affiliated Sixth People's Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: Primary malignant bone tumors are rare forms of cancer and include mainly bone sarcomas, which are categorized into 3 common types based on tissue origin: osteosarcoma, chondrosarcoma and Ewing sarcoma. A phase II trial was designed to explore the anlotinib activity in patients with relapsed or metastatic primary malignant bone tumor. **Methods:** Eligible pts were received 12mg of anlotinib once daily, 2 weeks on and 1 week off until progression or unacceptable toxicity. Key-eligibility criteria were aged 14-70 years, histologically confirmed diagnosis of osteosarcoma, chondrosarcoma, bone derived malignant fibrous histiocytoma, giant cell tumor, Ewing sarcoma and PNET, confirmed previous chemotherapy failure, ECOG 0-1(0-2 for amputation pts), required at least one measurable lesion. We observed PFS, OS, ORR, DCR and AE in this study. **Results:** From August 2018 to April 2019, 42 pts were included. Of 42 efficacy-evaluable pts, 25 were man, median age was 28 (14-68) years. There were 29 pts of osteosarcoma, 9 pts of chondrosarcoma, 3pts of Ewing sarcoma and 1 pt of bone derived malignant fibrous histiocytoma. The progression-free rate at 12 weeks ($PFR_{12weeks}$), ORR and DCR were 71.3%, 9.52% and 78.57%. Median PFS was 5.26 months (95%CI = 3.48-8.44) . Median OS was 11.40 months (95%CI = 10.09, [ ). Median PFS of osteosarcoma and chondrosarcoma was 4.83 months (95%CI = 3.48, 7.13) and 2.76 months (95%CI = 1.31, [ ) respectively. The most common Gr 3-5 anlotinib-related AEs were hypertension (19.05%), hypertriglyceridemia (9.52%), hand-foot syndrome (7.14%), and proteinuria (4.76%). **Conclusions:** The phase II study shows a promising activity of anlotinib in patients with relapsed or metastatic primary malignant bone tumor and an acceptable toxicity. Clinical trial information: NCT03527888. Research Sponsor: None.

11526 Poster Session (Board #414), Fri, 8:00 AM-11:00 AM

Preliminary evaluate the safety and efficacy of anlotinib in advanced sarcoma patients in multi-line therapy. *First Author: Yao Weitao, Hen Nan Cancer Hospital, The Affiliated Cancer Hospital of Zheng Zhou University, Zhengzhou City, China*

Background: Patients with advanced bone and soft tissue sarcoma are mostly treated with chemotherapy, but the effect is poor. Anlotinib hydrochloride is a multi-targeted receptor of tyrosine kinase inhibitors (TKI), which has demonstrated therapeutic effects on a variety of sarcoma subtypes, and is approved for the treatment of advanced soft tissue sarcomas in China. **Methods:** This is a single-arm, prospective, single-center clinical study. The included criteria were patients with pathological diagnose of bone and soft tissue sarcoma, at least one measurable lesion (according to RECIST 1.1), failed of more than first-line therapy (except for alveolar soft tissue sarcoma) in the last 6 months, with the normal function of main organs. All patients received anlotinib for more than 1 month. The primary study endpoint was objective response rate (ORR). Disease control rate (DCR) and side effects was also calculated. **Results:** At the latest follow up in Jan. 20th, 2020, a total of 31 patients were enrolled. The median age of the patients was 38 (8-79) years. The main subtypes included osteosarcoma (25.8%), undifferentiated pleomorphic sarcoma (19.4%), synovial sarcoma (16.1%), fibrosarcoma (12.9%). 83.9% of patients received for at least third-line therapy of anlotinib. The oral administration time was 1.5-15 months, with the average of 4.34 months. The ORR was 29%. The DCR was 77.4%. Patients who had received other TKI drugs had an ORR of 20% and a DCR of 70% in 10 cases (32.2%) in this group. mPFS and mOS have not been reached. Adverse events were mainly in grades I and II, including 6 (19.4%) of anorexia or diarrhea, 5 (16.1%) of pain, 4 (12.9%) of hand-foot syndrome, 3 (9.7%)of hypertension, fatigue and mucosa ulcer each. One case had hypertension in grades III. **Conclusions:** Anlotinib has shown a definite effect in the treatment of advanced sarcomas. Effectiveness can also be observed in patients who have failed in other targeted therapy. The adverse events are minor and can be tolerated. Clinical trial information: NCT04223583. Research Sponsor: None.

11527 Poster Session (Board #415), Fri, 8:00 AM-11:00 AM

A randomized, double-blind, phase II clinical trial of GI-6301 (yeast-brachyury vaccine) versus placebo in combination with standard of care definitive radiotherapy in locally advanced, unresectable, chordoma. *First Author: Peter Joseph DeMaria, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Chordoma is a rare neoplasm of the notochord that overexpresses brachyury, a transcription factor associated with epithelial-to-mesenchymal transition, metastasis, poor prognosis, and chemotherapy resistance. GI-6301 is a recombinant yeast-brachyury vaccine shown to demonstrate brachyury-specific immunogenicity, excellent safety profile, and some evidence of clinical activity in patients with chordoma in a previous phase I trial. Radiation therapy (RT) can modulate the tumor to become an immunostimulatory milieu. Preclinical studies have shown a synergistic effect combining RT with vaccine, thus prompting this clinical trial evaluating the combination of GI-6301 with RT in chordoma (NCT02383498). **Methods:** Adults with locally advanced, unresectable chordoma were treated on a randomized, double-blind, placebo controlled, phase 2 clinical trial. Patients received 3 doses of GI-6301 (80 x 107 yeast cells) vs placebo followed by photon or proton RT, followed by GI-6301 vs placebo until disease progression. Primary outcome was overall response rate (ORR) defined as a complete response or partial response in the irradiated tumor site at 24 months. Immune assays were conducted to evaluate immunogenicity. Due to slow accrual, an unplanned interim analysis was undertaken. **Results:** 24 pts were randomized and treated between May 2015 and September 2019. Vaccine was well tolerated with no dose reductions or treatment discontinuation. Treatment-related serious adverse events included: nausea/emesis (2); fatigue (2); dehydration (2); diarrhea (1); radiation necrosis (1); stroke (1); sepsis (1). There was no difference in ORR between the two arms. Pre-existing brachyury-specific T-cells were detected in the majority of patients but did not correlate with response to therapy. Most patients developed T-cell responses during therapy, regardless of treatment arm. **Conclusions:** There was no difference in ORR between the two arms. GI-6301 was well tolerated with toxicities related to RT, not vaccine. The trial was stopped early due to low conditional power for finding a statistical difference at the planned end of accrual, based on findings to date. Future studies will define utility of vaccines targeting brachyury in chordoma. Clinical trial information: NCT02383498. Research Sponsor: U.S. National Institutes of Health.

Increased pathological complete response rate with neoadjuvant denosumab in locally advanced giant cell tumor. *First Author: Gabriela Monte Tenorio Taveira, Hospital do Câncer de Pernambuco, Recife, Brazil*

Background: Giant cell bone tumor corresponds to 5% of bone tumors, has an osteolytic pattern and mainly affects long bone epiphyses in young adults. Despite being considered benign, it can metastasize and is treated as a locally destructive tumor, since it causes pain, limited joint movement and impaired function, with a risk of pathological fractures. The use of denosumab for surgical downstaging and reduction of recurrence is being studied, but the standard of treatment is still surgical. **Methods:** 15-year experience in monitoring 40 patients at the Cancer Hospital of Pernambuco-BR, who used neoadjuvant denosumab. They received Denosumab 120mg on D1, D8 and D15 as attack phase and subsequent maintenance with 120mg monthly. **Results:** The 40 patients made an average of 10 doses of neoadjuvant denosumab. Mostly located in the femur (41%) and tibia (23%), but with rare disorders in talus or orbit. Metastasis occurred in 6%, with site in lung and bones. Most were women (62%) around 21-40 years old, with Capanacci III classification at 72%. In this group, 28 had locally advanced disease and 12 had unresectable or metastatic disease. After using neoadjuvant denosumab, 75% have already had a biopsy, of which 63% (19/30) had a complete pathological response in biopsy. Of the patients with no post-denosumab neoplasia, 26% (5/19) had recurrence after medication and surgical procedure. Neoadjuvant treatment with denosumab, a monoclonal antibody that binds to RANKL, has been shown to benefit from histological response and surgical downstaging. We found 63% of complete pathological response in the 30 patients who underwent biopsy after medication, with bone sclerosis and hypocellular fibrous tissue as the main finding. Of these, 26% had disease recurrence after surgery. These data follow the international standard of disease recurrence rate, which is around 30%. **Conclusions:** We hope that the use of neoadjuvant desonumab will be more widespread and that it will be able to perform surgical downstaging, allowing less invasive and morbid procedures. Thus achieving greater joint preservation at the expense of a disease recurrence rate similar or less than standard surgical treatment. Research Sponsor: None.

11529 Poster Session (Board #417), Fri, 8:00 AM-11:00 AM

Maximum tumor dimension and tumor volume as prognostic factors in patients with newly diagnosed localized Ewing sarcoma (ES)- a report from the Children's Oncology Group (COG). *First Author: Leo Mascarenhas, Children's Hospital Los Angeles, University of Southern California, Keck School of Medicine, Los Angeles, CA*

Background: Maximum tumor dimension > 8 cm. and large tumor volume have been reported to be adverse prognostic factors in patients with ES but have not been prospectively evaluated in the context of a phase 3 clinical trial with interval compressed chemotherapy. **Methods:** COG AEWS1031 (NCT01231906) was a randomized phase 3 clinical trial comparing interval compressed chemotherapy regimens in patients with newly diagnosed localized ES of bone and soft tissue. A correlative objective of AEWS1031 was to evaluate tumor size and volume as prognostic factors. Institution-reported dimensions of the primary tumor from baseline imaging were prospectively collected. For inclusion in this analysis, patients had to have at least 1 tumor dimension reported for tumor size analyses and dimensions in 3 axes for tumor volume analyses. Maximum dimension was dichotomized as less than vs. > / = 8cm. Tumor volume was dichotomized as less than vs. > / = 200 mL. Event-free (EFS) and overall survival (OS) from enrollment were calculated using Kaplan-Meier methods and compared between groups using a two-sided log-rank test. Hazard ratios (HR) and confidence intervals (CI) were calculated using the Cox model. **Results:** The 5-year EFS and OS of the 629 eligible patients was 78% (95% CI: 75-81%) and 87% (95% CI: 84-90%) respectively and there was no significant difference in both EFS and OS between the randomized interval compressed chemotherapy arms of AEWS1031. 590 of 629 (94%) patients were evaluable for maximum tumor dimension and 307 (52%) had tumors > / = 8 cm. Patients with tumors > / = 8 cm were at significantly increased risk for EFS events (p = 0.016) with estimated 5-year EFS of 73.7% (95% CI: 68.1 vs.78.4%) vs. 82.9% (95% CI 77.7-87.1%) for patients with tumors < 8 cm [HR: 1.53 (1.08-2.17)]. For tumor volume, 586 of 629 patients (93%) were evaluable and 180 (31%) had tumors > / = 200 mL. Patients with tumor volume > / = 200 mL were at significantly increased risk for EFS events (p = 0.003) with estimated 5-year EFS of 70% (95% CI: 62.3-76.4%) vs. 81.6% (95% CI: 77.2-85.2%) for patients with tumors < 200 mL [HR: 1.69 (1.2-2.39)]. **Conclusions:** Maximum tumor dimension and tumor volume as defined are both prognostic in patients with newly diagnosed localized ES treated with interval compressed chemotherapy. Clinical trial information: NCT01231906. Research Sponsor: U.S. National Institutes of Health.

11530 Poster Session (Board #418), Fri, 8:00 AM-11:00 AM

Characterizing the landscape of genomic variants in high-risk pediatric osteosarcoma. *First Author: Amanda Marinoff, Dana–Farber Cancer Institute, Boston, MA*

Background: Survival rates for patients with metastatic and/or recurrent osteosarcoma are poor, and treatment strategies have remained unchanged for more than three decades. Genomic characterization can identify new treatment strategies and improve risk stratification. To date, sequencing studies of osteosarcoma have focused on newly diagnosed patients. We present one of the first reports of osteosarcoma genomics in a high-risk cohort. **Methods:** 92 samples from 92 patients were sequenced in a CLIA/CAP laboratory with a targeted NGS panel test. Patients were enrolled in one of two studies. The PROFILE study enrolls all patients seen at Dana-Farber Cancer Institute, and the GAIN study enrolls patients with metastatic and/or recurrent cancer at 11 institutions. Sequencing was performed using primary tumor samples at biopsy and/or from sites of metastasis when available. **Results:** 33 patients were enrolled on the PROFILE study, and 59 were enrolled on GAIN. Diagnostic stage was available for 65 (67%) of patients. 37% had metastatic disease at diagnosis. The 3-year overall survival (OS) was 71% for the entire study population, 56% for patients with metastatic disease at diagnosis, and 81% for patients with initially localized disease. The presence of metastases at diagnosis was significantly associated with poor outcome ($p < 0.0087$) and was the only independent clinical prognostic factor identified. Genomic analysis revealed frequent alterations in TP53 (37%), RB1 (15%), CDKN2A (13%), MYC (12%), CDKN1A (12%), ATRX (10%), and CCND3 (8%). Patients whose tumors had MYC amplification (defined as ≥ 6 copies) had a 3-year OS of 39% compared with a 3-year OS of 76% in the absence of MYC amplification, a difference with borderline statistical significance ($p = 0.051$). **Conclusions:** In the first study to examine genomic alterations detected by targeted gene panel sequencing in a CAP-certified laboratory in a large population of pediatric patients with higher risk osteosarcoma, the most frequently occurring events were similar to those found in prior reports. MYC amplification, reported as a possible poor prognostic factor in other studies, was present in 12% of patients and was associated with a worse OS, though this finding did not reach statistical significance. Research Sponsor: Institutional/ Philanthropic.

11531 Poster Session (Board #419), Fri, 8:00 AM-11:00 AM

Genomic analysis of advanced malignant soft tissue tumors to suggest effect of genome-wide loss-of-heterozygosity of germline mutations/variants on anti-PD-1 immunotherapy response and survival of the patients. *First Author: Katsuhito Takahashi, Kameda Medical Center, Center for Multidisciplinary Treatment of Sarcoma, Department of Sarcoma Medicine, Kamogawa, Japan*

Background: Malignant soft tissue tumor is a rare cancer with few therapeutic options. Although recent genomic characterization of soft tissue sarcoma revealed massive CNA and an excess of polygenic burden of pathological germline variants, their clinical and therapeutic significance remains to be understood. **Methods:** We recruited 155 patients with malignant soft tissue tumors (135 female and 20 male, mean age 51, 100 LMS, 19 LPS, 4 ESS, 3 UPS, 3 AS, 3 MPT, 3 GIST and others) of confirmed metastasis/recurrence. Whole exome sequencing was performed as reported in 2018ASCO. The MSI status was analyzed by PCR. Tumor immune microenvironment was assessed by immunohistochemistry. **Results:** Of the 595 COSMIC genes, heterozygous germline mutations/variants of the genome-wide 0-44 genes (av. 9.7/tumor) showed somatic loss-of-heterozygosity (LOH) with allele frequency of more than 70%. Patients with less than 33% LOH (n=53) in the total of somatic and LOH mutations showed improved 5-year survival rate compared with those (n=102) with more LOH (71% vs 52%, p=0.037). LMS (n=100) had higher value of LOH mutations than other tumors (n=55)(av. 55.5 vs 31.2%, $p<0.001$). Two patients with bone metastasis, one from liver undifferentiated sarcoma (case 1) and the other from uterine LMS (case 2) were identified as MSI-High and resultant higher TMB of 6.48 and 6.60/Mb, respectively than 1.47/Mb in av. Tumors from both cases had de novo mutations of MMR deficiency as EXO I (A153V) and WRN (S1120F) in case 1 and MSH2 (G674D) in case 2. Case 1 with pleural dissemination was treated with 5 cycles of Pembrolizumab (200mg/body, d1 q3weeks) but was progressive disease, while case 2 had no evaluable lesion after surgical removal of bone metastasis. Number of CD8+ T-cell infiltration (TIL), one of the best parameter with response to PD-1 blockade, was much higher in case 2 than in case 1 (av. 907 vs 290/mm^2). Case 2 had no LOH mutations while case 1 had 37% LOH with more total mutations in tumor (16.1 vs 85.9/Mb). Higher values of LOH (av. 67 vs 19%) were clearly correlated with decreased density of CD8+TIL in tumor tissues (av. 9.6 vs 429/mm^2, n=5, p=0.018). **Conclusions:** Our results, for the first time, suggest that in malignant soft tissue tumors, accumulation of genome-wide LOH of germline mutations/variants, from which self-antigens could be generated, may influence tumor immune microenvironment, and thus influence immunotherapy response and survival of the patients. Research Sponsor: Japan Sarcoma Association Fund for Promotion of Genomic Medicine of Rare Cancers, The Osaka Foundation for The Prevention of Cancer and Lifestyle -related Diseases Research Grant.

Outcomes of patients (pts) with advanced gastro-intestinal stromal tumors (GIST) treated with multi-kinase inhibitors other than imatinib (IM) as first-line treatment. *First Author: Alice Boileve, Institut Gustave Roussy, Villejuif, France*

Background: IM is the standard first-line therapy in advanced GIST, with a median progression-free survival (PFS) of 30 months. Recent multi-kinase inhibitors (MKIs) such as nilotinib, dasatinib or masitinib have been tested as first-line therapies in phase II/III studies. This might theoretically result in increased PFS (by the addition of a new line of treatment), or in early emergence of resistance to approved MKIs. **Methods:** A retrospective chart review was performed in GIST pts who received investigational MKIs (in phase II/III trials) as first-line treatment, followed by IM as second line. Data on demographics, molecular profile, PFS, and overall survival (OS) were collected in two French referral centers. **Results:** Of 47 pts, (57% females), 22 (47%) had a *KIT* exon 11 mutation, one a *KIT* exon 9 mutation (2%), one a *PDGFR* D842V mutation (2%). Five patients were wild-type for *KIT* and *PDGFR*. The mutational status was unknown in 18 pts (38 %). From 2005 to 2011, 21 pts (45%) received masitinib, 18 (38%) received dasatinib and 8 pts (17%) received nilotinib. Median PFS on first-line treatment was 18.9 months [95%IC: 9.0-26.0]. Median time-to-failure (TTF) with IM was 19.7 months [95%IC: 14.8-53.4]. Median time to second relapse was 50.2 months [95%IC: 31.2-92.2]. Thirty-five patients (74.5%) were dead at the end of follow-up. The median OS from time of initial diagnosis was 5.9 years [95%IC: 4.5-8.2]. **Conclusions:** GIST pts who received MKIs other than IM as first-line treatment and IM as second-line had a time to second relapse longer than that observed historically with IM in first line. This suggests that using MKIs other than IM in first line does not decrease IM efficacy in second line. Further comparative studies are needed to confirm these findings, but this is encouraging to further develop studies with other MKIs in the first line setting. Research Sponsor: None.

11533 Poster Session (Board #421), Fri, 8:00 AM-11:00 AM

Role of adjuvant imatinib dose in radically resected GIST harboring KIT exon 9 mutations. *First Author: Bruno Vincenzi, Policlinico Universitario Campus, Bio-Medico, Rome, Italy*

Background: Gastrointestinal stromal tumors (GIST) with a driver mutation in *KIT* exon 9 (Ex9) represent about 10% of all newly diagnosed cases. In the metastatic setting, Ex9-mutated GIST patients benefit from higher doses of imatinib (800 mg/day vs standard 400 mg/day). The additional therapeutic benefit from a higher dose of imatinib in the adjuvant setting in this molecular subgroup has not been confirmed. **Methods:** We retrospectively identified 105 patients (pts) with resected Ex9-mutated GIST treated with adjuvant imatinib (800 mg/day or 400 mg/day) in 15 different European centers. Disease-Free Survival (DFS) and Imatinib Failure-Free Survival (IFFS) were calculated and analyzed according to the daily dose of imatinib and relevant clinical and pathological variables. Kaplan–Meier curves were used to estimate survival in univariate analyses, and the log-rank test was used to compare the groups. Hazard Ratios (HR) with 95% confidence intervals (CI) were calculated using a univariable Cox model. A multivariate Cox regression model was also performed. **Results:** Of the 105 pts who met the inclusion criteria, 69 (65.7%) were treated with 400 mg/day and 36 (34.3%) with 800 mg/day. The risk score (AFIP-Miettinen criteria) between the two dose groups was not statistically different (P = 0.29). Median DFS was 73.0 months (mo) in the 400 mg/day group and 61.9 mo in the 800 mg/day group (HR = 0.82, 95% CI: 0.47-1.47; *P* = 0.50). Median IFFS was 156.8 mo in the 400/day mg group and 117.4 mo in the 800 mg/day group (HR = 0.66, 95% CI: 0.34-1.29; *P* = 0.19). In a multivariable analysis, the variables statistically associated with DFS were mitotic count, the longest tumor diameter and the duration of adjuvant therapy. Mitotic count and the duration of adjuvant therapy were also associated with IFFS. Importantly, the daily imatinib dose was not associated with survival in either analysis (Table). **Conclusions:** This is the largest reported cohort of pts with Ex9-mutated GIST treated with either the 400 mg/day or the 800 mg/day dose of adjuvant imatinib. Although retrospective in nature, the data confirm the prognostic value of mitotic count and suggest that patients with Ex9-mutated GIST derive no additional survival benefit from the 800 mg/day dose. Research Sponsor: None.

11534 Poster Session (Board #422), Fri, 8:00 AM-11:00 AM

Laparoscopic versus open surgery for gastrointestinal stromal tumor in esophagogastric junction: A multi-center, retrospective cohort analysis with propensity score matching. *First Author: Wenjun Xiong, Guangdong Provincial Hospital of Chinese Medicine, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China*

Background: Laparoscopic resection is increasingly performed for Gastrointestinal stromal tumor (GIST). Nevertheless, laparoscopic approach for the GIST located in the esophagogastric junction (EGJ-GIST) represent a surgical challenge. This study aims to investigate the efficacy of laparoscopic surgery and open procedure for EGJ-GIST through the propensity score matching (PSM) method. **Methods:** Between April 2006 and April 2018, 1824 patients underwent surgery were finally diagnosed with primary gastric GIST at four medical centers in South China. EGJ-GIST was defined as a GIST with an upper border of less than 5 cm from the EG line. Among them, 228 patients were identified and retrospectively reviewed with regard to clinicopathological characteristics, operative information and long-term outcomes. The PSM methods was used to eliminate the selection bias. **Results:** After PSM, 102 cases, consisted of 51 laparoscopic (LA) and 51 open surgery (OP), were enrolled. The match factors contained year of surgery, gender, age, BMI, tumor size, mitotic rate, recurrence risk and adjuvant tyrosine kinase inhibitors treatment. The LA group was superior to the OP group in operative time (108.5±56.5 vs. 169.3±79.0 min, $P < 0.001$), blood loss (54.6±81.9 vs. 104.9±156.4 ml, $P = 0.042$), time to liquid intake (3.1±1.8 vs. 4.3±2.2 d, $P = 0.003$), hospital stay (6.0±2.3 vs. 9.9±8.1, $P = 0.001$), and postoperative complication (5.9% vs. 25.5%, $P = 0.006$). The median follow-up was 55 (range, 2-153) months in the entire cohort. No significant differences were detected in either the relapse-free survival (RFS, $P = 0.109$) or overall survival (OS, $P = 0.113$) between two groups. The 1-, 3-, and 5-year RFS in the LA and OP groups were 100.0%, 95.5%, 91.0% and 100.0%, 90.8%, 85.7%, respectively. The 1-, 3-, and 5-year OS in the LA and OP group were 100%, 95.6%, 91.3% and 100.0%, 91.1%, 85.4%, respectively. **Conclusions:** Laparoscopic surgery for EGJ-GIST is associated with the advantages of shorter operative time, reduced blood loss, shorter time to liquid intake and shorter length of stay, all without compromising post-operative outcomes and long-term survival. Research Sponsor: None.

11535 Poster Session (Board #423), Fri, 8:00 AM-11:00 AM

Quality of life (QoL) and self-reported function with ripretinib in ≥4th-line therapy for patients with gastrointestinal stromal tumors (GIST): Analyses from INVICTUS. *First Author: Michael C. Heinrich, Portland VA Health Care System and OHSU Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: Ripretinib is a novel switch-control tyrosine kinase inhibitor (TKI) that broadly inhibits KIT and PDGFRA kinase signaling through a dual mechanism of action. In INVICTUS (NCT03353753), a randomized, double-blind, placebo-controlled trial of ripretinib in ≥4th-line advanced GIST, ripretinib reduced the risk of disease progression or death by 85% vs placebo and had a favorable overall safety profile in patients previously treated with ≥3 prior TKIs. **Methods:** As part of the INVICTUS trial, patient reported outcome (PRO) measures were collected using EQ-5D-5L (EQ5D) and EORTC QLQ-C30 (C30). In prespecified and additional analyses, ANCOVA models were built to compare changes from baseline to cycle 2 day 1 (C2D1) for PRO measures within the ripretinib and placebo arms and determine the difference between treatment arms. PRO measures included the EQ5D visual analogue scale (VAS) and the C30 physical functioning (PF) and role functioning (RF) scales (all scores range from 0–100; higher scores are better). The C30 overall health and overall QoL questions were also assessed (scores range from 1–7; higher scores are better). Fixed effects included treatment arm, number of previous anticancer treatments (3 vs ≥4), and ECOG score at baseline (0 vs 1/2). **Results:** Overall, 129 patients were randomized and 128 received treatment (85 to ripretinib 150 mg QD; 43 to placebo). All PRO p-values are nominal, and no statistical significance is being claimed. VAS scores improved an average 3.7 points from baseline to C2D1 with ripretinib vs an average decline of 8.9 with placebo (P = 0.004; improvement or no change, 67% vs 41% of patients, respectively). Similarly, the average PF score improved 1.6 points with ripretinib and decreased 8.9 with placebo (P = 0.004; improvement or no change, 68% vs 44%). RF scores also improved an average of 3.5 points with ripretinib vs a decrease of 17.1 with placebo (P = 0.001; improvement or no change, 77% vs 50%). For the overall health and overall QoL questions, scores increased with ripretinib an average of 0.20 and 0.28, respectively, and decreased 0.78 and 0.76 with placebo (both P = 0.001; improvement or no change, 74% vs 47% and 79% vs 59%, respectively). **Conclusions:** Based on the 5 PRO measures assessed, when compared with placebo and best supportive care, ripretinib provided patient-benefit in advanced GIST with PRO measures of role and physical function, VAS, overall health, and overall QoL remaining stable. Clinical trial information: NCT03353753. Research Sponsor: Deciphera, LLC.

11536 Poster Session (Board #424), Fri, 8:00 AM-11:00 AM

Lower-dosing ponatinib in pre-treated GIST: Results of the POETIG phase II trial. *First Author: Johanna Falkenhorst, Department of Medical Oncology, University Hospital Essen, West German Cancer Center, University Duisburg-Essen, Essen, Germany*

Background: Despite long-lasting responses to imatinib most metastatic gastrointestinal stromal tumors (GIST) eventually progress and subsequent treatments are associated with limited duration of disease control. Ponatinib is a potent KIT inhibitor with a strong activity against secondary mutations in exon 17, including the highly resistant D816 mutations of KIT. Based on the dose-depending toxicity profile we sought to evaluate the safety and activity of lower dosing (30mg) ponatinib in pretreated patients with KIT-mutant GIST. We here report safety data for the whole cohort and first efficacy data for the last line cohort within a planned interim analysis. **Methods:** This multicenter phase 2 trial (NCT03171389) recruited patients with advanced, unresectable GIST progressing after imatinib (Cohort A/B: absence/presence of KIT Exon 13/14 mutations by plasma sequencing) or imatinib, sunitinib and regorafenib (Cohort C). Patients were treated with 30mg oral ponatinib daily in 4-week-cycles. The primary endpoint was the clinical benefit rate at 16 weeks as measured by mRECIST1.1 criteria. **Results:** At the cutoff date of 31st Jan 2020, 39 patients were evaluable for safety analysis (25 male, 14 female, median age 60 (38-86) years). Median duration of treatment was 65 (14-699) days. 66.7% of all patients observed Grade 3/4 adverse events (AEs), most common were pain (10/39), hypertension (6/39), GGT or lipase increase (both 5/39), and fever (3/39). One AE of special interest was observed (myocardial infarction, rated not related to study drug) and 20/39 patients experienced at least 1 severe AE (6/39 possibly related to ponatinib). Within the last line cohort, 20 patients were evaluable for efficacy. Clinical benefit rate was 35% (CI 15.4-59.2%). Median progression-free survival was 86 days with single patients yielding long-lasting responses (75% quartile 210 days, maximum: 420 days). **Conclusions:** Treatment with ponatinib was tolerable at a dose of 30mg qd with a toxicity profile comparable to other TKIs used in GIST. The majority of grade 3/4 AEs were hypertension or asymptomatic increases of laboratory values and thromboembolic events were rare. In a heavily pretreated patient population that lacks alternative treatment options the clinical activity was notable. An updated analysis including predictive biomarkers will be presented. Clinical trial information: NCT03171389. Research Sponsor: Arbeitsgemeinschaft Internistische Onkologie, Germany, Pharmaceutical/ Biotech Company.

11537 Poster Session (Board #425), Fri, 8:00 AM-11:00 AM

Identification of SDHA germline mutations in sporadic SDHA mutant gastrointestinal stromal tumors (GIST): The need of a genetic counselling. *First Author: Margherita Nannini, Medical Oncology Unit, Sant'Orsola-Malpighi Hospital, Bologna, Italy*

Background: SDH-*deficient* GIST, as defined by the loss of expression of SDHB, account up to about 10% of all gastric GIST and generally affect younger population. Germline mutations in SDHB, SDHC, and SDHD occur in about 20–30% of SDH-*deficient*, that may be referred to a hereditary condition known as hereditary GIST-paraganglioma syndrome (Carney-Stratakis Syndrome), whereas germline SDHA mutations have been rarely described in apparently sporadic cases. Currently, even germline testing is recommended for SDH-*deficient* GIST, there are no clear guidelines for genetic counselling and follow-up of SDH*x* mutation carriers and relatives, especially for SDHA mutant GIST not yet linked to well-defined hereditary syndrome. The aim of this work was to study the SDHA gene in the normal DNA of patients with SDHA mutant GIST. **Methods:** Thirteen patients carrying SDHA-mutant GIST were studied (8F/5M). Median age of diagnosis was 45,9 years (range 25-74). All GIST were located in the stomach and 3 patients out 13 presented a metastatic disease. In all cases except one, the GIST was the only cancer presentation and no personal or familial history of cancer was revealed. All cases were negative for SDHB immunohistochemistry. Germline mutations were identified through Sanger sequencing of SDHA in the normal counterpart. **Results:** Germline mutations were identified in all patients for which normal counterpart was available: 4 cases harboured truncating mutations (S384X, R31X and W119X); 5 cases carried pathogenic missense mutations (G233V, R171H, R589Q, G257A and R600Q) and 2 cases had splice site alterations (c.457-3_457-1 delCAG and c.456+9 C > T). In 8 cases the tumor DNA showed the loss of the corresponding wild-type allele, while in the other 3 cases compound heterozygosity for an additional somatic mutation was detected (R589W, R451C,and R171C). In 2 patients, unfortunately, normal DNA was not available, however both tumours carried two mutational hits on SDHA (one with heterozygous G419R and E564K, and one with homozygous R585Q). Of note, 5 patients presented un-usaul SDHA related clinical characteristics as were not young adult (> 50 years-old) or no multifocal GIST. **Conclusions:** We demonstrated that germline SDHA mutations are highly frequent in SDHA-*deficient* GIST. Therefore, although a clear syndrome has not been defined, genetic counselling and follow-up of SDHA mutation carriers and relatives should be clarified. Research Sponsor: None.

11538 Poster Session (Board #426), Fri, 8:00 AM-11:00 AM

Long-term results of selective internal radioembolization (SIRT) to control progressive liver metastases of gastro-intestinal stromal tumors (GIST) beyond treatment with tyrosine kinase inhibitors (TKI). *First Author: Peter Hohenberger, Division of Surgical Oncology and Thoracic Surgery, Mannheim University Medical Centre, University of Heidelberg, Mannheim, Germany*

Background: Liver and peritoneum are the main area of metastatic spread in GIST. Liver resection does not play a role for hepatic metastases in comparison to f.e. colorectal cancer. If hepatic metastases are the only or major area of tumor progression and are resistant to available TKIs due to a missing mutation in *KIT/PDGFRA/SDH* ('wildtype') or after treatment with 1st/2nd/3rd/4th line therapy, interventional radioembolization with yttrium-90 (^{90}Y) microspheres are promising treatment options, as radiation doses as high as 200Gy can be applied locally. We analyzed the long-term results of SIRT with respect to hepatic-progression-free survival (HEP-PFS) in a consecutive cohort of patients.. **Methods:** From 1/2008 to 1/2018, 25 pts (12f, 13m) with biopsy proven liver metastases of GIST which were the only (n = 13) or the dominant site of progression (n = 12) were treated by SIRT. Median age at GIST diagnosis had been 51.8 yrs and when receiving SIRT was 57.6yrs (range, 18–75yrs). The mutational status was 'wildtype' (n = 7, 2 NF-1), exon 11 (n = 7), exon 11+2nd mutation (n = 6), exon 9 (n = 3), exon 9+2ndmut (n = 1), and, exon 13 (n = 1). All patients except of two had prior TKI therapy: 1 line n = 3, 2 lines n = 11, 3-4 lines n = 9. Follow-up after SIRT was done via dynamic MRI and contrast-enhanced (CE)-CT, the median follow-up is 30.6 mos (range, 12-100mos) and all patients were followed until death. **Results:** The median hepatic-progression free survival (HEP-PFS) after SIRT was 17 months (range, 5-53+, 95%CI 11.8-22.1 mos). Of the patients with concomitant extrahepatic disease, the extraHEP-PFS was median 10 months. Twelve patients received next-line TKI therapy for progressive extrahepatic disease, whereas six patients required this for progressive liver metastases. When comparing the results according to the mutational status, patients with a 'wildtype' tumor showed a better median HEP-PFS of 19 mos (range, 12-53+, 95%CI 16.7-21.2 mos.) in comparison to *KIT* exon 9/11/13 mutated patients with only 14 months (range, 4-34 mos., 95%CI 6.5-21.4 mos), $p < 0.11$ (Wilcoxon). **Conclusions:** 90Y radioembolization (SIRT) offers a safe and effective treatment for patients with liver metastases of GISTs being the dominant site of tumor progression and with no drug treatment options available. In patients known to have no mutation in *KIT/PDGFRA* (wt, also NF-1 associated) it looks whether the results might be even more promising and SIRT could be used in early treatment lines. 11539 Poster Session (Board #427), Fri, 8:00 AM-11:00 AM

Safety profile of ripretinib, including impact of alopecia, and Palmar-Plantar Erythrodysesthesia Syndrome (PPES) on patient-reported outcomes (PROs), in ≥ fourth-line advanced gastrointestinal stromal tumors (GIST): Analyses from INVICTUS. *First Author: Suzanne George, Dana-Farber Cancer Institute, Boston, MA*

Background: Ripretinib is a novel switch-control TKI that broadly inhibits KIT and PDGFRA kinase signaling. In INVICTUS (NCT03353753), a randomized, double-blind, placebo (PBO)-controlled trial of ripretinib in ≥4th-line advanced GIST, ripretinib reduced the risk of disease progression or death by 85% vs PBO with a favorable overall safety profile. Common (> 20%) adverse events (AEs) included, but were not limited to, alopecia and PPES. Exploratory analyses evaluated the impact of alopecia and PPES on quality of life (QoL). **Methods:** Patients (pts) with advanced GIST previously treated with at least imatinib, sunitinib, and regorafenib were randomized (2:1) to ripretinib 150 mg QD or PBO. AEs were graded using CTCAE v4 and PROs collected using EQ-5D-5L (EQ5D) and EORTC QLQ-C30 (C30). Repeated measures (RM) models assessed the impact of alopecia and PPES on 5 PROs (EQ5D visual analogue scale; and C30 physical functioning, role functioning, and the overall health and overall QoL questions) within the ripretinib arm. Fixed effects were sex, alopecia/PPES, and ECOG scores at baseline. **Results:** 128/129 randomized pts received treatment (85 ripretinib 150 mg QD; 43 PBO). Alopecia, regardless of causality, occurred in 44 (51.8%) on ripretinib (34 [40.0%] grade 1; 10 [11.8%] grade 2) and 2 (4.7%) on PBO (both grade 1). PPES occurred in 18 (21.2%) on ripretinib (11 [12.9%] grade 1; 7 [8.2%] grade 2); none on PBO. The median times in days to first occurrence and worst severity grade with ripretinib were 57.0 and 62.5 for alopecia; 56.5 and 57.0 for PPES. The RM models showed a slight trend towards improvement in PRO score over time for pts with alopecia; the only association reaching a P-value of < 0.05 was between alopecia and increased overall QoL. None of the associations between PPES and PRO scores reach $P < 0.05$. All PRO p-values are nominal, and no statistical significance is being claimed. **Conclusions:** Ripretinib had a favorable overall safety and tolerability profile. When stratified by alopecia and PPES, patient-reported assessments of function, overall health, and overall QoL were maintained over time. For both alopecia and PPES, onset and maximum severity occurred almost simultaneously, indicating that these events generally did not progressively worsen. These results suggest that alopecia and PPES are manageable and do not have a negative effect on function, overall health, and QoL. Clinical trial information: NCT03353753. Research Sponsor: Deciphera, LLC.

11540 Poster Session (Board #428), Fri, 8:00 AM-11:00 AM

A phase II trial of the DNA methyl transferase inhibitor, SGI-110 (Guadecitabine), in children and adults with SDH-deficient GIST, pheochromocytoma, and paraganglioma, and HLRCC-associated kidney cancer. *First Author: Mary Frances Wedekind, Pediatric Oncology Branch, NCI, NIH, Bethesda, MD*

Background: Loss of activity of the Krebs cycle component succinate dehydrogenase (SDH) complex is a mechanism of tumorigenesis in SDH-deficient cancers. Accumulation of the metabolite succinate inhibits α-ketoglutarate-dependent dioxygenases leading to DNA hypermethylation. Guadecitabine is a small molecule DNA methyltransferase inhibitor. We conducted a Phase II study to test the hypothesis that guadecitabine will impact tumor growth by reversing DNA hypermethylation in tumors with Krebs cycle abnormalities (NCT03165721). Study Objectives: Our primary objective was to assess the clinical activity of guadecitabine in patients with SDH-deficient GIST, PHEO/PGL, and HLRCC-associated renal cell carcinoma. Secondarily, we desired to evaluate the toxicities of patients on treatment with guadecitabine. **Methods:** We conducted a single site, open label, phase II study using a small optimal two-stage design to evaluate response in SDH-deficient GIST, PHEO/PGL, and HLRCC-associated renal cell carcinoma. Patients >12 years of age received guadecitabine subcutaneously at 45mg/m^2/day for 5 consecutive days on a 28-day cycle. Activity via imaging response was assessed utilizing RECISTv1.1. Toxicities were graded using version 4.0 of the NCI Common Toxicity Criteria. All patients were included in analysis. **Results:** We enrolled nine patients (6F:3M) with an age range of 18-57 years. Seven patients had SDH-deficient GIST (78%), one patient with paraganglioma (11%), and one with HLRCC-associated renal cell carcinoma (11%). No patients had a complete or partial response. Five patients came off study due to progression (56%) with one death due to disease progression in the patient with HLRCC-associated renal cell carcinoma (11%). Three patients (33%) withdrew due to lack of response with stable disease. One patient was withdrawn due to investigator's discretion (11%). Toxicities possibly, probably, or definitely related to drug included grade 3 leukopenia (11%) febrile neutropenia (11%), grade 3-4 neutropenia (22%) requiring dose reductions, grade 3 hypertension (11%), grade 2 lung infection requiring hospitalization (11%). **Conclusions:** In this single site, open label, phase II study in patients with SDH-deficient GIST, PHEO/PGL, and HLRCC-associated renal cell cancer guadecitabine was tolerated by the majority of patients. No complete or partial responses were observed. Clinical trial information: NCT03165721. Research Sponsor: U.S. National Institutes of Health.

11541 Poster Session (Board #429), Fri, 8:00 AM-11:00 AM

Primary adult retroperitoneal sarcoma (RS): Comprehensive genomic profiling (CGP) study. *First Author: Andrea Necchi, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: We performed CGP on 315 cases of RS to discover targetable genomic alterations (GA) and their potential impact on potential targeted and immunotherapy (IO) selection. **Methods:** FFPE tissues from 315 clinically advanced RS tissues underwent hybrid-capture based CGP (DNA and RNA). Tumor mutational burden (TMB) was determined on up to 1.2 Mbp of sequenced DNA, and tumor cell PD-L1 expression was determined by IHC (Dako 22C3) (low = 1-49%; High = >50% tumor cell staining). **Results:** 155 liposarcomas (LPS), 74 leiomyosarcomas (LMS), 46 pleomorphic sarcomas (PLS), 7 solitary fibrous tumors (SFT), 6 malignant peripheral nerve sheath tumors (MPNST), 5 synovial sarcomas (SS) and 5 dendritic follicular cell sarcomas (DFCS) were studied; 17 cases were excluded. Median age was 59. There were 5.1 GA/tumor, none were MSI-high, median TMB was low at 2.4; PD-L1 IHC staining was low-positive in 21% and high-positive in 5%. MPNST patients were younger (median 28 years vs. 59 years). LPS was more frequent in men and LMS in women. LPS had more GA/tumor than LMS, with DFCS having the highest and SS the lowest. *TP53* and *RB1* GA were the highest in LMS and *CDK4/6* and *MDM2* GA the highest in LPS. Molecular targets in mTOR pathway were most frequently altered. Targetable gene fusions in *ALK*, *ROS1* and *NTRK1-3* were rare. Non-targetable fusions in *HMGA2* (LPS and some PLS), *STAT6* (SFT) and *SS18* (SS) were also identified. **Conclusions:** RS in our cohort are predominantly composed of LPS, LMS and PLS and we identified a small proportion with "actionable" genomic targets on CGP, albeit in association with uncertain mTOR pathway inhibitor benefit and uncommon targetable kinase fusions. Our analysis suggests that a small subset of RS may respond to immunotherapy based on putative biomarker expression. Research Sponsor: Foundation Medicine Inc.

11542 Poster Session (Board #430), Fri, 8:00 AM-11:00 AM

Phase I study results of APG-115, a MDM2-p53 antagonist in Chinese patients with advanced liposarcoma and other solid tumors. *First Author: Xing Zhang, Melanoma and Sarcoma Medical Oncology Unit, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: APG-115 is a potent, small-molecule MDM2 inhibitor and immune modulator with promising antitumor activities in various tumors, especially those wild-type *TP53* with MDM2 amplification (*TP53*^{wt}+MDM2 amp). To better delineate safety, optimal dosage, and potential target population, we report updated results. **Methods:** Patients with advanced liposarcoma and other solid tumors received APG-115 (100-200 mg) orally every other day for 21 days of a 28-day cycle. The primary endpoints were safety and tolerability. Efficacy (assessed by RECIST v1.1), pharmacokinetics (PK) and pharmacodynamics (PD) have also been analyzed. **Results:** Enrollment of this Phase I study (CTR20170975) was completed. As of January 7, 2020, 21 patients (14 liposarcomas, 2 synovial sarcomas, 2 adenoid cystic carcinomas, 1 chondrosarcoma, 1 osteosarcoma, 1 rhabdomyosarcoma) were treated in 3 dose levels of APG-115: 100 mg (n = 11), 150 mg (n = 8) and 200 mg (n = 2). The median number of cycles of APG-115 was 2 (0; 6). Two DLTs were observed at 200 mg, thrombocytopenia and febrile neutropenia. The most common treatment-emergent adverse events (TEAEs) (≥20%) included leukopenia, thrombocytopenia, neutropenia, anemia, increased blood creatinine, hypercholesterolemia, hypertriglyceridemia, hypoalbuminemia, vomiting, and nausea. The incidence of TEAEs was much lower at 100 mg. Serious AEs occurred in 5 patients (23.8%) which were assessed as possibly drug related by investigators. In 20 efficacy-evaluable patients, there was 1 patient with a partial response, 12 patients with stable disease, and 7 patients with progressive disease, yielding a disease control rate (CR, PR, SD) of 61.9%. Among the 13 patients (9 liposarcomas) who benefited, 11 had *TP53*^{wt} and 7 had *TP53*^{wt}+MDM2 amp, including one liposarcoma patient (150 mg) who had a PR, she was kept-up over 10 months, even though the treatment was discontinued for over 5 months, indicating the host immune modulatory effects of APG-115. Another patient with liposarcoma (100 mg, *TP53*^{wt}+MDM2 amp) had 28.5% tumor shrinkage at cycle 4 and remained on treatment. PK results showed an approximately dose-proportional increase in exposure on Day 1. PK-PD analyses showed the serum macrophage inhibitory cytokine-1 (MIC-1) increased with increased APG-115 exposure. **Conclusions:** The phase I data have demonstrated that APG-115 monotherapy was well tolerated, with minimal toxicity at 100mg (RP2D), and conferred encouraging anti-tumor activities in patients with liposarcomas. Clinical trial information: CTR20170975. Research Sponsor: Ascentage Pharma (Suzhou) Co., Ltd. Suzhou, China.

11543 Poster Session (Board #431), Fri, 8:00 AM-11:00 AM

Prognostic role of MRP1 in localized high-risk soft tissue sarcoma (STS): Translational research associated to randomized phase III trial (ISG-STS 1001). *First Author: Javier Martin Broto, Virgen del Rocio University Hospital, Institute of Biomedicine Research (IBIS)/CSIC/Universidad de Sevilla, Seville, Spain*

Background: The ceiling-drug effect seen for most active drugs in STS could be related, partially, to multidrug resistance mechanisms (MDRM). We previously reported the independent prognostic role for RFS and OS of MRP1 in high-risk localized STS of limbs and trunk-wall treated with epirubicin and ifosfamide (Mol Cancer Ther.2014 13(1):249-59). A translational study was carried out within the randomized phase III trial of epirubicin plus ifosfamide vs histotype-tailored neoadjuvant chemotherapy (NCT01710176), to investigate MRP1 prognostic value using the trial population as validation set. **Methods:** Patients enrolled in the trial were invited to participate, through the informed consent, to this analysis. IHC used QCRL-1 (Santa Cruz biotechnology) MRP1 monoclonal antibody. TMAs were built on the highest-grade area of each tumor, being the procedure blinded for clinical data. MRP1 expression was grouped as low (≤ 25% positive cells) vs high (> 25% positive cells) expression. For data analysis, patients were grouped as A) epirubicin plus ifosfamide control arm and B) histotype-tailored experimental arm. Drugs used in group B were: gemcitabine-docetaxel (UPS), gemcitabine-DTIC (LMS), trabectedin (High-grade (HG) myxoid LPS), ifosfamide-etoposide (MPNST) and high-dose ifosfamide (SS). Prognostic value of MRP1's extension was analyzed using Cox's proportional hazard regression. A p-value < 0.05 was considered statistically significant. **Results:** 175 patients were analyzed (median age 49; males 61%) with median follow-up of 4.66 y. Group A (n = 88) included HG-myxoid LPS (27%), SS (25%), UPS (24%), LMS (12%) MPNST (10%) and others (2%); group B (n = 87) included UPS (38%), SS (24%), HG-myxoid LPS (20%), LMS (10%) and MPNST (8%). MRP1 high extension was distributed as follows: 48% (A) and 57% (B). High MRP-1 expression showed significantly worse prognosis for disease-free survival (DFS) (HR 2.71 (1.31-5.62) p = 0.007) and a trend towards worse OS (HR = 2.75 (0.97-7.81) p = 0.058) in group A. No correlation was seen between MRP-1 expression and DFS (p = 0.384) or OS (p = 0.665), in group B. **Conclusions:** MRP1 overexpression was related to significant worse prognosis in 2 prospective randomized series of high-risk, localized, STS treated with neoadjuvant epirubicin and ifosfamide. These agents are both substrate of MRP1; this could add rationale for a possible predictive role, as MDRM, for the two most active drugs in STS. A trial combining epirubicin, ifosfamide and MRP1 inhibitor is currently under design. Research Sponsor: European Union grant (Eurosarc FP7 278472).

11544 Poster Session (Board #432), Fri, 8:00 AM-11:00 AM

SAR-096: A phase II trial of ribociclib in combination with everolimus in advanced dedifferentiated liposarcoma (DDL), and leiomyosarcoma (LMS). *First Author: Sujana Movva, Fox Chase Cancer Center, Philadelphia, PA*

Background: Inhibition of CDK4 is being studied in a variety of sarcomas, especially dedifferentiated liposarcoma (DDL) where prolonged progression free survival has been noted. Exposure to CDK4 inhibitors in Rb+ leiomyosarcoma (LMS) cell lines leads to decreased cell proliferation, and increased senescence, and G0/G1-phase arrest. When combined, ribociclib a CDK4 inhibitor and everolimus, an mTOR inhibitor show synergistic growth inhibition in multiple tumor models. **Methods:** Patients (pts) were enrolled to one of two cohorts: DDL or Rb+ LMS. LMS pts were required to have 1 prior line of therapy; DDL pts required no prior therapy. There were no limits to prior therapies in either group. Progression on prior therapy and measurable disease by RECIST 1.1 was also required. Ribociclib was given at 300 mg daily for 21/28 days and everolimus was given continuously at 2.5 mg daily in 28 day cycles. The primary endpoint was progression free rate at 16 weeks. A Simon two-stage design was utilized and if at least 8 out of 24 pts were progression free at 16 weeks, the treatment was declared promising for the cohort. Here in we present data on the LMS cohort. **Results:** Twenty-four LMS pts, 83% (n = 20) female, 58% (n = 14) uterine primary were treated. Median prior lines of therapy was 3.5 (range 1-9). Of 22 pts with complete data, 6 (27.2%) met the primary endpoint of non-progression at 16 weeks. Median PFS was 19.6 weeks (range 2.8-84), with progression as best response occurring in 13 pts. There were no objective responses. Five pts who had progressive disease on multiple lines of therapy experienced prolonged progression free survival (23-84 weeks). Grade 3-4, toxicities included neutropenia (29%), thrombocytopenia (12.5%) and leucopenia (12.5%) being most common. Tissue samples pre and on therapy as well as blood were collected in 21 and 18 pts respectively to evaluate pharmacodynamic changes. **Conclusions:** Final data on the primary endpoint for the LMS cohort is pending; it is notable that several heavily pre-treated LMS pts experienced prolonged progression free survival for $>$ 9 months. Updated results and biology correlatives will be presented. Clinical trial information: NCT03114527. Research Sponsor: Novartis, U.S. National Institutes of Health.

11545 Poster Session (Board #433), Fri, 8:00 AM-11:00 AM

Genomic landscape of angiosarcoma: A targeted and immunotherapy biomarker analysis of 143 patients. *First Author: Andrea P. Espejo Freire, University of Miami-Sylvester Comprehensive Cancer Center, Jackson Memorial Hospital, Miami, FL*

Background: Targeted therapies for angiosarcoma (AS) patients have limited efficacy. Although significant responses to immunotherapy (IO-therapy) have been observed in cutaneous AS, its efficacy across all types of AS is not known. Herein, we describe genetic and molecular biomarkers of AS in order to propose potential therapeutic options. **Methods:** We retrospectively reviewed 143 AS tumors profiled by Next-Generation Sequencing (NGS) 592-gene panel (Caris Life Sciences,Irving, TX, USA). Whole transcriptome sequencing (WTS) was performed on 53 tumors. Mutations and copy number amplifications (CNAs) were analyzed and grouped by pathway. Biomarkers potentially associated with response to IO-therapy (TMB-High [$\geq$10/Mb], MSI-High, and PD-L1 [IHC $\geq$ 2+ and 5%]) were also analyzed. AS subtypes based on primary tumor site were compared. P-values were corrected using a Benjamini & Hochberg method. **Results:** Sample median age was 67 (range 22-89), 61% were female, and 29% were classified as metastatic/recurrent. The most commonly mutated genes were TP53 (29%), ARID1A (17%), POT1 (16%), and ATRX (13%); MYC CNA was found in 23% of cases. IO-therapy markers were present in 36.4% of cases (TMB-High in 26%, PD-L1+ 21.8%, MSI-High 0.7%). Pathway alterations were detected in 86% of AS cases. By pathway, TP53 was altered in 31%, cell cycle 30%, DNA damage repair (DDR) 21%, RAS 18%, PI3K 15% and chromatin remodeling 14%. By site, head/neck (HN) AS had the highest rate of IO-therapy markers (65%, $p < 0.05$) [TMB-High (63%, $p < 0.0001$)], TP53 mutation (51%, $p = 0.07$), and POT1A mutation (41%, $p < 0.01$). MYC CNA was highest in breast (63%) and extremity (40%) AS ($p < 0.0001$). DDR alterations were present in 56% ($p = 0.09$) of cutaneous AS and ranged from 12-27% in other subtypes (not significant, NS). RAS and PI3K alterations ranged from 6-27% across all subtypes (NS). **Conclusions:** Our findings suggest differential angiosarcoma biology across primary sites. HN AS had more frequent markers of potential IO-therapy response, as well as DDR alterations. Next in frequency, we found ARID1A which is possibly associated with overactive EZH2, a target of tazemetostat. MYC amplification suggests a role targeting cell cycle via cyclin-dependent kinase or bromodomain inhibitors in breast and extremity ASs. Finally, RAS and PI3K are mutated in a low percentage of cases, explaining the limited benefit of tyrosine kinase inhibitors in AS. Future AS clinical trials should be designed with consideration of primary site, IO-therapy response biomarkers, and activated pathway. Research Sponsor: None.

11546 Poster Session (Board #434), Fri, 8:00 AM-11:00 AM

Immune-checkpoint genes as predictive biomarkers of trabectedin in advanced soft-tissue sarcoma (STS): A Spanish Group for Research on Sarcomas (GEIS) translational study. *First Author: David Silva Moura, Group of Advanced Therapies and Biomarkers in Sarcomas, Institute of Biomedicine of Seville, Ibis/Hospital Universitario Virgen Del Rocío/Csic/Universidad De Sevilla, Seville, Spain*

Background: Despite several second-line options are accessible for the treatment of advanced STS, there is a lack of predictive biomarkers available to support the rational selection of these drugs. Trabectedin specifically targets mononuclear cell lineage (macrophages and monocytes) that ultimately could inhibit tumor angiogenesis. Moreover, trabectedin seems to induce the expression of immune-checkpoint proteins (e.g. PD-L1); however, the predictive value of these factors remains unknown. We present the analyses of immune-checkpoint genes (*CD274*, *CD86*, *CTLA4*, *HAVCR2*, *LAG3* and *PDCD1*) and *CD163*, *CD4*, *CD68* and *CD8A* expression as potential predictive factors of response to trabectedin in a subset of STS patients of the GEIS registry. **Methods:** Selection criteria included patients with STS, pretreated with at least 2 lines in the advanced setting (one line being trabectedin), with paraffin block available and ethic committee's approval. Direct transcriptomics was performed using HTG Molecular Oncology Biomarker Pathway panel (HTG Molecular Diagnostics, Inc.; Tucson, AZ, USA), following manufacturers' instructions. Data analyses were performed taking into account the median Log2 of expression of each gene and by correlating it with progression-free survival (PFS) for trabectedin, and overall survival measured from the starting date of trabectedin treatment (OS). **Results:** Among 387 registered patients, fitting with the inclusions criteria, 139 cases were used for gene expression analyses, as the discovery set. Patients had median age of 52 years, 54% were females and had a median follow-up from diagnosis of 44 months. High expression of *CD274* (PD-L1) was significantly associated with better PFS of trabectedin (5.4 *vs.* 3.0 months; p= 0.006). Similar results were obtained with high expression of *CTLA4* and *LAG3*: 6.0 vs 3.1 months; $p = 0.005$ and 5.4 vs 2.7 months; $p = 0.042$, respectively. Expression of *CTLA4* and *LAG3* showed no significant impact in OS; whereas *CD274* high expression showed a trend towards better OS (17.9 vs 10.2 months; $p = 0.077$). Also, no significant correlation was achieved for *CD163*, *CD4*, *CD68*, *CD8A*, *CD86* and *HAVCR2*; *PDCD1* (PD-1) showed a trend towards better PFS of trabectedin, $p = 0.114$. **Conclusions:** The expression of selected immune-checkpoint genes exhibited a potential predictive value for trabectedin in advanced STS. Validation studies (at the transcriptional and protein level) are currently ongoing to confirm their potential predictive role. Research Sponsor: Spanish Group for Research on Sarcomas (GEIS).

11547 Poster Session (Board #435), Fri, 8:00 AM-11:00 AM

Cardiac safety of trabectedin monotherapy and in combination with pegylated liposomal doxorubicin in patients with sarcomas and ovarian cancer. *First Author: Robin Lewis Jones, Royal Marsden Hospital/Institute of Cancer Research, London, United Kingdom*

Background: Trabectedin (T) is an established option as monotherapy for advanced soft tissue sarcomas (STS; Leiomyosarcomas and Liposarcomas in the USA) and in combination with pegylated liposomal doxorubicin (PLD) for recurrent ovarian cancer (ROC). This retrospective analysis evaluated the cardiac safety profile in over 1500 patients (pts) from clinical trials administering T monotherapy for STS or in combination with PLD (T+PLD) for ROC. **Methods:** Integrated cardiac safety data was analyzed from ten Phase 2 trials and one Phase 3 trial in STS (T) and two Phase 3 ROC trials (T+PLD). Cardiac-related treatment-emergent adverse events (TEAEs) were summarized using MedDRA terminology and by Kaplan-Meier analysis for time-to-event variables. Subgroup analyses were performed for cardiac-related TEAEs, including any significant decrease in LVEF. **Results:** Integrated data on T monotherapy included 982 pts (Table). Of these, 110 (11.2%) pts who received $\geq$1 dose of T experienced a cardiac-related TEAE, including tachycardia (3.1%), palpitations (1.5%), LVEF decrease (1.3%), sinus tachycardia (1.0%), and/or congestive cardiac failure (1.0%). A multivariate analysis revealed factors associated with increased risk to be cardiovascular medical history (risk ratio [RR]: 1.90; 95% CI: 1.24-2.91; p = 0.003) and age $>$ 65 years (RR: 1.78; 95% CI: 1.12,2.83; $p = 0.014$). Cardiac-related TEAEs were reported in 78 (12.6%) of 619 pts receiving T+PLD (Table). Incidence of cardiac-related TEAEs was greater with T+PLD compared with PLD monotherapy (12.6% vs 5.6%). A multivariate analysis showed that pts were at increased risk for experiencing cardiac-related TEAEs when treated with T+PLD compared to PLD monotherapy (RR: 2.70; 95% CI: 1.75,4.17; $p < 0.0001$) and when there was a history of prior cardiac medication (RR: 1.88; 95% CI: 1.16,3.05; $p = 0.010$). **Conclusions:** Although infrequent, patients receiving T after prior anthracyclines or in combination with PLD are at risk for cardiac dysfunction, and appropriate clinical awareness and monitoring is encouraged to optimize patient outcomes. Research Sponsor: Janssen.

A phase Ib study of ribociclib in combination with doxorubicin in advanced soft tissue sarcomas (aSTS). *First Author: Lara E. Davis, Oregon Health and Science University, Portland, OR*

Background: aSTS are typically treated with single agent doxorubicin (dox). CDK4 inhibitors such as ribociclib (ribo) may have a role in treating STS, which frequently rely on hyperphosphorylation of Rb to evade the Rb checkpoint. We hypothesized that dox efficacy could be increased by inhibiting Rb phosphorylation with a short course of ribo, then removing ribo to permit cell cycle progression prior to dox, thus potentiating the DNA-damaging effects of dox. **Methods:** Open label, dose-finding study of ribo and dox in dox-naïve patients (pts) with Rb+ aSTS. Rb status determined by IHC. Primary objective to determine the recommended phase 2 dose (RP2D). Secondary objective of antitumor activity. Pts received ribo 400-600 mg PO QD x7d followed by 72h rest before dox 60-75 mg/m2 IV, q21d. Pts free from progression of disease after 6 cycles continued on ribo maintenance at 600 mg QD q3/4wk. Dose-limiting toxicity (DLT) period was cycle 1, with target toxicity rate of 30% using a modified toxicity probability interval (mTPI) design. Growth factor support was not allowed during DLT period. **Results:** 9 screened pts were ineligible by Rb status. 16 pts enrolled with 15 evaluable for dose determination (7 dedifferentiated LPS, 8 other subtypes). 4 of 7 pts treated at starting dose level (400 mg ribo, 75 mg/m2 dox) had a DLT; all febrile neutropenia. 1 of 8 pts treated at dose level -1 (400 mg ribo, 60 mg/m2 dox) had a DLT of gr4 anemia. Febrile neutropenia events occurred during cycle 1, when growth factors were prohibited. Toxicity was similar to historical dox AEs (Table). Two partial responses for overall response rate (ORR) of 13%. Five (33%) were progression-free at 18 wks. Correlative studies ongoing. **Conclusions:** This study determined a RP2D of ribo 400 mg with dox 60 mg/m2 when used in combination for the treatment of aSTS. Clinical trial information: NCT03009201. Research Sponsor: Novartis.

Number (%) of pts with grade 3-4 AEs attributed to treatment.

AE	All grades	Gr ≥3
Anemia	9 (56%)	1 (6%)
Febrile neutropenia	4 (25%)	4 (25%)
Lymphocyte count decreased	10 (63%)	4 (25%)
Mucositis oral	5 (31%)	1 (6%)
Neutrophil count decreased	10 (63%)	8 (50%)
Platelet count decreased	6 (38%)	1 (6%)
White blood cell decreased	12 (75%)	8 (50%)

11549 Poster Session (Board #437), Fri, 8:00 AM-11:00 AM

Comparison of different systemic therapeutic regimes in resectable high-risk soft tissue sarcoma: Results of a network meta-analysis. *First Author: Jan Haussmann, Heinrich Heine University, Düsseldorf, Germany*

Background: The treatment of high-risk soft tissue sarcoma of the trunk or the extremities consists of surgical resection with risk-adapted radiation therapy. Further treatment options which can significantly improve local and systemic tumor control including chemotherapy are not well established. Due to the heterogeneity of disease different systemic approaches as well as their application during different time points have been attempted. **Methods:** We conducted a literature search for randomized clinical trials in the treatment of localized, resectable high-risk soft tissue sarcoma comparing different treatment modalities according to the PRISMA guidelines. We extracted published hazard ratios and number of events for the endpoints of overall and disease-free survival (OS; DFS) as well as local and distant recurrence-free interval (LRFI; DRFI). The different modalities were compared in a network meta-analysis against the defined standard treatment surgery ± radiotherapy using the inverse-variance heterogeneity model (ivhet) with the help of the Microsoft Excel add-in Meta-XL V5.3. **Results:** The literature search identified 25 studies including 3489 patients. The network analysis showed that adjuvant chemotherapy (adjCTx) results in a significant improvement in overall survival (HR = 0.86; CI-95%: 0.75-0.97; p = 0.017) compared to the standard treatment of surgery ± radiatherapy alone. Combined treatment with regional hyperthermia and neoadjuvant chemotherapy (HTx+nadjCTx) also improves OS (HR = 0.45; CI-95%: 0.20-1.00; p = 0.049). Preoperative chemotherapy alone (nadjCTx) as well as perioperative chemotherapy (periopCTx) resulted both in non-statistically significant improvements in OS (HR = 0.61; CI-95%: 0.29-1.29; p = 0.195) and (HR = 0.48; CI-95%: 0.15-1.55; p = 0.218). Histology-tailored neoadjuvant chemotherapy (tNaCTx) also showed no effect on overall survival (HR = 1.08; CI-95%: 0.45-2.61; p = 0.868). The analysis of DFS, LRFI and DRFI disclosed a similar pattern between the different treatment regimens. **Conclusions:** The addition of cytotoxic chemotherapy in resectable high-risk soft tissue sarcomas provides a measurable benefit in overall survival. Shifting of systemic therapy to the neoadjuvant setting and combination with regional hyperthermia might be favored. Predictive clinical and molecular markers are needed to evaluate and limit potentional risks prospectively going forward. Research Sponsor: None.

11550 Poster Session (Board #438), Fri, 8:00 AM-11:00 AM

Phase Ib study of decitabine in combination with gemcitabine in treatment of advanced soft tissue and bone sarcomas. *First Author: Varun Monga, Holden Comprehensive Cancer Center, University of Iowa, Iowa City, IA*

Background: Sarcomas are a heterogeneous group of tumors and are associated with high rates of metastases leading to poor prognosis. Numerous epigenetic changes including hypermethylation have been identified in several sarcoma subtypes. Restoration of normal methylation patterns using DNA hypomethylating agent when combined with chemotherapy has shown to slow tumor growth in preclinical studies. Low continuous dosing of hypomethylating agent has epigenetic modulating effect with less toxicity. We conducted a Phase 1b study evaluating safety & tolerability and identifying the recommended phase 2 dose (RP2D) of subcutaneous (SQ) decitabine (DEC) given with fixed dose infusion gemcitabine (GEM) in patients with advanced soft tissue sarcomas (STS) and bone sarcomas. **Methods:** Eligible patients at least age 18 yrs with metastatic histologically confirmed STS or bone sarcoma after progression on one line or if refused adriamycin for STS were included. Prior GEM use was permitted. A modified 3+3 dose escalation design was used exploring two dose cohorts of DEC, 0.1 and 0.2 mg/kg SQ administered on a twice weekly schedule for three weeks and GEM given as 900 mg/m^2, IV over 90 min on days 1, 8 & 15 of a 28-day cycle. Treatment was continued until disease progression or unacceptable toxicity. Dose limiting toxicity (DLT) was defined as any drug related non-hematological grade 3 or 4 toxicity per CTCAE v4.0. Disease assessment was performed every 8 weeks using RECIST v1.1. **Results:** 31 patients (25 STS & 6 bone sarcomas) were enrolled of which 7 were non-evaluable. There were 12 evaluable patients in each dosing cohort. Of the total 744 adverse events (AE) 17.2% were grade 3/4 and most were neutropenia without neutropenic fever. 45.7% AEs were possibly (44.6%) or probably (1.1%) attributed to DEC use. The toxicities were not significantly different between DEC doses. No DLTs were observed. One patient died due to progressive disease. **Conclusions:** Combination of fixed dose infusion GEM with low dose subcutaneous DEC is moderately toxic. Most toxicities were hematological. While there were few responses, the RP2D of DEC selected was 0.1 mg/kg as it showed prolonged disease stabilization. Clinical trial information: NCT02959164. Research Sponsor: Holden Comprehensive Cancer Center.

	Decitabine	
Best response	**0.1 mg/kg N = 12**	**0.2 mg/kg N = 12**
Partial Response	2 (16.7%)	2 (16.7%)
Stable Disease	7 (58.3%)	3 (25%)
Progressive Disease	3 (25%)	7 (58.3%)

Partial responses were noted in leiomyosarcoma, chondrosarcoma, adenosarcoma and carcinosarcoma. A clinical benefit rate of 58% was noted. Eleven patients had previously received and progressed on GEM based therapy.

11552 Poster Session (Board #440), Fri, 8:00 AM-11:00 AM

A phase I trial of pomalidomide in combination with liposomal doxorubicin in patients with Kaposi sarcoma with or without other KSHV-associated diseases. *First Author: Ramya Ramaswami, HIV/AIDS Malignancy Branch, CCR, NCI, Bethesda, MD*

Background: Kaposi sarcoma herpesvirus (KSHV, also known as human herpesvirus 8 [HHV-8]), is the causative agent of Kaposi sarcoma (KS), a multicentric angioproliferative tumor, a form of multicentric Castleman disease (KSHV-MCD), and KSHV inflammatory cytokine syndrome (KICS). KS can be difficult to treat when it occurs with KSHV-MCD or KICS; resulting in high mortality rates. Liposomal doxorubicin (LD) is an FDA-approved treatment for KS. Pomalidomide, an oral immunomodulatory drug, is safe and has demonstrated activity in KS, but the activity of the combination (pomalidomide+LD) in KS alone or with KSHV-associated diseases is unknown. **Methods:** The primary objective was to evaluate safety and tolerability of pomalidomide+LD in two groups of patients with KS requiring systemic therapy: Group I (GI)- KS alone; Group II (GII)- KS with concurrent KSHV-MCD or KICS. Patients received LD at 20 mg/m^2 intravenously on day 1 of a 28-day cycle combined with pomalidomide once daily on days 1 to 21 at escalating dose levels (DL) (I - 2mg, II - 3mg, or III- 4mg) in a 3+3 design until plateau of response or other pre-specified criteria. Patients received 81mg of aspirin daily as thromboprophylaxis. KS responses were evaluated using the modified AIDS Clinical Trial Group criteria. **Results:** Thirty-four cisgender men, all with T1-stage KS [21 patients (62%) in GI and 13 patients (38%) in GII] were treated; 32 (94%) were HIV-infected and 22 (65%) had prior chemotherapy for KS (15/21 GI and 7/13 GII). There were no dose-limiting toxicities (DLTs) at DLIII for GI, and additional patients were treated at DLIII. In GII, grade 3 rash and pharyngeal edema were DLTs observed at 3mg of pomalidomide. Overall a median of 6 cycles were administered; the most common grade 3/4 toxicity was neutropenia. Among evaluable patients receiving >2 cycles,17/21 patients in GI had a response (all partial) (81% [95% confidence interval (CI) 58-95%]) and 5/10 patients in GII had a response (4 partial and 1 complete) (50% [95% CI 19-81%]). **Conclusions:** Pomalidomide+LD was well-tolerated and active in heavily pretreated patients with KS alone. In patients with KS and other KSHV-associated diseases, activity was noted but less well-tolerated. Clinical trial information: NCT02659930. Research Sponsor: U.S. National Institutes of Health, CRADA with Celgene.

11553 Poster Session (Board #441), Fri, 8:00 AM-11:00 AM

Apatinib for patients (pts) with advanced soft tissue sarcoma (STS) after chemotherapy: A prospective, open-label, single-arm, multicentered study. *First Author: Haiyan Hu, Affiliated Sixth People's Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: The development of STS therapeutics has been challenging, especially patients who failed chemotherapy. Anti-angiogenesis inhibitors had shown activity in STS, Apatinib is a TKI targeting on VEGFR-2 which has shown activity in many solid tumors. **Methods:** A Phase II, open-label, Single-arm, multicentered study was conducted in previously treated pts with advanced STS in China. The patients received apatinib 500mg orally qd in a 28-day-cycle, until disease progression or unacceptable adverse events. Antitumor response assessment was performed every 8 weeks per RECIST V1.1. The primary endpoint was PFS rate in 6 months and secondary endpoint was ORR and OS. **Results:** As cut-off on Jan 20th 2019, a total of 53 patients were enrolled in 9 centers, 51 patients received at least 2 cycles of Apatinib, 1 patient is still in treatment. The main histological subtypes were alveolar soft part sarcoma(n = 11), synovial sarcoma(n = 6), leiomyosarcoma (n = 6), clear cell sarcoma(n = 6) and undifferentiated pleomorphic sarcoma(n = 5). Overall, 27 of 51 patients were progression free at six months and the 6-m PFS rate was 53.32% (95%CI 37.76%, 66.63%). Until final follow-up, the ORR was 18.75% (9/48) and DCR was 87.5% (42/48). Additionally, median PFS was 7.13 (95%CI 3.84, 9.23) months and median OS has reached up to 24.67 (9.30-NE) months. Adverse events (AEs) were detected among all pts, hypertension and proteinuria are the most common AEs, occurred in 84.91% and 73.57% pts respectively. Grade 3/4 related adverse events were detected in 86.79% of pts, Grade 3/4 hypertension was the most common grade3/4 AE (56.60%). **Conclusions:** Overall, the present study demonstrates that apatinib has a clinically meaningful anti-tumor activity in pretreated STS pts, showing durable responses and prolonged overall survival. Some of the pts had a long-time benefit from the treatment. Apatinib was safe and generally well tolerated. Further studies on specific STS subtypes would be meaningful. Clinical trial information: NCT03064243. Research Sponsor: Jiangsu Hengrui Pharmaceutical CO.,LTD.

11554 Poster Session (Board #442), Fri, 8:00 AM-11:00 AM

Which patients with pre-treated locally advanced or metastatic sarcoma benefit most from trabectedin treatment: First results of a retrospective study of the German Interdisciplinary Sarcoma Group (GISG-14 - ReTraSarc). *First Author: Daniel Pink, Helios Klinikum Bad Saarow-Sarcoma Center Berlin-Brandenburg and University Medicine Greifswald, Germany, Bad Saarow, Germany*

Background: Despite the growing amount of published data regarding the outcomes of sarcoma patients treated with trabectedin, still some questions remain unanswered. The aim of the ReTraSarc trial (NCT03284320) was to evaluate the efficacy and safety of trabectedin in a large German population. **Methods:** Patients treated between 2007-2018 were retrospectively analyzed. All patients had histologically confirmed soft tissue (STS; n = 478) or bone (BS; n = 31) sarcoma; either metastatic (n = 468) or locally advanced (n = 41) disease, and had received at least one cycle of trabectedin. Based on follow-up data (until October 2019), progression-free survival (PFS) and overall survival (OS) after initiation of trabectedin treatment were estimated according to the Kaplan-Meier method. **Results:** A total of 509 patents were analyzed. Patients had a mean age of 54 years for STS and 30 years for BS-patients, and 25.4% of them aged > 65 years. Overall, 71.4% of patients had a good performance status (ECOG 0/1), and 37.7% received two prior lines, 28.3% three and 34% received > 3 prior lines of systemic treatment. Patients received a median of 3 cycles (IQR: 2-6 cycles) of trabectedin. Trabectedin resulted in an objective response rate (ORR) of 10% with a 37.4% of disease control rate (DCR). The median PFS and OS were 2.5 months (IQR: 1.4-6.1 months) and 8.2 months (IQR: 3-21 months), respectively. Significantly more patients with liposarcoma (22.1%; 95% CI: 15.2-32.2) were free from progression at 12 months after treatment as compared with patients with leiomyosarcoma (8.5%; 95% CI: 4.8-14.9). More analyses of effectiveness and safety are in progress (e.g. stratified per sarcoma subtypes or therapeutic line) and will be presented. **Conclusions:** The results of this real-life study, with a large number of patients and long-term follow-up, allow us to better analyze PFS and OS in sarcoma patients treated with trabectedin, given in different treatment lines and after dose modifications and/or cycle delays. Additionally, the results of this study enable us to evaluate the real-life impact of rechallenge with trabectedin in a further therapy line. Clinical trial information: NCT03284320. Research Sponsor: PharmaMar.

11555 Poster Session (Board #443), Fri, 8:00 AM-11:00 AM

Efficacy and safety of hypofractionated preoperative radiotherapy in treatment of patient with primary locally advanced soft tissue sarcoma of limbs/trunk wall. *First Author: Hanna Kosela, Department of Soft Tissue/Bone Sarcoma and Melanoma; Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland*

Background: Soft tissue sarcomas (STS) are rare often malignant tumors. The primary treatment of most STS is radical resection with adjuvant radiotherapy. Our previous study showed that the use of preoperative hypofractionated radiotherapy is safe and efficient in the treatment of unselected group of patients with STS. Aim of this study was to assess the use of the treatment scheme in patients with primary STS treated in one institution. **Methods:** 311 patients (52% female) with primary locally advanced STS participated in this prospective trial conducted from 2010 till 2017. Median age was 55 years (range: 17-91). Median follow up is 57 months (95%CI 55-61). The most common subtypes were pleomorphic sarcoma, liposarcoma and synovial sarcoma. Median tumor size was 11cm. 258 patients (83%) had high grade tumors. The most common tumor localization were lower limbs (72%). 30% of patients received preoperative chemotherapy. For five consecutive days radiotherapy in 5 x 5Gy fraction was applied, with immediate (2-4 days) resection of the tumor. **Results:** In 260 patients (83.6%) clear surgical margins (R0) were obtained. 107 patients were dead at the time of the analysis.5-year overall survival is 63%. 156 (50%) had a recurrence of the disease. Local recurrence (LR) was found in 13.8% of the patients. Median time from surgery to LR was 14.7 months. In 56% of patients with LR another limb spearing radical surgery could be performed. Factors that had a significant adverse impact on LR were histological subtype (p = 0.017) and surgical margin status (p = 0.013). Factors that had a significant adverse impact on overall survival were tumor size (p < 0.0001), grade (p = 0.0047) and surgical margin status (p = 0.013). 96 patients (30.8%) had any kind of treatment toxicity, factor having negative impact on the toxicity was lower limb location of the tumor (p = 0.0012). 20 patients (6.4%) required surgery for treatment of the complications. 14.6% patients had prolonged healing of the wound (> 1 month), 8.3% had wound dehiscence, 1.4% required prolonged punctures of the lymph fluid, 2.3% had severe fibrosis leading to contracture of limb, 11% patients prolonged edema of the operated limb. 0.9% of patients had a fracture of the treated limb. **Conclusions:** In this group, with a big percentage of patients with large, high grade STS use of hypofractionated preoperative radiotherapy was associated with similar local control when compared to published studies. The early toxicity is tolerable, with a small amount of late complications. Research Sponsor: None.

11556 Poster Session (Board #444), Fri, 8:00 AM-11:00 AM

Activity of cabazitaxel in patients with metastatic or inoperable locally advanced dedifferentiated liposarcoma: European Organization for Research and Treatment of Cancer (EORTC) Phase II trial 1202. *First Author: Roberta Sanfilippo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The optimal treatment for patients with advanced dedifferentiated (DD) liposarcoma (LPS) remains uncertain. Single agents which are most effective include doxorubicin and ifosfamide but, as with soft tissue sarcomas (STS) in general, objective response rates (ORR) and progression free survival (PFS) are very modest. Cabazitaxel exerts its effect through inhibition of microtubular disassembly and has been shown to be relatively safe, effective and well-tolerated. EORTC 1202 assessed whether cabazitaxel demonstrated sufficient antitumor activity in patients with metastatic or inoperable locally advanced DD LPS to justify further investigation in a phase III setting. **Methods:** This was an international multi-center, open label single arm phase II trial. Eligible patients with metastatic or inoperable locally advanced DD LPS were treated with cabazitaxel 25mg/m^2 IV infusion over 1 hour every 21 days. Primary endpoint was PFS rate at 12 weeks assessed by local investigator per RECIST 1.1. Based on a Simon two-stage design, at least 4 out of 17 (Stage 1) and 11 out of 37 (Stage 2) eligible and evaluable patients who are progression-free at 12 weeks were needed. **Results:** Forty patients were registered by 10 institutions in 4 countries between March 2015 and March 2019, with 2 patients being ineligible. Among the 38 eligible patients who started treatment, 3 (7.5 %) were still on treatment at the time of analysis. The number of cycles ranged from 1 to 30, with a median of 5; 26 patients (65%) received at least 4 cycles of cabazitaxel. Among the first 17 (Stage 1) and 37 (Stage 2), 11 and 20 patients were progression-free at 12 weeks respectively, satisfying the study decision rules. The PFS rate at 12 weeks for all 38 eligible patients was 52.6% (conditional 1-sided 95 % CI 38.3 – 100). Two patients (5.3%) achieved a confirmed partial response (PR) and 23 stable disease (SD) (60.5%). Disease control (PR+SD) was achieved in 25 patients (65.8%). Median PFS was 7.4 months (95%CI 2.8-10.3). The most common cabazitaxel -related grade >3 adverse events in all 40 registered patients were neutropenia (60%), febrile neutropenia (25%), fatigue (12.5%), and anemia (10%). There were no cabazitaxel-related deaths. **Conclusions:** EORTC 1202 met its primary endpoint, with 20/37 pts (54%) being progression-free at 12 weeks. Results of this trial confirm activity of cabazitaxel in patients with metastatic or inoperable locally advanced DD LPS and warrant further exploration of the drug. Clinical trial information: NCT01913652. Research Sponsor: Sanofi Aventis, Other Foundation.

11557 Poster Session (Board #445), Fri, 8:00 AM-11:00 AM

A phase I study of TGF-β inhibitor, vactosertib in combination with imatinib in patients with advanced desmoid tumor (aggressive fibromatosis). *First Author: Hyo Song Kim, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Desmoid tumor (aggressive fibromatosis) is fibroproliferative neoplasm arising from deep connective tissues. TCGA pan-cancer analysis revealed high expression TGF-β responsive signature in desmoid tumor. This phase I study assessed the safety, tolerability, and pharmacokinetics of the TGF-β inhibitor, vactosertib in combination with imatinib for desmoid tumor. **Methods:** Patients with advanced desmoid tumors not treatable by surgery or radiotherapy were eligible. The primary objective is to assess the safety and recommended phase 2 dose (RP2D) of vactosertib given 5 days on and 2 days off in combination with imatinib (400 mg QD). Two dose levels of vactosertib were tested; cohort -1 (100 mg BID) and cohort 1(200 mg BID). Secondary objectives include pharmacokinetics, anti-tumor activity by response rate (RECIST v1.1), and biomarker analysis. **Results:** Seven patients (cohort -1, n = 4; cohort 1, n = 3) were enrolled and finished the safety evaluation. The most frequently reported treatment related adverse events were myalgia (57.1%), fatigue (42.8%), diarrhea (42.8%), anemia (28.5%) and stomatitis (28.5%) with mostly grade 1. No dose limiting toxicity was observed. Tumor response included 2 (28.5%) partial response (PR) and 2 stable disease (SD) in the cohort -1, and 3 SD in the cohort 1. The time to response were 5.5 and 8.2 months and all 7 cases are ongoing. Updated safety, pharmacokinetics, efficacy and biomarker data will be presented at the meeting. **Conclusions:** The combination of vactosertib plus imatinib was well tolerated and showed promising activity in desmoid tumor. RP2D of vactosertib was defined as 200 mg BID. Further efficacy will be explored in the phase 2 part of the study. Clinical trial information: NCT03802084. Research Sponsor: None.

11558 Poster Session (Board #446), Fri, 8:00 AM-11:00 AM

Prognostic role of % changes in longest tumor diameter (LTD) in localized high-risk soft tissue sarcoma (STS) treated with neoadjuvant chemotherapy in a randomized clinical trial. *First Author: Silvia Stacchiotti, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: We investigated the prognostic relevance of % change in LTD in patients (pts) with localized high-risk STS treated with neoadjuvant chemotherapy in a phase 3 randomized trial (NCT01710176), aimed at comparing 3 cycles of a neoadjuvant histology-tailored (HT) over 3 cycles of standard anthracycline + ifosfamide chemotherapy (S). **Methods:** Pts with localized high-risk STS of extremities or trunk wall, and a diagnosis of myxoid liposarcoma, leiomyosarcoma, synovial sarcoma, malignant peripheral nerve sheath tumors, undifferentiated pleomorphic sarcoma were randomly assigned to receive 3 cycles of S or HT. Pts affected by myxofibrosarcoma, pleomorphic liposarcoma, pleomorphic rhabomyosarcoma unclassified spindle cell sarcoma were prospectively registered and treated by S. Change of LTD was assessed comparing baseline dimension with that measured after 3 cycles of S or HT, before surgery. Only pts treated with neodjuvant chemotherapy alone were selected for the analysis. We first investigated Overall Survival (OS) from surgery of the groups identified by "any % reduction", "no-change" or "increase" in LTD by Kaplan-Meier estimates and log-rank tests. Then we searched for cutoffs able to separate prognosis among pts with a LTD reduction applying the change-point method proposed by Contal - O'Quigley. **Results:** Of 325 pts who entered the study and evaluable for response, 181 received neoadjuvant chemotherapy alone (92 S and 89 HT group respectively) and were analyzed, while 144 received concurrent chemo-radiotherapy and were excluded. In the whole population, % changes in LTD were significantly associated (log rank p = 0.032) to OS. "Any % reduction in LTD (101/181pts) displayed a better prognosis compared to "no-change" (28/181 pts) or "any % increase" (52/181). The change-point analysis was applied to all, S and HT groups separately; a cutoff of = / > 18.75% decrease in LTD was the optimal predictor of outcome for the S group (p = 0.031), while no size cut-off could be identified for the HT group. **Conclusions:** In our study, % change in LTD of pts treated with neoadjuvant chemotherapy for localized high-risk STS correlated with OS. However, a % decrease in LTD cut-off able to predict the best outcome could be identified only for pts treated in the S group, while no differences in outcome were found by any % LTD change in the HT group. Interestingly, the LTD cut-off identified in the S group was lower than the one selected to define a response by RECIST (= / > 18.75% decrease in LTD vs = / > 30%). Clinical trial information: NCT01710176. Research Sponsor: None.

11559 Poster Session (Board #447), Fri, 8:00 AM-11:00 AM

Phase II study of eribulin and pembrolizumab in patients (pts) with metastatic soft tissue sarcomas (STS): Report of LMS cohort. *First Author: Michael Nathenson, Department of Medical Oncology; Dana-Farber Cancer Institute, Boston, MA*

Background: Responses to single agent PD-1/PD-L1 inhibitors in STS remain limited with occasional responses in undifferentiated pleomorphic sarcomas (UPS), liposarcomas (LPS), and other sarcomas, and rare responses in leiomyosarcoma (LMS). Since cytotoxics and/or targeted therapies such as CDK4/6 inhibitors may alter the tumor microenvironment (TME) and potentiate the effect of immunotherapy, combination approaches may be needed to potentiate STS immunotherapy. The mechanism by which eribulin controls LPS may involve TME modification, and therefore it is attractive to test in combination with pembrolizumab in STS subtypes. This report summarizes the results from the LMS cohort from this ongoing trial. **Methods:** Pts treated with at least one prior therapy received eribulin 1.4mg/m2 (day 1, 8) and pembrolizumab 200mg (day 1), every 21 days. Pts continued therapy until progressive disease, death, or unacceptable toxicity. Primary endpoint was progression-free survival (PFS) at 12 weeks, with 60% PFS at 12 weeks required to deem the combination promising. Tumor assessments (RECIST 1.1) were performed at screening and every 6 weeks thereafter. Secondary endpoints included overall survival (OS), objective response rate (ORR), and clinical benefit rate (CBR). **Results:** Nineteen pts with LMS were enrolled from May 2019 to Sept 2019. The median age was 62 (range 48-80). Eleven (58%) patients had uterine LMS. The median # of prior therapies was 4 (range 1-7). The median follow-up was 19.7 weeks. The PFS at 12 weeks was 42.1% (90% CI: 27.0%-65.5%), with median PFS of 11.1 weeks. Median OS was not reached during the follow-up period. There was 1 partial response, and 5 confirmed stable disease for ORR of 5.3% and CBR of 26.3%, after 12 weeks. The rate of grade 3 or higher toxicity was 68% overall, most commonly neutropenia, anemia, weight loss, diarrhea, elevations of lipase, and alkaline phosphatase. These side effects were reversible. The most common adverse events were fatigue, neutropenia, anorexia, AST increase, and nausea. **Conclusions:** Eribulin and pembrolizumab in LMS did not meet the predefined endpoint for efficacy. The LPS and "other STS subtype" cohorts of this trial are actively enrolling. Clinical trial information: NCT03899805. Research Sponsor: Eisai, Pharmaceutical/Biotech Company.

11560 Poster Session (Board #448), Fri, 8:00 AM-11:00 AM

Nationwide incidence of sarcomas and tumors of intermediate malignancy in the NETSARC network with central pathology review: Correlation with published clinical research. *First Author: Gonzague De Pinieux, Hopital Trousseau, Tours, France*

Background: Since 2010, presentation to a designated sarcoma tumor board and pathological review by an expert network are mandatory for sarcoma patients in France. NETSARC+ (merging the 3 initial RREPS, RESOS & NETSARC) collected prospectively all cases of reviewed sarcomas and tumors of intermediate malignancy (TIM) nationwide. We report on the incidence of subtypes according to WHO classification from 2013 to 2016. **Methods:** Sarcoma expert pathologists reviewed samples were all prospectively integrated in the database; the results using the latest WHO classification are presented for the years 2013 to 2016, including yearly variations. Correlation of the incidence of each histotype with dedicated published clinical trials was conducted. **Results:** 139 different histological subtypes are reported among the 25172 patients with sarcomas (n = 18710, 64%) or TIM (n = 6460, 36%), respectively n = 5838, n = 6153, n = 6654, and n = 6527 yearly from 2013 to 2016. Over these 4 years, the observed yearly incidence of sarcomas, TIM, and all was therefore 79.7, 24.9 and 95.1/10e6/year, above that previously reported. GIST, liposarcoma, leiomyosarcomas, undifferentiated sarcomas represented 13%, 13%, 11% and 11% of all sarcomas. Only GIST, as a single entity exceeded a yearly incidence above 10/million per year. There were respectively 30, 63 and 66 different histological subtypes of sarcomas or TIM (single entities or lumped together, e.g. MPNST, or vascular sarcomas...) with an incidence ranging from 10 to 1/10e6/year, 1-0.1/10e6 per year, or < 0.1/10e6/year respectively. The 2 later "incidence groups" included 21% of the patients. The incidence of 8 histotypes varied significantly over this 4 years. Patients with tumors with an incidence above 1/10e6 per year have significantly higher numbers of dedicated published phase III and phase II clinical trials (p < 10e-6). **Conclusions:** This nationwide registry of sarcoma patients with an histology reviewed by sarcoma experts shows that the incidence of sarcoma and TIM is higher than previously reported, may vary over years for some histotypes, and that tumors with an incidence < 10e6 have a much lower access to clinical trials. Research Sponsor: Institut National du Cancer.

11561 Poster Session (Board #449), Fri, 8:00 AM-11:00 AM

Multicenter, open-label phase II study of daily oral regorafenib for chemotherapy-refractory, metastatic and locally advanced angiosarcoma. *First Author: Mark Agulnik, Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: Angiosarcoma has a particularly poor prognosis with 5-year overall survival rates of approximately 30-40%. Treatment of locally advanced and metastatic angiosarcoma is inadequate. Data strongly suggest concurrent, potent inhibition of VEGFR and Tie2 represents an attractive therapeutic strategy in angiosarcoma. Regorafenib displays potent VEGFR and Tie2 receptor inhibition and also possesses activity against additional potential targets in angiosarcoma including PDGFRs, RAF, KIT and FGFR, amongst others. **Methods:** A multicenter phase II study of regorafenib in patients with locally advanced or metastatic angiosarcoma was conducted through the Midwest Sarcoma Trials Partnership. Adequate performance status, organ function, measurable disease (RECIST 1.1) and 1-4 prior therapies were required. Regorafenib 160 mg PO daily was given in 28-day cycles (21 days on, 7 days off) until disease progression (PD) or unacceptable toxicity. The primary endpoint was progression-free survival (PFS), assessed at 16 weeks. Secondary endpoints include overall response rate (ORR), clinical benefit rate (CBR), OS, and safety and tolerability. A Simon 2-stage design was used. **Results:** After final enrollment of the second stage, a total of 31 pts were enrolled at 6 sites, 23 are evaluable for response. Median age was 65 (range 30-91); 50% were female, 67.7% had metastatic disease. PFS at 4 months is 52.2% with a median PFS and OS of 3.55 and 11.4 months. 1 confirmed CR and 2 PR, 12 SD and 8 PD were observed. ORR and CBR are 14.29 and 65.2%, respectively. No uncommon grade 3-4 adverse events were observed. 6 pts were non-evaluable due to refusal of further therapy and 2 patients progressed prior to first evaluation. **Conclusions:** Regorafenib was well tolerated in this study of pretreated patients with angiosarcomas and met its primary endpoint with a median PFS $>$ 45% at 4 months. Treatment was feasible and did not reveal any previously unreported toxicities. Efficacy outcomes were complicated by early withdrawals of patients. RECIST responses were encouraging and regorafenib has a clinically meaningful 4-month PFS. Clinical trial information: NCT02048722. Research Sponsor: Bayer.

11562 Poster Session (Board #450), Fri, 8:00 AM-11:00 AM

A randomized phase II study of MLN0128 (M) versus pazopanib (P) in patients (pt) with advanced sarcoma (Alliance A091304). *First Author: Matthew Ingham, Columbia University Irving Medical Center, New York, NY*

Background: Soft tissue sarcoma (STS) is a heterogeneous malignancy of connective tissue. Although mTOR is implicated in STS pathogenesis, clinical activity from mTORC1 inhibitors is modest. M, a potent selective mTORC1/mTORC2 inhibitor, was more effective in STS preclinical models than inhibitors of mTORC1, IGF1R and mTORC1+IGF1R, owing to more complete suppression of PI3K/AKT/mTOR and abrogation of feedback AKT activation. P, an oral multikinase inhibitor, is approved for non-adipocytic STS and often used after progression (PD) on chemotherapy. In phase 1, the RP2D of M was 30 mg weekly. A091304 was to evaluate M as a novel targeted therapy for STS. **Methods:** In A091304, pts were randomized 1:1 to M 30 mg weekly or P 800 mg daily. Eligibility required Eastern Cooperative Oncology Group PS $\leq$ 1, progression on $\geq$ 1 prior chemotherapy and specific STS subtypes (cohort 1: UPS; 2: LMS; 3: MPNST, SS). Crossover to M was allowed after PD on P. 1° endpoint was progression-free survival (PFS). Assuming median PFS of P was 4.6 months (mo), 98 pts yielded 80% power to detect a hazard ratio of 0.66 favoring M [1-sided test, alpha = 0.15] and including 1 planned futility analysis. 2° endpoints were response rate, clinical benefit rate (CBR) at 4 mo and safety. After 4 of the first 12 pts randomized to P experienced $\geq$ grade (gr) 3 toxicity, the study was amended to begin at P 400 mg, allowing titration to 800 per investigator discretion. **Results:** After protocol amendment, 114 pt underwent randomization (M: 56, P: 58), and 111 initiated treatment. Median PFS was 2 mo for M and 2.1 mo for P (HR = 1.47; 1-sided 85% upper confidence boundary = 1.85), with 2 partial responses in each arm. CBR was 5.4% for M and 13.8% for P. Median OS was 10.7 mo for M and 13.9 mo for P (HR = 1.41; 95% CI 0.80-2.49). 26/43 pt with PD on P crossed over to M. Median PFS after crossover was 1.8 mo (95% CI 1.5-3.5). Gr 3 drug-related adverse events (AEs) occurred in 36% on M and 41% on P; gr 4 toxicity was rare. AEs were consistent with known effects of M and P. **Conclusions:** P at 400 mg daily (allowing escalation to 800 mg per investigator discretion) demonstrated a shorter PFS as compared prior randomized studies with P. Despite this, M failed to demonstrate superior clinical activity as compared to P at the interim analysis. Further work will examine activity within histology-specific cohorts and evaluate available tissue samples for evidence of pharmacodynamic activity. Support: U10CA180821, U10CA180882, U10CA180888, UG1CA233324 (SWOG); https://acknowledgments.alliancefound.org. Clinical trial information: NCT02601209. Research Sponsor: U.S. National Institutes of Health.

11564 Poster Session (Board #452), Fri, 8:00 AM-11:00 AM

Efficacy, safety, and immune priming effect of tazemetostat in patients with epithelioid sarcoma. *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Epithelioid sarcoma (ES) is a rare, aggressive soft tissue sarcoma characterized by loss of inhibitor of integrase 1 (INI1), allowing enhancer of zeste homologue 2 (EZH2) to repress cell differentiation and promote tumorigenesis. Tazemetostat (TAZ) is a selective inhibitor of EZH2 approved by the FDA for treatment of patients (pts) aged $\geq$16 years with metastatic or locally advanced ES ineligible for complete resection. **Methods:** This open-label, multicenter, multi-cohort phase 2 study (NCT02601950) evaluated safety and efficacy of TAZ in pts with INI1-negative tumors. ES pts were enrolled in Cohorts 5 and 6; pts in Cohort 6 underwent mandatory pre-dose (at screening) and post-dose biopsies (at Day 1 of cycle 2). Herein, we report the interim efficacy and safety data from Cohort 6. **Results:** As of July 31 2019, 44 pts were enrolled into Cohort 6 and treated with TAZ 800 mg BID. The objective response rate (ORR) was 11.4%; 4 pts (9.1%) had a partial response and 1 pt (2.3%) had a complete response (Table). Another 17 pts (38.6%) had stable disease (SD). 18 pts had progressive disease; 13 of these pts remained on study beyond progression. Progression-free survival (PFS) and overall survival (OS) at 56 weeks were 19.4% and 59.4%, respectively. In a pooled posthoc analysis of 106 ES pts from Cohorts 5 (n = 62), and 6, ORR was 13.2%. Grade 34 adverse events (AEs) were reported in 16 pts (36.4%), most commonly anemia (6.8%; n = 3) and tumor pain (6.8%; n = 3). 3 pts (6.8%) experienced grade 34 treatment-related AEs. One pt discontinued study drug and there were no treatment-emergent dose reductions or treatment-related deaths. These safety data from Cohort 6 are consistent with previously reported data from Cohort 5. 19 paired biopsies were included for translational endpoint analyses. Preliminary RNA seq and pathway analyses are currently ongoing and updated data, including additional biomarker data will be presented. **Conclusions:** Consistent with previously reported data from the completed Cohort 5, TAZ demonstrated clinically meaningful, durable, single agent activity in ES pts. Efficacy data from Cohort 6 continue to mature with 8 patients still on treatment. TAZ was well tolerated with a low incidence of treatment related AEs. Clinical trial information: NCT02601950. Research Sponsor: Epizyme, Inc.

11565 Poster Session (Board #453), Fri, 8:00 AM-11:00 AM

Cost-utility analysis of surveillance strategies for soft tissue sarcoma recurrence. *First Author: Bonny Chau, University of Washington, Seattle, WA*

Background: Soft tissue sarcomas (STS) are uncommon malignancies with significant biological and clinical variation. After primary curative therapy, patients enter a program of surveillance for recurrence with periodic chest x-rays (CXR) or computed tomography (CT). We compared costs and health outcomes of CXR and CT at a range of frequencies and durations of follow-up. **Methods:** We used a Markov model to simulate a cohort of 10,000 STS patients through their surveillance experience for lung metastasis after completion of definitive treatment for stage II or III primary disease. Health states in the model were no evidence of disease, recurrence, and death. We assessed the method of chest imaging, duration of follow-up, and interval (every 3 months or 6 months) of surveillance in the first 3 years. Cost effectiveness was assessed for each screening modality and screening frequency. Recurrence probabilities, utilities, treatment costs, and other parameters were from previously published data. Outcomes were costs, quality-adjusted life-years (QALYs) and incremental cost-effectiveness ratios (ICER). **Results:** The initial evaluation comparing screening every 3 months for 3 years, every 6 months for years 4 and 5, and annually from years 6 to 10 resulted in 632,264 QALYs and $1,038,351,481 costs for CT, compared to 631,834 QALYs and $746,019,937 for CXR, resulting in an ICER of $679,322/QALY. In comparing screening intervals, less frequent screening intervals of every 6 months compared to every 3 months for the first three years using CT resulted in an ICER of $690,527/QALY and for CXR, the ICER was $271,423/QALY. In comparing screening duration between 6 years and 10 years of follow-up, strategies with longer follow-up resulted in slightly higher QALYs in each of the comparison scenarios, at a much higher cost. **Conclusions:** In our evaluation, more frequent screening the first 3 years and longer duration of surveillance resulted in higher QALYs in both screening modalities. However, in the comparisons the ICERs exceed common willingness to pay thresholds of $150,000/QALY gained; CXR is the more cost-effective imaging modality. Limitation of this model includes the simplification of disease progression and heterogeneity in STS. Research Sponsor: None.

TPS11567 Poster Session (Board #455), Fri, 8:00 AM-11:00 AM

A phase I/II clinical trial of the reversible LSD1 inhibitor, seclidemstat, in patients with relapsed/refractory Ewing sarcoma. *First Author: Damon R. Reed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Ewing sarcoma (ES) is a rare, aggressive bone and soft tissue cancer that predominantly afflicts adolescents and young adults. Novel therapeutic agents are needed as there are no approved targeted treatments for this disease. ES is characterized by a chromosomal translocation resulting in an EWS/ETS fusion oncoprotein, a transcription factor that results in aberrant gene expression leading to ES progression. Lysine specific demethylase 1 (LSD1) associates with EWS/ETS oncoproteins to alter gene expression and contribute to disease progression. Directly inhibiting EWS/ETS is challenging and little progress has been made, though targeting LSD1 presents a viable therapeutic strategy for ES. Seclidemstat (SP-2577, Salarius Pharmaceuticals) is a first-in-class, orally bioavailable, small molecule with reversible and noncompetitive selective inhibition of LSD1 at low nanomolar concentrations (IC_{50}: 25-50 nM). Seclidemstat inhibits LSD1's scaffolding functions and enzymatic activity to help reverse aberrant gene expression. *In vitro* data show that treatment with seclidemstat, or seclidemstat analog, modulates EWS/ETS transcriptional activity, down-regulating oncogene expression and up-regulating tumor-suppressor gene expression. In *in vivo* xenograft studies (e.g., SK-N-MC, A673), mice treated with seclidemstat show significant tumor growth inhibition/regression vs the control vehicle group. **Methods:** This phase 1/2 clinical study of seclidemstat is being conducted in relapsed or refractory ES (NCT03600649). The trial is an open-label, non-randomized dose-escalation/dose-expansion study designed to determine the maximum tolerated dose through single-patient dose escalation followed by traditional 3+3 design. The primary objective is to assess seclidemstat's safety and tolerability while secondary objectives include pharmacokinetics, efficacy and exploratory pharmacodynamic markers. Patients must be $\geq$12 years old, have received at least 1 prior line of therapy including a prior camptothecin-based regimen, with a life expectancy $>$ 4 months. All patients receive seclidemstat twice-daily (BID) as oral tablets until unacceptable toxicity or disease progression. Patients are followed for survival until the end of study. The trial is currently recruiting across 8 locations in the United States. Upon identification of the recommended phase 2 dose, that cohort will be expanded to enroll a total of 20 patients. Clinical trial information: NCT03600649. Research Sponsor: Salarius Pharmaceuticals, Other Foundation, The Cancer Prevention and Research Institute of Texas (CPRIT).

TPS11568 Poster Session (Board #456), Fri, 8:00 AM-11:00 AM

LENVAGIST - A multicenter, comparative, placebo-controlled, double-blinded, phase II study of the efficacy of lenvatinib in patients with locally advanced or metastatic GIST after failure of imatinib and sunitinib. *First Author: Axel Le Cesne, Institut Gustave Roussy, Villejuif, France*

Background: GastroIntestinal Stromal Tumors (GIST) are paradigmatic models of cancers with a driver mutation of an oncogene, in which imatinib is recommended as adjuvant therapy or treatment of locally advanced and metastatic forms. After failure of imatinib (either progression or toxicity), sunitinib and regorafenib are indicated as 2nd and 3rd lines, respectively. Beyond approved drugs, tyrosine kinase inhibitors (TKI) can bring clinical benefit because some clones remain sensitive to TKI. Lenvatinib is a broad spectrum TKI targeting KIT, RET, PDGFRA, VEGFR 1-3 and FGFR 1-4, that is approved in the treatment of differentiated thyroid carcinoma and metastatic renal cell carcinoma and hepatocellular carcinoma. **Methods:** This prospective, randomized, placebo-controlled, double-blinded, multicenter trial evaluates the efficacy and safety of Lenvatinib in adult GIST patients (pts) who failed at least to previous imatinib and sunitinib. Seventy-four pts will be randomly allocated in a 1:1 ratio to receive either oral lenvatinib, at a daily dose of 24mg, or its matching placebo, continuously, until progression of disease (PD) or unacceptable toxicity. Randomization will be stratified according to the number of different previous anticancer drugs (2 or $>$ 2). The primary objective is to compare the Progression-free survival (PFS) between arms. The expected median PFS are 1.5 month in the control arm and 3.0 months in the experimental arm (HR = 0.5). Seventy one events will provide 90% power to show significant improvement in PFS, using a 2-sided log-rank test at a 10% level. Secondary endpoints include the overall survival, the objective response rate, the best overall response, the quality of life and the safety profile. Patients allocated in the placebo arm who experience PD (RECIST 1.1) may switch to active lenvatinib. Radiological endpoints will be evaluated using the RECIST 1.1. Translational objectives will be to identify blood and tumor parameters as predictive markers of lenvatinib efficacy. Recruitment has been activated in January 2020. Ten participating sites of the French Sarcoma Group will participate in the trial. Clinical trial information: NCT04193553. Research Sponsor: EISAI.

TPS11569 Poster Session (Board #457), Fri, 8:00 AM-11:00 AM

SPEARHEAD-1: A phase II trial of ADP-A2M4 SPEAR T cells in patients with advanced synovial sarcoma or myxoid/round cell liposarcoma. *First Author: Dejka M. Araujo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ADP-A2M4 specific peptide enhanced affinity receptor (SPEAR) T-cells are genetically engineered to target MAGE-A4^{+} tumors in the context of HLA-A*02. MAGE-A4 has been described as having high expression in synovial sarcoma (SS) and myxoid/round cell liposarcoma (MRCLS) [1, 2]. This Phase 2 trial was initiated based on the favorable benefit:risk profile of ADP-A2M4 observed in a Phase 1 trial (NCT03132922) of ADP-A2M4 which demonstrated compelling clinical responses in patients with SS. **Methods:** This Phase 2, open-label trial (SPEARHEAD-1; NCT04044768) is designed to evaluate the efficacy, safety and tolerability of ADP-A2M4 in patients with advanced/metastatic SS or MRCLS who are HLA-A*02 positive and whose tumors express the MAGE-A4 protein. Enrolled patients are to undergo apheresis, and their isolated T-cells are then transduced with the MAGE-A4^{c1032} TCR, and expanded. Prior to ADP-A2M4 infusion, patients are to receive lymphodepleting chemotherapy consisting of fludarabine (30 mg/m^2/day x 4 days) and cyclophosphamide (600 mg/m^2/day x 3 days). Patients are to receive $1 - 10 \times 10^9$ transduced T-cells. An independent Data Safety Monitoring Board will review ongoing safety and benefit:risk during the interventional phase of the study. Disease will be assessed by independent review per RECIST v1.1 by CT/MRI at weeks 4, 8, 12, 16, 24, and every 2 months thereafter until confirmed disease progression. As of 24 Jan 2020, there were 17 clinical sites open in the US, one in Canada, and two in Spain. References: 1. Iura K, et al. TPS11570 Poster Session (Board #458), Fri, 8:00 AM-11:00 AM

NCI protocol 10250: A phase II study of temozolomide and olaparib for the treatment of advanced uterine leiomyosarcoma. *First Author: Matthew Ingham, Columbia University Irving Medical Center, New York, NY*

Background: Soft tissue sarcoma (STS) is a heterogenous malignancy of mesenchymal origin and includes more than 50 biologically distinct subtypes. Leiomyosarcoma (LMS), a neoplasm of smooth muscle origin, represents up to 20% of STS. The uterus is the most common site of origin in women. Advanced uterine LMS (uLMS) is initially treated with gemcitabine + docetaxel or anthracycline-based chemotherapy but overall survival remains $<$ 24 mos. Besides recurrent alterations in RB1, TP53 and ATRX, insight into cancer biology of uLMS remains limited. Recently, whole exome and transcriptomic sequencing studies suggest uLMS harbors characteristic defects in the homologous recombination (HR) DNA repair pathway and thus features of BRCAness. HR-deficient cancers are unable to efficiently repair double-stranded DNA breaks and appear sensitive to treatment with poly ADP-ribose polymerase (PARP) inhibitors. In preclinical studies, the combination of temozolomide (T), an alkylating agent, and olaparib (O), a PARP inhibitor, was synergistic and markedly suppressed proliferation of uLMS models. A recent phase II study in small cell lung cancer defined the RP2D for T + O where the chief toxicity was myelosuppression. **Methods:** NCI Protocol #10250 is a single-arm, open-label, multi-center phase II clinical trial of T + O in patients with advanced uLMS. Eligible pts have ECOG PS $\leq$ 2, progression on $\geq$ 1 prior line of therapy and disease measurable by RECIST v1.1 and amenable to image-guided biopsy. Pts receive T 75 mg/m2 PO daily + O 200 mg PO BID on days 1-7 in 21-day cycles. The 1° endpoint is objective response rate (ORR). A one-stage binomial design is used to evaluate for an ORR $\leq$ 10% (null hypothesis) versus $\geq$ 35% (alternative hypothesis). The design calls for 22 patients. If 5/22 respond, the treatment is promising. This design yields 93% power and 1-sided type I error of 6%. 2° endpoints include progression free survival and safety. All pts undergo tumor biopsies pre-treatment and during cycle 2. Tissue is used for correlative analysis interrogating uLMS for features of BRCAness through (a) whole exome sequencing/RNAseq to evaluate for alterations in HR pathway component genes, (b) RAD51 foci formation by immunohistochemistry as a functional marker of HR pathway activity and (c) protein expression of Schlafen family member number 11 (SLFN11), an emerging biomarker for PARPi. Tumors are also evaluated for MGMT protein expression, a known determinant of sensitivity to T. The study opened to accrual 10/2019. Clinical trial information: NCT03880019. Research Sponsor: U.S. National Institutes of Health, Conquer Cancer Foundation of the American Society of Clinical Oncology.

TPS11571 Poster Session (Board #459), Fri, 8:00 AM-11:00 AM

Safety and activity of autologous T cells with enhanced NY-ESO-1–specific T-cell receptor (GSK3377794) in HLA-a*02$^+$ previously-treated and -untreated patients with advanced metastatic/unresectable synovial sarcoma: A master protocol study design (IGNYTE-ESO). *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: T cells modified to target NY-ESO-1 have shown encouraging activity in HLA-A*02$^+$ patients with NY-ESO-1–positive synovial sarcoma. NY-ESO-1 is a cancer/testis antigen that is expressed across multiple tumor types and highly expressed in synovial sarcoma. NY-ESO-1 TCR T (GSK3377794) are autologous polyclonal T cells transduced by a self-inactivating lentiviral vector to express an affinity-enhanced TCR able to recognize NY-ESO-1 epitope in complex with HLA-A*02. Ongoing trials are evaluating GSK3377794 in multiple solid tumors and multiple myeloma. **Methods:** This study (NCT03967223) uses a Master Protocol design that allows investigation of GSK3377794 in multiple tumor types under the same protocol in separate substudies. The first two are single-arm substudies in patients with advanced metastatic or unresectable synovial sarcoma: treatment-naïve (1st line [1L], substudy 1; n = 10 planned) and progressing after anthracycline-based chemotherapy (2L+, substudy 2; n = 55 planned). Patients must be aged ≥10 years, have adequate organ function, ECOG performance status 0–1, measurable disease, and no central nervous system metastases. Excluded prior treatments include gene therapy with an integrating vector or NY-ESO-1–specific T cells, vaccine or targeting antibody, or allogeneic stem cell transplant. Patients will undergo leukapheresis and manufacture of GSK3377794; lymphodepletion then GSK3377794 infusion, followed by safety and disease assessments; and long-term follow-up for 15 years (under a separate protocol). The primary objective of substudy 2 is overall response rate per RECIST v1.1 by central independent review. Secondary objectives include time to response, duration of response, disease control rate, progression-free survival, overall survival, plus safety and tolerability. Exploratory objectives include assessment of the correlation of T-cell persistence with safety, clinical responses, and infused T-cell phenotype. Evaluation of quality of life and daily functioning of patients will also be assessed. Enrollment began in December 2019. These data are presented on behalf of the original authors with their permission. A similar presentation (P453) was presented at the SITC Annual Meeting, National Harbor, MD, USA, Nov 6–10, 2019. Funding: GlaxoSmithKline (208467) Clinical trial information: NCT03967223. Research Sponsor: GlaxoSmithKline.

TPS11572 Poster Session (Board #460), Fri, 8:00 AM-11:00 AM

The TNT protocol: A phase II study using talimogene laherparepvec (TVEC), nivolumab (N) and trabectedin (T) as first, second/third line therapy for advanced sarcoma, including desmoid tumor and chordoma. *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Talimogene laherparepvec (TVEC), an oncolytic HSV expressing huGMCSF, may be synergistic with trabectedin (T) and nivolumab (N) in treating advanced sarcoma. Objectives: (1) To evaluate the best overall response by RECIST v1.1, progression-free survival rate (PFS), and overall survival rate, (2) To determine the incidence of conversion of an unresectable tumor to a resectable one, and (3) To evaluate the incidence of adverse events related to the drug combination. **Methods:** This is an open label phase 2 study. A total of 40 patients will receive T (1.2 mg/m2 CIV over 24 hours q3 weeks), N (240 mg IV over 30 min q 2 weeks) and TVEC (intratumorally q 2 weeks according to tumor size). Eligible patients are those with histopathologically confirmed diagnosis of locally advanced, unresectable or metastatic sarcoma including desmoid tumor and chordoma, previously untreated or treated, with measurable disease by RECIST v1.1, and at least, one accessible tumor for intratumoral injection of TVEC. Currently, 31 of the 40 patients have been enrolled. Statistical Considerations: Continuous variables will be summarized by the sample size (n), mean, standard deviation, first and third quartiles, minimum and maximum. Categorical variables will be summarized by the n and percent in each category. Point estimates for efficacy endpoint incidences will be accompanied by a 2-sided 95% exact binomial CI. Time to event endpoints will be summarized descriptively using the KM method. Safety (incidence and severity of adverse events and significant laboratory abnormalities) will be performed on all patients (ITT population). Patient incidence of all treatment emergent AEs will be tabulated by system organ class and preferred term. Clinical trial information: 03886311. Research Sponsor: AmGen.

TPS11573 Poster Session (Board #461), Fri, 8:00 AM-11:00 AM

A phase Ib/III randomized, double-blind, placebo-controlled study of tazemetostat plus doxorubicin as frontline therapy for patients with advanced epithelioid sarcoma. *First Author: Shiraj Sen, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: Epithelioid sarcoma (ES) is characterized by loss of inhibitor of integrase 1 (INI1), allowing enhancer of zeste homologue 2 (EZH2) to repress cell differentiation and promote tumorigenesis. Tazemetostat (TAZ) is an EZH2 inhibitor approved by the FDA as monotherapy for the treatment of patients (pts) aged ≥16 years with metastatic or locally advanced ES ineligible for complete resection. The most common (> 20%) adverse events include pain, fatigue, nausea, decreased appetite, vomiting, and constipation. TAZ demonstrated anticancer activity in ES pts who previously received doxorubicin (dox), a commonly used front line FDA approved therapy for soft tissue sarcomas (STS), including ES. Preclinical studies have demonstrated synergy between TAZ and dox. This phase 1b/3 study (NCT04204941) is assessing the safety and efficacy of TAZ + dox in pts with advanced ES. **Methods:** This study is enrolling treatment-naïve adult pts with histologically confirmed STS (phase 1b) or INI1-deficient ES pts (phase 3) with ECOG performance status of 0-2 and life expectancy of ≥3 months. The open-label phase 1b portion is currently enrolling up to 24 patients with STS. The primary objectives are to evaluate the safety and tolerability of TAZ + dox, and to identify the recommended phase 3 dose (RP3D). Using a standard 3 + 3 design, TAZ will be evaluated at 3 dose levels (400 mg, 600 mg, and 800 mg orally BID) with standard fixed dose of dox (75 mg/m^2 on day 1 of 21-day cycles for up to 6 cycles). After completion of dox, pts will continue to receive TAZ monotherapy until disease progression or intolerable toxicity. Up to 12 additional pts will be enrolled at the maximum tolerated dose for collection of additional safety and pharmacokinetic (PK) data. The double-blind phase 3 study will randomize (1:1) up to 140 pts to receive either TAZ (RP3D) + dox (75 mg/m^2) or placebo + dox. The adaptive study design will allow sample size re-estimation (at interim analysis) to up to 200 pts. Pts may continue TAZ or placebo monotherapy after completing 6 cycles of TAZ + dox. Tumor assessments will be performed at screening and every 6 weeks from the start of dosing. The primary objective of phase 3 will be to evaluate the progression-free survival (PFS) by independent review committee. Secondary objectives will include assessment of PFS by investigators, overall survival, safety, disease control rate, overall response rate, duration of response, time to subsequent anticancer therapy, PFS on next treatment, quality of life, and PK. Clinical trial information: NCT04204941. Research Sponsor: Epizyme, Inc.

12000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Multisite randomized trial of integrated palliative and oncology care for patients with acute myeloid leukemia (AML). *First Author: Areej El-Jawahri, Massachusetts General Hospital, Boston, MA*

Background: Patients with AML receiving intensive chemotherapy experience substantial decline in their quality of life (QOL) and mood during their hospitalization for induction chemotherapy and often receive aggressive care at the end of life (EOL). We sought to examine the effect of integrated palliative and oncology care on QOL, mood, post-traumatic stress (PTSD) symptoms, and EOL outcomes in patients with AML. **Methods:** We conducted a multi-site randomized trial of integrated palliative and oncology care (n = 86) versus usual oncology care (n = 74) for patients with AML undergoing intensive chemotherapy. Patients assigned to the intervention were seen by palliative care clinicians at least twice per week during their hospitalization for induction chemotherapy and all subsequent hospitalizations. Patients completed the Functional Assessment of Cancer Therapy-Leukemia, the Hospital Anxiety and Depression Scale, and the PTSD Checklist to assess their QOL, mood, and PTSD symptoms at baseline, weeks 2, 4, 12, and 24. The primary endpoint was QOL at week-2. We used analysis of covariance and mixed linear effect models, controlling for baseline scores, to assess the effect of the intervention on patient-reported outcomes. **Results:** Between 1/2017 and 7/2019, we enrolled 160/235 (68.1%) of eligible patients. Compared to those receiving usual care, intervention patients reported better QOL (107.59 vs. 116.45, P = 0.039) and lower depression (7.20 vs. 5.68, P = 0.021), anxiety (5.94 vs. 4.53, P = 0.018), and PTSD symptoms (31.69 vs. 27.79, P = 0.009) at week 2. Intervention effects were sustained up to week 24 for QOL (B = 2.35, P = 0.048), depression (B = -0.42, P = 0.039), anxiety (B = -0.38, P = 0.042), and PTSD symptoms (B = -1.43, P = 0.002). Among deceased participants, those receiving the intervention were more likely to report discussing their EOL care preferences with their clinicians (75.0% vs. 40.0%, P = 0.009) and less likely to receive chemotherapy in the last 30 days of life (34.9% vs. 65.9%, P = 0.008). There was no difference in hospice utilization or hospitalization at the EOL. **Conclusions:** The integrated palliative and oncology care model for patients with AML receiving intensive chemotherapy led to substantial improvements in patients' QOL, psychological distress, and EOL care. Thus, palliative care should be considered a new standard of care for patients with AML. Clinical trial information: NCT02975869. Research Sponsor: Lymphoma and Leukemia Society.

12001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A randomized trial of a palliative care intervention for patients on phase I studies. *First Author: Thomas J. Smith, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: The purpose of this study was to test a Palliative Care Intervention for patients with solid tumors enrolled in phase I therapeutic trials. **Methods:** This randomized trial compared patients accrued to phase I Clinical Trials in groups of Usual Care compared to a Palliative Care Intervention (PCI) in two comprehensive cancer centers. The PCI included assessment of quality of life (QOL) and symptoms, an interdisciplinary meeting to discuss the care plan, including goals of care, and two nurse-delivered teaching sessions. Subjects (n=479) were followed for 24 weeks, with 12 weeks as the primary outcome point. **Results:** Outcomes revealed that relative to Usual Care, PCI subjects showed less Psychological Distress (1.9 in Intervention and 1.2 in Control pts, p=0.03) and a trend toward improved QOL (3.7 versus 1.6, p=0.07), with differences between sites. We observed high rates of symptom-management admissions (41.3%) and low rates of Advance Directive completion (39%), and use of supportive care services including hospice (30.7%, for only1.2 months duration), despite a median survival for all patients in both groups of 10.1 months from initiating a phase 1 study until death. Patient satisfaction with oncology care was already high at baseline, and we did not see clinically significant changes in those scores by week 12. **Conclusions:** Palliative care interventions can improve QOL outcomes and distress for patients participating in phase 1 trials. Greater integration of PC is needed to provide quality care to these patients and to support transitions from treatment to supportive care, especially at the end of life. Clinical trial information: NCT01828775. Research Sponsor: U.S. National Institutes of Health.

12002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Effect of integrating machine learning mortality estimates with behavioral nudges to increase serious illness conversions among patients with cancer: A stepped-wedge cluster randomized trial. *First Author: Chris Manz, University of Pennsylvania, Philadelphia, PA*

Background: Most patients with cancer die without a documented serious illness conversation (SIC) about prognosis and goals. Interventions that increase SICs between oncology clinicians and patients may improve goal-concordant care and end-of-life outcomes. **Methods:** In this stepped-wedge cluster randomized trial (NCT03984773), we tested the effect of an intervention delivering machine learning-based mortality estimates with behavioral nudges to oncologists to increase SICs among patients with cancer. The clinician-focused intervention consisted of 1) weekly emails providing individual SIC performance feedback (number of SICs in the past month) and peer comparisons; 2) a list of patients scheduled for the next week with a ≥10% predicted risk of 6 month mortality by a validated machine learning prognostic algorithm, and 3) automated opt-out text prompts on the patient's appointment day to consider an SIC. Eight medical oncology clinics were randomized to receive the intervention in a stepped-wedge fashion every four weeks for a total of 16 weeks. Medical oncology clinicians were included if they were trained to use the SIC Guide (Ariadne Labs, Boston MA). Patients were included if they had an outpatient encounter with an eligible clinician between June 17 and November 1, 2019. The primary outcome was the percent of patient encounters with a documented SIC. Intention to treat analyses adjusted for clinic and wedge fixed effects and clustered at the oncologist level. **Results:** The sample consisted of 78 clinicians and 14,607 patients. The mean age of patients was 61.7 years, 55.7% were female, 70.4% were white, and 19.6% were black. The percent of patient encounters with an SIC was 1.2% (106/8536) during the pre-intervention period and 4.0% (401/10,152) during the intervention period. In intention to treat adjusted analyses, the intervention led to a significant increase in SICs (adjusted odds ratio, 3.7; 95% CI, 2.5 to 5.4, *P* value < 0.0001). **Conclusions:** An intervention consisting of machine learning mortality estimates and behavioral nudges to oncology clinicians increased SICs by three-fold over 16 weeks, a significant difference.This is one of the first studies evaluating a machine learning-based behavioral intervention to improve serious illness communication in oncology. Secondary analyses (completed April 2020) will clarify whether this intervention leads to a sustained increase in SIC rates and improves goal-concordant care and end-of-life outcomes. Clinical trial information: NCT03984773. Research Sponsor: Penn Center for Precision Medicine Accelerator Grant.

12003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

ACUFOCIN: Randomized clinical trial of ACUpuncture plus standard care versus standard care alone FOr Chemotherapy Induced peripheral Neuropathy (CIPN). *First Author: Andrew M. Wardley, The Christie NHS Foundation Trust, Manchester Academic Health Science Centre & Division of Cancer Sciences, School of Medical Sciences, Faculty of Biology Medicine & Health, University of Manchester, Manchester, United Kingdom*

Background: CIPN is a dose limiting toxicity, and a major clinical challenge. This study aims to explore the use of acupuncture with standard care (Acu +SC) against SC alone, to reduce symptoms of CIPN. **Methods:** A phase II, randomised, parallel group design was used to investigate the effectiveness of a 10 week course of acupuncture to manage CIPN. Patients experiencing CIPN ≥ Grade II (CTCAE v4.03), recording a 'Most Troublesome' CIPN symptom score of ≥ 3 using the "Measure Yourself Medical Outcome Profile" (MYMOP 2), were randomised (1:1) to either Acu+SC or SC alone. The primary end-point was a ≥ 2 point improvement in MYMOP2 score at week 10 (logistic regression adjusted for stratification factors and baseline MYMOP2 score). The necessary sample size was 100 patients;120 were randomised to allow for attrition (90% power; 10% one-sided alpha), for a hypothesised improvement in success proportions from 30% to 55%. **Results:** 120 patients were randomised to ACUFOCIN; diagnosis: breast 61 (51%), multiple myeloma 9 (8%), GI 48 (40%), gynaecological 2 (2%). MYMOP2 score for most troubling CIPN symptom at baseline: 3-4 33 (28%), 5-6 87 (73%). CTCAE CIPN at baseline; grade II 103 (86%), grade III 17 (14%). Baseline characteristics were balanced between arms. Primary outcome data were available for 108 participants with 36/54 (67%) successes in the Acu+SC arm compared to 18/55 (33%) in the SC arm. Adjusted success odds ratio was 4.3 (95% CI 1.9-9.6; p < 0.001; Acu+SC vs SC). Additionally, 27/53 (51%) participants achieved a CIPN success (grade ≤ I) in the Acu+SC arm compared to 4/56 (7%) in the SC arm with adjusted odds ratio 13.1 (95% CI 4.1-41.7; p < 0.001; Acu+SC vs SC). Significant reduction in week 10 pain score; mean difference (SC+Acu – SC alone) -1.45 with 95% CI (-2.25, -0.65) after adjustment for week 1 pain, breast cancer diagnosis and treatment complete status. (note pain on a 0-10 scale). Significant increase in the EORTC QLQ-C30 summary score; mean difference (SC+Acu – SC alone) 9.51 with 95% CI (5.01, 14.02) after adjustment for the baseline score, breast cancer diagnosis and treatment complete status. (note summary score on a 0-100 scale). Significant effects seen at week 10 are also present at week 6. The week 6 effect estimates are consistently less than the week 10 effects (but not usually statistically significantly so). **Conclusions:** In this patient cohort, a 10 week course of acupuncture significantly improved symptoms of CIPN. These results support further investigation within a phase III trial. Clinical trial information: NCT02275403. Research Sponsor: National Institute for Health Research.

12004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Effects of electroacupuncture and auricular acupuncture for chronic pain in cancer survivors: The PEACE randomized controlled trial. *First Author: Jun J. Mao, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The national opioid crisis has created new challenges in oncology pain management and highlighted an urgent need for non-pharmacological treatments. We evaluated the comparative effectiveness of electro-acupuncture (EA) and auricular acupuncture (AA) versus usual care (UC) for chronic musculoskeletal pain in cancer survivors. **Methods:** We conducted a randomized controlled trial of cancer survivors experiencing moderate-severe musculoskeletal pain for at least 3 months. EA used a semi-individualized protocol involving electrical stimulation of needles placed in the body. AA used the standardized Battlefield Acupuncture protocol involving up to 10 needles placed in the ears. EA and AA groups received 10 weekly treatments, whereas participants in the UC group received standard care prescribed by their providers. The primary endpoint was average pain severity change measured by the Brief Pain Inventory at week 12 compared to baseline. Functional interference and quality of life were secondary outcomes. We analyzed longitudinal mixed-effects models based on intent-to-treat principles. **Results:** Among 360 participants, mean age (SD) was 62.1 (12.7) years, 251 (69.7%) were women, and 88 (24.4%) were non-white. Compared from baseline to week 12, EA significantly reduced pain severity by 1.9 points (95% Confidence Interval 1.5-2.3, $p < 0.001$), and AA significantly reduced pain severity by 1.6 points (1.1-2.0, $p < 0.001$). AA was non-inferior to EA at reducing pain severity ($p = 0.04$). Both EA and AA also significantly improved functional interference (both $p < 0.001$), physical health (both $p < 0.001$), and mental health ($p = 0.003$, $p < 0.001$) compared to UC. Adverse events (AEs) were mild in both groups; however, 16 (11.2%) in AA stopped treatment due to AEs (mostly ear discomfort) as compared to 1 in EA (0.7%), $p = 0.001$. **Conclusions:** Among cancer survivors with chronic musculoskeletal pain, both EA and AA effectively reduced pain and improved quality of life. AA was non-inferior to EA at reducing pain but associated with higher discontinuation rates. These results will guide implementation of acupuncture in oncology care to address the unmet pain management needs of cancer survivors in the era of the opioid epidemic. Clinical trial information: NCT02979574. Research Sponsor: Department of Defense, U.S. National Institutes of Health.

12005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Effects of YOCAS yoga, cognitive behavioral therapy, and survivorship health education on insomnia: A URCC NCORP Research Base Phase III RCT in 740 cancer survivors. *First Author: Karen Michelle Mustian, University of Rochester Medical Center, Rochester, NY*

Background: Insomnia, a prevalent and troublesome side effect experienced by cancer survivors, significantly impairs recovery and survival. We conducted a nationwide, multicenter, phase III, blinded, randomized controlled trial testing whether 1) yoga is superior to survivorship health education (SHE) and 2) yoga is non-inferior to cognitive behavioral therapy for insomnia (CBT-I) for treating insomnia in survivors. **Methods:** The trial was conducted via the University of Rochester Cancer Center NCI Community Oncology Research Program (URCC NCORP) Research Base. Participants were cancer survivors between 2-60 months post adjuvant therapy, with insomnia, no metastatic disease, and no yoga participation during the previous 3 months. Survivors were randomized into 1) YOCAS yoga (2x/wk; 75 min/sess for 4 wks with pranayama, asana, and dhyana, N = 251), 2) CBT-I (1x/wk, 90 min/sess for 8 wks with sleep hygiene, stimulus control, sleep restriction, and cognitive therapy, N = 238), or 3) SHE (2x/wk; 75 min/sess for 4 wks with ASCO-recommended survivorship education, N = 251). Insomnia was assessed pre- and post-intervention via the Insomnia Severity Index. **Results:** 740 eligible cancer survivors were enrolled (93% female, mean age = 56 + 11, 75% breast cancer). ANCOVAs with baseline values as covariates revealed YOCAS is significantly better than SHE for treating insomnia at post-intervention (CS = change score; CS mean diff = -1.43, SE = 0.42, $p < 0.01$). Yoga participants demonstrated greater improvements in insomnia from pre- to post-intervention (CS = -3.61, SE = 0.30) compared to SHE participants (CS = -2.19, SE = 0.33, all $p < 0.01$). Intent-to-treat analyses of non-inferiority (non-inferiority margin set at 1.15 a priori) showed YOCAS is inferior to CBT-I (CS mean diff = 3.52, CI = 2.55 - 4.50, $p < 0.01$). However, analyses of non-inferiority using the optimal treatment effect in fully compliant survivors were inconclusive regarding whether YOCAS is non-inferior to CBT-I for treating insomnia (CS mean diff = 2.20, CI = 0.42 - 3.98, $p = 0.09$). Significantly more survivors withdrew from CBT-I and SHE due, in part, to disliking the interventions compared to YOCAS (30%, 25%, and 16%, respectively, $p < 0.01$). **Conclusions:** YOCAS yoga is better than SHE and results are inconclusive as to whether yoga is non-inferior to CBT-I for treating insomnia among survivors. Clinicians should consider prescribing YOCAS and CBT-I for survivors reporting insomnia. Funding: NCI UG1CA189961, R01CA181064, T32CA102618. Clinical trial information: NCT02613364. Research Sponsor: U.S. National Institutes of Health.

12006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Neuroleptic rotation for refractory agitation in cancer patients with delirium in the acute palliative care unit: A double-blind randomized clinical trial. *First Author: David Hui, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Terminal agitation commonly occurs in the last days of life and is highly distressing. The role of neuroleptics is controversial and few studies have examined agitation as a primary outcome. We assessed the effect of 3 neuroleptic strategies on refractory agitation in cancer patients with terminal delirium. **Methods:** In this single-center, double-blind, double-dummy parallel group randomized trial, patients admitted to a palliative and supportive care unit with refractory agitation despite low dose haloperidol were randomized in a 1:1:1 ratio to (1) haloperidol dose escalation, (2) neuroleptic rotation to chlorpromazine, or (3) combined haloperidol and chlorpromazine. Intravenous medications at equivalent doses were scheduled every 4 h and every 1 h as needed until discharge. The primary outcome was change in Richmond Agitation Sedation Scale (RASS) from time 0 to 24 hours. With 15 patients per group and 13 measurements over time, we had 90% power to detect an effect size of 0.2 with alpha=2.5%. One way ANOVA was used to examine within group differences. We also compared among groups with the Wilcoxon rank sum test. **Results:** 68 patients were enrolled and 45 received the blinded study interventions. The median survival was 73 h (95% CI 49, 106 h). RASS decreased significantly within 30 minutes and remained low at 24 hours in the dose escalation group (mean RASS change between 0 and 24 h [95% CI]: -3.6 [-5, -2.2]) v. rotation group (-3.3 [-4.4, -2.2]) v. combination group (-3 [-4.6, -1.4]), with no difference among groups (P=0.71). A majority of patients were perceived to be more comfortable after treatment by blinded caregivers (escalation v. rotation v. combination: 62% v. 71% v. 60%; P=0.83) and bedside nurses (64% v. 75% v. 64%; P=0.82); however, the rotation group had significantly fewer breakthrough restlessness (escalation v. rotation v. combination: 73% v. 19% v. 50%; P=0.009), required fewer upward dose titration (escalation v. rotation v. combination: 27% v. 6% v. 50%; P=0.03) and required less rescue neuroleptics in the first 24 hours (haloperidol equivalent: 4 mg vs. 2 mg vs. 6 mg, P=0.09, trend only). Hypotension was more frequently observed with chlorpromazine. Overall survival did not differ (>0.99). **Conclusions:** Preliminary data from this study supported that all 3 strategies of neuroleptics reduced agitation and improved comfort in patients with terminal delirium; however, neuroleptic rotation provided better agitation control and confirmatory studies are needed. Clinical trial information: NCT03021486. Research Sponsor: U.S. National Institutes of Health.

12007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase III randomized, double-blind placebo controlled study of armodafinil (Nuvigil) to reduce cancer-related fatigue in patients with high-grade glioma (Alliance A221101). *First Author: Alyx B. Porter, Mayo Clinic, Phoenix, AZ*

Background: Up to 96% of patients with high grade glioma (HGG) report moderate to severe fatigue. Armodafinil, the R-enantiomer of modafinil, is a psychostimulant with low potential for abuse that has shown potential for improving severe fatigue in HGG patients. **Methods:** In this phase III double blinded placebo-controlled study, adults with HGG and moderate to severe fatigue, > 4 weeks after completing radiotherapy, were randomized to receive armodafinil daily (150 mg or 250 mg) or placebo for a total of 8 weeks. The primary outcome was efficacy in treating severe fatigue. Secondary outcomes included evaluation of tolerability, neurocognitive function, and quality of life. Patients were evaluated at baseline, 4 and 8 weeks. **Results:** A total of 328 patients were enrolled between 6/3/13-3/1/19. There were 103 (150 mg arm), 97 (250 mg arm) and 97 (placebo arm) evaluable patients with primary endpoint data available. The median age was 60 years (20-85) with a median Brief Fatigue Inventory (BFI) *worst* fatigue score of 8 (6-10). 60.3% were male, 80.5% received concomitant chemotherapy, and 39.7% were on corticosteroids. The global fatigue score at end of weeks 4 and 8 were lower than at baseline ($p<0.0001$) and in the 250 mg arm than placebo ($p=0.0356$) and was higher for corticosteroid users than non-users ($p=0.0002$). There was no statistically significant difference for clinically meaningful improvement in BFI *usual* fatigue score from baseline to end of week 8 between the three arms ($p=0.9601$). Patients reported an improvement in concentration at week 4 from baseline on the 150 mg arm($P=0.0311$). There was no statistically significant difference on neurocognitive tests from baseline to end of week 4 ($p>0.05$) or week 8 ($p>0.05$) between arms. More patients reported insomnia on the 250 mg arm ($p=0.0083$). **Conclusions:** There is no meaningful benefit of the use of armodafinil to reduce moderate to severe fatigue in patients with HGG. In certain cases there may be benefit of armodafinil 150 mg to aid concentration without the risk of insomnia.Support: UG1CA189823;U10CA180868 (NRG). Clinical trial information: NCT01781468. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

12008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results of crossover phase II component of randomized placebo-controlled trial evaluating oral THC/cannabis extract for refractory chemotherapy-induced nausea and vomiting (CINV). *First Author: Peter S. Grimison, Chris O'Brien Lifehouse, Sydney, Australia*

Background: The aim of this multi-centre, randomised, double-blinded, placebo-controlled, phase 2/3 trial is to determine efficacy of addition of oral cannabis in adults with any malignancy of any stage, experiencing CINV during moderate-highly emetogenic intravenous chemotherapy, despite guideline-consistent anti-emetic prophylaxis, requiring ≥ 2 chemotherapy cycles. Here we report the crossover phase 2 component results. **Methods:** Treatment consisted of 1 cycle of oral THC 2.5mg/CBD 2.5mg (TN-TC11M) capsules *tds* days -1 to 5 and 1 cycle matching placebo in a crossover design, then blinded patient preference for a 3rd cycle. Primary end-point is difference in proportion of patients with 'complete response' (no emesis & no use of rescue medications) during 0-120 hours from chemotherapy between cycles. 80 patients provides 80% power with 2p of 0.1 to detect a 20% difference. **Results:** 81 patients recruited (2016-9). 72 completing 2 cycles are included in efficacy analyses. 78 not withdrawing consent are included in safety analyses. Median age was 55 years (range 29-80), 78% were female, 42% report historic cannabis use, 55% were treated with curative intent. Most common regimens were AC (26%), FOLFOX (17%). All received steroids & 5-HT3 antagonist, 79% received NK-1 antagonist, 4% received olanzapine. Efficacy is shown in table. 83% preferred cannabis to placebo. Most common bothersome cannabinoid-related adverse events (cannabis, placebo) were sedation (19%,4%), dizziness (10%,1%), disorientation (3%,0%). No SAEs were attributed to THC/CBD. **Conclusions:** Addition of oral THC/CBD to standard anti-emetics was associated with less nausea & vomiting but additional side effects. Most preferred THC/CBD to placebo. Based on these positive results, the definitive parallel phase 3 trial component continues (additional n=170). A geriatric assessment (GA) intervention to reduce treatment toxicity in older patients with advanced cancer: A University of Rochester Cancer Center NCI community oncology research program cluster randomized clinical trial (CRCT). *First Author: Supriya Gupta Mohile, University of Rochester James Wilmot Cancer Institute, Rochester, NY*

Background: GA evaluates aging-related domains (e.g., function) known to be associated with cancer treatment toxicity. In this CRCT, we evaluated if providing a GA summary with management recommendations to oncologists can reduce toxicity in older patients (pts) with advanced cancer receiving chemotherapy and/or other agents with a high reported prevalence of grade 3-5 toxicity. **Methods:** Pts aged > 70 with incurable solid tumors or lymphoma and > 1 impaired GA domain starting a new treatment regimen were enrolled. Community oncology practices were randomized to intervention (oncologists received GA summary/recommendations for impairments) or usual care (none given). The primary outcome was proportion of pts who experienced any grade 3-5 toxicity (CTCAE v.4) within 3 months. Practice staff prospectively captured toxicities; blinded oncology clinicians reviewed medical records to verify. Secondary outcomes included 6 month overall survival (OS) and treatment intensity (standard vs reduced). Outcomes were analyzed using generalized linear mixed/Cox models with Arm as a fixed effect, controlling for practice. **Results:** From 2013-19, 718 pts were enrolled from 41 practices. Age (mean 77 yrs), sex (43% women), number of impaired GA domains (median 4/8), and treatment type (chemotherapy 88%) were not different by Arm. More pts in intervention were Black (12% vs 3%, p<0.01), had GI cancer (38% vs 31%, p<0.01), and had prior chemotherapy (31% vs 23%, p=0.02). Pts in intervention experienced a lower proportion of grade 3-5 toxicity (175/349; 50%) than pts in usual care (262/369; 71%). The relative risk (RR: intervention vs usual care) of grade 3-5 toxicity was 0.74 (95% CI: 0.63-0.87; p=0.0002); the difference was mostly driven by non-heme toxicities (RR 0.73; 95% CI: 0.53-1.0, p<0.05). OS was not significantly different (71% vs 74%, p=0.3). More pts in intervention received reduced intensity treatment at cycle 1 (49% vs 35%, RR 0.81, p=0.01). Dose modifications due to toxicity were lower in intervention (42% vs 58%, p<0.0001), but results were not significant after controlling for practice (RR 0.85; 95% CI: 0.67-1.08, p=0.2). **Conclusions:** Providing GA information to oncologists reduces the proportion of older pts who experience grade 3-5 toxicity from high-risk palliative cancer treatment, without compromising OS. Reduced treatment intensity at cycle 1 may explain these results. Funding: R01CA177592, U01CA233167, UG1CA189961. Clinical trial information: NCT02054741. Geriatric assessment-driven intervention (GAIN) on chemotherapy toxicity in older adults with cancer: A randomized controlled trial. *First Author: Daneng Li, City of Hope National Medical Center, Duarte, CA*

Background: Geriatric assessment (GA) can predict chemotherapy (chemo) toxicity in older adults (age ≥65) with cancer. However, evidence regarding the effect of GA-driven intervention (GAIN) on the incidence of chemo toxicity has been limited. Therefore, we conducted a randomized controlled trial evaluating the impact of GAIN vs. standard of care (SOC) on chemo toxicity in older adults with cancer. **Methods:** Patients (pts) age ≥65, diagnosed with a solid malignancy, and starting a new chemo regimen at City of Hope were eligible (NCT02517034). In a 2:1 ratio, 600 pts were randomly assigned to either GAIN (n = 398) or SOC (n = 202) arms. All pts completed a baseline GA prior to chemo. In the GAIN arm, a multidisciplinary team led by a geriatric oncologist, nurse practitioner, social worker, physical/occupation therapist, nutritionist, and pharmacist, reviewed GA results and implemented interventions based on predefined triggers built into the GA's various domains. In the SOC arm, GA results were sent to treating oncologists to use at their discretion. Pts were followed until either end of chemo or 6 months after start of chemo, whichever occurred first. The primary endpoint was incidence of grade 3-5 chemo-related toxicity (NCI CTCAE v.4.0). Secondary endpoints included advance directive (AD) completion, emergency room (ER) visits, hospitalizations, and average length of stay (ALOS). Chi-square and Fisher's exact tests were used to compare the categorical outcomes, and Kruskal-Wallis test was used to compare the ALOS between arms. **Results:** Pt characteristics were balanced between arms. Median age was 71 (range 65-91). Cancer types included: 33% gastrointestinal, 23% breast, 16% lung, 15% genitourinary, and 13% other. Most (71%) had stage IV disease. The incidence of grade 3-5 chemo-related toxicity was 50.5% (95% CI: 45.6-55.4%) in the GAIN arm and 60.4% (95% CI: 53.7-67.1%) in the SOC arm (p = 0.02). Compared to SOC, the GAIN arm had a reduction of 9.9% (95% CI: 1.6-18.2%) in chemo-related toxicity. At the end of study, AD completion increased 24.1% in the GAIN arm vs. 10.4% in the SOC arm (p < 0.001). No significant differences in ER visits (27.4% vs. 30.7%), hospitalizations (22.1% vs. 19.3%), or ALOS (median 4.8 vs. 5.0 days) were observed between the GAIN and SOC arms, respectively. **Conclusions:** Integration of multidisciplinary GA-driven interventions reduced grade 3-5 chemo-related toxicity and improved AD completion in older adults with cancer. GA-driven interventions should be included as a part of cancer care for all older adults. Clinical trial information: NCT02517034. Integrated geriatric assessment and treatment (INTEGERATE) in older people with cancer planned for systemic anticancer therapy. *First Author: Wee-Kheng Soo, Monash University Eastern Health Clinical School, Box Hill, Australia*

Background: Older people experience significant adverse effects of cancer and anti-cancer therapy due to age-related vulnerabilities, including medical, functional, cognitive, nutritional and psychosocial issues. Comprehensive geriatric assessment and management (CGAM) provides a powerful framework to assess an older person's health status and offers a coordinated, person-centered approach to care. Despite its effectiveness, the uptake of CGAM in oncology has been limited due to a lack of randomized evidence in this setting. This study evaluated the effectiveness of CGAM in older people with cancer. **Methods:** INTEGERATE is a prospective, randomized, parallel group, open-label study in patients aged >70 years with cancer planned for chemotherapy, targeted therapy or immunotherapy. Patients were randomly assigned (1:1) to receive either geriatrician-led CGAM integrated with usual care (integrated oncogeriatric care) or usual care alone, using minimization to balance treatment intent, cancer type, age, sex and performance status. Health-related quality of life (HRQOL) was assessed using the European Organisation for Research and Treatment of Cancer (EORTC) QLQ-C30 and QLQ-ELD14 at 0, 12, 18 and 24 weeks. The primary outcome was HRQOL measured by the validated Elderly Functional Index (ELFI) score. Major secondary outcomes included function, mood, nutrition, health utility, treatment delivery, healthcare utilization and survival. **Results:** Of the 154 patients who underwent randomization, 13 died by week 12 and 130 (92.2% of the remaining patients) completed at least two primary outcome assessments. For the primary outcome, patients in the intervention group had significantly better ELFI score than the usual care group across all followup timepoints, with a maximal difference at week 18 (estimated marginal mean ELFI score 72.0 vs 58.7, p= 0.001). In addition, significant differences favoring the intervention group over the usual care group were seen in HRQOL (domains: physical, role and social functioning; mobility, burden of illness and future worries), unplanned hospital admissions (-1.2 admissions per person-years, p< 0.001) and early treatment discontinuation (32.9% vs 53.2%, p = 0.01). **Conclusions:** Integrated oncogeriatric care led to improvements in HRQOL, unplanned hospital admissions and treatment discontinuation in older people receiving systemic anti-cancer therapy. Older people (>70 years) planned for anti-cancer therapy should receive CGAM to optimize their clinical care and health outcomes. Clinical trial information: ACTRN12614000399695. Randomized trial of a perioperative geriatric intervention for older adults with cancer. *First Author: Carolyn L. Qian, Massachusetts General Hospital, Boston, MA*

Background: Older adults with gastrointestinal (GI) cancers undergoing surgery often experience poor outcomes, such as prolonged postoperative (post-op) length of stay (LOS), intensive care unit (ICU) use, and readmissions. Involvement of geriatricians in the care of older adults with cancer can improve outcomes. We conducted a randomized trial of a perioperative geriatric intervention in older adults with GI cancers undergoing surgery. **Methods:** We randomly assigned patients age ≥65 with GI cancers planning to undergo surgical resection to receive a perioperative geriatric intervention or usual care. Intervention patients met with a geriatrician preoperatively in the outpatient setting and post-op as an inpatient consultant. The geriatrician conducted a geriatric assessment and made recommendations to the surgical/oncology teams. The primary end point was post-op LOS. Secondary end points included post-op ICU use, readmission risk, and patient-reported symptom burden (Edmonton Symptom Assessment System [ESAS]) and depression symptoms (Geriatric Depression Scale). We conducted both intention-to-treat (ITT) and per protocol (PP) analyses. **Results:** From 9/13/16-4/30/19, we randomized 160 patients (72.4% enrollment rate; median age = 72 [65-92]). The ITT analyses included 137/160 patients who underwent surgery (usual care = 68/78, intervention = 69/82). The PP analyses included the 68 usual care patients and the 30/69 intervention patients who received both pre- and post-op intervention components. In ITT analyses, we found no significant differences between intervention and usual care in post-op LOS (7.2 v 8.2 days, P = .37), ICU use (23.3% v 32.4%, p = .23), and readmission rates within 90 days of surgery (21.7% v 25.0%, p = .65). Intervention patients reported lower depression symptoms (B = -1.39, P < .01) at post-op day 5 and fewer moderate/severe ESAS symptoms at post-op day 60 (B = -1.09, P = .02). In PP analyses, intervention patients had significantly shorter post-op LOS (5.9 v 8.2 days, P = .02) and lower rates of post-op ICU use (13.3% v 32.4%, p < .05), but readmission rates were not significantly different (16.7% v 25.0%, p = .36). **Conclusions:** Although this perioperative geriatric intervention did not have a significant impact on the primary end point in ITT analysis, we found encouraging results in several secondary outcomes and for the subgroup of patients who received the planned intervention. Future studies of this perioperative geriatric intervention should include efforts, such as telehealth visits, to ensure the intervention is delivered as planned. Clinical trial information: NCT02810652. Research Sponsor: NCCN Foundation Young Investigator Award.

Effect of early integration of specialized palliative care into standard oncologic treatment on the quality of life of patients with advanced head and neck cancers: A phase III randomized controlled trial. *First Author: Pankaj Singhai, Tata Memorial Centre, Mumbai, India*

Background: Early palliative care is an important aspect of palliative treatment but has never been evaluated in head and neck cancer. Hence we performed this study. **Methods:** This was an open-label phase 3 randomised study which enrolled adult patients with squamous cell carcinoma of the head and neck region which warranted palliative systemic therapy. They were 1:1 allocated to either systemic therapy with (EPC arm) or without the addition of early palliative care service (STD arm). Patients were administered the Edmonton Symptom Assessment Scale (ESAS-r) and FACIT HN questionnaire at baseline and 4 weekly thereafter for 12 weeks. The primary endpoint was change in the quality of life (QOL) measured using FACIT HN 12 weeks after randomization. The secondary endpoints were changed in symptom burden at 12 weeks in ESAS-r and overall survival. A repeated-measures analysis of covariance (ANCOVA) was performed to examine the effects of arm and stratum on change in QOL (or symptom score), after controlling for baseline score. **Results:** Ninety patients were randomised in each arm between 1st June 2016 to 14th August 2017. The compliance with the questionnaires was 100% at baseline. In EPC arm the 70 patients were alive at 3 months and 67 (95.7%) completed the FACIT HN and 64 (91.4%) completed ESAS-r questionnaires. While in the STD arm out of 69 alive the corresponding figures were 61(88.4%) and 59 (85.5%) respectively. There was no statistical difference in change in QOL scores and ΔESAS-r at 12 weeks between the 2 arms (Table). The median overall survival was similar between the 2 arms. (Hazard ratio for death-1.006 (95%CI 0.7347-1.346)). **Conclusion:** In this phase 3 study, integration of early palliative care in head and neck cancer patients did not result in improvement in the quality of life scores, symptom scores or overall survival. Clinical trial information: CTRI/2016/03/006693. Research Sponsor: Tata Memorial Center Research Administration Council.

Δ Scores	Early Palliative Care arm	Standard arm	P-value

Randomized trial of a symptom monitoring intervention for hospitalized patients with advanced cancer (NCT03396510). *First Author: Ryan David Nipp, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Hospitalized patients with advanced cancer experience a high symptom burden, which is associated with poor clinical outcomes and increased health care use. Symptom monitoring interventions are increasingly becoming standard of care in oncology, but studies of these interventions in the hospital setting are lacking. We evaluated the impact of a symptom monitoring intervention in hospitalized patients with advanced cancer. **Methods:** We randomly assigned hospitalized patients with advanced cancer who were admitted to the oncology service to a symptom monitoring intervention or usual care. Patients in both arms reported their symptoms (Edmonton Symptom Assessment System [ESAS] and Patient Health Questionnaire 4 [PHQ4], higher scores on both indicate greater symptom severity) daily via tablet computers. Patients assigned to the intervention had their symptom reports presented graphically with alerts for moderate/severe symptoms during daily oncology rounds. The primary endpoint was the proportion of days with improved symptoms for those who completed two or more days of symptoms. Secondary endpoints included hospital length of stay (LOS) and readmission rates. **Results:** From 2/2018-10/2019, we randomized 390 patients (76.2% enrollment rate); 320 completed two or more days of symptoms (median age=65.6 [range 18.8-93.2]; 43.8% female). The most common cancers were gastrointestinal (36.9%), lung (18.8%), and genitourinary (12.2%). Nearly half of patients (48.5%) had one or more comorbid conditions in addition to cancer. We found no significant differences between intervention and usual care regarding the proportion of days with improved ESAS total (B=-0.05, P=.17), ESAS physical (B=-0.02, P=.52), PHQ4 anxiety (B=-0.03, P=.33), and PHQ4 depression (B=-0.02, P=.44) symptoms. Intervention patients also did not differ from usual care with respect to secondary endpoints of hospital LOS (7.50 v 7.59 days, P=.88) and readmission rates within 30 days of discharge (32.5% v 25.6%, P=.18). **Conclusions:** For hospitalized patients with advanced cancer, this symptom monitoring intervention did not have a significant impact on their symptom burden and health care use. These findings do not support the routine integration of this type of symptom monitoring intervention for hospitalized patients with advanced cancer. The positive outcomes seen in previous studies of symptom monitoring interventions may not be reproduced in other patient populations and care settings. Support: UG1CA189823; Clinical trial information: NCT03396510. Research Sponsor: U.S. National Institutes of Health.

Impact of augmented intelligence (AI) on utilization of palliative care (PC) services in oncology. *First Author: Ajeet Gajra, Cardinal Health, Dublin, OH*

Background: Timely integration of palliative care in the management of patients with advanced cancer is a quality benchmark in oncology. However, PC is often underutilized as evidenced by delays in identification of appropriate patients, in referrals to a PC service, and in enrollment to hospice. Jvion has developed a prescriptive analytics solution, the Machine, which combines AI algorithms with machine learning techniques and applies them to clinical and exogenous datasets to identify patients with a propensity for poor outcomes. The Machine was applied to risk for patients' mortality within next 30 days, and recommended patient-specific, dynamic, and actionable insights. Use of the Machine requires no additional documentation within the electronic health record (EHR) and the insights generated can be integrated back in to any EHR to help inform the care plan. Herein, we report the results of a study evaluating the impact of AI-driven insights on PC utilization at a large community oncology practice. **Methods:** All patients were scored weekly using the Machine PC vector. The Machine risk stratified the patients and generated recommendations for the provider to consider as they developed a care plan. Patients identified as "at risk" by the Machine were assessed for a supportive care visit (PC referral) and then were referred as deemed clinically appropriate. The average monthly rates of PC consults and hospice referrals were calculated 5 months prior to and for 17 months after the launch of the Machine in the practice. **Results:** The oncology practice has 21 providers managing an average of 4329 unique patients per month (PPM). The mean rate of PC consults increased from 17.3 to 29.1 per 1000 PPM pre and post Machine deployment respectively (+168%). The mean monthly rate of hospice referrals increased by 8-fold from 0.2 to 1.6 per 1000 PPM pre and post deployment respectively. Eliminating the first 6 months of Machine deployment to account for user learning curve, the mean rates of monthly PC consults nearly doubled over baseline to 33.0, and hospice referrals rose 12-fold to 2.4 per 1000 patients in months 7-17 post Machine deployment. **Conclusions:** This oncology practice found deployment of this novel AI solution to be feasible and effective at generating actionable insights. These AI driven insights could be incorporated into workflow and improved the decision-making for whether and when a patient should be referred to PC and/or hospice services for end of life care. Further study is needed to confirm the value of AI for management of cancer patients at end of life. Research Sponsor: Jvion and Cardinal Health.

Risk of cardiovascular disease in women with and without a history of breast cancer: The Pathways Heart Study. *First Author: Heather Greenlee, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Breast cancer (BC) survivors are at increased risk of cardiovascular disease (CVD) following diagnosis, as compared to women without BC. To provide a population-based estimate of CVD risk in BC survivors, we compared risk of CVD events in women with and without BC history enrolled in the Kaiser Permanente Northern California (KPNC) integrated health system. **Methods:** Data were extracted from KPNC electronic health records. All invasive BC cases diagnosed between 2005-2013 were identified and matched 1:5 with non-BC controls on birth year, race/ethnicity and KPNC membership at date of BC diagnosis. Cox regression models were used to assess differences in the hazard of four major CVD events (ischemic heart disease (IHD), heart failure (HF), cardiomyopathy, and stroke). Models were adjusted for factors known to influence risk of breast cancer or CVD.Other CVD events included arrhythmia, cardiac arrest, carotid disease, myocarditis/pericarditis, transient ischemic attack, valvular disease, and venous thromboembolism (VTE). We additionally examined subgroups of cases who received chemotherapy, radiation, and endocrine therapy, and their controls. **Results:** A total of 14,942 women with a new diagnosis of invasive BC were identified and matched to 74,702 women without BC history. On average, women were 62.0 years, 28.3 kg/m^{2}BMI, 64.9% non-Hispanic white. Among all cases and controls, there were no significant differences in hazard of developing IHD, cardiomyopathy, and stroke; there was a borderline difference in HF (HR: 1.08, 95% CI: 0.99, 1.19). Cases were more likely to have a cardiac arrest (HR: 1.39, 95% CI: 1.09, 1.78) and develop VTE (HR: 1.97, 95% CI: 1.74, 2.23). Women treated with chemotherapy were more likely than controls to develop HF (HR: 1.44, 95% CI: 1.21, 1.72), cardiomyopathy (HR: 2.01, 95% CI: 1.02, 3.98), and VTE (HR: 3.15, 95% CI: 2.62, 3.79). Women who received radiation therapy were more likely to develop carotid disease (HR: 5.49, 95% CI: 1.22, 24.66) and VTE (HR: 1.65, 95% CI: 1.35, 2.03) than controls. Women who received endocrine therapy were more likely to experience a cardiac arrest (HR: 1.49, 95% CI: 1.07, 2.09) and develop VTE (HR: 1.70, 95% CI: 1.42, 2.03) than controls. **Conclusions:** Women with BC were at increased risk of heart failure, cardiomyopathy, cardiac arrest, VTE and carotid disease. These risks varied by cancer treatment, with higher risk in those who received chemotherapy. Future studies should explore the effects of chemotherapy class and radiation dose exposure on diverse CVD endpoints in BC survivors. Research Sponsor: U.S. National Institutes of Health.

Onset of cardiovascular disease risk factors in women with and without a history of breast cancer: The Pathways Heart Study. *First Author: Marilyn L. Kwan, Kaiser Permanente, Oakland, CA*

Background: Women with a history of breast cancer (BC) are at increased long-term risk of dying from cardiovascular disease (CVD). However, the onset of CVD risk factors in women with BC has not been well-described. We compared risk of incident CVD risk factors in women with and without BC enrolled in the Kaiser Permanente Northern California (KPNC) integrated health system. **Methods:** Data were extracted from KPNC electronic health records. All invasive BC cases diagnosed between 2005-2013 were identified and matched 1:5 with controls on birth year, race/ethnicity and KPNC membership at the date of BC diagnosis. Cox regression models assessed the hazard of incident hypertension (based on diagnosis codes and filled prescriptions), dyslipidemia (based on diagnosis codes, filled prescriptions, and lab values), and diabetes (KPNC Diabetes Registry). Models were adjusted for baseline BMI, menopausal status, smoking status, neighborhood median household income, education, prevalent CVD conditions, and other baseline CVD risk factors. Subgroups of women who received chemotherapy, radiation therapy, and endocrine therapy were compared with controls. **Results:** A total of 14,942 women with a new diagnosis of invasive BC were identified and matched to 74,702 controls. On average, women were 62.0 years, 28.3 kg/m^{2}BMI, 64.9% non-Hispanic white. Overall, cases were more likely to develop hypertension (HR: 1.18, 95% CI: 1.13, 1.24) and diabetes (HR: 1.23, 95% CI: 1.16, 1.31). Across the board, receipt of any of the three therapies (chemotherapy, radiation therapy and endocrine therapy) was associated with increased risk of hypertension and diabetes, compared to controls. Risk-factor specific hazard ratios for receipt of chemotherapy were (HR 1.18, 95% CI: 1.10, 1.27) and (HR 1.38, 95% CI: 1.26, 1.51), for hypertension and diabetes, respectively. For receipt of radiation therapy, risk-factor specific hazard ratios were (HR: 1.17, 95% CI: 1.09, 1.26) and (HR: 1.15, 95% CI: 1.04, 1.27), for hypertension and diabetes, respectively. Risk-factor specific hazard ratios for receipt of endocrine therapy were (HR: 1.22, 95% CI: 1.14, 1.30) and (HR: 1.16, 95% CI: 1.06, 1.27), for hypertension and diabetes, respectively. **Conclusions:** The risk of developing hypertension and diabetes is increased in women with BC who received chemotherapy, radiation therapy, and/or endocrine therapy. Future studies should examine the roles of CVD risk factor diagnosis and management on cardiometabolic risk in women with a BC history. Research Sponsor: U.S. National Institutes of Health.

Effect of a tailored exercise intervention during or after chemotherapy on cardiovascular morbidity in cancer patients. *First Author: Gabriela G.F. Giovanna Femma van der Schoot, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Cancer treatment outcome may be impaired due to treatment-related adverse effects like decreased cardiorespiratory fitness. Evidence on exercise during or after chemotherapy shows positive effects on cardiorespiratory fitness, fatigue and quality of life (QoL) in cancer patients. However, optimal timing of starting exercise is unknown. This study aimed to investigate if an exercise intervention that starts during chemotherapy (early group) is superior to a program starting after completion of chemotherapy (late group) to reduce cardiovascular morbidity. **Methods:** In this multicenter randomized controlled trial, 266 patients (testicular-, (n = 95), breast-, (n = 139), and colon cancer (n = 30) or non-Hodgkin lymphoma (NHL) (n = 2)), treated with curative chemotherapy were randomized to a 24 week aerobic and resistance exercise intervention starting either early, i.e. during chemotherapy (n = 131) or late, i.e. at completion of chemotherapy (n = 135) (NCT01642680). Effect on VO_2 peak was evaluated with intention-to-treat linear mixed-effect models, adjusted for baseline values (T0) and diagnosis at post-chemotherapy (T1), post-exercise intervention (T2) and 1-year post-exercise intervention (T3, i.e., primary endpoint). Here we report T0, T1 and T2 data. Secondary endpoints were QoL (EORTC-QLQ-C30) and fatigue (MFI-20), with higher scores indicating more fatigue. **Results:** Median age was 33 yrs for testicular-, 52 yrs for breast- and 64 yrs for colon cancer and NHL patients. Patients in the early group declined significantly less in VO_2 peak and QoL at T1 compared to the late group (adjusted between-group differences were 3.2 ml/min/kg (95% confidence interval CI 2.3 to 4.1, $P < 0.0001$) and 5.8 (95% CI 0.6 to 10.9, P = 0.028). Patients in the early group experienced reduced general and physical fatigue at T1 (adjusted between-group differences were -2.0 (95% CI -3.3 to -0.8, P = 0.002) and -2.9 (95% CI -4.3 to -1.5, $P < 0.0001$). At T2, VO_2 peak, QoL, general and physical fatigue were comparable and regained baseline levels (adjusted between-group differences - 0.08 ml/min/kg (P = 0.9), -1.4 (P = 0.7), 0.7 (P = 0.3) and 0.2 (P = 0.7), respectively. **Conclusions:** A supervised exercise program for patients with testicular-, breast- and colon cancer that is initiated at start of curative chemotherapy effectively reduces a decline in VO_2 peak and QoL and reduces fatigue. After completion of the exercise intervention, initiated both during and after chemotherapy, patients regained their baseline VO_2 peak, levels of fatigue and QoL. Clinical trial information: NCT01642680. Research Sponsor: Dutch Cancer Society. Grant: DCS 2011-5265.

Predictive model of aromatase inhibitor non-adherence using patient-reported outcomes in women with breast cancer (SWOG S1105). *First Author: Dawn L. Hershman, Columbia University Medical Center, New York, NY*

Background: Non-adherence to aromatase inhibitors (AIs) for breast cancer is common and increases risk of recurrence. Few prospective studies have systematically evaluated factors associated with non-adherence. We analyzed baseline sociodemographic, prescription, and patient reported outcome (PRO) symptoms and quality-of-life to identify factors associated with non-adherence prospectively over 3-years. **Methods:** Patients enrolled in SWOG S1105 were required to have been on an AI for ≥30 days. Patients were assessed for non-adherence to AIs every 3 months for 36 months, with non-adherence defined as urine AI metabolite assay results satisfying any of the following: < 10 ng/mL, undetectable, specimen submitted outside of the ± 21 day follow-up appointment window, or no submitted specimen. At baseline patients were asked about insurance, pill number dispensed and medication cost, and they completed PROs focused on pain and endocrine symptoms (BPI (Brief Pain Inventory), FACT-ES (Endocrine Symptoms)), as well as their beliefs about medications (TSQM (Treatment Satisfaction Questionnaire for Medicine) and BMQ (Brief Medication Questionnaire)). PRO scales were split at the median creating high vs low binary predictors. We determined the association of baseline factors and non-adherence at 36 months. We also evaluated an adverse risk model for AI non-adherence by summing the number of statistically significant adverse factors associated with non-adherence. Logistic regression was used. **Results:** In total, 724 patients were registered from 40 institutions between May, 2012 and September, 2013. The median age was 60.9 years, and 64.5% were on AI < 12 months prior to registration. Overall, 35.9% were non-adherent at 36 months. Younger patients (< 65 years) were less adherent (39% vs. 29% non-adherence, OR = 1.51, p = 0.02). Baseline scores on the BPI, FACT-ES, BMQ and TSQM were each statistically significantly associated with AI adherence. Non-adherence was significantly higher among patients scoring poorly on all 4 PRO instruments (65%) compared to those scoring poorly 0 or 1 PRO instruments (27%; OR, 4.68 [2.84-7.73], p < .0001). For each increase in the number of adverse risk PRO scores, the risk of non-adherence increased by 45% (OR = 1.45, p < .0001). Similar results were found when age was included in the score. **Conclusions:** Presence of multiple baseline risk factors identified through PRO instruments increases non-adherence to AI's 4-fold. Use of PROs can identify patients for targeted interventions to improve adherence. Impact of baseline symptom burden as assessed by patient-reported outcomes (PROs) on overall survival (OS) of patients with metastatic cancer. *First Author: Atul Batra, Tom Baker Cancer Center, Calgary, AB, Canada*

Background: Patients with metastatic cancer experience variable symptom burden, but serial symptom assessments using PROs may be challenging to implement in routine clinical practices. We aimed to determine if a single measurement of symptom burden at the time of metastatic diagnosis is associated with survival. **Methods:** We examined prospectively collected baseline PROs of patients newly diagnosed with metastatic breast, lung, colorectal, or prostate cancer using the revised Edmonton Symptom Assessment System (ESASr) questionnaire from a large province (Alberta, Canada) between 2016 and 2019. The ESASr was categorized into physical (PH), psychosocial (PS), and total symptom (TS) domains whereby scores were classified as mild (0-3), moderate (4-6), or severe (7-10). Multivariable Cox proportional hazards models were constructed to evaluate the effect of baseline symptom scores on OS. **Results:** We identified 1,315 patients, of whom 57% were men and median age was 66 (IQR, 27-93) years. There were 180, 601, 240, and 294 patients with breast, lung, colorectal, and prostate cancer, respectively. Approximately one-quarter of all patients reported moderate to severe PH, PS, and TS scores, with lung cancer patients experiencing the highest symptom intensity across all domains ($P<0.0001$). While age did not affect symptom scores, women were more likely to report severe PH, PS, and TS scores as compared to men ($P=0.02$, 0.002, and 0.007, respectively). On multivariable Cox regression analysis, older age (HR 1.02, 95% CI, 1.02-1.03, $P<0.0001$) and female sex (HR 1.67, 95% CI, 1.39-1.99, $P<0.0001$) were predictive of worse OS as were severe baseline PH and TS scores (see Table) . However, baseline PS scores were not related to OS. **Conclusions:** A single assessment of baseline symptom burden using the ESASr in patients with metastatic cancer has significant prognostic value. This may represent a feasible first step toward routine collection of PROs in real-world settings where serial symptom measurements can be challenging to implement. Research Sponsor: None.

OS by symptom burden.

Group (n)	Median OS, in months (95% CI)	HR (95% CI)	*P* value
PH			
Mild (885)	33.5 (30.2-36.4)	-	-
Moderate (368)	12.2 (10.1-15.1)	1.68 (1.32-2.13)	<0.0001
Severe (62)	10.8 (4.9-17.7)	1.89 (1.26-2.83)	0.002
PS			
Mild (946)	29.1 (25.5-33.3)	-	-
Moderate (243)	16.1 (12.4-20.8)	1.15 (0.94-1.41)	0.17
Severe (117)	10.7 (8.1-16.9)	1.13 (0.85-1.52)	0.39
TS			
Mild (924)	32.5 (28.6-35.1)	-	-
Moderate (350)	12.2 (10.1-15.1)	1.27 (0.96-1.68)	0.09
Severe (41)	7.9 (3.5-16.9)	1.71 (1.01-2.91)	0.04

Integrating PROs with prognostic value into oncologic care: High ESAS global distress score associated with lower overall survival in advanced cancer patients. *First Author: Ishwaria Mohan Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite compelling data supporting their use, patient reported outcomes (PROs) are not widely integrated into routine cancer care. In our Palliative Care (PC) practice, all patients complete the Edmonton Symptom Assessment Scale (ESAS), a simple, validated 10-item PRO tool which uses a 0 to 10 rating of 10 common symptoms (pain, fatigue, nausea, drowsiness, appetite, sleep, dyspnea, well-being, anxiety & depression). Our team has previously validated the Global Distress Score (GDS), a sum of 9 physical + psychosocial ESAS items. Here, we studied the implementation of the GDS as a streamlined way to capture the overall symptom burden while providing prognostic value. **Methods:** We queried a PC database for patients w metastatic cancer at time of 1st PC visit. GDS was calculated & grouped into 3 cohorts based on previous work & clinical experience: high (GDS of 35+), Moderate (16-34) or Low (0-15). Overall Survival was defined as time from 1st PC visit date to death. Regression analysis, ANOVA and t-tests were conducted. **Results:** 333 patients met the inclusion criteria: median age 62.4y (range 20.5-88.4y), 25 AYA (15-39y), 169 mid age (35-64y), 140 seniors (65y+); 190 female 143 male; median prior therapies 2 (range 0-11), 227 patients were in 2nd line + above therapy. Median ECOG PS 2; 124 patients w ECOG PS 3 & 33 w ECOG PS 4. 262 patients had died at time of analysis. Lower OS was associated w higher GDS (r 0.21, $P < 0.001$). OS in Low, Mod, High GDS cohorts was 13.1m, 7.9m, & 3.7m, respectively ($p < 0.001$). There were no sig OS difference between 3 age cohorts (AYA 5.2m, mid age 6m, seniors 5.4m, p0.56). **Conclusions:** Higher GDS score was associated with a clinically significant decrease in overall survival highlighting the potential of the ESAS as a PRO tool in prognostication and clinical decision making for patients with advanced cancers with a high symptom burden. In the realm of increasingly complex PRO instruments, the ESAS represents a simple, well-validated tool which, in our studies and 25 years of clinical experience, takes the patient less than a minute to complete, with subscores such as the GDS which carry a highly prognostic utility for patients with advanced cancers. Temporal trends in opioid prescribing patterns among oncologists in the Medicare population. *First Author: Vikram Jairam, Department of Therapeutic Radiology, Yale School of Medicine, New Haven, CT*

Background: In the wake of the United States (U.S.) opioid epidemic, there have been significant governmental and societal efforts to curb opioid prescribing. However, it is unknown whether these efforts have affected prescribing among oncologists, whose patient population often requires narcotics for symptom management. We investigated temporal patterns in opioid prescribing for Medicare patients among oncologists. **Methods:** We queried the Centers for Medicare and Medicaid Services Part D prescriber dataset to identify independently practicing physicians between January 1, 2013 and December 31, 2017. We used population-averaged multivariable negative binomial regression to estimate the association between time and per-provider opioid prescribing rate, defined as number of opioid claims (original prescriptions and refills) per 100 patients, among oncologists and non-oncologists on both a national and statewide level. All models were adjusted for provider characteristics and annual total patient count per provider. **Results:** The final study sample included 20,513 oncologists and 711,636 non-oncologists. From 2013 to 2017, the national opioid prescribing rate declined by 19.3% (68.8 to 55.5 opioid prescriptions per 100 patients; $P< 0.001$) among oncologists and 20.4% (50.7 to 40.3 prescriptions per 100 patients; $P< 0.001$) among non-oncologists. During this timeframe, 40 U.S. states experienced a significant ($P< 0.05$) decrease in opioid prescribing among oncologists, most notably in Vermont (-43.2%), Idaho (-34.5%), and Maine (-32.8%). In comparison, all 50 states exhibited a significant decline ($P< 0.05$) in opioid prescribing among non-oncologists. In 5 states, opioid prescribing decreased more among oncologists than non-oncologists, including Oklahoma (-24.6% vs. -7.1%), Idaho (-34.5% vs. -17.8%), Utah (-31.7% vs. -18.7%), Texas (-19.9% vs. -14.7%), and New York (-24.0% vs. -19.7%) (all $P< 0.05$). **Conclusions:** Between 2013 and 2017, the opioid prescribing rate decreased by approximately 20% nationwide among both oncologists and non-oncologists. These findings raise concerns about whether opioid prescribing legislation and guidelines intended for the non-cancer population are being applied inappropriately to patients with cancer and survivors. Prevalence and temporal trends of prescription drug use in cancer survivors: A population study, 2001 to 2016. *First Author: Elisa Liu, NYU School of Medicine, New York, NY*

Background: The burden of prescription drug use is higher in cancer survivors than the general population. We examined the prevalence and temporal trends of prescription drug use among cancer survivors, with an emphasis on central nervous system (CNS) active medications used to manage long-term cancer sequelae. **Methods:** Adult respondents with (n=3207) and without (n=40,440) a prior cancer diagnosis from 8 cycles (2001-2016) of the National Health and Nutritional Examinational Survey (NHANES) were evaluated for prescription drug usage. Cross-sectional analyses and temporal trends across cycles were evaluated and weighted to represent the US adult population. **Results:** Cancer survivors report higher rates of prescription drug usage (85.1% vs 54.3%, p<0.001, and 75.8%, p<0.001) and polypharmacy (27.8% vs 10.7%, p<0.001, and 22.7%, p<0.001) than both unadjusted and age-adjusted controls. Younger survivors report greater usage of CNS (36.8% vs 13.1%, p<0.001), psychotherapeutic (18.4% vs 7.7%, p<0.001), hormonal agents (19.1% vs 10.1%, p=0.003), and gastrointestinal (10.7% vs 4.7%, p=0.02) than controls, while differences are attenuated in older cohorts. Among broad drug categories, the usage of cardiovascular (p-trend<0.001), metabolic (p-trend<0.001), and immunologic agents (p-trend=0.01) has increased. Among CNS active subclasses, the usage of anticonvulsants (p-trend<0.001), anxiolytics (p-trend =0.02), narcotics (p-trend=0.02) and GABA analogs (p-trend<0.001) has increased. When comparing respondents with and without a history of cancer, the increased usage of anti-depressant prescription medications (18.3% vs 1.5% p<0.001), including SSRIs (11.2% vs 1.0%, p<0.001), SSNRIs (3.5% vs 0.3%, p<0.001), tricyclics (2.8% vs 0.1%, p<0.001), among cancer survivors was disproportionate compared to the increased proportion of positive depression screens (9.2% vs 7.0%, p=0.006). **Conclusions:** Cancer survivors report higher prescription drug use for both chronic conditions and late effects of cancer. The usage of CNS active medications, many of which are used on and off label for their pain management properties, has increased. The higher rates of pharmaceutical use may result in unanticipated long-term toxicities and financial burdens. Research Sponsor: None.

FDA analysis of ECOG performance status and safety outcomes. *First Author: Harpreet Singh, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Patients with poor performance status are often excluded from clinical trials. The FDA has published several guidances on modernizing oncology clinical trial eligibility criteria to more accurately reflect the patient population. Many patients receiving novel oncology therapeutics are heavily pretreated, and often have comorbidities, organ dysfunction, and frailty syndromes. Little is known about the safety of novel therapeutics in patients with poor performance status. **Methods:** Data from six randomized trials (n=4465) leading to registration for several solid tumor and malignant hematologic cancers, including multiple therapeutic mechanisms of action, such as EGFR TKI's, immune checkpoint inhibitors (ICI), and chemotherapy, were pooled. Cumulative incidence of Grade 3-5 adverse events and serious adverse events at Days 30, 90, and 180 were evaluated based on ECOG 0-2. Rates of treatment discontinuation by ECOG was also examined. **Results:** Cumulative incidence of toxicity events at days 30, 90, and 180 are shown in Table. Patient dropout rates due to death were 3.9%, 6.7%, and 10.9%; dropout rates due to disease progression were 66.5%, 66.6% and 56.9%; and dropout rates due to reasons other than progression or death were 29.7%, 26.7% and 32.1% for ECOG PS 0, 1 and 2, respectively. **Conclusions:** This FDA exploratory analysis of safety outcomes in registration trials based on ECOG suggests increasing rates of adverse events and rates of treatment discontinuation due to death with worsening performance status. Discontinuation rates due to disease progression and other reasons did not appear to be worse for ECOG 2 compared to 0-1. These findings were consistent across therapies (targeted therapy, ICI, chemotherapy). All trials in the analysis led to FDA approval, thus inclusion of patients with ECOG 2 did not adversely affect the trial outcome for this set of FDA approved agents. ECOG performance status eligibility criteria should be evaluated and modified on a frequent basis during drug development. Additional analysis of trials which enroll patients with ECOG 2 is needed. Research Sponsor: None.

Cumulative incidence of AEs at days 30, 90, and 180.

	ECOG 0 (n= 1260)	ECOG 1 (n= 2402)	ECOG 2-3 (n=803)
Serious Adverse Events			
Day 30	14.6%	19.3%	29.1%
Day 90	24.9%	33.8%	44.3%
Day 180	30.2%	40.4%	50.6%
Grade 3-5 Adverse Events			
Day 30	32.3%	36.5%	47.8%
Day 90	49.5%	55.5%	63.1%
Day 180	56.2%	63.1%	68.1%

Aggressive care at end-of-life in the Veteran's Health Administration versus fee-for-service Medicare among patients with advanced lung cancer. *First Author: Carolyn J Presley, The Ohio State University, Columbus, OH*

Background: The Veteran's Health Administration (VHA) allows simultaneous receipt of cancer treatment and hospice care, termed concurrent care, while fee-for-service Medicare does not. Although many physicians who care for patients in the VHA also care for private sector patients, it is unclear whether there is a "spillover" relation between end of life (EOL) care in the VHA and Medicare systems at the regional level. We examined temporal trends, as well as regional-level associations between Medicare and VHA EOL practice for patients with advanced lung cancer. **Methods:** We conducted a retrospective study on VHA and SEER-Medicare (SM) decedents from 2006-2012 with stage IV non-small cell lung cancer (NSCLC) who received any lung cancer care. Aggressive care (AC) at EOL was defined as any of the following within 30 days of death– intensive care unit (ICU) admission, no-hospice care, cardiopulmonary resuscitation(CPR), mechanical ventilation (MV), > 1 inpatient admission and receipt of chemotherapy. Descriptive statistics were used to compare outcomes. We also analyzed the association between Medicare hospital referral region (HRR) hospice admissions, Medicare HRR EOL spending, and VHA AC use adjusted for patient's characteristics using a random intercept mixed effect logistic regression model after matching VHA facilities with Medicare facilities in a particular HRR. **Results:** AC use significantly decreased during the study period, from 46% to 31% among 18,371 Veterans and from 42% to 38% among 25,283 in the SM cohort, (t-test $P < .05$). Hospice use significantly increased within both cohorts ($p < .001$). The receipt of chemotherapy at EOL was similar for both cohorts throughout the study period. Veterans who received care in regions with higher hospice admissions among Medicare beneficiaries were significantly less likely to receive AC at EOL (adjusted Odds Ratio (aOR): 0.13 95%CI: 0.08-0.23, $P < .001$) than veterans in regions with lower Medicare hospice use. Medicare HRR spending at the EOL was not associated with receipt of AC among Medicare beneficiaries (aOR): 1.004 95%CI: 1.00-1.009, P = 0.07). **Conclusions:** Perhaps due to availability of concurrent care, VHA patients received less aggressive care at EOL as compared to SM patients. At the regional level, greater hospice use among Medicare beneficiaries was significantly associated with reduced AC within the VHA. 12026 Poster Session (Board #314), Fri, 8:00 AM-11:00 AM

Impact of palliative care on end-of-life outcomes in hematologic malignancies. *First Author: Ari Pelcovits, Brown University, Providence, RI*

Background: Patients (pts) with hematologic malignancies (HMs) receive more aggressive end-of-life (EOL) care and often die in the hospital. The impact of palliative care (PC) on EOL quality outcomes in HMs has not been well described. In 2017 we embedded a PC specialist within our inpatient malignant hematology team to facilitate the use of early PC. We sought to determine if this practice was accompanied by a shift in EOL outcomes. **Methods:** We conducted a retrospective review of pts diagnosed with acute myeloid leukemia (AML) at our institution in the 2 years before (Cohort A) and after (Cohort B) implementation of embedded PC. We identified pts who received PC and if it was early (during initial inpatient stay) or late (sometime after). We then examined EOL quality outcomes: hospitalizations and intensive care (ICU) admissions in the last 30 days of life, chemotherapy use in the last 14 days of life, and use of hospice and death out of hospital (DOH), using Fisher's exact test to compare proportions. **Results:** Among 139 AML pts, 46 in Cohort A, 93 in Cohort B, we identified 34 and 47 decedents in each cohort respectively. The use of PC was significantly higher in Cohort B (75% vs 43%, $P= 0.0006$), with a significant increase in early PC (52% vs 11%, $P < 0.0001$). There was no significant improvement in EOL quality outcomes between Cohort A and B, or uniquely among pts receiving early PC ($P > 0.05$); however, PC use in general across all cohorts was associated with significant increase in hospice use and fewer ICU admissions (P =0.016 and 0.0043, respectively). Among pts not receiving PC, a numerical improvement was noted in EOL metrics between Cohorts A and B ($P > 0.05$; see table). **Conclusions:** PC for pts with AML was associated with significantly better EOL quality outcomes. We also observed improvement in EOL metrics over time among pts not receiving PC, which may indicate a culture shift with the embedded PC service, whose benefit extended to pts not directly receiving PC. Embedding a PC specialist and early PC in AML, however, was not significantly associated directly with EOL care improvements. The value of these interventions in HMs may be better measured using patient-reported outcomes and quality of life measures rather than strict EOL outcomes. Further research should consider potential differential role of PC among pts with HM undergoing aggressive/curative, or non-intense/palliative therapy. Research Sponsor: None.

	Overall				No PC	
	Cohort A	Cohort B	PC	No PC	Cohort A	Cohort B
Hospice Use	59%	63%	72%	43%	31%	58%

12027 Poster Session (Board #315), Fri, 8:00 AM-11:00 AM

The adoption of immune checkpoint inhibitors and patterns of care at the end of life. *First Author: Fauzia Riaz, Stanford School of Medicine, Stanford, CA*

Background: As immune checkpoint inhibitors (ICIs) have transformed the care of patients with cancer, it is unclear whether treatment at end of life (EOL) has changed. Because aggressive therapy at EOL is associated with increased costs and patient distress, we explored the association between the FDA approvals of ICIs and treatment patterns at EOL. **Methods:** We conducted a retrospective, observational study using patient-level data from the Flatiron health EHR-derived de-identified database. Patients had advanced melanoma, non-small cell lung cancer (NSCLC) (cancer types with an ICI indication) or microsatellite stable (MSS) colon cancer (a cancer type without an ICI indication) and died between 2013 and 2017. We calculated annual proportions of decedents who received systemic cancer therapy in the final 30 days of life and used logistic regression to model the association between the post-ICI Federal Drug Administration (FDA) approval time period and use of systemic therapy at EOL, adjusting for patient characteristics. We also assessed the use of chemotherapy or targeted/biologic therapies at EOL, before and after FDA approval of ICIs using Pearson Chi Square test. **Results:** There was an increase in use of EOL systemic cancer therapy in the post-ICI approval period for both melanoma (33.9% to 43.2%, p-value < 0.001) and NSCLC (37.4% to 40.3%, p-value < 0.001). In contrast, the control group of decedents with MSS colon cancer demonstrated no significant increase in use of systemic therapy at EOL. After controlling for patient characteristics, there was a significantly higher odds of receiving systemic treatment at EOL in the post-ICI time period compared to the pre-ICI time period in melanoma (OR 1.42, 95% CI 1.09-1.86, p-value < 0.001) and NSCLC (OR 1.13, 95% CI 1.06-1.20, p value < 0.001), with no significant difference in receipt of systemic therapy in patients with MSS colon cancer. After FDA approval of ICIs, patients with NSCLC and melanoma had a decrease in the use of chemotherapy, with a concomitant increase in use of ICIs at EOL. Decedents with MSS colon cancer did not have a statistically significant change in use of chemotherapy or targeted/biologic therapies during the study period. **Conclusions:** The adoption of ICIs was associated with a substantive increase in the use of systemic therapy at EOL in melanoma, and a smaller yet significant increase in NSCLC. Research Sponsor: U.S. National Institutes of Health.

12028 Poster Session (Board #316), Fri, 8:00 AM-11:00 AM

Impact of performance status on response and survival among patients receiving checkpoint inhibitors for advanced solid tumors. *First Author: Mridula Krishnan, University of Nebraska Medical Center, Omaha, NE*

Background: Clinical trials leading to the approval of immune checkpoint inhibition (ICI) have almost exclusively been performed in patients with good performance status (ECOG PS of 0-1). However, ICI remains an attractive option for patients with advanced tumors and poor performance status, considering their overall tolerability. While use of ICI in patients with poor PS (ECOG PS of 2 or greater) has been rapidly adopted, whether these patients derive the same benefits as expected in the studied populations is largely unknown. We therefore performed an institutional retrospective analysis of all patients treated with palliative single agent anti-PD1 or anti-PDL1 to determine response and survival for those with poor performance status. **Methods:** We retrospectively identified patients with advanced solid tumor malignancies who were treated with ICI monotherapy with palliative intent at our institution between 2015-2019. The primary objective was to compare overall survival (OS) for patients with good PS (ECOG PS 0-1) with those with poor PS (ECOG PS 2 or 3-4). The log-rank test compared the survival among patients with different ECOG PS. In addition, we used a proportional hazards model to assess association between ECOG PS and the OS with adjustment for age, gender, and smoking status. A secondary objective was to compare overall response rates (ORR) of the three ECOG PS groups which were evaluated with a binary rate model. **Results:** We identified 266 patients treated with ICI, 87 with NSCLC, 34 with melanoma, 33 with RCC, 24 with bladder cancer, 22 with head/neck cancer, and the rest with other histologies. 187 (70%) were ECOG PS 0-1, 62 (23%) were ECOG PS 2, and 17 (7%) were ECOG PS 3-4. 89 of these patients (33%) were still alive at time of last follow-up. Across all tumor types, patients with ECOG PS 0-1 had superior survival compared to ECOG PS 2 (median survival 12.4 months vs 4.6 months, HR 0.41, $p < 0.001$). Median survival for ECOG PS 3-4 was lower at 2.3 months. The ORR for ECOG PS 0-1 (23%) was significantly higher to that of ECOG PS 2 (6%, $p = 0.02$). ORR for ECOG PS 3-4 was 12%. **Conclusions:** Despite the appeal of ICI for patients with advanced malignancy and poor performance status, outcomes were poor. Survival and objective response rates for patients with ECOG PS 2 and higher were significantly worse than those with ECOG PS 0-1. ICI treatment comes with cost, including potentially forgoing early hospice referral or optimal support at the end of life. Prospective trials defining the activity and role of ICI in poor PS are urgently needed. Research Sponsor: None.

12029 Poster Session (Board #317), Fri, 8:00 AM-11:00 AM

Prospective study comparing self-administered geriatric assessment to provider's routine clinical assessment of older patients with metastatic breast cancer treated at community oncology practices. *First Author: Rino S. Seedor, Fox Chase Cancer Center, Philadelphia, PA*

Background: Geriatric Assessment (GA) is recommended for evaluating an older cancer patient's (pt) fitness for treatment. We conducted a prospective study evaluating the current gaps that exist in the assessment of older pts with metastatic breast cancer (MBC) in community practices (CP). **Methods:** Self-administered validated GA was compared to provider assessment (PA) of MBC pts $\geq$ 65-years-old treated at CP in the US. Providers were blinded to the GA results until their evaluation was completed. Differences in PA vs GA detected abnormalities were assessed using McNemar's test. The effect of patient/provider factors on the rate of abnormalities not identified was assessed using regression models, clustering by provider and adjusting for the number of prior pts seen. **Results:** 100 pts were enrolled across 9 CP (median age 73.9, (65-90)). GA detected a total of 356 abnormalities in 96/100 (96%) pts, of which 223 required immediate interventions. African American and widowed/single pts were more likely to have abnormalities identified by GA. On average PA did not identify abnormalities detected by validated GA in 2 of 8 domains. 73% of functional status, 86% of social support, 44% of nutritional, and 96% of cognitive abnormalities detected by GA were not identified by PA (all $P < 0.0001$). Providers with more years of clinical experience were more likely to identify abnormalities (compared to < 5 years (y) in practice: 5-10 y in practice, $p = 0.149$; 11-15 y in practice, $p = 0.028$; > 15 y in practice, $p = 0.017$). GA had the most significant impact on pts with decreased ECOG PS ($p = 0.045$). Pts found to have an abnormal Timed Up and Go (TUG) test were more likely to have additional abnormalities in other domains (mean 4.3 vs 2.1, Wilcoxon $p < 0.001$), and more abnormalities not identified by the PA ($p < 0.001$). Providers were "surprised" by GA results in 33% of cases, mainly with cognitive or social support findings, and reported plans for management change for 40% of pts based on GA findings. **Conclusions:** Including a GA in the care of older pts with MBC in CP is beneficial as validated GA has a high detection rate of abnormalities not detected by PA. 12030 Poster Session (Board #318), Fri, 8:00 AM-11:00 AM

Development and validation of an early death risk score for older patients treated with chemotherapy for cancer. *First Author: Jaime Feliu Batlle, Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain*

Background: Determining life expectancy in older patients is needed to select the best treatment strategy. We aimed to develop and validate a score to predict early death risk (< 6 months) in elderly patients with cancer that are planned to initiate chemotherapy treatment. **Methods:** Patients over 70 years starting new chemotherapy regimens were prospectively included in a multicenter study. A pre-chemotherapy assessment that included sociodemographics, tumor/treatment variables, and geriatric assessment variables, was performed. Association between these factors and early death was examined by using multivariate logistic regression. Score points were assigned to each risk factor based on their b coefficient. We validated the risk score with an external validation cohort of 206 patients. **Results:** Three hundred forty two patients were included in the training cohort. The independent predictors for early death were metastasic cancers (odds ratio [OR] 4.8, 95% confidence interval [CI], [2.4-9.6]), ECOG performance status (OR 2.3, 95% CI:1.084-5.232), ADL (OR 1.7, 95% CI:1.08-3.5), serum albumin levels (3.3, 95% CI: 1.6-6.6), BMI (OR 2.4, 95% CI:1,2-4.8), serum GGT levels (OR 1.5, 95% CI:1.05-1.8) and hemoglobin levels (OR 2.3, 95% CI:1.2-4.6). With these results, a score was to stratify patients regarding their risk of early death: low (0 to 2 points; 5%), intermediate (3 to 5 points; 19%) or high (6 to 14 points; 50%) ($p < 0.001$). The area under the curve of the receiver-operating characteristic (ROC) curve was 0.79 for the training cohort (95% CI, 0.74 to 0.85), and 0.70 (95% CI: 0.60-0.80) for the validation cohort (difference between cohorts not statistically different). **Conclusions:** We developed a highly accurate tool that uses basic clinical and analytical information to predict the probability of early death in elderly patients with cancer that are planned to initiate chemotherapy treatment. This tool can help physicians in decision making for this population of patients. Research Sponsor: None.

12031 Poster Session (Board #319), Fri, 8:00 AM-11:00 AM

Is there a benefit of immune checkpoint inhibitors for patients over 75 years of age with advanced cancer in first and second line setting: A meta-analysis. *First Author: Thierry Landre, UCOG-HUPSSD-APHP, Paris, France*

Background: The impact of aging on Immune Checkpoint Inhibitors (ICIs) effectiveness is controversial. Currently, data from clinical studies do not show any difference between patients over 65 years and those under 65 years. We propose to compare the clinical benefit of ICIs in those over 75 and in those under 75. **Methods:** We performed a meta-analysis of published randomized control trials (RCTs) concerning ICIs versus standard therapy in patients with advanced solid tumours. Overall Survival (OS) among the older ($\geq$75 years) was compared with that of younger patients (< 75 years) in first and second line setting. Hazard ratios (HRs) with their 95% confidence interval (CI) were collected from the studies and pooled. **Results:** Fifteen phase III studies evaluating anti-PD-1 (nivolumab or pembrolizumab), anti-PD-L1 (atezolizumab or avelumab) or anti-CTLA-4 (ipilimumab) were included. Patients were enrolled for Non-Small-Cell-Lung-Cancer, Renal-Cell-Carcinoma, Melanoma, Head-and-Neck-Squamous-Cell-Carcinoma or Gastric-Cancer. Eight studies assessed treatment in first line setting and seven in second line. The median age was 64 years, with 906 patients over 75 years of age and 5233 younger. In first line setting, HRs for death were 0.78 (95% CI: 0.61-0.99) in patients $\geq$75 years versus 0.84 (95% CI: 0.71-1.00) in younger. In second line setting, HRs for death were 1.02 (95% CI: 0.77-1.36) in patients $\geq$75 years versus 0.68 (95% CI: 0.61-0.75) in younger with a statistically significant difference observed between subgroups (p interaction = 0.009). **Conclusions:** ICIs appears to be effective in patients over 75 years of age. However, the survival benefit comes mainly from the first line of treatment. This result encourages the use of ICIs early in the therapeutic management of patients over 75 years of age. Research Sponsor: None.

12032 Poster Session (Board #320), Fri, 8:00 AM-11:00 AM

Omission of adjuvant chemotherapy in elderly patients with early stage breast cancer. *First Author: Sung Jun Ma, Department of Radiation Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Breast cancer incidence in elderly population over 70 years is anticipated to grow up to 35% by 2030. However, this elderly population is under-represented in the TAILORx (Trial Assigning Individualized Options for Treatment) with less than 5% of the entire study cohort. As the omission of radiation therapy among the elderly with favorable prognosis is a reasonable alternative option, omission of chemotherapy has not been prospectively investigated. To address this knowledge gap, we conducted an observational cohort study to evaluate the omission of chemotherapy in elderly patients with early breast cancer. **Methods:** The National Cancer Database (NCDB) was queried for patients above the age of 70 diagnosed with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative, pT1-2N0 breast cancer who underwent hormone therapy with or without chemotherapy (2010-2015). Kaplan-Meier method and Cox multivariable analysis (MVA) were performed for survival analysis. Propensity score matching in a 1:1 ratio without any replacement was used to address selection bias. Sensitivity analysis was performed on a subgroup of those with a high 21-gene recurrence score (RS) $>$ 25. **Results:** A total of 12004 patients were identified, including 10802 and 1202 patients with and without adjuvant chemotherapy, respectively. The median follow up was 38.2 months (IQR 22.5-57.2). On univariate analysis, chemotherapy was not associated with improved overall survival (HR 0.96, p = 0.71), ineligible for inclusion in the final MVA model. On interaction analysis, the use of chemotherapy had no interaction with RS (p = 0.46), age (p = 0.08), tumor size (p = 0.23), tumor grade (p = 0.42), and comorbidity score (p = 0.22). On 1030 and 689 matched pairs for all RS and RS $>$ 25, respectively, there was no association of overall survival with chemotherapy (all RS: HR 0.76, p = 0.08; RS $>$ 25: HR 0.74, p = 0.10). **Conclusions:** For elderly patients with early stage breast cancer, the addition of adjuvant chemotherapy may not be associated with improved survival even in the setting of high RS $>$ 25. Given the toxicity profile of systemic therapy, shared decision making between clinicians and elderly patients is needed to individualize treatment options. Research Sponsor: None.

Factors associated with referral for perioperative geriatric comanagement (GERI-CO) program in 12,398 older adults with cancer. *First Author: Armin Shahrokni, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: At ASCO 2019, we showed that the Memorial Sloan Kettering (MSK) Geriatric Co-management (GERI-CO) program was associated with improvement in 90-day postoperative mortality rate. Now, we present factors associated with the use of such program. **Methods:** At MSK, patients aged 75+ can be referred for perioperative GERI-CO. We retrospectively reviewed the available data of patients aged 75+ who underwent surgery within two months of their initial visit with the surgeon (2011 to 2019). Patients that were referred for GERI-CO were compared with those who were not: sociodemographic, frailty, comorbid conditions, and surgery characteristics. Frailty level was determined using the MSK Frailty Index (score ranges from 0-11, higher scores suggest more frailty). Multivariable regression analysis was used to assess factors associated with the use of the GERI-CO Program. **Results:** In total 12,398 patients (4422, 35.7% GERI-CO) were included. Average time from surgical consult to geriatric visit was 9 days. Patients in the GERI-CO program were older (80.7 vs. 79.6), less likely to be non-Hispanic White (87% vs. 91%), have English as primary language (84% vs. 89%), and be fit (12% vs. 17% with MSK-FI 0). They were more likely to have stroke history (5% vs. 4%), have diabetes (DM) (25% vs.20%), hypertension (78% vs. 71%), and peripheral vascular disease (14% vs. 12%), but less likely to have cardiac disease (22% vs. 26%), myocardial infarction (MI) (7% vs. 10%), pulmonary disease (13% vs. 16%). Patients referred for GERI-CO were more likely to undergo 3+ hours surgeries (25% vs. 8%), with 100+ cc intraoperative blood loss (41% vs. 22%), and hospital length of stay (LOS) of 3+ days (42% vs. 19%). In multivariable analysis, being frail (OR = 1.3 and 1.6 for MSK-FI 1-2 and 3+), longer surgery (OR = 2.6 and 3.6 for operation time 1.5-3 and 3+ hours), longer LOS (OR = 1.3 and 1.5 for LOS 1-2 and 3+ days), older age (OR = 1.06), having DM (OR = 1.15) were associated with higher likelihood of GERI-CO while having history of cardiac disease (OR = 0.55), MI (OR = 0.84), pulmonary disease (OR = 0.69) were associated with less likelihood of referral for GERI-CO. **Conclusions:** Our result shows the unique characteristics of patients managed in the GERI-CO program. This has implications for both implementation of GERI-CO program in other institutions and assessing outcomes of these patients. Research Sponsor: U.S. National Institutes of Health.

12035 Poster Session (Board #323), Fri, 8:00 AM-11:00 AM

Abbreviated geriatric assessment (GA) in new oncology patients and its association with early death. *First Author: Michael Maranzano, University of Chicago Medical Center, Chicago, IL*

Background: The ASCO 2018 Geriatric Oncology Guidelines support the broad application of GA to risk-stratify patients age ≥65 undergoing cancer-directed therapy. Despite this, GA has not been widely adopted due largely to perceived time and resource constraints. We administered an abbreviated GA by medical assistants (MAs) in an outpatient oncology clinic to explore its feasibility and correlation with adverse events. **Methods:** This is a single-institution, retrospective study of adults establishing oncology care at an academic medical center from 11/2016-4/2017. MAs completed an abbreviated GA of well-validated tests. Cognitive function was screened by the Mini-Cog (score $<$ 4) and physical function by the Five Times Sit-to-Stand Test (FTSST ≥ 15 seconds). Patient-reported Outcomes (PRO) screened for malnutrition by the Malnutrition Screening Test (MST ≥ 2), for vulnerability by Vulnerable Elders Survey (VES-13 ≥ 3) and for depression by Patient Health Questionnaire-4 (PHQ-4 $>$ 2). The first result within 3 months of the initial visit was used for analysis. ED visits, inpatient admissions and early death, defined as within the first 6 months from the initial visit, were collected from the electronic medical record. GA results and baseline characteristics were modeled for these events using univariate logistic regression. Multivariable regression was performed when univariate regression revealed at least 2 factors with p$<$ 0.1. **Results:** New patients 65+ years (n=304, median age 72) established care in our practice during this six-month period. Nearly all patients (n=285, 94%) completed at least one GA test. Fewer patients completed the Mini-Cog and FTSST (60% completed) compared to the PRO screenings (83-90% completed). Those with any positive GA screening test were nearly 3 times as likely to die within 6 months of their initial outpatient visit compared with those with no deficits (OR 2.95, 95% CI 1.11-9.30). Those with FTSST ≥ 15 sec or unable to complete were more likely to have an ED visit within 6 months (OR 2.40, 95%CI 1.04-5.46).No other individual screening test had a statistically significant association with adverse events. **Conclusions:** An abbreviated version of GA completed by MAs can be incorporated into new oncology patient visits for all older adults, and those with any abnormalities on screening tests had a higher likelihood of early death. Research Sponsor: None.

Adverse events by abbreviated GA.

	At Least 1 Positive Screening Test n = 143	All Negative Screening Tests n = 131
Death	15 (11%)	5 (4%)*
ED Visit	33 (23%)	28 (21%)
Admission	53 (37%)	52 (40%)

*p $<$ 0.05

12036 Poster Session (Board #324), Fri, 8:00 AM-11:00 AM

Association of geriatric comanagement with reduction in adverse surgical outcomes among patients 75 or older with cancer with prolonged hospital stay. *First Author: Armin Shahrokni, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients with prolonged hospital stay following surgery are at higher risk of readmission, emergency room visits, and mortality. In our study, we assessed the relationship between Geriatric Comanagement (GERI-CO) and adverse outcomes among these patients. **Methods:** In a retrospective study, patients aged 75+ with cancer who had hospital length of stay longer than 75% of cohort (8 days or longer) postoperatively at Memorial Sloan Kettering Cancer Center from 2011-18 were studied. GERI-CO status was obtained from medical records. Differences in sociodemographic, frailty, surgery, and comorbid conditions between GERI-CO and non-GERI-CO patients were assessed. Frailty was assessed by Memorial Sloan Kettering Frailty Index, score 0 to 11, higher score reflective of more frailty. Composite adverse outcome is a composite score of 30-day readmission, or emergency room visit, or 90 day mortality. Multivariable regression analysis was used to assess the relationship between GERI-CO and postoperative adverse outcome. **Results:** In total 1118 patients (634, 56.7% in the GERI-CO) were included. Patients in GERI-CO were older (80.8 vs. 79.9), more likely to undergo 3+ hours of surgery (66% vs. 43%), have 100+ cc intraoperative blood loss (78% vs. 72%), and have liver disease (16% vs. 10%), but were less likely to have kidney disease (19% vs. 25%), cardiac disease (28% vs. 35%), myocardial infarction (8% vs. 12%), pulmonary disease (15% vs. 20%), ASA-PS 4+ (11% vs. 21%) compared to non-GERI-CO patients. Gender, Frailty and the rest of comorbid conditions, and average length of stay (15 days) did not differ between groups. GERI-CO patients were less likely to have 30-day hospital admission (11% vs. 18%), emergency room visit (14% vs. 22%), or 90 day mortality (6% vs. 15%), and composite adverse outcome (20% vs. 37%) compared to non-GERI-CO patients. In the multivariable analysis, after adjustment for age, frailty, ASA-PS, operation time, intraoperative blood loss, kidney, cardiac and pulmonary disease, patients in GERI-CO were less likely to have composite adverse outcome (OR = 0.57, p = 0.002). **Conclusions:** GERI-CO program for patients with prolonged length of stay following surgery is associated with reduced 30-day hospital readmission, emergency room use, and 90-day mortality. Research Sponsor: U.S. National Institutes of Health.

12037 Poster Session (Board #325), Fri, 8:00 AM-11:00 AM

Treatment patterns and outcomes by age in metastatic melanoma: A study of the National Cancer Database. *First Author: Justin Moyers, Loma Linda University Medical Center, Loma Linda, CA*

Background: Metastatic melanoma carries poor prognosis and traditional chemotherapy has limited efficacy. Immune checkpoint inhibitors (ICI) have drastically improved disease outcomes since first approved in 2011. Elderly patients were underrepresented in landmark early trials of ICI leading to limited clinical trial data on efficacy and treatment patterns in this population. We aimed to examine the real-world IO outcomes and demographics of elderly patients in the National Cancer Database. **Methods:** We queried the database for patients with stage IV melanoma diagnosed between 2011-2015 with survival data available. Patients were divided into receipt of immunotherapy (IO) or no receipt of IO; those without documentation were excluded. Cases were separated into 3 cohorts of age at diagnosis (60 years-old or younger, 61-74 years-old, and 75 years-old and greater). Descriptive variables were compared by Chi-squared analysis and survival analyses were performed by Kaplan-Meier method and log-rank test. **Results:** 11,265 cases met inclusion criteria: 4,117 aged 60 or less, 3,940 aged 61-74, and 3,208 aged 75 or older. Those receiving immuno-oncologic agents (IO) in all age groups showed a longer median OS (mOS) than those who did not receive IO (mOS overall 17.28 v 7.49; $p<0.01$). Survival was longer in all age cohorts when IO was received compared to not received; ages less than 60 (mOS 20.3 v 9.2m; $p<0.01$), ages 61-74 (mOS 15.5 v 7.8m; $p<0.01$), and ages 75 or greater (mOS 14.4 v 5.8m; $p<0.01$). A greater percentage of patients received IO in younger than older cohorts, 20.1% in $\geq$ 75, 37.6% in 61-74, and 42.3% in $\leq$ 60; $p<0.01$. Additional descriptive variables shown in the table were compared between the cohorts include care at academic or integrated cancer network, uninsured, Charlson-Deyo Comorbidity Index (CDCI) of 2 or greater, and documented inclusion of palliative care treatment. **Conclusions:** Substantial survival benefit is realized with IO in all age cohorts although elderly cohorts did not receive IO as often as younger cohort. Elderly patients experienced lower rates of care at academic/network cancer programs, lower uninsured rate, and higher CDCI. Research Sponsor: None.

Variable	Age Category ≤60 years	61-74 years	≥ 75 years	p-value
Patients (n)	4117	3940	3208	
Received Immunotherapy (%)	42.3	37.6	20.1	<0.01
Treated in Academic or Network Cancer Programs (%)	59.0	55.9	48.9	<0.01
Uninsured (%)	8.7	3.0	0.5	<0.01
CDCI of 2 or greater (%)	4.2	8.3	10.5	<0.01
Palliative care included in treatment (%)	4.2	3.2	4.2	0.14

12038 Poster Session (Board #326), Fri, 8:00 AM-11:00 AM

Metastasis free survival in older men with nonmetastatic castration-resistant prostate cancer treated with androgen receptor inhibitors: An FDA-pooled analysis. *First Author: Harpreet Singh, U.S. Food and Drug Administration, Silver Spring, MD*

Background: The FDA has approved three androgen receptor (AR) inhibitors for nonmetastatic castration-resistant prostate cancer (nmCRPC) based on improvements in metastasis-free survival (MFS). MFS is an earlier endpoint, defined as the time from randomization to either imaging-detectable distant disease or death. This pooled analysis examines MFS, time to initiation of cytotoxic chemotherapy (TTCyto), and safety outcomes in men over 80 treated with AR inhibitors. **Methods:** Data was pooled from three randomized controlled studies (n=4117) of AR inhibitors for nmCRPC. The treatment effect of AR inhibitors on MFS and TTCyto across age groups was evaluated using Kaplan-Meier estimates and a Cox proportional hazards regression model. Hazard Ratios for MFS and TTCyto were adjusted for baseline ECOG, total Gleason score, PSA doubling time, and prior bone-targeting therapy. **Results:** For patients age 80 years or older (n=675) who were treated with AR inhibitors, the hazard ratio was 0.38 (95% CI 0.29, 0.49) with an estimated median MFS of 40 months (95% CI 36, 41) versus 22 months (95% CI 18, 29) for those treated with placebo (n=348). For patients <80 (n=2019) treated with AR inhibitors, the HR was 0.31 (95% CI 0.27, 0.36) with an estimated median MFS of 41 months (95% CI 36, NR) versus 16 months (95% CI 15, 18) for those treated with placebo (n=1075). Patients over 80 also derived similar improvements in time to initiation of cytotoxic chemotherapy (HR 0.43 95% CI 0.23, 0.82), compared to their younger counterparts (HR 0.41 95% CI 0.33, 0.50). See Table for selected safety outcomes. **Conclusions:** In an exploratory subgroup analysis, older men (≥80) with nmCRPC derived similar benefit in MFS and time to initiation of cytotoxic chemotherapy with AR inhibitors compared with younger patients. Men age 80 and above experienced higher rates of Grade 3-4 adverse events, serious adverse events, falls, and fractures. This trend towards increased toxicity was observed regardless of treatment arm. Analysis of patient reported outcomes is ongoing. Research Sponsor: None.

Toxicity and selected adverse events of AR inhibitors by age.

	Androgen Receptor Inhibitors		Placebo	
	Age < 80 (n=2015)	Age ≥ 80 (n=672)	Age < 80 (n= 1073)	Age ≥ 80 (n=344)
Grade 1-2	1123 (55.7)	323 (48.1)	608 (56.7)	177 (51.5)
Grade 3-4	603 (29.9)	249 (37.1)	244 (22.7)	106 (30.8)
Serious Adverse Events	461 (22.9)	206 (30.7)	190 (17.7)	99 (28.8)
Falls	166 (8.2)	101 (15)	51 (4.8)	27 (7.8)
Fractures	157 (7.8)	70 (10.4)	41 (3.8)	35 (10.2)

Hospitalizations following cancer diagnosis: National values for frequency, duration, and charges. *First Author: Michael T. Halpern, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: US medical care costs for cancer are projected to be $158 billion in 2020. Hospitalization is a substantial component of these costs; however, little is known about national patterns of hospitalization among individuals with cancer. This study used Medicare data to determine national rates and charges for hospitalizations among older cancer patients. **Methods:** We used data from 100% of individuals diagnosed with cancer in SEER-Medicare in the most recent 5 years available, 2011-2015. Analyses determined proportion of patients hospitalized, number/duration of hospitalizations, and charges by patient clinical and sociodemographic characteristics within 12 months of diagnosis. **Results:** Among 307,944 unique patients, 65% were hospitalized in the first year following diagnosis. Rates ranged from 34% for patients with in situ disease to 82%-84% for patients with advanced disease; 31% had 2 or more hospitalizations. Hospitalization rates were lowest among skin melanoma (25%) and breast (42%) cancer patients, highest for brain/nervous system (97%) and ovarian (96%) cancer patients. Hospitalized patients had a mean of 2.1 hospitalizations; mean days per hospitalization within 12 months was 8.8 (median 4). Duration of hospitalization varied little by stage at diagnosis. Mean days per hospitalization was shortest for thyroid and prostate cancer patients (5.7 & 6.0 days), longest for colorectal cancer and leukemia patients (10.6 & 11.3 days). DRGs varied substantially by cancer type; DRG for chemotherapy administration was more frequent among hospitalizations for patients with hematologic malignancies or distant stage disease. Mean Medicare charge (2016 $) per hospitalization was $67,368 (median $41,973), and was lowest for breast cancer patients ($48,021), highest for leukemia patients ($91,799). Patient charges per hospitalization averaged $1107 (median $1317) and showed little variation by cancer type or stage. **Conclusions:** Most older individuals experience at least one hospitalization within 12 months of cancer diagnosis. Frequency, duration, and charges of hospitalizations vary by cancer type and stage. This nationally representative information will aid in projecting cancer care costs and potential economic impacts of new therapies and treatment program. Research Sponsor: None.

12040 Poster Session (Board #328), Fri, 8:00 AM-11:00 AM

Communication about comorbidities among 527 older patients with advanced cancer and their oncologists and caregivers: A multisite cluster-randomized controlled trial. *First Author: Amber Kleckner, University of Rochester Medical Center, Rochester, NY*

Background: Older patients with advanced cancer often have comorbidities that increase the risk of toxicity from neoplastic therapy but are not always considered in treatment planning. We assessed the utility of a geriatric assessment (GA) intervention to increase the number and quality of discussions about comorbidities among oncologists, older patients, and caregivers. **Methods:** This multi-site trial enrolled patients who were ≥70 years, had advanced solid tumors or lymphoma, had ≥1 GA impairment, and who were considering or receiving cancer treatment. All patients received the GA and completed an Older Americans Resources and Services Comorbidity survey, which evaluated 15 conditions and interference with activities (clinical impairment = ≥3 comorbidities or ≥1 highly interfering). Oncology practices were randomized to intervention (GA with a summary with management recommendations provided to oncologists) or usual care (GA only). The clinic visit after GA was audio-recorded, transcribed, and coded for GA topics including comorbidity. Generalized linear mixed models adjusting for site (random effect) were used to assess the effect of the intervention. **Results:** Patients (n=527 evaluable, 76.6±5.2 years, 49% female) and oncologists (n=131, 63 in intervention) were enrolled from 31 sites. In total, 94.5% of patients had ≥1 comorbidity with an average of 3.2±1.9; 64% were clinically impaired by comorbidity (p=0.76 between arms). The intervention arm had twice the number of conversations about comorbidities (1.02 vs. 0.52 conversations per patient, difference 0.50, 95% CI 0.18-0.81, p=0.004) and conversations were more likely to be initiated by the oncologist ($p<0.001$, Table). Moreover, among patients who had conversations about comorbidities, more patients in the intervention arm had discussions specifically addressing comorbidities (e.g., cancer treatment modification, communication with the primary care physician; 24.3% vs. 7.5%, p=0.003). **Conclusions:** Providing oncologists with a GA summary and recommendations encouraged them to engage in more discussions about their patients' comorbidities with the goal of addressing interactions between comorbidities, cancer, and its treatments. Funds: PCORI CD4634, NCI UG1CA189961 Clinical trial information: NCT02107443. Research Sponsor: U.S. National Institutes of Health, Patient-Centered Outcomes Research Institute.

12041 Poster Session (Board #329), Fri, 8:00 AM-11:00 AM

Gait speed and recommended treatment intensity among older adults with blood cancers. *First Author: Andrew Hantel, Dana-Farber Cancer Institute, Boston, MA*

Background: Gait speed identifies frailty and predicts survival among older adults with hematologic malignancies (Liu, *Blood*, 2019). It is not known if gait speed correlates with the intensity of oncologists' recommended treatment in this population. **Methods:** From 2/2015-11/2019, patients ≥75 years presenting for an initial hematologic malignancy consultation at the Dana-Farber Cancer Institute were approached for a screening frailty assessment including a 4-meter gait speed test, reported as <0.4, 0.4-0.6, 0.6-0.8, or >0.8 meters/second (m/s). Faster gait speed is associated with less frailty and predicts better survival. Gait speed was not reported to the oncologist. Treatment recommendations were categorized into standard, reduced, or no therapy based on NCCN guidelines, as applicable. Gait/treatment intensity "mismatches" were characterized as patients with lowest quartile gait speed recommended standard intensity and highest quartile not recommended standard intensity. Multivariable regression was performed to assess if gait speed predicted treatment intensity (controlling for age, sex, ECOG performance status [PS], and disease type). **Results:** Of 786 patients enrolled, 408 required active treatment where NCCN guidelines vary by fitness. Mismatches were seen in 26.7% of patients (Table: column percentages with 95% CI, mismatches starred): 10 (21.3%) with lowest quartile gait speed recommended standard intensity and 99 (55.0%) with highest quartile recommended reduced or no therapy. In multivariable analysis, PS was predictive of no therapy as compared to standard intensity (all $p<0.02$) and age was predictive of reduced as compared to standard intensity ($p<0.01$); gait speed was not reliably predictive in either case. **Conclusions:** In this large cohort of older adults with hematologic malignancies, gait/treatment intensity mismatches occurred in over one-quarter of patients. Oncologists' recommendations were predicted by age and PS but not gait speed. Given that gait speed is a strong predictor of survival in this population, oncologists should integrate it to minimize over- and under-treatment when making treatment recommendations. 12044 Poster Session (Board #332), Fri, 8:00 AM-11:00 AM

Investigating the disparate enrollment of older adults on phase I clinical trials: Evolving participation patterns of patients 65 years and older w advanced cancer on phase I trials. *First Author: Ishwaria Mohan Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: While safety and dose-finding remain the primary objective of Phase 1 trials, the potential for clinical benefit has taken a greater meaning in the last decade with the novel therapies. With data from phase I trials being submitted for regulatory approval, the finer details of these studies are under even more scrutiny: in particular, do the trial participants reflect the general patient population for whom the drug may be indicated? To that end, we investigated age-based enrollment on phase I clinical trials over time. **Methods:** We queried a prospectively maintained database at a major phase I trials center to identify eligible patients and demographic + clinical variables including phase I trial characteristics, age at date of enrollment into 3 age-based cohorts: AYA ages 15-39y, mid-age 40-64y, older adults aged 65y+. We calculated descriptive statistics, and explored correlations (Pearson/Spearman) and associations (linear regression) between age and independent variables. **Results:** Over a 3-year period (1/1/17 to 12/31/19), we identified 6267 pts enrolled on 338 phase I trials. Median overall age 58.4y (range 15.5-95.1y). 729 (12%, median age 34.8y) were AYA, 3652 (58%, median age 55.4y) mid-age and 1886 (30%, median 70y) older adults, of whom 870 pts were aged 70-79y and 76 pts aged 80y+ (18 being >85y). There was no association b/w senior participation and year of enrollment (2017 31%, 2018 29%, 2019 30%, b/w age and type of therapy (i.e. targeted vs immunotherapy, etc.) or b/w age and # of drugs given on trial (single agent vs combo) (all $p > 0.05$). **Conclusions:** Older adults remain underrepresented on phase I trials esp. when compared to incidence of cancer in that age group (30% enrollment vs 60% incidence), a discordance more staggering in the oldest old pts (85y+; only 18 pts enrolled over 3 yrs when compared to 140,690 pts 85y+ w a new cancer dx in just 2019). Once enrolled, older adults received similar types of phase I therapies with comparable number of drugs as compared to middle age patients, i.e. older adults were just as likely to get immunotherapy or targeted therapy as well mono- vs combo therapy as mid-age pts. Research Sponsor: None.

12045 Poster Session (Board #333), Fri, 8:00 AM-11:00 AM

Association of geriatric conditions with survival and health care use in older adults with colon cancer living in long-term care facilities. *First Author: Daniel E Lage, Harvard Medical School, Boston, MA*

Background: Older adults with colon cancer residing in nursing homes are at risk for experiencing geriatric conditions such as cognitive decline, limitations in activities of daily living (ADLs), needing pain medications, and incontinence, due to cancer and its treatment. We sought to investigate these factors pre- and post-diagnosis and explored their relationship with health care use and survival. **Methods:** We identified 483 patients age 65+ with colon cancer from 2011-2015 in SEER-Medicare with linked quarterly nursing home assessments from the Minimum Data Set both pre- and post-cancer diagnosis. We determined the number of geriatric conditions (cognitive functioning, limitation in any ADL, pain medication use, bowel/urinary incontinence) at the pre- and post-cancer diagnosis assessment. We created four groups based on changes in these factors from pre- to post- assessment: improved (n = 105), worsened (n = 25), remained limited (n = 240), never limited (n = 113). Regression models estimated how changes from pre- to post-cancer diagnosis were associated with number of emergency department (ED) visits, hospitalizations, and survival, adjusted for age, sex, race/ethnicity, insurance status, cancer stage, number of pre-cancer comorbidities, urban/rural status, and time from diagnosis. **Results:** Overall, 55.3% of patients were age > 80 at diagnosis, with 64.8% female; 73.3% non-Hispanic white; and 9.9% Stage IV. Pre- versus post-diagnosis, 20.7% vs. 34.8% of patients were limited in cognitive functioning, and 75.4% vs. 77.8% were limited in ADLs. About a third of patients required pain medication, and about half of patients had urinary incontinence, which did not change pre- and post-diagnosis. Patients who remained limited had higher rates of ED visits (Risk ratio [RR] 1.05, $p < .01$) compared to those never limited. Those who worsened had higher rate of hospitalization (RR 1.44, $p < .01$) and ED visits (RR 1.63, $p < .01$). 12-month and 5-year survival was 46.7% and 6.1%, respectively. Factors associated with worse survival in a multivariable model included: remaining limited at both assessments (OR 1.52, $p < .01$), worsening from prior (OR 2.00, $p = .01$), as well as older age and higher cancer stage. **Conclusions:** Older adults with colon cancer residing in nursing homes have high prevalence of geriatric conditions and differential health care use and survival based on the presence of geriatric conditions, highlighting the need to consider geriatric conditions when providing cancer care to this population. Research Sponsor: American Cancer Society.

12046 Poster Session (Board #334), Fri, 8:00 AM-11:00 AM

Use of self-rated health to identify frailty and predict mortality in older adults with cancer. Results from the care study. *First Author: Mustafa Al Obaidi, University of Alabama at Birmingham, Birmingham, AL*

Background: Poor self-rated health (SRH) is a known predictor of mortality in the general adult population, but little is known about its use in older adults with cancer. The purpose of this study was to examine the association and ability of SRH to identify frail older adults and assess its ability to predict mortality in older adults with cancer. **Methods:** Using participants from the Cancer & Aging Resilience Evaluation (CARE) Registry who had undergone a geriatric assessment, we examined SRH using a single-item from the Patient-Reported Outcomes Measurement Information System (PROMIS) global health scale. SRH scores were dichotomized into Poor (poor and fair) and Good (good, very good, and excellent). Multivariable logistic regression analyses were used to examine associations between SRH and frailty (based on frailty index) and specific geriatric impairments adjusting for age, sex, comorbidity, cancer type and stage. Finally, the impact of SRH on all-cause mortality was assessed with a multivariable cox regression model. **Results:** A total of 708 participants with malignancy were included, median age was 68y, 41.5% male, and 74.6% White. Colorectal cancer was the most common cancer (27.1%) and 48.2% of the participants had Stage IV disease. Poor SRH was reported by 42% of participants and was associated with significantly higher odds of frailty (adjusted Odds Ratio [aOR] = 21.8; 95%CI 13.7-34.8). Similarly, poor SRH was independently associated with higher odds of impairments in Activities of Daily Living (ADL) (aOR = 5.6, 95%CI, 3.6-8.9), independent ADL (aOR = 8.4, 95%CI, 5.8-12.4), cognition (aOR = 4.6, 95%CI 2.3-9.3), malnutrition (aOR = 4.5, 95%CI 3.2-6.4), falls (aOR = 3.6, 95%CI 2.4-5.4), anxiety (aOR = 4.6, 95%CI 2.9-7.3), and depression (aOR = 5.4, 95%CI 3.0-9.7). The SRH demonstrated high sensitivity (84.3%) and specificity (78.4%) for identifying frailty, with a positive predictive value of 67% and negative predictive value of 90.6%. The 1y survival rate in those with Poor SRH was significantly worse (64.7% *vs* 84.3%, log rank p value < 0.001). In a multivariate cox regression analysis, poor SRH remained an independent predictor of worse survival (adjusted Hazard Ratio 2.29 [1.6-3.2], $p< 0.01$) after adjusting for age, sex, race, cancer type, stage, comorbidity, and planned treatment. **Conclusions:** Poor SRH is highly associated with frailty and could be a simple tool to identify frail older patients with cancer at risk for adverse events and increased mortality. Research Sponsor: U.S. National Institutes of Health.

12047 Poster Session (Board #335), Fri, 8:00 AM-11:00 AM

Geriatric assessment (GA) predictors of 1y mortality in older adults with gastrointestinal (GI) malignancies: Results from the CARE study. *First Author: Grant Richard Williams, University of Alabama Birmingham, Birmingham, AL*

Background: Chronologic age is an imperfect predictor of morbidity and mortality in older patients with newly-diagnosed GI malignancies. Identifying patients with GI malignancies that are at increased risk of mortality within the 1st year remains challenging given no prior studies have focused on this population, yet is critical to developing personalized treatment plans. To fill this gap, we examined predictors of 1y mortality using variables from a patient-reported GA in a prospective cohort of older adults with GI malignancies. **Methods:** Cancer and Aging Resilience Evaluation (CARE) is a prospective registry of older adults (≥60y) with cancer seen at UAB (J Geri Onc 2019; PMID 31005648). Patients with GI malignancies with GA completed within the timeframe of 3 mo. before and up to 6 mo. after diagnosis were included. Vital status (up to 12/7/2019) was ascertained by linking participants to LexisNexis. Multivariable Cox regression analysis was used to estimate associations between GA variables and 1y mortality, adjusting for age at cancer diagnosis, race, cancer stage (IV *vs.* I-III), cancer group (high risk: pancreatic, hepatobiliary, esophageal *vs.* low risk: colorectal, GIST, neuroendocrine, etc.), and planned chemotherapy (yes/no). **Results:** A total of 356 participants met eligibility criteria. Mean age at enrollment was 70y; 56.4% were females; 25% black; 47.1% had high-risk cancers. In unadjusted analysis, high-risk cancers, cancer stage, malnutrition, impaired performance status, limitations in social activities, impaired instrumental activities of daily living (IADL), physical health, mental health, anxiety, and ≥3 comorbidities were associated with higher 1y mortality. Our base model (demographic and clinical variables) demonstrated good discrimination (c statistic 0.758), but was improved with the addition of all significant GA variables (c-statistic 0.810). Fatigue and malnutrition were identified as the strongest predictors among the GA variables, and a model adding those to the base model retained high discrimination (c-statistic 0.804). The estimated 1yr survival was 53.1% for those with both fatigue and malnutrition compared to 88.1% in those with neither. **Conclusions:** Among older adults with GI malignancies, malnutrition and fatigue were the strongest GA predictors of 1yr mortality after adjusting for age and clinical factors. These findings provide evidence for developing targeted interventions in older patients with newly-diagnosed GI malignancies to reduce 1y mortality. Research Sponsor: U.S. National Institutes of Health.

12048 Poster Session (Board #336), Fri, 8:00 AM-11:00 AM

Association between chronological age and geriatric assessment (GA) to identify deficits in elderly adults with cancer: Findings from the Care Registry. *First Author: Grant Richard Williams, University of Alabama Birmingham, Birmingham, AL*

Background: Although ASCO and NCCN guidelines recommend that adults with cancer diagnosed at age ≥65y undergo a GA, the association between chronologic age and GA identified deficits remains understudied, and thus, the appropriate age cut-off for employing GA in clinical settings remains unknown. We addressed this gap by examining the association between chronologic age and GA deficits in older adults with cancer. **Methods:** The Cancer and Aging Resilience Evaluation (CARE) is an ongoing prospective registry of older adults (≥60y) with cancer at a single site. Eligible patients underwent a patient-reported GA adapted from the Cancer and Aging Research Group. The association between age categories (10y increments) and presence of GA deficits was tested using chi-squared tests of trend. Linear association between age and GA deficits was examined using Pearson correlation. **Results:** The median age at enrollment was 70y (60-96) for 08 participants; 58% were male. Most common cancer types were colorectal (27%), pancreatic (17%), and hepatobiliary (12%). No significant correlation was found between chronologic age and the number of GA deficits (r = 0.03). There was no association between the youngest (60-70y) vs. the oldest age groups (≥80y) with respect to the prevalence of GA deficits: frailty (33% *vs.* 33%, *p*= 0.97); impairment of activities of daily living (ADL) (20% *vs.* 16%, *p*= 0.7);impairment of instrumental ADL (50% vs 60%, *p*= 0.3); malnutrition (42% *vs.* 33%, *p* =0.4), cognitive impairment (8% *vs.* 6%, *p*= 0.6), falls (19% *vs.* 30%, *p* 0.1), anxiety (19% *vs.* 11%, *p*= 0.1) and depression (13.4% *vs.* 13.7%, *p*= 0.2) (Table). Prevalence of 3+ comorbidities was higher in the older patients (45% *vs.* 59%, *p*= 0.03). **Conclusions:** In our cohort of older adults with mostly gastrointestinal malignancies, age was not associated with GA identified deficits and the prevalence of most impairments was similar across age-groups. The use of chronologic age alone to identify which patients may benefit from GA is problematic, and adults 60yrs and above, or perhaps even younger, may derive benefits from a GA. Research Sponsor: U.S. National Institutes of Health.

12049 Poster Session (Board #337), Fri, 8:00 AM-11:00 AM

An international cohort study investigating the impact of age on clinical outcome in patients with hepatocellular carcinoma treated with sorafenib. *First Author: Rohini Sharma, Imperial College London, London, United Kingdom*

Background: There is no consensus on the effect of sorafenib dosing on efficacy and toxicity in elderly patients with hepatocellular carcinoma (HCC). Older patients are often empirically started on low dose therapy with the aim to avoid toxicities whilst maximising clinical efficacy. We aimed to verify whether age impacts on overall survival (OS) of patients with HCC, and whether a reduced starting dose of sorafenib impacts on OS or rates of toxicity experienced by the elderly. **Methods:** In this international, multicentre cohort study, patients with a confirmed diagnosis of advanced-stage HCC receiving sorafenib were recruited from seven specialist centres. Demographic and clinical data including development and grade of sorafenib toxicity and sorafenib starting dose were collected prospectively. Survival time (months) was recorded prospectively. Outcomes for those < or > 75 years were determined **Results:** A total of 5598 patients were recruited; 792 (14.1%) were over the age of 75. The elderly were more likely to have larger tumours (> 7cm)(39 vs 33%, p = 0.07) with Child-Pugh A liver function(67 vs 57.7%) and less portal vein thrombosis compared to those < 75years(22.1 vs 29.4)(p < 0.001). They were more likely to be commenced on lower starting dose of sorafenib i.e 400mg/200mg (38.7 vs 37.2%, P < 0.01). In terms of OS, there was no difference in the median OS of those >75 years and patients < 75 (7.3months vs 7.2months; HR 0.98 (95% CI 0.90–1.06), p = 0.63). There was no relationship between starting dose of sorafenib, 800mg vs 400mg/200mg, and OS between those < or > 75years. The elderly experienced a similar incidence of grade 2-4 sorafenib-related toxicity compared to < 75years(74.3 vs 61.7%, p = 0.051)(except for anorexia (14.0 vs 7.2%, p < 0.01) and rash (3.1 vs 6.3%, p < 0.05), irrespective of the dose prescribed. The elderly were more likely to discontinue sorafenib due to toxicity (27.0 vs 21.6%, p < 0.01). This did not vary between different starting doses of sorafenib. The mean duration of treatment was similar between those < and > 75 and, again, the starting dose of sorafenib did not affect treatment duration in the elderly. **Conclusions:** The median OS in the elderly is the same for that of patients under 75 years and is independent of the dose of sorafenib prescribed. Therefore, sorafenib should be offered to elderly patients and they should not be excluded from therapy Research Sponsor: None.

12050 Poster Session (Board #338), Fri, 8:00 AM-11:00 AM

External validation of two predictive scores of chemotherapy toxicities among older patients with solid cancer, from ELCAPA prospective cohort. *First Author: Maxime Frelaut, Institut Curie, Paris, France*

Background: Severe chemotherapy toxicities are frequent among older patients, and may have a major impact on mortality, comorbidities, and quality of life. Two scores were developed to predict severe toxicities: Chemotherapy Risk Assessment Scale for High-age patients (CRASH) score, and Cancer and Aging Research Group Study (CARG) score. The main objective of the present study was to evaluate the predictive value of both scores on an external cohort. Secondary objective was to identify individual predictive factors of severe chemotherapy toxicities. **Methods:** The Elderly Cancer Patients (ELCAPA) survey consists in a prospective cohort including patients aged 70 years or older referred for a geriatric assessment (GA) before anticancer treatment, such as chemotherapy for solid cancer. CARG and CRASH score were retrospectively collected. Main endpoint was grade 3/4/5 toxicities for CARG-score, hematologic grade 4/5 and non-hematologic grade 3/4/5 toxicities for CRASH-score. Calibration and discrimination (Area Under ROC Curve, AUC) were evaluated. **Results:** From July 2010 to March 2017, 248 patients were included. Among them, 150 (61%) experienced severe toxicity as defined in CARG study, and 126 (51%) as defined in CRASH study. There was no increased risk of toxicity in intermediate and high risk groups of CARG-score compared to low risk group (OR = 0.3, $IC_{95\%}$ [0.1 – 1.4], *p*= 0.1; and OR = 0.4, $IC_{95\%}$[0.1 – 1.7], *p*= 0.2 respectively, AUC-ROC = 0.55). Similarly, there was no more risk of severe toxicities in intermediate low, intermediate high, and high risk groups compared to low risk groups of CRASH combined score (respectively OR = 1, $IC_{95\%}$ [0.3 – 3.6], *p*= 0.99; OR = 1, $IC_{95\%}$ [0.3 – 3.4], *p*= 0.9; OR = 1.5, $IC_{95\%}$ [0.3 – 8.1], *p*= 0.67; AUC-ROC = 0.52). A multivariate predictive model including cancer type, performance status (PS 0 *vs.* PS 1-2), number of severe comorbidities (Cumulative Illness Rating Scale for Geriatrics, CIRS-G, ≥1 grade 3 or 4 comorbidity), body mass index (BMI > 25 kg/m² protective *vs.* normal BMI), and Chemotox score (1 *vs.* 0) had an AUC of 0.78. **Conclusions:** Neither CARG nor CRASH score was predictive of severe chemotherapy toxicities in the ELCAPA cohort. There is a need to identify new predictors of chemotherapy toxicity in older patients with solid cancers. Research Sponsor: INCA (Institut national du Cancer), Canceropôle Ile de France and Gérontopôle Ile de France.

12051 Poster Session (Board #339), Fri, 8:00 AM-11:00 AM

Regaining a satisfactory quality of life and predicting functional decline after major cancer surgery in older adults: The Geriatric Oncology Surgical Assessment and Functional rEcovery after Surgery (GOSAFE) study. *First Author: Isacco Montroni, Degli Infermi Hospital, Faenza, Italy, Faenza, Italy*

Background: Older cancer patients value quality of life (QoL) and functional outcomes as much as survival but surgical studies lack specific data. The international, multicenter GOSAFE study (ClinicalTrials.gov NCT03299270) aims to evaluate patients' QoL and functional recovery (FR) after cancer surgery and to assess predictors of FR **Methods:** GOSAFE prospectively collected functional and clinical data before and after major elective cancer surgery on senior adults (≥70 years). Surgical outcomes were recorded (30, 90, and 180 days post-operatively) with QoL (EQ-5D-3L) and FR (Activities of Daily Living (ADL), Timed Up and Go (TUG) and MiniCog), 26 centers enrolled patients from February 2017 to April 2019. **Results:** 942 patients underwent a major cancer resection. Median age was 78 (range 70-95); 52.2% males, ASA III-IV 49%. 934 (99%) lived at home, 51% lived alone, and 87% were able to go out. Patients dependent (ADL $<$ 5) were 8%. Frailty was detected by means of G8 ≤14 in 68.8% and fTRST ≥2 in 37% of patients. Major comorbidities (CCI $>$ 6) were reported in 36% and 21% had cognitive impairment according to MiniCog (2.2% self-reported). 25% had $>$ 3 kg weight loss, 27% were hospitalized in the last 90 days, 54% had ≥3 medications (6% none). Postoperative overall morbidity was 39.1% (30 day) and 22.5% (90 day), but Clavien-Dindo III-IV complications were only 13.4% and 6.9% respectively. 30/90/180-day mortality was 3.6/6/8.9% (10/30/33% in patients with severe functional disability). At 3 months after surgery, QoL was stable/improved (mean EQ-5D index 0.78 was equivalent before vs. after surgery, while the EQ-5D VAS score $>$ 60 raised from 74.3% at baseline to 80.2%, $p < 0.01$). 76.6% experienced postoperative FR/stability. Logistic regression analysis showed that ASA 3-4, CCI≥7 and CD III-IV complications are significantly associated with functional decline while a G8 $>$ 14 has a positive association with functional recovery. Age is not associated with functional outcomes. **Conclusions:** The largest prospective study on older patients undergoing structured frailty assessment before and after major elective cancer surgery has shown that QoL remains stable/improves after cancer surgery. The majority of patients return to independence and G8 can predict functional recovery. Older patients with multiple comorbidities, high ASA score or postoperative severe complications are likely to functionally deteriorate after oncologic surgery Clinical trial information: NCT03299270. Research Sponsor: None.

12052 Poster Session (Board #340), Fri, 8:00 AM-11:00 AM

Living life post cancer treatment (LLPCT): An assessment of a 12-week multidimensional wellness intervention to improve quality of life and physical activity in cancer survivors. *First Author: Christopher C. Marino, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Cancer survivors face unique health challenges with implications on health-related quality of life (HRQoL) and physical, social, and emotional well-being. With advancements in cancer treatment and aging populations, the prevalence of cancer survivors is expected to grow prompting the need for improved survivorship care delivery and comprehensive rehabilitative services. Living Life Post Cancer Treatment (LLPCT) is a community-based 12-week program that provides multidimensional support to patients of any cancer diagnosis transitioning from active treatment to post-treatment life. This single-arm intervention study aims to assess the program's impact on HRQoL and physical activity in cancer survivors. **Methods:** A total of 125 participants within 2 years of treatment completion were enrolled in a 12-week program comprised of 9 sessions of engaging workshops, personalized exercise training, and nutrition and psychosocial counseling with an interprofessional team of oncology providers, social workers, exercise trainers, and dietitians. The program consisted of 8 consecutive weekly sessions followed by a 1-month follow-up session at week 12. Ninety-six (77%) participants completed the eighth or ninth session of the program and were included in the analysis. A series of questionnaires were administered at baseline and weeks 8 and 12. Primary outcomes assessed were HRQoL using the Functional Assessment of Cancer Therapy-General (FACT-G) questionnaire and physical activity using average daily steps by pedometer and 2-minute step test performance. **Results:** Among the 96 participants (mean age 60.4 ± 11.7) who completed the program, the majority were female, white, and married. Post-intervention median FACT-G scores significantly increased from baseline at weeks 8 (+8.8, $p = 0.002$) and 12 (+7.3, $p < 0.001$). Average daily steps by pedometer increased by 1063 ($p = 0.003$) and 1233 ($p = 0.015$) and 2-minute step test performance increased by 18 ($p < 0.001$) and 21 ($p < 0.001$) steps at weeks 8 and 12, respectively. Participants reported high levels of satisfaction and improved self-efficacy to incorporate lifestyle modifications. **Conclusions:** These findings suggest that this 12-week intervention improves HRQoL and step-based physical activity levels in cancer survivors and could serve as a multidimensional model for post-treatment support. Further research is needed to determine if these benefits are sustained long-term. Research Sponsor: Our Clubhouse is a community-based non-profit organization funded primarily by individual contributions and partnerships with regional healthcare systems, specifically University of Pittsburgh Medical Center, Allegheny Health Network, and Excela Health.

12053 Poster Session (Board #341), Fri, 8:00 AM-11:00 AM

The impact of weight loss on physical function in overweight or obese breast cancer survivors. *First Author: Jennifer Y. Sheng, Johns Hopkins Hospital, Baltimore, MD*

Background: In the prospective POWER-remote trial, 51% and 12% of overweight/obese breast cancer survivors randomized to either a remotely delivered behavioral intervention or self-directed approach, respectively, lost ≥5% of baseline weight. We collected patient-reported outcomes (PROs) to examine the impact of >5% weight loss on symptoms, physical function (PF), and wellbeing. We hypothesized *a priori* that, regardless of study arm, those with ≥5% weight loss would have improved PF at 6 months v. those who did not. **Methods:** Women with stage 0-III breast cancer, who completed local therapy and chemotherapy, with a BMI ≥25 kg/m^2 were randomized to the 12-month intervention or self-directed weight loss. POWER-remote consists of telephone coaching and online tracking of diet, activity and weight. Women in the self-directed arm received a lifestyle booklet. All women completed PROs at baseline, 6 and 12 months: PROMIS PF, pain, fatigue, anxiety, depression, sleep; FACT-endocrine symptoms; MOS-sexual function. PROs were summarized descriptively and changes within and between groups were tested with multivariable mixed effects models, adjusted for age and baseline weight. **Results:** From 2013-2015, 96 women enrolled; 83 were evaluable at 6 months. At 6 months, PF scores improved in those with ≥5% weight loss v. not. While endocrine symptoms, fatigue, and anxiety improved in the group who lost ≥5%, differences between groups were not statistically significant. There was no significant change in sexual function, depression, or sleep within or between groups. Similar findings were seen across domains at 12 months, except pain improved in the group losing ≥5%. **Conclusions:** For overweight/obese breast cancer survivors, PF and other PROs improved among patients who lost ≥5%. These results support the patient-centered benefits of weight loss in this population. Clinical trial information: NCT01871116. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Other Government Agency.

Changes (Δ) in PROs at 6 months from baseline (BL) by weight loss (WL).

	6 month follow up		
	≥5% WL n=28	<5% WL n=55	P, between groups
Physical function

Moving toward precision: Understanding the heterogeneity of obesity. *First Author: Kin Wai (Tony) Hung, Olive View UCLA Medical Center, Sylmar, CA*

Background: Obesity is a global health epidemic and has been linked to detrimental impact on cancer incidence, recurrence, and mortality. Growing evidence have recognized the complex biopsychosocial relationship including microbial phenotypes that undermines the carcinogenic potential and heterogeneity of obesity. A precision understanding on obesity while at its infancy is necessary to accelerate reduction of its impact on cancer outcomes. **Methods:** With our aim to better understand the biopsychosocial relationship on obesity, we conducted a cross sectional study in healthy and obese individuals. Univariate and multivariate logistic regression models were used to examine obesity and its association with sociodemographic (age, gender, ethnicity, education, income, and marital status), clinical (waist to hip ratio), dietary-behavioral (daily calorie, fat, carbohydrate, protein consumption, and preference on cultural diet), and biological factors (gut microbiome). Parameters were controlled and corrected for multiple hypothesis testing. Gut microbial data using 16S rRNA sequencing were analyzed for alpha diversity, beta diversity, and association of taxa abundance. **Results:** Among 171 participants between July 2013 and August 2018, individuals were found to have a higher BMI if they were Hispanic [Adjusted Odds Ratio (AOR) 3.36, 95% CI 1.27-8.90], had an obese waist to hip ratio (AOR 8.51, 95% CI 3.45-21.02), and consumed an American diet (AOR 4.82, 95% CI 1.74-13.34). Multivariate permutation analysis controlling for BMI, sociodemographic, clinical, and dietary parameters found that Hispanic have a significantly different microbiome profile than non-Hispanic ($p = 0.042$). While microbial species richness (Chao1) were similar ($p = 0.22$), Hispanic had a lower microbial species evenness (Shannon) compared to non-Hispanic ($p = 0.029$). Differential expression of microbial species revealed a positive correlation of Firmicutes:Bacteroidetes ratio in individuals with higher BMI and consumed an American diet whereas a negative correlation to Hispanic ethnicity. **Conclusions:** Obesity association to Hispanic ethnicity uniquely expressed through microbial signature despite sociodemographic, clinical, and dietary differences. Microbial characterization as an emerging predictive marker for oncology therapeutics may also serve as selection biomarker in onco-obesity practices and clinical trials. Addressing ethnic disparities guided by microbial phenotypes may unlock novel understanding of obesity heterogeneity and transform its impact on cancer care. 12055 Poster Session (Board #343), Fri, 8:00 AM-11:00 AM

Randomized clinical trial on the effect of a supervised exercise program on quality of life, fatigue, and fitness following esophageal cancer treatment (PERFECT study). *First Author: Anne Maria May, Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands*

Background: Patients with potentially curable esophageal cancer are often treated with chemoradiotherapy followed by surgery. This treatment might have a negative impact on physical fitness, fatigue and quality of life (QoL). In patients with other types of cancer, evidence suggests that physical exercise reduces treatment related side effects. We investigated whether a supervised exercise program also beneficially affects QoL, fatigue and cardiorespiratory fitness (CRF) in patients after treatment for esophageal cancer. **Methods:** The multicenter PERFECT study randomly assigned patients in the first year after esophagectomy to an exercise intervention (EX) or usual care (UC) group. EX patients participated in a 12-week moderate to high intensity aerobic and resistance exercise program supervised by a physiotherapist. UC patients were advised to maintain their physical activity levels. Attendance and compliance with the exercise intervention protocol were retrieved from exercise logs. QoL (primary outcome, EORTC-QLQ-30, range 0-100), fatigue (MFI-20, range 4-20) and CRF (cardiopulmonary exercise testing) were assessed at baseline and after 12 weeks (post-intervention). The outcomes were analyzed as between-group differences using either linear mixed effects models or ANCOVA adjusted for baseline and stratification factors (i.e. sex, time since surgery, center), according to the intention-to-treat principle. **Results:** A total of 120 patients (age 64±8) were included and randomized to EX (n = 61) or UC (n = 59). Patients in the EX group participated in 96% (IQR:92-100%) of the supervised exercise sessions and compliance with all parts of the exercise program was high (> 90%). Post-intervention, global QoL was not statistically different between groups, but significant ($p < 0.05$) beneficial EX effects were found for QoL-Summary scores (between-group difference 3.5, 95% CI 0.2;6.8) and QoL-role functioning (9.4, 1.3;17.5). Physical fatigue wat non-significantly lower in the EX group (-1.2; -2.6;0.1, p = 0.08). CRF was significantly higher (VO_{2peak} (1.8 mL/min/kg, 0.6;3.0) following the EX intervention. **Conclusions:** Patients were well capable to complete an intensive supervised exercise program after esophageal cancer treatment, which led to small but significant improvements in several aspects of QoL and cardiorespiratory fitness. Our results suggest that supervised exercise is a beneficial addition to routine care of patients with esophageal cancer. Clinical trial information: NTR5045. Research Sponsor: World Cancer Research Fund The Netherlands (WCRF NL, project number 2013/997).

12056 Poster Session (Board #344), Fri, 8:00 AM-11:00 AM

Effect of evidence-based nutrition educational intervention on adherence to dietary guidelines (ADG) and weight management among early-stage breast cancer (EBC) patients (pts): A prospective trial. *First Author: Ilaria Trestini, Department of Oncology, University of Verona Hospital Trust, Verona, Italy*

Background: Excess adiposity is linked to an increased risk of worse outcome among EBC pts. Pts undergoing EBC treatment are susceptible to change in nutrition status. However, implementation and assessment of the adherence to lifestyle interventions have been limited. This prospective trial aimed to evaluate the impact of an evidence-based nutrition intervention, according to the ADG, in terms of body composition changes in EBC pts. **Methods:** Entry criteria: EBC pts candidate to neoadjuvant/adjuvant therapy. At study entry, pts received a nutrition evidence-based tailored intervention. Dietary and anthropometric assessments were evaluated at baseline and after 12-months nutritional intervention. Waist circumference (WC) was assessed as a surrogate measure of fat distribution. ADG was estimated by Med-Diet 14-item questionnaire. Health-Related Quality of Life was analysed with EORTC QLQ-C30. Descriptive statistics was adopted. Associations between variables and groups according to nutritional variables were analysed (Chi-square test). **Results:** From February 2016 to December 2019, 243 pts were enrolled (median age 49 years): 27.6%/48.6% neoadjuvant/adjuvant treatment. At baseline, 38.3% of pts were overweight and 23.9% were obese. Notably, tumor size was significantly correlated with WC in the whole population (p = 0.003). Moreover, pts with central obesity were more likely to present HER2-negative tumors (57.4% vs. 42.5%, p = 0.03). Most pts reported relevant nutrition impact symptoms and symptoms affected QoL. Particularly, dyspepsia and constipation were more prevalent in overweight and obese pts ($p < 0.0001$ and p = 0.009, respectively), as well as in pts who gained ≥5% of weight (p = 0.04 and p = 0.02, respectively). At baseline, there was low ADG. After the 12-months intervention, ADG significantly increased (median Med-Diet score: 6 vs.12, $p < 0.0001$). A high ADG (defines as a Med-Diet score ≥10) significantly correlated with: 1) loss of weight ≥5% from the baseline weight (p = 0.003); 2) change in terms of BMI; 3) prevalence of central obesity. **Conclusions:** A tailored evidence-based nutritional intervention for EBC pts represents a tool to improve their ADG, weight management and, thus, to potentially influence the disease outcome. Research Sponsor: None.

Variables	At baseline	After 12-months	p-value
BMI			p = 0.003
underweight	5 (3.3)	0 (0)	
normal weight	73 (48.0)	126 (82.9)

central obesity	58 (38.2)	11 (7.2)	

12057 Poster Session (Board #345), Fri, 8:00 AM-11:00 AM

The impact of high intensity interval training on functional performance, body composition and quality of life in a diverse group of cancer survivors. *First Author: Jennifer Lynn Beebe-Dimmer, Wayne State University School of Medicine, Karmanos Cancer Institute, Detroit, MI*

Background: Given the well-documented benefits of regular exercise to cancer survivors, in 2012, an expert panel assembled by the American Cancer Society recommended that patients engage in at least 150 minutes per week of moderate-to-vigorous physical activity. However, few patients meet this goal. We have also observed racial differences in reported participation in regular exercise among cancer survivors living in Metropolitan Detroit, Michigan. **Methods:** The CAPABLE study is a 12- week pilot exercise intervention that introduces cancer survivors to the sport of CrossFit. We evaluated the impact of this unique, high-intensity interval training method on functional performance, cardiovascular endurance, body composition and health-related quality of life (HRQOL) as measured by the Functional Assessment of Cancer Therapy (FACT) instrument. All measures were summarized at baseline and program exit. Paired signed rank tests were used to assess change in each of these measures over time. **Results:** Of the 48 participants enrolled in the pilot, 37 (77%) were considered adherent to the program (attending at least 75% of sessions over the 12-week period). The mean age of participants was 58.5 years, 73% identified as African American and the majority of participants were breast cancer survivors (N = 20). The mean body mass index (BMI) at baseline was 32.8 kg/m^2 decreasing to a mean of 31.7 kg/m^2 at exit (BMI change -1.1, $p < 0.001$). Similar changes were observed in % body fat measured by bioelectrical impedance. There were significant improvements in all measures of functional performance over 12-weeks (all $p < 0.001$). We observed significant and meaningful improvements in reported HRQOL measured by the FACT survey, overall (FACTG total change +9.5 ($p < 0.001$)) and in each one of the individual domains (physical, social, emotional, and functional well-being). **Conclusions:** We observed significant improvements in performance, body composition and quality of life among cancer survivors introduced to a high-intensity interval training program. Understanding and eliminating barriers to programs like these are critical to improving outcomes and reducing cancer health disparities. Clinical trial information: NCT03750981. Research Sponsor: Karmanos Cancer Institute.

12058 Poster Session (Board #346), Fri, 8:00 AM-11:00 AM

The impact of tobacco retail density on overall survival (OS) in lung cancer survivors. *First Author: Lawson Eng, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Continued smoking after a cancer diagnosis is associated with poorer outcomes. We previously identified that tobacco retail outlet density is negatively associated with cessation in lung cancer survivors (ASCO 2019). However, the impact of tobacco retail density on survival has not been evaluated. We evaluated the impact of tobacco retail density on OS in lung cancer patients (pts). **Methods:** Lung cancer pts diagnosed from 2009-2012 were recruited at diagnosis and completed a baseline questionnaire on their sociodemographics, ECOG and smoking history. Clinicopathologic data including stage, histology and OS data were collected. Validated tobacco retail location data obtained from Ministry of Health and pt home addresses were geocoded using ArcGIS 10.6.1, which calculated tobacco outlet density within 250 meters (m) and 500m from pts. Multivariable Cox proportional hazard models evaluated the impact of tobacco outlet density on OS adjusted for significant clinicodemographic covariates. **Results:** Among 1411 pts, median age 66, 53% female, 8% small cell/56% adenocarcinoma/17% squamous/19% other, 28% stage 1/9% stage 2/20% stage 3/35% stage 4, 38% were current smokers at diagnosis and 40% were ex-smokers; median OS was 24 months. On average, there was one vendor (range 0-23) within 250m and four vendors (range 0-44) within 500m from pts; 33% and 60% of pts lived within 250m and 500m from at least one vendor respectively. The final baseline multivariable model consisted of age, gender, stage, smoking status, ECOG and neighbourhood marginalization index ($P< 0.05$). Among all pts, not living within 250m to an outlet improved OS (aHR 0.84 [0.72-0.97] P= 0.02). Living near more outlets within 250 m (aHR 1.03 per outlet [1.00-1.05] P= 0.03) or 500 m (aHR 1.01 per outlet [1.00-1.02] P= 0.04) worsened OS. Subgroup analysis based on smoking status at diagnosis, identified that among current smokers, not living within 250m to an outlet improved OS (aHR 0.76 [0.60-0.97] P= 0.03), and among ex-smokers, living near more outlets within 500 m worsened OS (aHR 1.02 per outlet [0.99-1.03] P= 0.07); other associations showed similar directionality. Among 135 current smokers at diagnosis with follow-up smoking status, not living within 250m to an outlet continued to show a trend towards improved OS (aHR 0.57 [0.31-1.03] P= 0.06), after also adjusting for follow-up smoking status. **Conclusions:** Living near a greater density of tobacco outlets is associated with poorer OS among lung cancer pts. Reducing the density of tobacco outlets may be a strategy that can help improve lung cancer pt outcomes. Research Sponsor: Cancer Care Ontario - ON-PROST.

12059 Poster Session (Board #347), Fri, 8:00 AM-11:00 AM

Panel-based methodology for assessing the impact of public policies on cancer patients and survivors. *First Author: Amy Farner, American Cancer Society Cancer Action Network, Washington, DC*

Background: Cancer interventions are subject to a range of regulations, but data from large, nationally representative surveys are not always available in time to inform the policy process and do not always address issues specific to cancer patients and survivors. Understanding their experiences is critical to achieving policy solutions to issues such as access to effective pain relief, reducing unexpected medical bills, and reducing the impact of high prescription drug costs on treatment for lower income cancer patients. This research intended to better understand patient experiences and opinions in a statistically valid manner specifically targeted to the policy process. **Methods:** 3057 panelists were identified from ACS contacts, health systems, and social media advertising through ACS/ACS CAN pages and paid Facebook ads, to participate in a series of surveys across a year. The panel included diverse survivors across age, gender, race, ethnicity, economic status, and cancer type. Online surveys deployed semi-monthly on cancer survivorship topics impacted by current policy, including access to/affordability of care, pain treatment, and prescription drug costs. Responses were analyzed for the entire population and across subgroups of cancer survivors. **Results:** Each survey achieved a response rate between 35% and 50% of all panel members, resulting in a margin of error +/- 3% and 95% confidence level. Insights from cancer patient and survivor experiences helped support public policies through findings such as (but not limited to): 41% of those prescribed opioids had trouble getting their medicine, creating difficulty participating in work, family, or social events; extra trips to the doctor or pharmacy; negative impact on treatment, and trips to the Emergency Room due to uncontrolled pain; 24% received a surprise medical bill, increasing their anxiety, reducing likelihood to see a specialist, and reducing likelihood to seek emergency care during a serious health issue; and 31% of those with household income less than $30,000 report trouble affording prescription drugs and 17% have delayed or not filled a prescription due to cost. Findings supported the policy process by helping craft policy positions aligned with cancer patient preferences, raising public awareness, and communicating to policymakers the impact of policies on cancer. **Conclusions:** The panel methodology illustrates the impact of policy decisions on cancer patients and survivors. Findings provide an unprecedented level of input to the policy process for cancer patients and survivors. Research Sponsor: Bristol Meyers Squibb.

12060 Poster Session (Board #348), Fri, 8:00 AM-11:00 AM

Patterns of the risk for subsequent primary cancer among survivors of adult-onset cancers in the United States. *First Author: Hyuna Sung, American Cancer Society, Atlanta, GA*

Background: The number of cancer survivors who develop new cancers is projected to grow in the US. Few studies, however, have provided a comprehensive overview of the contemporary pattern in the risk of subsequent primary cancer (SPC) among survivors of adult-onset cancers. Herein, we evaluate overall and type-specific risks of SPCs among adult-onset cancer survivors by first primary cancer types and sex. **Methods:** We assessed the excess risk of SPCs among 1,442,374 persons aged 20-84 years who were diagnosed with first primary cancers from 1992-2010 and survived ≥5 years in the 12 Surveillance, Epidemiology, and End Results registries. We expressed the risks using excess absolute risk (EAR) per 10,000 person-years and standardized incidence ratio (SIR) by first primary cancer types and sex, compared to those expected in the general population. We also estimated percent contributions of each specific type of SPCs to the total EAR for all first primary cancers combined by sex. **Results:** The overall risk of SPCs was higher than expected for 24 of the 34 first primary types among male survivors and for 28 of the 35 first primary types among female survivors. The greatest SIR and EAR were estimated after laryngeal cancer in both men (SIR = 1.74, 95%CI = 1.67-1.82; EAR = 159.3, 95%CI = 143.6-175.5) and women (SIR = 2.48, 95% CI = 2.26-2.73; EAR = 202.7; 95%CI = 171.8-236). There were 290 type-specific associations with significantly higher risk of SPC, 36% of which being reciprocal, predominantly among smoking-associated, HPV-associated, and hematologic cancers. The SIRs in men ranged from 1.05 (95%CI = 1.00-1.10; EAR = 1.69) for lung/bronchus cancer after colorectal cancer to 73.9 (95%CI = 58.3-92.3; EAR = 23.3) for anal cancer after Kaposi sarcoma; and in women the SIRs ranged from 1.08 (95%CI = 1.02-1.15; EAR = 0.36) for pancreatic cancer after breast cancer to 19.9 (95%CI = 15.0-26.0; EAR = 39.5) for oral cavity/pharyngeal cancer after laryngeal cancer. For all first primary cancers combined, lung/bronchus cancer comprised the greatest proportion of the total EAR of SPCs, 34.6% in men and 29.1% in women, followed by urinary bladder (11.8%) and oral cavity/pharynx (7.5%) in men and by corpus uterus (12.9%) and colorectum (7.6%) in women. **Conclusions:** Despite the substantial heterogeneity in the risk of SPCs across the first primary types, only a few cancers comprised a considerable proportion of the total excess risk among survivors. Better understanding of contributing factors to these patterns will inform survivorship care plans and care delivery. Research Sponsor: None.

12061 Poster Session (Board #349), Fri, 8:00 AM-11:00 AM

Impact of immune checkpoint and BRAF inhibitors on the incidence of second primary malignancies (SPM) in melanoma. *First Author: Nibash Budhathoki, NYU Winthrop Hospital, Mineola, NY*

Background: Prior studies have shown an increased risk of SPM in melanoma, however there is limited data on the incidence of SPM following the 2011 approvals of immune checkpoint (ipilimumab) and BRAF (vemurafenib) inhibitors, which have become standard of care. We present data comparing SPM rates before and after introduction of these agents for advanced cutaneous melanoma. **Methods:** Adult melanoma patients with regional or distant metastases were identified from SEER-18 database and divided into cohorts: 2005-2010 and 2011-2016. SPM was defined as tumors diagnosed ≥6 months from diagnosis of the primary cancer. SEER*stat was used to calculate SPM by multiple primary standardized incidence ratio based on observed (O) and expected (E) cases. The expected numbers of new cancers of specific types were estimated by assuming that incidence rates for new primary tumors corresponded to sex, age, and calendar time–specific SEER rates for similar invasive primary cancers and applying those rates to the accumulated person-years (PYR) of observation. Excess absolute risk (EAR) of malignancy per 10,000 PYR at risk was calculated as $([O - E]/PYR) \times 10{,}000$. **Results:** As shown in the table, from before 2005-2010, 421 of 7991 patients (5.2%) with advanced melanoma had 444 SPM (O/E ratio 2.2, 95% CI 1.9-2.4, $P < 0.0001$, EAR 157). In comparison, from 2011-2016, 527 of 9341 patients (5.6%) developed 584 SPM (O/E ratio 2.5, 95% CI 2.3-2.7, $P < 0.0001$, EAR 193). Incidence of AML, myeloma, and pancreatic cancer increased in 2005-2010, while soft tissue malignancies increased from 2011-2016. The incidence of thyroid, brain, and small bowel tumors increased in both groups from 2005-2016. **Conclusions:** There is a distinct pattern as well as increased latency of SPM in patients with advanced melanoma in the era of immune checkpoint and BRAF inhibitors. We speculate that reduction in chemotherapy use, augmentation of immunosurveillance, and inhibition of oncogenic pathways may impact the pathogenesis of SPM. Research Sponsor: None.

Summary	2005-2010	2011-2016
Total number of patients	7991	9341
Male	5096 (63.7%)	5996 (64%)
Female	2895 (36.3%)	3345 (36%)
White	7683 (96.1%)	8987 (96%)
Black	122 (1.5%)	127 (1.4%)
Other races	186 (2.3%)	127 (1.4%)
Total number of SPMs	444	584
Total patients with SPM	421 (5.3%)	527 (5.6%)
Patients with 1 SPM	400 (5.0%)	431 (4.6%)
Patients with 2 SPM	19 (0.23%)	35 (0.4%)
Patients with 3 SPM	2 (0.02%)	11 (0.1%)
Median years of age at diagnosis of SPM (range)	66 (20-94)	69 (23-101)
Median latency time to development of SPM (range)	18 months (6-64)	41 months (6-200)

12062 Poster Session (Board #350), Fri, 8:00 AM-11:00 AM

Effects of radiation therapy on clonal hematopoiesis. *First Author: Leslie Ann Modlin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clonal hematopoiesis (CH), characterized by recurrent somatic mutations in blood, is a common age-associated condition that portends an increased risk of myeloid neoplasms and cardiac disease. Oncologic therapies appear to promote CH, including ionizing radiation therapy (RT) (OR = 1.4, $p < 10^{-6}$) and systemic DNA-damaging agents (OR = 1.2, $p = 8 \times 10^{-4}$). How various RT parameters (e.g. target site, dose, fractionation, modality) may influence CH is unknown. **Methods:** CH mutations were identified via targeted, deep-coverage next-generation sequencing from paired peripheral blood and tumor samples (MSK-IMPACT). CH was defined as a somatic blood mutation with a minimum variant allele frequency of 2%. Putative driver mutations (CH-PD) were identified from OncoKB and other published sources. Clinical and RT characteristics were abstracted from medical records. To account for differences in RT dose and fractionation, equivalent radiation dose in 2 Gy fractions (EQD_2) with an α/β ratio of 3 for late effects was calculated. Univariate and logistic regression modeling for associations between clinical and treatment parameters and CH were performed. **Results:** We identified 2,195 patients who received RT before blood draw and 7,832 who did not, encompassing 57 histologies. A median of 267 days elapsed between the end of RT and blood draw. After RT, 22% of patients had at least one CH-PD mutation (n = 486). The most common single anatomic sites radiated were pelvis, chest wall/breast, and head and neck. Conventional RT was used in 2% (n = 46), 3D-conformal in 14% (n = 308), intensity modulated RT in 36% (n = 787), volumetric modulated arc RT in 12% (n = 263), multiple techniques in 26% (n = 560), and unknown in 11% (n = 231). There was no association between RT modality and presence of CH-PD ($p > 0.05$ for all between group comparisons of modality). On multivariate regression after controlling for age, race, time from diagnosis to blood draw, smoking status, and for chemotherapy class, cytotoxic, immune, or targeted therapies in the entire cohort, EQD_2 was associated with CH-PD ($p = 0.012 \times 10^{-3}$). Evaluating EQD_2 by irradiated anatomic site, total pelvic dose by EQD_2 in 10 Gy increments remained significantly associated with CH-PD (OR = 1.07, p = 0.0046), as was head and neck EQD_2 (OR = 1.046, p = 0.032). **Conclusions:** CH-PD was associated with higher radiation dose for pelvic or head and neck RT, but not other anatomic sites after controlling for systemic therapies. RT modality was not associated with CH-PD. Ongoing work will directly evaluate the bone marrow dosimetry of various treatment approaches using phantom-based modeling. Impact of preexisting cardiovascular disease (CVD) on treatments and outcomes of patients with breast or lung cancer. *First Author: Atul Batra, Tom Baker Cancer Center, Calgary, AB, Canada*

Background: Prior cardio-oncology and geriatric oncology research has mainly focused on cancer treatments and their late effects on cardiac health, but little information is known about how cardiac health may influence subsequent cancer treatments. This real-world study aimed to evaluate the associations of pre-existing CVD on treatment adherence and survival in patients with breast or lung cancer. **Methods:** We linked administrative data from the population-based cancer registry, electronic medical records, and billing claims in a large province (Alberta, Canada) over a 10-year time period (2006-2015). Multivariable logistic regression analyses were performed to identify associations of CVD with cancer treatments. Multivariable Cox proportional hazards models were constructed to determine the effect of CVD on overall survival (OS), while adjusting for receipt of cancer treatments. **Results:** We identified 46,227 patients with breast or lung cancer, of whom 77% were women and median age was 65 years. While 82% of patients with breast cancer were early stage, 50% with lung cancer had metastasis. The prevalence of pre-existing CVD was 20% where congestive heart failure was most frequent. In logistic regression, CVD was associated with lower odds of receiving appropriate chemotherapy (OR, 0.60, 95% CI, 0.56-0.65, *P*<.0001), radiotherapy (OR, 0.76, 95% CI, 0.72-0.81, *P*<.0001), and surgery (OR, 0.60, 95% CI, 0.54-0.66, *P* <.0001), irrespective of tumor site (Table). The 5-year OS was lower in patients with baseline CVD as compared to those without (46% vs 58%, *P<0.0001*). Upon adjusting for stage and treatment, CVD continued to correlate with worse OS (HR, 1.23, 95% CI, 1.19-1.26; *P*<.0001). **Conclusions:** Cancer patients with prior CVD were less likely to receive standard cancer therapy. Even among those who underwent cancer treatments, worse outcomes were observed in those with CVD. Early cardio-oncology and geriatric oncology engagement may reduce treatment bias and ensure that carefully selected patients with a cardiac history are still offered appropriate cancer therapy. Research Sponsor: None.

Odds of receiving appropriate cancer therapy in patients with pre-existing CVD (vs. those without CVD).

Fatigue in long-term survivors with ovarian cancer: Results of Expression VI – Carolin meets HANNA – Holistic analysis of Long-term survival with ovarian cancer—The international NOGGO, ENGOT and GCIG survey. *First Author: Hannah Woopen, NOGGO and Department of Gynecology, European Competence Center for Ovarian Cancer, Charité, University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: Long-term survivors (LTS) with ovarian cancer may be cured from cancer but frequently experience long-term toxicities such as fatigue with a huge impact on quality of life. Aim of this study was to evaluate factors associated with fatigue in LTS. **Methods:** Within the study "Carolin meets HANNA" (www.carolinmeetshanna.com) long-term survivors with ovarian cancer (LTS) were recruited since 11/2016. Long-term survival was defined as an ovarian cancer diagnosis more than eight years ago. **Results:** Until 12/2019 473 LTS could be recruited. 211 LTS (44.5%) have experienced fatigue. At the time point of recruitment in 23.4% (111 LTS) fatigue was still present. LTS with fatigue were not more frequently under current treatment compared to LTS without fatigue (p = 0.348). LTS with fatigue were not younger at initial diagnosis (50.4 vs. 51.9 years, p = 0.228). 58.6% of LTS with fatigue compared to 41.5% without fatigue have developed recurrent disease (p = 0.002) and LTS had more frequently more than one recurrence (66.1% vs. 51.7%, p = 0.055). Fatigue was associated with worse health status (2.9 vs. 2.2 on a scale from 1-5, p < 0.001). Fatigue was associated with medical complaints in general (82.0% vs. 43.0%, p < 0.001). Symptoms such as nausea and vomiting (p < 0.001), loss of appetite (p < 0.001), constipation (p < 0.001), diarrhea (p < 0.001), weight loss (p = 0.001) and bloating (p < 0.001) were more frequent in LTS with fatigue. This also accounts for cognitive disorders (39.6% vs. 10.5%, p < 0.001), depression (23.4% vs. 7.4%, p < 0.001), polyneuropathy (39.6% vs. 13.2%, p < 0.001) and cardiovascular disease (11.7% vs. 3.6%, p = 0.002). LTS with fatigue regard themselves more frequently as cancer patient (73.9% vs. 40.8%), p < 0.001). **Conclusions:** Fatigue is still very common in LTS despite the long survival time. Fatigue is associated with worsened health status and other long-term side effects underlining the impact on LTS. There is a high need for survivorship clinics that should ask for and, if necessary, should address still existing side effects such as fatigue. Research Sponsor: German Ovarian Cancer Foundation, Pharmaceutical/Biotech Company.

12066 Poster Session (Board #354), Fri, 8:00 AM-11:00 AM

Efficacy of ear acupuncture on sleep quality in breast cancer survivors: A randomized controlled trial. *First Author: Melanie Désirée Hoextermann, Department of Internal and Integrative Medicine, Evang. Kliniken Essen-Mitte, Faculty of Medicine, University of Duisburg-Essen, Essen, Germany, Essen, Germany*

Background: Among females, breast cancer is the most commonly diagnosed cancer worldwide. Sleep problems impair 40 to 70 % of breast cancer survivors. The aim of this randomized controlled trial was to evaluate the effect of ear acupuncture on sleep quality in breast cancer survivors. **Methods:** Fifty-two female breast cancer survivors (mean age 55.73 ± 8.10) were randomized to either 10 treatments of ear acupuncture within five weeks (N = 26) or to a single session of psycho-education and given an advice booklet concerning insomnia (N = 26). Both interventions were delivered in a group setting. Primary outcome was sleep quality (measured by the Pittsburgh Sleep Quality Index) at week 5 corrected for treatment expectancies. Secondary outcomes were inflammation parameters (interleukin-6) at week 5, sleep quality at week 17, and stress, anxiety, depressive symptoms, quality of life and fatigue 5 weeks and 17 weeks after randomization. **Results:** Intention-to-treat analysis showed a significantly stronger increase of sleep quality in the ear acupuncture group compared to the psycho-education group (p= .031; d = 0.64) at week 5. Furthermore, ear acupuncture improved stress (p= .030; d = 0.64), anxiety (p = .001; d = 0.97), and fatigue (p = .012; d = 0.75) at week 5 compared to psycho-education. No significant group difference was found on any outcome at week 17. No serious adverse events occurred during the study period. **Conclusions:** Group ear acupuncture may be a helpful intervention in tackling sleep problems in breast cancer survivors in the short term and may reduce stress, anxiety and fatigue as well. Long-term effects remain questionable. Clinical trial information: NCT03874598. Research Sponsor: Karl and Veronica Carstens-Foundation.

12068 Poster Session (Board #356), Fri, 8:00 AM-11:00 AM

Lifelong disease burden of chemotherapy in Hodgkin lymphoma (HL): A simulation study from the St. Jude Lifetime (SJLIFE) Cohort and HL International Study for Individual Care (HoLISTIC). *First Author: Susan K. Parsons, Tufts Medical Center, Boston, MA*

Background: Current emphasis for childhood and young adults with HL is to maintain high cure rates while concurrently identifying regimens to reduce excess long-term mortality/morbidity. Thus, understanding the late effects (LE) of contemporary clinical trials (CCT) for HL is critical. **Methods:** We used simulation to estimate the projected life expectancy (LExp), quality adjusted life-expectancy (QALE) & cause of death (COD) in a large cohort of HL CCT patients (pts) in the recently established HoLISTIC consortium by linking long-term risk models from the SJLIFE cohort. Individual patient data (IPD) on bleomycin, alkylating agents and anthracycline were extracted & harmonized for 982 HL pts in 5 prospective CCT (mean diagnosis age 19y, range 3-30y; 51% male; all treated with chemotherapy only; progression-free survival [PFS] >5y) in the HoLISTIC database. LExp, QALE & COD were projected using a previously developed microsimulation model (Bhakta, *Blood [Supplement]*, 2019) that incorporated mortality & incidence of LEs by diagnosis age, sex, race, treatment exposures & attained age estimated from 5,522 adult 10-y survivors of childhood cancers in the SJLIFE cohort (56% male; mean age at last follow-up 35y, range 19-68). Microsimulation was applied to 10,000 randomly selected survivors of HL CCT cohort, from 10y after HL diagnosis until death to project the LExp, QALE & COD. **Results:** Assuming 10-y PFS, LExp and QALEs projected for the HL CCT cohort using adjusted US general population rates linked with the SJLIFE microsimulation model, COD and trial-specific exposures are shown in the Table. **Conclusions:** A novel lifetime simulation approach was used to project LExp, QALE & COD by linking together IPD from CCTs with the long-term risk model of the SJLIFE survivorship cohort. Despite differences in PFS, reflecting in part the variation in risk/stage status, the projected long-term outcomes were similar. Our approach highlights a new opportunity to inform future clinical trial design and aid provider & patient decision-making. Research Sponsor: None.

12069 Poster Session (Board #357), Fri, 8:00 AM-11:00 AM

Long-term follow-up assessment of cardiac safety in SAFE-HEaRt, a clinical trial evaluating the use of HER2-targeted therapies in patients with HER2-positive breast cancer and compromised heart function. *First Author: Katia Khoury, Georgetown Lombardi Cancer Center, Washington, DC*

Background: HER2-targeted therapies are associated with cardiotoxicity, mostly asymptomatic and reversible. The impact of withholding these therapies on breast cancer outcomes is unknown. SAFE-HEaRt trial was the first study to evaluate the safety of HER2-targeted agents in patients with reduced left ventricular ejection fraction (LVEF) receiving concomitant cardioprotective medications and close cardiac monitoring. We report the 3-year follow-up (f/u) results. **Methods:** Thirty patients with stage I-IV HER2-positive breast cancer receiving trastuzumab, pertuzumab or ado-trastuzumab emtansine (TDM-1), with asymptomatic LVEF 40-49%, were started on beta blockers (ß-blockers) and/or ACE inhibitors/ARBs, with the primary endpoint being completion of HER2-targeted therapy without cardiac events (CE) or protocol-defined asymptomatic worsening of LVEF. **Results:** Patients were accrued from 10/2013 to 12/2017 and median f/u as of 2/7/20 is 37 months. The study met its primary endpoint with 27 patients (90%) completing their HER2-targeted therapies without cardiac issues. 24 patients were reconsented for long-term f/u. There were 23 evaluable patients (1 lost for f/u). Off study, 2 patients continued treatment with trastuzumab, 3 with trastuzumab and pertuzumab, and 3 with TDM-1 for metastatic disease. 1 of the 2 patients who had developed a CE with symptomatic heart failure (HF) died of progressive oncological disease, and the second had LVEF recovery on cardiac medications after completion of adjuvant HER2-targeted therapy. Almost 5 years later, she had an asymptomatic decline in her LVEF to 35% after deciding to stop her ß-blocker and ARB. Of the remaining 21 patients, 15 had recovery of their LVEF to $\geq$50%, 9 of whom remain on cardiac medications. 5 patients had stable LVEF 40-49% and remain asymptomatic on cardiac medications. Only 1 patient had symptoms suggestive of HF, with last documented LVEF stable at 45-50%, but she has not sought medical care for the last 15 months since relocating to another country. There were no new CE and no cardiac deaths. Mean LVEF was 45% at baseline, 46% at end of treatment, and 51.5% at long term f/u. **Conclusions:** Long-term f/u of the SAFE-HEaRt study continues to provide safety data of HER2-targeted therapy use in patients with compromised heart function. The late development of cardiac dysfunction is uncommon and continued multi-disciplinary oncologic and cardiac care of patients is essential for improved patient outcomes. Clinical trial information: NCT04143594. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

12070 Poster Session (Board #358), Fri, 8:00 AM-11:00 AM

Assessing the roles of inflammation and blood brain barrier permeability in cognitive impairment: A nationwide longitudinal study of patients receiving chemotherapy and non-cancer controls. *First Author: Elizabeth Belcher, University of Rochester Medical Center, Rochester, NY*

Background: Cognitive impairment is a prevalent side effect of chemotherapy. We have previously shown that chemotherapy treatment is associated with worse performance on the Rapid Visual Processing test (RVP), an objective measure of sustained attention, over time compared to non-cancer controls. Better understanding of the biologic mechanisms underlying cognitive impairment in cancer patients is needed. The pro-inflammatory cytokine tumor necrosis factor alpha (TNFα) has been implicated in increasing blood brain barrier (BBB) permeability, which in turn is associated with cognitive impairment. This study assessed the relationships of TNFα and S100β, a biomarker of BBB permeability, to each other and to RVP performance over time. **Methods:** We analyzed a subset of participants (n = 89 patients, n = 52 controls, mean age = 60) from a prospective longitudinal study of women with breast cancer receiving chemotherapy and non-cancer controls. TNFα and S100β were measured in serum pre-chemotherapy (T1, $\leq$7 days before first treatment) and post-chemotherapy (T2, $\leq$1 month after last treatment) and at corresponding times for controls. Sustained attention was assessed by total correct rejections on the RVP test at T1 and T2. Separate linear regression models including all participants were used to relate 1) baseline TNFα and S100β levels to change in RVP performance over time, 2) change in TNFα and S100β to change in RVP performance over time, and 3) change in TNFα to change in S100β. Models were adjusted for age. 4) T-tests were used to compare the TNFα and S100β change scores (T1 to T2) of patients vs controls. **Results:** Greater increase (T1 to T2) in the pro-inflammatory cytokine TNFα was associated with worse cognition, measured by performance on RVP over time ($p = 0.02$). Higher baseline S100β, a biomarker of BBB permeability, was associated with worse performance on RVP over time ($p = 0.09$). Increase in TNFα was associated with increase in S100β ($p = 0.11$). S100β increased from T1 to T2 in patients relative to controls ($p = 0.09$). **Conclusions:** These results suggest that higher TNFα may be related to increases in blood brain barrier permeability and worse cognition. Future studies will further define the link between inflammation, blood brain barrier permeability and chemotherapy-related cognitive decline, with the goal of informing the development of new interventions. Effects of GC4419 (avasopasem manganese) on chronic kidney disease in head and neck cancer patients treated with radiation and cisplatin. *First Author: Emily J. Steinbach, University of Iowa, Iowa City, IA*

Background: Nephrotoxicity is a major complication of platinum-based chemotherapy and ranges in incidence from 31-68%. The effects of platinum-based chemotherapeutics on long-term renal outcomes (chronic kidney disease, CKD) profoundly affect morbidity and mortality. Concurrent chemoradiotherapy (CRT) including cisplatin is standard for locally advanced squamous cell head and neck cancer (HNC) but is accompanied by the risk of CKD. In a randomized, multi-center, placebo-controlled Phase 2b trial (NCT02508389) of GC4419 (avasopasem manganese) in HNC patients receiving CRT, avasopasem reduced the duration, incidence, and severity of severe oral mucositis (Anderson et al, JCO 2019). Avasopasem did not appear to alter the safety profile of CRT in that trial, including incidence of adverse events of kidney injury or azotemia. **Methods:** Pre- and post-treatment markers of kidney function including blood urea nitrogen (BUN), serum creatinine (sCr), and estimated glomerular filtration rate (eGFR) were retrospectively evaluated for a subset of 52 of the trial patients who received 3 cycles x 100 mg/m^2 cisplatin plus placebo or 30 or 90 mg of avasopasem intravenously prior to RT, and 7 comparator patients who received the same CRT outside the study. Kidney function was evaluated between 3- and 24-months post-completion of cisplatin-radiation therapy by two-way analysis of variance (-ANOVA) as defined by the Kidney Disease Improving Global Outcomes (KDIGO) CKD staging. **Results:** Baseline patient characteristics were skewed towards a male population but were balanced across all treatment arms with regards to baseline kidney function (comparator + placebo, n = 19; 30 mg GC4419, n = 18; 90 mg GC4419, n = 15). Treatment with 90 mg GC4419 demonstrated normal BUN values (10-20 mg/dL) at 3, 6, and 18 months and normal sCr values (0.6-1.2 mg/dL) between 3 and 24 months as compared to the placebo arm + comparator group, which exhibited statistically elevated BUN and sCr ($p < 0.05$). Treatment with 90 mg GC4419 also demonstrated significantly higher eGFR between 3 and 24 months post-chemoradiation ($p < 0.05$) compared to the placebo arm + comparator group. 90 mg GC4419 treatment significantly reduced the incidence of CKD compared to the placebo arm and comparator group, as determined by fold change in sCr values and eGFR measurements $<$ 60 mL/min (stage G3a/b, G4, or G5 CKD). **Conclusions:** Avasopasem has the potential to reduce the incidence and severity of CKD in patients receiving cisplatin therapy. Clinical trial information: NCT02508389. Research Sponsor: Galera Therapeutics, Inc.

12072 Poster Session (Board #360), Fri, 8:00 AM-11:00 AM

Patient reported outcomes in older breast cancer survivors. *First Author: Sharon H. Giordano, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The majority of breast cancer patients are age 66 years or older at diagnosis, yet little is known about the symptom burden of older breast cancer survivors. **Methods:** Using the same process as for SEER-Medicare, data from the Texas Cancer Registry (TCR) and Medicare claims were linked. From this TCR-Medicare dataset, patients age 65 years and older at diagnosis, with localized or regional breast cancer, diagnosed in 2012 and 2013, and still alive in 2018 were identified. To assess long-term outcomes, a mailed survey, which included selected questions from the NCI's PRO-CTCAE question bank, was sent to 4591 eligible patients along with a $10 gift card. Non-responders were sent a follow-up questionnaire at 4-6 weeks and 8-10 weeks after initial mailing. The percentage reporting symptoms, overall and by treatment received, are described. **Results:** 1594 survivors completed the questionnaire (35% response rate). Median time from diagnosis to survey completion was 67 months. 70% of responders were age 65-74, 26% age 75-84, and 3% age 85+ at diagnosis. 84% were non-Hispanic white, 6% black, and 9% Hispanic. 77% had localized stage disease and 23% had regional disease at diagnosis. 58% had lumpectomy, 36% had mastectomy, and 2% reported no surgery. 77% had ER+ breast cancer. 28% received adjuvant chemotherapy. 48% had Part D claims for adjuvant endocrine therapy. PROs are reported in Table, overall and by use of chemotherapy and endocrine therapy. **Conclusions:** Older breast cancer survivors, particularly those who were treated with chemotherapy, experience a high symptom burden. Research Sponsor: CPRIT, Other Foundation.

Financial toxicity among breast cancer survivors with health insurance. *First Author: Wendy Landier, University of Alabama at Birmingham, Birmingham, AL*

Background: Cancer treatment and its sequelae have been associated with financial toxicity in breast cancer survivors, particularly those who have no health insurance. However, the prevalence of financial toxicity in the insured survivors, and the underlying factors are not well understood. **Methods:** Breast cancer survivors attending a survivorship clinic (University of Alabama at Birmingham) completed a survey assessing demographics, financial toxicity (i.e., material resources; food/housing/energy insecurity), and health-related quality of life (HRQL: SF-36). Clinical characteristics were abstracted from medical records. A multivariable logistic regression model was developed to understand factors associated with financial toxicity; the model included survivor age, race, socioeconomic status, insurance type, marital status, cancer stage, time since diagnosis, current medications, and physical and mental domains of HRQL. **Results:** The 368 participants (1% male; 67% white, 25% African American, 8% other) were a median of 61y of age (range, 33-86y) and 4.3y post-diagnosis (1-34y) at survey completion; 90% had stage 0-II disease; 34% were single (not currently married/partnered); type of health insurance included private/military (57%), Medicare (39%), and Medicaid/self-pay (4%). Overall, 31% reported financial toxicity; 26% endorsed not being able to live at current standard of living $>$ 2 mo. if they lost all current sources of income; 6% endorsed energy insecurity, 5% endorsed food insecurity, and 4% endorsed housing insecurity. In a multivariable model, financial toxicity was associated with age $\leq$60y at survey (Odds Ratio [OR] 5.1; 95% confidence interval [CI] 2.0-13.3); household income $<$ $50K/y (OR 5.3; 95%CI 2.5-11.2); being single (OR 2.6; 95%CI 1.3-5.4); and lower physical (OR 2.6; 95%CI 1.2-5.4) and mental (OR 2.2; 95%CI 1.2-4.3) HRQL. Cancer stage, race, time from diagnosis, and insurance type were not associated with financial toxicity. The prevalence of financial toxicity among survivors who were single, $\leq$60y at survey, and with household income $<$ $50k/y was 79.3%, compared with 6.7% among those who were older, married/partnered, and with higher income. **Conclusions:** Financial toxicity is prevalent among insured breast cancer survivors several years after cancer diagnosis, and is exacerbated among the younger survivors who are single, with low household income, and endorse poorer physical and mental quality of life. These findings inform the need to develop interventions to mitigate financial toxicity among at-risk breast cancer survivors. Research Sponsor: Breast Cancer Research Foundation of Alabama.

12074 Poster Session (Board #362), Fri, 8:00 AM-11:00 AM

Cutaneous pigmentary changes related to anticancer therapy in African Americans. *First Author: Dulce M. Barrios M.S, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pigmentary disorders are known to disproportionately affect individuals with darker skin, including African Americans (AAs)— a historically underrepresented population in oncology research. However, reports on the prevalence and characterization of anticancer-therapy related cutaneous pigmentary changes in this population are lacking. **Methods:** A retrospective analysis of AA cancer patients that ever received a hematopoietic stem cell transplantation (HSCT) and/or systemic oncologic therapy within six months prior to diagnosis of cutaneous hypo- or hyperpigmentation at our institution between 4/18/2012 and 8/26/2019 was conducted. Clinical and management characteristics were summarized; severity of pigmentary changes was assessed using the Common Terminology Criteria for Adverse Events version 5.0 (CTCAE v.5.0). **Results:** From a total of 1342 AA patients evaluated by oncodermatologists during the study period, 121 (9%) met inclusion criteria. Average age in this cohort was 52, and 102 (84%) were women. Breast (63, 52%), gastrointestinal (14, 12%), and hematologic malignancies (13, 11%) comprised the majority of cancer diagnoses. Most (93, 77%) patients had skin hyperpigmentation (84, 69%) or hypopigmentation (9, 7%) as a primary CTCAE diagnosis; the rest had secondary post-inflammatory hyperpigmentation (28, 23%). A higher proportion (105, 87%) of pigmentary alterations was attributed to single agents [i.e. chemo- (55, 46%), radiation (16, 13%), targeted (12, 10%), endocrine (9, 7%), and supportive oncologic (6, 5%) therapy] versus combination treatment (16, 13%). Five (4%) patients had graft versus host disease associated with allogeneic HSCT, four (80%) of which presented as cutaneous hypopigmentation. Hand foot syndrome (24, 20%), acneiform rash (24, 20%), and radiation dermatitis (16, 13%) were commonly diagnosed dermatologic adverse events (dAEs), generally classified as mild/grade 1 (67, 55%) in severity. For management, skin lightening agents +/- emollients (36, 30%) or emollients alone (25, 21%) were highly recommended. Topical corticosteroids +/- emollients were prescribed just as frequently as reassurance and/or avoidance of sun exposure (22, 18%). **Conclusions:** Cutaneous pigmentary changes related to cytotoxic chemotherapy, radiation and/or targeted oncologic therapy are common in AA cancer patients. Undertreatment of these dAEs, possibly due to under-recognition in darker skin, warrants further investigation to assess impact on quality of life and help improve management in this population. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

12075 Poster Session (Board #363), Fri, 8:00 AM-11:00 AM

Long-term cancer survival in cohorts of U.S. health professionals. *First Author: En Cheng, Yale University, New Haven, CT*

Background: Few studies have investigated long-term survival and causes of death among men and women diagnosed with major cancers. **Methods:** We estimated overall and cause-specific mortality rates for men diagnosed with prostate, lung and bronchus, colon and rectum, bladder, and melanoma cancer in the Health Professionals Follow-up Study between 1986-2010+, and women with breast, lung and bronchus, colon and rectum, uterine corpus, thyroid, and ovarian cancer in the Nurses' Health Study (NHS) between 1976-2010+ and NHS II between 1989-2010+. Kaplan-Meier curves were used to calculate cumulative mortality rates at 5, 10, 15, 20, and 30 years and competing risk methods were used to calculate cumulative cancer-specific mortality rates of major causes at 5, 10, 15, 20, and 30 years. Additionally, among women 40-year mortality rates were calculated. **Results:** Except for lung and ovarian, most major cancer patients are more likely to die from other causes than the index cancer. We observed two basic patterns for cumulative cancer-specific mortality rates. The first pattern is greatly diminished risk of index cancer-specific mortality 10 years or more following diagnosis - for colorectal cancer, cancer-specific mortality rate increased by less than 3% between 10 to 30- or 40-year following diagnosis (among men, from 35.1% to 36.7%; among women, from 34.8% to 37.7%), and this pattern also applied to bladder, melanoma, or uterine corpus cancer. The second one is sustained, but nevertheless low, excess risk - prostate cancer-specific mortality rate increased gradually and almost linearly from 5.3% to 15.1% after diagnosis from 5 to 30 years, and for breast cancer, it increased likewise from 7.2% to 18.9% after diagnosis from 5 to 40 years. **Conclusions:** Except for lung and ovarian cancers, patients diagnosed with major cancers were more likely to die from causes other than cancer. Colorectal, bladder, melanoma or uterine corpus cancer patients surviving more than 10 years after diagnosis are unlikely to ever die from that disease. Research Sponsor: U.S. National Institutes of Health.

All-cause* and cancer-specific† mortality rates of men (1986-2018) and women (1976-2018) diagnosed with major cancers.

	Men				Women		
		30-year				40-year	
Cancer Types	N	AC	CS	Cancer Types	N	AC	CS
Prostate	6,993	86.5	15.1	Breast	19,904	70.9	18.9
Lung and bronchus	1,309	98.1	83.1	Lung and bronchus	4,251	98.1	80.8

Risk of secondary hematologic malignancies in patients with ovarian cancer treated with PARP inhibitors: A combined meta-analysis of seven phase III randomized controlled trials. *First Author: Thura Htut, Department of Haematology, Aberdeen Royal Infirmary, Foresterhill Health Campus, Aberdeen, United Kingdom*

Background: Ovarian cancer (OC) is a leading cause of death from gynecologic cancers in women worldwide. Poly adenosine diphosphate ribose polymerase (PARP) inhibitors prevent the repair of single-strand breaks and generate double-strand breaks in tumor cells and have recently shown survival benefits in OC. Yet, the impact on the risk of secondary hematologic malignancies (SHM) remains uncertain. We performed a combined meta-analysis of randomized controlled trials (RCT) to determine the risk of SHM in patients with advanced OC treated with PARP inhibitors. **Methods:** MEDLINE, EMBASE databases and meeting abstracts from inception through January 2020 were queried. Phase III RCTs utilizing PARP inhibitors maintenance in advanced OC were eligible. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Heterogeneity was assessed with I^2 and Cochran's Q- statistic. Fixed effects model was applied. **Results:** A total of 4,445 patients with advanced OC from seven phase III RCTs were included. The study arm used olaparib or niraparib or rucaparib or veliparib or olaparib +bevacizumab while the control arm utilized placebo or bevacizumab. Randomization ratio was 2:1 in all studies. The I^2 statistic for heterogeneity was 0, suggesting some heterogeneity among RCTs. The overall SHM incidence was 0.80% in PARP inhibitors group vs 0.47% in control group (RR 1.45; 95% CI: 0.68 – 3.07, P = 0.34). In patients with newly diagnosed OC (n = 3,044), the incidence was 0.59% vs 0.09% in control group (RR 2.7; 95% CI: 0.7—10.37, P = 0.15). In recurrent OC subset (n = 1,401), 1.28% were reported in both study and control arms (RR 0.96; 95% CI: 0.38-2.46, P = 0.94). SHM was noted in 1.3% in the olaparib subgroup compared to 1% in the control with RR of 1.24 (95% CI: 0.46 –3.31, P = 0.67). SHM occurred in 0.7% in the niraparib subgroup compared to 0.47% in the control with RR of 1.28 (95% CI: 0.30-5.45, P = 0.74). **Conclusions:** Our study demonstrated that the risk of SHM was not significantly increased in patients who received PARP inhibitors compared to control arm, despite attaining survival benefits. Further studies and long term follow up are necessary to define the actual relation and definitive incidence. Research Sponsor: None.

12077 Poster Session (Board #365), Fri, 8:00 AM-11:00 AM

High flow oxygen for dyspnea in hospitalized patients with cancer: A 4x4 crossover randomized clinical trial. *First Author: David Hui, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Dyspnea is common in hospitalized cancer patients and highly distressing. High flow oxygen (HFOx) is administered for oxygenation in this setting; however, its effect on dyspnea has not been well examined, particularly among non-hypoxemic patients. In this phase II trial, we assessed the effect of HFOx, high flow air (HFAir), low flow oxygen (LFOx) and low flow air (LFAir) on dyspnea. We hypothesized that HFO and HFA can alleviate dyspnea. **Methods:** This double-blind, 4x4 crossover clinical trial enrolled hospitalized patients with cancer who were dyspneic (NRS $\geq$3 at rest) and non-hypoxemic (SpO2>90% on room air). Patients were randomized to 10 minutes of HFOx, HFAir, LFOx and LFAir in different orders. The flow rate was titrated between 20-60 L/min in the high flow groups and 2 L/min in the low flow groups. The primary outcome was dyspnea 0-10 numeric rating scale (NRS) "now", where 0=none and 10=worst. Secondary outcomes included modified Borg scale dyspnea intensity and unpleasantness, adverse effects, and overall preference. We compared among the interventions with a linear mixed model adjusting for time, treatment effect, period effect and carryover effect. **Results:** 17 patients completed 55 interventions in a random order. Mean age 51, 58% female, mean baseline dyspnea NRS 6.3 (SD 1.7). The absolute change of dyspnea NRS between 0 and 10 minutes was -1.8 (SD 1.7) for HFOx, -1.8 (2.0) for HFAir, -0.5 (0.8) for LFOx and -0.6 (1.2) for LFAir. In mixed model analysis, HFOx group provided greater dyspnea relief than LFOx (mean difference [95% CI] -0.80 [-1.45, -0.15], P=0.02) and LFAir (-1.24 [-1.90, -0.57], P<0.001). HFAir also provided a significantly greater dyspnea relief than LFOx (-0.95 [-1.61, -0.30], P=0.005) and LFAir (-1.39 [-2.05, -0.73], P<0.001). No difference was found between HFOx and HFAir nor between LFOx and LFAir. There was no significant carryover effect. Dyspnea Borg scale intensity and unpleasantness showed similar changes. Oxygen saturation increased in the HFOx group (97.2% to 99.7%) and LFOx group (95.5% to 98.2%) but not HFAir nor LFAir groups. HFOx was well tolerated. At the end of the study, 7 (54%), 4 (31%), 1 (8%) and 1 (8%) patients blindly preferred HFOx, HFAir, LFOx and LFAir, respectively. **Conclusions:** For the first time, we found that HFOx and HFAir provided a rapid and clinically significant reduction of dyspnea at rest in hospitalized cancer patients even when they were non-hypoxemic, supporting a role for high flow devices to provide palliation beyond oxygenation. Larger studies are needed to confirm these findings. Clinical trial information: NCT02932332. Research Sponsor: Sabin Family Foundation Fellowship Award.

12078 Poster Session (Board #366), Fri, 8:00 AM-11:00 AM

Patient controlled analgesia (PCA) vs non-PCA intravenous hydromorphone titration for severe cancer pain: A multi-center, phase III trial, HMORCT09-1. *First Author: Rongbo Lin, Gastrointestinal Medical Oncology, Fujian Cancer Hospital, Fuzhou, China*

Background: The titration of opioid dosage is necessary for adequate pain relief with acceptable side effects among individuals with cancer pain. The titration process can be achieved by non-patient administration or PCA pump. The aim of this study was to evaluate the efficacy of PCA versus non-PAC titration for severe cancer pain. **Methods:** Patients with severe cancer pain (NRS $\geq$ 7/10 at rest) were randomized into PCA or non-PCA titration and stratified by opioid tolerance or intolerance. For PCA, the pump was set as no continuous dose, hydromorphone bolus dose was 10%-20% of the total equianalgesic of past 24h for opioid tolerance, or 0.5 mg for opioid intolerance. The lockout time was 15 min. For non-PCA, initial hydromorphone bolus was the same with PCA. Reassess pain at 15 min. The dose of hydromorphone was increased by 50%-100% if pain unchanged or increased, or repeated if NRS was 4-6, or continue at current dose as needed if NRS$\leq$3. The primary endpoint was the time to successful titration (TST) - time from start to the time of pain controlled at NRS $\leq$ 3 in two consecutive evaluation with 15-min intervals, which was tested by K-M curve. **Results:** A total of 214 patients were randomized (106 in PCA, 108 in non-PCA) in 17 study sites. The most common sites of primary cancer were lung (21.03%), stomach (15.89%), colorectal (14.49%) etc. Median TSTs were 0.50h in PCA, 0.79h in non-PCA, HR 1.64 (95% CI 1.23, 2.17, P = 0.00127). In opioid tolerance, 0.50h in PCA, 1.00h in non-PCA (HR 1.92, 95% CI 1.32, 2.78, P = 0.0025). while in opioid intolerance, 0.50h in PCA and 0.50 in non-PCA (HR 1.35, 95% CI 0.88, 2.04, P = 0.162). The median dosage of hydromorphone for TST was 1.00mg (P_{25}, P_{75} 0.50, 2.00) in PCA, 1.50mg (P_{25}, P_{75} 1.00, 2.50) in non-PCA (P = 0.086). In opioid tolerance, 1.00mg (P_{25}, P_{75} 1.00, 2.00) in PCA, 2.00mg (P_{25}, P_{75} 1.00, 4.00) in non-PCA (P = 0.009). In opioid intolerance, 1.00mg (P_{25}, P_{75} 0.50, 2.00) in PCA and 1.00 mg (P_{25}, P_{75} 0.50, 2.00) non-PCA (P = 0.793). Mean patient satisfaction assessed by ESAS score was significantly superior in PCA to non-PCA (0.62$\pm$0.67 vs 1.27$\pm$0.98 for ITT, 0.66$\pm$0.66 vs 1.39$\pm$1.00 for opioid tolerance, and 0.56$\pm$0.69 vs 1.13$\pm$0.95 for opioid intolerance). Adverse events were similar in both PCA/non-PCA groups. **Conclusions:** PCA IV hydromorphone titration provided quicker analgesic effect, higher patients satisfaction, and a similar tolerability as compared to non-PCA administration in patients with severe cancer pain. Clinical trial information: NCT03375515. Research Sponsor: None.

12079 Poster Session (Board #367), Fri, 8:00 AM-11:00 AM

Using digital engagement to proactively manage symptoms in patients on capecitabine. *First Author: Mandeep Sohal, CVS Health, Woonsocket, RI*

Background: Adherence to oral chemotherapy is a challenge due to the toxic adverse events (AEs) patients' experience. Capecitabine (CAP) may cause patients to experience AEs such as diarrhea and hand and foot syndrome (HFS), leading to therapy non-adherence. Digital patient engagement has successfully improved patient adherence and has been used to monitor AEs in a variety of cancer types. We used proprietary secure messaging to engage specialty patients receiving CAP and to message them at the expected onset of diarrhea and HFS; nurse care management was deployed for patients reporting an AE. The objective of this study was to determine whether nurse engagement using digital tools to manage oncology AEs resulted in improved medication adherence. **Methods:** CAP patients were sent outgoing SMS branching logic messages during November 2019, and respondents reporting AEs were engaged by nurses using a proprietary secure messaging platform. Nurses made clinical interventions in these patients by either making a pharmacologic or non-pharmacologic recommendation or referring the patient to an oncologist. The number of patients responding to outgoing SMS and secure messaging, nurse interventions, and medication fill history were measured. We compared 30-day post-intervention proportion of days covered (PDC) in the intervention group (those that engaged with nurses and received digital adherence and clinical messages) to standard of care (those who received digital adherence and clinical messages but did not engage) using the Student's t-test. **Results:** 1,421 outgoing messages were sent to utilizers of CAP; 95 patients replied indicating the occurrence of either diarrhea or HFS. Nurse care managers reached 49 (52%) unique patients resulting in 54 interventions where care coordination was provided. The majority of engaged patients reached (74%) had symptom resolution as a result of nurse intervention. PDC was 79.3% in the intervention group and 68.8% (p = 0.038) in the standard of care group. **Conclusions:** SMS and secure messaging patients with AEs on CAP resulted in clinical interventions by nurse care managers. Nurse intervention resulted in the majority of patients having symptomatic resolution and therapy continuation. PDC indicated greater medication adherence in the engaged group. These results for one drug suggest that nurse digital engagement can be effective in increasing adherence for patients treated with oral oncolytics suffering from AEs. Proactive symptom tracking supports the early identification of potential AEs and effective nurse care coordination. Research Sponsor: CVS Health.

12080 Poster Session (Board #368), Fri, 8:00 AM-11:00 AM

Relationships between worry about dying in patients with advanced cancer and their illness understanding, treatment preferences, and advance care planning. *First Author: Rachel Rodenbach, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Patients with advanced cancer often worry about dying, yet little is known about the role their fears play regarding future care. We aimed to explore relationships between patients' worry about dying and their illness understanding, treatment preference, and advance care planning. **Methods:** This cross-sectional study uses baseline data from a community-based, primary palliative care intervention trial. Patients had metastatic solid tumors, an Eastern Cooperative Oncology Group performance status of 0-2, and their oncologist "would not be surprised" if they died in the next year. Using patients' response to "I worry about dying" (not at all, a little bit, somewhat, quite a bit, or very much) from the Functional Assessment of Chronic Illness - Palliative Care survey instrument, univariate and multivariate analyses assessed associations with illness understanding (report of being terminally ill or not), treatment preference (life-extending vs. symptom-focused), and advance care planning (completion of an advance directive or not). We also performed sensitivity analyses substituting "I feel scared about my future" (strongly disagree, disagree, agree, or strongly agree) from the Herth Hope Index for "I worry about dying." **Results:** Of 672 patients, 54% were female, 94% white, and 69% currently receiving chemotherapy. 47% reported worrying about dying "not at all," while 9.7% worried "quite a bit" or "very much." In regression analysis, those who worried "quite a bit" or "very much" were more likely to describe themselves as terminally ill (adjusted odds ratio (AOR)=1.98, 95% CI=1.10-3.54, p=0.021) and more likely to prefer life-extending treatment over symptom-focused care (AOR=2.61, 95% CI=1.30-5.22, p=0.007) compared with patients who reported not worrying about dying. They also were less likely to have completed an advance directive (AOR=0.49, 95% CI=0.25-0.94, p=0.032). The same relationships were observed using patients' response to "I feel scared about my future." **Conclusions:** Patients with advanced cancer who worry more about dying can affirm they are terminally ill and are more likely to want life-extending treatment over symptom care while less likely to engage in advance care planning. Understanding these patients' decision making is critical to ensuring that their values are known and understood near the end of life. Research Sponsor: U.S. National Institutes of Health.

12081 Poster Session (Board #369), Fri, 8:00 AM-11:00 AM

Results of a randomized, open-label, multicenter trial to assess the safety, dose, and schedule ofRRx-001(001) in reducing incidence, severity and duration of severe oral mucositis (SOM) inpatients receiving concomitant chemoradiation (CRT) for advanced head and neck cancer (HNC). *First Author: Marcelo Raul Bonomi, James Cancer Hospital Solove Research Institute, The Ohio State University, Columbus, OH*

Background: SOM occurs in 70% of patients receiving CRT for HNC with consequent pain, treatment interruptions and increased costs of care. Supraphysiologic levels of oxidative stress are key SOM initiators. 001 activates nuclear factor erythroid related factor 2 (Nrf2) increasing expression of multiple antioxidant genes including superoxide dismutase glutathione peroxidase and glutathione S-transferase. This trial examined the effect of dose and schedule on safety and efficacy of 001. Primary efficacy endpoint was duration of SOM (WHO criteria assessed); secondary endpoints included time to onset, incidence grade 4 through 60Gy and 70Gy. **Methods:** Locally advanced HNC treated with definitive or postoperative CRT (cisplatin + RT) received one of 3 001 schedules: (ARM1) 2 doses/wk for 2 weeks (prior to) CRT. ARMS 2, 3: prior to + 2 doses or 6 doses with CRT respectively or standard of care (SOC). **Results:** 53 patients randomized, 45 evaluable. Benefit trends for endpoints were consistent across all 3 001 arms with greatest effect size in pre-treatment only, ARM1. Compared to SOC, 001 reduced duration of SOM by 45% (40 vs 22 days). Through 60Gy and 70Gy a reduction of 95% and 79% in duration SOM was also observed (17 vs 1 day, and 23 vs 5 days) respectively. No patients in ARM1 developed grade 4, (0% vs SOC 30%). Side effects were comparable to SOC. **Conclusions:** In this small, open label trial, 001 demonstrated a favorable risk-benefit profile supported by reductions in overall SOM duration including through 60Gy and 70Gy with no grade ARM1 was most effective suggesting short periods of Nrf2 activation before CRT oxidative stress generation may increase the threshold and buffering capacity of upregulated antioxidants. Larger, blinded trials, confirming the observed dose, schedule and treatment effects are warranted. Clinical trial information: NCT03515538. Research Sponsor: Prothex Pharma, Inc.

12082 Poster Session (Board #370), Fri, 8:00 AM-11:00 AM

Value of oncologist generated "surprise question" in predicting survival in metastatic cancer. *First Author: Stephen B. Edge, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Treating patients with metastatic cancer (MCA) requires timely integration of palliative and hospice care (PHC). The Surprise Question (SQ-"Would you be surprised if your patient died in the next year?") may help predict short-term mortality in patients with chronic disease and prompt initiation of PHC. There limited data on the utility of the SQ in oncology and none controlling for age and cancer site (CS). This study evaluates the SQ in MCA. **Methods:** SQ data were collected using a clinical oncology pathway program (COP) in which the treating oncologist is required to answer the SQ for all patients with MCA. The cohort includes MCA patients with SQ entries from 5-1-2018 to 4-30-2019 providing cohorts with 6- and 12-months follow-up (f/u) from the date of the SQ. Vital status was determined as of 1-15-20. Over 90% of deaths are reported with 3 months of death. Models using SQ response (yes/no), cancer site and age were tested with logistic regression (LR) with Akaike Information Criterion (AIC) for model selection (lower number best model) and ANOVA to assess the value of the SQ in predicting mortality. **Results:** There were 655 and 1276 patients with MCA in COP with 1 year and 6 months f/u from the SQ, respectively. The proportion with the SQ response "No" (shorter expected survival) varied by cancer site (range 19% – 82% - e.g. breast 42%; pancreas 81%). The SQ was the best predictor compared to cancer site and age for 6 and 12-month mortality (LR Model A – lowest AIC). The odds ratio of death at one year from SQ-No vs. SQ-Yes was 3.8 (95% CI 2.7, 5.4) with a strong association between SQ response and 1-year and 6-month mortality ($p < 0.001$). See Table. **Conclusions:** Oncologist assessment of survival expectancy by the SQ in MCA is a strong predictor of mortality beyond cancer site and age. The treating oncologist's response to SQ can serve as a simple and reliable predictive tool to identify those with MCA likely to die sooner who may benefit from timely referral to PHC. Research Sponsor: None.

Follow-up Time	6-month	6-month SQ-No	6-month SQ-Yes	1-year	1-year SQ-No	1-year SQ-Yes
Total at Risk	1276	972	604	655	328	327
Mortality	324 (25%)	230 (34%)	94 (16%)	278 (42%)	191 (58%	87 (26%)
Pearson's c^2 test			$p_{val}<$ 0.001			$p_{val}<$ 0.001
Model Description	AIC	Comparison	p_{val}	AIC	Comparison	p_{val}

12083 Poster Session (Board #371), Fri, 8:00 AM-11:00 AM

Assessing the impact of antiemetic guideline compliance on prevention of chemotherapy-induced nausea and vomiting (CINV): Results of the Nausea/Emesis Registry in Oncology (NERO). *First Author: Matti S. Aapro, Clinique de Genolier, Genolier, Switzerland*

Background: Evidence-based antiemetic guidelines offer predominantly consistent recommendations for CINV prophylaxis. However, studies and surveys suggest that adherence to these recommendations is suboptimal. We explored potential inconsistencies between clinical practice and guideline-recommended treatment with a registry evaluating the effect of guideline-consistent CINV prophylaxis (GCCP) on patient outcomes. **Methods:** This was a prospective, non-interventional, observational, multicenter study designed to assess overall (0-120 h) complete response (CR: no emesis/no rescue use) rates in patients who received GCCP or guideline inconsistent CINV prophylaxis (GICP) using diaries for 5 days following chemotherapy. Cycle 1 results are presented in patients who received either 1) anthracycline/cyclosphosphamide (AC) highly emetogenic chemotherapy (HEC), non-AC HEC or carboplatin, with GCCP for all these groups consisting of prophylaxis with an NK_1 receptor antagonist (RA), 5-HT_3RA, and dexamethasone (DEX) prior to chemotherapy or 2) moderately emetogenic chemotherapy (MEC), with GCCP consisting of a 5-HT_3RA and DEX prior to chemotherapy as per MASCC 2016 guidelines. CR rates for cohorts deemed to be GCCP and GICP were compared using a chi-square test. **Results:** A total of 1,089 patients were part of the cycle 1 efficacy evaluation. Overall GCCP was 23% for all patients. CR rates were significantly higher in patients receiving GCCP versus GICP (Table). **Conclusions:** Consistent with prior studies, GCCP was very low. The primary endpoint of the study was achieved as there was a significant benefit of almost 10% improved prevention of CINV when administering GCCP. As per MASCC/ESMO guidelines such an absolute difference should be practice changing. Comprehensive multifaceted strategies are needed to achieve better adherence to antiemetic guidelines. Research Sponsor: Angelini Pharma Oestereich GmbH.

All Patients (N = 1089)	GCCP	GICP
Proportions of Patients who Received GCCP vs. GICP	251/1089 **(23.0%)**	838/1089 **(77.0%)**
Overall CR Rates	156/251 **(62.2%)***	441/838 **(52.6%)**

*Statistically significant difference ($P < 0.05$, chi-square test) between GCCP vs. GICP group

Symptom burden as a predictor of emergency room use and unplanned hospitalization in patients with head and neck cancer: A population-based study. *First Author: Christopher Noel, Department of Otolaryngology Head and Neck Surgery, Faculty of Medicine, University of Toronto, Toronto, ON, Canada*

Background: Symptoms are common in oncology patients, though they remain undetected and untreated by clinicians in up to 50% of cases. Integrating patient reported outcomes (PRO) within routine clinical practice has been suggested as a way to improve detection. In order to inform an effective and efficient PRO symptom screening program, we sought to determine whether outpatient symptom scores could predict emergency room use and unplanned hospitalization (ER/Hosp) in a cancer patient population. **Methods:** This was a population-based study of patients diagnosed with head and neck cancer who had completed at least one outpatient Edmonton Symptom Assessment System (ESAS) assessment between January 2007 and March 2018 in Ontario. Logistic regression models were used to determine the relationship between reported outpatient ESAS scores and ER/Hosp use in the 14-day period following ESAS completion. A generalized estimating equations approach was incorporated to account for possible patient-level clustering. **Results:** There were 11,761 unique patients identified with a total of 73,282 ESAS assessments. There were 5,203 ER/Hosp outcome events. In adjusted analysis, the odds of ER/Hosp use increased log linearly with ESAS score (1.23 per 1 unit increase in index ESAS score, [95% confidence interval (CI) 1.22 – 1.25]). This corresponds to a 9.23 (95%CI 7.22-11.33) higher odds of ER/Hosp use for the maximum index ESAS score of 10. Seven of the nine ESAS symptom scores were significantly associated with ER/Hosp use with pain, appetite and shortness of breath demonstrating the strongest association. **Conclusions:** ESAS scores are independently associated with 14-day ER/Hosp in head and neck cancer patients. Appropriate and timely management of symptom burden may reduce rates of ER/Hosp. Research Sponsor: Canadian Institute of Health Research Terry Fox New Investigator Award, Other Foundation, Other Government Agency.

Logistic regression models for odds of 14-day ER use or unplanned hospitalization (ER/Hosp) by Index ESAS score.

ESAS Score (0-10)	Univariable		Multivariable*		14-day ER/Hosp use (%)
	OR	(95% CI)	OR	(95% CI)	
0	1	REF	1	REF	1.5
1	1.55	(1.21-1.99)	1.51	(1.17-1.95)	2.3
2	1.68	(1.34-2.10)	1.57	(1.24-1.97)	2.4
3	2.60	(2.09-3.23)	2.33	(1.87-2.90)	3.8

Optimizing management of the oncological patient with pulmonary embolism: Validation of the epiphany index—PERSEO study. *First Author: Manuel Sánchez Cánovas, Department of Hematology and Medical Oncology, Hospital G. Universitario Morales Meseguer, IMIB-Arrixaca, Murcia, Spain*

Background: EPIPHANY is the first algorithm to predict serious complications in both suspected and unsuspected cancer-associated pulmonary embolism (PE), overcoming limitations of previous models. **Methods:** PERSEO is a prospective multicenter study. We recruited cancer patients with both incidental and symptomatic PE treated between Oct. 2017 and Dec. 2019. The primary aim was to determine the percentage of serious complications in patients at low predicted risk, with at least 3% accuracy. We also compared the predictive parameters of EPIPHANY with other available scores for prediction 15-day serious complications and 30-day mortality. **Results:** Cohort includes 831 patients (men, 58.6%; median age, 66 years). Most frequent tumors were lung (27.1%), colorectal (19%) and breast (7.8%). 78.6% had stage IV disease, and 77.6% were receiving antineoplastic treatment. EPIPHANY classified 27%, 24% and 49% of patients as low, medium and high risk, respectively. The rate of 15-day serious complications increased significantly across these prognostic categories: 2.67 (95% CI 0.6 - 4.8), 8.9% (95% CI 0.5 - 12.8), and 25.9% (95% CI 21.7 - 30.2), for low, intermediate, and high risk patients, respectively ($p<0.001$, linear-by-linear test). In comparison with other validated scores, EPIPHANY has a higher negative predictive value, lower negative likelihood-ratio, and comparable sensitivity (Table). **Conclusions:** The EPIPHANY index is able to identify a subgroup of patients with cancer-associated pulmonary embolism at very low risk of serious complications or short-term mortality, with potential implications for decision making. Research Sponsor: Leo Pharma.

Frequency and prediction of non-medical opioid use behaviors (NMOU) among advanced cancer patients referred to a supportive care center (SCC). *First Author: Sriram Yennu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: One of the methodological barriers to conducting research on interventions for NOMU (Aberrant Opioid Use Behaviors) among cancer patients is the lack of data on the frequency of this problem. Although the frequency of risk factors has been established by our group and others, not all the patients with risk factors will be diagnosed with having NMOU behaviors, and some patients with no previous risk factors will engage in NMOU. AIM: To characterize the overall frequency of NMOU for a duration of 3 months, as well independent predictors for NMOU. **Methods:** In this retrospective study, 1558 consecutive patients referred to supportive care clinic (SCC) from 3/18/2016 to 6/6/2018 were reviewed for development of NMOU using established diagnostic criteria. Patients were eligible if they were $\geq$18 years, had a diagnosis of cancer, and were on opioids for pain for at least a week. All patients were assessed with the Edmonton Symptom Assessment Scale (ESAS), SOAPP-14, and CAGE-AID. Descriptive statistics, spearman correlation coefficient, multivariate analysis were performed. **Results:** 299 patients (19%) had $\geq$1 NMOU behavior. The median (IQR) NMOU behavior was 1 (1-2); range 1-10. Most NMOU occurred at 1st and 2nd follow up visits. The most frequent NMOU behavior was unscheduled clinic visit for inappropriate refills. 29/299 (10%) NMOU patients received specialized care for high-risk for aberrant opioid misuse by interdisciplinary team. Results of multivariate logistic regression model showed Marital status (Divorced vs. Married, OR=1.47, 95% CI: 0.98, 2.22, p=0.654 (marginally significant); Single vs. Married, OR=1.68, 95% CI: 1.15, 2.46, p=0.0079), SOAPP (Positive vs. Negative, OR=1.42, 95% CI: 1.05, 1.93, p=0.0238), morphine equivalent daily dose (MEDD) (OR=1.004, 95% CI: (1.003, 1.006), $p<0.0001$) and ESAS pain (OR=1.11, 95% CI: 1.06, 1.17, $p<0.0001$) were independently associated with the presence of NMOU during follow-up visits. **Conclusions:** 19% cancer patients followed at SCC had detectable NMOU behaviors. Being single, SOAPP+, pain severity and high MEDD were independent predictors for NMOU. This information will assist clinicians and investigators designing clinical and research programs in this important field. Research Sponsor: Institutional funds.

12087 Poster Session (Board #375), Fri, 8:00 AM-11:00 AM

Feasibility of olanzapine at reduced dose in highly emetogenic chemotherapy: A randomised controlled trial against aprepitant in triple therapy (FORESIGHT). *First Author: Michelle Chen, CISSS Monteregie-Centre-Hopital Charles LeMoyne, Greenfield Park, QC, Canada*

Background: Olanzapine is used as an adjunct antiemetic in oncology as salvage therapy and in four-drug prophylaxis. Growing literature supports its effectiveness in initial three-drug prophylaxis in highly emetogenic chemotherapy (HEC). **Methods:** This prospective, multi-centre, open-label study evaluated the feasibility of a large-scale randomized controlled trial comparing the effectiveness and tolerability of 5 mg olanzapine once daily for four days (starting the night before chemotherapy) versus standard dose aprepitant (in tritherapy with standard ondansetron and dexamethasone) in treatment-naive patients receiving the first cycle of a HEC. Secondary outcomes included: complete response (no nausea, no emesis, no use of rescue medication), complete remission (no emesis, no rescue medication), intensity of patient-reported nausea and emesis on a visual analog scale, quality of life (scored with the Functional Living Index Emesis [FLIE]), and incidence of adverse events. **Results:** We randomized 30 patients in an intent-to-treat analysis. The large-scale trial was deemed not feasible without support from a research centre. Complete response rates were significantly higher in the olanzapine group in the delayed phase (24-120h post-chemotherapy) (86,7% v 21,4%, $p < 0,001$) and overall phase (0-120h post-chemotherapy) (60,0% v 21,4%, $p = 0,04$). Similar results were observed for complete remission. Intensity of patient-reported nausea was significantly lower in the olanzapine group in the delayed phase ($p = 0,001$). FLIE scores were significantly lower for the nausea domain (mean 62,3 v 60,9, $p = 0,004$) and overall score (124,3 v 108,8, $p = 0,006$). Depression on the ESAS-R was more common in the aprepitant group (0% v 38%, $p = 0,01$). Other adverse events were not significantly different. **Conclusions:** Support from a research centre must be ensured for study feasibility. Tritherapy olanzapine significantly improved complete response and remission in the delayed and overall phases post-chemotherapy among patients receiving HEC. It was also associated with higher quality of life and a reassuring safety profile. This feasibility trial, despite its small sample size, is one of the first prospective randomised trials to suggest similar efficacy of 5 mg olanzapine to aprepitant and to measure a difference in patient quality of life with this regimen. Clinical trial information: NCT04075955. Research Sponsor: Funding was provided by the Pharmacy department of the CISSS Monteregie-Centre.

12088 Poster Session (Board #376), Fri, 8:00 AM-11:00 AM

Efficacy and safety of direct oral anticoagulants (DOACs) and low molecular weight heparin (LMWH) for primary prevention of venous thromboembolism (VTE) in ambulatory cancer patients. *First Author: Mina Shenouda, Tampa General Hospital, Tampa, FL*

Background: Active malignancy is a well described risk factor for thrombosis. Randomized clinical trials (RCT) have evaluated anticoagulation (AC) with DOACs or LMWH for prevention of VTE in ambulatory cancer patients. This objective of this meta-analysis is to evaluate the efficacy and safety of DOACs and LMWH thromboprophylaxis in adult patients with active solid organ malignancy or lymphoma. **Methods:** We conducted a search of MEDLINE, EMBASE, and CENTRAL from 10/31/2009-11/31/2019. Data for meta-analysis was extracted from studies that met inclusion criteria (RCT, ambulatory patients age >18 years with active solid organ malignancy or lymphoma, prophylactic AC with DOAC or LMWH). Risk ratio (RR) were calculated for primary (efficacy) end point of VTE occurrence and secondary (safety) end points of major bleeding (MB) and clinically relevant non-major (CRNMB). Subgroup analyses of efficacy and safety endpoints were conducted based on AC and cancer types. **Results:** Eleven trials met inclusion criteria with total of 7741 participants. Two trials evaluated DOACs and nine trials evaluated LWMH for thromboprophylaxis. Efficacy results are noted in Table. Safety outcomes for MB and CRNMB for AC were RR 1.83 (95% CI 1.26, 2.65), p=0.001 and RR 1.36 (95% CI 1.05, 1.76), p=0.02. Safety outcomes for MB and CRNMB for DOAC were RR 1.95 (95% CI 0.88, 4.30), p=0.10 and RR 1.35 (95% CI 0.80, 2.27), p=0.26. Safety outcomes for MB and CRNMB for LMWH were RR 2.05 (95% CI 1.19, 3.51), p=0.009 and RR 1.44 (95% CI 1.01, 2.05), p=0.04. **Conclusions:** Both DOACs and LMWH decrease risk for VTE development in ambulatory adult cancer patients. MB and CRNMB were significantly increased in patients taking LMWH but not in patients taking DOACs. A large clinical trial using DOACs for thromboprophylaxis would help elucidate the thrombosis and bleeding event rate in ambulatory cancer patients. Research Sponsor: None.

Efficacy outcomes.

Intervention	Outcome/ Subgroup	# Studies	Participants	Risk Ratio (95% CI)	p-value
AC	VTE	11	7741	0.74 (0.36, 061)	<0.00001
DOACs	VTE	2	1404	0.55 (0.34, 0.90)	0.02
LMWH	VTE	9	6337	0.44 (0.32, 0.61)	<0.00001
AC	VTE/ Pancreas	5	1011	0.33 (0.13, 0.81)	0.02

12089 Poster Session (Board #377), Fri, 8:00 AM-11:00 AM

Improving cancer pain control: Potential impact of *CYP2D6* pharmacogenomic (PGx) testing in oncology (Onc) patients. *First Author: Natalie Reizine, University of Chicago Medical Center, Chicago, IL*

Background: Several opioid analgesics have well-known germline PGx associations which may predict either inefficacy or exaggerated (toxic) responses, depending on the patient's genotype. Despite this, germline PGx testing has not been routinely incorporated into oncology care. We hypothesized that *CYP2D6* germline PGx profiling offers the potential to improve oncology patients' pain control by identifying individuals at increased risk for inadequate analgesia with standard opioid dosing. **Methods:** We retrospectively analyzed the medication histories of over 81,000 adult oncology patients treated at the University of Chicago from 2012-2018 for exposure to opioids. *CYP2D6* genotype (permitting assignment of metabolizer phenotype: normal metabolizer [NM], intermediate metabolizer [IM], or poor metabolizer [PM]) was determined post-hoc for 127 patients who were genotyped for other reasons unrelated to pain prescribing. The primary endpoint was the number of opioids required for pain control over the course of longitudinal care, comparing PM/IMs with NMs. The secondary endpoint was the number of hospitalizations for pain control. **Results:** Over 47,000 oncology patients were exposed to opioids, with an average of 2.67±1.6 different opioid medication exposures per patient. Thirteen percent of genotyped patients were IM/PM, who were at risk for inadequate analgesia. IM/PM patients demonstrated an increased number of different opioid exposures (4.5±2.1) compared to NM (2.7±2.1, P value = 0.002). IM/PM patients were also more likely to have a pain related hospitalization (OR 4.17, CI 1.3-13.2, P = 0.016). **Conclusions:** Based on population prevalence, we estimate that > 6000 oncology patients (1000 patients/year) who received opioids at our center were IM/PM and thus at risk for inadequate analgesia due to genetic predisposition. CYP2D6 germline PGx profiling offers the potential to improve oncology patients' pain management. Research Sponsor: Benjamin McAllister Fellowship, Clinical Therapeutics Training Grant â€“ T32GM007019.

12090 Poster Session (Board #378), Fri, 8:00 AM-11:00 AM

Phase II randomized controlled trial (RCT) of medical intensive nutrition therapy (MINT) to improve chemotherapy (CT) tolerability in malnourished patients with solid tumor malignancies. *First Author: Michael Shusterman, Weill Cornell Medicine, New York-Presbyterian Hospital, New York, NY*

Background: Malnutrition is an underrecognized predictor of inferior cancer related outcomes. Subjective global assessment (SGA), a brief validated survey for malnutrition, may predict increased CT toxicity. This phase II RCT was performed to validate SGA as a predictive tool for malnutrition and to evaluate the impact of MINT on CT associated toxicity. **Methods:** CT naive pts screened by SGA were assigned to well-nourished (SGA A) or malnourished (SGA B/C) cohorts. Both cohorts were followed for CT delivery, toxicity, quality of life (QOL) by FACT-G, biomarkers, radiology, and survival. SGA B/C pts, stratified by regimen/disease, were randomized 1:1 to MINT vs. usual care. The MINT cohort received weekly registered dietician counseling and symptom assessment over the 8-week study period. Percent standard and planned CT doses were calculated. Wilcoxon rank sum tests were used for differences between groups, log-rank tests for survival, and multivariable linear regression for adjusted comparisons. **Results:** 186 eligible pts were enrolled (94 SGA A, 92 SGA B/C). SGA A were younger (median age [range]; 63 [22, 89] vs. 70 [22, 91], p = 0.011) and more fit (ECOG 0-1; 96.8% vs. 72.8%, p < 0.001). Baseline QOL was higher for SGA A (median [range], 87 [34, 115]) vs SGA B/C (70 [31, 101], p < 0.001). SGA A was associated with higher CT delivery: median proportion of planned CT (1 [Q1 0.87, Q3 1] vs 0.94 [0.70, 1], p = 0.022) and standard CT (0.91 [0.72, 1] vs. 0.74 [0.57, 0.95] p < 0.001). Adjusted for age/ECOG, SGA A remained associated with > 80% of planned (OR 2.32, p = 0.05) and standard (OR 2.33, p = 0.04) CT. SGA B/C pts (n = 92) were randomized to MINT vs usual care: median nutrition encounters MINT 5.5 vs. usual care 0.5; we observed no differences in CT delivery: median proportion of planned CT (0.91 [0.69, 1] vs. 0.94 [0.74, 1], p = 0.84) and standard CT (0.75 [0.58, 0.96] vs 0.71 [0.52, 0.99], p = 0.59). SGA A was associated with a longer 12-month survival (77.8% [95% CI 69.6%, 86.9%]) vs. B/C (53.3% [42.8%, 66.4%], p < 0.0001; 12-month survival was similar for MINT (52.3% [38.1%, 71.9%]) vs usual care (54.4% [40.2%, 73.6%], p = 0.58). **Conclusions:** SGA is a validated tool to characterize malnutrition in pts receiving CT. Malnourished pts received significantly less CT, experienced worse baseline QOL, and had worse 12-month survival. Intensive medical nutrition therapy was not associated with differences in CT associated toxicity. Novel nutritional interventions are still needed to improve pt outcomes. Research Sponsor: Sandra and Edward Meyer Cancer Center Internal Grant.

12091 Poster Session (Board #379), Fri, 8:00 AM-11:00 AM

A systematic review of evidence for cannabis and cannabinoids as adjuvant therapy in palliative and supportive oncology care. *First Author: Sebastian Jugl, Department of Pharmaceutical Outcomes & Policy, College of Pharmacy, University of Florida; Center for Drug Evaluation and Safety (CoDES), Gainesville, FL*

Background: Medical cannabis use is increasing significantly in the United States as states reduce restrictions. However, ambiguity concerning the evidence for medical cannabis efficacy and safety, especially in the field of oncology, is persistent. Clinicians therefore face challenges in examining benefits and risks of medical cannabis as adjuvant treatment for cancer patients. This study identifies and evaluates the most recent available evidence for the efficacy of cannabis and cannabinoids as adjuvant in supportive and/or palliative use in patients with cancer. **Methods:** Electronic databases searched included PubMed, Embase, Web of Science, and Cochrane Library to identify studies published following the latest available systematic review, between July 2016 through October 2019. Studies conducted outside the United States, studies not evaluating cannabis or cannabinoids in Oncology care, and preclinical studies were excluded. Findings were organized in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) framework. Lastly, qualitative synthesis was used to generate summary statements about the role of cannabis and cannabinoids as adjuvant in supportive and/or palliative cancer care. **Results:** We screened 2,267 articles and included 96 studies in our qualitative synthesis. Among those were 2 RCT's (1 completed), 6 Systematic reviews with Meta-analysis, 4 Systematic reviews without Meta-analysis, 71 other types of reviews and 13 observational studies. The most frequently reported outcomes assessed were efficacy of cannabis and cannabinoids for: pain (40 of 96; 17 indicating improvement), nausea and vomiting (26 of 96; 20 indicating improvement), cachexia (22 of 96; 2 indicating improvement), and utilization patterns of cannabis and/or cannabinoids among cancer patients (8 of 96). **Conclusions:** Latest available prevalence estimates indicate that a significant proportion of patients in the United States with cancer use cannabis and/or cannabinoids (18.3-40.0%). There is substantial evidence for the effectiveness of cannabis and cannabinoids in treating cancer-related pain; specifically, oromucosal THC/CBD spray. There is conclusive evidence for the effectiveness of cannabis and cannabinoids in relieving chemotherapy-induced nausea and vomiting; specifically, oral THC. There is inconclusive evidence regarding the effectiveness of cannabis and cannabinoids in treating cancer-related cachexia. 12092 Poster Session (Board #380), Fri, 8:00 AM-11:00 AM

Quality of life in patients with locally advanced head and neck cancer undergoing chemoradiation with once-a-week versus once-every-three-weeks cisplatin. *First Author: Nandini Sharrel Menon, Tata Memorial Hospital, Mumbai, India*

Background: This trial was conducted to compare the efficacy of low dose once-a-week cisplatin with once-every-3-weeks cisplatin with radiation in locally advanced head and neck squamous cell carcinoma (LAHNSCC). The current analysis focuses on the quality of life (QoL) of patients in this trial. **Methods:** In this phase III randomized trial, patients with stage III or IV non-metastatic LAHNSCC were randomized to receive cisplatin 30 mg/m^2 once a week or cisplatin 100 mg/m^2 once every 3 weeks concurrently with curative intent radiotherapy. The primary endpoint was locoregional control. QoL was a key secondary endpoint. QoL was assessed using the EORTC QLQ-C30 (v.3) and EORTC QLQ-H&N35 (v.1). QoL data were assessed at baseline and days 22 and 43 during treatment; at the end of chemoradiation and at each follow-up. The linear mixed effects model was used for longitudinal analysis of QoL domains to determine the impact of treatment (arm) and time on QoL scores. **Results:** Three hundred patients were enrolled, 150 in each arm. QoL data from 283 patients with at least one assessable questionnaire were analyzed. The pretreatment QoL scores were similar in both the arms in all domains. There was no significant difference in the global health status/QoL with respect to the treatment arm (P=0.608) or time (P=0.0544). There was no significant difference in the longitudinal QoL scores between the two treatment arms in all domains except the physical function (P= .0074), constipation (P= .0326), trouble with social contact (P= .0321) and sexuality (P= .0004). There was a decline in the QoL scores in all domains in both arms during treatment. After completion of treatment, the QoL scores started improving steadily up to 1 year and plateaued thereafter in both arms. **Conclusions:** The use of once-every-three weeks cisplatin significantly improved the locoregional control without adversely impacting the quality of life as compared to once-a-week cisplatin in combination with radical radiotherapy in locally advanced HNSCC. Clinical trial information: CTRI/2012/10/ 003062.. Research Sponsor: Tata Memorial Centre Research Administration Council.

12093 Poster Session (Board #381), Fri, 8:00 AM-11:00 AM

Patient-reported distress and healthcare utilization in patients with advanced cancer. *First Author: Jordan Danielle Hildenbrand, Duke University School of Medicine, Durham, NC*

Background: The National Comprehensive Cancer Network (NCCN) defines distress as an unpleasant, multidimensional experience that may interfere with patient behavior, emotions, and ability to cope with illness. Distress screening is a critical aspect of comprehensive cancer treatment, but the relationship between patient-reported distress and healthcare utilization remains unclear. We assessed this relationship in patients with advanced cancers historically associated with high utilization, specifically non-small cell lung cancer (NSCLC) and non-colorectal gastrointestinal (NCRGI) cancer. **Methods:** We extracted data from the electronic medical record of adult patients with metastatic NSCLC and NCRGI cancers who were receiving active treatment, visited outpatient Duke Cancer Institute clinics between July 2013 and January 2017, and completed at least two self-report NCCN Distress Thermometer (DT) and Problem List (PL) surveys as part of routine clinical care between July 2013 and March 2019. Mixed effects logistic regression was used to estimate the odds of hospitalization or emergency room (ER) visit within either 3 or 6 months after each self-reported DT, with adjustment for age at first distress score, sex, primary tumor site, race (white vs. non-white) and duration of participation (i.e., time from first distress score to 3 months after the last distress score) information from the EMR. **Results:** A total of 11,027 DT scores were collected from 848 patients, with 508 (60%) having NSCLC, 340 (40%) having NCRGI cancer, and 192 (23%) reporting actionable distress (i.e., DT score $\geq$4). Actionable distress was associated with higher odds of hospitalization or visiting the ER within 3 months (OR = 1.37; 95% CI = 1.19, 1.58; $p < 0.001$) and 6 months (OR = 1.19; 95% CI = 1.03, 1.37; p = 0.019) after DT self-report. Patients who had an average DT score of $\geq$4 were more likely to report the following problems at least once: worry (89% of patients), nervousness (79%), fatigue (95%), pain (92%), sleep problems (79%), and eating problems (79%). **Conclusions:** Patient-reported distress is associated with greater healthcare utilization in patients with advanced NSCLC and NCRGI cancers who are receiving active treatment. These patients report high burden of physical and emotional problems. Actionable distress may be a useful indicator of patients in need of specialist palliative care interventions. Research Sponsor: None.

12094 Poster Session (Board #382), Fri, 8:00 AM-11:00 AM

A community oncology palliative care program: Pain-related inpatient utilization in oncology care model (OCM) patients. *First Author: Adil Jamal Akhtar, Michigan Health Professionals, Sterling Heights, MI*

Background: Oncology Division of Michigan Health Professionals (MHP) participates in OCM. A comprehensive community oncology program for early and timely involvement of palliative care (PC) was launched in September 2017 to help achieve the OCM program goals of high-quality, cost-effective, coordinated care. PC provides a single point of care for all-cause pain management. PC program included pre-program training and continuous education for early and timely involvement of PC. This study aims to assess the educative effect of PC to reduce pain-related inpatient admissions (Pain IP) in all MHP OCM patients, irrespective of PC-referral. **Methods:** This initiative was led by palliative care physicians and included continuous education and reinforcement of the benefits, every 2-4 weeks, by sharing PC outcomes data with MHP physicians. Physician feedback was part of the program enhancements that were regularly reviewed during monthly MHP physician meetings. Retrospective claims review was performed with OCM episodes from Oct 2016 – Mar 2019. Monthly Pain IP utilization (based on diagnosis code) per 1000 OCM patients (UPK) was analyzed within pre- and post- PC Program start (Sep 2017). Cost per Pain IP included mean of 30-day follow-up skilled nursing facility (SNF) stay and 30-day outpatient facility expenses. Monthly historical Pain IP (pre-PC UPK) was compared to post-PC Pain IP UPK to calculate OCM savings from PC education at MHP. **Results:** Pain IP peaked at 7.12 UPK in September 2017 when PC program training and education started, then fell as low as 0.87 UPK in January 2019. Unit cost per Pain IP was $12,473. Post-PC (Sep 2017 – Mar 2019), there were 40 fewer Pain IP admissions compared to Pre-PC Pain IP for a total cost savings of $498,920. **Conclusions:** After PC Program, Pain IP decreased in MHP OCM population (PC-referred and PC not referred). This trend suggests PC training and continuous education for OCM providers is reducing IP utilization. This also translated to a significant cost saving for OCM/Medicare of $498,920. Study was limited by OCM claims available as of December 2019. Results may be refreshed as more data becomes available. Research Sponsor: None.

12095 Poster Session (Board #383), Fri, 8:00 AM-11:00 AM

Antiemetic prophylaxis with NEPA: Final results of the German AKYPRO study. *First Author: Joerg Peter Schilling, Onkologische Schwerpunktpraxis, Berlin, Germany*

Background: NEPA is a fixed combination antiemetic of the NK_1-receptor-antagonist (RA) netupitant and the 5-HT_3-RA palonosetron. Primary objective of this prospective non-interventional study in Germany was to assess quality of life of cancer patients (pts) undergoing moderately (MEC) or highly (HEC) emetogenic chemotherapy (CT) who received NEPA for prophylaxis of nausea and vomiting (CINV). Secondary objectives were patient reported outcomes as well as effectiveness and safety of NEPA. Here we report final data of the quality of life analysis. **Methods:** The study included 2.405 pts in 162 centers receiving 3 consecutive cycles of CT as one or two day MEC or HEC. Primary endpoint was impact of quality of life (QoL) due to vomiting or nausea, documented by Functional Living Index–Emesis (FLIE) questionnaires. Effectiveness was reported in patient diaries. Complete response (CR) was defined as no emesis and no rescue medication (RM). Non-significant nausea (NSN) was no or mild nausea. Adverse events (AEs) were reported on d1–21 of each cycle. **Results:** 2.173 patients were included in the final analysis (full analysis set; FAS). The majority of patients (n = 1976; 91%) received 1-day chemotherapy, 64% HEC, 36% MEC. Median age was 58 years and the majority (85%) was female. Cancer diagnoses: breast 66%, gastrointestinal 10%, ovarian 7% or lung 5%, other 12%. Chemotherapy: AC 57%, carboplatin 19%, cisplatin 8%, oxaliplatin 8% and other 8%. 84% of pts with HEC and 82% with MEC felt no impact on daily life due to vomiting in cycle 1 remaining constant in C2 and C3. 54% HEC patients and 59% MEC patients reported no impact on daily life due to nausea in cycle 1. CR rates ranged between 81-84% and were comparable between different HEC or MEC. NSN rates in MEC ranged from 75% (MEC) to 62% (HEC). Drug-related AEs were rare with constipation, fatigue, insomnia, and nausea as the most common (in $>$ 1% pts). **Conclusions:** NEPA was highly effective in the prevention of CINV and maintenance of QoL in this real world study. Over 80% of pts reported that their daily live was not influenced by emesis while nausea was more difficult to control. Effectiveness was high and patients and physicians estimate was comparable**.** Research Sponsor: Riemser Pharma.

Myelopreservation and reduced use of supportive care with trilaciclib in patients with small cell lung cancer. *First Author: Jared Weiss, Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC*

Background: Chemotherapy (CT) is a mainstay of cancer treatment; however, its side effects, notably myelosuppression, cause significant suffering. Trilaciclib (T) is an IV CDK4/6 inhibitor that protects hematopoietic stem and progenitor cells by preventing proliferation during CT administration. Results from three randomized, double-blind, placebo (P)-controlled phase II trials in patients (pts) with extensive-stage small cell lung cancer (ES-SCLC) have previously been reported. Data from these studies were pooled to understand the effects of T on specific myelosuppression endpoints with greater statistical precision. **Methods:** All pts received standard CT (etoposide/carboplatin [E/C], E/C/atezolizumab, or topotecan) plus T or P. Analyses were conducted on pooled intent-to-treat datasets from three ES-SCLC studies (NCT02499770; NCT03041311; NCT02514447). **Results:** 123 pts were treated with T and 119 with P. Median age in both groups was 64 years. Addition of T decreased measures of myelosuppression and the need for supportive care interventions (Table). From the pooled dataset, median OS and PFS (months [95% CI]) were comparable between pts treated with T vs P (OS: 10.6 [9.1, 11.7] vs 10.6 [7.9, 12.8]; PFS: 5.3 [4.6, 6.1] vs 5.0 [4.4, 5.5], respectively). Fewer pts on T had grade 3/4 hematologic events (54 [44.3%]) vs P (91 [77.1%]). Among pts who continued after cycle 1, 11 pts (9.2%) treated with T had $\geq$1 CT dose reduction vs 36 (30.8%) with P. **Conclusions:** T significantly and meaningfully reduced both CT-induced myelosuppression and its consequences, with no detrimental effect on PFS or OS, thus improving the patient experience with CT in ES-SCLC. T has potential to become a new standard of care for preventing myelosuppression in SCLC. Research Sponsor: G1 Therapeutics, Inc.

Development and validation of a risk prediction model for poor performance status and severe symptoms among cancer patients. *First Author: Hsien Seow, McMaster University, Hamilton, ON, Canada*

Background: Existing cancer predictive tools focus on survival, but few incorporate patient-reported outcomes to predict quality-of-life domains, such as symptoms and performance status. The objective was to develop and validate a predictive cancer model (called PROVIEW) for poor performance status and severe symptoms over time. **Methods:** We used a retrospective, population-based, cohort study of patients, with a cancer diagnosis, in Ontario, Canada between 2008-2015. We randomly selected 60% of patients for model derivation and 40% for validation. Using the derivation cohort, we developed multivariable logistic regression models with baseline characteristics, using a backward stepwise variable selection process. The primary outcome was odds of having poor performance status six months from index date, as measured by a score $<=30$ out of 100 on the Palliative Performance Scale. The index date for each model was diagnosis (Year 0), which was then re-calculated at each of 4 annual survivor marks after diagnosis (up to Year 4). Secondary outcomes included having severe pain, dyspnea, well-being, or depression, as measured by a score of $>=7$ out of 10 on the Edmonton Symptom Assessment System. Covariates included demographics, clinical information, current symptoms and performance status, and healthcare utilization. Model performance was assessed by AUC statistics and calibration plots. **Results:** Our population-based cohort identified 125,479 cancer patients for the performance status model in Year 0. The median diagnosis age was 64 years, 57% were female, and the most common cancers were breast (24%), lung (13%), and prostate (9%). 32% had Stage 3 or 4 disease. In Year 0 after backwards selection, the odds of having a poor performance status in 6 months was increased by more than 10% when the patient had: COPD, dementia, diabetes; radiation treatment; a hospital admission in the prior 3 months; high pain or depression; a current performance status $<=30$; any issues with appetite; or received end-of-life homecare. Generally, these variables were also associated with a $>10\%$ increased odds in other years and for the secondary outcomes. The average AUC across all 25 models is 0.7676 which indicates high model discrimination. **Conclusions:** The PROVIEW model accurately predicts risk of having a poor performance status or severe symptoms over time among cancer patients. It has the potential to be a useful online tool for patients to integrate earlier supportive and palliative care. Research Sponsor: Canadian Institutes of Health Research.

The impact of the use of opioids among older breast cancer survivors and adverse events. *First Author: Aaron N Winn, Medical College of Wisconsin, Milwaukee, WI*

Background: Older adults and cancer survivors are underrepresented in the literature underpinning recent opioid prescribing guidelines. As prevention of unnecessary persistent opioid use and inadvertent opioid-related harms gains importance in clinical practice, it is necessary to fully capture the risks of opioid related adverse events among patients with cancer pain. The objective of this study was to determine the association between opioid use after cancer diagnosis and comprehensive opioid-related adverse events among older adult breast cancer survivors. **Methods:** We conducted a retrospective cohort study using Surveillance, Epidemiology, and End Results tumor registry data linked with Medicare administrative claims data from 2007-2016 of women with newly diagnosed non-metastatic breast cancer. The study observation period was the year following a patient's end of active cancer treatment. The primary exposure was a daily measure of opioid exposure based on Part D prescription claims. The primary outcomes were daily indicators of all-cause hospitalization, substance use event and a composite of other opioid-related adverse events (infections, gastrointestinal events, falls/fractures, cardiovascular events) and each component of the composite adverse event. We estimated the association of current opioid use and the immediate risk of an outcome event the following day using modified Poisson generalized estimating equation models. We adjusted for patient demographics, cancer characteristics and cancer treatments received. **Results:** We found that opioid exposure more than doubled the immediate risk of all-cause hospitalization (aRR = 2.77; 95%CI = 2.57, 2.99; $p < 0.001$) and having a composite adverse event (aRR = 2.50; 95%CI = 2.18, 2.87; $p < 0.001$) and dramatically increases the immediate risk of a substance use event (aRR = 14.26; 95%CI = 7.11, 28.59; $p < 0.001$). We find consistent results when looking at individual components of the composite adverse event measure. **Conclusions:** Older adult breast cancer survivors with continued prescription opioid use in the year after completing active cancer treatment experienced an immediate increased risk of all-cause hospitalization, substance use events, and myriad opioid-related adverse effects. Inflammatory and clinical risk factors for chemotherapy-induced peripheral neuropathy (CIPN): A nationwide longitudinal study in 143 cancer patients during chemotherapy. *First Author: Ian Kleckner, University of Rochester Medical Center, Rochester, NY*

Background: CIPN is a common dose-limiting side effect of taxane and platinum chemotherapy. It is difficult for clinicians to predict who will experience CIPN before initiating chemotherapy, partly because the etiology of CIPN is poorly understood. Specifically, although inflammation putatively plays a role in CIPN, there is limited evidence of the role of inflammation in CIPN in humans. Here, we identified the strongest predictors of CIPN using variables measured before taxane or platinum chemotherapy, including serum inflammation. **Methods:** 143 sedentary patients with cancer (81% breast, 7% colon, 5% lung; 7% other; mean age 56 years) receiving taxane or platinum chemotherapy rated the severity of (a) numbness and tingling, and (b) hot/coldness in hands/feet on 0-10 point scales before and after their first 6 weeks of chemotherapy. Linear regression models were fit to predict CIPN symptom severity at 6 weeks using variables related to inflammation (serum IL-1β, IL-6, IL-8, IL-10, IFN-γ, sTNFR1; 69 patients who gave blood), clinical factors (cancer stage, baseline neuropathy, fatigue, anxiety, depression, using diabetes medications), behavior (daily pedometer steps), and demographics (age, race) measured before chemotherapy. The final model was identified by the smallest AIC goodness of fit. **Results:** The strongest pre-chemotherapy predictors of numbness and tingling after 6 weeks of taxane and/or platinum chemotherapy were worse patient-reported fatigue/anxiety/depression (explaining 25% of variance), platinum chemotherapy (7%), and older age (5%). The strongest predictors of hot/coldness in hands/feet included worse baseline neuropathy (13%), platinum chemotherapy (8%), and fatigue/anxiety/depression (6%). In the 69 patients with serum data, a more pro-inflammatory state was a risk factor for CIPN as higher levels of pro-inflammatory IL-1β (7%) predicted numbness/tingling, and lower levels of anti-inflammatory IL-10 (7%) predicted hot/coldness in hands/feet. **Conclusions:** The strongest pre-chemotherapy predictors of CIPN included worse fatigue/anxiety/depression and platinum chemotherapy in this sedentary population of cancer patients (mostly breast). A pro-inflammatory state before chemotherapy may also increase risk for CIPN, suggesting that inflammation may underlie the etiology of CIPN in humans. Clinicians should consider assessing these factors to inform the patient's risk for CIPN. Funding: NCI UG1CA189961, NCI K07 K07CA221931, T32CA102618. Clinical trial information: NCT00924651. Depression, anxiety, and patterns of mental health care among men with prostate cancer on androgen deprivation therapy (ADT). *First Author: Phoebe A. Tsao, Department of Hematology/Oncology, University of Michigan Medical School, Ann Arbor, MI*

Background: ADT is associated with an increased risk of depression and anxiety, raising the concern that a substantial portion of men with prostate cancer need mental health care. We sought to investigate the development of depression or anxiety and subsequent patterns of mental health care in men with prostate cancer on ADT. **Methods:** Clinformatics DataMart, a claims database of commercially insured patients, was used to identify men with prostate cancer who received ADT between 2001-2015 and had continuous enrollment for 1 year before and 2 years after starting ADT. We determined the rate of incident diagnoses of depression or anxiety and the incident use of mental health treatments - psychotherapy and psychiatric medications ($\geq$ 5 day supply) - after the start of ADT. **Results:** Among 37,388 men in the final analytic cohort, 11.3% (n=4239, 95% confidence interval (CI) 11.0-11.6%) received new diagnoses of depression or anxiety: 5.8% depression (95% CI, 5.5-6.0%), 3.7% anxiety (95% CI 3.5-3.9%), and 1.8% both (95% CI, 1.7-1.9%). Those who received a diagnosis of depression or anxiety were more likely to be white (68% v. 64%, $p<0.01$); no differences were noted in age, education, or household income. Among those with a new diagnosis of depression or anxiety, 0.07% received psychotherapy (95% CI, 0.02-0.23%), 34.9% a selective serotonin reuptake inhibitor (95% CI, 33.5-36.4%), 11.6% a serotonin norepinephrine reuptake inhibitor (95% CI, 10.7-12.6%), and 19.9% a benzodiazepine (95% CI, 18.7-21.1%). **Conclusions:** Among men with prostate cancer receiving ADT, more than 1 in 10 received a new diagnosis of depression or anxiety. Of those, 1 in 5 were introduced to a benzodiazepine, a drug class with risks of dependence, cognitive impairment, falls, and fractures, whereas receipt of psychotherapy was rare. Further investigation into how to improve the mental health care of men on ADT is needed. Research Sponsor: None.

Scalp cooling to prevent chemotherapy induced alopecia (CIA) in black patients: Differences in efficacy? *First Author: Asma Ali Dilawari, MedStar Washington Cancer Institute, Lombardi Comprehensive Cancer Center, Washington, DC*

Background: The Paxman scalp cooling device has been used for over 20 years to prevent CIA, obtaining FDA clearance in the U.S. in 2017. Prior studies reported 50-80% success and high patient satisfaction yet included few or no black patients. In the U.S. this may reflect disparities in access due to cost, awareness, or availability. We opened a prospective observational study combining patient-reported outcomes with clinical assessments of alopecia and planned to deliver scalp cooling to 30 black patients receiving chemotherapy for breast cancer. **Methods:** Patients who self-identified racially as black, had a new diagnosis of stage I-III breast cancer, and planned to receive chemotherapy with taxane-containing regimens were eligible. Anthracycline (AC) and non-anthracycline (NAC) chemotherapy agents were included; costs for the intervention were covered by Paxman and internal philanthropic funding. Patients who declined scalp cooling were approached for enrollment as controls. Primary endpoints were grade of alopecia as measured by providers and patient self-report using Modified Dean Scale and Visual Analog Scale (VAS) respectively. Hair preservation was defined as <50% hair loss (<grade 2) by Dean and score < 50 on VAS. Secondary endpoints were alopecia by NCI grading scale and psychosocial from CADS and EORTC QLQ BR45 questionnaires. **Results:** 15 out of 30 planned participants enrolled by February 2020 with interim analysis and hold in accrual due to lack of efficacy. Four patients remain on treatment. Of 11 scalp cooling patients who completed chemotherapy, 0 prevented significant alopecia. Nine discontinued use of scalp cooling before completion (1 due to scheduling, 8 due to >grade 3 alopecia). The 2 patients who used scalp cooling for the duration had >grade 3 alopecia before the last cycle of treatment. **Conclusions:** Scalp cooling is an important supportive therapy that can reduce chance of alopecia, a bothersome side effect for patients. Our experience indicates decreased efficacy in black patients with both AC and NAC regimens. This is an important negative result to explore. Discussions with the Paxman team and providers with expertise in alopecia are underway to explore contributing factors such as hair thickness, prior hair treatments, and cap design. Research Sponsor: Paxman Scalp Cooling Company and Four Seasons Washington Cancer Institute Philanthropic Fund.

Palliative referrals in advanced cancer patients: Utilizing the Supportive and Palliative Care Indicators Tool and Rothman Index. *First Author: Abigail Sy Chan, Sinai Hospital of Baltimore, Baltimore, MD*

Backgroun1d: Timely identification of palliative care needs have the ability to reduce hospitalizations and improve QOL. The Supportive & Palliative Care Indicators Tool (SPICT) is used to identify patients with advanced stage medical conditions who may need special care planning. The Rothman Index (RI) detects patients at high risk of acutely decompensating in the inpatient setting and has been validated to assess 24-hour mortality risk. We used SPICT and RI in cancer patients admitted to the hospital and evaluated their roles in recognizing early palliative care needs and 6-month mortality. **Methods:** Advanced/metastatic cancer patients admitted to our institution from Jan 1, 2019 to June 30, 2019 were retrospectively reviewed. Patient demographics, length of hospital stay (LOS), comorbidities, palliative/hospice care referrals, vital status, initial RI score, and computed SPICT scores were obtained. Worse clinical indicators were defined as SPICT positive if it met > 2 clinical indicators or RI < 60. Univariate and bivariate analyses were performed. **Results:** A total of 227 patients were included, mean age 68, 34% Caucasians, 63% Blacks, 59% female, median comorbidities of 3, with majority having lung and GI malignancies. A total of 137 (60%) were SPICT +, 47 (21%) had RI < 60, and 38 (17%) concurrent SPICT + and RI < 60. SPICT + patients were more likely to have longer hospital stay, change in code status, more palliative/hospice referrals, and increased mortality. Those with RI < 60 had similar results (Table). SPICT + patients are more likely to have RI < 60 (p = 0.0013). **Conclusions:** SPICT and RI are valuable tools in predicting 6-month mortality and palliative/hospice care referrals. These can also be utilized to initiate early palliative and goals of care discussions in patients with advanced cancer. Research Sponsor: None.

Impact of embedded palliative care providers compared to externally available palliative care services on the number of patients receiving palliative care referrals in a large community oncology practice. *First Author: Garrett Young, OneOncology, Nashville, TN*

Background: Palliative care improves quality of life and may increase overall survival in patients with solid tumor malignancies. Despite having the ability to refer patients to in-home and external palliative care services, we observed low palliative care referral rates in our practice of 90 oncologists across 30 clinics. We tested whether embedding palliative care providers directly in clinic would improve palliative care referral rates for solid tumor patients. **Methods:** Between 2017 and 2020, we embedded an independent palliative care provider into five clinics across middle Tennessee. Access to external palliative care services was present both before and after the intervention. Using data from our EHR and billing systems, we performed a pre-post analysis measuring palliative care referrals in the six-month periods immediately before (pre-intervention period) and after (post-intervention period) a palliative care provider was embedded in each clinic. Statistical significance was assessed using Welch's two sample t-test. **Results:** 8,636 unique solid tumor patients were seen in the five clinics during the study periods (Table). Despite having the ability to refer patients to external palliative care services in the pre-intervention period, the placement of a palliative care provider into clinic increased the number of solid tumor patients that received a palliative care referral per month at all clinics (min.: 200%; max.: 990%; median: 600%). Four of the five increases were statistically significant (p-values < 0.05). **Conclusions:** Even when external palliative care services are available, embedding palliative care providers into community oncology clinics significantly increases the rate of palliative care referrals for solid tumor patients. Research Sponsor: None.

Change in palliative care order rates after placing a palliative care provider in clinic.

A highly effective and practical desensitization regimen: Results in comparable clinical outcomes for multiple myeloma patients with skin rash after immunomodulatory drugs. *First Author: Amin Firoozmand, University Hospitals Seidman Comprehensive Cancer Center, Cleveland, OH*

Background: Immunomodulatory drugs (IMiDs) are backbone of myeloma therapy for patients with Multiple Myeloma (MM). The incidence of IMiD-associated rash is up to 27% in some reports impeding maximal benefit of this agent. The optimal management of IMiDs-associated skin is unclear. The concurrent weekly Dexamethasone (Dex) does not diminish the incidence of skin eruptions with IMiDs (Sviggum, et al. 2006), therefore we designed a low dose daily and tapering corticosteroid regimen to tame this immune response upon restarting IMiDs and allow desensitization and reinstitution of the same IMiD. Furthermore, we assessed the impact of this desensitization regimen on clinical outcome. **Methods:** A total of 160 patients were evaluated. The incidence of rash was found to be 13% (n = 21). A cohort of age- and gender-matched without rash (n = 39) was randomly selected. The effects of rash on overall and progression free survival (OS and PFS) were further estimated using Cox regression controlling the effects of age and gender. **Results:** Median time to development of rash after IMiD initiation was 28 days (range, 2-232). Rashes were graded as low (I-II) in 89% (n = 17) and high (III-IV) in 19% of pts. All pts were managed by temporary treatment interruption and upon clearance of rash, re-institution of the same IMiD concomitantly with a standardized 3-week steroid rash prophylaxis protocol (prednisone at 10 mg daily for 10 days, followed by 5 mg daily for 10 days, followed by 5 mg on alternate days for 10 days). As a result, all patients were able to restart the same IMiD with none re-experiencing any dermatologic adverse effect afterward. Comparing to no-rash controls, there was no significant difference in PFS (0.13) or OS (p = 0.12) in multivariate regression model. **Conclusions:** Proposed 3-week corticosteroid regimen showed 100% success rate in reinstituting IMiDs in our cohort. It may provide a highly effective and practical short term immunosuppression required to enable patients to restart IMiDs and enjoy comparable outcome to pts without skin rash. High-dose vitamin D supplementation for cancer-treatment-induced bone loss in 164 breast and prostate cancer patients: A pooled analysis of two randomized controlled trials (RCTs). *First Author: Luke Joseph Peppone, University of Rochester Medical Center, Rochester, NY*

Background: Aromatase Inhibitor (AI) therapy and androgen deprivation therapy (ADT) significantly accelerate bone loss and increase fracture risk. Vitamin D (VITD) protects against bone loss, but it is unclear whether the recommended daily allowance (RDA; 600 IU/day for ages 51-70) of VITD is sufficient for cancer patients. Data from two RCTs were pooled to examine the safety and efficacy of high-dose VITD versus the RDA of VITD on bone mineral density (BMD). **Methods:** 164 breast and prostate cancer patients on AIs and ADT, respectively, with low VITD (<32 ng/ml) were randomized to either high-dose VITD (50,000 IU/week; n=99) or placebo (n=65) for 24 weeks. All subjects received 600 IU/day of VITD. Of the 99 subjects assigned to high-dose VITD, 38 breast subjects also received the Exercise for Cancer Patients (EXCAP) program combining walking and resistance training. Serum VITD and calcium were assessed at weeks 0, 6, 12, 18, and 24. BMD was assessed at the hip and spine via DXA at weeks 0 and 24. The effect of high-dose VITD was tested via ANCOVA model adjusted for cancer type, baseline BMD and VITD. **Results:** High-dose VITD significantly reduced the amount of hip BMD loss versus the RDA of VITD (high-dose VITD: −0.8% vs placebo: −2.6%; p<0.01) over 24 weeks. Hip BMD loss was greater for subjects on ADT (high-dose VITD: −1.5% vs placebo: −4.1%; p=0.03) than subjects on AI therapy (high-dose VITD: −0.2% vs placebo: −1.7%; p=0.02). Among the high-dose VITD group, there was no BMD difference at the total hip between those who received EXCAP exercise vs no EXCAP (p=0.96). The largest differences in BMD were for those with lower baseline VITD levels (<27 ng/ml) for both total hip (high-dose VITD: −0.6% vs placebo: −3.2%; p<0.001) and femoral neck (high-dose VITD: +0.2% vs placebo: −2.4%; p=0.03). No between-group pooled differences were noted for total spine BMD (high-dose VITD: −0.2% vs placebo: −0.1%; p=0.82). High-dose VITD increased serum VITD without negatively affecting serum calcium (Table). **Conclusions:** High-dose VITD was safe and effective in significantly reducing hip BMD loss, with the largest benefit in those with lower baseline VITD levels. A phase III RCT is needed to confirm these findings. NCI Funding: K07 CA168911/R21 CA175793/UG1 CA189961/T32 CA102618 Clinical trial information: NCT02064946, NCT01419730. Safety and effectiveness of medical cannabis as a complementary option for supportive cancer care: Results from the Cannabis Pilot Project. *First Author: Antonio Vigano, McGill University Health Centre, Montréal, QC, Canada*

Background: Access to medical cannabis (MC) is a common request by patients and caregivers in supportive cancer care (SCC). However, health-care professionals require more evidence on MC safety and effectiveness. **Methods:** The Cannabis Pilot Project (CPP) was implemented at the Cedars Cancer Centre of the McGill University Health Centre to evaluate MC as a complementary option for symptom control in SCC. Referral to the CPP was reserved for patients who were receiving SCC but had not obtained adequate symptom relief. An interdisciplinary team (physician, nurse and research coordinator) was established to systematically assess patients, prescribe and monitor MC treatments and record data on their safety and effectiveness. Patients were enrolled in the CPP between February 2018 and December 2019 and reassessed at intervals of one to six months. **Results:** Ninety-six cancer patients (mean age 60.0y (±13.9); 41 (42.7%) males) had at least one follow-up (FUP) and were included in the study. The main cancer types were breast (19.8%), lung (9.4%) and colorectal (9.4%). Adverse events (top three: drowsiness, low energy and nausea) were reported in 28% of patients, with 9% having to stop MC. Mean Brief Pain Inventory scores significantly improved between baseline, FUP-2 and FUP-3 for worst pain (5.4± SEM 0.3 vs 4.3±0.3 and 3.7±0.4) and average pain severity (4.2±0.2 vs 3.2±0.3 and 3.2±0.4). Anorexia improved (3.4±0.3 vs 2.2±0.4 and 1.7±0.4), as measured via the revised Edmonton Symptom Assessment System (ESAS-r). ESAS-r wellbeing improved significantly between baseline and FUP-1 (4.4±0.2 vs 3.7±0.2). Between baseline and each FUP, approximately a third of patients dropped their use of concurrent medications (including analgesics, antidepressants and anxiolytics), as measured by the Medication Quantification Scale. **Conclusions:** The CPP data support the safety and effectiveness of MC as a complementary option for improving pain control, appetite and quality of life in SCC. 12107 Poster Session (Board #395), Fri, 8:00 AM-11:00 AM

Validity of patient-reported outcomes to describe the symptom experience of patients enrolled on phase I clinical trials. *First Author: Ramy Sedhom, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Symptoms are common among patients enrolled in phase I trials. To integrate the patient perspective, the National Cancer Institute developed a patient-reported outcomes version of the CTCAE (PRO-CTCAE) to capture symptomatic adverse events (AEs) directly from patients; however, the tool has not been used often in early phase trials or in palliative care studies. Our overall objective was to assess the validity of PRO-CTCAE items to previously validated assessments of quality of life (FACT-G) and psychological distress (Distress Thermometer). We utilized data from a randomized trial testing a palliative care intervention for patients with cancer enrolled on phase I trials. **Methods:** Patients (n = 481) were accrued to the parent study prior to initiating a Phase I clinical trial with data collected at baseline, 4, and 12 weeks. We determined the correlation of PRO-CTCAE with Distress Level, FACT-G total and subscale domain scores. Aggregate scores using PRO-CTCAE were calculated to explore the effect of overall symptom frequency, severity, and interference by calculating the total of all scored items classified within each of those domains. We used these metrics to identify associations between this and other validated tools. **Results:** Patients were predominantly female (56.8%), over age 60, and 30.7% were minority populations. Correlations between PRO-CTCAE items and corresponding FACT-G (total and subscales) and Distress levels reached statistical significance for all items ($p < 0.001$). Importantly, many of symptoms captured would have been missed using HRQOL assessment tools. Some of these symptoms affected nearly 50% of patients and were frequently rated as severe or very severe. The correlation coefficient for Distress Level for all PRO-CTCAE items was small to moderate (Pearson $r = 0.33$ to 0.46). Pearson's correlation coefficient for FACT-G total was moderate ($r = -0.45$ to -0.69). Mood items of the PRO-CTCAE had stronger associations (Pearson $r > 0.5$). PRO-CTCAE symptom interference scores had the strongest correlation with Distress (Pearson $r = 0.46$) and FACT-G Total (Pearson $r = -0.69$). **Conclusions:** Patients entering Phase I trials are willing to report on symptoms they experience as a result of advancing disease and adverse effects from experimental treatment. Evidence demonstrates favorable validity of PRO-CTCAE in a heterogeneous US sample of patients undergoing cancer treatment on phase I trials. The granular assessment of symptomatic AEs may be on increasing importance as we enter a new therapeutic era in oncology. Clinical trial information: NCT01828775. Research Sponsor: U.S. National Institutes of Health.

A survey of cannabis use for symptom palliation in breast cancer patients by age and stage. *First Author: Marisa C. Weiss, Breastcancer.org, Ardmore, PA*

Background: Most US states have legalized medical cannabis for the treatment of serious conditions, including cancer. It is not well known which symptoms breast cancer patients seek to control with cannabis. **Methods:** Members of the Breastcancer.org and Healthline communities were invited to participate in this survey between 12/16/2019 and 1/19/2020. Eligibility criteria included age ≥18 years, resident of the US and a breast cancer diagnosis within the past 5 years. Eligible respondent data were analyzed for the symptomatic profile of cannabis users. Symptoms were compared between two groups using a Chi-square test of independence. The survey was led by Socanna, conducted by Outcomes Insights, and supported by a grant from Ananda Health/Ecofibre. **Results:** Among the 832 respondents who completed screening, 725 met the eligibility criteria, and 612 (84%) completed the survey. The median age of respondents was 57 years, and 85% had non-metastatic disease An estimated 42% of respondents have used medical cannabis to treat symptoms or side effects of breast cancer. Medical cannabis users reported using cannabis to treat insomnia (70%), joint and muscle aches, discomfort, stiffness, or pain (59%), anxiety (57%), and stress (51%). The medical cannabis users less than 50-year-old were more likely to use cannabis to treat these symptoms than their over 50-year-old counterparts, however, the differences were not statistically significant. Medical cannabis users under age 50 used cannabis significantly more than over 50 to treat nausea/vomiting (58% vs 40%; p = 0.010) and inflammation (34% vs 20%; p = 0.021). Medical cannabis users with metastatic disease were more likely to use medical cannabis to treat chronic pain 60% vs 41%; p = 0.017) than non-metastatic users. Post-surgery patients were most likely to use cannabis for nerve pain; and those who were beyond treatment, for stress. Patients suffered an average of 5 symptoms. **Conclusions:** A significant proportion of breast cancer patients reported using cannabis to treat a combination of symptoms from their cancer and its treatment. Although younger patients are somewhat more likely to use this form of palliative management, older patients are suffering from the same symptoms and their use is nearly as high. More research is needed on the personalization of safe and effective symptomatic management with medical cannabis, for people of all ages, stages, and forms of treatment. The Quebec Cannabis Registry: a pharmacovigilance and effectiveness study on the use of medical cannabis in cancer patients. *First Author: Antonio Vigano, McGill University Health Centre, Montréal, QC, Canada*

Background: The Quebec Cannabis Registry (QCR) was launched in 2015 to allow physicians to prescribe medical cannabis (MC) in the province of Quebec, Canada. This study aimed to investigate the safety and effectiveness of MC in cancer patients using pharmacovigilance data prospectively collected for up to 24 months. **Methods:** Patients were enrolled in the QCR between May 2015 and October 2018 and followed every 3 months. Study outcomes included adverse events (AE), pain severity and interference (Brief-Pain Inventory), wellbeing (Revised-Edmonton Symptom Assessment Scale) and overall health scale (EQ5D5L) at baseline and at each follow-up (F-UP). Significance of changes over time were assessed using repeated-measures ANOVA. **Results:** Out of the 2991 patients enrolled in the QCR, 358 (12.8%) were cancer patients (mean age 57.7 ($\pm$ 14.6); 171 (47.8%) males). The main cancer types were breast (16.2%), lung (11.7%), leukemia (11.5%) and colorectal (11.2%). MC was prescribed primarily for pain (72.1%), anxiety (4.7%), nausea (4.5%), anorexia (3.9%), and insomnia (3.1%). A total of 13 patients (3.6%) reported AE with only three being serious (one unrelated to MC: stroke; and two possibly related: diarrhea, from CBD oil overdose and pneumonia from smoking MC). Mean scores significantly ($p < 0.05$) improved between baseline and 3 months F-UP for pain severity (4.8 ± 1.5 vs 4.1 ± 1.8), pain interference (4.6 ± 1.8 vs 3.8 ± 1.7), and the overall health scale (60 ± 21 vs 71 ± 18). Well-being scores also significantly improved between baseline and 6 months F-UP (4.4 ± 2.1 vs 3.5 ± 2.8). **Conclusions:** Population-based data shows that cancer patients can benefit safely and effectively from MC as a complementary treatment, when prescribed and monitored under medical-nursing supervision. Research Sponsor: College des Medecins de Quebec - Canadian Consortium for the Investigation of Cannabis - Canopy Growth.

12110 Poster Session (Board #398), Fri, 8:00 AM-11:00 AM

Questions prompt lists used by palliative care teams help trigger discussions on prognosis and end-of-life issues with advanced cancer patients. *First Author: Carole Bouleuc, Supportive Care Department, Institut Curie, Paris, France*

Background: Accuracy of prognosis perception is a key element to allow advanced cancer patients to make informed decisions and to reflect on their end-of-life priorities. This study aims to explore whether a question prompt list can promote discussions on prognosis and end-of-life issues during palliative care consultations for advanced cancer patients. **Methods:** In this multicentric randomised study, patients assigned in the interventional arm receive a question prompt list during the first palliative care consultation (T1) after referral by oncologists. The primary endpoint is the number of questions asked by patients during the second palliative care consultation (T2) one month later. Secondary objectives are anxiety and depression, quality-of-life, satisfaction with care, coping assessed at baseline (T1) and at two months (T3). Palliative care teams from 3 french comprehensive cancer centers participate in the study. Main inclusion criteria were adult patients with metastatic non-haematological cancer referred to the palliative care team and with an estimated life expectancy less than one year. **Results:** Patients (n = 71) in the QPL arm asked more questions (mean 21.8 versus 18.2, p-value = 0.03) during the palliative care consultations compared to patients in the control arm (n = 71). These questions addressed palliative care (mean 5.6 versus 3.7, p-value = 0.012) and end-of-life issues (mean 2.2 versus 1, p = 0.018) more frequently than in the control arm. At two months, compared to baseline, there was no change in anxio-depressive symptoms or quality of life. **Conclusions:** QPL favours discussion on prognosis and end-of-life care during the palliative care consultations for advanced cancer patients. Clinical trial information: NCT02854293. Research Sponsor: INCA.

12111 Poster Session (Board #399), Fri, 8:00 AM-11:00 AM

A prospective analysis of chemotherapy-induced nausea and vomiting in gastrointestinal cancers: Results from a tertiary cancer center. *First Author: Akhil Kapoor, Tata Memorial Hospital, Mumbai, India*

Background: Chemotherapy-induced nausea and vomiting (CINV) is a bothersome side-effect associated with cancer chemotherapy which adversely impacts both quality of life and the ability to carry out the activities of daily living. This study was conducted to assess the proportion of patients developing CINV after receiving chemotherapy for gastrointestinal (GI) cancers, in spite of receiving antiemetic prophylaxis as per the standard guidelines. **Methods:** Consecutive patients with GI malignancy who had not received previous chemotherapy were eligible for enrollment in the study if they were scheduled to receive at least one cycle of chemotherapy. SPSS version 20 was used for all statistical calculations. **Results:** 701 patients fulfilling the eligibility criteria were included in this study, out of which 55.4% were males, median age was 51 years (range 22-77). Biliary tract cancer (34%) was the most common diagnosis followed by colorectal (30.2%) and gastric cancer (19.6%). As per MASCC guidelines, 22.1% patients received highly emetogenic chemotherapy, 56.0% moderately emetogenic chemotherapy (MEC) while 19.9% received regimen with low emetogenicity. Failure to achieve complete response (CR, absence of acute and delayed CINV) was found in 27.4% patients. On separately analysing MEC group, overall CR was not achieved in 33.8% with failure in acute settings in 17.8% and delayed in 16.0% patients. Only significant factor for not achieving CR was use of oxaliplatin based chemotherapy (p = 0.018 for acute and p = 0.014 for delayed CINV). **Conclusions:** More than one fourth patients failed to achieve complete response for CINV in gastrointestinal cancers despite using prophylaxis as per standard guidelines. Use of oxaliplatin based therapy is an important factor for MEC causing CINV. There is urgent need to update the guidelines for prophylaxis in this setting. Research Sponsor: None.

12112 Poster Session (Board #400), Fri, 8:00 AM-11:00 AM

Overall survival (OS) and healthcare utilization results of a randomized controlled trial (RCT) assessing a patient navigation (PN) intervention to increase early access to supportive care (SC) for patients with metastatic cancer in a resource-limited setting. *First Author: Miguel Araujo, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Delegacion Tlalpan, Mexico*

Background: We previously reported improvements in access to SC, advance directive completion, and pain control in a RCT comparing a patient navigator-led early SC intervention vs. usual care among patients with newly-diagnosed metastatic cancer in Mexico (NCT03293849). We now present results on healthcare utilization and OS. **Methods:** Patients were randomized to PN or usual oncology care. Patients in the PN arm received SC interventions by a navigator-led multidisciplinary team (palliative care, physical therapy, geriatrics, psychology) in the first 12 weeks after diagnosis. At 12-weeks, patients allocated to usual care were able to cross-over to PN and receive multidisciplinary SC. We analyzed the number (no.) of emergency room (ER) visits, their cause, and whether they were potentially avoidable (as determined by expert consensus), using descriptive statistics and X2 tests. OS was estimated using the Kaplan-Meier method and the log-rank test. **Results:** 133 patients (median age 60, range 23-93; 52% male) were randomized (66 PN, 67 control) from 08/17 to 04/18. Median follow-up was 22.8 months. 61% had gastrointestinal tumors, and 45% had a calculated life expectancy $\leq$6 months. 69% of patients randomized to usual care crossed-over to PN and received SC interventions. 80% of patients attended the ER $\geq$once (median no. of visits = 2). No difference was found between patients randomized to early SC or usual care in ER visits (2.4 vs. 2.3, p = 0.58). Out of a total 316 ER visits, the most common reason was infections (n = 69, 22%), followed by pain (n = 40, 13%), and indwelling catheter-related complications (n = 23, 7%). 41% of ER visits were considered as potentially avoidable, with no difference in avoidable visits found between arms (1.7 vs. 1.7, p = 0.49). No differences between arms were found in no. of hospitalizations (0.8 vs. 0.6 p = 0.82). Survival results were assessed after 64% of patients had died (n = 85), finding no statistically significant OS difference between the early SC intervention and the usual care arms (11.0 vs 13.0 months, p = 0.77) **Conclusions:** In the context of a limited-resource healthcare system, the early delivery of SC did not improve healthcare utilization, reduce avoidable ER visits, or prolong OS compared to the implementation of SC at a later time, which might be partially explained by the unavailability of hospice or home care, and by high rates of cross-over between arms. Clinical trial information: NCT03293849. Research Sponsor: Global Cancer Institute.

12113 Poster Session (Board #401), Fri, 8:00 AM-11:00 AM

Evaluation of the incidence of acute nausea and vomiting after administration of an amino acid solution containing only arginine and lysine with lutetium Lu-177 dotatate. *First Author: Nicholas Alonzo, Stanford Health Care, Stanford, CA*

Background: Lutetium Lu-177 dotatate is used to treat patients with gastroenteropancreatic neuroendocrine tumors, and an amino acid (AA) solution must be administered concurrently to mitigate nephrotoxicity. AA solutions may lead to increased rates of nausea and vomiting (NV) due to the inclusion of unnecessary non-essential and essential AA. **Methods:** This study is a single academic center retrospective chart review from October 6th, 2015 to December 17th, 2019 evaluating the incidence of acute NV in adult patients after administration of an AA solution containing only arginine 25 grams and lysine 25 grams in 1 liter of normal saline (Arginine-Lysine amino acid [AL AA]) with lutetium Lu-177 dotatate. The incidence of acute NV will be compared to the historical incidence in patients administered Parenteral amino acids 10%, Aminosyn II 10% or Clinisol 15% (commercial AA). Secondary endpoints include the incidence of rescue anti-emetic usage and the percentage of patients that require interruption of the AA infusion. Acute NV are defined as any occurrence of NV within twenty-four hours of the AA infusion. **Results:** 53 patients received a total of 164 treatments with the AL AA, while 18 patients received a total of 48 treatments with the commercial AA. The AL AA significantly decreased the incidence of acute NV, the mean AA infusion time, the interruption of the AA infusion, and the utilization of rescue anti-emetics compared to the commercial AA (Table) in patients on lutetium Lu-177 dotatate. **Conclusions:** The study findings support the use of an AL AA to be administered concurrently with lutetium Lu-177 dotatate to minimize commercial AA related acute NV. Research Sponsor: None.

Infusion specific outcomes.

	AL AA, (n = 164)	Commercial AA, (n = 48)	P-Value
Incidence of acute nausea, n (%)	33 (20.1)	31 (64.6)	< 0.0001
Incidence of acute vomiting, n (%)	2 (1.2)	5 (10.4)	0.0072
Amino acid infusion time, mean minutes	252.8	403.6	< 0.0001
Interruption or prolonged amino acid infusion, n (%)	2 (1.2)	15 (31.3)	< 0.0001

Associations of functional, psychosocial, and medical factors with cognitive impairment in older, chemotherapy-naïve patients with early breast cancer. *First Author: Zev Nakamura, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Cognitive decline related to cancer and its treatments is a common concern among patients receiving treatment for cancer. Routine cognitive screening in oncology practice has been limited by the absence of a reliable, cancer-specific cognitive test. The Blessed Orientation Memory Concentration Test (BOMC) [1], has been incorporated in cancer-specific geriatric assessments, but there is no established cutpoint for cancer-related cognitive impairment. Recent research suggests that BOMC scores ≥ 5 may represent cognitive impairment in older patients with cancer. The purpose of this study was to identify cognitive impairment and associated characteristics in chemotherapy-naïve patients with breast cancer. **Methods:** Women with stage I-III breast cancer were recruited between 2009 and 2018. The BOMC (range 0-28, higher is worse function) was administered prior to chemotherapy. Associations between cognitive dysfunction (BOMC ≥ 5) and functional, psychosocial, medical variable were assessed using log binomial regression analysis. **Results:** In a sample of 331 women with breast cancer, the mean age was 65.2 years and 68.6% were 65 and older. Twenty-seven percent demonstrated cognitive impairment prior to treatment. Patients with Time Up and Go Test (TUG) ≥ 14 had increased risk of cognitive impairment compared to those with TUG < 14 (44% vs. 23%, p = 0.0002). After controlling for demographic factors, the estimated increase in risk was 66% (RR: 1.66, 95% CI (1.20, 2.31), p = 0.002). For Medical Outcomes Survey (MOS) Physical Function, after controlling for demographic factors, each 1 point increase in physical function (range 0-20, higher is better function) was associated with a 5% decrease in risk of cognitive impairment (p = 0.0004). **Conclusions:** Using a newly proposed BOMC cutpoint of ≥ 5, our study identified cognitive impairment in over 25% of older, chemotherapy naïve women with breast cancer. This is similar to what has been reported using rigorous neuropsychological testing in comparable populations. Additionally, we found that this degree of cognitive dysfunction was associated with both patient-reported and clinician-assessed impairment in physical function, further supporting the clinical relevance of this new cutpoint. CIFeR: A novel Clinician-lead Intervention to address Fear of cancer Recurrence (FCR) in breast cancer survivors. *First Author: Jia Liu, Psycho-Oncology Co-operative Research Group, Camperdown, Australia*

Background: FCR affects 50-70% of cancer survivors. There are no validated oncologist-delivered FCR interventions. This multicentre, single-arm study sought to determine the helpfulness, feasibility and efficacy of an oncologist-delivered FCR intervention. **Methods:** Women were invited to participate if they had completed local treatment, chemotherapy and/or HER2 targeted therapy for early stage breast cancer and had a FCR score >0 on the 42-item FCR Inventory. The brief intervention, delivered by their medical oncologist at routine follow-up, entailed 1) FCR normalisation; 2) provision of personalised prognostic information; 3) take-home education sheet on recurrence symptoms; and 4) advice on managing worry. Consultations were audio-recorded. FCR, need for help, depression and anxiety were assessed before the intervention (T0), and at one week (T1) and three months (T2) after the intervention. Satisfaction with the intervention was assessed at T1. The primary outcome was participant-rated helpfulness. Secondary outcomes included feasibility (response rate, time taken for intervention) and efficacy. **Results:** Five oncologists delivered the intervention to 61 women (255 women invited; response rate 24%). The mean age was 57 $\pm$ 13 years. The mean time since breast cancer diagnosis was 2.5 $\pm$ 1.3 years. Forty-three (72%) were on adjuvant hormonal therapy. Overall, 58 women (95%) found the intervention helpful and 59 (98%) would recommend it to others. FCR severity, and the proportion of women with clinically significant FCR decreased significantly over time. There were no significant changes in unmet need, depression, or anxiety. Forty (66%) of consultations were recorded. Mean consultation length was 22 minutes (range 12-37 minutes) and mean intervention length was 9 minutes (3-20 minutes). The intervention was perceived as useful and feasible by oncologists, all of whom have used components of the intervention to help manage FCR in other breast cancer patients. **Conclusions:** A brief oncologist-delivered intervention to address FCR is helpful and feasible, and has shown preliminary efficacy in reducing FCR. Plans for an implementation study amongst oncologists in Australia are underway. Clinical trial information: ACTRN12618001615279. Research Sponsor: Sydney Breast Cancer Foundation, AVANT Foundation.

Nonconscious nonverbal synchrony and patient and physician affect and rapport in cancer treatment discussions with black and white patients. *First Author: Lauren M. Hamel, Karmanos Cancer Center, Wayne State University, Detroit, MI*

Background: Clinical communication is poorer with Black patients than with White patients, but most studies are limited to verbal communication. Nonverbal synchrony, the subtle, nonconscious coordination of movement between individuals, has been shown to reflect relationship quality. We investigated nonverbal synchrony's association with patient and physician affect and rapport in cancer treatment discussions, and if those associations differed by patient race. **Methods:** We used motion detection software to measure overall synchrony and synchrony based on who is leading in the interaction (similar to leading in dancing) in video recordings of 68 Black patients and 163 White patients discussing treatment with their non-Black physicians. Additionally, naïve observers rated the interaction for six constructs: patient and physician positive and negative affect and patient-physician positive and negative rapport. We examined associations between nonverbal synchrony and the six constructs. **Results:** In interactions with Black patients, overall synchrony was positively associated with patients' positive affect and positive patient-physician rapport and negatively associated with patients' negative affect and negative patient-physician rapport. When the physician was leading, synchrony was positively associated with patients' positive affect and positive patient-physician rapport and negatively associated with patients' negative affect and negative patient-physician rapport. When the patient was leading, synchrony was positively associated with patients' and physicians' positive affect and positive patient-physician rapport, and negatively associated with patients' negative affect and negative patient-physician rapport. In interactions with White patients, overall synchrony was positively associated with patient positive affect; when the physician was leading, synchrony was negatively associated with patient negative affect. **Conclusions:** This is the first study to use an innovative measure of dynamic communication in patient-physician cancer treatment discussions. Nonverbal synchrony was related to patient and physician affect and rapport in interactions with Black patients, but only patient affect in interactions with White patients, suggesting *nonverbal synchrony is particularly important in interactions with Black patients.* Next steps include investigating associations with patient outcomes (e.g., satisfaction). Findings could contribute to physician training. Research Sponsor: U.S. National Institutes of Health.

12117 Poster Session (Board #405), Fri, 8:00 AM-11:00 AM

Health and cancer concerns among siblings of childhood cancer survivors: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Sonia Morales, Children's Hospital of Orange County, Orange, CA*

Background: Siblings of long-term survivors of childhood cancer can be at risk for persistent concerns regarding their future health and risk for cancer. We examined self-perceived future health and cancer risk concerns among such siblings. **Methods:** 3,969 siblings (median age 29 [range 18–56] years) of 5+ year matched pair cancer survivors (n= 3,969; age 25 [6–48] years; time since diagnosis 19.6 [9.6-33.8] years) in the CCSS self-reported physical/psychosocial problems, including concerns regarding future health and cancer risk (dichotomized as concerned vs not concerned). Chronic health conditions (CHC) were graded using the Common Terminology Criteria for Adverse Events system: mild (grade 1), moderate (grade 2), severe/disabling (grade 3),or life-threatening (grade 4). Sibling demographics, their matched survivor's diagnosis, era and treatment components, complications (death, relapse, disfigurement) as well as self-reported health status and CHCs for siblings and survivors were examined as potential risk factors for concern using multivariable logistic regression. Adjusted odds ratios (OR) and 95% confidence intervals (CI) are reported. **Results:** The prevalence of siblings reporting concerns regarding health and cancer risk decreased based on decades of matched survivor diagnosis: 1970-79 (73.3%; 63.9%), 1980-89 (67.2%; 62.6%), 1990-99 (45.7%; 52.3%). Risk factors for concerns included sibling poor/fair current health (future health OR 3.65, 95% CI 2.37-5.62; cancer risk OR 1.54, 1.12-2.13) compared to good/very good/excellent health. Sibling grade 2 (future health OR 1.46, 1.23-1.74; cancer risk OR 1.20, 1.01-1.42) or grade 3-4 CHCs (future health OR 1.37, 1.09-1.71; cancer risk OR 1.28, 1.03-1.58) were associated with greater concerns compared to those with less than grade 2 CHCs. Survivor treatment with chemotherapy/radiation was associated with elevated cancer risk concerns (OR 1.51, 1.13-2.02) compared to surgery/no therapy. Siblings of survivors with grade 3-4 CHCs (OR 1.35, 1.12-1.63) had greater future health concerns compared to those with less than grade 2 CHCs. Sibling bereavement was a risk factor for future health (OR 1.45, 1.04-2.03) and cancer risk (OR 1.44, 1.05-1.99) concerns. **Conclusions:** The prevalence of sibling concerns regarding future health and cancer have diminished in more recent decades. Subgroups of siblings are at-risk for concerns over future health and cancer risk, partially determined by medical characteristics of their survivor and their own health status. Research Sponsor: None.

12118 Poster Session (Board #406), Fri, 8:00 AM-11:00 AM

Defining patient-elicited concepts unique to adolescents and young adults with cancer. *First Author: Viswatej Avutu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Adolescents and young adults (AYAs) require a multidisciplinary approach to cancer care due to complex biopsychosocial variables and varied developmental maturity. Currently, age and diagnosis determine referral to pediatric or adult oncology with differing care paradigms and service utilization. These issues, in conjunction with differences in tumor biology and lower accrual to clinical trials, have contributed to marginal improvements in outcomes for AYAs. Compounding this dilemma is a lack of validated patient-reported outcome measures (PROs) for AYAs. Tracking standardized PROs longitudinally is a crucial step in understanding psychosocial variables, identifying tailored needs, improving outcomes and standardizing care. However, developing a PRO tool for AYAs first requires identifying AYA-unique domains. **Methods:** Three, 90-minute focus groups were conducted with AYAs treated at Memorial Sloan Kettering in the context of 1) pediatric oncology, 2) medical oncology, and 3) either service. Topics explored included: experiences of cancer care as an AYA; physical, social and emotional concerns; and information needs, including appropriateness, timing, and depth of information. Thematic content analysis of transcripts was performed by four interdisciplinary coders in weekly iterative consensus rounds. Phase one consisted of identification of key domains to guide line-by-line coding with NVivo software. Phase two consisted of independent review and categorization of codes, followed by three successive consensus meetings to identify distinct themes. **Results:** A mean of 6 patients (range 5-7) participated in each of the 3 groups; the total sample (n = 17) included 9 males and 8 females, ages 19-35 years (median 26). Four AYA-unique themes were identified: 1. AYAs have an uncertain sense of the future and desire more engagement in conversations pertaining to survivorship, long-term effects and transition to outpatient life. 2. Cancer as an AYA is a socially-isolating experience, prompting a strong desire to connect with peers during and post-treatment. 3. AYAs want control over who can be present during discussions with their care team as the presence of loved ones can impede or facilitate communication. 4. AYAs may be living far away from loved ones during treatment and lack supports needed to help them navigate treatment and daily life. **Conclusions:** Concept elicitation via focus groups identified novel themes related to survivorship, isolation, communication and social support, which can inform development of AYA-specific PROs. Research Sponsor: Memorial Sloan Kettering Cancer Center Patient and Family Advisory Council for Quality Grant.

12119 Poster Session (Board #407), Fri, 8:00 AM-11:00 AM

An intervention RCT-study aimed at improving mental health and increasing understanding of fertility preservation with Oncofertility! Psycho-Education And Couple Enrichment (O!PEACE) therapy. *First Author: Nao Suzuki, Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Although ASCO revised Guidelines (2013) recommends referring to psychological professionals if cancer patients show concerns or anxiety about fertility, there is no evidence regarding the efficacy of psychotherapy. The aim of this study is to examine whether the Psycho-Education And Couple Enrichment (O!PEACE) therapy can reduce psychiatric symptoms and improve stress coping and marital relationship in breast cancer patients. **Methods:** Trial design: multicenter randomized controlled trial, pre-post design. Subjects were women aged 20–39 years with breast cancer before cancer treatment and their husbands. Couples were randomly assigned to receive O!PEACE therapy (n = 37) or not (usual care: n = 37). Assessments of PTSD symptoms, depression and anxiety were made as the primary end points at baseline and at the end of therapy before cancer treatment. Stress coping strategies, resilience, marital relationships, and marital communication were examined as secondary end points. **Results:** Four participants in O!PEACE therapy and one participant in the usual care withdrew from the trial. Intention-to-treat analyses were conducted using analysis of covariance after multiple imputation by R and SPSS. Series of ANCOVAs were integrated according to Rubin's rule. A significant decrease was observed in the primary outcome of PTSD symptoms, from baseline to post-intervention, in women who participated in O!PEACE therapy ($p = .011$, $\eta_p^2 = .089$). According to post-hoc analyses, for patients with a higher baseline IES-R-J score, O!PEACE therapy resulted in a significantly higher reduction in follow-up assessment IES-R-J score when compared with usual care ($U = 172.80$, $p = .027$, $r = .258$): 59.3% of the women in O!PEACE therapy showed a 5-point or greater reduction, whereas in usual care, 30.0% showed a 5-point or greater reduction. For husbands, the O!PEACE therapy also showed a significant improvement of giving up and blaming others as the stress coping strategy and escape-avoidance coping strategy in their marital communication. For breast cancer patients, the O!PEACE therapy significantly improved support from husbands and the patients' knowledge level of oncofertility compared with those receiving usual care. **Conclusions:** Only two counseling sessions of O!PEACE therapy can reduce patients' distress, improve their husbands' coping style, and may build a better cooperative relationship for couples in terms of fertility preservation and cancer treatment. Clinical trial information: UMIN000017754. Research Sponsor: Health Labour Sciences Research Grant #H26-Cancer-017, The Ministry of Health Labour and Welfare in Japan.

12120 Poster Session (Board #408), Fri, 8:00 AM-11:00 AM

Relationship between caregiver burden and psychological distress among stem cell transplant (SCT) recipients prior to transplant. *First Author: Carlisle Topping, Massachusetts General Hospital, Boston, MA*

Background: SCT is a potentially curative therapy for patients with hematologic malignancies that involves prolonged hospitalization, intensive follow-up, and a considerable risk of morbidity and mortality. Family and friends caring for SCT recipients experience substantial caregiving burden as they prepare for SCT. Previous research demonstrates caregiver distress is highest pre-transplant and is comparable to or higher than patient-reported distress. However, the extent of this distress and its relationship to certain domains of quality of life (QOL) and caregiving burden is currently unknown. **Methods:** We conducted a secondary analysis of cross-sectional data from two supportive care studies focused on caregivers of SCT recipients. Caregivers completed the Hospital Anxiety and Depression Scale (HADS) and the CareGiver Oncology QOL questionnaire to assess their psychological distress and QOL prior to SCT. Scores >8 on the HADS anxiety and depression subscales indicated clinically significant symptoms. We selected eight domains from the CareGiver Oncology QOL questionnaire including social support, physical wellbeing, self-efficacy, coping, leisure time, financial stability, private life concerns, and caregiving burden. Multivariate regression models adjusted for age, sex, caregiver relationship, and SCT type were used to examine associations between these domains and caregivers' anxiety and depression symptoms. **Results:** A total of 193 caregivers (age *M*= 57 years, 70% female, 52% allogeneic transplant) were enrolled with a majority caring for their spouse (80%), parent (8%) or child (5%). Overall 47% and 16% of caregivers reported clinically significant anxiety and depression symptoms, respectively. Low social support, physical well-being, coping and leisure time as well as high caregiver burden, private life concerns and financial distress were associated with both caregiver anxiety and depression symptoms ($p < .05$). Low self-efficacy was associated with higher anxiety symptoms ($p < .05$). **Conclusions:** Caregivers of SCT recipients experience substantial anxiety and depression symptoms prior to SCT. Impairments across multiple QOL domains are associated with caregiver's psychological distress. Psychosocial interventions designed to improve coping, reduce caregiving burden, and enhance QOL are needed for caregivers prior to transplant. Research Sponsor: Lymphoma and Leukemia Society.

12121 Poster Session (Board #409), Fri, 8:00 AM-11:00 AM

Effect of linguistic acculturation on self-efficacy and anxiety in caregivers of Latina breast cancer survivors. *First Author: Ilana Schlam, Medstar Washington Cancer Institute, Washington, DC*

Background: Latina breast cancer survivors and their caregivers face unique challenges. Acculturation is the acquisition of the cultural elements of a dominant society. Higher acculturation in Latino survivors is positively correlated with self-efficacy in patient-provider communication and improved patient-reported outcomes. There is a paucity of research on how language acculturation affects caregiver and patient outcomes. We examined associations over time between linguistic acculturation among caregivers of Latina survivors and outcomes of caregiver self-efficacy and anxiety. **Methods:** We partnered with four community-based organizations that serve Latino families facing cancer. We enrolled 136 Latina breast cancer survivors and their caregivers for a randomized trial comparing a dyadic coping intervention to usual care (e.g., support groups). Participants completed surveys including demographic and clinical information, the short acculturation scale for Hispanics, caregiver inventory to assess self-efficacy and PROMIS domains of anxiety at baseline and 6-months after the intervention. **Results:** In multivariate linear regressions models, we examined the effect of acculturation on caregiver self-efficacy and anxiety, controlling for demographics (patient and caregiver age, caregiver education, employment), patient treatment history (chemotherapy and surgery) patient and caregiver language preference (Spanish or English) and intervention arm (intervention vs. usual care). Greater caregiver self-efficacy at 6-months was associated with younger patient age (t=-2.93, p=.004), older caregiver age (t=2.63, p = .01), female caregiver gender (t=2.79, p = .006) and higher acculturation (t=2.01, p=.04), controlling for baseline self-efficacy, patient language and randomization group. Caregiver anxiety was not related to caregiver acculturation or patient language preferences. **Conclusions:** Caregivers' language acculturation was significantly associated with their self-efficacy over time, suggesting that caregivers with lower acculturation experience lower confidence in their provision of care for Latina survivors. These findings are particularly salient because participants for this study were enrolled from organizations with bilingual services. Caregivers of Latina survivors without access to these community resources may face even more striking challenges. Future work can explore how caregivers' confidence relates to survivors' adherence to care and patient outcomes over time. Research Sponsor: None.

12122 Poster Session (Board #410), Fri, 8:00 AM-11:00 AM

Enhanced coping and self-efficacy in caregivers of hematopoietic stem cell transplant (HCT) recipients: Identifying mechanisms of a multimodal psychosocial intervention. *First Author: Madeleine Elyze, Massachusetts General Hospital, Boston, MA*

Background: A brief multimodal psychosocial intervention (BMT-CARE) for caregivers of HCT recipients demonstrated promising efficacy for improving caregiver quality of life (QOL), mood, coping skills, and self-efficacy. We examined whether improvements in coping and self-efficacy mediated the intervention effects on QOL and mood. **Methods:** We conducted a randomized clinical trial of BMT-CARE for caregivers of patients undergoing autologous or allogeneic HCT at a single institution. Caregivers were randomly assigned to BMT-CARE or usual care. BMT-CARE was tailored to the HCT trajectory and integrated treatment-related education and self-care with cognitive-behavioral skills and caregiving-specific strategies to promote coping. Caregivers completed self-report measures of QOL (CareGiver Oncology QOL), depression and anxiety symptoms (Hospital Anxiety and Depression Scale), coping skills (Measure of Current Status), and self-efficacy (Cancer Self-Efficacy Scale-Transplant) at enrollment and 60 days post-HCT. We used causal mediation regression models to examine whether changes in coping and self-efficacy mediated intervention effects on QOL, depression and anxiety symptoms. **Results:** Caregivers randomized to BMT-CARE reported improved self-efficacy (adjusted means: 156.20 vs. 147.06, P=0.023) and coping skills (adjusted means: 36.54 vs. 25.41, P<0.001). Improved coping and self-efficacy partially mediated the intervention effects on 60-day QOL (indirect effect=6.93, SE=1.85, 95% CI [3.71, 11.05]). Similarly, improved coping and self-efficacy partially mediated reductions in 60-day depression and anxiety symptoms (indirect effect depression=-1.19, SE=0.42, 95% CI [-2.23, -0.53]; indirect effect anxiety=-1.46, SE=0.55, 95% CI [-2.52, -0.43]). Combined improvements in coping and self-efficacy accounted for 67%, 80%, and 39% of the total intervention effect on QOL and depression and anxiety symptoms, respectively. **Conclusions:** A brief multimodal intervention for caregivers of HCT recipients may improve QOL and mood by enhancing coping skills and self-efficacy. These findings offer important insights into the mechanisms by which caregiver-directed interventions may enhance caregiver QOL and reduce their psychological distress. Research Sponsor: Lymphoma and Leukemia Society.

12123 Poster Session (Board #411), Fri, 8:00 AM-11:00 AM

Video conference intervention for distance caregivers (DCGs) of patients with cancer: Improving psychological outcomes. *First Author: Sara L Douglas, Case Western Reserve University and Case Comprehensive Cancer Center, Cleveland, OH*

Background: Family caregivers are increasingly involved in providing care and support for patients with cancer. Approximately 20% of caregivers live > 1 hour away from the patient and are considered DCGs. DCGs report higher distress and anxiety than local caregivers—often due to lack of first hand information and a high degree of uncertainty regarding the patient's condition. **Methods:** This RCT was conducted at a large, urban comprehensive cancer center. Patients of all cancer types were eligible if they had monthly oncologist appointments and were receiving treatment. DCGs were randomized to one of three arms. Arm 1 received 4 monthly videoconference coaching sessions with a nurse practitioner or social worker focused upon information and support, participated in patient's appointments with the oncologist via videoconference over the 4 month study period, and had access to a website designed for DCGs. Arm 2 did not receive the coaching sessions but received the other 2 components of Arm 1. Arm 3 received access to the DCG website only. Primary variables of interest were DCG distress and anxiety. DCGs completed online surveys prior to randomization and at the completion of the intervention period. PROMIS Anxiety and the NCCN distress thermometer were used. **Results:** Between November, 2016 and October, 2019, 441 patient-dyads were enrolled. Mean DCG age was 47 years; 71% were female, 65% Caucasian, 63% were the child of the patient and 81% were employed. Mean patient age was 65 years, 60% were female, 30% had GI cancer and 18% had hematologic cancer. For patients with solid tumor cancers, 59% were Stage IV. RMANOVA was used to examine the change in anxiety t-scores over time by arms of the intervention, controlling for DCG age, race, and gender. There was a significant anxiety by group interaction (p = .03) with Arm 1 being the only group that showed a significant reduction in anxiety over time (21.2% improved, ES = .57). Distress followed a similar pattern with a significant distress by group interaction (p = .02) with Arm 1 demonstrating the greatest improvement in distress over time (54.3%). **Conclusions:** These data suggest that the use of a coaching videoconference intervention made significant and clinically meaningful differences in anxiety and distress for these important members of the family caregiving team. Clinical trial information: NCT02666183. Research Sponsor: U.S. National Institutes of Health.

TPS12124 Poster Session (Board #412), Fri, 8:00 AM-11:00 AM

The effect of longitudinal exercise programming in breast cancer patients. *First Author: Jami Aya Fukui, University of Hawaii Cancer Center, Honolulu, HI*

Background: Obesity and weight gain are significant concerns for breast cancer survivors. Obesity at diagnosis is an established negative prognostic factor and studies suggest that post-diagnosis weight gain may increase risk for recurrence and decrease disease free survival. Various interventions such as dietary modification, physical activity, individualized counseling, cognitive behavioral therapy, and combinations of these interventions have been studied in order to identify strategies for weight loss in breast cancer survivors. However, one of the main challenges have been to show sustainability in these interventions. Given the adverse consequences of weight gain after diagnosis, continued efforts to identify appropriate weight management interventions aimed at promoting overall health and long term survivorship are needed. **Methods:** We have opened an investigator initiated Breast Cancer Exercise Study that provides a tailored exercise program and body health assessments for breast cancer patients along their treatment journey. We are enrolling women diagnosed with breast cancer up to 2 years after their diagnosis into a two 12-week exercise program. Participants' biometrics and physical assessments will be assessed at baseline to determine the appropriate exercise intensity to implement. Women will attend private 1:1, 90min sessions, 3 days/week. At the end of the initial 12-week program, biometric assessments are again performed and participants are then randomized to either: a) continue with individual exercise classes, 2 days/week or b) continue with group exercise classes, 2 days/week. The study follows their long term outcomes including cancer recurrence, exercise adherence as well as quality of life symptoms. The functional health assessment and subsequent personalized exercise program utilizes kinesiology students from University of Hawaii-Manoa during their clinical practicum and is based at our community partner facility the Rehabilitation Hospital of the Pacific. Body assessments and other biomarkers are evaluated through expertise at University of Hawaii Cancer Center. Collectively, our study exemplifies our partnership with community facilities, utilizes cutting edge research and incorporates local students, to provide an important health program for cancer patients all the while enriching our understanding of the unique patient population. The results of this project may help to develop standardized exercise protocols for breast cancer survivors and provide insights to other important health concerns. Clinical trial information: NCT04013568. Research Sponsor: None.

TPS12125 Poster Session (Board #413), Fri, 8:00 AM-11:00 AM

A phase Ib adaptive study of dasatinib for the prevention of oxaliplatin-induced neuropathy in patients with metastatic colorectal cancer receiving FOLFOX chemotherapy and bevacizumab. *First Author: Anne M. Noonan, The Ohio State University Comprehensive Cancer Center, Arthur G. James Cancer Hospital, Columbus, OH*

Background: Neurotoxicity is one of the most significant and disabling side effects of oxaliplatin and frequently limits the cumulative amount that can be used. The mechanism of oxaliplatin-induced neurotoxicity remains uncertain, although our preliminary studies suggest that oxaliplatin uptake by organic cation transporter 2 (OCT2) into mouse and rat dorsal root ganglion is a prerequisite for oxaliplatin-induced peripheral neuropathy. The activity of OCT2 is dependent on tyrosine phosphorylation by the SRC-kinase family member Yes1, which is highly sensitive to inhibition by several FDA-approved, small molecule kinase inhibitors such as dasatinib. We have previously shown that pre-treatment with oral dasatinib prevented acute and chronic oxaliplatin-induced peripheral neuropathy in mouse and rat models. **Methods:** This is a phase Ib dose-finding study of dasatinib given in combination with mFOLFOX6 with or without bevacizumab. The study explores the hypothesis that the addition of dasatinib prior to oxaliplatin will inhibit OCT2 activity and reduce oxaliplatin-induced neuropathy. This hypothesis will be tested in a Bayesian Phase 1b trial with adaptive dose selection using efficacy-toxicity trade-offs (modified toxicity-efficacy probability interval dose-finding design) in patients with confirmed stage IV colorectal cancer who are candidates for mFOLFOX6 with bevacizumab therapy. Patients who have documented peripheral neuropathy or prior exposure to oxaliplatin will be excluded. The primary objective is to determine the recommended Phase 2 dose which is defined as the lowest intermittent dose of dasatinib that affects serum biomarkers of OCT2, including methylnicotinamide and creatinine, by $\geq$2-fold without influencing the clearance of oxaliplatin by $>$ 20%. The following doses will be used: oxaliplatin 85mg/m^2 IV, 5FU bolus 400mg/m^2 IV bolus with Leucovorin 400mg/m^2, bevacizumab 5mg/kg, followed by infusional 5FU 2400mg/m^2 IV over 46 hours given on a day 1 and 15 schedule every 28 days. Dasatinib will be administered at one of 2 dose levels – 100mg or 140mg po. Dasatinib will be given 24 hours and 30 mins prior to oxaliplatin on C1D14, C1D15 respectively and repeated on C1D28 and C2D1. Secondary objectives include evaluation of the influence of dasatinib on the pharmacokinetics of oxaliplatin and vice versa. Quality of life will be explored using the CIPN20 questionnaire. The trial opened to enrollment in Dec 2019 (NCT04164069) and is accepting patients. Clinical trial information: NCT04164069. Research Sponsor: Pelotonia IDEA grant.

TPS12126 Poster Session (Board #414), Fri, 8:00 AM-11:00 AM

Feasibility of a digital medicine program in optimizing opioid pain control in cancer patients (SWOG S1916). *First Author: Sherry Shen, Columbia University Medical Center, New York, NY*

Background: The undertreatment of pain in patients with advanced or metastatic cancer is well described in cancer research. Overcoming barriers that prevent successful use of opioid analgesics for cancer pain requires a clear understanding of how individuals use oral medications at home. The Proteus Discover is a digital medicine program (DMP) consisting of an FDA-approved ingestible sensor made of dietary minerals co-encapsulated with patients' medications, a wearable sensor patch, and a mobile device app that enables patients to electronically transmit their medication adherence patterns. Use of the DMP has demonstrated improved clinical outcomes vs. usual care in patients with diabetes and hypertension, shown superiority over directly-observed therapy in tuberculosis and has been studied in the treatment of patients with hepatitis C, HIV, cancer and severe mental illness, but it has not been previously studied with opioids or in monitoring cancer-related pain. **Methods:** We are conducting a multicenter pilot study at SWOG NCORP sites to test the feasibility of using the DMP to monitor opioid use in the treatment of metastatic cancer pain. Eligible patients must have a diagnosis of metastatic cancer, have a baseline Brief Pain Inventory worst pain score of $\geq$3, be deemed by their physician to need initiation or up-titration of oxycodone-acetaminophen for pain control, and be able to read English. Primary outcomes include: (1) study accrual of 60 patients within six months of study activation at all participating sites; (2) patient retention defined as $\geq$50 patients completing the study, and; (3) adherence to the DMP defined as $\geq$66% of patients wearing the sensor patch for $\geq$28 days of the 42-day observation period. Secondary outcomes include change in Brief Pain Inventory pain scores, opioid medication consumption, number of safety alert triggers for high consumption, hospital or emergency room visits for pain, activity levels, and frequency of changes to the pain control regimen. The study will enroll patients at six sites; the first patient was enrolled on 1/20/2020. If successful, this study will inform design of a randomized controlled trial of the DMP vs. usual care in optimizing medication utilization and controlling cancer-related pain. Clinical trial information: NCT04194528. Research Sponsor: U.S. National Institutes of Health, Proteus Digital Health.

TPS12127 Poster Session (Board #415), Fri, 8:00 AM-11:00 AM

An oro-buccal nanoparticle delivered cannabis medicine for pain management in cancer: A clinical trial in progress. *First Author: Stephen John Clarke, Northern Cancer Institute, Sydney, Australia*

Background: Cannabinoid molecules derived from Cannabis sativa L. have been posited to ameliorate conditions, including pain, chemotherapy induced nausea and multiple sclerosis associated spasticity. The clinical use of cannabinoids refers to a wide variety of formulations and extracts that may contain different active ingredients and adulterants as well as inter batch variability. Novel matrix formulations (e.g., water-soluble nanoparticles) for cannabis delivery may add further efficacy and tolerability to standard routes of administration (e.g., oral / gastrointestinal, inhaled, sublingual). This is further emphasized by the dysbiotic effects on the intestinal microbiome reported for oral formulations of medicinal cannabis, and which resulted in reduced efficacy. Similar results have been reported for other psychotropic compounds, such as alcohol and nicotine. Therapeutic use of cannabinoid formulations may be mode of delivery dependent in order to achieve safe, tolerable and effective doses. **Methods:** A water soluble oro-buccal nanoparticle spray with a racemic 1:1 mixture of Delta9Tetrahydrocannabinol (D9THC) and Cannabidiol (CBD), which bypasses the gastrointestinal system and first pass metabolism by accessing the systemic circulation via the facial lymphatics system, was investigated in patients with advanced cancer and unrelieved pain in a single ascending dose and multiple ascending dose in a first-in-human study. **Results:** The THC / CBD combination delivered as a submicron particle demonstrated safety, tolerability and a pharmacokinetic profile suitable for maintenance analgesic therapy. Preliminary analysis found an overall (n = 25) improvement in pain scores, especially in the subgroup of patients with bone metastases (n = 8), who obtained a greater than 30% average reduction in pain severity. 1 Clinical trial information: ACTRN12617001480370. Research Sponsor: Medlab Clinical.

TPS12128 Poster Session (Board #416), Fri, 8:00 AM-11:00 AM

A phase Ib study of the safety and pharmacology of nilotinib to prevent paclitaxel-induced peripheral neuropathy in patients with breast cancer. *First Author: Elizabeth J. Adams, Ohio State University Wexner Medical Center, Columbus, OH*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a debilitating adverse effect of paclitaxel, but convincing evidence for a preventative technique founded on mechanistic rationale is lacking. We previously report that paclitaxel accumulation is mediated by the murine organic anion transporting polypeptide, OATP1B2 in mice (OATP1B1 and OATP1B3 in humans) (Leblanc, J Clin Invest, 2018). We found that paclitaxel induces acute and chronic neurotoxicity in mice in an OATP1B2-dependent manner, which is reversed by pre-treatment with FDA-approved tyrosine kinase inhibitor, nilotinib. **Methods:** This phase Ib dose finding study of nilotinib in combination with weekly paclitaxel is investigating the hypothesis that intermittent dosing of nilotinib 24 hours before paclitaxel infusion (excluding C1D1) and again 30 minutes before paclitaxel infusion will inhibit OATP1B1 and prevent CIPN. This hypothesis will be assessed using an adaptive Bayesian method for dose finding based on efficacy-toxicity trade-offs in patients with breast cancer stages I-III who qualify for paclitaxel therapy. Patients with previous $\geq$ grade 2 neuropathy on breast cancer therapies will be excluded. The primary objectives are to find the recommended phase II dose of nilotinib in combination with paclitaxel for early stage breast cancer, defined as the lowest intermittent dose of nilotinib that temporarily inhibits OATP1B1 function without affecting paclitaxel plasma pharmacokinetics (PK), and to determine the toxicity profile of nilotinib in combination with paclitaxel. OATP1B1 inhibition by nilotinib will be assessed via validated surrogate endogenous substrates, glycochenodeoxycholate sulfate (GCDGA-S) and chenodeoxycholate-24-glucuronide (CDCA-24G). Effective OATP1B1 inhibition will be $\geq$5-fold increase in AUC of GCDCA-S from pre- to post- treatment or detectable CDCA-24G levels post-treatment. The 4 nilotinib dose levels are 50 mg (dose level -1), 100 mg (dose level 1), 200 mg (dose level 2), 300 mg (dose level 3). IV paclitaxel dose of 80 mg/m^2 on D1,8,15 for 12 total weekly doses will be used. Oral nilotinib will be administered 24 hours before paclitaxel infusion on C1D7,D14 and again 30 minutes before infusion on C1D8,D15. Secondary objectives are to determine paclitaxel's effect on PK of nilotinib and vice versa. Quality of life via CIPN-20 survey, disease free survival, event free survival, overall survival are exploratory objectives. NCT04205903 enrollment opened February 2020 and is accepting patients. Clinical trial information: NCT04205903. Research Sponsor: U.S. National Institutes of Health.

TPS12129 Poster Session (Board #417), Fri, 8:00 AM-11:00 AM

Use of simulation for training family caregivers of patients receiving radiation therapy. *First Author: Susan R Mazanec, Case Western Reserve Univ, Cleveland, OH*

Background: Positive treatment outcomes and avoidance of complications are dependent to a large extent on the care provided by family members. However, family caregivers report feeling unprepared to assume the multiple, complex tasks of caregiving, including tracheostomy care, tube feedings, wound and colostomy care, pain management, and emotional support. Despite being a critical extension of the oncology healthcare team, training of caregivers to manage symptoms, deal with communication issues with the care recipients, and take care of their own physical and emotional health as caregivers, is not integrated into clinical practice. The purpose of this clinical trial is to measure the effect of a psychoeducational caregiver intervention that incorporates simulation techniques focused on skill development to improve caregiver and patient outcomes. Simulation, commonly used in training healthcare professionals, is a form of experiential learning that creates events or situations to mimic clinical situations. Use of simulation for skills training in family caregivers of patients with cancer is rarely studied. **Methods:** This two-group, randomized clinical trial, which opened to accrual in December 2019, will recruit 180 caregivers from University Hospitals Seidman Cancer Center. Patients must be receiving radiation therapy for a diagnosis of stage I - III cancers of the rectum, anus, and esophagus; stage III NSCLC; or stage I – IV A/B head/neck cancer. Adult caregivers must be identified by the patient as their primary caregiver, who is providing daily assistance and/or emotional support. The intervention involves three in-person, one-on-one sessions during radiation treatments. The control group is usual care. Data will be collected at baseline, at the end of radiation treatment, and 4 and 20 weeks post-radiation treatment. The primary outcome is caregiver anxiety at 20 weeks postradiation treatment. Other caregiver outcomes include depression, health-related quality of life [HRQOL], and fatigue. Patient outcomes (HRQOL and interrupted treatment course) and healthcare utilization outcomes (unplanned hospital admission, emergency room visits, and use of intravenous fluids) will be measured. The analysis will consist of linear mixed model repeated measures, mediation and moderation tests, and Poisson regression methods. Clinical trial information: NCT04055948. Research Sponsor: U.S. National Institutes of Health.

TPS12130 Poster Session (Board #418), Fri, 8:00 AM-11:00 AM

Effects of an e-home based symptom management and mindfulness training program on quality of life in breast cancer survivors. *First Author: Karis Kin-Fong Cheng, National University of Singapore, Singapre, Singapore*

Background: The first five years post-treatment for breast cancer are a critical phase, when the survivors may face a multitude of problems, including persistent and/or late-emerging symptoms following the cancer and its treatment, psychosocial distress associated with the risk of cancer recurrence, chronic uncertainty and social disruption. Thus, this trial will answer the research questions of 'Will the combined symptom management and mindfulness-based training programme be a promising approach to assist women with breast cancer in transition from treatment to survivorship?', and 'Since breast cancer survivors have infrequent clinical follow-up, will e-Home based system provide a feasible option for post-treatment care?' **Methods:** We aim to develop an e-Home based symptom management and mindfulness training programme for breast cancer survivors and to determine its effects on the endpoints including quality of life, symptom distress, psychosocial adjustment, psychological morbidity, and unplanned outpatient attendance or hospitalisation in breast cancer survivors. (ClinicalTrials.gov Identifier: NCT02931864) We employ a randomised clinical trial with four study arms (with 47 subjects, who have completed cancer treatment for stage 0 to 3 breast cancer between 6 months to 5 years previously, in each arm) together with a process evaluation; group 1 (usual care), group 2 (experimental group: five weekly sessions of online symptom management + mindfulness training programme and usual care), group 3 (comparison group 1: online symptom management programme and usual care), and group 4 (comparison group 2: online mindfulness training programme and usual care). Subjects will complete questionnaires measures of 6-item Social Support Questionnaire, Breast Cancer Survivor Self- Efficacy Scale, the Quality of Life-Cancer Survivor Scale, Memorial Symptom Assessment Scale, Psychosocial Adjustment to Illness Scale, short version of the Fear of Recurrence Scale, Hospital and anxiety Depression Scale, and Five Facet Mindfulness Questionnaire at baseline, at 8 weeks from time 1 (time 2), at 12 weeks from time 1 (time 3) and at 24 weeks from time 1 (time 4). Intention-to-treat approach will be used. Repeated measures analysis of variance will be used to examine the differences on outcome measures among the experimental, comparison, and control groups across study time points. Currently, 162 of 188 planned subjects have been enrolled and the trial continues as planned. Clinical trial information: NCT02931864. Research Sponsor: Singapore Cancer Society Research Fund.
