2020 ASCO ANNUAL MEETING PROCEEDINGS ABSTRACTS

continued on following page

Journal of Clinical Oncology (ISSN 0732-183X) is published 36 times a year, three times monthly, by the American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Periodicals postage is paid at Alexandria, VA, and at additional mailing offices. Publication Mail Agreement Number 863289.

Editorial correspondence should be addressed to Stephen A. Cannistra, MD, *Journal of Clinical Oncology,* 2318 Mill Road, Suite 800, Alexandria, VA 22314. Phone: 703-797-1900; Fax: 703-684-8720. E-mail: jco@asco.org. Internet: ascopubs.org/journal/jco.

POSTMASTER: Send address changes to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. ASCO members should send changes of address to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Nonmembers should send changes of address to *Journal of Clinical Oncology* Customer Service, 2318 Mill Road, Suite 800, Alexandria, VA 22314.

2020 annual subscription rates, effective September 1, 2019: United States and possessions: individual, $656 one year, $1,247 two years; single issue, $40. International: individual, $910 one year, $1,729 two years; single issue, $50. Student and resident: United States and possessions: $318; all other countries, $421. To receive student/resident rate, orders must be accompanied by name of affiliated institution, date of term, and the signature of program/residency coordinator on institution letterhead. Orders will be billed at individual rate until proof of status is received. JCO Digital Library (US and International Online Only): Tier 1 $1,070; Tier 2 $1,221; Tier 3 $1,761. Tiers 4-6 contact ACCUCOMS (All countries except Japan) and USACO (Japan) for quote. See http://ascopubs.org/pb-assets/pdfs/ASCO-institutional-catalog-1536072550257.pdf for descriptions of each tier. Subscriptions are accepted on a 12-month basis. Prices are subject to change without notice. Current prices are in effect for back volumes and back issues. Back issues sold in conjunction with a subscription rate are on a prorated basis. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. *JCO* Legacy Archive (electronic back issues from January 1983 through December 2003) is also available; please inquire.

Letter From the Editor

The *2020 ASCO Annual Meeting Proceedings* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 2,400 abstracts selected by the ASCO Scientific Program Committee for presentation as part of the ASCO Annual Meeting. Publication-only abstracts are included in the online supplement to the May 20 issue of *Journal of Clinical Oncology* at JCO.org. Abstracts can be also accessed online through the ASCO Meeting Library (meetinglibrary.asco.org). Online abstracts include the full list of abstract authors and their disclosure information.

All abstracts carry *Journal of Clinical Oncology* citations, for example:

J Clin Oncol 38:15s, 2020 (suppl; abstr 1)

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Important Tiers and Pricing Notes
Additional rates along with tier descriptions are available online at http://ascopubs.org/pb-assets/pdfs/ASCO-institutional-catalog-1536072550257.pdf

1. Prices are in effect from September 1, 2019, through August 31, 2020. Prices are subject to change.
2. Add-on prints are available for $940 in the US and $1,359 outside the US.
3. For multisite licenses, please contact the appropriate agent for a quote.
4. Subscribers outside the US, add $150 per print subscription for expedited delivery.
5. Single-issue price: $40 US, $50 international.
6. Prices quoted are in US dollars, and payments must be made in US dollars.
7. Except on consortia orders, the publisher allows for a 5% discount on Tiers 1-3 to recognized subscription agents.

Prices are subject to change without notice. Current prices are in effect for back volumes and back issues. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. Back issues sold in conjunction with a subscription are on a prorated basis.

Free Public Access
Journal of Clinical Oncology (*JCO*) provides free online access to original research articles older than one year at jco.org. In addition, all ASCO Special Articles, Rapid Communications, Editorials, Comments and Controversies articles, the Art of Oncology series, and Correspondence articles are free immediately upon publication.

Disclaimer
The ideas and opinions expressed in *JCO* do not necessarily reflect those of the American Society of Clinical Oncology (ASCO). The mention of any product, service, or therapy in this publication or in any advertisement in this publication should not be construed as an endorsement of the products mentioned. It is the responsibility of the treating physician or other health care provider, relying on independent experience and knowledge of the patient, to determine drug dosages and the best treatment for the patient. Readers are advised to check the appropriate medical literature and the product information currently provided by the manufacturer of each drug to be administered to verify approved uses, the dosage, method, and duration of administration, or contraindications. Readers are also encouraged to contact the manufacturer with questions about the features or limitations of any products. ASCO assumes no responsibility for any injury or damage to persons or property arising out of or related to any use of the material contained in this publication or to any errors or omissions.

ASCO Abstracts Policy

Public Release of Abstracts

The abstracts published in the *2020 ASCO Annual Meeting Proceedings*, including those abstracts published but not presented at the Meeting, were publicly released by ASCO at 5:00 PM (EDT) on Wednesday, May 13, 2020. These abstracts are publicly available online through ASCO.org, the official website of the Society. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released on ASCO.org at 5:00 PM (EDT) on Thursday, May 28, 2020.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on ASCO.org.

Conflict of Interest Disclosure

As the CE provider for the activity, ASCO is committed to balance, objectivity, and scientific rigor in the management of financial interactions with for-profit health care companies that could create real or perceived conflicts of interest. Participants in the activity have disclosed their financial relationships in accordance with ASCO's Policy for Relationships with Companies; review the policy at asco.org/rwc.

ASCO offers a comprehensive disclosure management system, using one disclosure for all ASCO activities. Members and participants in activities use coi.asco.org to disclose all interactions with companies. Their disclosure is kept on file and can be confirmed or updated with each new activity.

Please email coi@asco.org with specific questions or concerns.

LBA1 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Maintenance avelumab + best supportive care (BSC) versus BSC alone after platinum-based first-line (1L) chemotherapy in advanced urothelial carcinoma (UC): JAVELIN Bladder 100 phase III interim analysis. *First Author: Thomas Powles, Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, St Bartholomew's Hospital, London, United Kingdom*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

LBA2 **Plenary Session, Sun, 1:00 PM-4:00 PM**

A randomized phase III trial of systemic therapy plus early local therapy versus systemic therapy alone in women with de novo stage IV breast cancer: A trial of the ECOG-ACRIN Research Group (E2108). *First Author: Seema Ahsan Khan, Northwestern Memorial Hospital, Chicago, IL*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

LBA3 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Carfilzomib, lenalidomide, and dexamethasone (KRd) versus bortezomib, lenalidomide, and dexamethasone (VRd) for initial therapy of newly diagnosed multiple myeloma (NDMM): Results of ENDURANCE (E1A11) phase III trial. *First Author: Shaji Kumar, Mayo Clinic, Rochester, MN*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

LBA4 **Plenary Session, Sun, 1:00 PM-4:00 PM**

First-line therapy of pembrolizumab versus standard of care (SOC) in microsatellite instability-high/mismatch repair deficient metastatic colorectal cancer: The phase III, KEYNOTE-177 study. *First Author: Thierry Andre, Sorbonne University and Saint-Antoine Hospital, Paris, France*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

LBA5 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Osimertinib as adjuvant therapy in patients (pts) with stage IB–IIIA EGFR mutation positive (EGFRm) NSCLC after complete tumor resection: ADAURA. *First Author: Roy S. Herbst, Medical Oncology, Yale School of Medicine and Yale Cancer Center, New Haven, CT*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

100 Clinical Science Symposium, Sat, 1:00 PM-2:30 PM

Phase I study of teclistamab, a humanized B-cell maturation antigen (BCMA) x CD3 bispecific antibody, in relapsed/refractory multiple myeloma (R/R MM). *First Author: Saad Zafar Usmani, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Teclistamab (JNJ-64007957) is a bispecific BCMA x CD3 antibody that induces T cell-mediated cytotoxicity against BCMA-expressing myeloma cells. Initial results from an ongoing study of teclistamab in RRMM (NCT03145181) are presented. **Methods:** Pts have MM and are RR to standard therapies. Primary objective for part 1 is to identify a recommended phase 2 dose(s). Multiple intravenous (iv) doses ± priming doses were explored. Adverse events (AEs) were graded per CTCAE v4.03 and cytokine release syndrome (CRS) per Lee *et al* 2014. Response was investigator-assessed using IMWG criteria; minimal residual disease (MRD) in bone marrow was assessed by next generation sequencing. **Results:** As of 31 Jan 2020, 66 pts had received iv teclistamab (0.3–270 μg/kg). Median age was 64 y (24–82), median prior therapies was 6 (2–14), 97% triple-class exposed, 83% triple-class refractory, and 38% penta-drug refractory. Most common treatment-related AEs (all grade) were CRS (56%), neutropenia (26%), and anemia (23%). CRS events were all grade 1–2 and generally confined to initial doses. 8% of pts had treatment-related neurotoxicity (3% grade ≥3), and 9% had infusion related reaction. Infection-related AEs were reported in 61% of pts (21% grade ≥3). 2 dose-limiting toxicities were reported: grade 4 delirium (resolved after 16 days) and grade 4 thrombocytopenia (resolved after 1 day). 36% of pts had treatment-related grade ≥3 AEs; neutropenia (20%) and anemia (14%) were most frequent. Only 1 grade 5 AE was reported (respiratory failure in the setting of pneumonia deemed unrelated by the investigator). PK results indicate that the half-life of teclistamab supports weekly dosing. On-target pharmacodynamic activity (T cell redistribution and activation along with transient release of cytokines) was observed at doses ≥9.6 μg/kg. Cytokine production was modulated with step-up dosing while T cell activation was maintained. 65 pts were evaluable for response. Activity was observed starting at treatment doses ≥38.4 μg/kg, with 20/52 (38%) pts achieving a response. At the highest dose, 7/9 (78%) pts responded (1 response pending confirmation). Of MRD-evaluable pts who had complete response, 2/2 were MRD negative at 10^{-6} with treatment ongoing > 12 mo. **Conclusions:** Teclistamab has manageable safety across all doses explored. A 78% overall response rate was observed at the highest weekly treatment dose in pts with advanced RRMM, supporting further evaluation of teclistamab in expansion cohorts. Clinical trial information: NCT03145181. Research Sponsor: Janssen R&D.

101 Clinical Science Symposium, Sat, 1:00 PM-2:30 PM

Safety and clinical activity of gene-engineered T-cell therapy targeting HPV-16 E7 for epithelial cancers. *First Author: Christian S. Hinrichs, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Genetically engineered T-cell therapy has shown remarkable clinical activity in hematologic malignancies. It is not known if this type of treatment can be applied effectively to epithelial cancers, which account for 80% to 90% of human malignancies. **Methods:** We conducted a phase I clinical trial with a 3 + 3 dose escalation in which patients with metastatic HPV-16+ epithelial cancers were treated with a one-time infusion of genetically engineered T cells expressing a T-cell receptor targeting an HLA-A*02:01-restricted epitope of HPV-16 E7 (E7 TCR-T cells). A lymphocyte-depleting conditioning regimen was administered before cell infusion, and high-dose systemic aldesleukin was administered after cell infusion. **Results:** Twelve patients, previously treated with a median of 4 (range, 3 to 7) anticancer agents, were treated. The cell dose was not limited by toxicity. Six patients demonstrated objective clinical responses, which included regression of bulky tumors and complete elimination of some tumors. Responses occurred in patients with vulvar, anal, head and neck, and cervical cancer. Four patients who previously received PD-1-based therapy responded. Response duration ranged from 3 to 9 months. Sustained, high-level engraftment of E7 TCR-T cells in peripheral blood was observed (median after approximately 6 weeks, 66% of total T cells, range 1% to 88%) and correlated with cell dose but not with clinical response. Infused T cell characteristics did not correlate strongly with response. Of the 4 resistant tumors that were studied, 3 demonstrated genetic defects in *HLA-A*02:01* or *B2M* (necessary components of the target complex) and 1 demonstrated copy loss with decreased expression of antigen presentation and interferon response molecules (i.e. *TAP1, TAP2*, *IFNGR1*, *IFNGR2*). Of the 3 sensitive tumors studied, 0 showed genetic defects in these molecules. **Conclusions:** E7 TCR-T cells demonstrated safety and clinical activity in the treatment of highly refractory metastatic HPV-16+ cancers. Treatment resistance was linked to definitive genetic defects in the targeted peptide-HLA complex and to manifold defects in antigen processing and interferon response. Clinical trial information: NCT02858310. Research Sponsor: NIH, Pharmaceutical/ Biotech Company.

102 Clinical Science Symposium, Sat, 1:00 PM-2:30 PM

Phase I dose escalation and expansion trial to assess the safety and efficacy of ADP-A2M4 SPEAR T cells in advanced solid tumors. *First Author: David S. Hong, MD Anderson Cancer Center, Houston, TX*

Background: MAGE-A4 is a cancer/testis antigen with expression in many solid tumors promoting cell growth by preventing cell cycle arrest and apoptosis. This study (NCT03132922) evaluated safety and efficacy of SPEAR T-cells directed against the MAGE-A4 peptide expressed in 9 tumor types. **Methods:** This Phase I dose-escalation, expansion trial evaluated patients (pt) who were HLA-A*02 positive with advanced cancers that expressed the MAGE-A4 protein. Autologous T-cells from eligible patients were isolated, transduced with a lentiviral vector containing the MAGE-A4^{c1032} TCR, and expanded. Prior to ADP-A2M4 infusion, pts received a lymphodepletion regimen of cyclophosphamide and fludarabine. Cohorts 1, 2, 3, and expansion were to receive transduced cell doses of up to: 0.12×10^9, 1.2×10^9, 6×10^9, and 10×10^9, respectively. **Results:** As of 23 October 2019, 9 pts were treated in dose escalation with no DLTs; 25 pts were treated in expansion. Median age was 56.5 yr (range: 31-78). All pts received prior chemotherapy. Most common (> 30%) AEs ≥Grade 3 were lymphopenia, leukopenia, neutropenia, anemia, thrombocytopenia, and febrile neutropenia. Two pts had trial-related deaths (aplastic anemia and CVA) leading to modification of the lymphodepletion regimen and eligibility criteria. In Cohort 3/expansion (28 pts), Best Overall Response was PR (7), SD (11), PD (5), non-evaluable (5). All PRs, at the time of data cut-off, were in patients with synovial sarcoma. Transduced T-cells were detectable in all patients. Tumor infiltration of SPEAR T-cells was detectable in several cohort 3/ expansion pts. **Conclusions:** The Phase I single agent ADP-A2M4 trial will complete enrollment shortly and updated data will be presented. ADP-A2M4 shows promising efficacy and a manageable safety profile at a dose range of $1.2 - 10 \times 10^9$. Clinical activity in various tumors has led to a separate ongoing low dose radiation sub-study of this trial, a Phase II trial in sarcoma (SPEARHEAD-1, NCT04044768), and a Phase I trial (SURPASS, NCT04044859) with ADP-A2M4CD8, a next-generation SPEAR T-cell targeting MAGE-A4. Clinical trial information: NCT03132922. Research Sponsor: Adaptimmune Therapeutics plc.

103 Clinical Science Symposium, Sat, 3:30 PM-5:00 PM

NOMINATOR: Feasibility of genomic testing of rare cancers to match cancer to treatment. *First Author: Damien Kee, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Rare cancers (RCs) often lack proven treatments and consequently have poorer outcomes. Identification of molecular biomarkers can facilitate treatment selection and trials access for RC patients (pts) where histology-based trials are not feasible. We assessed the potential for next-generation sequencing (NGS) to impact RC care. **Methods:** Pts with a rare histology, poor-prognosis solid-tumor and no standard of care therapy underwent NGS genomic profiling of paired FFPE tumor and blood (PMCC comprehensive cancer panel; 391 genes). A virtual molecular tumour board (MTB) reviewed curated results regarding diagnosis, actionability (OncoKB) and treatment recommendations. **Results:** Between July 2017 and Nov 2019, 121 pt were prospectively enrolled across 4 Australian sites. 109 (91%) pts had a tumour with an incidence of < 1/100,000 person/years with 83 diverse RC histologies represented. 100 (83%) cases were successfully sequenced. The most commonly aberrant genes (> 10%) were: TP53 (45%), CDKN2A/B, RB1, PTEN and NF1. 51 (51%) had at least one potentially actionable finding, with 27 matched to a clinically validated drug (OncoKB level 3 or better) [Table]. In 6 cases NGS resulted in a revised diagnosis (includes 4 with FDA approved therapy). Actionable germline mutations were detected in 3 individuals of which 2 were previously known. The majority of pts remain in follow-up, however, 8 died prior to or within 28 days of NGS result availability. Drug access remains a limitation with only 12 receiving therapy based on NGS/MTB guidance. Clinical trial information: ACTRN12616001000493. **Conclusions:** NGS in RCs is feasible with potential impact in half of cases. Earlier testing and improved off-label/trial drug access is necessary to increase the likelihood that RC patients may benefit from molecularly guided therapy. Research Sponsor: Melbourne Health, Other Government Agency.

OncoKB Level (Best result per tumour)	N (100)	Genetic biomarker/Diagnosis

104 Clinical Science Symposium, Sat, 3:30 PM-5:00 PM

Different response to ALK inhibitors in EML4-ALK positive mediastinal cancer of unknown primary. *First Author: Chunhong Hu, Department of Oncology, The Second Xiangya Hospital, Central South University, Changsha, China*

Background: With the development of next-generation sequencing (NGS) and precision medicine, targeted therapy especially molecule-driven therapy irrespective of tumor site may play an important role in cancer patients with druggable targets. Cancer of unknown primary (CUP) especially mediastinal CUP (MCUP) has poor prognosis with empirical chemotherapy but may harbor targetable genetic alterations. In the study, we evaluate the response to ALK inhibitors in ALK-positive MCUP. **Methods:** We queried the cancer database of the Second Xiangya hospitalfrom 2018.10 to 2019.12 for patients with ALK-positive cancers regardless of tumor site.Then we selected ALK-positive MCUP patients treated with ALK inhibitors, on which both NGS and programmed death-ligand 1 (PD-L1) testing were performed. **Results:** Forty-eightpatients with ALK-positive cancers were registered in the database. Two MCUP patients were found and showed different response. The first MCUP patient obtaining remarkable response to alectinib harbored ALK/TP53 co-mutation and TERT wild type accompanied by low PD-L1 expression, while the second one showing stable disease with crizotinib carried ALK/TP53/TERT co-mutation and high PD-L1 expression. **Conclusions:** We reveal for the first time that ALK inhibitors are applied to MCUP as first-line therapy and alectinib is firstly reported to treat MCUP patients. ALK inhibitor alectinib is expected to improve outcomes of patients with ALK-positive MCUP. NGS and PD-L1 testing should be recommended for MCUP to get more information about therapy and efficacy. Research Sponsor: None.

Published cases with ALK-positive mediastinal carcinomas of unknown primary.

Year	Age	Sex	Smoke	Histology	Tumor sites	Gene alterations	Therapy	Follow-up (months)	Outcome
2014	55	Female	No	ADC	Mediastinum, neck LNs, breast	ALK fusion	Chemo, crizotinib	>3	Alive without progression
2016	45	Female	No	ADC	Mediastinum, hilar, pleural, adrenal, brain	EML4-ALK fusion	CRT, crizotinib	>40	Alive with recurrence
2016	52	Male	Yes	PDC	Mediastinum	EML4-ALK fusion	Surgery	36	Alive without recurrence
2016	26	Female	Yes	ADC	Ovarian, mediastinal, neck LNs, rib	EML4-ALK fusion	CRT	44	Alive with recurrence
2016	78	Female	Yes	PDC	Mesenteric, pretracheal LNs, bone	EML4-ALK fusion	Symptomatic care	N/A	N/A
2019	31	Female	N/A	ADC	Lung, mediastinum, liver, muscle, skeleton	EML4-ALK fusion	Chemo, crizotinb, brigatinib	6	Alive with progression

105 Clinical Science Symposium, Sat, 3:30 PM-5:00 PM

Utility of circulating cell-free DNA (cfDNA) analysis in patients with carcinoma of unknown primary (CUP) in identifying alterations with strong evidence for response or resistance to targeted therapy. *First Author: Caroline Weipert, Guardant Health, Redwood City, CA*

Background: CUP is a rare, heterogeneous group of cancers with an overall poor prognosis; the standard treatment remains chemotherapy. The OncoKB database is a curated list of somatic molecular alterations. Alterations with the highest classification must be an FDA-recognized biomarker associated with response to an FDA-approved drug (Level 1), be recommended by major guidelines or expert panels as predictive of response to an FDA-approved drug (Level 2) or be predictive of resistance to an FDA-approved drug (R1). We explored the landscape of alterations classified as Level 1, 2 or R1 based on the OncoKB scale in a large cohort of CUP patients tested via a well-validated cfDNA assay. **Methods:** We queried consecutive samples from advanced cancer patients with a listed diagnosis of CUP who underwent testing via a commercially available liquid biopsy assay (Guardant360) between November 2016 and November 2019. The cfDNA assay included targeted next-generation sequencing of 73- to 74-genes specifically curated to include genes with potential targeted therapy options. Alterations were classified based on their ranking in the OncoKB database as of January 2020. **Results:** In total we identified 2,022 samples with a diagnosis of CUP, and 90.0% of these samples had >1 cfDNA alteration detected. The median age of patients was 68 years and 51% were female. Overall, 20.7% of patients had a Level 1 alteration, 9.5% had a Level 2 alteration, and 23.9% had an R1 alteration (select alterations outlined in Table). **Conclusions:** cfDNA analysis of patients with advanced CUP identified a significant number of patients with alterations associated with strong evidence for either response or resistance to treatment based on the OncoKB classification schema. While many of these alterations are associated with approvals in specific cancer types, the identification of these alterations suggests many CUP patients may have targeted therapy options. We will present case examples illustrating patient outcomes from CUP patients who received targeting therapy based on cfDNA results. Research Sponsor: None.

Alteration	# of Patients (%)

NivoCUP: An open-label phase II study on the efficacy of nivolumab in cancer of unknown primary. *First Author: Junko Tanizaki, Kishiwada City Hospital, Kishiwada, Japan*

Background: CUP has a poor prognosis with a median survival of less than 12 months. Given the recent approval of immune checkpoint inhibitors in several cancer types, we performed a multicenter phase II study of nivolumab in CUP patients (pts). **Methods:** The main population of this study is CUP pts who were previously treated with more than one line of systemic chemotherapy. Previously untreated CUP pts were also enrolled for exploratory analysis. Pathological examination (including IHC), CT, FDG-PET, gastroscopy and colonoscopy and medical examination were mandatory for diagnosis of CUP before enrollment. CUP pts belonging to favorable prognosis groups were excluded from the trial. Nivolumab (240 mg/body) was delivered as an intravenous infusion every 2 weeks for up to 52 cycles until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) according to RECIST 1.1 by an Independent Endpoint Review Committee in previously treated pts. The secondary objectives include investigator-assessed ORR, progression-free survival (PFS), overall survival (OS), safety and the association between the efficacy of nivolumab and PD-L1 expression. **Results:** A total of 56 CUP pts, 45 previously treated and 11 previously untreated pts, were enrolled in this trial. The median age was 65.5 years, 22 pts were male. Median follow-up was 8.05 mo (range, 0.1 to 20.7 mo). Of 45 previously treated pts, 2 and 9 had an investigator-assessed complete response and partial response (ORR 24.4%, 95% CI: 12.9-39.5%), with a median PFS (mPFS) and OS (mOS) of 5.4 mo (95% CI: 2.6-6.9) and 15.1 mo (95% CI: 8.3-NR), respectively. Among 11 previously untreated pts, 1 pt had partial response (ORR 9.1%, 95% CI: 0.2-41.3%). The mPFS was 3.9 mo and the mOS was not reached in untreated pts (95% CI: 1.1-5.6, and 95% CI: 2.6-NR, respectively). Nivolumab demonstrated a mPFS of 5.1mo (95% CI: 2.7-5.6) and a mOS of 15.9 mo (95% CI: 8.4-NR) in an overall population. Immune-related adverse events occurred in 57% of overall pts with 5% of grade 3 or higher, and the most common were rash (27%), hypothyroidism (16%), and diarrhea/colitis (16%). No treatment related death was observed. **Conclusions:** In pts with previously treated and untreated CUP, nivolumab demonstrated durable antitumor activity with a manageable safety. Clinical trial information: UMIN000030649. Research Sponsor: ONO PHARMACEUTICAL CO., LTD.

107 Clinical Science Symposium, Sun, 10:30 AM-12:00 PM

Updated entrectinib data in children and adolescents with recurrent or refractory solid tumors, including primary CNS tumors. *First Author: Ami Vijay Desai, University of Chicago Medical Center, Chicago, IL*

Background: The phase 1/2 STARTRK-NG trial (NCT02650401) is evaluating entrectinib, a CNS-penetrant oral inhibitor of TRK, ROS1 and ALK tyrosine kinases, in children and adolescents < 21 years old with recurrent/refractory solid tumors, including primary CNS tumors. **Methods:** After determining the recommended dose as 550mg/m^2/day in all-comers, expansion cohorts with gene-fusion-positive CNS/solid tumors (*NTRK1/2/3* and *ROS1*) are being enrolled. **Results:** As of 1 July 2019 (data cut-off), 34 patients (4.9 months to 20 years old; median age 7 years) have been evaluated for response to treatment with entrectinib. Responses were classified as complete response (CR), partial response (PR), stable disease (SD), or progressive disease (PD) using RANO for CNS tumors, RECISTv1.1 for solid tumors, or Curie score for neuroblastomas. Responses in fusion-positive patients were assessed by blinded independent central review (BICR), and occurred at doses ≥400mg/m^2. Best responses in patients with fusion-positive CNS tumors (n = 8) were four CR (*ETV6-NTRK3, EML1-NTRK2, GOPC-ROS1,* and *TPR-NTRK1*), two PR (*KANK1-NTRK2* and *EEF1G-ROS1*), and two PD (*EML4-ALK* and *PARP6-NTRK3*). In patients with fusion-positive solid tumors (n = 6) best responses were three CR (*DCTN1-ALK, ETV6-NTRK3,* and *ETV6-NTRK3*), and three PR (*TFG-ROS1, EML4-NTRK3,* and *KIF5B-ALK*). Responses (Investigator-assessed) in patients with non-fusion tumors (n = 20) were one CR (*ALK F1174L* mutation), four SD, ten PD, and five patients were unevaluable or had no data. The objective response rate (defined as the total number of CR and PR) in fusion-positive patients was 86% (12/14) versus 5% (1/20) in non-fusion patients. Similarly, PFS was 17.5 months (95% CI 7.4–NE) in fusion-positive patients versus 1.9 months (1.8–5.7; p = 0.0002) in non-fusion patients. Most commonly reported treatment-related adverse events included weight gain (n = 14 [5 Grade 3/4]), elevated creatinine (n = 13), anemia (n = 13), nausea (n = 11), increased ALT (n = 10 [1 Grade 3/4]), increased AST (n = 10 [1 Grade 3/4]), decreased neutrophils (n = 9 [6 Grade 3/4]), and bone fractures (n = 7, of which 4 were treatment related). **Conclusions:** In children and adolescents < 21 years old, entrectinib has produced striking, rapid, and durable responses in solid tumors with target gene fusions, especially in high-grade CNS neoplasms. Clinical trial information: NCT02650401. Research Sponsor: Hoffmann-La Roche.

FOENIX-CCA2: A phase II, open-label, multicenter study of futibatinib in patients (pts) with intrahepatic cholangiocarcinoma (iCCA) harboring *FGFR2* gene fusions or other rearrangements. *First Author: Lipika Goyal, Massachusetts General Hospital, Boston, MA*

Background: Patients (pts) with intrahepatic cholangiocarcinoma (iCCA) have a 5-year survival rate of 24%. There is no standard treatment for advanced disease after first-line chemotherapy. Fibroblast growth factor receptor-2 (*FGFR2*) gene fusions occur in 10% to 20% of pts with iCCA, offering a promising therapeutic avenue for this disease. Futibatinib is a highly selective irreversible FGFR1-4 inhibitor given as a continuous once-daily (QD) oral regimen. This phase 2 registrational trial was initiated because of results from a phase 1 dose escalation/expansion study showing tolerability and preliminary efficacy of futibatinib in pts with iCCA with *FGFR2* fusions. **Methods:** FOENIX-CCA2 (NCT02052778), a single-arm multicenter phase 2 study, enrolled pts with locally advanced/metastatic unresectable iCCA harboring *FGFR2* gene fusions or other rearrangements, disease progression after ≥1 line of systemic therapy (including gemcitabine plus platinum-based chemotherapy), no prior FGFR inhibitor treatment, and an ECOG performance status of 0 or 1. Pts received futibatinib 20 mg QD until disease progression/unacceptable toxicity. The primary endpoint is objective response rate (ORR) based on independent central radiology review. Secondary endpoints include disease control rate (DCR), duration of response (DOR), and safety. **Results:** A total of 103 pts were enrolled. For this interim analysis, data are reported for the 67 pts (65%) with ≥6 months of follow-up. Of these, 82.1% of pts had tumors harboring an *FGFR2* fusion. One, 2, or ≥3 prior therapies were received by 44.8%, 28.4%, and 26.9% of pts, respectively. ORR was 34.3% (all partial response, n = 23), and DCR was 76.1%; assessment was pending for 8 pts. Median time to response was 1.6 months (range, 1.0-4.9), and median DOR was 6.2 months (range, 2.1-14.2). The most common treatment-related adverse events (AEs; all grade, grade ≥3) were hyperphosphatemia (79.1%, 25.4%), diarrhea (37.3%, 0%), and dry mouth (32.8%, 0%). Any-cause grade ≥3 AEs were reported in 73.1% of pts. Dose delay or dose reduction was required in 65.7% and 53.7% of pts, respectively; 6.0% of pts discontinued treatment because of AEs. **Conclusions:** Preliminary assessment of these phase 2 data indicate efficacy and tolerability of futibatinib for treatment of pts with iCCA harboring *FGFR2* fusions or other rearrangements who have progressed after chemotherapy. Continued analysis of the study population is underway. Clinical trial information: NCT02052778. Research Sponsor: Taiho Oncology, Inc.

109 Clinical Science Symposium, Sun, 10:30 AM-12:00 PM

Clinical activity of the RET inhibitor pralsetinib (BLU-667) in patients with RET fusion+ solid tumors. *First Author: Vivek Subbiah, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: RET gene fusions are targetable oncogenic drivers in multiple tumor types, including up to 20% of papillary thyroid cancers (PTC). Pralsetinib is an investigational, highly potent, selective inhibitor of oncogenic RET alterations. In the registration-enabling Phase 1/2 ARROW study (NCT03037385), pralsetinib demonstrated an overall response rate (ORR; response-evaluable patients [REP], central review) of 73% (19/26) in treatment-naïve patients and 61% (49/80; 2 pending confirmation) in platinum-exposed patients with RET fusion+ non-small cell lung cancer (NSCLC) and was well tolerated (data cut-off November 18, 2019). We provide an update on the clinical activity of pralsetinib in other RET fusion+ solid tumor types. **Methods:** ARROW consists of a phase 1 dose escalation (30–600 mg once [QD] or twice daily) followed by a phase 2 expansion (400 mg QD) in patients with advanced RET-altered solid tumors. Primary objectives were ORR and safety. **Results:** As of November 18, 2019, 29 patients with metastatic solid tumor types other than NSCLC (16 PTC, 1 undifferentiated thyroid, 3 pancreatic, 3 colon, 6 other) bearing a RET fusion have received pralsetinib. Efficacy data are presented for REP enrolled by July 11, 2019. In patients with thyroid cancer that is RET fusion+, ORR (investigator assessment) was 75% (9/12; all confirmed). Median (range) duration of response (DOR) was 14.5 (3.7+, 16.8) months (mo), with 67% of responding patients continuing treatment. Two patients with stable disease were continuing treatment at 11.5+ and 19.3+ mo. In other RET fusion+ cancers, ORR was 60% (3/5; all confirmed) with partial responses in 2/2 patients with pancreatic cancer (DOR 5.5, 7.4+ mo) and 1 patient with intrahepatic bile duct carcinoma (DOR 7.5 mo). Two patients with colon cancer had stable disease for 7.3 and 9.3 mo. Responses were observed across multiple fusion genotypes. In the entire safety population (all patients treated with 400 mg QD pralsetinib, regardless of diagnosis; n = 354), most treatment-related adverse events (TRAEs) were grade 1-2, and included increased aspartate aminotransferase (31%), anemia (22%), increased alanine aminotransferase (21%), constipation (21%) and hypertension (20%). Only 4% of patients in the safety population discontinued due to TRAEs. **Conclusions:** Pralsetinib demonstrated broad and durable antitumor activity across multiple advanced solid tumor types, regardless of RET fusion genotype, and was well tolerated. The study is ongoing and still enrolling patients in this cohort. Clinical trial information: NCT03037385. Research Sponsor: Blueprint Medicines Inc.

Thoracic Cancers International COVID-19 Collaboration (TERAVOLT): Impact of type of cancer therapy and COVID therapy on survival. *First Author: Leora Horn, Department of Medicine, Vanderbilt Ingram Cancer Center, Nashville, TN*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 p.m. ET on Thursday, May 28.

500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Primary analysis of KAITLIN: A phase III study of trastuzumab emtansine (T-DM1) + pertuzumab versus trastuzumab + pertuzumab + taxane, after anthracyclines as adjuvant therapy for high-risk HER2-positive early breast cancer (EBC). *First Author: Nadia Harbeck, Brustzentrum der Universität München (LMU), Munich, Germany*

Background: The standard of care for HER2-positive EBC is chemotherapy plus one year of HER2-directed therapy. However, recurrence—particularly in high-risk populations—remains a problem, as does systemic chemotherapy-associated toxicity. In KAITLIN, we aimed to improve efficacy and reduce toxicity by replacing taxanes and trastuzumab with T-DM1. **Methods:** KAITLIN (NCT01966471) is a phase 3, randomized, open-label study that enrolled 1846 patients with adequately excised, centrally confirmed HER2-positive EBC either node-positive (LN+); or node-negative, HR-negative, and tumor size > 2.0 cm. Within 9 weeks of surgery, patients were randomized 1:1 to 3-4 cycles of anthracycline-based chemotherapy followed by 18 cycles of T-DM1 3.6 mg/kg + pertuzumab 420 mg q3w (loading dose [LD] 840 mg) (AC-KP) or taxane (3-4 cycles) + concurrent trastuzumab 6 mg/kg (LD 8 mg/kg) + pertuzumab 420 mg q3w (LD 840 mg) (AC-THP). Patients were stratified by world region, nodal status, HR status, and anthracycline type. Adjuvant radiotherapy and/or endocrine therapy was administered after 4 cycles of HER2-targeted therapy when indicated. The co-primary endpoints were invasive disease-free survival (IDFS) in the LN+ and in the ITT populations applying a hierarchical testing procedure. Secondary endpoints included overall survival (OS), patient-reported outcomes (PROs), and safety. **Results:** KAITLIN did not meet its co-primary endpoints. In LN+ patients (n = 1658), there was no significant difference between arms in IDFS event risk (stratified hazard ratio = 0.97; 95%CI 0.71–1.32). Three-year IDFS was 94.1% with AC-THP and 92.7% with AC-KP. Results were similar in the ITT population (stratified hazard ratio = 0.98; 95%CI 0.72–1.32; 3-year IDFS: 94.2% vs 93.1%). OS data are immature with an event rate of ~4%–5% in each arm. During the study overall, there was a similar incidence of grade ≥3 AEs (55.4% vs 51.8%) and SAEs (23.3% vs 21.4%) with AC-THP and AC-KP, respectively. More patients receiving AC-KP than AC-THP discontinued T-DM1 or trastuzumab, respectively, because of AEs (26.8% vs 4.0%). PRO data will be presented. **Conclusions:** Replacing adjuvant taxane and trastuzumab with T-DM1 did not result in significantly improved efficacy or overall safety. Nonetheless, in this high-risk population, a favorable IDFS outcome was achieved in both study arms. HP + chemotherapy remains the standard of care for patients with high-risk HER2-positive EBC. Clinical trial information: NCT01966471. Research Sponsor: F. Hoffmann-La Roche.

501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Three-year follow-up of neoadjuvant chemotherapy with or without anthracyclines in the presence of dual HER2-blockade for HER2-positive breast cancer (TRAIN-2): A randomized phase III trial. *First Author: Anna van der Voort, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The multicenter phase III TRAIN-2 study showed high pathological complete response (pCR) rates after neoadjuvant chemotherapy with and without anthracylines plus dual HER2-blockade in stage II-III HER2-positive breast cancer patients (67% vs 68%, p = 0.95) (NCT01996267). Here we report 3-year efficacy and safety outcomes. **Methods:** Patients were randomly assigned (1:1) to receive 3 cycles 5-fluoruoracil (500mg/m^2), epirubicin (90mg/m^2), and cyclophosphamide (500mg/m^2) followed by 6 cycles paclitaxel (80mg/m^2 day 1 and 8) and carboplatin (AUC = 6mg/ml·min) (FEC-PC) or 9 cycles paclitaxel and carboplatin (PC). Both regimens were combined with trastuzumab (T; 6mg/kg, loading dose 8mg/kg) and pertuzumab (Ptz; 420mg, loading dose 840mg). Patients completed one year of trastuzumab, radiotherapy and endocrine therapy as indicated. The primary endpoint pCR was previously reported. Secondary efficacy endpoints reported here are event-free-survival (EFS) defined as time from randomization to first event (disease progression resulting in inoperability, recurrence [contralateral DCIS excluded], secondary primary malignancies, or death) and overall survival (OS), both in the intention-to-treat population. Safety endpoints are reported for patients treated with at least one dose of study medication. **Results:** 438 patients were randomized (219/arm) and evaluable for long-term efficacy endpoints. After a median follow-up of 48.8 months 23 EFS events occurred in the FECT-PTC-Ptz-arm and 21 in the PTC-Ptz-arm (HR 0.90; 95% CI 0.50-1.63). Three-year EFS estimates were 92.7% (95% CI: 89.3-96.2) for FECT-PTC-Ptz and 93.6% (95% CI: 90.4-96.9) for PTC-Ptz. Three-year OS estimates were 97.7% (95% CI: 95.7-99.7) for FECT-PTC-Ptz and 98.2% (95% CI: 96.4-100) for PTC-Ptz. These results were irrespective of hormone receptor and nodal status. LVEF decline ≥10% from baseline and < 50% was more common in patients who received anthracyclines than in the PTC-Ptz arm (8.6% vs. 3.2%, p = 0.021). Two patients in the FECT-PTC-Ptz arm developed acute leukemia. No other new safety concerns were seen. **Conclusions:** The 3-year follow-up of the TRAIN-2 study confirms the results of the primary outcome that anthracylines do not improve efficacy and are associated with clinically relevant toxicity. A neoadjuvant carboplatin-taxane based regimen with dual HER2-blockade can be considered in all stage II-III breast cancer patients, regardless of hormone receptor and nodal status. Clinical trial information: NCT01996267. Research Sponsor: Roche.

502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Biomarker data from KATHERINE: A phase III study of adjuvant trastuzumab emtansine (T-DM1) versus trastuzumab (H) in patients with residual invasive disease after neoadjuvant therapy for HER2-positive breast cancer. *First Author: Carsten Denkert, Philipps University Marburg, Marburg, Germany*

Background: The phase 3 KATHERINE study (NCT01772472) compared adjuvant T-DM1 versus H in patients with residual invasive breast cancer after neoadjuvant chemotherapy plus HER2-targeted therapy. Here we report exploratory analyses of the relationship between invasive disease-free survival (IDFS) and biomarkers potentially related to response. **Methods:** Formalin fixed paraffin-embedded tissue samples were collected before neoadjuvant treatment and/or at surgery. Surgical samples were used for analyses, except when only pre-treatment samples were available (~20% of cases). DNA was derived to identify *PIK3CA* hotspot mutations and gene expression (RNA) analysis was used to detect HER2, PD-L1, CD8 and predefined immune signatures including 3-gene, 5-gene, Teffector, chemokine signaling, and checkpoint inhibitor signatures. RNA analysis was adjusted for tumor content and expression levels were dichotomized at the median into low (≤) and high (>) groups. The effect of treatment and biomarkers on IDFS was assessed. **Results:** *PIK3CA* mutation (mut) status was available from 1363 (91.7%) patients. T-DM1 IDFS benefit was independent of *PIK3CA* mut status (mut: HR 0.54; 95%CI 0.23–0.90; non-mut: HR 0.48; 95% CI 0.35–0.65) and no impact of *PIK3CA* mut was observed within either treatment arm. Gene expression data were available from 1059 (71.3%) patients. Similar gene expression levels were observed between treatment arms, but, unlike the surgical samples (n = 815), the pre-treatment samples (n = 244) were not representative of the ITT population. Thus, subsequent analyses were based on surgical samples (H n = 398; T-DM1 n = 417). Consistent treatment benefit with T-DM1 vs H was observed across the single-gene and immune gene-signature subgroups as in the ITT population. High vs low HER2 expression was associated with worse outcome (HR 2.02; 95% CI 1.32–3.11) within the H arm, but not within the T-DM1 arm (HR 1.01; 95% CI 0.56–1.83). High vs low PD-L1 expression was associated with better outcome within the H arm (HR 0.66; 95% CI 0.44–1.00) but not within the T-DM1 arm (HR 1.05; 95% CI 0.59–1.87). Similar trends were observed in the checkpoint inhibitor subgroups. **Conclusions:** These exploratory analyses provide the first data on the relationship between biomarker expression in residual disease after HER2-targeted therapy and outcomes. *PIK3CA* mut status did not influence outcomes with H or T-DM1. T-DM1 benefit appeared to be independent of all biomarkers assessed. Clinical trial information: NCT01772472. Research Sponsor: F. Hoffmann-La Roche Ltd.

503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Chemotherapy (CT) de-escalation using an FDG-PET/CT (F-PET) and pathological response-adapted strategy in HER2[+] early breast cancer (EBC): PHERGain Trial. *First Author: Javier Cortes, IOB Institute of Oncology, Hospital Quirónsalud, Medica Scientia Innovation Research, and Vall d'Hebron University of Oncology, Barcelona, Spain*

Background: Dual trastuzumab plus pertuzumab (HP) has shown promising pathologic complete response (pCR) rates in HER2[+] EBC although lower to CT regimens. Identification of new markers of sensitivity to HP could help to de-escalate CT. PHERGain assessed early metabolic response by F-PET to neoadjuvant HP and the opportunity of CT de-escalation with a response-adapted strategy in patients (pts) with HER2[+] EBC. **Methods:** PHERGain randomized (1:4 ratio) centrally-confirmed HER2[+] stage I-III EBC pts to receive either docetaxel (T), carboplatin (C), and HP (cohort A) or HP ± endocrine therapy (ET) (cohort B). Randomization was stratified by hormone receptor (HR) status. Pts with subclinical metastases by F-PET were included in a different cohort (cohort C). Centrally-reviewed F-PET was performed prior to randomization and after 2 cycles of TX (cohorts A/B). Cohort A pts completed a total of 6 cycles regardless of F-PET results. Cohort B/PET-responder (RX) pts continued with HP ± ET for 6 cycles, while PET-non-RX pts were switched to receive 6 cycles of TCHP. After surgery, cohort B/PET-RX pts who did not achieve a pCR received 6 cycles of TCHP and all pts from cohorts A/B completed 18 cycles of HP. Cohort C pts received 6 cycles of TCHP. Co-primary endpoints were breast/axilla pCR rate (ypT0/isN0) among cohort B/PET-RX pts and 3-year invasive disease-free survival (iDFS) in pts allocated to cohort B. **Results:** A total of 376 pts were included (71 pts in cohort A, 285 pts in cohort B, and 20 pts in cohort C). In cohort B, median age was 50 years, 49.2% had node-positive disease, and 67.4% had HR+ tumors. pCR in cohort A was achieved in 41 pts (57.7%, 95% CI 47.4-69.4%) and it was observed in 101 pts included in cohort B (35.4%, 95% CI 29.9-41.3%). Among cohort B pts, 227 (79.6%) were PET-RX; 86 of them (37.9%, 95% CI 31.6-44.5%) obtained a pCR. Among PET-non-RX pts, 15 (25.9%, 95% CI 15.3-39%) achieved a pCR after adding CT (TCHP). PET-RX pCR by HR status was 44.3% for HR[-] and 35% for HR[+] (p = 0.184). The incidence of commonly reported adverse events (AEs) was higher in pts allocated to cohort A (grade≥3 AEs 58.8 vs 12%; serious AEs 29.4 vs 4.6%). The rate of pts with a ≥10% global health status decline in cohorts A and B were 40.8 and 23.5%, respectively. **Conclusions:** F-PET identify pts with HER2[+] EBC who are more likely to benefit from CT-free dual HER2-blockade with HP. Follow-up is ongoing for iDFS endpoint. Depending on the results of this second co-primary endpoint, this strategy could select a group of HER2[+] EBC pts who would not need CT. Clinical trial information: NCT03161353. Research Sponsor: F. Hoffmann-La Roche Ltd.

504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

ALTERNATE: Neoadjuvant endocrine treatment (NET) approaches for clinical stage II or III estrogen receptor-positive HER2-negative breast cancer (ER+ HER2- BC) in postmenopausal (PM) women: Alliance A011106. *First Author: Cynthia X. Ma, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: For PM patients (pts) with locally advanced ER+ HER2- BC, NET improves breast conservation surgery (BCS) rates, and modified preoperative endocrine prognostic index (mPEPI) 0, defined as pT1-2 pN0 Ki67< 2.7%, or pathologic complete response (pCR: no invasive disease in breast or lymph node) is associated with low risk of recurrence without adjuvant chemotherapy (CT). The ALTERNATE trial was initiated to assess if the endocrine-sensitive disease rate (ESDR: number of mPEPI 0 pts/number of eligible pts initiating NET) with fulvestrant (F) or F+anastrozole (A) is improved relative to A alone (reported here) and if the 5-year (yr) recurrence-free survival (RFS) rate for pts with mPEPI 0 on A alone without CT is ≥ 95% (awaits further follow-up). **Methods:** PM pts with clinical stage II/III ER+ HER2- BC were randomized 1:1:1 to 1 mg A po daily, 500 mg F IM every 4 week (wk)s after loading dose, or A+F for 6 months. Ki67 was tested centrally on biopsies acquired prior to NET, wk 4, wk 12 and at surgery. Pts with Ki67 >10% at wk 4 or 12 were recommended to go off protocol-directed ET and switch to CT. Pts with mPEPI 0 at surgery were recommended to continue assigned ET for 1.5 yrs followed by A for a total of 5 yrs ET (and not to receive CT). The primary endpoint of the neoadjuvant phase was ESDR. ESDR of each F arm was compared to that of the A alone arm. With 425 pts per arm, a one-tailed alpha = 0.025 chi-square test of two independent proportions has 84% power to detect an increase of ≥10% in ESDR for F or F+A compared to the A arm, assuming ESDR ≤30% in A. **Results:** 1362 pts (A 452; F 454; A+F 456) were enrolled Feb 2014 to Nov 2018. 63 pts were excluded (did not start NET). Of the remaining 1299 pts (A 434; F 431, A+F 434), 42% were cN1-3 and 73% were considered candidates for BCS. ESDR was 18.6% (95%CI: 15.1-22.7%) with A, 22.7% (95%CI: 18.9-27.0%) with F, and 20.5% (95%CI: 16.8-24.6%) with A+F. No significant difference in ESDR was found between A and F (p=0.15) or A and A+F (p=0.55). Among the 825 pts with wk 4 Ki67 < 10% who completed NET and surgery, ESDR and the BCS rate were 27.7% and 70.3% with A; 29.6% and 68.1% with F, and 26.8% and 69.9% with A+F, respectively. **Conclusion:** Neither F nor F+A significantly improved ESDR compared to A alone in PM pts with locally advanced ER+ HER2- BC. RFS data are awaited. Support: U10CA180821, U10CA180882, U24CA196171, https://acknowledgments.alliancefound.org; NCI BIQSFP, BCRF, Genentech, AstraZeneca. Clinical trial information: NCT01953588. 505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Letrozole + ribociclib versus letrozole + placebo as neoadjuvant therapy for ER+ breast cancer (FELINE trial). *First Author: Qamar J. Khan, University of Kansas Medical Center, Westwood, KS*

Background: Ribociclib (R) + letrozole (L) is superior to L in metastatic breast cancer (BC). Preoperative endocrine prognostic index (PEPI) score 0 after neoadjuvant endocrine therapy (NET) is associated with low risk of relapse without chemotherapy in ER+ BC. On-therapy change in Ki-67 predicts adjuvant recurrence. FELINE is a biomarker-based multicenter randomized trial comparing changes in Ki-67 and PEPI between L+ Placebo (P) & L+R. **Methods:** Postmenopausal women with >2 cm or node+ ER+ HER2- BC were randomized 1:1:1 between L+P, L+R 400 mg continuous dose (Rc) and L+R 600 mg, 3 weeks on/1 week off - intermittent dose (Ri). Treatment was continued for six 28-day cycles. Core biopsies, blood samples were obtained at baseline, Day 14 cycle 1 (D14C1), and surgery. Clinical measurement, mammogram and US were obtained at baseline, surgery; MRI at baseline, week 8. Primary endpoint was rate of PEPI score 0 between L+P and L+R (i+c combined). Other endpoints were change in centrally performed Ki-67, complete cell cycle arrest (CCCA): Ki-67 <2.7%, clinical/imaging response, and difference in response & toxicity between the two R (Rc and Ri) arms. **Results:** From 2/2016 to 8/2018, 120 women were enrolled at 9 US centers. Thirty-eight were randomized to L+P and 82 to L+R groups (41 in Ri and Rc). Treatment groups were balanced at baseline. PEPI score of 0 was equal (25%) in L+P & L+R groups. CCCA at D14C1 was observed in 52% vs. 92% in L+P, L+R respectively ($p < 0.0001$). CCCA at surgery was observed in 63.3% vs. 71.4% in L+P, L+R respectively (p = NS). A significant increase in Ki-67 was observed between D14C1 and surgery in 66% vs. 33% in L+R, L+P respectively (p = 0.006). There was no difference in clinical, mammographic, US or MRI response between L+P and L+R. CCCA at D14C1 and surgery was similar in Ri & Rc arms. Grade >3 AEs were observed in 4 (10%) patients in L+P, 23 (56%) in L+Ri, 19 (46%) in L+Rc arms. **Conclusions:** Addition of R to L as NET did not result in more women with a PEPI score of 0. At D14C1 twice as many women on L+R had CCCA compared to L+P (92% vs 52%). However, significantly more women on L+R had increased proliferation between D14C1 and surgery, resulting in similar CCCA at surgery. Correlative studies are being performed to determine mechanisms of on-therapy acquired resistance to ribociclib. Continuous and intermittent doses of R have similar efficacy, toxicity. Clinical trial information: NCT02712723. Research Sponsor: Novartis.

	L+P	L+R	p-value
PEPI 0 (%)	25.8	25.4	0.96
D14C1-Ki-67 > 10% (%)	17.2	4.0	0.025*
CCCA at D14C1 (%)	51.7	91.9	< 0.0001*
CCCA at surgery (%)	63.3	71.4	0.42
Ki-67 increase D14C1 to surgery (%)	33.3	65.7	0.006*

506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

MINDACT: Long-term results of the large prospective trial testing the 70-gene signature MammaPrint as guidance for adjuvant chemotherapy in breast cancer patients. *First Author: Fatima Cardoso, Champalimaud Clinical Center/Champalimaud Foundation, Lisbon, Portugal*

Background: The 70-gene signature MammaPrint has been shown to identify breast cancer patients for whom adjuvant chemotherapy (CT) could be safely omitted even in the presence of unfavorable standard clinical-pathological criteria. The MINDACT primary endpoint at 5 years median follow-up was met in 2016 (Cardoso et al, NEJM 2016) with a distant metastasis free survival (DMFS) rate at 5 years of 94.7% (95% CI: 92.5-96.2) in clinical high (C-High) / genomic low (G-Low) risk patients who received no CT. Longer follow-up is now available. **Methods:** 6693 patients were enrolled in the prospective phase III randomized MINDACT study (EORTC 10041/BIG3-04) between 2007-2011. We assessed the DMFS rate at 5 years in the primary test (PT) population of C-High / G-Low patients who were randomized to receive no CT (n = 644). As secondary analysis, we evaluated DMFS and overall survival (OS) in the intention to treat (ITT) population of the C-High / G-Low group randomized to CT vs no CT (n = 749 and 748 respectively). Comparisons between CT and no CT groups are low-powered. We used Kaplan-Meier estimates for time to event endpoints and hazard ratios (HR) with 95% CI from cox-regression models adjusted for stratification factors used for the randomization. **Results:** The median follow-up is 8.7 years, resulting in an updated 5-year DMFS rate for the PT population of C-High / G-Low patients with no CT of 95.1% (95% CI 93.1-96.6). The updated outcomes of the ITT population of C-High / G-Low patients are shown in the table. Further analyses will update the suggested age-dependent effect of CT omission for luminal breast cancer seen at 5 years in pre- versus post-menopausal women as in Tailor-X (Piccart et al, SABCS 2019). **Conclusions:** The primary DMFS endpoint at 5 years continues to be met in CT untreated C-High / G-Low risk women, confirming MINDACT as a positive de-escalation study. With longer follow-up and in line with the natural history of luminal breast cancer, more distant relapses do occur but the estimated gain of 2.6% for CT administration in C-High / G-Low patients remains small in light of CT harmful effects. The level IA evidence for the clinical utility of the 70-gene signature for adjuvant CT decision making is maintained. Clinical trial information: NCT00433589. Research Sponsor: MINDACT was supported by grants from the European Commission Framework Programme VI (FP6-LSHC-CT-2004-503426, "TRANSBIG Network of Excellence"), the Breast Cancer Research Foundation, the U.S. National Cancer Institute, the European Breast Cancer Council-, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

C-High / G-Low patients (ITT population): updated outcomes		
	DMFS with CT	**DMFS without CT**
At 5 years (95% CI)	95.7% (93.9-96.9)	94.8% (92.9-96.2)
At 8 years (95% CI)	92.0% (89.6-93.8)	89.4% (86.8-91.5)
	OS with CT	OS without CT
At 8 years (95% CI)	95.7% (93.9-97.0)	94.3% (92.2-95.8)

507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase III trial of metronomic capecitabine maintenance after standard treatment in operable triple-negative breast cancer (SYSUCC-001). *First Author: XI Wang, Departments of Breast Oncology, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Triple-negative breast cancer (TNBC) has a relatively high relapse rate and poor outcome after standard therapy among all subtypes of breast cancer. Effective strategies to reduce risk of relapse and death are unmet medical needs. **Methods:** In this phase III trial, patients with operable TNBC were randomly assigned to receive metronomic capecitabine (650 mg/m^2 twice daily continuously for one year) as maintenance therapy or observation after standard local and systemic treatment for curative intent. The primary end point was disease-free survival (DFS). Secondary end points included distant disease-free survival (DDFS), overall survival (OS) and safety. **Results:** A total of 434 patients were randomly assigned to capecitabine group (n = 221) or observation group (n = 213). At a median follow-up of 56.5 months, 5-year DFS was significantly better in capecitabine group than in observation group (83% vs. 73%, HR, 0.63; 95% CI, 0.42 to 0.96; $p = 0.027$). 5-year DDFS was also significantly better in capecitabine group than in observation group (85% vs. 76%, HR, 0.56; 95% CI, 0.37 to 0.90; $p = 0.016$). However, 5-year OS was not significantly different between two groups (85% vs. 81%, HR, 0.74; 95% CI, 0.47 to 1.18; $p = 0.203$). Two hundred and two (91.4%) of patients completed one year of capecitabine therapy as planned. The most common capecitabine-related adverse events were hand-foot syndrome (46%), leukopenia (24%), Hyperbilirubinemia (13%), gastrointestinal pain (7%) and elevated serum transaminases (5%). **Conclusions:** Maintenance therapy with metronomic capecitabine for one year following standard treatment significantly improved DFS in operable TNBC, which was safe and well tolerated. (SYSUCC-001, ClinicaltTrials.gov number, NCT01112826). Clinical trial information: NCT01112826. Research Sponsor: the Sun Yat-sen University Clinical Research 5010 Program (Grant No. 2012014).

508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Primary results of NRG Oncology / NSABP B-43: Phase III trial comparing concurrent trastuzumab (T) and radiation therapy (RT) with RT alone for women with HER2-positive ductal carcinoma in situ (DCIS) after lumpectomy. *First Author: Melody A. Cobleigh, NRG Oncology, and Rush University Cancer Center, Chicago, PA*

Background: Preclinical studies report that T can boost RT effectiveness. The primary aim of this trial assessed the efficacy of concurrent T + RT vs RT alone in preventing recurrence of ipsilateral breast cancer, ipsilateral skin cancer, or ipsilateral DCIS (IBTR) in women with DCIS. **Methods:** Eligibility: Women ≥18 yrs, ECOG performance status 0 or 1, DCIS resected by lumpectomy, and clear margins. Whole-breast RT after randomization was with 25+ fractions or accelerated with 16-17 fractions. RT boost was allowed. Centralized HER2 testing and ER and/or PR were required before entry. Stratification was by menopausal status, adjuvant endocrine therapy plan, and nuclear grade. T was given at 8 mg/kg IV within 1 wk before and 5 days after RT began (Dose 1) and at 6 mg/kg IV 3 wks after Dose 1 (Dose 2). Definitive intent-to-treat primary analysis was to be conducted when either 163 IBTR events were recorded or when all accrued pts were on study for ≥5 yrs. **Results:** 2014 pts were randomized (11/9/08 to 12/8/14);1998 (99.2%) had follow-up information. Median follow-up time on 12/31/19 was 79.2 mos. 2001 pts had RT information, 1965 (98.2%) completed RT: 988 (98.3%) in the RT arm and 977 (98.1%) in the RT+T arm. 996 pts had T compliance information in the RT+T arm, 939 (94.3%) completed two doses of T, 25 (2.5%) had one dose of T, and 32 (3.2%) did not receive T. At primary definitive analysis, 114 IBTR events occurred: 63 in the RT arm and 51 in the RT+T arm (HR = 0.81 [95% CI: 0.56-1.17], p-value = 0.26). 38 were invasive: 18 in the RT arm and 20 in the RT+T arm (HR = 1.11 [95% CI: 0.59-2.10], p-value = 0.74). 76 were DCIS: 45 in the RT arm and 31 in the RT+T arm (HR = 0.68 [95% CI: 0.43-1.08], p-value = 0.10). Annual IBTR event rates were 0.99%/yr in the RT group and 0.80%/yr in the RT+T group. There were 288 events of any kind [iDFS-DCIS] (DFS): 155 in the RT arm and 133 in the RT+T arm (HR = 0.84 [95% CI: 0.66-1.05], p-value = 0.13) and 48 deaths: 26 in the RT arm and 22 in the RT+T arm (OS HR = 0.85 [95% CI: 0.48-1.51], p = 0.59). The study did not reach the 163 protocol-specified events, so the definitive analysis was triggered by all pts having been on study for ≥5 years. **Conclusions:** The addition of T to RT did not achieve the protocol objective of 36% reduction in the IBTR rate but did achieve a modest, statistically non-significant reduction of 19%. Support: U10-180868, -180822, UG1-189867; Genentech. The authors thank Elaina Harper and Marlon Jones for data management. Clinical trial information: NCT00769379. Immune phenotype and response to neoadjuvant systemic therapy (NAST) in triple negative breast cancer (TNBC). *First Author: Clinton Yam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In TNBC patients (pts) receiving NAST, increasing tumor infiltrating lymphocytes (TILs) is associated with higher pathologic complete response (pCR) rates. However, since the presence of TIL do not consistently predict pCR, the current study was undertaken to more fully characterize the immune cell response and its association with pCR. **Methods:** T cell receptor (TCR) sequencing, PD-L1 immunohistochemistry and multiplex immunofluorescence were performed on prospectively collected pre-NAST tumor samples from 98 pts with stage I-III TNBC enrolled in ARTEMIS (NCT: 02276443). TCR clonality was calculated using Shannon's entropy. PD-L1+ was defined as ≥1% immune cell staining. Response to NAST was defined using the residual cancer burden (RCB) index. Associations between TCR clonality, immune phenotype, and response were examined with the Wilcoxon rank sum test, Spearman's rank correlation and multivariable logistic regression using stepwise elimination (threshold $p > 0.2$), as appropriate. **Results:** The pCR rate was 39% (38/98). pCR was associated with higher TCR clonality (median = 0.2 [in pts with pCR] vs 0.1 [in pts with residual disease], p = 0.05). Notably, the association between pCR and higher TCR clonality was observed in pts with ≥5% TIL (n = 61; p = 0.05) but not in pts with < 5% TIL (n = 37; p = 0.87). Among pts with ≥5% TIL, TCR clonality emerged as the only independent predictor of response in a multivariable model of tumor immune characteristics (odds ratio/0.1 increase in TCR clonality: 3.0, p = 0.021). PD-L1+ status was associated with higher TCR clonality (median = 0.2 [in PD-L1+] vs 0.1 [in PD-L1-], p = 0.004). Higher TCR clonality was associated with higher CD3+ (rho = 0.32, p = 0.0018) and CD3+CD8+ (rho = 0.33, p = 0.0013) infiltration but lower expression of PD-1 on CD3+ (rho = -0.24, p = 0.021) and CD3+CD8+ cells (rho = -0.21, p = 0.037). **Conclusions:** In TNBC, a more clonal T cell population is associated with an immunologically active microenvironment (higher CD3+ and CD3/8+ T cell; lower PD-1+CD3+ and PD-1+CD3/8+ T cell; PD-L1+) and favorable response to NAST, especially in pts with ≥5% TIL, suggesting a role for deep immune phenotyping in further refining the predictive value of TILs. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology, MD Anderson Breast Cancer Moonshot Program.

Role of intratumoral NK cells in triple-negative breast cancer in the FinXX trial and Mayo Clinic cohort. *First Author: Saranya Chumsri, Mayo Clinic, Jacksonville, FL*

Background: Several studies have established the critical role of preexisting immune response in triple negative breast cancer (TNBC). Most studies evaluated the tumor infiltrating lymphocytes in stroma. However, limited data are available with regards to the importance of specific subtypes and spatial distribution of these immune infiltrates. **Methods:** NanoString IO360 gene expression analysis and Digital Spatial Profiling (DSP) were used. DSP was used to quantify 39 immune-related proteins in stromal and tumor-enriched segments from 44 TNBC samples from the FinXX trial (NCT00114816) and 335 samples from the Mayo Clinic (MC) cohort of centrally reviewed TNBC (Leon-Ferre BCRT 2018). In FinXX trial, 22 patients with recurrence and 22 patients without recurrence were included. In MC cohort, 217/335 patients received adjuvant chemotherapy while 118 patients had surgery only without adjuvant chemotherapy. Regions were segmented based on pancytokeratin staining. The general linear model was used for statistical analysis of differential expression with recurrence free survival (RFS) as a categorical variable (recur yes or no). Kaplan-Meier estimates and Cox regression models were also used for analysis. **Results:** In the FinXX trial, using global gene expression analysis with IO360, there was no signature significantly associated with RFS. However, using DSP, high protein expression of CD56 in the tumor-enriched segments was associated with significant improvement in RFS (HR 0.26, 95%CI 0.09-0.78, p 0.01). Nevertheless, CD56 expression in the stroma (HR 0.66, 95%CI 0.29-1.53, p 0.33) and all segments (HR 0.53, 95%CI 0.23-1.25, p 0.14) was not significantly associated with improved outcome. We further validated these findings in the MC TNBC cohort where intratumoral CD56 expression was associated with a significant improvement in RFS (HR 0.23, p 0.002) but not stromal CD56 (p 0.79). Interestingly, when evaluating the MC TNBC cohort according to receipt of chemotherapy, intratumoral CD56 was associated with improved outcome only in patients who received chemotherapy (p 0.02 vs. 0.07). In both cohorts, higher expressions of intratumoral PD-L1, HLA-DR, and CD8 were associated with improved outcome. **Conclusions:** Using an in-depth analysis with spatially defined context, we identify that intratumoral CD56-positive NK cells are associated with improved outcome in TNBC. Our study highlights the potential role of NK cells in TNBC and future implications for biomarkers and therapeutic targets.Support: W81XWH-15-1-0292, P50CA116201-9, P50CA015083. Association of T- and B-cell receptor repertoires with molecular subtypes and outcome in HER2+ breast cancer: An analysis of the NeoALTTO clinical trial. *First Author: Mattia Rediti, Breast Cancer Translational Research Laboratory J.-C. Heuson, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium*

Background: Clinicopathological and molecular features, including estrogen receptor (ER) status and PAM50 subtypes, have shown an association with immunogenicity and tumor-infiltrating lymphocyte (TIL) levels in breast cancer (BC). To investigate the complexity of the immune response in HER2+ BC, we explored the association of T- and B-cell receptor (TCR and BCR) repertoires with clinicopathological characteristics, PAM50 subtypes and outcome in the NeoALTTO phase III trial. **Methods:** RNA sequencing (RNAseq) data from baseline tumor biopsies were available for 254 out of the 455 patients enrolled. TCR and BCR repertoires were extracted from RNAseq data using the MiXCR software. Repertoire and diversity measures (read counts, number of clones, evenness, Gini index, Shannon entropy, length of the complementarity-determining region 3 [CDR3], top and second top clone proportions) were estimated. PAM50 subtypes were computed from RNAseq data. Univariate and multivariate (adjusted for clinicopathological characteristics, TIL levels dichotomized using the median value of 12.5% and treatment arm) Cox proportional hazard models were used for survival analysis, while logistic regressions were used for pathological complete response (pCR), defined as ypT0/is. All results reported had a false discovery rate (FDR) <0.05. **Results:** Higher BCR read counts, number of clones and Gini index were significantly associated with ER-negative as well as grade 3 tumors. Among the PAM50 subtypes, HER2-enriched (HER2-E) showed significantly higher BCR read counts, number of clones and Gini index along with lower evenness compared to luminal A and B, as well as higher length of CDR3 than luminal A. Of note, basal-like showed similar BCR diversity measures to HER2-E. No significant differences were noted for TCR diversity measures. In multivariate analyses, neither TCR nor BCR features were associated with pCR, while BCR evenness (HR 1.5; 95%CI 1.1-2.1) and Gini index (HR 0.66; 95%CI 0.5-0.88) were associated with event-free survival. **Conclusions:** BCR repertoire measures suggest a clonal expansion in HER2-E and basal-like PAM50 subtypes. Furthermore, the implementation of BCR-derived biomarkers can help to identify patients with an improved clinical outcome after neoadjuvant anti-HER2 treatment. Our findings highlight the heterogeneity of the immune response within HER2+ BC and provide support for biomarker-driven treatment strategies including immunotherapy in this BC subtype. Further validation is required. Clinical trial information: NCT00553358. Research Sponsor: NeoALTTO study was funded by GSK and later Novartis. The RNA sequencing on which the analyses described in this abstract are based was funded by GSK., Other Foundation.

Breast cancer index (BCI) predicts benefit of two-and-a-half versus five years of extended endocrine therapy in HR+ breast cancer patients treated in the ideal trial. *First Author: Gerrit-Jan Liefers, Leiden University Medical Center, Leiden, Netherlands*

Background: For postmenopausal women with hormone receptor positive (HR+) breast cancer, the optimal duration of extended endocrine therapy (EET), after completing 5 years of initial aromatase inhibitor (AI)–based adjuvant therapy, remains unclear. BCI [HOXB13/IL17BR (H/I)] is a gene expression-based biomarker that has been demonstrated to predict EET benefit in the MA.17 and Trans-aTTom studies in patients treated with adjuvant tamoxifen. The current study examined the ability of BCI (H/I) to predict endocrine benefit from 2.5 vs. 5 years of extended letrozole in the IDEAL trial. **Methods:** All patients with available tumor specimens were eligible for this blinded prospective-retrospective study. The primary endpoint was Recurrence-Free Interval (RFI). Median follow-up was 9.1 years from randomization. Kaplan-Meier and Cox proportional hazards regression analysis were used to analyze the differential benefit of EET with statistical significance of the interaction between BCI (H/I) and treatment assessed by likelihood ratio test. **Results:** 908 HR+ patients (73% pN+, median 59y, 45% pT1, 48% pT2, disease free at 2.5 years) were included, with 88% and 68% receiving prior treatment with an AI or chemotherapy, respectively. BCI by H/I status (High vs. Low) was significantly predictive of response from extended letrozole in the overall (N = 908) and pN+ (N = 664) cohorts. Notably, BCI (H/I) predicted EET benefit in patients that received any primary adjuvant therapy with an AI (N = 794). Treatment to biomarker interaction was significant in the overall (p = 0.045), pN+ (p = 0.029) and any prior AI (p = 0.025) cohorts, adjusted for age, pT stage, grade, nodal status, prior endocrine therapy and prior chemotherapy. **Conclusions:** Novel findings from this study demonstrate that BCI predicts endocrine benefit from extended letrozole in postmenopausal patients treated with primary adjuvant AI. These results support the growing body of evidence that BCI by H/I status predicts preferential endocrine response in distinct subgroups of patients, and further support its role as an important genomic tool to inform the risk-benefit regarding duration of extended endocrine therapy. Clinical trial information: NTR3077, BOOG 2006-05, Eudra-CT 2006-003958-16. Research Sponsor: Biotheranostics, Inc.

Validation of MAF biomarker for response prediction to adjuvant bisphosphonates in 2 clinical trials: AZURE and NSABP-B34. *First Author: Alexander H. G. Paterson, Tom Baker Cancer Center, Calgary, AB, Canada*

Background: An Early Breast Cancer Trialists' Collaborative Group (EBCTCG) meta-analysis indicates that adjuvant bisphosphonates increase time to bone recurrence and survival in postmenopausal breast cancer patients, but results of individual trials have been inconclusive. Retrospective analyses of AZURE, a trial of adjuvant zoledronic acid, showed MAF (a transcription factor of the AP-1 family) amplification status predicted bisphosphonate benefit independently of menopause for invasive disease-free survival (IDFS) and overall survival (OS). Validation of MAF amplification status as a potential companion diagnostic for adjuvant bisphosphonates was confirmed using NSABP-B34 specimens. **Methods:** The randomized, placebo-controlled NSABP B-34 study of women with stage 1-3 breast cancer were assigned to adjuvant systemic therapy plus oral clodronate 1600 mg daily or placebo for 3 years. The primary endpoint was disease-free survival (DFS) with overall survival (OS) as a secondary outcome. MAF amplification was assessed by fluorescence in-situ hybridization on anonymized sections of breast tumor tissue in all patients with tumor samples and performed in a laboratory blind to treatment assignment. Protocol and analysis plans were pre-specified. Disease outcomes were analysed using intention to treat principles. **Results:** 2496 B-34 patients contributed tumor samples (from 2001-2004), of whom 1883 (75%) were evaluable (947 placebo and 936 clodronate). 1515 (80%) tumors were MAF negative (766 placebo and 749 clodronate) and 368 were MAF positive. At median follow-up of 108 months, MAF was prognostic for DFS, OS and bone-metastasis-free survival in the control group (MAF-positive vs MAF-negative: HRDFS=1·39, 95%CI 1·01-1·92; p=0.045; HROS=1·59, 95%CI 1·08-2·33; p=0.018; HRBM=2·03, 95%CI 1·13-3·68; p=0.016). In patients with MAF-negative tumors, clodronate gave higher DFS and OS than controls at 60 months (HRDFS=0·70, 95%CI 0·51-0·94; p=0.020 and HROS=0·59, 95%CI 0·37-0·93; p=0.024), the latter maintained through follow-up (HROS=0·74, 95%CI 0·54-1.00; p=0.047), but not in patients with MAF-positive tumors - consistent with previous AZURE results. **Conclusions:** MAF benefit prediction from adjuvant bisphosphonates was confirmed using specimens from 2 randomized clinical trials (AZURE and NSABP-B-34) conducted and analyzed in similar manner using the same validated tests and clinical endpoints. These results are evidence towards introducing MAF testing into clinical practice. Research Sponsor: Inbiomotion, NSABP.

Response to neoadjuvant chemotherapy and the 21-gene breast recurrence score in young women with estrogen receptor-positive early breast cancer. *First Author: Tal Sella, 450 Brookline Ave, Boston, MA*

Background: The *21-gene Breast Recurrence Score* predicts benefit from adjuvant chemotherapy in estrogen receptor positive (ER+), HER-2 negative (-) breast cancer (BC). We aimed to examine whether the 21-gene assay predicts response to neoadjuvant chemotherapy (NAC). **Methods:** We identified patients with stage I-III ER+/HER2− BC treated with NAC from the Young Women's Breast Cancer Study, a prospective cohort of women diagnosed with BC at age ≤ 40 years. The 21-gene assay was performed on tumor specimens removed prior to NAC either as part of clinical care or retrospectively for research. Pathologic complete response (pCR) was defined as no residual invasive tumor (ypT0/is ypN0). The relationship between Recurrence Score result (RS) and pCR was evaluated using logistic regression modeling. **Results:** 76 women in the cohort had undergone NAC for ER+, HER2- BC and were eligible for this analysis: 5 had undergone clinical 21-gene assay testing, 71 had banked specimens retrospectively tested. Median age at diagnosis was 36.7 (24.3-40). Most tumors were of ductal histology (78%), high grade (51%), progesterone receptor (PgR) positive (86%), ≥T2 (88%), clinically node positive (74%), and anthracycline and taxane containing protocols were administered in 86% of cases. RS ranged between 5-75 with 50% > 25 and only 4 < 11. Mean RS was significantly higher among tumors achieving pCR vs. non-pCR response (51.9 vs. 26.6, $p_{wilcoxon}$= 0.0005). pCR rate in patients with RS > 25 was 21% (8/38) vs. 5% in patients with RS < 25 (2/38), with both pCRs in the <25 group in patients with RS 21-25. In univariable analysis, PgR negativity (odds ratio (OR) 5.62, 95% confidence interval (CI) 1.27-24.89, p = 0.02), high grade (OR 9.03, 95%CI 1.07-76.32, p = 0.04) and higher RS as a continuous variable (OR 1.08, 95%CI 1.04-1.13, p = 0.0003) were associated with a greater likelihood of pCR. In multivariable analysis only RS remained significantly associated with pCR (OR: 1.07, 95%CI 1.01-1.12, p = 0.01): a 7% increase in the odds of pCR for every 1-point increase in RS. **Conclusions:** In young women with ER+, HER2- BC who received NAC, higher pretreatment RS was associated with an increased likelihood of pCR. Genomic expression profiling assays may have a role in decision-making in young women in need of neoadjuvant therapy. For women with low likelihood of benefiting from NAC, alternative approaches are clearly warranted. Given the demonstrated efficacy of neoadjuvant endocrine therapy in post-menopausal women, further evaluation in young women should be pursued. De-escalated chemotherapy versus endocrine therapy plus pertuzumab+ trastuzumab for HR+/HER2+ early breast cancer (BC): First efficacy results from the neoadjuvant WSG-TP-II study. *First Author: Oleg Gluz, Breast Center Niederrhein, University Clinics Cologne and West German Study Group, Moenchengladbach, Germany*

Background: HR+/HER2+ breast cancer (BC) is a distinct entity associated with better prognosis compared to HR-/HER2+ BC. However, combination of chemotherapy (CT) with (dual) anti-HER2 blockade is standard in HER2+ early BC (EBC), irrespective of HR-status. Despite of some promising data on combination of endocrine therapy (ET) with dual anti-HER2 blockade in EBC and metastatic HR+/HER2+ BC, no prospective comparison of neoadjuvant CT vs. ET + dual HER2-blockade has yet been performed. **Methods:** In the prospective WSG TP-II phase II-trial (NCT03272477; Sponsor: Palleos GmbH, Wiesbaden, Germany), 207 patients (pts) (257 screened; 40 centers) with centrally confirmed HR+/HER2+ EBC were randomized to 12 weeks of standard ET (n=100) vs. paclitaxel 80 mg/m^2 weekly (n=107) +trastuzumab+pertuzumab q3w for all pts. Primary endpoint was pCR (ypT0/is/ypN0). Secondary endpoints include safety, disease-free and overall survival, translational research, and quality of life (QoL). Omission of further CT was allowed in all pts with pCR; dual HER2-blockade was administered in the adjuvant setting in all pts. **Results:** Baseline characteristics were well balanced between the arms. Median age was 53 years; 58% had cT2-4, 28% had cN+; 43% had G3 tumors. pCR data were available in 198 pts (ET: n=96; Pac: n=102). pCR was observed in 24% (95% CI: 16-34%) with ET+T+P vs. 57% (95% CI: 47-67%) with Pac+T+P (OR 0.24, 95% CI: 0-0.46, p<0.001). In multivariable logistic regression analysis and corresponding sensitivity analysis (bootstrap/subsample inclusion frequencies and lasso regression) including study arm, BMI, menopausal, cT, and cN status, histological grade, HER2-status, Ki67, ER, PR as continuous variables, only study arm and HER2 3+ status were significantly associated with pCR. Neoadjuvant treatment was well tolerated in both study arms and completed per protocol in 93/92 (ET+P+T/Pac+P+T) patients. Only 9/13 SAEs (ET+P+T/Pac+P+T) were reported during neoadjuvant therapy. PAM50 and QoL analysis are ongoing. **Conclusions:** WSG TP-II is the first randomized prospective trial comparing two neoadjuvant de-escalation treatments in HR+/HER2+ EBC. The excellent pCR rate of 57% after only 12 weeks of Pac+P+T was clearly superior to the still promising 24% pCR rate in pts treated by ET+P+T. In both arms, treatment efficacy was most pronounced in HER2 3+ tumors. Survival results need to be awaited before definite recommendations for a de-escalated regimen in HR+/HER2+ EBC can be made. Clinical trial information: 2016-005157-21. Research Sponsor: Roche.

GAIN-2: Neo-/adjuvant phase III trial to compare intense dose-dense chemotherapy (CT) to tailored dose-dense CT in patients (pts) with high risk early breast cancer (EBC): Results on safety and interim invasive disease-free survival (iDFS). *First Author: Volker Moebus, Internal Medicine II, Dept. of Hematology & Oncology University of Frankfurt, Frankfurt, Germany*

Background: GAIN-2 (NCT01690702) compared efficacy and safety of intense, dose-dense epirubicin, nab-paclitaxel, and cyclophosphamide (iddEnPC) vs dose-dense, dose-tailored epirubicin/ cyclophosphamide followed by dose-dense, dose-tailored docetaxel (dtEC-dtD) as adjuvant or neoadjuvant CT for node-positive or high risk node-negative EBC. Here, we report safety results and interim analysis (IA) of the primary endpoint iDFS. **Methods:** Pts (luminal A ≥N2; luminal B N+; HER2+ and TNBC) were randomized between iddEnPC (E 150 mg/m2, nP 330 mg/m2, C 2000 mg/m2, all q2w x 3) or dtEC-dtD (dtEC q2w x 4 followed after 1 week rest by dtD q2w x 4). Primary objective was to compare iDFS. 797 events are needed to detect a hazard ratio of 0.819 with a 2-sided log-rank-test with 80% power and α=0.05. The IA of iDFS was planned after 50% of the events have occurred. Safety and compliance were secondary objectives. **Results:** Between 10/2012 and 09/2018, 2887 pts were randomized and 2857 started treatment (iddEnPC 1429; dtEC-dtD 1428). Median age was 51 (range 18-75) years. Overall, 18.1% were luminal A, 31.5% luminal B/HER2-, 18.8% hormone-receptor (HR)+/HER2+, 8.5% HR-/HER2+ and 23.2% TNBC. Overall, 88.1% of pts completed all treatment in both arms. 66.8% with iddEnPC vs 58.8% with dtEC-dtD delayed CT dose ($p<0.001$). Grade 3-4 non-hematological adverse events (AEs) were more frequent with iddEnPC (iddEnPC 50.8% vs dtEC-dtD 45.1%, p=0.002). Grade 3-4 leukopenia, neutropenia, febrile neutropenia, arthralgia, and peripheral sensory neuropathy were significantly higher with iddEnPC. There were 1464 serious AEs (iddEnPC 870 vs dtEC-dtD 594) and 26 (9 vs 17) predefined AEs of special interest (anaphylaxis, any AE affecting cranial nerves, macula edema). Two deaths occurred during dtEC-dtD. After a median follow-up of 45.8 months, there was no difference in iDFS between arms (log-rank p=0.9102, hazard ratio iddEnPC vs dtEC-dtD 1.01, 95% CI 0.83-1.23). **Conclusions:** No new safety concerns were observed. Use of both iddEnPC and dtEC-dtD appears feasible in the (neo)adjuvant treatment of high risk EBC. Clinical trial information: NCT01690702. Research Sponsor: None.

Comprehensive profiling of androgen receptor-positive (AR+) triple-negative breast cancer (TNBC) patients (pts) treated with standard neoadjuvant therapy (NAT) +/- enzalutamide. *First Author: Bora Lim, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The luminal androgen receptor (LAR) subtype of TNBC has a low pathologic complete response (pCR) rate after NAT. We determined the pCR rate of the enzalutamide and paclitaxel (ZT) regimen for pts with anthracycline-insensitive AR^+ TNBC (NCT02689427), and related biomarkers. **Methods:** ARTEMIS (NCT02276443) is a non-randomized trial to determine if NAT can be used to personalized therapy. Pts received 4 cycles of doxorubicin-based NAT (AC). Pts with insensitive disease by imaging were offered clinical trials as the second phase of NAT based upon molecular profiling of pre-treatment biopsies. Immunohistochemistry (IHC) of $AR^+ \geq 10\%$ was the threshold for selecting ZT (enzalutamide 160 or 120 mg PO qD + paclitaxel 80 mg/m^2 qW for 12 cycles). pCR was determined by surgery after NAT. Trial had two-stage Phase II design, and we report the completed first stage. We evaluated the concordance between Vanderbilt LAR subtype by molecular profiling (microarray and RNAseq) and IHC %AR^+ cells. Frequency of PI3K pathway alterations within the LAR subtype was assessed. **Results:** 267 pts had tumors profiled by IHC, 220 by microarray, 187 by RNAseq and 197 by whole exome sequencing. 96 pts had post-AC RNAseq. LAR scores from both RNAseq and microarray profiling (n = 139) were highly concordant (R = 0.89, $P < 0.001$) and identified ~10% of TNBCs tested as LAR. The %AR^+ cells from IHC correlated with LAR subtype scores according to RNAseq (R = 0.6, $P < 0.001$), with a cut-point of $\geq$30% AR^+ having the best concordance with LAR subtype. Unlike other subtypes, by serial profiling, LAR TNBCs did not change subtype signatures after exposure to AC. LAR TNBCs had low rates of pCR (23%) and high rates of PI3K pathway activating aberrations (85%); however PI3K aberrations did not correlate with pCR. Seventeen patients with AC-insensitive TNBC received ZT. Five of 15 patients (33.3%) had responses (pCR or RCB-I). Toxicities are Grade (Gr) 4 syncope (n = 1), Gr3 abnormal liver function (n = 2), Gr3 neutropenia (n = 4). IHC & LAR subtype scores did not statistically associate with response to ZT (P = 0.8, P = 0.9). However, all responders to ZT had an upregulated androgen response pathway (ssGSEA $Z > 1$) as measured by transcriptomic analysis in pre-treatment biopsies analysis (P = 0.05, ppv = 0.56, npv = 1). **Conclusions:** The LAR TNBC subtype has a low pCR rate to NAT. Among pts with AC-insensitive TNBC, baseline upregulated androgen response pathway and LAR subtype may benefit from the ZT regimen, potentially by PI3K targeting. Clinical trial information: NCT02689427. Research Sponsor: Pfizer, MD Anderson Cancer Center.

Defining the mutational landscape of 3,217 primary breast cancer transcriptomes through large-scale RNA-seq within the Sweden Cancerome Analysis Network: Breast Project (SCAN-B; NCT03430492). *First Author: Christian Brueffer, Lund University, Division of Oncology, Lund, Sweden*

Background: Breast cancer is a disease of genomic alterations, of which the complete panorama of somatic mutations and how these relate to molecular subtypes and therapy response is incompletely understood. The Sweden Cancerome Analysis Network-Breast project (SCAN-B; ClinicalTrials.gov NCT02306096) is a multi-center population-based ongoing prospective observational study elucidating the global transcriptomic profiles for thousands of patients and tumors using RNA sequencing. Since September 2010, over 15,000 patients with breast cancer have been enrolled at 9 hospitals across a wide geography of Sweden, comprising greater than 90% of all eligible patients in the catchment area. **Methods:** Within SCAN-B, we developed an optimized bioinformatics pipeline for detection of single nucleotide variants and small insertions and deletions from RNA-seq data. From this, we describe the mutational landscape of 3,217 primary breast cancer transcriptomes, and relate it to patient overall survival in a real-world setting (median follow-up 75 months, range 2-105 months). **Results:** We demonstrate that RNA-seq can be used to call mutations in important breast cancer genes such as PIK3CA, TP53, ESR1, and ERBB2, as well as mutation status of key molecular pathways and tumor mutational burden, identify mutations in one or more potentially druggable genes in 85.3% percent of cases, and reveal significant relationships to patient outcome within specific treatment groups. To make this rich and growing mutational portraiture of breast cancer available for the wider research community, we developed an open source interactive web application, SCAN-B MutationExplorer, publicly accessible at http://oncogenomics.bmc.lu.se/MutationExplorer. **Conclusions:** These results add another dimension to the use of RNA-seq as a potential clinical tool, where both gene expression-based signatures and gene mutation-based biomarkers can be interrogated simultaneously and in real-time within one week of tumor sampling. Ipsilateral invasive cancer risk after diagnosis with ductal carcinoma in situ (DCIS): Comparison of patients with and without index surgery. *First Author: Marc D Ryser, Duke University School of Medicine, Durham, NC*

Background: Most women diagnosed with ductal carcinoma in situ (DCIS) undergo surgical resection, potentially leading to overtreatment of patients who would not develop clinically significant breast cancer in the absence of locoregional treatment. We compared the risk of ipsilateral invasive breast cancer (iIBC) between DCIS patients who received breast conserving surgery (BCS) for their index diagnosis of DCIS (BCS group) and patients who did not receive any locoregional treatment within 6 months of diagnosis (surveillance [SV] group). **Methods:** A treatment-stratified random sample of patients diagnosed with screen-detected and biopsy-confirmed DCIS in 2008-14 was selected from 1,330 Commission on Cancer-accredited facilities (20/site). Excluding patients who received a mastectomy ≤6 months, the final analytic cohort contained 14,245 (88.2%) BCS and 1,914 (11.8%) SV patients. Subsequent breast events were abstracted up to 10 years after diagnosis. Primary outcome was the 8-year absolute difference in iIBC risk between BCS and SV; a subgroup analysis was performed for grade I/II patients. A propensity score (PS) model for treatment was fitted with sampling design (SD) weighting and random effects for patients within facilities. Absolute risk differences were estimated using PS-SD-weighted Kaplan Meier estimators. **Results:** Overall, median age at diagnosis was 61 years (IQR: 52-69) and median follow-up was 5.8 years (95% CI 5.7-6.1). The majority of patients were Caucasian (81.9%), with estrogen receptor-positive (80.6%), and nuclear grade I/II (54.5%) DCIS. The fraction of patients with a Charlson comorbidity score of ≥2 was higher in SV (14.2%) compared to BCS (6.4%, $p < 0.001$). The 8-year risk of iIBC was 3.0% (95% CI: 2.4%-3.6%) for BCS and 7.7% (95% CI: 4.9%-10.5%) for SV, with an absolute risk difference of 4.7% (95% CI: 4.5%-4.9%; log-rank $p < 0.001$). Among patients with grade I/II tumors, the 8-year risk of iIBC was 3.1% (95% CI: 2.3%-4.0%) for BCS and 6.1% (95% CI: 2.5%-9.8%) for SV; difference: 3.0% (95% CI: 2.7%-3.2%; p = 0.005). **Conclusions:** Despite an increased risk of iIBC in SV patients compared to BCS patients, the 8-year risk did not exceed 10% in either group. The risk of recurrence in BCS patients was comparable to previously reported estimates. These data demonstrate a considerable degree of overtreatment among patients with non-high grade DCIS. Prospective clinical trials will help determine the tradeoffs between universally directed as opposed to selectively applied surgery for low risk DCIS. Research Sponsor: PCORI/PCS-1505-30497.

Towards data-driven decision-making for breast cancer patients undergoing mastectomy and reconstruction: Prediction of individual patient-reported outcomes at two-year follow-up using machine learning. *First Author: André Pfob, PROVE Center, Harvard Medical School & Brigham and Women's Hospital, Boston, MA*

Background: Post-surgical satisfaction with breasts is a key outcome for women undergoing cancer-related mastectomy and reconstruction. Current decision making relies on group-level evidence, which may not offer optimal choice of treatment for individuals. We developed and validated machine learning algorithms to predict individual post-surgical breast-satisfaction. We aim to facilitate individualized data-driven decision making in breast cancer. **Methods:** We collected clinical, perioperative, and patient-reported data from 3058 women who underwent breast reconstruction due to breast cancer across 11 sites in North America. We trained and evaluated four algorithms (regularized regression, Support Vector Machine, Neural Network, Regression Tree) to predict significant changes in satisfaction with breasts at 2-year follow up using the validated BREAST-Q measure. Accuracy and area under the receiver operating characteristics curve (AUC) were used to determine algorithm performance in the test sample. **Results:** Machine learning algorithms were able to accurately predict changes in women's satisfaction with breasts (see table). Baseline satisfaction with breasts was the most informative predictor of outcome, followed by radiation during or after reconstruction, nipple-sparing and mixed mastectomy, implant-based reconstruction, chemotherapy, unilateral mastectomy, lower psychological well-being, and obesity. **Conclusions:** We reveal the crucial role of patient-reported outcomes in determining post-operative outcomes and that Machine Learning algorithms are suitable to identify individuals who might benefit from alternative treatment decisions than suggested by group-level evidence. We provide a web-based tool for individuals considering mastectomy and reconstruction. importdemo.com. Clinical trial information: NCT01723423. Research Sponsor: U.S. National Institutes of Health.

Evaluation of algorithms trained to predict significant changes compared to baseline in satisfaction with breasts at two-year follow up.

		Satisfaction lower than baseline	Satisfaction greater than baseline
Regularized Regression	Accuracy	.90	.83
	(95%CI)	(.86 – .92)	(.79 – .86)
	AUC	.87	.78
	(95%CI)	(.83 – .91)	(.73 – .83)

Dementia risk among post-menopausal women treated with endocrine therapy for early-stage breast cancer in Ontario, Canada. *First Author: Phillip S. Blanchette, London Regional Cancer Program, Western University, London, ON, Canada*

Background: The association between anti-estrogen therapy and risk of dementia remains controversial. We performed a population-based real-world study investigating the association between endocrine therapy use and dementia. **Methods:** We used health administrative data collected from post-menopausal women (aged ≥66 years) who were diagnosed with breast cancer and started on adjuvant endocrine therapy from 2005-2012. Patients were classified by use of either an aromatase inhibitor or tamoxifen and followed to measure an unadjusted cumulative incidence of developing dementia. A multivariable analysis adjusting for age, income quintile, medical comorbidities, and duration of endocrine therapy was completed using a Cox-proportional hazards model. **Results:** We identified 12,077 patients of whom 73% were treated with an aromatase inhibitor and 27% with tamoxifen. The median age was 73 years (IQR 69-78), 64% of patients were treated with lumpectomy, and 19% received adjuvant chemotherapy. The unadjusted event rate for developing dementia was Hazard Ratio (HR)= 0.70 (95% confidence interval (CI)=0.63-0.78, p-value<0.0001) among patients receiving an aromatase inhibitor versus tamoxifen and the 5-year dementia incidence rate was 7.4% versus 9.2% respectively. Our multivariable analysis showed a significant decrease in the rate of dementia in patients treated with an aromatase inhibitor compared to tamoxifen (HR=0.88, 95% CI 0.78-0.98, p-value=0.02) with a median of 5.9 years of follow-up. Factors associated with the development of dementia included older age, previous history of ischemic heart disease, diabetes, hypertension and stroke. Duration of endocrine therapy and previous use of adjuvant chemotherapy were not associated with dementia in our study. **Conclusions:** This investigation indicates that use of aromatase inhibitors compared to tamoxifen is associated with a lower risk of developing dementia among post-menopausal breast cancer patients. Further prospective studies investigating the neurocognitive effects of endocrine therapy are warranted. Research Sponsor: Divison of Medical Oncology Research Fund, London Regional Cancer Program, Other Government Agency.

522 Poster Session (Board #14), Fri, 8:00 AM-11:00 AM

HER2 status and prediction of extended endocrine benefit with breast cancer index (BCI) in HR+ patients in the adjuvant tamoxifen: To offer more? (aTTom) trial. *First Author: John Bartlett, Ontario Institute for Cancer Research, Toronto, ON, Canada*

Background: BCI is a validated gene expression-based assay that stratifies patients based on risk of overall (0-10y) and late (post-5y) distant recurrence (DR) and predicts likelihood of benefit from extended endocrine therapy (EET). The Trans-aTTom study established Level1B validation for BCI (H/I) to predict benefit from EET.[1] In this updated Trans-aTTom analysis including HER2 status, BCI (H/I) and prediction of endocrine benefit were further characterized. **Methods:** Centralized HER2 was determined for all cases according to current ASCO/CAP guidelines. Kaplan-Meier and Cox proportional hazards regression were conducted to assess primary and secondary endpoints of Recurrence-Free Interval (RFI) and Disease-Free Interval (DFI), respectively. A three-way interaction using likelihood ratio testing, which included treatment, BCI (H/I) and HER2, was performed to assess the effect of HER2 on BCI (H/I) prediction of EET benefit. **Results:** Of 789 N+ patients, 90% (N = 711) and 9% (N = 72) were HR+/HER2- and HR+/HER2+, respectively. In the HER2- subset, BCI (H/I)-High (48%) showed significant benefit from 10y vs. 5y of tamoxifen (9.4% RFI: HR = 0.35 [95% CI 0.15-0.81]; P = 0.047) while BCI (H/I)-Low patients did not (-2.1% RFI; HR = 1.15 [95% CI 0.78-1.69]; P = 0.491). For DFI, BCI (H/I)-High patients also showed significant benefit (10.3% DFI; HR = 0.41 [95% CI 0.18-0.91]; P = 0.047) while BCI (H/I)-Low patients did not (-1.7% DFI; HR = 1.10 [95% CI 0.75-1.62] P = 0.612). As demonstrated in the overall N+ cohort, significant interaction between BCI (H/I) and treatment was shown in the HER2- subset (RFI P = 0.045; DFI P = 0.044). Notably, three-way interaction evaluating BCI (H/I), treatment and HER2 status was not statistically significant (P = 0.85), indicating the ability of BCI (H/I) to predict benefit of EET activity was not significantly affected by HER2 status. **Conclusions:** In this updated Trans-aTTom analysis with HER2 data, BCI (H/I) showed similar predictive performance for EET response in the HER2- subset when compared to the overall N+ cohort. These data further support the clinical utility of BCI (H/I) as a predictive biomarker for informing EET benefit in HR+/HER2- and HR+/HER2+ disease. Clinical trial information: NCT00003678. Research Sponsor: Biotheranostics, Inc., Other Foundation, Ontario Institute for Cancer Research.

Treatment hazard ratios of 10y vs. 5y tamoxifen for BCI H/I-high patients.

	RFI (HR [95% CI])	DFI (HR [95% CI])
Overall HR+, N+ (N = 789)	0.33 (0.14 – 0.75)	0.43 (0.20 – 0.92)
HR+, N+, HER2- subset (N = 711)	0.35 (0.15 – 0.81)	0.41 (0.18 – 0.91)

Does chemotherapy affect survival of breast cancer (BC) patients with recurrence score 26-30? *First Author: Sowmya Goranta, Hurley Medical Center/Michigan State University, Flint, MI*

Background: The Oncotype-DX recurrence score (RS) allows providers to identify hormone receptor positive and HER2-negative breast cancer (BC) patients that may benefit from adjuvant chemotherapy (AC). The TAILORx Trial showed no benefit of AC among patients with RS of 11-25, except for patients younger than 50 years. There are, however, limited studies examining any benefit of AC among those with RS of 26-30. We sought to examine the effect of AC on BC-specific survival among these patients utilizing a national database. **Methods:** We queried the Surveillance, Epidemiology, and End Results database for newly diagnosed female BC patients between 2010-2015. We included patients with T1-T3, hormone receptor positive, HER2-negative, and lymph node-negative BC with RS of 26-30. Patients with tumors 5 mm or less and with incomplete records were excluded. Cox Proportional-Hazards Model was done to examine the effect of AC on BC-specific survival. A sub-group analysis was performed for patients younger than 50 years to examine the effect of AC on BC-specific survival. **Results:** We included 2,982 patients, of whom 1,686 (56.5%) received AC. Administration of AC was associated with lower age (56.5 [9.2] vs 61.8 [9.7], $p < 0.001$), Grade III&IV (39.7% vs 30.2%, $p < 0.001$), married or patients with partners (66.5% vs 61.5%, $p < 0.001$), and T stage > 1 (31.3% vs 26.8%, p = 0.03). AC was not associated with insurance status, race, and histology. Overall 5-year BC-specific survival was 97.3% (96.2-98.3%). After adjustment through cox regression, AC was found to not have an effect on survival (HR: 0.54 [0.27-1.10], p = 0.09). There were 579 (19.4%) patients that were younger than 50 years, and AC did not have an effect on survival among these patients (HR: 0.44 [0.08-2.44], p = 0.35). Similarly, among the 2,403 (80.6%) patients aged 50 or older, AC did not have an effect on survival (HR: 0.49 [0.22-1.11], p = 0.09). **Conclusions:** In this retrospective analysis, administration of AC was associated with lower age, higher grade, marital status, and T stage. AC did not affect BC-specific survival among patients with a RS of 26-30. Subgroup analysis did not show any benefit of AC among patients younger than 50 years or among those 50 or older. Further prospective randomized trials are warranted to identify subgroups that may potentially benefit from AC. Research Sponsor: None.

524 Poster Session (Board #16), Fri, 8:00 AM-11:00 AM

Statistical machine learning model to predict Oncotype DX risk category in women over age 50. *First Author: Kate R. Pawloski, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The 21-gene Oncotype DX Breast Recurrence Score multigene assay (RS) identifies women with ER positive, HER negative, axillary node-negative breast cancer (BC) for whom chemotherapy provides no invasive disease-free survival benefit compared to endocrine therapy alone. International adoption of RS testing is limited by cost and resource availability. We created a supervised statistical machine learning model using standard clinicopathologic data to predict RS risk category in women $>$ 50 years old. **Methods:** From 2012 to 2018, women with ER positive, HER2 negative, pathologically node-negative BC of all ages were retrospectively identified from a prospective institutional database. Standard clinicopathologic data and RS were collected. Per institutional protocol, RS are ordered for all early-stage, ER positive tumors $>$ 5 mm. Data were randomly split into training (n=3755) and validation sets (n=1609). A random forest model with 500 trees was developed on the training set, then evaluated on the validation set. Model predictors included age, tumor size, histologic subtype, hormone receptor status, lymphovascular invasion, and overall grade. The model was used to predict RS category (low risk: RS $\leq$ 25, high risk: RS $>$ 25) in women $>$ 50 years old. **Results:** 5364 unique tumors in 5189 women were identified. 3731 (70%) of tumors were identified in women $>$ 50 years; median age was 63 years (IQR 57-69). In women $>$ 50, median tumor size was 12 mm (IQR 9-17). Most tumors were invasive ductal (79%), low or intermediate grade (79%), and LVI was absent in 82% of tumors. Median ER staining by IHC was 95%; 28% of tumors had negative or weakly positive PR staining (1-20%). The model correctly classified 96.8% of patients as low risk (95% CI: 95.7-97.7). Negative predictive value for identifying low risk category was also high (92.3%, 90.7-93.6). Sensitivity for identifying high-risk women was 44.7% (37.4-52.1) and positive predictive value was 67.2% (58.2-75.3). A classification table on the validation set includes tumors with complete data available, including predictors and RS. **Conclusions:** Our model was highly specific (96.8%) for identifying women $>$ 50 with RS $\leq$ 25 who do not benefit from adjuvant chemotherapy. This model may be utilized in lieu of RS testing if cost and availability are prohibitive. True RS $>$ 25 was not as well predicted. The model will be refined following pathologic review of discordant cases to reduce false negatives. Research Sponsor: U.S. National Institutes of Health.

Classification table on the validation set [n=1467].

	True RS > 25	True RS ≤ 25
Model predicted RS > 25	84	41
Model predicted RS ≤ 25	104	1238

525 Poster Session (Board #17), Fri, 8:00 AM-11:00 AM

Early-stage breast cancer (BC) patients: Factors associated with aromatase inhibitor-induced musculoskeletal symptoms. *First Author: Simran Arora Elder, University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD*

Background: Hormone receptor positive (HR+) breast cancer comprises the largest subgroup of breast cancer. Aromatase Inhibitors (AI) are a key treatment for HR+ BC patients (pts) and reduce mortality. Aromatase Inhibitor-Associated Musculoskeletal Symptoms (AIMSS), defined as myalgias, arthralgias, or joint stiffness, occur in up to 50% of pts leading to low adherence to and often discontinuation of therapy. Little is known of the mechanism of AIMSS or its predisposing risk factors. This study aims to identify risk factors associated with AIMSS development in BC patients on AI therapy. **Methods:** We conducted a medical record review of pts with non-metastatic HR+ BC on adjuvant AI therapy between January 2009 and June 2017 at the University of Maryland Comprehensive Cancer Center. This study included 194 ptswho were free of arthralgia prior to AI therapy. We analyzed pts' demographics, lifestyle factors, reproductive history, tumor characteristics, medications, cancer treatment, co-morbidities, AI type, onset and severity of AIMSS. Severe AIMSS was defined as requiring change in AI therapy or discontinuation. Multivariable-adjusted logistic regression was used to identify risk factors for severe AIMSS. **Results:** The mean age of participants was 61. The mean BMI at diagnosis was 30 kg/m^2. 41% of pts were White, 40% were Black, 7% other and 12% unknown. Most (79%) did not have a history of tamoxifen and 16% were on GnRH agonists. Most (71%) used letrozole as initial AI therapy; 18% anastrozole; and 11% exemestane. 56% experienced AIMSS while on AI therapy and 20% required change or hold of AI therapy. 4% permanently discontinued AI due to AIMSS severity. BMI at diagnosis was significantly positively associated with risk of AIMSS. Multivariate odds ratio (95% confidence intervals) comparing the highest to lowest tertile of body mass index (BMI) at diagnosis was 4.01 (1.07-10.90; P_{trend}: 0.05). There were no significant associations with race, smoking, reproductive factors, type of AI therapy, tamoxifen use prior to AI therapy, medication use, experience of other cancer treatments, and tumor characteristics. **Conclusions:** 56% of BC pts on adjuvant AI therapy experienced AIMSS. 24% of these changed, held or discontinued AI regimen due to severe AIMSS. Higher BMI at diagnosis was associated with a higher risk of AIMSS. Our results confirm clinical significance of AIMSS among BC pts on AI therapy and suggest BMI as a modifiable factor for AIMSS. A larger study is warranted to replicate our findings and seek other possible risk factors for AIMSS. Research Sponsor: None.

CX-2009, a CD166-directed probody drug conjugate (PDC): Results from the first-in-human study in patients (Pts) with advanced cancer including breast cancer (BC). *First Author: Valentina Boni, START Madrid, CIOCC, Madrid, Spain*

Background: CX-2009 is a PROBODY drug conjugate (PDC) directed against CD166 (ALCAM) and conjugated to DM4, a potent microtubule inhibitor (MTI). CD166 is overexpressed in carcinomas but is also ubiquitously expressed in normal epithelium and thus has not been previously considered a viable target for a traditional antibody drug conjugate. PDCs have a peptide mask that blocks normal tissue binding and can be removed by tumor-associated proteases, thereby limiting off-tumor/on-target binding. CX-2009 demonstrated preclinical activity in multiple solid tumor models. Here we report results of the first in human study in patients with advanced cancer. **Methods:** In this phase I multi-part dose-escalation study, pts with advanced solid tumors received CX-2009 0.25–10 mpk IV every 14 or 21 days (Q2W or Q3W). Tumor types were selected based on expected high CD166 expression and MTI sensitivity. **Results:** The dose-escalation phase of the trial enrolled 43 pts; 49 additional pts were subsequently enrolled between 4–10 mpk to collect biomarker data and define the recommended phase II dose (RP2D), for a total of 92 pts as of 30 Nov 2019 (39 pts with breast cancer [BC], 22 ovarian [OC], 12 non-small cell lung [NSCLC], 9 head/neck squamous cell [HNSCC], 10 other) with a median of 6 (range 1–19) prior therapies. Median number of CX-2009 doses was 2 (range, 1–15). For Q3W dosing, one dose limiting toxicity (DLT; grade 3 vomiting) was observed at 8 mpk; MTD was not reached up to 10 mpk. The RP2D for Q3W schedule was 7 mpk based on safety, dose-response, and population pharmacokinetic simulations. Q2W dosing continues; DLTs were observed at 6 mpk. Common treatment-related adverse events (TRAEs) at 7 mpk (n=9) were nausea (44%), fatigue, infusion-related reactions (both 33%), vomiting and arthralgias (both 22%). Grade 3 TRAEs occurred in 2 pts (nausea/vomiting; peripheral neuropathy). No pts discontinued at 7 mpk due to TRAEs. Ocular toxicity was dose dependent; mild to moderate reversible keratitis/blurred vision was seen in 3 pts at 7 mpk and mitigated by ocular prophylaxis. Partial responses were seen in 8 pts (2 confirmed, both HR+/HER2- BC) treated between 4–10 mpk, including BC (n=5), OC (n=2), and HNSCC (n=1). SD ($\geq$1 on-study scan) was observed in 21 pts, 5 had SD $\geq$3 mos. **Conclusions:** CX-2009 at 7 mpk is the RP2D on Q3W schedule. Phase II expansion has begun in pts with HR+/HER2- BC. The Q2W schedule will continue to enroll pts to define the RP2D. CX-2009 will also be studied in combination with CX-072, a PD-L1 PROBODY therapeutic (NCT03149549) Clinical trial information: NCT03149549. Research Sponsor: CytomX Therapeutics, Inc.

527 Poster Session (Board #19), Fri, 8:00 AM-11:00 AM

Adherence to extended adjuvant endocrine therapy following Breast Cancer Index (BCI) testing in women with early-stage hormone receptor (HR)-positive breast cancers. *First Author: Julia Foldi, Yale Cancer Center, New Haven, CT*

Background: Evidence suggests continuing endocrine therapy (ET) beyond 5 years (yr) may reduce breast cancer recurrence in early stage HR+ breast cancers. Given the modest benefit and potentially serious adverse effects of extended ET (EET), improved approaches to identify patients who are at increased risk of late distant recurrence and who derive benefit from EET are critical. Guidelines recommend shared decision-making between oncologists and patients. The adherence rate to EET by 5 yr is only 50-60%. BCI is a gene-expression assay used to predict late distant recurrence and is predictive of benefit from EET. We assessed adherence to EET in women who had BCI testing. **Methods:** Women with stage I-III HR+ breast cancer s/p 3.5 yr of adjuvant ET and had BCI testing at our institution (8/2013-7/2015) were included. Pts who had $<$ 4 yr of follow-up since BCI testing were excluded. Information including demographics, tumor characteristics, treatment history, number DXA scans, history of osteopenia/osteoporosis were collected. Data on medication adherence was based on prescriptions in the electronic health record. **Results:** 102 pts were included in our analysis. The median age was 61yr (46-89 yr). The majority of pts had stage I (63%), N0 (77%) and HER2- (90%) disease. 50 pts (46%) received chemotherapy. 44 (43%) received tamoxifen and 79 (77%) had an aromatase inhibitor. BCI categorized 61 (60%) pts as low risk, 26 (25%) as intermediate, and 15 (15%) as high risk for late distant recurrence. 61 (60%) and 41 (40%) pts were predicted to have low and high likelihood of benefit from EET, respectively. All 15 (100%) pts categorized as high risk for late recurrence were predicted to have a high likelihood to benefit from EET; all were recommended to continue EET by their oncologist and all 15 elected EET. 11 (73%) completed 10 yr or were on EET at last follow-up. Of the 4 (27%) pts who stopped before 10 yr, 1 pt had metastatic recurrence and 3 had intolerable side effects. Pts on EET underwent an avg of 1.91 DXA scans, compared with 1.23 for those who stopped ET at 5 yr ($p = 0.003$). At a median follow-up of 10 yr from diagnosis, there were 2 metastatic (1/15 in the high risk and 1/26 in the intermediate risk group) and 1 local recurrence (1/61 in the low risk group). **Conclusions:** In pts who continued ET beyond 5 years based on BCI testing and discussion with their oncologist, the rates of adherence and persistence to EET were higher than those previously published. EET may increase the number of DXA scans performed. Research Sponsor: Biotheranostics Inc.

Safety and efficacy of single-agent adjuvant trastuzumab in older women with early-stage breast cancer. *First Author: Cynthia Owusu, Case Western Reserve University School of Medicine, Cleveland, OH*

Background: Older adults with multiple comorbidities and poor functional status may not be appropriate candidates for chemotherapy. We conducted a phase II trial to examine the safety and efficacy of single-agent Trastuzumab for older women with early stage Human Epidermal Growth Factor Receptor Type 2 (Her2)-positive breast cancer. **Methods:** This was a single-arm open label multi-institutional clinical trial of adjuvant single-agent Trastuzumab in women aged ≥ 60 years with stage I-III Her2-positive breast cancer who had either declined chemotherapy or were not chemotherapy candidates. Patients received Trastuzumab monotherapy, (8 mg/kg) for cycle 1 followed by (6 mg/kg) every 3 weeks for 12 months. The primary end point was one-year cumulative incidence of symptomatic congestive heart failure with reduced ejection fraction (HFrEF). Secondary endpoints were disease free survival (DFS) and overall survival (OS) at 5 years. **Results:** Fifty-six patients were enrolled across four centers with a median follow-up period of 5.0 years, (range 0-6.5). The median age was 72.5 years (range 60-90), 64% had stage I disease, 77% had estrogen-receptor positive disease and 82% had node-negative breast cancer. Only two patients had symptomatic congestive HFrEF with a one-year cumulative incidence of 3.6%; (95% confidence interval [CI], 0.09 to 13.8). Five patients had asymptomatic declines in ejection fraction with a one-year cumulative incidence of 9.1%; (95% CI, 3.9 to 20.1). The 5-year DFS was 86.4%; (95% CI, 73.6 to 93.3). Among seven relapses seen, two were due to distant metastatic breast cancer. The 5-year rate of overall survival was 90.2%; (95% CI, 78.1 to 95.8). Among five deaths, one was due to distant metastatic breast cancer. **Conclusions:** Among older women with stage I-III HER2-positive breast cancer who decline chemotherapy or are not chemotherapy candidates, treatment with her2 targeted therapy only without chemotherapy may offer a reasonable treatment option without an inordinate rate of cardiac toxicity. Clinical trial information: NCT00796978. Research Sponsor: Genentech.

529 Poster Session (Board #21), Fri, 8:00 AM-11:00 AM

Value of clinical treatment score post-5 years (CTS5) for late relapse risk assessment in patients with early-stage HER2+ breast cancer (BC) in the north central cancer treatment group (NCCTG) N9831 (Alliance) trial. *First Author: Tanmayi Pai, Mayo Clinic Florida, Jacksonville, FL*

Background: Multiple prognostic models exist to predict late relapse risk in early stage hormone receptor-positive (HR+) breast cancer (BC). The CTS5 is one such model that has been validated in HR+ HER2-negative BC. The value of this model in HR+ HER2+ has not been established. Here, we assessed CTS5 in patients (pts) with early stage HER2+ BC treated in the NCCTG N9831 (Alliance) trial. **Methods:** Pts with stage I-III HER2+ HR+ BC who survived ≥ 5 years were included. The online CTS5 calculator was used to determine CTS5 score and risk group (low, intermediate, and high) based on age, tumor size, grade, and number of involved nodes. Kaplan-Meier (KM) estimates, Cox regression models, and C index were used for analysis. **Results:** From 3,130 pts, 1,204 pts met the criteria and were included. Median age was 49 (22-79) years and median tumor size was 2.4 (0.1-12) cm. 63.6% had grade 3 tumors, 33.6% grade 2, and 2.8% grade 1. Median follow up was 10.89 (5.01-15.32) years. Based on CTS5, 821 (68.2%) pts were classified as high risk, 289 (24%) as intermediate risk, and 94 (7.8%) as low risk. Overall, using univariate Cox regression analysis, there was no statistically significant difference in recurrence free survival (RFS) among pts with intermediate vs. low (HR 0.47 95%CI 0.18-1.22, p = 0.12) and high vs. low (HR1.23 95%CI0.57-2.67, p = 0.6) with the C index of 0.58. Among pts who received concurrent trastuzumab (H) with HR+ BC, there was also no statistical difference in RFS between high vs. low (HR 0.68 95%CI0.24-1.97, p = 0.48) with the C index of 0.55. Paradoxically, pts with intermediate risk had better RFS than low risk (HR 0.18 95%CI0.03-0.97, p = 0.05). As a continuous variable, there is also no significant improvement in RFS per 1 unit increase in CTS5 score (HR 1.19 95%CI 0.73-1.96, p = 0.49) with the C index of 0.54. After 5 years, 7.06% (n = 30/425) of HR+ pts treated with concurrent H recurred. **Conclusions:** The CTS5 model is not prognostic in pts with early stage HR+ HER2+ BC receiving adjuvant H. While most HR+ HER2+ pts are classified as high risk by CTS5, the recurrence between years 5-10 was low in pts who received adjuvant H. This study highlights the need to develop a new predictive model for risk of late relapse in this specific group of pts to enable clinicians to determine which pts would benefit from extended adjuvant endocrine therapy. The predictive potential of the spatial signature of lymphocytes in breast cancer patients. *First Author: Nora Balint-Lahat, Chaim Sheba Medical Center, Tel-Hashomer, Israel*

Background: Tumor-infiltrating lymphocytes in breast cancer have emerged as both a prognostic and a potentially predictive immunotherapy biomarker. Advancements in artificial intelligence can extract pathology-based spatial immune fingerprints for use as treatment decision support tools. **Methods:** We examined 908 primary breast cancer patients with whole slide images (WSI) available from TCGA database. Digital structuring of WSIs included automated detection of lymphocytes, tumor and tumor adjacent stroma, using deep learning-based semantic segmentation. Prognosis was defined as progression free interval (PFI). A Cox Survival analysis was used to detect prognostic spatial features. We used principal component analysis (PCA) to reduce and decorrelate significant features. The resulting PCA features were used to fit the final model. The model was then validated on an independent database of WSI of breast lumpectomies, from two tertiary hospitals in Israel. **Results:** The analysis included 908 WSI. The average age was 58.4 years old, with a majority of early stage breast cancer (76.7%, stage I and II). The detection performance for tumor area and lymphocytes reached F1 scores of 99% and 97% respectively, in comparison to human annotation. In the Kaplan Meier (KM) analysis of 414 early stage luminal breast cancers, a high number of lymphocyte clusters (LC) and a high ratio between stromal lymphocyte density and tumor lymphocyte density (LD-S/LD-T) were significantly associated with longer PFI (p = 0.005 and p = 0.038, respectively). Based on these features, two continuous PCA features were added to the multivariate model, and remained significantly associated with PFI after adjusting for age (HR = 1.19, 95% CI 1.05-1.35; HR = 1.26 95% CI 1.03-1.55). The validation set was underpowered (n = 79) and data is still being collected. In a preliminary KM analysis of 37 early stage luminal breast cancer cases from the validation set, LD-S/LD-T was significantly associated with longer PFI (p = 0.046). **Conclusions:** In our study, LC and LD-S/LD-T, presumably surrogate measures of peritumoral lymphocytes, were found significantly associated with longer PFI. Research Sponsor: Nucleai.

531 Poster Session (Board #23), Fri, 8:00 AM-11:00 AM

Phase II study of adjuvant endocrine therapy with CDK 4/6 inhibitor, ribociclib, for localized ER+/HER2- breast cancer (LEADER). *First Author: Laura Spring, Massachusetts General Hospital, Boston, MA*

Background: Given the success of CDK 4/6 inhibitors for ER+/HER2- metastatic breast cancer, there is much interest in exploring these agents in early breast cancer to potentially reduce recurrence risk. However, tolerability and adherence are important considerations in the adjuvant setting. We evaluated the tolerability and adherence of adjuvant endocrine therapy with the CDK 4/6 inhibitor, ribociclib, in two different schedules, in a prospective phase II clinical trial. **Methods:** Eligible patients were those with localized stage I-III ER+ (≥ 10%), HER2- breast cancer who had completed surgery and were on adjuvant endocrine therapy with at least one year or more of treatment remaining. Patients were randomized to receive continuous ribociclib (400 mg daily of 28-day cycle; arm 1) or intermittent ribociclib (600 mg daily on days 1-21 of 28-day cycle; arm 2) for one year, in addition to an aromatase inhibitor (plus GnRH agonist if premenopausal). Toxicities were evaluated using CTCAE version 4.03. Adherence was monitored by review of patient diaries and pill count. **Results:** Of the 81 patients enrolled, 24 discontinued early. The table shows the current status of the patients based on treatment arm (data cut-off as of 1/31/20; updated results will be presented at meeting). A total of 8 serious adverse events (AEs) have occurred thus far: grade 3 transaminitis (1), grade 4 transaminitis (3), grade 3 colitis (1), grade 3 infection (2), and grade 4 lymphopenia (1). The most common grade 3 or greater AEs leading to study discontinuation thus far were transaminitis (8.6%), neutropenia (2.5%), and fatigue (2.5%). No patients discontinued early due to prolonged QTc. Adherence results will be reported at the meeting. **Conclusions:** Interim results demonstrate that while serious AEs with one year of adjuvant ribociclib are low, a number of patients discontinued adjuvant CDK 4/6 inhibitor. Tolerability and adherence patterns will need to be carefully considered with CDK 4/6 inhibitors in the adjuvant setting. Clinical trial information: NCT03285412. Research Sponsor: Novartis.

Estimation of absolute benefit of S-1 postoperative therapy for ER-positive, HER2-negative breast cancer: Exploratory analysis of the phase III potent trial. *First Author: Masahiro Takada, Department of Breast Surgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Background: Estimation of risk of recurrence is critical for adjuvant therapy decision making in patients with primary breast cancer. The POTENT trial examined outcomes associated with standard postoperative endocrine therapy with/without S-1 in patients with estrogen receptor (ER)-positive and human epidermal growth factor receptor 2 (HER2)-negative primary breast cancer (Toi et al, San Antonio Breast Cancer Symposium 2019). The aim of this study was to investigate absolute treatment effect across recurrence risk score to individualize indication for the concurrent administration of standard postoperative endocrine therapy with S-1. **Methods:** The POTENT trial included 1930 patients with ER-positive and HER2-negative breast cancer. The primary end point was invasive disease-free survival (iDFS). A continuous, composite measure of recurrence risk for each patient was determined from a Cox model incorporating age, tumor size, nodal status, grade, estrogen receptor, and Ki-67 expression levels. Absolute treatment effect of S-1 was estimated in each risk group defined by the composite risk score. **Results:** Of 1930 patients, we included the data from 1897 patients without unavailable data. Tumor grade, ER expression, and Ki-67 expression were available from central assessment. A Cox proportional hazards model for iDFS was estimated in standard endocrine therapy only group (N = 954). Age was excluded from the model because it did not add prognostic information. 5-year iDFS estimates were 91.6%, 82.0%, and 67.2% for low, intermediate, and high composite risk group, respectively. Absolute improvement in 5-year iDFS by the addition of S-1 to standard endocrine therapy were 0.9%, 6.7%, and 8.1% for low, intermediate, and high composite risk group, respectively. Hazard ratio for S-1 in each risk group were 0.86 (95%CI: 0.45-1.63, P = 0.642), 0.51 (95%CI: 0.34-0.78, P = 0.001), and 0.71 (95%CI: 0.49-1.02, P = 0.064), respectively. Continuous value of composite risk was also prognostic in a Cox proportional hazards model stratified by S-1 and neoadjuvant/adjuvant chemotherapy use (HR 2.58, 95%CI: 2.13-3.11, P $<$ 0.0001). **Conclusions:** Patients with ER-positive and HER2-negative disease, and intermediate to high risk, defined by clinicopathological factors, experienced absolute improvement of about 7-8% in 5-year iDFS with addition of S-1 to standard endocrine therapy, while improvement was minimal in those at low risk. Clinical trial information: 000003969. Research Sponsor: Taiho Pharmaceutical Co., Ltd.

533 Poster Session (Board #25), Fri, 8:00 AM-11:00 AM

Factors associated with adjuvant endocrine therapy adherence in non-metastatic breast cancer. *First Author: Joan Marie Neuner, Medcl Coll of Wisconsin, Milwaukee, WI*

Background: Over 50% of breast cancer patients prescribed adjuvant endocrine therapy (ET) are nonadherent during the recommended 5-year course of therapy. We investigated the role of cancer medication delivery on adherence, including mail order pharmacy use, number of pharmacies and copays. **Methods:** We conducted a retrospective cohort study of 15,769 commercially insured breast cancer patients age 18-64 with newly diagnosed breast cancer in 2007-2015 that initiated ET. Incident breast cancer was identified by a validated algorithm which identifies mainly non-metastatic breast cancer. We examined the association between 12-month AET adherence (proportion of days covered by fills $\geq$0.80) and mail order pharmacy use, number of pharmacies, and AET copays. We used Poisson regression to estimate nonadherence risk ratios and adjusted for demographics (age, income, race, urbanicity), comorbidities, total medications, primary cancer treatments (surgery, radiation, chemo, and ET initiated), and generic AI availability. Sensitivity analyses were conducted using alternate specifications for independent variables. To test whether any observed differences were due to self-selection, we also conducted a negative control analysis. **Results:** Most patients were white (74.4%) and age 55-64 (43.3%). Only 16% of patients used a mail order pharmacy for ET fills, most patients only used one pharmacy (58.8%) and 25.2% had a co-pay of $20 or more. In the primary analysis, mail order patients were more likely to be adherent to their ET (aRR 1.21; 95% CI 1.18-1.24), patients using one pharmacy were more likely to be adherent (1 vs 3+: aRR 1.09; 95% CI 1.06-1.13), and patients with lower copays were more likely to be adherent (quartile 1 vs 4: aRR 1.04; 95% CI 1.01-1.08). Results were consistent across sensitivity analyses, and there was no association between mail order and copays and the negative control outcome of any pneumonia diagnoses. **Conclusions:** Medication delivery factors are associated with adherence to breast cancer AET. Future work should investigate whether interventions to streamline medication delivery could improve adherence for this population. Research Sponsor: U.S. National Institutes of Health.

Disparities in receipt of and time to adjuvant therapy after lumpectomy. *First Author: Irene Dankwa-Mullan, IBM Watson Health, Bethesda, MD*

Background: Adjuvant treatment after breast conserving surgery (BCS) has been shown to improve outcomes, but the degree of uptake varies considerably. We sought to examine factors associated with post-BCS receipt of and time to treatment (TTT) for adjuvant radiation therapy (ART), cytotoxic chemotherapy (ACT) and endocrine therapy (AET) among women with breast cancer. **Methods:** IBM MarketScan claims data were used to select women diagnosed with non-metastatic invasive breast cancer from 01/01/2012 to 03/31/2018, who received primary BCS without any neoadjuvant therapy, and who had continuous insurance eligibility 60 days post-BCS. Logistic and quantile regressions were used to identify factors associated with receipt of adjuvant therapy (ART, ACT, AET) and median TTT in days for ART (rTTT), ACT (cTTT), and AET (eTTT), respectively, after adjustment for covariates including age, year, region, insurance plan type, comorbidities, and a vector of ZIP3-level measures (e.g., community race/ethnicity-density, education level) from the 2019 Area Health Resource Files. **Results:** 36,270 patients were identified: 11,996 (33%) received ART only, 4,837 (13%) received ACT only, 3,458 (10 %) received AET only, 5,752 (16%) received both ART and AET, and 9,909 (27%) received no adjuvant therapy within 6 months of BCS. (318) 1% of patients received combinations of either ART, AET or ACT. Relative to having no adjuvant therapy, patients $>$ 80 years were significantly less likely to receive ART only (relative risk ratio [RRR] 0.65), ACT only (RRR 0.05), or combination ART/AET (RRR 0.66) but more likely to receive AET alone (RRR 3.61) (all $p < .001$). Patients from communities with high proportions of Black (RRR 0.14), Asian (RRR 0.13), or Hispanic (RRR 0.45) residents were significantly less likely to receive combination ART and AET (all $p < .001$). Having HIV/AIDS (+11 days; $p = .01$) and residing in highly concentrated Black (+8.5 days; $p = .01$) and Asian (+12.2 days; $p = .04$) communities were associated with longer rTTT. Longer cTTT was associated with having comorbidities of cerebrovascular disease (+6.0 days; $p < .001$), moderate to severe liver disease (+12.3 days; $p < .001$) and residing in high-density Asian communities (+18.0 days; $p < .001$). Shorter eTTT (-11.4 days; $p = .06$) and cTTT (-14.8 days; $p < .001$) was observed in patients with comorbidities of dementia. **Conclusions:** Results from this cohort of privately insured patients demonstrate disparities in receipt of post-BCS adjuvant radiation and systemic therapy along multiple demographic dimensions and expose opportunities to promote timely receipt of care. Research Sponsor: None.

535 Poster Session (Board #27), Fri, 8:00 AM-11:00 AM

Real-world patterns of treatment and recurrence by frailty status among older women with HR-positive, HER2-negative early breast cancer. *First Author: Gregory Sampang Calip, University of Illinois at Chicago, College of Pharmacy, Chicago, IL*

Background: Frail health status impacts clinical decision making for older cancer patients and their families, and frailty is independently associated with increased risks of mortality. Our objective was to describe differences in treatment and rates of recurrence by frailty status among older women with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative early breast cancer. **Methods:** We performed a large, population-based retrospective cohort study of women aged 65 years and older diagnosed with first primary stage I-III HR+/HER2- breast cancer using the Surveillance, Epidemiology, and End Results Medicare-linked database between 2007 and 2015. Using administrative health claims, we ascertained information on breast cancer treatment and utilized validated claims-based algorithms to determine frailty status (robust, pre-frail, and frail) and identify subsequent invasive breast cancer recurrences. Relative hazards of recurrence were determined using Fine and Gray competing risks regression models with estimated subdistribution hazard ratios (SHR) and robust 95% confidence intervals (CI). **Results:** From an overall cohort of 46,027 women, most women (56%) were classified as robust at breast cancer diagnosis, whereas 37% and 7% were identified as pre-frail and frail, respectively. Compared to robust patients, frail patients were more likely to have stage III disease (10% vs. 7%) and receive mastectomy (27% vs. 18%), and less likely to receive radiation (35% vs. 57%) or chemotherapy (5% vs. 9%). Five-year cumulative incidences of recurrence were 15%, 18% and 22% among robust, pre-frail, and frail women, respectively. In multivariable competing risks models adjusted for age, race, stage, and treatment, frail (SHR 1.28, 95%CI 1.17-1.41) and pre-frail (SHR 1.15, 95%CI 1.09-1.21) women had a significantly increased risk of breast cancer recurrence. **Conclusions:** Independent of differences in treatment, frailty was associated with increased breast cancer recurrence risk in this population-based cohort of older women. However, the vast majority of older women living with HR+/HER2- early breast cancer were not identified as frail. These study results suggest that age alone is not an adequate indicator of physical resilience and underscores the need to consider additional factors when assessing the benefits and risks of treatments for the prevention of recurrence among HR+/HER2- early breast cancer patients. 536 Poster Session (Board #28), Fri, 8:00 AM-11:00 AM

Trends in utilization of hypofractionated whole breast radiation in breast cancer: An analysis of the National Cancer Database. *First Author: Steven Gerard Woodward, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: Utilization of hypofractionated radiation (HR) as a component of breast conserving treatment (BCT) in breast cancer is lacking in the U.S. despite studies demonstrating its efficacy and guidelines supporting its use from the American Society for Radiation Oncology (ASTRO) in 2011 and 2018. Little is known regarding national trends in uptake and factors associated with uptake of HR in the U.S. since the 2011 ASTRO guidelines. **Methods:** We performed a retrospective review of the National Cancer Data Base (2012-2016) on patients undergoing BCT. Logistic regression modeling was used to identify relationships between patient, hospital, and tumor factors with the use of HR or traditional radiation (TR). **Results:** A total of 360,834 cases of BCT were identified with 65% (n=235,783) undergoing TR and 35% (n=125,051) undergoing HR. The odds of utilization of HR increased with year of diagnosis, patient age, higher median income, private insurance, treatment at an academic center, travel distance to treatment >20 miles, smaller tumors, lymph node negative disease, and without use of chemotherapy (p-values <0.0001, Table). **Conclusions:** Despite studies demonstrating the efficacy of its use and the support of ASTRO, HR utilization in the U.S. is still lacking. By understanding which patient populations are still not receiving the benefit of this therapy we can improve our utilization of HR in the U.S. leading to reduced healthcare costs and patient satisfaction. Research Sponsor: None.

Impact of delays in initiation of adjuvant endocrine therapy and survival among patients with breast cancer. *First Author: Kimberley Lee, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Time to adjuvant endocrine therapy concerns patients and clinicians, but its impact on overall survival is not clear. There are no population level studies that address this question. Our primary objective is to describe the relationship between time from diagnosis of breast cancer to start of adjuvant endocrine therapy and overall survival. **Methods:** This is a population-based cohort study using prospectively collected population level data from the National Cancer Database (NCDB). The NCDB prospectively collects data on incident cancer cases from over 1500 Commission on Cancer-accredited facilities nationally. NCDB captures approximately 70% of incident cases of cancer in the United States. The participants are women with Stage II and III estrogen or progesterone receptor positive, human epidermal receptor 2 negative, invasive breast cancer who underwent definitive surgical treatment. **Results:** Of the 391,594 women in this study, 12,162 (3.1%) began treatment with adjuvant endocrine therapy more than 12 months after initial diagnosis of hormone receptor positive, invasive breast cancer. Mean age at diagnosis was 59.7 years (SD 13.4). Predictors of delayed initiation of adjuvant endocrine therapy include Black race or Hispanic ethnicity (adjusted odds ratio [aOR] of Black vs White, 1.57; 95% CI, 1.48-1.66; $P < .001$, Hispanic vs White, aOR 1.22, 95% CI 1.13-1.32; $P < .001$), Insurance other than private insurance (Medicare vs Private, aOR 1.09, 95% CI 1.01-1.17; $P = .007$, Medicaid vs Private, aOR 1.36, 95% CI 1.28-1.45; $P < .001$), higher stage of disease at diagnosis (Stage III vs II, aOR 1.24, 95% CI 1.19-1.30; $P < .001$), and delayed surgery or chemotherapy (Delayed surgery vs On-time lumpectomy, aOR 2.76, 95% CI 2.60-2.93; $P < .001$ and Delayed chemotherapy vs no chemotherapy, aOR 11.5, 95%CI 10.6-12.5). With median follow-up of 63.2 months, 67,335 (17.2%) patients died by the end of follow-up. Delayed initiation of AET resulted in no change in the hazard of death (HR, 1.00; 95% CI, 0.95-1.05; $P = .97$) compared to initiation within 12 months of diagnosis after adjusting for age, race and ethnicity, insurance type, urban vs rural residence, neighborhood income and education, comorbidity, cancer grade, stage, and receipt of timely or delayed surgery, chemotherapy, and/or radiation therapy. **Conclusions:** These results suggest that there may be no detriment to survival if initiation of adjuvant endocrine therapy occurs 12 to 24 months after initial diagnosis compared to within 12 months of diagnosis, as currently recommended. Research Sponsor: U.S. National Institutes of Health.

538 Poster Session (Board #30), Fri, 8:00 AM-11:00 AM

Genome-wide association study of steady-state letrozole concentration in patients with breast cancer. *First Author: Daniel Louis Hertz, University of Michigan College of Pharmacy, Ann Arbor, MI*

Background: Letrozole is a non-steroidal aromatase inhibitor (AI) used to treat hormone receptor positive (HR+) breast cancer. Variability in letrozole efficacy and toxicity may be partially attributable to variable systemic drug exposure, which may be influenced by germline variants in the enzymes responsible for letrozole metabolism, including CYP2A6. The objective of this genome-wide association study (GWAS) was to identify genetic variants that affect steady state letrozole concentrations. **Methods:** The Exemestane and Letrozole Pharmacogenetics (ELPh) Study randomized 503 post-menopausal patients with HR+ non-metastatic breast cancer to exemestane or letrozole treatment. Germline DNA was collected pre-treatment and blood samples were collected after 1 or 3 months of treatment to measure steady-state letrozole concentration via HPLC/MS. Genome-wide genotyping was conducted on the Infinium Global Screening Array to the Haplotype Reference Panel (> 2 million variants). The association of each polymorphism with square-root transformed letrozole concentration was tested in self-reported white patients via linear regression using the standard alpha for genome-wide significance ($\alpha = 5x10^{-8}$) assuming an additive genetic model and correcting for age and body mass index. **Results:** 228 patients met inclusion criteria and had all necessary data. Each variant allele of rs7937 a patient carried increased their letrozole concentration ~22.9 ng/mL (standard error = 4.01, $p = 3.51x10^{-8}$, Table) and this variant explained 13% of the variability in letrozole concentrations. rs7937 is located ~50 kB upstream of *CYP2A6*, and has previously been identified in GWAS of CYP2A6-related phenotypes, including nicotine metabolism and lung cancer. **Conclusions:** This GWAS confirmed that steady-state letrozole concentrations are partially determined by germline polymorphisms affecting CYP2A6 activity. If letrozole concentrations affect treatment efficacy or toxicity, CYP2A6 genetics may be useful to individualize letrozole dosing to improve clinical outcomes in patients with HR+ breast cancer. Research Sponsor: Breast Cancer Research Foundation.

	Wild-type (n = 62)	Heterozygous (n = 118)	Homozygous variant (n = 48)
Mean (ng/mL) (±std dev) letrozole concentration	74.6 (35.8)	98.3 (43.2)	120.4 (46.4)

Is hypofractionated radiation associated with improved timely completion of adjuvant radiation in breast conserving therapy? A National Cancer Database study. *First Author: Steven Gerard Woodward, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: Timely completion (TC) of adjuvant radiation therapy following breast conservation therapy (BCT) has been associated with improved mortality and disease-free survival (DFS). Little data exists comparing TC of hypofractionated radiation (HR) and traditional radiation (TR). **Methods:** We performed a retrospective review of the National Cancer Data Base (2012-2016) on patients undergoing BCT. A multivariable logistic regression model was used to compare TC of HR (within 5 weeks of initiation) and TR (within 7 weeks of initiation) with interaction terms to look at within treatment effects of patient, tumor, and facility characteristics. **Results:** A total of 360,834 patients who underwent BCT were identified with 65% (n=235,783) undergoing TR and 35% (n=125,051) undergoing HR. TC of HR was achieved in 93.5% of patients and 74.2% of TR patients (p<0.0001). Across categories of year of diagnosis, age, race, median income, facility type, distance to treatment, T-stage, chemotherapy use, and lymph node status it was found that rate of TC was greater in HR compared to TR. The effect on TC by these factors was different in HR patients compared to TR in all categories except median income, distance to treatment, and T-stage (table). **Conclusions:** The decision between use of HR or TR in BCT is an essential component in treatment of breast cancer patients. Providers may improve mortality and DFS by identifying patients who are more likely to finish HR or TR on time based on patient, facility, and tumor factors. Research Sponsor: None.

Real-world analysis of clinical and economic impact of 21-gene recurrence score (RS) testing in early-stage breast cancer (ESBC) in Ireland. *First Author: Lynda M McSorley, Galway University Hospital, Galway, Ireland*

Background: Treatment of hormone receptor positive (HR+) ESBC is evolving. The use of chemotherapy (CT) is declining with use of the 21-gene RS assay. This validated tool predicts the likelihood of adjuvant CT benefit in HR+ ESBC. Results from the TAILOR-x study suggest up to 70% of HR+ node negative ESBC patients (pts) may avoid CT with RS ≤25. Our objectives were to assess the clinical and economic impact of RS testing on treatment decisions using real-world data. **Methods:** From October 2011 to February 2019, a retrospective, cross-sectional observational study was conducted of HR+ node negative ESBC pts who had RS testing in Ireland. A survey of Irish breast medical oncologists provided the assumption for the decision impact analysis that grade (G) 1 pts would not receive CT pre RS testing and G2/3 pts would receive CT. Using TAILOR-x results, pts were classified low risk (RS ≤ 25) and high risk (RS > 25). Data was collected via electronic patient records. Descriptive statistics were used. Cost data was obtained via the National Healthcare Pricing Regulatory Authority. The economic analysis was adjusted for changing treatment and assay costs over the study period. **Results:** 963pts were identified. Mean age 56 years. Mean tumour size 1.87cm. 114 (11.8%), 636(66%), 211(22%), 2(0.2%) pts had G1, G2, G3 and unknown G respectively (resp). 797pts (82.8%) had low RS, 159 (16.5%) had high RS, and 7pts(0.7%) unknown RS. 251pts(26%) were aged < 51 at diagnosis. Of these, 45(17.9%), 145(57.8%), 58(23%), 3(1.2) had G1, G2, G3 and unknown G resp. 208pts(82.9%) had RS ≤ 25, 39pts(15.5%) had RS > 25 and 4pts(1.6%) unknown RS. In the RS ≤ 25 group, 111pts(44%) had RS 0-15, 59(23.5%) had RS16-20, and 38(15.1%) had RS21-25. Post RS testing 595pts(61.8%) had a change in CT decision; 586 changed to hormone therapy (HT) alone, and 9 from HT to CT. In total, 227pts(23.5%) received CT, and 3pts(0.3%) declined. Of pts treated with CT; 9(4%) had RS 0-15, 89(39.2%) had RS16-25**,** 129(56.8%) had RS > 25. The most common CT regimen was docetaxel and cyclophosphamide(TC), administered to 121pts(53%). RS assay use achieved a 69% change in treatment decision among G2/3 pts and a net 61% reduction in CT use. This resulted in savings of over €4 million in treatment costs. Deducting the assay cost, net savings of over one million euro was achieved. **Conclusions:** Ireland was the first public healthcare system to approve reimbursement for RS testing. Over the 8 year period of the study, a net 61% reduction in CT use in Irish pts with HR+ ESBC was achieved with conservative net savings of over €1,000,000. Research Sponsor: None.

541 Poster Session (Board #33), Fri, 8:00 AM-11:00 AM

CanAssist breast: An affordable breast cancer prognostic test validated on Asian patients. *First Author: Poonam Patil, Manipal Hospital, Bangalore, India*

Background: Treatment decisions for early stage HR+/HER2neu- breast cancer patients in the West routinely depend on prognostic tests that predict risk of recurrence. However, such tests are rarely used in Asia due to prohibitive costs and lack of validation data on Asian patients. Chemotherapy is thus often a default treatment leading to physiological and financial toxicity. To address these, we have developed CanAssist Breast (CAB) as an affordable IHC-based prognostic test, retrospectively validated on ~1400 patients, 63% South Asians and rest Caucasians. To date CAB has been prescribed by 180+ doctors across 30 cities in India for ~600 patients in clinics, enabling personalized treatment decisions. **Methods:** Primary surgical FFPE blocks and clinical follow-up data were obtained from hospitals. GraphPad Prism and MedCalc were respectively used for Kaplan-Meier survival analyses and Cox logistic regression to calculate hazard ratios. **Results:** The median age of diagnosis in the validation cohort was 56 years, 63% patients with stage II disease and 60% node negative tumors. Distant Metastasis Free Survival (DMFS) in the low-risk category of the validation cohort was 95%, and 84% in high-risk (P < 0.0001). Similar results were obtained with the Caucasian subgroup, as also with the chemotherapy-naive subgroup (30% of the cohort), demonstrating that risk stratification by CAB is unaffected by race or chemotherapy. Next, the performance of CAB was compared with Oncotype DX (ODX). 83% patients stratified as low risk by ODX (RS 0-25) in a sub-cohort of 109 were also stratified as low-risk by CAB. To assess the impact of CAB in treatment decision making, we assessed the data of 589 patients who have undergone CAB testing so far, 288 were identified as low-risk. 93% of these CAB low-risk patients were not given chemotherapy, demonstrating the clinical impact of CAB. **Conclusions:** CAB is the first test of its kind to be retrospectively validated in Asia. It shows high concordance with ODX in risk stratification of patients. CAB has been in clinical practice in India and near-India markets for 2 years and is helping clinicians and patients in making affordable treatment decisions. Research Sponsor: OncoStem Diagnostics.

542 Poster Session (Board #34), Fri, 8:00 AM-11:00 AM

Association of intraoperative opioids with improved recurrence-free survival in triple-negative breast cancer. *First Author: Giacomo Montagna, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Opioid-induced immunomodulation may be of particular importance in triple negative breast cancer (TNBC) where an immune response is associated with improved outcome and response to immunotherapy. We evaluated the association between intraoperative opioids and outcomes in a large TNBC cohort. **Methods:** Consecutive patients with stage I-III primary TNBC treated between 03/2010 and 12/2016 were identified from our prospectively maintained database. Total intraoperative opioid dose was extracted from anesthetic records and converted to oral morphine milligram equivalents (MME) (10 MME = 50 mcg fentanyl IV). Univariable and multivariable (MVA) Cox proportional hazards analysis (adjusting for relevant clinicopathological features, (neo)adjuvant therapy, anesthesia technique and morbidity score), were performed to quantify the association between opioid exposure and recurrence-free survival (RFS) and overall survival (OS). **Results:** 1143 patients were included. Median age was 54 years (IQR 45, 64). 911 (80%) had ductal histology, 359 (31%) had nodal metastases, and 1070 (94%) were poorly differentiated. 781 (68%) received adjuvant chemotherapy and 313 (27%) received neoadjuvant chemotherapy. 525 (46%) received total intravenous anesthesia and 618 (54%) had general anesthesia. Median intraoperative opioid dose was 30 MME (IQR 20, 60). 5-year RFS was 81% (95% CI 79%-84%), 5-year OS was 86% (95% CI 84%-88%). In MVA, higher opioid administration was associated with favorable RFS but did not significantly affect OS (Table). **Conclusions:** Our study is the first to directly evaluate intraoperative opioid administration in TNBC and suggests a protective effect on RFS. Future work will focus on elucidating the underlying mechanism for this effect, including possible modulation of endogenous opioid signaling pathways and immunologic correlates. PD-1 protein and gene expression in early breast cancer: Prognostic implications. *First Author: Ioannis Zerdes, Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden*

Background: We have previously shown the prognostic value of PD-L1 protein and gene expression in early breast cancer (BC), however, the prognostic role of PD-1 expression remains unclear. **Methods:** The prognostic value of PD-1 in early BC was investigated using three different approaches: i) evaluation of PD-1 at the protein (IHC, immunohistochemistry in tissue microarrays) and mRNA levels in a retrospective patient cohort of 586 patients treated for early BC in Stockholm, Sweden between 1997-2005, ii) systematic review and trial-level meta-analysis of studies published in Medline, Embase, Cochrane Library and Web of Science Core Collection libraries on the prognostic value of PD-1 IHC expression, and iii) pooled analysis of transcriptomic data from 39 publicly available datasets for the prognostic capacity of PD-1 gene expression. Univariate and multivariable Cox regression models were used. **Results:** In the retrospective study cohort, PD-1 protein was significantly associated with biologically high-risk characteristics. PD-1 protein, but not gene expression, was correlated with improved overall survival (OS) (adjusted HR = 0.73, 95% CI 0.55 – 0.96, p = 0.023 and adjusted HR = 0.88, 95% CI 0.68 – 1.13, p = 0.307, respectively). In the trial-level meta-analysis, 4736 entries were initially identified and 15 studies, including our original cohort, fulfilled the predefined eligibility criteria. PD-1 IHC expression was not prognostic in unselected patients. However, a significant correlation to improved disease-free survival was seen within the triple-negative subtype (pooled multivariate HR = 0.57, 95% CI 0.29 – 0.90, p = 0.02). In the pooled gene expression analysis, PD-1 gene expression was associated with improved OS in the entire population (adjusted HR = 0.89, 95% CI 0.80 – 0.99, p = 0.025) and in basal-like (adjusted HR = 0.77, 95% CI 0.63 – 0.95, p = 0.014) tumors. **Conclusions:** PD-1 expression at the RNA and protein levels represent promising prognostic factors, especially in the triple-negative and basal-like subtypes. Standardization and further validation are needed prior to clinical implementation. Research Sponsor: Swedish Cancer Society, Cancer Society in Stockholm, Swedish Breast Cancer Association.

546 Poster Session (Board #38), Fri, 8:00 AM-11:00 AM

Tumor-infiltrating lymphocytes in ipsilateral breast tumor recurrences predict prognosis. *First Author: Axel Stenmark Tullberg, Sahlgrenska University Hospital, Västra Frölunda, Sweden*

Background: The antitumoral immune response is dynamic and changes with tumor progression. Previous studies show that immunohistochemical (IHC) assessment of TILs in local recurrences can predict prognosis. It is not clear how adjuvant radiotherapy (RT) can alter the local immune response or if gene expression analyses of TILs in recurrences can provide prognostic information. **Methods:** Matched biopsies from primary tumors and ipsilateral breast tumor recurrences (IBTRs) from the randomized SweBCG91RT trial were assessed for TILs. Analyses were performed using gene expression (86 matched pairs) and IHC assessment (126 matched pairs). **Results:** The median time to IBTR was 8.0 years among irradiated patients and 3.6 years among unirradiated patients. In the gene expression analyses, higher absolute values of CD8+ T cells, CD4+ effector memory and CD8+ effector memory T cells in the recurrence could significantly predict a decreased risk of subsequent distant metastasis. In addition, a net increase of these cells in the IBTR compared to the primary tumor was associated with a significantly lower risk of metastasis. TILs did not change significantly between the matched tumors for the whole group or among irradiated patients versus unirradiated patients in the gene expression or IHC analyses. Surprisingly, the group with unchanged TILs levels as measured by IHC had the lowest risk of metastasis while an increase or a decrease in TILs was significantly associated with an increased risk. **Conclusions:** Cytotoxic and memory T cells in the recurrence protect against subsequent distant metastasis although IHC measurement of TILs could not confirm these results. No significant differences in TILs infiltration between irradiated versus unirradiated patients could be determined in the recurrences. Further analyses including changes of subtypes between the primary tumor and the recurrence will be presented. A novel biosignature to assess residual risk in ductal carcinoma in situ (DCIS) patients after standard treatment. *First Author: Troy Bremer, PreludeDx, Laguna Hills, CA*

Background: There is an unmet need to identify women diagnosed with DCIS with elevated risk after standard treatment for whom enhanced treatment strategies should be considered. A response type (RSt) signature has been assessed in women treated with breast conserving surgery (BCS) with or without radiotherapy (RT), or with mastectomy. **Methods:** Women diagnosed with pure DCIS and treated with BCS or, BCS with whole breast RT were consecutively collected in Sweden, 1986-2004 and the USA, 1999-2008. A third cohort treated with mastectomy was collected in Sweden from 1986-2004. Patients with FFPE tissue were included unless they had prior or simultaneous invasive breast cancer (IBC). The RSt and DCISionRT biosignatures were calculated using biomarkers (p16/INK4A, Ki-67, COX-2, PgR, HER2, FOXA1, SIAH2), scored by board certified pathologists. Pathology and clinical data were collected from medical records. Only women at elevated risk by DCISionRT (DS $>$ 3) and negative margins were included in analysis. Total breast event risk included either ipsilateral DCIS or IBC. Multivariate Cox proportional hazards and survival analysis were used to assess cumulative incidence risk differences, hazard ratios, and 10-year risks adjusted for year of diagnosis. **Results:** Women with a poor RSt were all HER2 positive and remained at particularly elevated risk after BCS and RT (23% 10-yr risk, $p < 0.0001$, Table), with a risk profile similar to women treated with BCS without RT (RSt not evaluated). The distribution of age and size were not statistically different for good versus poor RSt, but poor RSt were more commonly Grade 3. In a small cohort of women treated with mastectomy, those women with a poor RSt were still at elevated risk after surgery, comparered to women with a good RSt (HR = 5.4, p = 0.014). The 10-year risk profile for women with a good RSt treated with BCS plus RT or mastectomy, was low (table). **Conclusions:** A novel biosignature identified women with a good and poor RSt, where the good RSt identified women with an apparent substantial benefit from RT, as well as women with a poor RSt who remained at particularly elevated risk after RT, and for whom enhanced treatment strategies should be considered. Additional validation studies are ongoing. Research Sponsor: PreludeDx, Other Government Agency.

Elevated DCISionRT Risk, DS > 3 and Negative Margins	Patients	Events	10-year Risk (95% CI) *
BCS with no RT	106	29	22% (10-32)
BCS+RT; Good RSt	141	5	4% (0-8)

Novel association of pre-chemotherapy immune cell profiles with functional decline and resilience in women with breast cancer receiving chemotherapy. *First Author: Nikesha Gilmore, University of Rochester Medical Center, Rochester, NY*

Background: Chemotherapy adversely affects physical function. While many patients recover after treatment (i.e. are resilient), some are unable to return to their pre-treatment function (i.e. are non-resilient). Since immune dysfunction may play a role in functional decline, we assessed the relationship of pre-chemotherapy immune cell profiles with functional decline and resilience in women with breast cancer receiving chemotherapy. **Methods:** This study was based on a large nationwide cohort study in women with stage I-III breast cancer. Physical function was measured by the Functional Assessment of Cancer Therapy: General – Physical subscale (FACT-PWB) ≤7 days before chemotherapy (T1), ≤1 month after chemotherapy (T2), and 6 months after T2 (T3). Functional decline at T2 and T3 was defined as $>$ 1 point decrease (clinically meaningful difference) in FACT-PWD score from T1. Patients were considered non-resilient if they had T2 functional decline and did not return to within 1 point of their baseline FACT-PWB score by T3. Immune cell counts, neutrophil:lymphocyte ratio (NLR), and lymphocyte:monocyte ratio (LMR) were obtained at T1. Multivariate logistic regressions were used to determine whether immune cell counts and ratios were associated with functional decline and being non-resilient controlling for baseline FACT-PWD, age, race, education, and marital status. **Results:** One-third of patients (178/529; mean age 53, range 22-81) had functional decline from T1-T3. Of the 59% (n = 310) of patients with functional decline at T2, 50% (n = 147) did not recover by T3 (i.e. were non-resilient). Patients with a low ($<$ median) NLR at T1 were twice as likely to have functional decline by T3 than those with a high (≥ median) NLR [Adjusted Odds Ratio (AOR) 1.8, 95% CI: 1.2-2.8, $p < 0.01$]. Similarly, in patients with functional decline at T2, those with a low NLR at T1 were twice as likely to be non-resilient than those with high NLR (AOR: 1.9, 95% CI: 1.1-3.2, p = 0.01). Conversely, patients with high T1 lymphocytes were twice as likely to be non-resilient than those with low lymphocytes (AOR: 1.8, 95% CI: 1.1-3.1, p = 0.02). **Conclusions:** One-third of women with breast cancer have clinically meaningful, persistent functional decline six months after completing chemotherapy. Higher pre-chemotherapy lymphocytes and lower NLR may be useful to identify which women are at increased risk of functional decline and reduced ability to regain baseline physical function. These findings can inform interventions to ameliorate this decline. Research Sponsor: U.S. National Institutes of Health.

Expanding criteria for prognostic stage IA disease in HR+ breast cancer. *First Author: Olga Kantor, Dana-Farber/Brigham and Women's Cancer Center, Boston, MA*

Background: The 8th ed AJCC staging system incorporated grade, receptor status and the Oncotype DX Recurrence Score (RS) result into staging. Based on TAILORx trial data and evidence of utility for RS results in node positive disease, this study was undertaken to determine if staging should incorporate expanded RS criteria. **Methods:** Patients (pts) with T1-3N0-3 HR+HER2- disease undergoing surgery 2010-15 were identified in the SEER database. 5yr DSS was estimated based on T and N category, grade and RS result; differences were compared between pts with path prognostic stage IA disease and all other groups. **Results:** 154,054 pts were identified; median follow up was 49 mo (range 0-83). RS results were obtained in 60,886 (39.5%); RS $<$11 in 13,570 (22.3%) and RS 11-25 in 39,240 (64.5%). The table details 5yr DSS rates. 5yr DSS for path prognostic stage IA pts (n=114,675, 73.4%) was 98.2%. Among all pts with RS $<$11, 5yr DSS was excellent and not significantly different than for path prognostic stage IA pts. For those with RS 11-25 not receiving chemo, 5yr DSS was inferior to path prognostic stage IA disease for T1-2N1 pts and for those with T2-3N0 disease although among N0 pts the differences were numerically small (1.4%-2.5% vs overall path prognostic stage IA). **Conclusions:** Pts with Recurrence Score $<$11 have excellent 5yr DSS regardless of T and N category or grade suggesting further modification of the AJCC staging system using this cutoff. Additional study is required to optimize staging for patients with Recurrence Score 11-25. Research Sponsor: None.

Distinct genomic profiles of 589 Chinese early-stage breast cancer. *First Author: Ning Liao, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China, Guangzhou, China*

Background: Extensive efforts by The Cancer Genome Atlas (TCGA) Network had provided much of our current understanding of the molecular profile of various solid tumors including breast tumors; however, Asian patients were underrepresented in this cohort. In this study, we aimed to elucidate the comprehensive genetic alteration profile of early-stage breast tumors among Chinese patients. **Methods:** Surgical tissue samples from 589 Chinese women with stage I-III breast cancer with various histology and molecular subtype consecutively diagnosed at Guangdong Provincial People's Hospital were sequenced using a panel targeting 520 cancer-related genes spanning 1.64Mb of the human genome. Clinical and genomic data from our cohort was compared with publicly-available data from 1,046 stage I-III breast cancer patients from the TCGA dataset. **Results:** Based on the analysis of the genetic alteration profile from our cohort, at least one genetic alteration was observed from 98% of the tumor samples, with *TP53* (47%), *PIK3CA* (45%), *ERBB2* (30%), and *CDK12* (18%) as the most commonly altered genes. The most common genetic alteration types were copy number amplification (43.6%) and missense mutations (36.8%). As compared with the TCGA dataset, our cohort is mostly composed of women 50 years and younger (59.1% vs. 30.4%, $P< 0.001$), with significantly fewer patients with lobular carcinoma histology (2.4% vs. 19.0%, $P< 0.001$), and significantly more patients with pathologic stage I tumors (23.3% vs. 17.3%, $P= 0.012$). Consistently, genetic alterations detected from our cohort affected genes involved in PI3K (63% vs. 56%, $P= 0.009$) and cell cycle (23% vs. 35%, $P< 0.001$) pathways, with statistically different genetic alteration rates as compared with the TCGA dataset. Comparison of genetic alteration profile between the two cohorts revealed that our cohort had more frequent genetic alterations in genes including *PIK3CA* ($P< 0.001$), *TP53*, particularly in hotspot mutations Q192* ($P< 0.001$) and A307V/del ($P= 0.02$), and *ERBB2* amplification ($P< 0.001$). **Conclusions:** Our study contributes to the understanding of the key pathways and specific genetic alterations harbored by Chinese patients with early-stage breast cancer that could potentially be developed as markers of treatment response to targeted therapeutics. Research Sponsor: This study was supported by funding from National Natural Science Foundation of China (Grant No.81602645),Guangdong Provincial Natural Science Foundation (Grant No.2016A030313768).

553 Poster Session (Board #45), Fri, 8:00 AM-11:00 AM

Next-generation sequencing (NGS) identifies a new breast cancer subtype with HER2 low-amplification status as a candidate for targeted therapy. *First Author: Guo-Chun Zhang, Department of Breast Cancer, Cancer Center, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: HER2 expression or amplification qualify patients to receive targeted therapeutics against HER2; however, traditional methods of quantifying HER2 amplification using fluorescence in situ hybridization (FISH) do not include a reliable definition for low level amplification. With the promising response rate of patients with low HER2 amplified-metastatic breast cancer to subsequent-line trastuzumab deruxtecan (DS-8201a) therapy, there is a need to improve the existing criteria to accurately identify patients with low HER2. In our study, we investigate whether HER2 amplification quantified by NGS could provide a method to stratify patients into subgroups. **Methods:** A total of 774 patients diagnosed with breast cancer from Guangdong Provincial People's Hospital (GDPH) who underwent targeted NGS using 520 or 33 cancer-related genes and had their HER2 status evaluated with either FISH or IHC were included in this study. HER2 status were defined as per 2018 ASCO/ACP guidelines. **Results:** Our results demonstrate that NGS could quantify HER2 amplification with high sensitivity and specificity, with area under the curve of 0.990 [95%CI: 0.982-0.999]. The receiver operating curve indicated an optimal cut-off of 2.62 copy number (CN) for identifying IHC/FISH HER2-negative status with 97.8% specificity. Meanwhile, the cut-off of $\geq$ 3.62 CN identified patients with IHC/FISH HER2-positive status with 99.8% specificity. Among the 774 patients, 65.8% (n = 509) had HER2 CN of $\leq$ 2.62 and were classified as HER2 non-amplified, while 25.8% (n = 199) had HER2 CN of $\geq$ 3.62, classified as HER2-amplified. The remaining 66 patients (8.5%) had HER2 CN between 2.62 and 3.62, and were the patients with heterogeneous IHC/FISH results, classified using NGS as HER2 low-amplified. Patients with low-amplified (49.0% vs. 38.8%, $P < 0.001$) and amplified (50.3% vs. 38.8%, $P < 0.001$) HER2 had significantly more number of copy number amplifications in other gene, including CDK12, RARA, and SPOP ($P < 0.001$, $P < 0.001$) than patients with HER2 non-amplified, indicating distinct mutation profile. **Conclusions:** Our results demonstrate that NGS could provide a more accurate stratification of patients based on their HER2 amplification levels. Patients with low levels of HER2 amplification has a distinct mutation profile, suggesting that NGS could serve as a robust tool to identify patients with HER2 amplification, whether high or low, who could benefit treatment with targeted agents designed against heterogeneous HER2 expression. Research Sponsor: This study was supported by funding from National Natural Science Foundation of China (Grant No.81602645), Guangdong Provincial Natural Science Foundation (Grant No.2016A030313768).

554 Poster Session (Board #46), Fri, 8:00 AM-11:00 AM

Somatic and germline mutation profiles of Chinese breast cancer patients younger than 35. *First Author: Ning Liao, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China, Guangzhou, China*

Background: Limited studies have investigated the molecular underpinnings driving breast cancer development in Chinese younger women. Based from our previous data, more Chinese women are diagnosed with early-onset breast cancer than in the West. In our study, we aim to investigate the comprehensive mutational profile of Chinese women 35 years old and younger ($\leq$35y) diagnosed with breast cancer. **Methods:** Targeted sequencing was performed on surgically-removed tumor tissues and blood samples collected from 589 women diagnosed with stage I-III breast cancer of various molecular subtypes at the Guangdong Provincial People's Hospital (GPDH) using a gene panel interrogating 520 cancer-related genes. We compared the data of 53 women aged $\leq$35y from our cohort to the data from 33 breast cancer patients aged $\leq$35y included in The Cancer Genome Atlas (TCGA) dataset. **Results:** Among the women aged $\leq$35y with early-stage breast cancer from both cohorts, our cohort had more number of hormone receptor-positive (HR+) patients (GPDH, 72% vs. TCGA, 61%, $P< 0.001$). Analysis revealed an overall mutation detection rate of 98% in our cohort, with mutations affecting genes involved in the PI3K pathway (47%) and cell cycle pathway (23%). *TP53* and *PIK3CA* were the most commonly mutated genes, with mutation rates of 51% and 25% from our cohort. No statistical difference in mutation profile was found between GPDH and TCGA cohorts. Moreover, germline mutations considered as pathogenic and likely pathogenic (P/LP) in breast cancer susceptibility genes including *BRCA1* (n = 4), *BRCA2* (n = 2), *PALB2* (n = 1), *PMS2* (n = 1), *PTEN* (n = 1), and *ATM* (n = 1) were detected from 18.9% (10/53) of the patients from our cohort. Women aged $\leq$35y had significantly more germline *BRCA1* mutations than patients $>$ 35y from our cohort (7.5%, 4/53 vs. 2.1%, 11/536 $P= 0.049$). **Conclusions:** Our study has identified the involvement of PI3K and cell cycle as the two key pathways in the early development of breast tumors in younger women. In addition, our results also support the role of P/LP germline mutations in breast oncogenesis in Chinese patients with early-onset breast cancer, indicating the need to include a more comprehensive germline mutation screening in our population. Research Sponsor: This study was supported by funding from National Natural Science Foundation of China (Grant No.81602645), Guangdong Provincial Natural Science Foundation (Grant No.2016A030313768).

555 Poster Session (Board #47), Fri, 8:00 AM-11:00 AM

Modulation by treatment of tumor infiltrating lymphocytes (TILs) and PDL1 expression in triple-negative breast cancer in the ETNA trial. *First Author: Giampaolo Bianchini, IRCCS San Raffaele Hospital, Milan, Italy*

Background: We assessed TILs and PDL1 expression before, during and after neoadjuvant treatment in TNBC patients enrolled in the ETNA study, and investigated associations with clinical outcome. **Methods:** In ETNA patients randomly received paclitaxel or nab-paclitaxel followed by 4 cycles of an anthracycline regimen, including 219 centrally confirmed TNBC. We successfully measured stromal and intratumoral TILs (sTILs, iTILs) and PDL1 status (Ventana SP142, IC$\geq$1%) on biopsies before [n = 186/213 (84.9%)], on d1 cycle 2 (d1c2) of therapy [n = 41/186 (22.0%)], and at surgery [SX, n = 65/129 (34.9%)]. We investigated the expression and modulation over time of TILs and PDL1 and their association with pCR and event-free survival (EFS). **Results:** Prevalence of PDL1+ was 35.5% (baseline), 20.6% (d1c2) and 30.1% (SX). At each time-point sTILs and iTILs were higher in PDL1+ cases ($p\leq0.01$). An effect of age of the tumor blocks (5-7.5 years) or pre-analytical issues could not be ruled out for the relatively low rate of PDL1 positivity. Paired PDL1 at baseline and d1c2 showed conversion in 25.7% (pos to neg [11.4%] or neg to pos [14.3%]). Comparing PDL1 at baseline and SX, the conversion rate was 30% (pos to neg [8.3%] or neg to pos [21.6%]). sTILs and iTILs significantly increased at cycle 2, more significantly in pCR ($p\leq0.001$) than in RD ($p\leq0.05$) cases, and a not significant trend of decrease was observed at surgery PDL1+ tumors had a higher pCR rate (54.7% vs 32.5%, p = 0.004). PDL1 retained significance (OR 2.00 [1.04-3.88], p = 0.039) after adjustment for sTILs (OR 1.21 [1.03-1.42], p = 0.021). High iTILs and sTILs at d1c2, but not PDL1 status, were predictive of pCR. Notably, adjusting for sTILs, PDL1+ tumors at d1c2 showed a trend for association with lower pCR rate (OR 0.06 [0.01-1.15], p = 0.062). sTILs at cycle 2 was the most informative variable (OR 1.61 [1.28-1.61], p = 0.004) and provided independent information to baseline biomarkers. Baseline PDL1 and biomarkers at cycle 2 were not associated with EFS. In surgical samples with RD, higher sTILs, but not iTILs and PDL1 status, were associated with a trend for a lower risk of recurrence (HR 0.19 [0.02-1.39], p = 0.068). **Conclusions:** sTILs assessment on core biopsies after one cycle of taxane is a promising early biomarker of pCR. PDL1, as well as sTILs and iTILs, provided independent prediction of pCR and were strongly modulated by treatment. The modulation of PDL1 expression should be considered whenever PDL1 is assessed in view of identifying candidates to atezolizumab in 1st line advanced setting. Basal subtype and clinical estrogen receptor status of genomically basal breast tumors in Caucasian, African American, and Latin American patients. *First Author: Virginia G. Kaklamani, University of Texas San Antonio MD Anderson Cancer Center, San Antonio, TX*

Background: Genomically basal-type breast cancer is a heterogenous subtype that occurs at higher frequencies in non-Caucasian patients. Triple negative breast cancer (TNBC) has been refined into distinct transcriptomic groups including the basal-like immunoactive (BLIA), basal-like immunosuppressed (BLIS), luminal androgen receptor (LAR), and mesenchymal (MES) subtypes. Here we report the distribution of triple negative subtypes in genomically basal cancers from Caucasian (CA), African American (AA), and Latin American (LA) patients and the association of clinical estrogen receptor (ER) status. **Methods:** The FLEX Registry (NCT03053193) is an ongoing, prospective study evaluating primary tumors from patients with stage I-III breast cancer who receive the 70-gene signature and 80-gene signature (80-GS) molecular testing and consent to clinically annotated full transcriptome data collection. This sub-analysis evaluated 143 80-GS Basal type tumors from patients with self-reported ethnicity (60 CA, 59 AA, 24 LA). TNBC subtypes BLIA, BLIS, LAR, and MES were derived using an adjusted version of the 80-gene centroid signature published by Burstein and colleagues (2015). Differences in clinical ER expression between ethnicities were assessed by Fisher's exact test. **Results:** Basal indices from 80-GS were not influenced by patient ethnicity (one-way ANOVA, p = 0.182). The frequency of BLIA, BLIS, LAR, and MES subtypes did not vary significantly by ethnicity (Fisher's exact test, p = 0.671). The majority of tumors in all ethnic groups were BLIS (67% CA, 75% AA, 63% LA), followed by BLIA (22% CA, 22% AA, 25% LA), with low frequency of LAR (5% CA, 1.7% AA, 8.3% LA) and MES (5% CA, 1.7% AA, 4.2% LA) subtypes. Nearly one third (31%) of Basal type tumors were defined by IHC as ER positive and were present in all TNBC subtypes (39% BLIA, 29% BLIS, 33% LAR, and 20% MES); ER receptor expression ranged from 1-90% and was not associated with specific basal subtype (p = 0.8) nor ethnicity (P = 0.76). Progesterone receptor expression ranged from 1-50%. **Conclusions:** This analysis demonstrated that genomic Basal type tumor classification by 80-GS encompasses all TNBC subtypes evaluated regardless of ethnicity. Additionally, we show that IHC ER positive tumors occur in all TNBC subtypes assessed. These findings confirm the heterogeneous nature of basal breast tumors in CA, AA, and LA patients and highlight the clinical need to delineate basal biology in the ER+ cohort to advance treatment for basal-like tumors. Clinical trial information: NCT03053193. Research Sponsor: Agendia.

The quantitation of thioredoxin 1 from serum as a novel means to detect breast cancer (BC). *First Author: Kyoung Hoon Suh, E&S Healthcare, Daejeon, South Korea*

Background: Breast cancer (BC) is the most common cancer and the second leading cause of cancer death in women. Enormous effort has been conducted without success to develop a means to detect BC using the blood. We have reported that the level of thioredoxin 1 (Trx1) in serum could be a novel standard to evaluate the risk of BC. Therefore, we have investigated the clinical utility of Trx1 as a biomarker to detect BC by testing sera from normal women, women with BC, women with five other types of cancer. **Methods:** We have developed an ELISA kit that quantitates Trx1 in sera. The level of Trx1 was determined in each serum from normal healthy women (n = 114), as well as patients with BC (n = 106), cervical cancer (n = 17), lung cancer (n = 14), stomach cancer (n = 9), and thyroid cancer (n = 4). BC patients were recruited according to their age and cancer stage. Each test was duplicated more than three times, and test results were analyzed by ROC analysis, one-way ANOVA tests, and unpaired t-tests. **Results:** The mean value of Trx1 from normal women was 5.60±4.39(±SD) and that from BC was 22.25±7.07. The Trx1 level was effective to distinguish BC serum from healthy serum with a sensitivity of 94.3% and specificity of 93.9% (AUC 0.985, $p < 0.001$). The levels of Trx1 from BC patients were higher than the cut-off value of 14.13 U/ml regardless of age, stage, histological grade, type, ER/PR/HER2 expression profile, and proliferation activity of BC cells. The levels of Trx1 from the other five types of cancers (2.34±1.82 - 3.64±2.99) were low enough to be distinguishable from BC. Especially, Trx1 levels could rescue patients whose mammography resulted in a false judgement. **Conclusions:** These results indicated that the blood level of Trx1 is an effective and accurate method to detect breast cancer, and particularly as a complement to mammography. Next generation sequencing reveals CCNE1 amplification as an independent prognostic factor for triple negative breast cancer (TNBC) patients. *First Author: Xin Huang, Peking Union Medical College Hospital, Beijing, China*

Background: Triple negative breast cancer (TNBC) has the worst prognosis among breast cancer due to the heterogeneity as well as lack of better therapeutic approach. It remains controversial whether *BRCA* status is the predictor of survival in TNBC. Besides, both germline and somatic mutation may contribute to the prognosis. This study is to explore the potential predictors and therapeutic targets based on genetic data and clinicopathological parameters. **Methods:** Seventy-five TNBC patients were enrolled with approximately 2:1 based on *BRCA* status. Genetic data was analysed by comprehensive genomic profiling 508 key cancer related genes. DAVID was applied to perform pathway enrichment analysis of significant enriched genetic alterations. Cox regression model was applied to evaluate disease-free survival (DFS) and overall survival (OS). Immuno-chemistry (IHC) was used to validate clinically meaningful genetic alteration. **Results:** In this study, 27 germline mutations were detected, including 26 homologous recombination repair (HRR) pathway gene mutations and 1 mismatch repair gene mutation among them 16 *BRCA1* mutations and 5 *BRCA2* mutations were found. Germline HRR including *BRCA1/2* mutation marginally affected DFS ($p = 0.0624$ and 0.15, respectively). We found 480 somatic genetic alterations including 110 copy number variations (CNV). The median value of TMB was determined to be 4.1 Muts/Mb which divided 74 TNBC patients into TMB-low (TMB-l) and TMB-high (TMB-h) group. TMB-l group had inferior DFS to TMB-h ($p = 0.0457$). *CCNE1* (with 5% frequency) copy number gain was specifically enriched in TMB-l group but mutually exclusive with *BRCA1/2* mutation. TNBC with *CCNE1* gain displayed worse DFS ($p < 0.0001$). Cox multivariate regression analysis indicated *CCNE1* gain was an independent risk factors for DFS [HR = 13.48 (95% CI 2.62-69.23), $p = 0.002$)]. Pathway analysis indicated *CCNE1* harmed prognosis through regulation of transcription in G1/S phase. Expression of cyclin E1 was validated by IHC, which would be presented later. **Conclusions:** Comprehensive genomic profiling disclosed various potential prognostic markers for TNBC by integrating clinical characters. Especially, amplified *CCNE1* may be a potential prognostic marker and therapeutic target. Research Sponsor: None.

CCNE1	DFS			OS		
Kaplan-Meier univariate		$p < 0.0001$			$p = 0.166$

Novel estrogen receptor beta agonist S-equol decreases tumor proliferation in patients with triple negative breast cancer (TNBC). *First Author: Kate Ida Lathrop, The University of Texas San Antonio Mays Cancer Center, San Antonio, TX*

Background: Patients with TNBC breast cancer have inferior treatment outcomes compared to other breast cancer subtypes and targeted therapies are lacking. S-equol is a novel oral Estrogen Receptor (ER) Beta agonist with preclinical data showing suppression of TNBC cellular proliferation. We therefore conducted an early phase window of opportunity trial to evaluate the impact of S-equol on Ki-67 change in patients with TNBC. **Methods:** This neoadjuvant window trial enrolled 39 patients with confirmed TNBC on diagnostic core needle biopsy. Cohort A (20 patients) received a daily dose of 50 mg daily and Cohort B (19 patients) received a higher dose of 150 mg daily. Paired biopsies were evaluable for 36 patients. Both cohorts were treated for a duration of 10-21 days. Primary outcome was change from pre- to post-treatment Ki-67 evaluated by paired t-test. All tests were 2-sided with a significance level of 0.05. Statistics were conducted within an accountable data analysis process in R (ADAPR). Secondary outcomes included toxicity and correlative biomarkers. **Results:** The mean (SD) pre-treatment was 68% (21.99) and post-treatment 59% (20.62). The average decrease in Ki-67 was 8% (P = 0.00206, 95% CI -13.46 to -3.26). A Ki-67 decrease of at least 20% from baseline was observed in 28% of the patients. S-equol was well tolerated with the most common toxicities being nausea, constipation, diarrhea, and headache. All toxicities were grade one. Treatment compliance was greater than 95%. Planned correlative studies included RNA-seq. A total of 161 genes are differentially expressed with fold change $> = 2$ and p value < 0.05. The top genes of the differential expression list include BMP5, S100A7, FABP7, SCGB2A2, CH507-338C24.1, and DUSP1. Gene Set Enrichment Analysis (GSEA) indicates that top enriched gene modules are related to interferon function and immune response, most of which are downregulated in the post-treatment group. **Conclusions:** S-equol is a novel well tolerated oral ER-Beta agonist with inhibition of proliferation in patients with TNBC as measured by a decrease in Ki-67. RNA-seq data supports potential immune activation during this short period of drug exposure. Future studies aim to evaluate S-equol as an immune activating agent for combination with immunotherapies such as checkpoint inhibitors in TNBC. Clinical trial information: NCT02352025. Research Sponsor: Ausio Pharmaceuticals.

561 Poster Session (Board #53), Fri, 8:00 AM-11:00 AM

Incidence of PI3K pathway alteration and response to neoadjuvant therapy (NAT) in triple negative breast cancer (TNBC) subtypes. *First Author: Reva K Basho, Cedars-Sinai Medical Center, Houston, TX*

Background: Limited cell line and human data suggest that TNBCs characterized as mesenchymal and luminal androgen receptor (LAR) commonly have alterations in the PI3K pathway. More data is needed to better characterize the role of the PI3K pathway across TNBC subtypes. **Methods:** Pre-treatment tumor biopsies were collected from operable TNBC patients (pts) enrolled on a clinical trial of genomically tailored NAT (ARTEMIS; NCT02276443). Tumors were categorized into 5 groups using the Pietenpol criteria: basal-like (BL) comprised of BL-1 and BL-2, mesenchymal and mesenchymal stem-like (M), immunomodulatory (IM), LAR, or unspecified (UNS). Using whole exome sequencing data, variants (single nucleotide polymorphisms and insertions/deletions) and copy number variations (CNVs) were identified in 32 genes known to activate the PI3K pathway. **Results:** Tumor subtyping and pathologic response to NAT was available in 127 pts (clinical stage I: 9; II: 84; III: 34). PI3K pathway alteration defined as a variant in one of the evaluated genes and/or deletion of PTEN was seen in 76 (60%) tumors. The most frequent alterations were: PTEN deletion (21%), PIK3CA variant (11%), and PIK3R1 variant (8%). PI3K alteration and residual cancer burden (RCB) rates across TNBC subtypes are shown in the table. There was a significant difference in pathologic complete response (pCR)/RCB 0 rate after NAT across TNBC subtypes (chi^2 test; P = 0.02). There was a significant difference in the incidence of PI3K pathway alteration across TNBC subtypes (chi^2 test; $P < 0.01$). Overall, the presence of PI3K alteration was not associated with pCR (Fisher exact test; P = 0.85). Pts with M tumors had a higher rate of substantial residual disease (RCB II-III) after NAT. Presence of PI3K pathway alteration was common in the M subtype and associated with RCB II-III (82% in PI3K-altered vs 33% in wild-type tumors; Fisher exact test; P = 0.02). Presence of PI3K pathway alteration was common but not associated with response in the LAR subtype. **Conclusions:** The incidence of PI3K pathway alteration varied by TNBC subtype but was not associated with pathologic response to NAT with the exception of increased substantial residual disease (RCB II-III) in the M subtype. Research Sponsor: MD Anderson MoonShot, Conquer Cancer Foundation of the American Society of Clinical Oncology.

Impact of metastases directed radiation therapy on CDK4/6 inhibitors dose reduction and treatment discontinuation for metastatic HR+/HER2- breast cancer (MBC). *First Author: Icro Meattini, Radiation Oncology Unit-Oncology Department, University of Florence, Florence, Italy*

Background: Cyclin-Dependent Kinase 4/6 inhibitors (CDK4/6i) represent the standard I-II line for hormonal receptors positive/human epidermal growth factor receptor 2 negative metastatic breast cancer (MBC) patients. Metastases directed radiotherapy (RT) for these patients is commonly used with palliative or radical schedules during systemic treatment. Although encouraging preliminary results were published, there is still a lack of robust data on the safety concerning RT during CDK4/6i treatment. **Methods:** we analyzed at Our Institution 85 consecutive patients treated in I (n=47) and II line (n=38) for MBC with CDK4/6i between April 2017 and September 2019 (22 ribociclib, 63 palbociclib). Overall, 25 (29.4%) patients received metastases directed RT during CDK4/6i treatment, including 14 concomitant (16.5%) and 11 sequential (12.9%). Estimated CDK4/6i half-life is 26 and 30 hours for palbociclib and ribociclib, respectively. Five half-lives are required to reduce drug concentration by 95-97%; thus, we also analyzed CDK4/6i treatment as non-concomitant or sequential to RT. Main endpoints of our analysis were impact of RT on CDK4/6i dose reduction and discontinuation, overall adverse events rate (any grade and grade ≥2), and neutropenia grade ≥2 as per CTCAE scale version 5.0. **Results:** at a median follow up of 12 months (range 3-29), we observed a CDK4/6i dose reduction in 35 patients (41.2%) and 5 patients (5.9%) discontinued treatment due to adverse events; 82 patients (96.5%) experienced any grade of toxicity, 72 (84.7%) a grade ≥2 and 70 patients (82.4%) neutropenia grade ≥2. We did not observe significant difference in terms of CDK4/6i dose reduction or discontinuation, any grade or grade ≥2 toxicity, neutropenia grade ≥2 in the comparison between patients receiving RT *versus* no RT and between patients receiving concomitant RT versus sequential RT versus no-RT (Table). **Conclusions:** our results showed that the prescription of a metastases directed RT during treatment with a CDK4/6i as I-II line for MBC did not significantly impact on dose reduction or discontinuation caused by an exceeding in adverse event rate. Although these promising results, caution should be used and cooperative initiatives strongly encouraged. Research Sponsor: None.

Endpoint	RT (n=25) *vs* No-RT (n=60), P-value	Concomitant RT (n=14) *vs* Sequential RT (n=11) *vs* No-RT (n=60), P-value
CDK4/6i dose reduction	1.0	0.88
CDK4/6i discontinuation	1.0	0.56
Adverse events, any grade	1.0	0.47
Adverse events, grade ≥2	0.096	0.14
Neutropenia, grade ≥2	0.057	0.087

563 Poster Session (Board #55), Fri, 8:00 AM-11:00 AM

Clinical utility of 18F-FDG-PET/CT in staging localized breast cancer prior to initiating preoperative systemic therapy. *First Author: Heidi Ko, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY*

Background: 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography (PET/CT) is recommended as an optional study in current National Comprehensive Cancer Network (NCCN) guidelines after computerized tomography and bone scan (CTBS) in patients with stage IIA-IIIC breast cancer. We evaluated our experience with use of PET/CT in this setting prior to beginning primary systemic therapy (PST) before planned surgery. **Methods:** We performed medical record abstractions to identify all adult female patients with clinical stage IIA to IIIC breast cancer diagnosed at Montefiore Medical Center from January 1, 2014 to January 1, 2019 who underwent PET/CT. We calculated the proportion of patients upstaged after PET/CT, stratified by their initial clinical stages and use of PST, and examined the cost and radiation exposure associated with PET/CT compared with CTBS. **Results:** 227 patients with 230 breast cancers (bilateral disease in 3) met the study inclusion criteria. PET/CT was the only staging done in 195 patients (86%); 32 patients had PET/CT based on suspicious findings from prior CTBS. Among these 195 patients with 196 breast cancers (bilateral disease in 1) that had PET/CT as the only staging done, the overall upstaging rate for regional nodal and/or distant metastasis was 37% (73/196), including 24% for stage IIA (9/38), 39% for IIB (31/79), 54% for IIIA (22/41), 27% for IIIB (8/30), and 37% for IIIC (3/8). The overall upstaging rate to stage IV was 14% (27/196), including 0% for stage IIA, 13% for IIB (10/79), 22% for IIIA (9/41), 17% for IIIB (5/30), and 37% for IIIC (3/8). The sensitivity and specificity of PET/CT in detecting distant metastasis was 100% and 94%, respectively. Our institution's total Medicare reimbursement rate of PET/CT is $1604.37 whereas CTBS is $1679.94. Radiation dose for PET/CT is 14 mSv whereas CTBS is 21 mSv. **Conclusions:** Approximately 37% of patients with clinical stage IIA-IIIC breast cancer who underwent PET/CT prior to PST showed more extensive disease, including 23% with more extensive regional nodal metastases and 14% with distant metastasis. Given the high detection rate, comparable cost, lower radiation dose and greater convenience, PET/CT should be considered as an alternative to CTBS rather than "optional" after CTBS, especially in patients who require an efficient and expeditious work up prior to initiating PST. Can sentinel node biopsy after neoadjuvant systemic chemotherapy (NAC) be safely omitted in selected patient with early breast cancer? *First Author: Atsushi Yoshida, St. Luke's International Hospital, Tokyo, Japan*

Background: There is a recent trend of performing minimum axillary surgery considering the prognostic value and fewer complications for primary breast cancer patients since the results of ACOSOG Z011. Nodal status after NAC is not be useful for postoperative treatment in most of cN0 patients. Therefore, sentinel node biopsy (SNB) may be omitted if ypN0 after NAC can be predicted in cN0 patients. We assessed clinicopathological factors associated with ypN0 after NAC in cN0 primary breast cancer patients. **Methods:** Two-institutional retrospective cohort study of clinically N0 breast cancer patients before NAC and who underwent breast surgery was conducted, including 419 consecutive patients between 2009 and 2016 in St. Luke's International Hospital and St. Marianna University School of Medicine hospital. Each institutional review board approved this study. In the patients with or without nodal metastasis on SNB after NAC, we compared clinicopathological factors including Estrogen Receptor (ER), Progesterone Receptor (PgR), human epidermal growth factor receptor 2 (HER2), Ki-67 on needle biopsy specimens, and tumor size before and after NAC on MRI findings. **Results:** Of the 419 patients, 380 patients (90.7%) were ypN0 and 39 patients (9.3%) were ypN+ after NAC. In univariate analysis, clinical complete response of primary tumor on MRI findings (MRI-CR) ($p<0.01$), ER-negative ($p<0.01$), PgR-negative ($p<0.01$), and high-Ki-67 >30% ($p<0.01$) were significantly associated with ypN0 on SNB after NAC. In multivariate analysis, MRI-CR (HR 5.12, $p<0.01$) and high-Ki-67 (HR 2.86, $p<0.01$) were independent predictive factors of ypN0 after NAC.According to breast cancer subtype, only one of 72 ER-negative and HER2-positive had significantly low risk of ypN+ (1.3%) comparing other subtypes ($p<0.01$). **Conclusions:** Achieving cCR of primary tumor after NAC and high-Ki67 in cN0 patients, especially in HER2 type breast cancer, might have ypN0. We are conducting prospective study to omit SNB for these populations based on these results, Research Sponsor: None.

Artificial intelligence to accurately identify breast cancer patients with a pathologic complete response for omission of surgery after neoadjuvant systemic therapy: An international multicenter analysis. *First Author: André Pfob, Department of Obstetrics and Gynecology, University Hospital Heidelberg, Heidelberg, Germany*

Background: Neoadjuvant systemic treatment elicits a pathologic complete response (pCR) in up to 80% of women with breast cancer. In such cases, breast surgery, the gold standard for confirming pCR in the breast, may be considered overtreatment. So far, no approach alone – e.g. imaging, vacuum-assisted biopsy (VAB) – has accurately detected and excluded residual disease without surgery in multicenter prospective trials. We evaluated the ability of Artificial Intelligence algorithms to securely identify patients with residual tumor in the breast to safely select patients who might be spared from surgery. **Methods:** We collected multicenter, international data from 570 women who were included in prospective trials with initial stage I-III breast cancer of all biological subtypes and at least partial response on imaging, undergoing VAB before guideline-adherent surgery. We trained an ensemble of algorithms (including Regularized Regression, Support Vector Machines, and Neural Network) using 27 patient, tumor and VAB variables. Data were randomly partitioned into training and test sample with a 3:1 ratio and developed with 10-fold cross-validation. Primary endpoint was the sensitivity to diagnose residual disease by algorithm compared to surgery. Diagnostic performance of the algorithm was further evaluated on an external, independent dataset. **Results:** The algorithm was able to reliably identify women with residual disease before surgery (see table): Sensitivity for the internal test set was 96.9% (94 of 97; 95%CI 91.2-99.4%) and for the external, independent dataset 96.2% (26 of 27; 95%CI 80.4-99.9%). Most informative predictor of residual disease were tumor cells diagnosed in the VAB specimen, DCIS in the initial diagnostic biopsy, grading, and largest diameter on imaging after neoadjuvant treatment. **Conclusions:** Safely selected patients without residual disease as assessed by our algorithm may be spared by breast surgery in future trials. Research Sponsor: DFG (German Research Foundation).

Evaluation of algorithm to diagnose residual disease in the breast.

	Internal test set		External dataset	
	Residual disease by algorithm	No residual disease by algorithm	Residual disease by algorithm	No residual disease by algorithm
Residual disease by surgery	94	3	26	1
No residual disease by surgery	38	38	13	10
Sensitivity (95% CI)	96.9%	(91.2-99.4)	96.2%	(80.4-99.9)

The impact of age on early breast cancer after breast conserving therapy: Results of a subanalysis from the accelerated partial breast irradiation IMRT Florence trial. *First Author: Icro Meattini, Radiation Oncology Unit-Oncology Department, University of Florence, Florence, Italy*

Background: The impact of age on local recurrence rate of patients affected by early breast cancer is still unclear. The standard of care for older adult largely varies depending on patient- and tumor-related features, but also on national guidelines. We recently presented the 10 years median follow update of the APBI-IMRT Florence phase III trial. The primary aim of the present analysis is to identify the potential relationship between age and ipsilateral breast tumor recurrence (IBTR) in this setting of patients. **Methods:** This retrospective analysis was performed on the whole series of 520 patients who were enrolled in the trial after breast conserving surgery and randomized to receive APBI or whole breast irradiation. We analyzed patients stratified by age (70+ vs 40-69 years). **Results:** At a median follow up time of 10.7 years, we recorded 15 IBTR events. Four hundred and three patients (77.5%) were aged less than 70 years old (11 IBTR) and 117 patients (22.5%) were aged 70 years or older (4 IBTR). At the univariate analysis the age (70+ vs 40-69 years) was not significantly correlated with IBTR occurrence (HR 1.33, 95% CI 0.42-4.17; p=0.63). The only significant prognostic factor was adjuvant endocrine therapy, also at the multivariable analysis (HR 0.26, 95% CI 0.07-0.94; p=0.041). Main results are summarized in the table. Within the luminal-like patients (n=437; 12 IBTR events), the age did not impact on the IBTR rate (HR 0.91, 95% CI 0.19-4.31; p=0.91) and adjuvant endocrine therapy lost its significance (HR 0.32, 95% CI 0.09-1.11; p=0.072). **Conclusions:** Our trial subanalysis did not demonstrate a significant effect of age on IBTR rate for early breast cancer patients receiving a breast conserving therapy. Due to the low number of events, the benefit of adjuvant endocrine therapy is unclear and calls for further investigations. Clinical trial information: NCT02104895. Research Sponsor: None.

Factors associated with axillary conversion after neoadjuvant chemotherapy in initially node positive breast cancer patients: A transSENTINA analysis. *First Author: Hans-Christian Kolberg, Marienhospital, Bottrop, Germany*

Background: Current study concepts in early breast cancer after neoadjuvant chemotherapy (NAT) are aiming at reducing morbidity by omission of axillary surgery in selected patients. Selection criteria for this strategy have to include the probability of conversion from cN1 to ycN0. We analyzed the association of clinical/pathological parameters and axillary conversion with data from arms C and D of the SENTINA trial (Kühn T et al., Lancet Oncol 2013). **Methods:** Patients were recruited to Arms C/D of the SENTINA trial in case they presented with clinically positive nodes before NAT. Based on their response to NAT they were then assigned to either arm C (clinically conversion to ycN0) or arm D (no clinical conversion (ycN+). In both the pre- and post-NAT scenarios, clinically involved lymph nodes were defined as palpable and/or suspect by ultrasound. Univariate logistic regression analyses were carried out to evaluate the association between clinical/pathological parameters and axillary conversion after NAT. **Results:** Of the 892 patients in arms C and D of the SENTINA trial 716 were evaluable for this analysis. After NAT, 593 patients converted to ycN0 and were therefore assigned to arm C; in contrast, 123 patients still had involved lymph nodes after NAT (ycN+) and were assigned to Arm D. Arms C and D were compared regarding the clinical/pathological parameters tumor diameter by ultrasound before and after NAT, grading, multifocality, ER status, PR status, HER2 status, pathological complete remission in the breast (breast pCR), morphology, lymphovascular invasion (LVI) and hemangiosis. Only small tumor diameter after NAT ($p = 0.0038$), achievement of breast pCR ($p = 0.0001$) and lack of LVI ($p = 0.0009$) were positively associated with axillary conversion from cN1 to ycN0 after NAT. **Conclusions:** Because of the small patient number in arm D, we were not able to identify an association between parameters of tumor biology (ER, PR, HER2 and TN status) and axillary conversion. However, favorable response of the primary tumor (represented both clinically by tumor diameter after NAT and pathologically by pCR in the breast) were positively associated with conversion from cN1 to ycN0. These results justify including patients with clinical and pathological response of the primary tumor in trials investigating de-escalation of axillary surgery after NAT. Validation of nomograms to predict non-sentinel lymph node metastasis after positive sentinel lymph node in breast cancer: Indian cohort background. *First Author: Asha Reddy, Tata Memorial Centre, Parel, India*

Background: Axillary lymph node metastasis is still the important prognostic factor in the management of breast cancer (BC). Where we have moved towards axillary conservation in clinically node negative (cN0), the debate on what after 1-2 sentinel lymph nodes positive (SLN+ve) still continues. The ideal situation would be wherein we can accurately predict which patient has a risk of additional non SLN+ve. Several nomograms have been developed to predict the risk of NonSLN+ve. But in view of the differences in tumor size and nodal burden between our patients and the western data, we conducted a study to validate some of these nomograms in our cohort of early BC with positive LN on Low axillary sampling (LAS). **Methods:** Clinicopathological data was collected for operable BC (OBC) with cN0 who underwent upfront SLNB or AS. This was entered into the various nomograms and the probability of the Non SLN+ve was calculated. Nomograms with AUC of greater than 0.7 were pre-defined as considerable discrimination. **Results:** From 2013 to 2018, 2350 women with cN0 OBC underwent LAS. Of which, 670 (28.5%) had a positive node on LAS. Median pT size was 3 cm with 327 (48%), LVI +ve 152 (77%) ENI +ve, 525 (78.4%) Hormone receptor +ve and 485 (72.4%) grade 3 tumors. Of 670, 239 (35.7%) had a NonSLN+ve on completion axillary dissection. The AUC values for nomograms included,ie. MSKCC, MDAnderson, Tenon, Cambridge, Shanghai, Mayo clinic and Turkish were 0.769, 0.77, 0.55, 0.74, 0.65, 0.529, 0.563 respectively. Only three nomograms, MDA, MSKCC and Cambridge had an AUC of more than 0.7. However, they were associated with poor sensitivity and specificity and high FNR (Table) making them clinically unreliable for this cohort. **Conclusions:** All 7 nomograms were not validated in our study. The larger T size and higher nodal burden of our cohort may be responsible for the same. We thus need to develop an Indian nomogram to predict the risk of non SLN+ve for our patients. Research Sponsor: None.

Nomogram	AUC	Sensitivity	Specificity	FNR
MSKCC	0.769	62.3%	84.5%	37.7%
MD Anderson	0.774	56.1%	86%	43.9%
Cambridge	0.74	60.7%	72.4%	27.6%

569 Poster Session (Board #61), Fri, 8:00 AM-11:00 AM

Breast cancer patient reported outcomes, depression, and objective measures of breast cosmesis. *First Author: Shauna McManus, Department of Biostatistics, Rollins School of Public Health, Emory University, Atlanta, GA*

Background: Patient-reported outcomes (PROs) of cosmesis after breast-conserving therapy (BCT) are increasingly emphasized as meaningful treatment endpoints but little is known about the relationship between objective measures, mood, and PROs following radiation (XRT). We hypothesized that pre-XRT depression, assessed by Inventory of Depressive Symptomatology Self-Report (IDS-SR), would influence PROs of breast cosmesis 1-year post-XRT independent of objective measures of breast asymmetry. **Methods:** 98 women were enrolled on two prospective longitudinal studies of breast cosmesis. Percentage breast retraction assessment (pBRA) was used as an objective measure of breast asymmetry pre- and 1 year post-XRT. At the same time points, pBRA was measured and compared with two different PRO ratings of cosmetic outcome (0-10 scale): 1) happiness with cosmesis and 2) perceived differences in treated vs. untreated breast. We performed univariate and multivariate analysis to evaluate the relationship between PROs, pBRA, IDS-SR scores, clinical, tumor, and treatment characteristics. **Results:** Among subjects, 50% were African American. Mean age was 56.45 years. At 1 year, 65.3% of patients were happy with their cosmetic outcome (Score $>$ 8) although 59.5% noted moderate to severe differences in the treated vs. untreated breast (Score $<$ 6). Mean pBRA increased from 7.20 (SD 3.88) pre-XRT to 9.69 (SD 6.22) confirming more breast asymmetry 1-year post-XRT. Prior to XRT, 23% of patients had moderate-to-severe depression (IDS-SR scores $>$ 26). In multivariate analyses, 1 year PROs of happiness with cosmetic outcome did not correlate with pBRA ($p = 0.3$) but were strongly correlated with pre and post-XRT depression (all $p < 0.05$). Patients were more likely to perceive differences in breast texture or asymmetry (i.e. lower PRO ratings of asymmetry) if they had higher pBRA measurements at 1 year (all $p = 0.004$). Neither pre- nor post- XRT depression were associated with specific PRO ratings of breast asymmetry in multivariate analysis. **Conclusions:** Our study suggests that PROs may not always reflect the effects of cancer treatment. For patients treated with BCT, baseline depression strongly influenced patient reported happiness with overall cosmetic outcome 1 year post-XRT. Perceived differences in the treated vs. untreated breast correlated with objective measures of breast asymmetry. Our data suggests that this PRO may be more indicative of treatment-related toxicities than patient ratings of overall satisfaction and happiness with cosmetic outcome. Clinical trial information: NCT03167359. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

570 Poster Session (Board #62), Fri, 8:00 AM-11:00 AM

Psychosocial outcomes following surgery in women with unilateral, nonhereditary breast cancer. *First Author: David Wai Lim, Womens College Hospital, Toronto, ON, Canada*

Background: Rates of bilateral mastectomy continue to rise in average-risk women with unilateral breast cancer. We aim to characterize psychosocial predictors of surgical procedure and how psychosocial outcomes change over time after surgery for breast cancer. **Methods:** A prospective cohort of women with unilateral, nonhereditary breast cancer were recruited at University Health Network in Toronto, Canada between 2014-2017. Women completed validated psychosocial questionnaires (BREAST-Q) pre-operatively, and 6 and 12 months after surgery. Outcomes were assessed between three surgical groups (unilateral lumpectomy, unilateral mastectomy, bilateral mastectomy). Predictors of surgical procedure were identified using a multinomial logistic regression model. Change in psychosocial scores over time according to procedure was assessed using linear mixed models. All models control for age, stage, reconstruction and treatment. *P* values $<$ .05 were considered statistically significant. **Results:** 506 women underwent surgery as follows: 216 unilateral lumpectomy (43%), 181 unilateral mastectomy (36%) and 109 bilateral mastectomy (22%). In the multinomial regression model, younger age ($p <$ .01), and lower chest physical ($p = .03$) and sexual well-being ($p = .02$) predicted having bilateral mastectomy over unilateral lumpectomy while younger age ($p <$ .01) and lower disease stage ($p = .02$) predicted bilateral mastectomy over unilateral mastectomy. The mixed model demonstrates that breast satisfaction follows a non-linear pattern of change over time, with 6- but not 12-month scores being significantly different from baseline ($p = .015$). Procedure predicts baseline satisfaction ($p = .016$), with bilateral mastectomy having worse satisfaction than unilateral lumpectomy. Procedure also predicts change in satisfaction, with unilateral and bilateral mastectomy having lower scores across time than lumpectomy. While a significant improvement in psychological well-being is detected by 12 months ($p = .02$), those with unilateral and bilateral mastectomy have worse psychological well-being over time compared to lumpectomy. Women having mastectomy start with worse physical well-being than those in the lumpectomy group, but their physical well-being does not decline as much as the lumpectomy group over time ($p <$ .01). **Conclusions:** Definitive surgical procedure affects the trajectory of psychosocial functioning over time. This emerging data may be used to further facilitate surgical decision-making in women considering contralateral prophylactic mastectomy. Research Sponsor: None.

571 Poster Session (Board #63), Fri, 8:00 AM-11:00 AM

Radioparp: A phase I of olaparib with radiation therapy (RT) in patients with inflammatory, locoregionally advanced or metastatic triple-negative breast cancer (TNBC) or patient with operated TNBC with residual disease—Preliminary results. *First Author: Youlia M. Kirova, Institut Curie, Paris, France*

Background: Preclinical studies have shown that cell lines and murine models of TNBC phenotype are more sensitive to PARP1 inhibitors. This evidence provides strong rationale for developing a new therapeutic approach to TNBC based on targeting the DNA-repair defects via PARP inhibition. **Methods:** The purpose of this study was to report the Maximal Tolerated Dose (MTD) of Olaparib (O) administered concurrently with locoregional RT and evaluate the Dose-Limiting Toxicity (DLT). **Results:** Twenty-four pts with performance status 0-1 were enrolled between 09/2017 and 11/2019. Of them, 21 underwent adjuvant RT-O because poor response to NAC, and 3 received preoperative RT+O because of progression after NAC. The patients' profile is given in table. All patients received full course RT-O, as following: 4 pts at dose 50mg bid; 8 at 100x2; 7 at 150x2, and 5 at 200x2. No DLT was observed. Two pts (8.7%) experienced acute grade 3 dermatitis no grade 4 toxicities related to the RT were observed. The O-related toxicity was acceptable with mostly grade 1-2 symptoms. The only grade 3-4 hematological toxicity was lymphopenia in 11 cases. **Conclusions:** Dose of O was escalated to the target dose of 200 mgx2, without DLT. Further follow up is needed to evaluate the late toxicities. Clinical trial information: NCT03109080. Research Sponsor: Astra Zeneca.

572 Poster Session (Board #64), Fri, 8:00 AM-11:00 AM

Impact of axillary lymph node dissection (ALND) on survival in patients with ypN1 breast cancer that receive regional nodal irradiation (RNI): A national cancer database (NCDB) analysis. *First Author: Michael Kharouta, Uni-University Hospitals Cleveland Medical Center, Seidman Cancer Center, Cleveland, OH*

Background: The innovation of sentinel lymph node biopsy (SLNB) has allowed many patients with invasive breast cancer to forego ALND. However, the benefit of ALND is unclear in patients with pathologic N1 disease detected on SLNB following neoadjuvant chemotherapy, particularly in patients who receive adjuvant regional nodal irradiation. **Methods:** The National Cancer Database (NCDB) was queried for women ages 18-75 with cT1-3N1, and ypT0-T3N1M0 invasive breast cancer who underwent definitive surgical resection with axillary staging and also received adjuvant RNI. Patients treated from 2012 – 2015 were included to allow for appropriate coding of extent of axillary surgery. Overall survival (OS) was estimated using the Kaplan-Meier method and compared between patients who received SLNB alone and ALND with or without SLNB utilizing log rank testing. Propensity matching was performed to reduce the impact of potential confounders and balance sample bias. Cox proportional hazards regression was used to identify predictors of overall survival. **Results:** A total of 1411 women were identified who met inclusion criteria. The median age was 52 (23-75) years. 206 (15%) women had SLNB alone and 1205 (85%) had ALND with or without SLNB. Five year OS was 73% in patients who underwent ALND compared to 76% in those who had SLNB alone ($p = 0.39$). Following propensity matching by age, race, Charlson Deyo Comorbid Condition score, pT stage, grade, ER status, and HER2 status, 5 year OS was 79% in patients who underwent SLNB alone vs. 69% in patients who had ALND performed ($p = 0.33$). On Cox regression analysis, none of the variables predicted for 5 year OS. **Conclusions:** ALND in addition to RNI did not improve survival in patients with cT1-3N1M0 and ypT0-3N1M0 breast cancer compared to SLNB and RNI. We await results of the Alliance 011202 randomized trial for prospective validation of ALND omission in a similar subset of patients. Research Sponsor: None.

4R Program results in breast cancer: the impact of 4R Care Delivery Model on timing and sequence of guideline recommended care. *First Author: Christine B. Weldon, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: We previously proposed a 4R care delivery model which enables patients and care teams to manage timing and sequence of interdependent, time sensitive care with a novel multimodality 4R Care Sequence plan (NCI ASCO Teams Project; Trosman, JOP 2016). We report final results of a program which tested 4R at 10 US centers (4 academic and 6 non-academic) from 2016 to 2019. **Methods:** 4R Sequences were provided to stage 0-III breast cancer patients (4R cohort, N = 422) at participating centers. Analyses of clinical and patient-reported data compared the 4R cohort to a historical control cohort of patients who received care pre-4R at the same centers (N = 466). **Results:** We significantly improved 5 guideline recommended referral metrics and 4 referral completion metrics indicating receipt of care by patients who were referred (Table). Although significantly increased, referrals to dental visit and smoking cessation before treatment remained low (< 20% and < 10% respectively). Patient survey comments indicated that insufficient lead time to quit smoking or obtain fertility consult before cancer treatment was a key barrier for completing these referrals. **Conclusions:** 4R markedly improved referral and receipt of interdependent guideline recommended breast cancer care for most metrics. Future 4R program should optimize the timing of referrals within the 4R Care Sequence to allow sufficient time for smoking cessation and fertility care before treatment initiation. Research Sponsor: None.

Metric	Guideline	% of patients referred: 4R cohort (N = 422) vs control (N = 466), p value	% of referral completion by referred patients: 4R cohort vs. control, p value (N = referrals for respective cohort and metric)
PCP visit before treatment	NCCN OAO	34% vs 28%, .05	67% (N = 143) vs 44% (N = 129), .0002
Genetic consult before surgery	NCCN BR/OV	43% vs 35%, .01	66% (N = 183) vs 53% (N = 163), .02
Flu shot before treatment	NCCN INF	39% vs 28%, .008	67% (N = 163) vs 53% (N = 130), .02
Dental visit before treatment	ADA	19% vs 5%, .0001	71% (N = 81) vs 57% (N = 23), .03
Smoking cessation before treatment	NCCN SC	5% vs 2%, .02	55% (N = 20) vs 44% (N = 9), NS
Fertility consult before treatment	NCCN BC, AYAO	8% vs 5%, .NS	59% (N = 34) vs 32% (N = 22), NS

574 Poster Session (Board #66), Fri, 8:00 AM-11:00 AM

Predicting nodal positivity in women with hormone receptor-positive (HR+), early stage breast cancer (ESBC). *First Author: Emily Miller Ray, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Omission of axillary surgery is appropriate in some patients with clinically node-negative (cN0), HR+ ESBC; however, there are no pre-operative tools to predict pathologic node positivity (pN+) in these women. We propose a clinically validated predictive model to inform treatment decisions regarding axillary evaluation. **Methods:** We constructed a cohort of adult women with ESBC (clinical T1/T2, N0, M0) diagnosed 2012-2016, who underwent lumpectomy or mastectomy and lymph node surgery without neoadjuvant therapy using the National Cancer Database breast cancer dataset. The dataset was non-randomly split into training (2012-2015) and testing (2016) for development and validation. Stepwise logistic regression was used to identify predictors of pathologic node positivity (pN0 vs pN+) in the training dataset. Potential predictors included: age, race, ethnicity, comorbidity score, histologic type, clinical T, ER positivity, PR positivity, HER2 positivity, and grade. Predictor variables required a bivariate p-value <0.30 to be entered into model, and an adjusted p-value <0.35 to stay in model. A partial score method was used to develop a lymph node prediction score (LNPS) by assigning a weighted value to each strong predictor variable (OR >1.5) and adding together the values for each included variable. LNPS was treated as a linear variable for prediction in validation dataset. **Results:** 423,068 women were included (2012-2015: 334,778; 2016: 88,290). Pathologic node positivity was 17% in 2012-2015 and 2016. All variables were included in the final stepwise model. Strong predictors were age, histologic type, clinical T, and grade. Scores ranged from 0-11. In the validation dataset, predicted pN+ by LNPS was very similar to actual pN+ (Table). A 1-point increase in LNPS was associated with a 3.3% increase in absolute risk of pN+. **Conclusions:** A novel lymph node prediction score can be used in HR+ cT1-T2 cN0 breast cancers to estimate the probability of pN+ and guide decisions regarding axillary surgical evaluation. Research Sponsor: None.

Predicted and actual probability of pN+ in the testing dataset.

LNPS[a]	N	Predicted pN+ (%)	Actual pN+ (%)	Difference (%)
0	1,507	6.5	3.2	3.3
1	871	7.9	5.0	2.9

Sentinel-Lymphnode Biopsy in primary breast cancer: 99mTc versus ICG—A prospective, randomized trial. *First Author: Peter Kern, University Duisburg-Essen, University Hospital of Essen, West-German Cancer Center, Women´s Department, Herten, Germany*

Background: Sentinel-Lymphnode Biopsy (SLNB) is the standard procedure in primary breast cancer, routinely performed with 99mTechnetium radioactive tracers. Awareness of nuclear waste, costs and time consumption lead to the desire of breast surgeons to find safe and effective alternative options for detection of sentinel lymph nodes (SLN) in breast cancer and melanoma. Indocyaningreen is a tracer which emits fluorescence with near-infrared light of 780-810 nm when injected in the peritumoral or periareolar region, enabling surgeons to detect SLN and lymphatic pathways at the breast. **Methods:** We performed a prospective, randomized trial with patients with primary breast cancer. Both detection methods have been applied to patients of the study cohort comparing the preparation time, time to identify, concordance of the two methods and costs. Reference method was preoperative lymphszintigraphy. **Results:** 55 patients have been analyzed in this first report. Preparation time was 75,8 min (range 60-120 min) for 99mTc-tracer and a standard of 20 min for ICG. Time to identify SLN at a mean of 3,8 min(range 1-15 min) for 99mTc and 3 min (range 1-8 min) for ICG. Concordance rates were 98,2 % for the 1st SLN, 93,8 % both for 2nd and 3rd SLN. After neoadjuvant chemotherapy, all SLN have been been detected by both techniques, in 3 patients additional SLN have been found by ICG. Costs have been cut down to 1/10 with the use of ICG, coming up to saving of 27 000 US-$ per each 100 SLNB procedures performed. **Conclusions:** We report a high concordance rate between the 2 techniques - 99mTechnetium and ICG with near-infrared - for detection of SLN in breast cancer. Preparation time is cut down to less than 30 %, and costs to less the 10 % of radioactive labelling. Clinical trial information: 18-8054-BO. Research Sponsor: University of Duisburg-Essen.

Re-excision rates among older breast cancer patients undergoing breast-conserving surgery (BCS): Impact of the SSO-ASTRO consensus guideline on margins. *First Author: Mariana Chavez-MacGregor, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BCS has been historically associated with a high re-excision rate, driven in part by the need of obtaining negative margins. The SSO-ASTRO consensus guideline on invasive margins, defined a negative margin as no ink on tumor. In this large population-based study of older breast cancer patients undergoing BCS for invasive breast cancer we evaluate the guideline impact on re-excision rates. **Methods:** Female patients diagnosed with stage I-II breast cancer between 2012-2015 were identified in the SEER-Medicare database. Patients were >66 years and underwent BCS. Patients treated with neoadjuvant chemotherapy were excluded. We defined the following time periods: pre-guideline (January 2012-September 2013); peri-guideline (October 2013-March 2014) and post-guideline (April 2014-December 2016). Re-excision was defined as a resection, BCS or mastectomy identified using ICD-9 or CPT codes between 4 and 90 days after initial BCS. Overall re-excision rates and 95%CI were calculated and groups compared using X^2test. Within subgroups we calculated re-excision rates for the pre and post-guideline periods and report the relative percent change. Regression model evaluated the association between time periods and re-excision while adjusting for important covariates, risk ratios (RRs) and 95%CI are presented. **Results:** 17001 patients were included. 6762 of them had BCS in the pre, 1786 in the peri, and 8453 in the post-guideline periods. Overall 22.6% of the patients had a re-excision. The rate decreased from 24.8% pre-guideline to 20.3% post-guideline (P < 0.001). The relative change in re-excision varied according to region (Midwest 3-7.3%, Northeast -20%, West -16.5% and South -13.5%) Differences in the relative change according to race/ethnicity were also seen (Whites -19.2, Blacks -15.3% and Hispanics -9.9%). In the multivariable model, BCS in the post-guideline period was associated with a decreased risk of re-excision (RR = 0.83; 95%CI 0.79-0.88). Lobular histology was associated with a higher risk of re-excision (RR = 1.31; 95%CI 1.21-1.42); greater surgeon volume was associated with lower risk of re-excision (RR = 0.89; 95%CI 0.82-0.95). **Conclusions:** There has been a statistically significant decrease in the re-excision rate after BCS associated with the dissemination of the SSO-ASTRO consensus guideline on invasive margins. Our study confirms the impact that guidelines have modifying patterns or practice, reducing the frequency of unnecessary interventions. Research Sponsor: Susan G. Kome, CIPRIT.

Neoadjuvant chemotherapy (NACT) and HER2 double inhibition including biosimilar trastuzumab (ONTRUZANT) for HER2-positive early breast cancer (EBC): Population-based real world data from the Danish Breast Cancer Group (DBCG). *First Author: Michael Andersson, Department of Oncology, Rigshospitalet University Hospital, Copenhagen, Denmark*

Background: Increasingly, HER2-positive early breast cancer (EBC) is treated by NACT combined with trastuzumab and pertuzumab followed by surgery. Ontruzant is registered as a biosimilar trastuzumab based on the totality of evidence including a randomized phase III study of NACT+Herceptin versus NACT+Ontruzant demonstrating similar pCR-rates (Pivot et al. J Clin Oncol 2018;36:968). However, no data exist for the efficacy of the combination of NACT with pertuzumab+Ontruzant (p+O). This investigator-initiated study was conducted to assess real world efficacy in HER2-positive EBC patients treated with NACT+p+O based on data from DBCG. DBCG has since 1977 provided guidelines for treatment of breast cancer and collected data from Danish hospital departments of surgery, pathology, and oncology prospectively on NACT, date and type of surgery and patho-anatomic findings. **Methods:** From the DBCG database, information was extracted for consecutive patients with unilateral early HER2-positive breast cancer registered to have received NACT+p+O from September 1, 2018 to August 31, 2019. pCR was defined as absence of residual invasive tumor in the breast and axillary lymph nodes (ypTO/Tis ypN0(i-)). **Results:** 215 patients received NACT+p+O. Median age was 54.8 years (range 24-81). NACT used, in combination with concurrent p+O, was cyclophosphamide+epirubicin followed by paclitaxel (62% on 6 cycles and 35% on 8 cycles) or other chemotherapy followed by paclitaxel (3%). Overall, 56% of patients achieved a pCR (Table). 68% of node-positive patients before receiving NACT+p+O had tumor-free axillary nodes after completing NACT+p+O. **Conclusions:** Real-world data from a nationwide population based study demonstrated a pCR-rate with NACT+p+O comparable to that seen in clinical studies with NACT+p+Herceptin (Chen et al. BMC Cancer 2019;19: 973). pCR-rate was highly dependent on estrogen receptor (ER)-status and malignancy grade but not on clinical nodal status and tumor size. 68% of patients with cN+ converted to ypN0(i-). Four-year follow-up of a phase III study comparing SB3 (trastuzumab biosimilar) and reference trastuzumab in HER2-positive early or locally advanced breast cancer in neoadjuvant setting. *First Author: Xavier Pivot, CHRU de Besançon–IRFC, Besançon, France*

Background: SB3 was approved in the US and EU as a biosimilar of reference trastuzumab (TRZ). Here, we report 4-year cardiac safety and survival outcomes. **Methods:** After completing neoadjuvant-adjuvant therapy in patients with HER2 positive early breast cancer, patients from selected countries participated in a 5-year follow-up study of a phase III trial (Pivot et al. Eur J Cancer 2019). The aim was to observe long-term cardiac safety and survival. EFS and OS were analyzed in subgroups by ADCC status within TRZ in ad-hoc analyses. **Results:** Of 875 patients randomized in the phase III trial, 367 patients (SB3, N=186; TRZ, N=181) were enrolled in the follow-up study. The median follow-up was 53 months. During the follow-up, the incidence of asymptomatic significant left ventricular ejection fraction (LVEF) decrease was low (SB3, n=1; TRZ, n=2), with all patients recovering with LVEF ≥ 50%. No cases of symptomatic congestive heart failure, cardiac death, or other significant cardiac condition were reported. 4-year EFS rates were 83.4% for SB3 and 80.7% for TRZ with a HR of 0.77 [95% CI 0.47, 1.27]. 4-year OS rates were 94.3% for SB3 and 89.6% for TRZ with a HR of 0.53 [95% CI 0.24, 1.16]. From ad-hoc analysis, a difference in EFS and OS was seen between Non-drifted TRZ and Drifted TRZ; Difference between SB3 and Non-drifted TRZ was not statistically significant. **Conclusions:** In a subset of patients from the phase III trial, comparable long-term cardiac safety and survival at 4-year supports biosimilarity between SB3 and TRZ. Ad-hoc analysis results by ADCC status suggest a possible correlation between ADCC and clinical efficacy. Further follow-up is needed. Clinical trial information: NCT02771795. Non-drifted TRZ, patients never exposed to any vials from an ADCC-drifted TRZ lot during neoadjuvant period; Drifted TRZ, patients exposed to at least one vial from an ADCC-drifted TRZ lot during neoadjuvant period. [a]HR was estimated with bpCR as a covariate.

579 Poster Session (Board #71), Fri, 8:00 AM-11:00 AM

Establishing analytical and clinical similarity between HD201 and herceptin. *First Author: Jocelyn Hii, Prestige Biopharma Pte Ltd, Singapore, Singapore*

Background: Trastuzumab, an approved prescription drug by EMA and FDA under the name Herceptin has become the key treatment in patients with HER2$^+$positive breast cancer. HD201, developed by Prestige Biopharma Pte Ltd is a biosimilar candidate to Herceptin. The biosimilarity of HD201 was established based on systematic stepwise comparisons between HD201 and reference product, Herceptin. In order to confirm clinical similarity of HD201 to Trastuzumab, two clinical studies were undertaken. **Methods:** First, in a double-blind, randomised and parallel group study, 101 randomised healthy human subjects were subjected to a single 6 mg/kg IV dose by body weight over 90-min infusion of either HD201, EU- and US-Herceptin group by assessing pharmacokinetic (PK) and safety (TROIKA-I). The second study was a randomised, double-blind, parallel group, equivalence, multicentre clinical phase III trial (TROIKA) designed to compare the efficacy based on total pathological complete response rate (tpCR), safety, and pharmacokinetics of HD201 to EU-Herceptin in patients with HER2 positive early breast cancer. Each group of ~250 subjects were administered with either HD201 or EU-Herceptin in combination with chemotherapy in neoadjuvant followed by the antibody alone in the adjuvant phase. **Results:** TROIKA-I study demonstrated that HD201 was safe and well tolerated with comparable PK as EU- and US-Herceptin. Based on the neoadjuvant data from TROIKA study, the tpCR rate in the HD201 and Herceptin treatment groups was comparable and the 95% CI was included within the pre-defined margins of equivalence (Table). The incidence and severity of reported TEAEs did not imply any significant safety concerns and were comparable between both groups. In addition, the comparison of steady-state C_{trough} between both arms in TROIKA study has established equivalence. **Conclusions:** The overall comparison exercise demonstrated the equivalence of HD201 to Herceptin. Clinical trial information: 2016-0040019-11. Research Sponsor: Private funding.

580 Poster Session (Board #72), Fri, 8:00 AM-11:00 AM

Influence of denosumab on disseminated tumor cells (DTC) in the bone marrow of breast cancer (BC) patients with neoadjuvant treatment: A GeparX translational substudy. *First Author: Pauline Wimberger, Department of Gynecology and Obstetrics, University Hospital Carl Gustav Carus, TU Dresden, Dresden, Germany*

Background: DTCs in the bone marrow are observed in up to 30% at primary diagnosis of BC and their presence is an independent prognostic factor for reduced survival. It was shown that antiresorptive therapy eradicates DTCs and improves prognosis in DTC-positive BC patients (pts). In the GeparX phase III prospective randomized trial, denosumab (a monoclonal IgG2-anti-RANKL-antibody) was investigated as add-on treatment to neoadjuvant chemotherapy (NACT) with two different nab-paclitaxel schedules in early high-risk primary BC. In a translational substudy, we analyzed for the first time the influence of short-term denosumab treatment (24 weeks) on the presence of DTCs. **Methods:** A total of 167 pts from the GeparX trial were analyzed for DTCs at baseline by immunocytochemistry using the pan-cytokeratin antibody A45-B/B3. Initially DTC-positive pts were re-analyzed for DTCs after NACT±Denosumab. **Results:** Overall, 60/167 pts (35.9%) treated with NACT±Denosumab had a pathological complete response (pCR; 55.4% in TNBC, 43.3% in HER2+, 15.3% in HR+/HER2-). At baseline, 43/167 pts (25.7%) were DTC-positive and 41 of those were available for re-analysis of DTCs after NACT±Denosumab. DTC eradication was observed in 77.8% after NACT+Denosumab and in 69.6% after NACT alone (p = 0.726). Due to the limited number of pts eligible for DTC-re-analysis after NACT, a subtype specific analysis for the effect of denosumab was not possible. There was no significant association between pCR and i) the presence of DTCs at baseline (37.1% DTC-negative vs 32.6% positive, p = 0.71) or ii) the eradication of DTCs after NACT±Denosumab (36.7% vs 27.3%, p = 0.72). Notably, in TNBC, we observed a tendency that DTC-positivity at baseline or DTC-persistence after NACT could be associated with reduced pCR rate (40.0% in DTC-positive vs. 66.7% in DTC-negative pts, p = 0.16; 25% in DTC-persistent pts vs. 50% in DTC-eradicated pts, p = 0.59). **Conclusions:** Denosumab in addition to NACT does not improve pCR, but the suspected effect of denosumab on DTC eradication should be further analyzed in TNBC. Key words: GeparX trial, denosumab, disseminated tumor cells, bone marrow, neoadjuvant chemotherapy. Funding: GeparX and DTC substudy were financially supported by Amgen and Celgene. Clinical trial information: NCT02682693. Research Sponsor: Amgen, Celgene.

581 Poster Session (Board #73), Fri, 8:00 AM-11:00 AM

The impact of pattern of tumor response and other post-treatment histologic features on local recurrence in patients treated with neoadjuvant chemotherapy and breast conservation. *First Author: Alison Laws, Dana-Farber/Brigham and Women's Cancer Center, Boston, MA*

Background: Residual disease after neoadjuvant chemotherapy (NAC) is a poor prognostic factor. The relationship between the pattern of tumor response and other post-treatment histologic features on local recurrence (LR) is not well studied. **Methods:** We identified 380 patients (pts) treated with NAC, breast-conserving surgery and radiation from 2002-2014. Pts with available surgical slides underwent detailed pathology review. Pathologic complete response (pCR) was defined as no invasive or in situ disease in the breast or axilla. Pattern of tumor response was defined as: none, scattered, or concentric. The degree of treatment effect was categorized as: absent, mild or marked. Univariate (UVA) and multivariate analyses (MVA) were performed to identify factors associated with LR. **Results:** 243 (64%) cases had complete slides available and formed the study cohort. 76 (31%) were ER+/HER2-, 90 (38%) ER-/HER2- and 77 (31%) HER2+. 98% of HER2+ pts received neoadjuvant trastuzumab; 89% of ER+ pts received adjuvant endocrine therapy. At median follow-up of 75 months, 10/243 (4.1%) pts had LR and 5-yr LR-free survival was 95.7%. LR occurred in 1/76 (1.3%) pts with breast pCR, 1/19 (5.2%) with residual DCIS, and 8/148 (5.4%) with residual invasive disease; including 6/78 (7.7%) with scattered tumor response, 2/46 (4.3%) with concentric response and 0/24 with no response. On UVA, age (OR $<$ 50 vs $\geq$50 5.9, p = 0.03) and residual DCIS with comedonecrosis (OR 8.2, $p < 0.01$) were significantly associated with LR. Presence of tumor bed at the margin (OR 4.6, p = 0.06) approached significance. The odds of LR were higher with scattered regression (OR 1.83 vs. concentric, p = 0.47) and lower with breast pCR (OR 0.23, p = 0.17), but these results were not statistically significant. Multicentric disease, receptor status, ypT, ypN, RCB score, degree of treatment effect, high-grade residual invasive disease, margin status of residual disease and lymphovascular invasion were not associated with LR (all $p > 0.05$). Age (OR $<$ 50 vs $\geq$50 7.4, p = 0.04) and residual DCIS with comedonecrosis (OR 7.5, p = 0.02) remained significant on MVA. **Conclusions:** With modern systemic therapy, LR rates after NAC, breast-conserving surgery and radiation are low, with less than 5% of patients experiencing a LR after a median follow-up of over 6 years. Young age and residual DCIS with comedonecrosis were associated with LR, but not pattern of tumor response. Research Sponsor: None.

582 Poster Session (Board #74), Fri, 8:00 AM-11:00 AM

Survival analysis of the prospective randomized Cher-Lob study evaluating the dual anti-HER2 treatment with trastuzumab and lapatinib plus chemotherapy as neoadjuvant therapy for HER2-positive breast cancer (BC). *First Author: Valentina Guarneri, Department of Surgery, Oncology and Gastroenterology, University of Padua and Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padua, Italy*

Background: The CHER-LOB randomized phase II study showed that the combination of lapatinib and trastuzumab plus chemotherapy increases the pathologic complete response (pCR) rate compared with chemotherapy plus either trastuzumab or lapatinib. Here we report the results of survival analysis according to treatment arm and pCR. **Methods:** The CherLOB study randomized 121 HER2-positive, stage II-IIIA breast cancer patients to anthracyclines/taxane-based chemotherapy plus trastuzumab, lapatinib, or both. After surgery, patients received adjuvant trastuzumab for up to 1 year. The primary end point of the study was met, with a relative increase of 80% in the pCR rate achieved with chemotherapy plus trastuzumab and lapatinib compared with chemotherapy plus either trastuzumab or lapatinib (Guarneri, J Clin Oncol 2012). Relapse-free survival (RFS) was calculated from randomization to breast cancer recurrence (locoregional or distant) or death from any cause, whichever first. Overall survival (OS) was calculated from randomization to death from any cause. **Results:** At a median follow up of 8.8 years, RFS rates at 5 years were: 85.8% in the trastuzumab + lapatinib arm, 77.8% in the trastuzumab arm, 78.1% in the lapatinib arm (log-rank p = 0.160). Patients treated with dual HER2 blockade (trastuzumab + lapatinib arm) experienced numerically better RFS as compared to patients treated with single HER2 blockade (trastuzumab arm and lapatinib arm combined): 5-yr RFS 85.8% vs 78.0%, log-rank p = 0.087; HR = 0.51, 95% CI 0.23-1.12, p = 0.093. The achievement of pCR was a strong prognostic factor. 5-yr RFS rate was 97.3% for pCR patients vs 72.9% for non-pCR patients (log-rank $p < 0.001$, HR = 0.12, 95% CI 0.03-0.49, p = 0.003); similar significant results were observed in both the estrogen receptor-negative and estrogen-receptor positive subgroups. OS was also improved in pCR patients: 8-yr OS rates were 97.2% vs 80.0% for non pCR patients (log-rank p = 0.028, HR = 0.14, 95% CI 0.02-1.08, p = 0.060). **Conclusions:** In the Cher-LOB study, there was a not statistically significant signal for a better RFS for patients who received dual HER2 blockade with trastuzumab and lapatinib plus chemotherapy as compared to patients treated with single anti-HER2 agent (trastuzumab or lapatinib) plus chemotherapy. Patients achieving a pCR had longer RFS and OS as compared to non-pCR patients. Clinical trial information: NCT00429299. 583 Poster Session (Board #75), Fri, 8:00 AM-11:00 AM

Prognostic impact of high stromal tumor-infiltrating lymphocytes (sTIL) in the absence of pathologic complete response (pCR) to neoadjuvant therapy (NAT) in early stage triple negative breast cancer (TNBC). *First Author: Nour Abuhadra, MD Anderson Hematology/Oncology Fellowship, Houston, TX*

Background: Pathologic complete response is an excellent surrogate for disease-free survival (DFS) and overall survival (OS) in TNBC. High sTIL is associated with improved pCR rates in TNBC. Recent data suggest that high sTIL is also associated with improved outcomes in patients who received no chemotherapy for early stage TNBC (Park, Annals of Oncology, 2019). Thus, we hypothesized that high sTIL may have prognostic impact in patients who do not achieve pCR to NAT. **Methods:** Pretreatment core biopsies from 182 patients with early-stage TNBC enrolled on the ARTEMIS trial (NCT02276443) were evaluated for sTIL by H&E. Patients were stratified according to sTIL (low $<$ 30%, and high $>$ 30%) and pCR (patients with pCR vs. no pCR). The primary outcome measure was DFS, defined from the date of diagnosis to the first local recurrence, distant metastases or death. Cox proportional hazards regression model was used. During follow-up 33 events for DFS were observed. **Results:** Among subjects who achieve pCR, DFS was excellent regardless of sTIL status and significantly better than those without pCR ($p < 0.05$). However, patients with high sTIL and no pCR demonstrated significantly worse DFS compared to all subjects having pCR (HR 0.18, 95% CI 0.04-0.76, p = 0.02). Additionally, we did not find a significant difference between high and low sTIL patients who did not achieve pCR. **Conclusions:** In early TNBC receiving NAT, for patients failing to achieve pCR, high sTIL was not associated with improved DFS; outcomes were comparable to those with low sTIL without pCR. Thus, high sTIL at baseline does not appear to confer an intrinsic prognostic benefit in the absence of pCR. Research Sponsor: CPRIT, MD Anderson Breast Moonshots Program.

584 Poster Session (Board #76), Fri, 8:00 AM-11:00 AM

Inhibiting fatty acid synthase in operable triple negative breast cancer. *First Author: Sagar D. Sardesai, The Ohio State University Comprehensive Cancer Center, Division of Medical Oncology, Columbus, OH*

Background: Fatty acid synthase (FASN) is overexpressed in 70% of newly diagnosed triple negative breast cancer (TNBC) and is associated with poor prognosis. *In vitro*, FASN overexpression induces drug resistance to DNA damaging agents. Proton pump inhibitors (PPI) selectively inhibit FASN activity and induce apoptosis in breast cancer cell lines with minimal effect on non-malignant cells. We report the results of a single arm phase II study of high dose omeprazole (OMP) in combination with anthracycline- taxane (AC-T) based neoadjuvant chemotherapy. **Methods:** Patients (pts) with operable TNBC independent of baseline FASN expression; and no prior PPI use within 12 months were enrolled. Pts began OMP 80 mg PO BID for 4-7 days prior to AC-T; carboplatin was allowed per physician discretion. OMP was continued until surgery. Paired biopsy samples were obtained before and after OMP monotherapy. The primary endpoint was pathologic complete response (pCR), defined as no residual invasive disease in breast or axilla, in pts with baseline FASN expression (FASN+) assessed using immunohistochemistry. Relevant secondary endpoints included pCR in the intent to treat population, change in FASN expression, enzyme activity and downstream target gene expression after OMP monotherapy; safety and limited OMP pharmacokinetics. We targeted a pCR rate of 60% in FASN+ pts (null pCR ~ 40%) with 80% power and alpha of 0.10. **Results:** A total of 42 pts were recruited from 5 US sites. Median age was 51y (28-72). Most pts had $>$cT2 (33, 79%) and $\geq$N1 (22, 52%) disease. 14 (33%) were African American. FASN expression prior to AC-T was identified in 28 (85%) samples available for analysis. The pCR rate was 71.4% (95% CI 51.3 to 86.8) in FASN+ pts and 71.8 %(95% CI 55.1 to 85.0) in all enrolled pts. Fifteen pts (36%) received carboplatin with AC-T; pCR in this subset was 73%. Peak OMP concentration was significantly higher than IC_{50} observed during preclinical testing; FASN positivity significantly decreased with OMP monotherapy from 0.53(SD 0.25) at baseline to 0.38(SD 0.30; p = 0.02). OMP was well tolerated with no known grade (G) 3 or 4 toxicities. Chemotherapy toxicity was similar to prior studies using AC-T with G3 or 4 neutropenia (19%), febrile neutropenia (7%) and peripheral neuropathy (7%) being the most common. **Conclusions:** Consistent with previous studies, FASN is frequently expressed in early stage TNBC. OMP can be safely administered in doses that inhibit FASN. The addition of high dose OMP to neoadjuvant AC-T yields a promising pCR rate without adding toxicity. Funded by the Breast Cancer Research Foundation. Clinical trial information: NCT02595372. Research Sponsor: Breast Cancer Research Foundation.

585 Poster Session (Board #77), Fri, 8:00 AM-11:00 AM

Neoadjuvant TCH (docetaxel/darboplatin/trastuzumab) versus EC-TH (epirubicin/cyclophosphamide followed by docetaxel/ trastuzumab) in patients with HER2-positive breast cancer (neoCARH): A randomised, open-label, multicenter, phase II trial. *First Author: Hong-Fei Gao, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, 510080, China, Guangzhou, China*

Background: The optimal neoadjuvant treatment for HER2-positive breast cancer is unknown. We wanted to compare the efficacy and safety of the anthracycline regimen EC-TH versus nonanthracycline regimen TCH in neoadjuvant setting for HER2-positive breast cancer. **Methods:** Patients with stage II or III HER2-positive breast cancer were randomly assigned to either four cycles of epirubicin/cyclophosphamide followed by four cycles of docetaxel and trastuzumab (EC-TH) every 3 weeks during all chemotherapy cycles, or six cycles of docetaxel and carboplatin plus trastuzumab (TCH) every 3 weeks. The primary endpoint was pathological complete response (defined as the absence of invasive tumour cells in breast and axilla, ypT0/is ypN0). This trial is registered with ClinicalTrials.gov, number NCT03140553. **Results:** From September 2016 to November 2019, 140 patients were randomly assigned, and 131 were evaluable for the primary end-point. The pathological complete response was recorded in 25 (38.5%, 95% confidence interval [CI] 26.6–50.2) of 65 patients in the EC-TH group and in 37 (56.1%, 44.1–68.0) of 66 in the TCH group (p=0.044). In the EC-TH group, 15 (23.1%) of 65 patients underwent breast-conserving surgery. In the TCH group, 21 (31.8%) of 66 patients underwent breast-conserving surgery. There was no difference in the proportions of patients undergoing breast-conserving surgery between the two treatment groups (p=0·262). The most common adverse events were neutropenia (in 23 [35.4%] of 65 patients in the EC-TH group vs 27 [40.9%] of 66 in the TCH group), anemia(in 33 [50.8%] of 65 patients in the EC-TH group vs 34 [51.5%] of 66 in the TCH group) and thrombocytopenia (in 5 [7.7%] of 65 patient in the EC-TH group vs 17 [25.8%] of 66 in the TCH group). **Conclusion**: This is the first multicenter prospective randomised phase II trial compare EC-TH with TCH for neoadjuvant therapy in HER2-positive breast cancer. There was a similar incidence of AEs but a higher pCR rate in TCH arm compared with the EC-TH arm. TCH regimen might be a preferred approach in patients with HER2-positive breast cancer. Long-term follow-up is required to confirm these results. Clinical trial information: NCT03140553. Research Sponsor: None.

586 Poster Session (Board #78), Fri, 8:00 AM-11:00 AM

Neoadjuvant docetaxel + carboplatin versus epirubicin+cyclophosphamide followed by docetaxel in triple-negative, early-stage breast cancer (NeoCART): Results from a multicenter, randomized controlled, open-label, phase II trial. *First Author: Liulu Zhang, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Taxane- and anthracycline-based neoadjuvant regimens have become a standard treatment for triple-negative breast cancer (TNBC). Previous studies have shown that adding carboplatin to neoadjuvant chemotherapy regimens significantly improved pCR rate in TNBC patients. The NeoCART study was designed to compare the efficacy and safety of docetaxel plus carboplatin with standard neoadjuvant chemotherapy in TNBC. **Methods:** NeoCART was designed as a multicenter, randomized controlled, open-label, phase 2 trial. The patients enrolled were at least 18 years old with previously untreated stage II-III (T1cN1-2 or T2-4N0-2) invasive TNBC who had an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1. All eligible patients were randomly assigned, in a 1:1 ratio, to the experimental arm (docetaxel (75 mg/m2) plus carboplatin (AUC 6) for six cycles) or the standard treatment arm (epirubicin 90 mg/m2 plus cyclophosphamide 600 mg/m2 four cycles, followed by docetaxel 100 mg/m2 for four cycles). The primary end point was the pCR rate (ypT0/is and ypN0). Secondary endpoints included event-free survival, frequency of breast-conserving surgery, and safety. **Results:** Between September 1, 2016, and December 31, 2019, 88 patients from 6 participating centers were included and randomized (44 patients to the DCb arm and 44 to the EC-D arm). In the primary end point analysis, 27 patients (61.4%, 95% CI 47.0 - 75.8) in the DCb group achieved a pCR compared with 17 patients (38·6%, 95% CI 24.3 - 53.0) in the EC-D group (odds ratio 2.52, 95% CI 2.4 - 43.1; p = 0.033). In different stage disease, the pCR rates of the DCb and the EC-D groups were 73.3% (22/30) vs 48.4% (15/31) in stage II (p = 0.046), and 35.7% (5/14) vs 15.4% (2/13) in stage III (p = 0.384). In patients with axillary lymph node involvement, the pCR rates were 45.8% (11/24) vs 30.8% (8/26) (p = 0.273); and 80.0% (16/20) vs 50.0% (9/18) with lymph node negative disease (p = 0.052). The frequency of breast-conserving surgery in the DCb and EC-D groups was 36.4% and 37.2%, respectively (p = 0·935). The grade 3/4 adverse events include anemia (4.5%), thrombocytopenia (2.3%), neutropenia (2.3%) and ALT/AST increased (2.3%) in the DCb group. **Conclusions:** Compared with the standard neoadjuvant regimen, docetaxel combined with carboplatin showed a higher pCR rate in TNBC. The higher pCR rate was more significant in patients with earlier disease stage and negative lymph node. Clinical trial information: NCT03154749. Research Sponsor: None.

587 Poster Session (Board #79), Fri, 8:00 AM-11:00 AM

Efficacy of neoadjuvant chemotherapy (NAC) in male breast cancer (MaBC) compared with female breast cancer (FBC): A National Cancer Database (NCDB) study. *First Author: Jose Pablo Leone, Dana-Farber Cancer Institute, Boston, MA*

Background: NAC is frequently used in the treatment of FBC. The efficacy of NAC in MaBC is unclear. Few studies have compared outcomes for MaBC and FBC after similar treatment. The aim of this study was to compare proportions of pathologic complete response (pCR) between MaBC and FBC according to tumor subtype (TS). Secondary aims were clinical response and overall survival (OS). **Methods:** We evaluated men and women with breast cancer treated with NAC between 2010 and 2016 with known hormone receptor (HR) status and human epidermal growth factor receptor 2 (HER2) status at NCDB centers. The proportion with pCR (ypT0/Tis ypN0) was compared for MaBC and FBC for each TS by Fisher's exact test. Logistic regression evaluated odds of pCR. OS was estimated by Kaplan-Meier and compared by log-rank test. **Results:** Of 7,721 MaBC and 859,096 FBC patients, 385 MaBC (5%) and 68,065 FBC (7.9%) underwent NAC and were included in this study. Median age for MaBC was 58 years (y) (range 23-88) and for FBC was 53 y (range 18-90). Within each TS, there were no significant differences in the distribution of tumor grade between MaBC and FBC. Clinical stage in MaBC and FBC were: Stage I: 8% v 11%, Stage II: 54% v 59%, Stage III: 38% v 30%; respectively. Median time from initiation of NAC to surgery was 143 days in MaBC and 148 days in FBC. Compared with FBC, MaBC had a lower proportion of complete clinical response (18% v 31%) and a higher proportion of no clinical response (14% v 7%); $p < 0.001$. Proportions and odds of pCR were numerically lower in MaBC compared with FBC for each TS and statistically significant for HR+/HER2- and HR+/HER2+ (table). pCR was associated with OS in both MaBC and FBC. Specifically, in MaBC who achieved pCR v not, 5 y OS was 90% v 64.7%; p = 0.02. In FBC who achieved pCR v not, 5 y OS was 91.9% v 75.3%; $p < 0.01$. Among pts receiving NAC, MaBC had worse OS at 5 y than FBC (67.1% v 79.0%; p = 0.02). **Conclusions:** Men receiving NAC achieved lower proportions of pCR than women and had significantly worse OS. However, pCR is prognostic in both MaBC and FBC. Limitations include small sample sizes for HR-/HER2+ and triple-negative TS and lack of detailed regimen information. Nevertheless, our results suggest that, compared with FBC, MaBC may be intrinsically more resistant to NAC. Research Sponsor: None.

	MaBC		FBC			
	N	pCR (ypT0/Tis ypN0) (%)	N	pCR (ypT0/Tis ypN0) (%)	p	Odds ratio (95% CI) pCR FBC v MaBC
HR+/HER2-	206	4.9	25,326	9.7	0.01	2.1 (1.1 – 4.0)
HR+/HER2+	112	16.1	15,539	33.6	<0.001	2.6 (1.6 – 4.4)
HR-/HER2+	25	44.0	8,198	53.2	0.42	1.4 (0.7 – 3.2)
Triple negative	42	21.4	19,002	32.1	0.18	1.7 (0.8 – 3.6)

588 Poster Session (Board #80), Fri, 8:00 AM-11:00 AM

Differential effects of epirubicin and docetaxel on the immune system in patients with breast cancer (BC). *First Author: Kerstin Wimmer, Department of Surgery and Comprehensive Cancer Center, Medical University Vienna, Vienna, Austria*

Background: Neoadjuvant chemotherapy (NAC) with epirubicin/cyclophosphamid (EC) followed by docetaxel (D) is currently a standard of care therapy in women with early, high-risk breast cancer (BC). New approaches aim to improve the outcome by combining chemo- with immunotherapy. It is therefore of great interest if chemotherapeutics differ in their effect on the immune system and if some substances are superior combination partners than others. **Methods:** 79 BC patients, who participated in the ABCSG-34 trial, were included. 39 patients were treated with 6 cycles of EC followed by 6 cycles of D and 40 received the reverse sequence (D→EC). Blood was collected before and after 6 cycles. The plasma levels of a variety of immune mediators were determined by multiplex bead array assay. The response to therapy was measured by Residual Cancer Burden (RCB)-score. A score of ≤1.36 was determined as good response. Lymphocyte activation was assessed after stimulation with phytohaemagglutinin (PHA) by flow cytometric analysis of IFNgamma. Additionally, lymphocytes of 6 healthy probands were stimulated with PHA and treated with E or D. The stimulation was quantified by measuring cluster formation after 5 days. Further, a human BC cell line (SK-BR3) was treated with E or D. The induced cell death was determined morphologically as well as by flow cytometry after staining of phosphatidylserine, Sub-G1 DNA and active caspase-3. **Results:** The treatment of BC patients with 6 cycles of EC resulted in a decrease of lymphocyte stimulation whereas 6 cycles of D had no effect. The plasma levels of most immune mediators decreased significantly after six cycles EC when compared to baseline. Under the influence of D, the effect was much weaker. The changes of Eotaxin and OPG during the first 6 cycles of D correlated with the RCB-score in the reverse group. A decrease in Eotaxin (p = 0.0136) or in OPG (p = 0.0487) correlated with good response. The in vitro lymphocyte stimulation assay showed that E and D have similar inhibitory effects on lymphocytes.The annexin V/PI analysis confirmed that E more often leads to apoptotic cell death in SK-BR3 cells than D (E:53% vs. D:14%). SK-BR3 cells formed more often polyploid cells when treated with D. This suggests that D induces a regulated form of necrosis whereas E apoptosis. **Conclusions:** This study is the first to compare the immunomodulatory effect of E and D in BC patients. E inhibits lymphocyte activation in vitro and in vivo and suppresses many soluble immune mediators. This suggests that it is not suited for combination with immunotherapies. D showed a much weaker effect. Research Sponsor: Georg-Stumpf-Stipendium.

589 Poster Session (Board #81), Fri, 8:00 AM-11:00 AM

Long-term outcomes of patients with HER2+ breast cancer with small-size residual disease (≤ypT1) in the absence of pathological response after trastuzumab-based neoadjuvant chemotherapy and without adjuvant T-DM1: A monocentric retrospective study. *First Author: Ludovic Doucet, ICO, Nantes Saint-Herblain, France*

Background: The Katherine trial has shown that adjuvant T-DM1 improved invasive disease free survival (iDFS) of patients with HER2+ breast cancer who did not achieve a pathological complete response (pCR) with trastuzumab-based neoadjuvant chemotherapy (NAC). However, some subgroups may benefit less from this treatment escalation. **Methods:** All HER2+ breast cancer patients treated with trastuzumab-based NAC between 2006 and 2016 were retrieved from our institution's database. Neo- or adjuvant T-DM1 was an exclusion criterion. We then selected the patients who did not achieve a pCR and analyzed the outcome (iDFS and overall survival (OS)) according to ypT, ypN and several factors analyzed in the Katherine trial. **Results:** Out of the 182 patients, 117 patients reached the inclusion criteria. Patient's characteristics were similar to the trastuzumab arm of the Katherine trial. With a median follow-up of 75.4 months (29.3–149.7), 28 events (24%) occurred, among which 22 distant relapses. In univariate analysis, ≤ypT1 vs > ypT1, ypN0 vs ypN+, no capsular rupture, signs of histological response (Sataloff not D in T or N) were associated with a better iDFS. In multivariate analysis, only ypT status remained significant. Of note, patients with ≤ypT1 (ypTis, ypT0, ypTmic, ypT1) (n = 81; 69%) had an excellent outcome: 3 years (y) and 5y iDFS rates of 90% (83.6-96.8) and 88.6% (81.9-95.9) respectively. The remaining patients (n = 36; 31%) had a significantly lower 3y and 5y iDFS: 69.2% (55.6-86.2) and 59.5% (45-78.6) respectively (p = 0.0017). OS in a multivariate analysis was also improved in pts with the smaller residual and/or node negative disease (3y OS rates of 100% (100-100) vs 92.1% (85.7-99); 5y OS rates of 96% (90.7-100) vs 81.1% (71.6-91.9); p = 0.02). **Conclusions:** In the absence of pCR after trastuzumab-based NAC, patients with pathological response scored as ≤ypT1 (ypTis,ypT0, ypTmic, ypT1) have an excellent outcome. These patients may derive less benefit from adjuvant T-DM1. Research Sponsor: None.

590 Poster Session (Board #82), Fri, 8:00 AM-11:00 AM

One-year follow-up of health-related quality of life in the Swedish PREDIX HER 2 trial, evaluating docetaxel, trastuzumab sc, pertuzumab versus trastuzumab emtansine as neoadjuvant treatment of HER2 positive breast cancer. *First Author: Yvonne Brandberg, Karolinska Institutet, Department of Oncology-Pathology (OnkPat), Karolinska University Hospital, Stockholm, Sweden*

Background: Neoadjuvant therapy combining docetaxel, trastuzumab and pertuzumab (DTP) was compared to trastuzumab emtansine (T-DM1) in the randomised phase II PREDIX HER2 trial. Patients, ≥18 years with HER2 positive breast cancer, ≥20mm or with verified lymph node metastases, were randomised to six courses of DTP (Standard group) or T-DM1 (Experimental group) before surgery. After operation patients in the Standard arm received two, and those in the Experimental arm four courses of EC. Since there were no differences in proportions of complete response at surgery and in the event-free survival between the groups, health-related quality of life (HRQoL) is of special interest. **Methods:** HRQoL was measured, using European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 + EORTC QLQ-BR23, before randomisation, after six courses before surgery, at three months and one year after surgery. **Results:** Response rate for the questionnaires varied between 87% and 99% for the 198 included patients. There were no between-group differences at baseline. Results after six courses revealed statistically significant differences (p≤0.01), favouring the Experimental group on 12 out of 21 of the EORTC QLQ-C30 and BR23 variables (Physical-, Role-, and Social- functioning, Global quality of Life, Fatigue, Dyspnea, and Diarrhea, Body image, Sexual functioning, Sexual enjoyment, Systemic therapy side effects and Upset by hair loss). Three months after surgery, however, statistically significant differences in favour of the Standard group were found for six variables (Physical functioning, Nausea/vomiting, Dyspnea, Constipation, Systemic therapy side effects, Upset by hair loss). No other between group differences were found with one exception: lower levels of Breast symptoms in the Experimental group. One possible explanation is that patients in the Experimental group were still on chemotherapy at that assessment point, whereas the majority in the Standard group had terminated their treatment. No differences were found between the groups at the one-year after surgery follow-up, where the levels on most variables had returned to baseline values. **Conclusions:** HRQoL was better in the Experimental group during neoadjuvant treatment. Three months after surgery, however, HRQoL was in favour or the Standard arm. HRQoL returned to baseline levels for most variables at the one-year follow-up and no between-group differences were found. Clinical trial information: NCT02568839. Research Sponsor: Swedish Cancer Society.

591 Poster Session (Board #83), Fri, 8:00 AM-11:00 AM

12-chemokine gene expression score in breast cancer patients treated with neoadjuvant chemotherapy. *First Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Although advances in immunotherapy for the treatment of breast cancer have been minimal compared with other cancers, studies demonstrating tumor-infiltrating lymphocytes and immunomodulatory gene activation in the tumor microenvironment suggest the importance of antitumor immune responses in clinical outcomes. A 12-chemokine gene score has been shown to predict the presence of ectopic lymph node-like structures (ELN) in the tumor microenvironment and improved survival in melanoma, colon cancer, and breast cancer patients (Prabhakaran, 2017). Here, we evaluated this signature in an independent dataset of breast cancer patients treated with neoadjuvant chemotherapy. **Methods:** Tumor specimens used in this retrospective analysis (n = 92) were from breast cancer patients enrolled in either MINT (NCT0151487) or NBRST (NCT01479101) neoadjuvant registry trials from 2011 to 2016. Clinical data were captured with informed consent, and 70-gene signature (70-GS), 80-gene signature (80-GS), and full transcriptome data were generated by Agendia, Inc. Gene expression data were quantile normalized using R limma package. Principal component analysis (PCA) was performed on the normalized dataset using R princomp package. Chemokine score (CS) was defined as the first principal component values resulting from PCA. 70-GS/80-GS and clinical data were evaluated in relation to CS. CS were compared using Mann-Whitney test. **Results:** Of 92 breast tumors available for analysis, 84% were 70-GS High Risk (HR). Tumors were 39% Luminal-type, 24% HER2-type, and 32% Basal-type by 80-GS. HR tumors had higher CS than 70-GS Low Risk (LR) tumors ($p < 0.001$). 80-GS Basal-type, HER2-type, and Luminal B tumors had higher CS than Luminal A tumors ($p < 0.01$ for each comparison). High grade and ER-negative tumors seemed to have a high CS, although not significantly. Tumors from patients who achieved a pathological complete response (pCR) following neoadjuvant chemotherapy had higher CS than patients with residual cancer burden (p = 0.048). **Conclusions:** The current study demonstrated a significantly higher CS in 70-GS HR tumors and those which achieved pCR following neoadjuvant chemotherapy. Although further study is needed to evaluate the association of high CS with tumor-associated ELN, these results support previous work demonstrating that, although high CS is associated with aggressive clinical features, it also predicts superior clinical outcomes. The current study suggests validation of the 12-chemokine gene score in an independent dataset of breast cancer patients. Research Sponsor: Agendia, Inc.

592 Poster Session (Board #84), Fri, 8:00 AM-11:00 AM

Liquid biopsy of the immune environment: Evaluation of peripheral blood mononuclear cells (PBMCs) with CyTOF and response to trastuzumab (T)-based neoadjuvant chemotherapy (NAC) in HER2+ breast cancer (BC). *First Author: Roberto Antonio Leon-Ferre, Mayo Clinic, Rochester, MN*

Background: Immune responses in the tumor microenvironment have prognostic and predictive value in BC. However, the potential of immune responses observed in peripheral blood as biomarkers in BC remains unclear. We have shown that a higher frequency of circulating monocytes and a lower frequency of antigen-experienced memory CD8+ T cells are associated with response to NAC in triple negative BC (Leon-Ferre et al SABCS 2019). Here, we used cytometry by time-of-flight (CyTOF) to evaluate associations between circulating immune cells, clinical features and response to T-based NAC in HER2+ BC. **Methods:** PBMC suspensions from 36 pts with stage I-III HER2+ BC were prospectively collected prior to initiation of T-based NAC, stained with 29 metal-tagged antibodies optimized to identify major human immune cell subsets, and acquired in the Helios CyTOF instrument. Differential abundance analysis of immune cells by clinical characteristics and by NAC response was evaluated using Wilcoxon rank sum test. % of immune cell subsets is presented as % of all PBMCs. **Results:** Most pts presented with ER- tumors (56%), measuring > 5cm (64%) and with nodal metastases (78%). After NAC, 16 pts (44%) achieved pathologic complete response (pCR). Analysis of preNAC PBMCs demonstrated a significantly higher number of B cells (8% vs 5%, p = 0.05) and effector memory CD8+ T cells (CD45RA-/CCR7-, 3 vs 1%, p = 0.02) in pts with pCR compared to those with residual disease. Of the B cell subsets, naïve B cells (CD24-/CD27-) were higher in pts who achieved pCR vs not (7% vs 4%, 0 = 0.04). Regarding clinical characteristics, cN+ pts at presentation exhibited a lower number of peripheral blood T cells compared to cN- pts (47% vs 63%, p = 0.03). Of the T cell subsets, overall CD4+ and naïve CD4+ T cells (CD45RA+/CCR7+) were lower in cN+ vs cN- pts (31% vs 45%, p = 0.05; and 11% vs 24%, p = 0.04). We also observed differences in CD56+/CD16- NK cells by ER status (ER- 1% vs ER+ 3%, p = 0.01), and a moderate negative correlation between age and % circulating CD8+ T cells (rho -0.4669, p = 0.004). **Conclusions:** Distinct peripheral blood immune cell profiles are observed in HER2+ BC at diagnosis, and are associated with response to T-based NAC and initial clinical characteristics. Notably, pts who later achieved pCR had a relative abundance of B cells and effector memory CD8+ T cells at diagnosis. These data suggest that immune cell phenotyping in peripheral blood may have potential as a biomarker to predict response to NAC in BC. 593 Poster Session (Board #85), Fri, 8:00 AM-11:00 AM

Impact of body composition on toxicity and pathological complete response in locally advanced breast cancer (BC). *First Author: Laura Sofia Munoz-Arcos, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY*

Background: Obesity, defined as body mass index (BMI) > 30 kg/m^2, has been associated with inferior outcomes in localized breast cancer (BC), including lower pathological complete response (pCR) to neoadjuvant chemotherapy (NAC). High BMI is usually associated with excess adipose tissue (AT), but also reflects skeletal muscle (SM) mass. Low SM mass (sarcopenia) has also been associated with inferior outcomes and more chemotherapy-associated toxicity. We aimed to evaluate the association of BMI, AT and SM tissue with pCR and toxicity after NAC for stage II-III breast cancer (BC). **Methods:** 191 patients with stage II-III BC received NAC, had information regarding baseline BMI, toxicity and pCR to NAC at surgery, and, had abdominal computerized tomography (CT) prior to NAC. Total AT (TAT), visceral AT (VAT), subcutaneous AT (SAT), SM area (SMA) and SM density (SMD) were measured by CT at the L3 level using the TOMOVISION software. SM index (SMI) was calculated (SMA/height) to assess for sarcopenia (SMI < 40). Association linking BMI, SAT, VAT, SMA and SMD to pCR and severe toxicity (ST ≥ grade 3) was evaluated using logistic regression models. **Results:** Patients were predominantly black (51%) with a median age of 54 years (interquartile range = 45-63). pCR was achieved in 31% (60/191) of patients. Of those, 47% (n = 28/60), 40% (n = 24/60) and 13% (n = 8/60) corresponded to HER2(+), triple negative, and hormone receptor-HR(+)/HER2(-) tumors, respectively. ST occurred in 38% (n = 73/191) of patients. Obesity and sarcopenia were present in 52% (n = 100/191) and 14% (n = 27/191) of patients, respectively. There was a statistically significant association between VAT and pCR (median VAT 95.3 cm^2 vs. 121.8 cm^2 in the pCR vs. no-pCR groups, respectively, p = 0.03). This association remained after adjusting for age, race, tumor grade, stage, BMI, SMD, HR and HER2 status (p = 0.04). There was a statistically significant association between SMA and ST (mean SMA 123 cm^2 vs. 130 cm^2 in the ST vs. no-ST groups, respectively, p = 0.03). This association disappeared after adjusting for age, race, BMI, VAT, SAT, and SMD (p = 0.21). **Conclusions:** This study provides evidence that in patients with stage II-III BC receiving NAC, excess VAT is associated with significantly lower pCR rates, and low SMA is associated with ST. Additional research is needed to elucidate the pathophysiologic mechanisms contributing to these associations. Research Sponsor: None.

594 Poster Session (Board #86), Fri, 8:00 AM-11:00 AM

Prediction of response to neoadjuvant hormonal therapy (NAHT) using upfront oncotype Dx recurrence score (RS): Results from the SAFIA phase III trial. *First Author: Khalid A Al-Saleh, King Saud University, College of Medicine, Riyadh, Saudi Arabia*

Background: While hormonal therapy (HT) is a fundamental treatment in breast cancer therapy, neoadjuvant NAHT is not considered standard. The SAFIA trial is a prospective international neoadjuvant Phase III investigating the potential role of the addition of palbociclib (P) in patients (pts) sensitive to HT. We report the results of induction Faslodex (+/- zoladex) in pts initially selected by RS < 31, in order to assess their individual HT sensitivity before double-blind randomization HT vs HT + P followed by surgery. **Materials and Methods:** A total of 308 pts (stages II and IIIA Luminal A/B HER2 negative) in 24 centers and 6 countries (Middle-East/Maghreb) underwent upfront RS to select pts for induction HT. Pts with RS < 31 received induction neoadjuvant fulvestrant (500 mg i.m Day 1, 14, 28 then q.4 weeks) + goseriline (3.6 mg s.c q.4 w for pre and peri-menopausal pts) for 4 months, followed by clinical and radiological assessment of the disease response before randomization. Response was defined as no progression: Complete Response-CR/ Partial Response-PR: > 50% and Minor Response-MR: < 50% to > 0%/ No Response-NR: progression > 0%. **Results:** A total of 70 pts (22%) with RS > 31 were excluded, leaving 238 eligible pts for NAHT, age (25-84); pre-peri/ post menopause: 135 (57%)/103 (43%); Luminal A/B: 112 (49%)/114 (51%); Stage II/IIIA: 196 (87%) / 29 (13%). One hundred and seventy-seven pts (177) have validated responses to induction NAHT: CR: 9 pts (5%) / MR: 105 pts (59%) for major response rate: 64% / MR: 56 pts (32%) / NR: 7 pts (4%); available RS 0-10: 23 pts (16%) / RS 11-18: 67 pts (47%) / RS 19-25: 34 pts (24%) / RS 26-30: 18 pts (13%). Correlations between Response to NAHT and RS are shown in the table below (not statistically significant). **Conclusions:** In our population, upfront Oncotype DX RS < 31 allowed to select pts for induction NAHT without loss of chances with a no-progression rate (CR+PR = MR) of 96%. No significant correlation was found between RS and response to NAHT. Upfront RS > 31 (22%) is selecting pts candidates for neoadjuvant chemotherapy with a potential high risk of endocrine resistance. Clinical trial information: ICRG1201. Research Sponsor: Investigator initiated trial funded by Pfizer and AstraZeneca, Other Government Agency.

595 Poster Session (Board #87), Fri, 8:00 AM-11:00 AM

Statistical modeling of a novel clinical trial design using neoadjuvant therapy (NAT) to personalize therapy in patients (pts) with triple-negative breast cancer (TNBC). *First Author: Stacy L. Moulder, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: 40-50% of pts with TNBC develop pathologic complete response (pCR) with adriamycin/cyclophosphamide (AC)àtaxane (T) NAT; thus, most pts treated in randomized trials (RCTs) adding experimental drugs (ED) to standard NAT do not benefit from trial participation. A personalized trial design that enriches for non-pCR to standard NAT would diminish toxicity from ED in pts who do not need them and enrich ED in high-risk pts that are most likely to benefit. **Methods:** ARTEMIS (NCT02276443) is a non-randomized trial to study personalization of NAT in TNBC. Tumor biopsies were performed pre-NAT and volumetric change by ultrasound (VCU) after 4 cycles of AC (or upon clinical progression) assessed response. Pts with sensitive TNBC (VCU >=70% after AC) had T as the second phase of NAT. Pts with <70% VCU were offered phase II trials. pCR was assessed at surgical resection. 273 pts had available pCR status and 222 had complete data to generate a model predictive of response using multivariate logistic regression with common clinical factors. Data was randomly divided into training (n=111) and validation (n=111) sets. **Results:** 85 pts (38%) had pCR and VCU after AC x 4 was the strongest predictor of pCR. Other factors significant on multivariate analysis and included in the model were T stage (T1-4), stromal TIL, Ki67 and PD-L1. When applied to the validation data set, the accuracy of this model for predicting pCR was 76.6%, sensitivity 78.6% and specificity 75.4%. The PPV was 66.0% and the NPV was 85.2% with a ROC curve AUC of 82.4%. Using these data, ED exposure (table) was estimated for the ARTEMIS study design vs a 1:1 or a 2:1 RCT design (with an estimated pCR in control arm=40%), with a demonstrated benefit for personalization. **Conclusions:** This modeling indicates that personalization of NAT trials has the potential to enrich ED exposure for non-responsive disease as well as diminish ED exposure in pts likely to achieve pCR with standard NAT. Improved prediction of pCR would further enhance personalized trial design. Clinical trial information: NCT02276443. Research Sponsor: MD Anderson Moon Shot.

TPS596 Poster Session (Board #88), Fri, 8:00 AM-11:00 AM

KEYLYNK-009: A phase II/III, open-label, randomized study of pembrolizumab (pembro) plus olaparib vs pembro plus chemotherapy after induction with first-line pembro plus chemotherapy in patients with locally recurrent inoperable or metastatic triple-negative breast cancer (TNBC). *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Combination therapy with immunotherapy + chemotherapy is a promising approach for first-line (1L) treatment of locally recurrent, inoperable TNBC or metastatic TNBC (mTNBC). However, an unmet need exists for effective and tolerable maintenance regimens in mTNBC to sustain clinical benefit after induction therapy and avoid potential toxicity or resistance in response to prolonged chemotherapy. The PARP inhibitor olaparib has demonstrated efficacy in the maintenance setting for multiple platinum-sensitive tumors, and the prevalence of *BRCA* mutations in TNBC may make these tumors particularly sensitive to DNA-damaging agents. Moreover, previous data suggest that combination therapy with olaparib and the PD-1 inhibitor pembro may have clinical benefits. KEYLYNK-009 (NCT04191135) is a phase II/III, open-label, randomized study of pembro + olaparib or pembro + chemotherapy after induction with 1L pembro + chemotherapy in patients with locally recurrent, inoperable TNBC or mTNBC. **Methods:** This 2-in-1 study design will enroll ~317 patients in phase II; if a planned efficacy boundary is met, ~615 additional patients will be enrolled in phase III. Patients eligible for induction therapy must have measurable, locally recurrent, inoperable TNBC that cannot be treated with curative intent or mTNBC previously untreated with chemotherapy in the metastatic setting. All patients will receive up to 6 cycles of induction therapy with pembro 200 mg every 3 wk (Q3W) + chemotherapy (carboplatin AUC 2 + gemcitabine 1000 mg/m^2). Patients eligible for postinduction treatment must achieve complete or partial response or maintain stable disease during induction after 4-6 treatment cycles, with ECOG PS 0/1 and no grade >1 toxicities related to induction therapy (excluding alopecia, Hb ≥9.0 g/dL, grade 2 hyper-/hypothyroidism, or grade 2 hyperglycemia). These patients will be randomized 1:1 to receive pembro 200 mg Q3W + olaparib 300 mg twice daily or continue pembro + chemotherapy (same as induction regimen). Olaparib and chemotherapy may continue until progression or unacceptable toxicity; pembro may continue for ≤35 cycles (including induction), unacceptable toxicity, or progression. Phase III dual primary endpoints are PFS per RECIST v1.1 by BICR and OS. Secondary endpoints include OS and PFS in patients with BRCAm, health-related quality of life, and safety. Enrollment is ongoing. Clinical trial information: NCT04191135. Research Sponsor: Merck Sharp & Dohme Corp.

TPS597 **Poster Session (Board #89), Fri, 8:00 AM-11:00 AM**

Randomized, phase II trial to evaluate the efficacy and safety of atezolizumab plus capecitabine adjuvant therapy compared to capecitabine monotherapy for triple receptor-negative breast cancer (TNBC) with residual invasive cancer after neoadjuvant chemotherapy (MIRINAE trial, KCSG-BR18-21). *First Author: In Hae Park, Division of Hemato-Oncology, Department of Internal Medicine, Korea University College of Medicine, Guro Hospital, Seoul, South Korea*

Background: Triple negative breast cancer (TNBC), lack of ER, PR and HER2 expression, is known to have aggressive clinical features such as early recurrence, drug resistance, and frequent distant metastasis at the diagnosis. The most effective chemotherapy combinations used for early TNBC include anthracycline, taxanes, and/or platinum agents. Achieving a pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) provides important prognostic information and is considered as a surrogate endpoint in many clinical trials especially with TNBC. Patients with residual invasive disease after NAC have a high risk for early relapse and worse prognosis compared to those with pCR. Therefore, patients who did not get pCR could be better candidates for additional adjuvant treatment because their risk of recurrence would be higher than those with pCR. The CREATE-X (capecitabine for residual cancer as adjuvant therapy) trial howed that adjuvant capecitabine treatment improved 5-yr rate of disease free survival in TNBC subtype. A recent study indicated that immunosuppressive microenvironment had developed even in early stage of TNBC with increased T cells with a high exhaustion signature which are targets of immune modulating agents. Therefore, earlier cooperation of immune modulating drugs would be beneficial by generating a long-lasting anti-tumor immune response to micrometastatic disease, thus preventing disease relapse or recurrence. **Methods:** This study is a phase II, multicenter, randomized open label trial of atezolizumab (anti-PD-L1 antibody) and capecitabine compared with capecitabine in patients with TNBC who had residual disease after NAC. 284 patients will be enrolled from 15 sites in Korea with a primary objective to access the 5-yr invasive disease-free survival (IDFS) rate. Secondary objectives include 5-yr IDFS rate in PD-L1 positive population, distant relapse free survival (DRFS), overall survival (OS), and safety. Major inclusion and exclusion criteria are followings; 1) histologically confirmed TNBC, 2) received anthracycline and taxane based NAC followed by complete breast surgery, 3) residual disease after NAC must be $\geq$1cm in the greatest dimension, and/or have macroscopically positive lymph nodes. The study is open with 13 patients enrolled at the time of submission. Clinical trial information: NCT03756298. Research Sponsor: Roche Korea.

TPS598 **Poster Session (Board #90), Fri, 8:00 AM-11:00 AM**

Phase III randomized study of adjuvant treatment with the ANTI-PD-L1 antibody avelumab for high-risk triple negative breast cancer patients: The A-BRAVE trial. *First Author: Pier Franco Conte, Department of Surgery, Oncology and Gastroenterology, University of Padova and Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padua, Italy*

Background: Chemotherapy represents, today, the only treatment option for triple negative breast cancer (TNBC) and still a considerable proportion of pts with primary TNBC experience disease relapse. The risk is particularly high in the presence of poor prognostic features, such as more advanced stage and, for pts treated with neoadjuvant chemotherapy, failure to achieve a pCR. Recent evidence suggest that immunotherapy can play a major role in TNBC pts. **Methods:** The A-BRAVE trial is an investigator-driven trial sponsored by the University of Padova (Dept. of Surgery, Oncology and Gastroenterology). This is a phase III, multicentric, randomized adjuvant study that compares 1 year of treatment with the anti PD-L1 avelumab vs observation for pts who completed treatment with radical intent for primary TNBC including surgery and chemotherapy. The study enrolls pts in two strata: -Stratum A: primary TNBC pts who completed surgery followed by adjuvant, defined according to one of the following stage categories: if pN2, any pT; if pN1, pT $>$ 2 cm; if pN0, pT $>$ 5 cm. -Stratum B: primary TNBC pts who completed neoadjuvant chemotherapy followed by surgery who did not achieve pCR. Pts who also received additional adjuvant chemotherapy for no more than 6 months are eligible in Stratum B, after the completion of the adjuvant chemotherapy. Pts are randomized (1:1, balanced for strata A and B) to receive Avelumab 10 mg/kg I.V. q2w for 1 year or to observation. The first and second co-primary endpoints are disease-free survival (DFS) in all pts and DFS in Stratum B pts. With a planned sample size of n = 474 pts the trial has 90% power to detect a HR = 0.60 for the first co-primary endpoint (n = 172 events required). Taking into account that the percentage of patients enrolled in the stratum B could range from 70 to 80%, there will be 70-79% power to detect a HR = 0.60 at alpha allocated in this patient subgroup (second co-primary endpoint). Secondary objectives include: DFS in PD-L1 positive pts, overall survival, safety, biomarkers. Tumor tissue, plasma samples and fecal samples are collected for biomarker analysis. The study is currently recruiting across 73 sites in Italy and UK. As of February 2020, n = 349 pts have been enrolled. EUDRACT 2016-000189-45. The authors present the A-BRAVE trial in progress on behalf of Italian and UK investigators. Clinical trial information: NCT02926196. Research Sponsor: The Trial is supported by Merck KGaA.

TPS599 **Poster Session (Board #91), Fri, 8:00 AM-11:00 AM**

Phase III, randomized, double-blind, placebo-controlled study to evaluate the efficacy and safety of adagloxad simolenin (OBI-822) and OBI-821 treatment in patients with early-stage triple-negative breast cancer (TNBC) at high risk for recurrence. *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Adagloxad simolenin (AS) is a therapeutic vaccine comprising the tumor-associated antigen Globo H linked to the carrier protein keyhole limpet hemocyanin (KLH). The KLH provides antigenic immune recognition and T-cell responses. AS is co-administered with a saponin-based adjuvant OBI-821 to induce a humoral response. A phase 2 trial showed that AS/OBI-821 exhibited a trend for superior progression-free survival vs placebo in patients whose breast cancers have higher Globo H expression. **Methods:** Patients with TNBC (ER/PR $<$ 5%, and HER2-negative) with nonmetastatic disease and either 1) residual invasive disease of $\geq$1 cm in the breast or $\geq$1 positive axillary node following neoadjuvant chemotherapy or 2) $\geq$4 axillary lymph nodes with invasive carcinoma treated with adjuvant chemotherapy are included. Patients are prescreened for Globo H expression using a validated IHC assay (H-score of $\geq$15). Patients will receive either AS (30 μg) with OBI-821 (100 μg) or volume-matched placebo (1:1), administered as SC injections. Up to 21 SC injections of study treatment (or placebo), will be administered over 100 weeks, given on the following schedule: weekly for 4 doses; every 2 weeks for 4 doses; every 4 weeks for 4 doses; and then every 8 weeks for 9 doses. Patients may terminate treatment due to disease recurrence or unacceptable toxicity, withdrawal of consent, protocol violation, loss to follow-up or death. The primary objective is to determine the effect of AS/OBI-821 treatment on invasive disease-free survival in patients with TNBC at high risk for recurrence. Secondary objectives are to determine the impact of AS/OBI-821 treatment on overall survival, quality of life (QoL), breast cancer-free interval, distant disease-free survival, safety, and tolerability. Imaging and clinical examination will be performed regularly for 5 years. QoL will be assessed using the EORTC Core Quality of Life Questionnaire (QLQ)-C30 plus the EORTC Breast Cancer-specific QLQ-BR23 questionnaire and the European Quality of Life 5 Dimensions 5 Levels (EQ-5D-5L) questionnaire. Adverse events will be graded/recorded as per National Cancer Institute CTCAE v5.0. An estimated 668 subjects will be enrolled, treated for up to 2 years and followed until occurrence of 187 events (invasive disease recurrence or death) or 3 years from last subject randomized. Survival follow-up is for 5 years from randomization of last subject. Clinical trial information: NTC03562637. Research Sponsor: OBI Pharma Inc.

TPS600 **Poster Session (Board #92), Fri, 8:00 AM-11:00 AM**

ABC trial (A011502): A randomized phase III double-blinded placebo-controlled trial of aspirin as adjuvant therapy breast cancer. *First Author: Wendy Y. Chen, Dana-Farber Cancer Institute, Boston, MA*

Background: In-vitro and in-vivo evidence suggest that aspirin may have an anti-tumor effect. Multiple epidemiologic studies have reported improved breast cancer survival among regular aspirin users compared to non-users. Pooled data from randomized trials of aspirin for cardiovascular disease have also reported a decreased risk of metastatic cancer among aspirin users. However, the exact benefits and risks for breast cancer survivors need to be confirmed in a randomized controlled trial. Even if the clinical effect were modest, the global impact would be substantial since aspirin is inexpensive and widely available. **Methods:** The primary objective is to compare the effect of 300 mg daily aspirin versus placebo upon invasive disease-free survival (iDFS) in high risk HER2 negative breast cancer patients. Secondary objectives include effects on overall survival, cardiovascular disease, toxicity, and adherence. A biospecimen repository will be created for correlative analyses including tumor collection at baseline and blood and urine samples and questionnaires assessing lifestyle factors associated with inflammation (pain, sleep, stress, and depression) at baseline and 2 years. Study design: Subjects will be randomized (1:1) to aspirin 300 mg vs placebo daily for 5 years in a double-blinded fashion. Stratification factors include hormone receptor (HR) status (positive vs negative), body mass index ($<$ or $\geq$ 30 kg/m2), and stage (II vs III). Subjects will be followed every 6 six months while on study drug, then annually for 10 years. Accrual goal is 2936 patients to reach 381 iDFS events. We have 80% power to detect HR 0.75 assuming 5-year iDFS on placebo of 77%. Eligibility: Eligible subjects include patients aged 18-70 diagnosed with a primary invasive HER2 negative breast cancer. If HR positive, tumors need to be node positive and diagnosed within the past 10 years. If HR negative, tumor can be node positive or T2-4N0 within 18 months of diagnosis. Subjects who are currently anticoagulated or those with a prior history of GI bleeding, atrial fibrillation, or myocardial infarction are excluded. Subjects who regularly use aspirin (defined as $\geq$ 5 days per week) need to stop 30 days prior to enrollment. Updated accrual numbers will be given at the time of presentation. Clinical trial information: NCT02927249. Research Sponsor: Department of Defense, U.S. National Institutes of Health.

TPS601 **Poster Session (Board #93), Fri, 8:00 AM-11:00 AM**

ADAPTcycle: Adjuvant dynamic marker-adjusted personalized therapy (ADAPT) comparing endocrine therapy plus ribociclib versus chemotherapy in intermediate-risk HR+/HER2- early breast cancer (EBC). *First Author: Nadia Harbeck, Breast Center, Dept. Obstetrics & Gynecology, University of Munich (LMU) and CCCLMU and West German Study Group, Munich, Germany*

Background: The WSG ADAPT trial program represents the concept of individualization of (neo)-adjuvant decision-making in EBC in a subtype-specific manner. The first WSG ADAPT umbrella trial aimed to establish early predictive molecular surrogate markers for response after a short 3-week induction treatment. The goals of the WSG ADAPT trial program are early response assessment and subtype-specific therapy tailoring to those patients who are most likely to benefit. **Methods:** WSG-ADAPTcycle is a prospective, multi-center, interventional, two-arm, open-label, (neo)adjuvant, non-blinded, randomized, controlled phase III trial (NCT04055493). It investigates whether patients (pts.) with HR+/HER2- EBC identified during screening as intermediate risk (based on Oncotype DX and response to 3 weeks of preoperative endocrine therapy [ET]) derive additional benefit from 2 years of the CDK4/6 inhibitor ribociclib combined with ET compared to chemotherapy (CT) (followed by standard ET). Co-primary endpoints are disease-free survival (DFS) and distant DFS. It is planned to screen 5600 pts and to randomize 1670 pts in a 3:2 ratio (ribociclib + ET/CT). Study start was in July 2019 (80 sites, enrollment period 36 months) and until date of submission, 180 pts. have been screened and 40 randomized. Pts with HR+/HER2- EBC with clinically enhanced risk (cT2-4 or Ki67 20% or G3 or cN+) are eligible if they fulfill the ADAPT intermediate-risk group criteria: either Recurrence Score (RS) $\leq$25 and $Ki67_{postendocrine} > 10\%$, RS $>$25 and $Ki67_{postendocrine} < 10\%$ in p/cN0-1 pts, or RS $\leq$25 and $Ki67_{postendocrine} < 10\%$ in c/pN2-3 pts. Treatment duration is 2 years for the ribociclib + ET (premenopausal: AI + GnRH) arm and 16-24 weeks for the CT arm; treatment is possible either in the neoadjuvant (ET + ribociclib duration 16 – 32 weeks) or adjuvant setting. ePROs are collected using CANKADO; ECG monitoring is performed using a novel cardiology-supported CANKADO-based eHealth method. Translational analyses: Exploratory tissue biomarker research will be conducted to assess alterations in molecular markers. In addition, ctDNA/ctRNA from optional blood samples will be assessed for mutations and gene expression. Conclusions: ADAPTcycle seeks to evaluate whether endocrine-based therapy with ET and a CDK 4/6 inhibitor is superior to CT followed by ET in patients with luminal EBC who may be undertreated with ET alone (based on either lack of endocrine responsiveness or high tumor burden). Clinical trial information: 2018-003749-40. Research Sponsor: Novartis, Exact Science.

TPS602 **Poster Session (Board #94), Fri, 8:00 AM-11:00 AM**

Understanding and predicting fatigue, cardiovascular (CV) decline & events after breast cancer treatment (UPBEAT): A prospective multi-center wake forest NCORP research-base study. *First Author: Susan Faye Dent, Duke University School of Medicine, Durham, NC*

Background: Modern treatment for breast cancer (BC) has led to improved survival; however, this improvement can be offset by an increase in cancer therapy-related morbidity and mortality. Over one-third of early stage BC patients treated with cancer therapy experience CV injury, left ventricular (LV) dysfunction, exercise intolerance, or fatigue. CV disease is a leading cause of mortality in BC survivors. There is limited information on the time course and long-term CV health of BC survivors. UPBEAT, a multicenter study, will prospectively evaluate CV risk factors and outcomes in early stage BC patients, treated with modern anticancer therapies. This will facilitate evaluation of primary CV prevention strategies in this patient population. **Methods:** This is a prospective cohort study of 840 patients with early stage (I-III) BC treated with chemotherapy +/- radiation and 160 controls. Baseline and serial longitudinal measures will examine the influence of cancer treatment on CV function, exercise capacity and fatigue, and the future development of CV events. The comprehensive assessment includes: ascertainment of cardiac biomarkers, CV risk factors, comorbidities, functional status (e.g., disability measures, expanded short physical performance battery), neurocognitive tests, behavioral risk factors, socio-demographics, and quality of life at baseline, 3-, 12-, and 24-mos. Outcomes measured at the same time points include a deep phenotyping of CV dysfunction (via cardiac MRI assessing LV end diastolic volume, LV end systolic volume, LV ejection fraction, myocardial strain, strain rate, left atrial volumes and mass, and aortic stiffness), exercise intolerance (submaximal as 6-minute walk test and maximal as VO2 peak via cardiopulmonary exercise test), and fatigue (via FACT-F). Eligibility criteria: age $>$ 18 years; ECOG 0-2, able to walk without symptoms; receiving chemotherapy +/- HER2 targeted agent(s). To date, 244 participants are enrolled through 12 NCORP or ECOG-ACRIN sites. An additional 7 sites are onboarding and will be enrolling later in the year. Participants will be followed for 9 years with active surveillance of CV events (i.e., heart failure, myocardial infarction, stroke, all-cause and CV death). EA NCORP Grant: 2 UG1 CA189828 06; Research Base Grant: 2UG1 CA189824; RO1: 1RO1CA199167. Clinical trial information: NCT02791581. Research Sponsor: Wake Forest University Health Sciences, Other Government Agency.

TPS603 **Poster Session (Board #95), Fri, 8:00 AM-11:00 AM**

Personalized neoadjuvant strategy in luminal A breast cancer to increase breast conserving surgery (BCS) rate [PLATO study]. *First Author: Ji Gwang Jung, Seoul National University Hospital, Seoul, South Korea*

Background: The most important and well established benefit of neoadjuvant therapy for breast cancer patients is increased breast conservation rate. However, in ER-positive and HER-2 negative breast cancer, the response to neoadjuvant chemotherapy (NCT) is not as good as other subtype of breast cancer, such as HER-2 or triple-negative breast cancer. In addition, with the advancement of multi-gene assay tools for this subtype, adjuvant chemotherapy is not needed at all in significant proportion of this subtype. Through a selective neoadjuvant therapy, either chemotherapy or endocrine therapy using histopathologic markers and 70-gene assay (Mammaprint. Agendia inc.), we hypothesize that we could increase the breast conservation rate in ER-positive and HER-2 negative breast cancer. **Methods:** This study is a non-randomized, phase II, prospective study. The main inclusion criteria is women with stage I-IIIA, ER-positive and HER-2 negative breast cancer that tumor size is measurable. BCS is not feasible considering the tumor size, location, and patient's breast size. Two surgeons in each institution will judge the feasibility of BCS. Main exclusion criteria is diffuse malignant microcalcification or multicentric breast cancer. The conversion rate from BCS-ineligible to BCS-eligible with NCT was 35.8% in ER-positive and HER-2 negative breast cancer in our previous study. We assumed that with the study regimen, the rate will be increased to 50.8% (15% increase). Given these estimates, under 10% type II error rate and 90% power, 122 patients in total will be enrolled from nine tertiary hospitals in Korea. All the patients initially will be tested with Mammaprint assay. When the Mammaprint result is high risk, the patients will receive NCT. When the Mammaprint result is low risk, the patients will receive neoadjuvant endocrine therapy. Postmenopausal women receive letrozole 2.5mg per day for 16 weeks. Premenopausal women receive leuprorelin every 4 weeks with letrozole for 16 weeks. Period of neoadjuvant endocrine therapy can be prolonged maximum 24 weeks by physician's decision. The primary endpoint is conversion rate from BCS-ineligible to BCS-eligible of more than 50%. The secondary endpoint is actual breast conservation rate, pathologic complete response, clinical response rate, and disease-free survival. Clinical trial information: NCT03900637. Research Sponsor: Agendia Inc., Pharmaceutical/Biotech Company.

TPS604 **Poster Session (Board #96), Fri, 8:00 AM-11:00 AM**

A phase III trial of nivolumab with neoadjuvant chemotherapy and adjuvant endocrine therapy in ER+/HER2- primary breast cancer: CheckMate 7FL. *First Author: Sherene Loi, Peter MacCallum Cancer Institute, Melbourne, VIC, Australia*

Background: Patients (pts) diagnosed with primary estrogen receptor-positive (ER+), human epidermal growth factor 2-negative (HER2−) breast cancer (BC) of high grade and/or low ER expression are at increased risk of relapse, despite current standard of care (SoC). Promising data assessing programmed death-1 (PD-1) inhibition coupled with neoadjuvant chemotherapy for pts with high-risk ER+, HER2− BC noted improved pathologic complete response (pCR), which is identified as a valid surrogate endpoint for long-term clinical outcomes. **Methods:** CheckMate 7FL (NCT04109066) is a randomized, double-blind, placebo-controlled, multicenter, global phase 3 study evaluating nivolumab (NIVO) vs placebo (PBO) in combination with neoadjuvant chemotherapy and adjuvant endocrine therapy (ET) in pts with high-risk, ER+, HER2− primary BC. Eligible pts are male or female, aged $\geq$18 years with newly diagnosed grade 2 with ER expression of 1–9%, or grade 3, T1c-2, cN1-2 (tumor size $\geq$2 cm) or T3-T4, cN0-cN2 ER+, HER2− BC. Pts eligible for neoadjuvant chemotherapy and surgery, with adequate organ function, ECOG PS of 0 or 1, and tissue available for biomarker assessments will be enrolled. Approximately 1200 pts will be randomized 1:1 to NIVO or PBO, stratified by programmed death ligand 1 (PD-L1) expression, tumor grade (2 or 3), axillary nodal status (+ or −), and anthracycline + cyclophosphamide schedule (Q3W or Q2W). In the neoadjuvant phase, pts will receive NIVO 360 mg Q3W or PBO + paclitaxel 80 mg/m^2 QW for four 3-week cycles, followed by NIVO 360 mg Q3W (or 240 mg Q2W) or matching PBO in combination with either doxorubicin 60 mg/m^2 or epirubicin 90 mg/m^2 and cyclophosphamide 600 mg/m^2 Q3W or Q2W for 4 cycles. Pts will undergo surgery after completion of the neoadjuvant phase. Following surgery, pts will enter the adjuvant phase and receive NIVO 480 mg Q4W or PBO for 7 cycles + investigator's choice of ET per local SoC. Primary endpoints are pCR (ypT0/is, ypN0) and event-free survival. Secondary endpoints include overall survival, disease-free survival, distant-metastasis-free survival, safety, pCR (ypT0 ypN0 and ypT0/is) rates, overall response rates, residual cancer burden, and quality of life. Interim analyses are planned. The study is currently enrolling. Clinical trial information: NCT04109066. Research Sponsor: Bristol-Myers Squibb.

TPS605 **Poster Session (Board #97), Fri, 8:00 AM-11:00 AM**

PREDIX II HER2: Improving pre-operative systemic therapy for human epidermal growth factor receptor 2 (HER2) amplified breast cancer (BC).

First Author: Renske Kornalijnslijper-Altena, Karolinska University Hospital, Stockholm, Sweden

Background: Neo-adjuvant systemic therapy (NAT) is the standard of care for most patients with early HER2-amplified and triple negative breast cancer (BC). Increasing the rate of pathological complete response (pCR) is highly meaningful for those patients, as pCR is strongly predictive for improved long-term disease-related outcomes. Clinical and preclinical evidence support the hypothesis that pCR-rates may be augmented by the addition of checkpoint inhibitors, such as monoclonal antibodies targeting the Programmed Death Ligand receptor 1 (PD-L1), to standard systemic NAT. Studies in different BC patient cohorts (e.g., IMPassion130, PANACEA, KATE2) have indicated that PD-L1 protein expression on tumor-infiltrating lymphocytes (TIL's) is a predictive marker for checkpoint inhibitor efficacy. **Methods:** We have initiated a phase II open-label, 2:1 randomized clinical trial where women with early HER2-amplified, PD-L1+ BC (cT2-3 and/or cN+) are treated with standard NAT (composed of anti-HER2 antibodies with a chemotherapy backbone of sequentially taxanes + carboplatin and epirubicin + cyclophosphamide [EC]) +/- atezolizumab during EC. N = 190 patients will be accrued in nine centers in Sweden to be able to demonstrate a 20% increase in pCR-rate, with a power of 80% and a two-sided alpha of 10%. Firstly, a prescreening is performed to select patients with a PD-L1 expression of $>$ 1% on TIL's. Important exclusion criteria are significant organ dysfunction and (with some exceptions) active auto-immune diseases. Extensive translational side-studies are performed to explore predictive markers for treatment efficacy, including clinicopathologic studies, molecular imaging and microbiome analyses, as well as monitoring of acute and chronic treatment-related toxicity, objective cognitive function and quality of life. As of February 11th, 4 patients have been prescreened and 1 enrolled in the trial. The clinical trial registry number is NCT03894007. Clinical trial information: NCT03894007. Research Sponsor: Swedish Research Council, Other Foundation, Pharmaceutical/Biotech Company.

1000 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

KEYNOTE-355: Randomized, double-blind, phase III study of pembrolizumab + chemotherapy versus placebo + chemotherapy for previously untreated locally recurrent inoperable or metastatic triple-negative breast cancer. *First Author: Javier Cortes, IOB Institute of Oncology, Quiron Group & Vall d´Hebron Institute of Oncology (VHIO), Madrid & Barcelona, Spain*

Background: Pembrolizumab (pembro) monotherapy showed promising antitumor activity and manageable safety in patients (pts) with metastatic TNBC in KEYNOTE-012, -086 and -119. KEYNOTE-355 (ClinicalTrials.gov, NCT02819518) compared pembro + chemotherapy (chemo) vs placebo (pbo) + chemo for previously untreated locally recurrent inoperable or metastatic TNBC. **Methods:** Pts with ≥6 mo DFI were randomized 2:1 to pembro + chemo (nab-paclitaxel; paclitaxel; or gemcitabine/carboplatin) or pbo + chemo for up to 35 administrations of pembro/pbo or until progression/intolerable toxicity. Pts were stratified by chemo type (taxane vs gemcitabine/carboplatin), PD-L1 status (CPS ≥1 vs <1), and prior (neo)adjuvant treatment with same-class chemo (yes vs no). Dual primary endpoints are PFS (RECIST v1.1, blinded independent central review) and OS by tumor PD-L1 expression (CPS ≥10 and ≥1) and in all pts. PFS was estimated using the Kaplan-Meier method. Stratified log-rank tests were used to assess treatment group differences. HR and 95% CIs were based on a stratified Cox regression model. AEs were monitored throughout the study and graded per NCI CTCAE v4.0. **Results:** As of Dec 11 2019, median follow-up was 17.5 mo for pembro + chemo (n=566) and 15.5 mo for chemo (n=281). Pembro + chemo significantly improved PFS vs chemo alone in pts with CPS ≥10 tumors (Table), meeting one of the protocol-defined primary objectives. Although the boundary for a statistically significant benefit of pembro + chemo in pts with CPS ≥1 tumors was not met and formal testing in ITT was not performed, the pembro treatment effect increased with PD-L1 enrichment (Table). OS follow-up is ongoing. Grade 3-5 treatment-related AE rates were 68.1% with pembro + chemo (2 deaths) vs 66.9% with chemo (0 deaths); rates of grade 3-4 immune-mediated AEs and infusion reactions were 5.5% vs 0%. Clinical trial information: NCT02819518. **Conclusion:** Pembro combined with several chemo partners showed a statistically significant and clinically meaningful improvement in PFS vs chemo alone in pts with previously untreated locally recurrent inoperable or metastatic TNBC whose tumors expressed PD-L1 (CPS ≥10). Pembro + chemo was generally well tolerated, with no new safety concerns. Research Sponsor: Merck & Co., Inc.

Population	Treatment	Median PFS, mo	HR (95% CI)	*P*-value	*P*-value boundary
CPS ≥10	P + C (n=220) vs C (n=103)	9.7 vs 5.6	0.65 (0.49-0.86)	0.0012	0.00411
CPS ≥1	P + C (n=425) vs C (n=211)	7.6 vs 5.6	0.74 (0.61-0.90)	0.0014	0.00111
ITT	P + C (n=566) vs C (n=281)	7.5 vs 5.6	0.82 (0.69-0.97)	-	n/a

1001 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

Results of a phase II randomized trial of cisplatin +/- veliparib in metastatic triple-negative breast cancer (TNBC) and/or germline *BRCA*-associated breast cancer (SWOG S1416). *First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS*

Background: PARP inhibitors(i) are effective in *BRCA*-mutation-associated metastatic breast cancer(MBC). However, there are no studies evaluating PARPi + platin chemotherapy in BRCA wild-type(wt) TNBC. Approximately 1/2 of *BRCA*wt TNBC demonstrate homologous recombination deficiency (HRD) resulting in a BRCA-like phenotype which might render them sensitive to PARPi. S1416 compared the efficacy of cisplatin plus PARPi veliparib (Vel) or placebo (P) in 3 groups of MBC: gBRCA+; BRCA-like; and non-BRCA-like. **Methods:** Patients (pts) with metastatic TNBC or g*BRCA1/2*-associated MBC, who had received < 1 line of prior therapy were treated with cisplatin (75mg/m2) plus Vel or P (300 mg po BID days 1-14), every 3 weeks. All pts underwent central *gBRCA* testing. *A priori* established multipronged biomarker panel was used to classify BRCAwt pts into BRCA-like and non-BRCA-like groups, and included myChoice HRD score, somatic *BRCA1/2* mutations, BRCA1 methylation and non-*BRCA1/2* HR germline mutations. Primary end-point was progression-free survival (PFS) in the three pre-defined groups; secondary end-points included objective response rate (ORR), overall survival (OS), toxicity. **Results:** 323/335 randomized pts were eligible for efficacy evaluation; 31% had received 1 prior chemotherapy for MBC. 248 pts were classified into the three groups: (1) 37 gBRCA+ (2) 101 BRCA-like; (3) 110 non- BRCA-like. Remaining 75 could not be classified due to missing biomarker information. In the gBRCA+ group (which reached 62% of its projected accrual), numerically better PFS was noted with Vel compared to P (HR=0.64; p=0.26) though this difference was not statistically significant. In BRCA-like group improved PFS was noted with Vel vs P (median PFS 5.7 vs 4.3 months HR=0.58; p=0.023, 1 years PFS 20% vs 7%). Numerically better OS (median OS 13.7 vs 12.1 months, HR=0.66; p=0.14) and ORR (45% vs 35%, p=0.38) were noted with Vel vs P in BRCA-like group. Non-BRCA-like group did not show benefit of veliparib for PFS (HR=0.85; p=0.43) neither did the unclassified group (HR=0.97). Grade 3/4 neutropenia (46% vs 19%) and anemia (23% vs 7%) occurred at higher frequency in Vel arm compared to P. **Conclusions:** Addition of Vel to cisplatin significantly improved PFS and showed a trend towards improved OS for BRCA-like advanced TNBC. Integral biomarkers used in this study identified a subgroup of BRCAwt TNBC who benefited from addition of PARPi to cisplatin; platinum plus PARPi combination should be explored further in BRCA-like TNBC. Clinical trial information: NCT02595905. Research Sponsor: U.S. National Institutes of Health, AbbVie Inc.

1002 **Oral Abstract Session, Fri, 8:00 AM-11:00 AM**

TBCRC 048: A phase II study of olaparib monotherapy in metastatic breast cancer patients with germline or somatic mutations in DNA damage response (DDR) pathway genes (Olaparib Expanded). *First Author: Nadine M. Tung, Beth Israel Deaconess Medical Center and Dana-Farber Cancer Institute, Boston, MA*

Background: Olaparib, a PARP inhibitor, is approved for HER2-negative MBC in g*BRCA1/2* mutation carriers. Olaparib Expanded, an investigator-initiated study, assessed the response to olaparib in MBC patients with s*BRCA1/2* mutations or g/s mutations in DDR-pathway genes other than *BRCA1/2*. **Methods:** Eligibility included: MBC with measurable disease; progression on < 2 metastatic chemotherapy regimens. Prior PARP inhibitor or progression on platinum was not allowed. Cohort 1 included patients with germline mutations in non-*BRCA1/2* DDR-pathway genes. In Cohort 2 were those with somatic mutations in these genes or *BRCA1/2;* germline testing was required only to exclude a *gBRCA* mutation if a s*BRCA* mutation was present. Patients received olaparib 300 mg bid until progression or unacceptable toxicity. For each cohort, a single-arm Simon two-stage design was used with 13 then 14 patients in the 1st and 2nd stages, respectively. The null hypothesis within each cohort [≤ 5% objective response rate (ORR)] would be rejected if > 4 responses were seen at the end of stage 2. Secondary endpoints include clinical benefit rate, progression-free survival, and duration of response. **Results:** 54 patients enrolled from March 2018 to Jan 2020; 1 ineligible s*BRCA2* was excluded. Median age was 59 yrs (range: 30-87). 40 patients had ER+ HER2-, 3 HER2+, and 10 TNBC. 87% had a mutation in *PALB2,* s*BRCA1/2*, *ATM* or *CHEK2*. ORR was 29.6% (8/27, 90%-CI: 15.6%-47.1%) in Cohort 1 and 38.5% (10/26, 90%-CI: 22.5%-56.4%) in Cohort 2. Responses were gene specific (Table): g*PALB2* and s*BRCA* mutations predicted response; no responses were seen with only a *CHEK2* or *ATM* mutation. To date, responses as long as 16.4 months have been observed. Responses were seen in all subtypes: 5/10 TNBC, 1/3 HER2+, 12/40 ER+ HER2-. 11 responses occurred after prior CDK4/6 inhibitor. In June 2020, final data for confirmed ORR and secondary endpoints will be reported. **Conclusion:** In this proof-of-principle study, single-agent olaparib successfully met its primary endpoint in both cohorts. Activity was seen largely in patients with MBC and s*BRCA1/2* or g*PALB2* mutations but not with *ATM* or *CHEK2* mutations. Clinical trial information: NCT03344965. Research Sponsor: Astra-Zeneca.

Pyrotinib or lapatinib plus capecitabine for HER2+ metastatic breast cancer (PHOEBE): A randomized phase III trial. *First Author: Binghe Xu, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Pyrotinib (an irreversible pan-ErbB inhibitor) plus capecitabine showed clinically meaningful benefits and acceptable tolerability in patients (pts) with HER2+ metastatic breast cancer (MBC) in phase 1 and 2 studies. **Methods:** This open-label, multicenter, randomized phase 3 study enrolled HER2+ MBC pts after trastuzumab and taxanes, and/or anthracyclines. Up to two prior lines of chemotherapy (chemo) for metastatic disease were allowed. Pts were randomly assigned (1:1) to receive pyrotinib 400 mg or lapatinib 1250 mg qd continuously plus capecitabine 1000 mg/m^2 bid on days 1–14 of 21-day cycles. The primary endpoint was progression-free survival (PFS) per blinded independent central review. **Results:** From Jul 2017 to Oct 2018, 267 pts were randomized to the pyrotinib (n=134) or lapatinib (n=133) arm. One pt in the lapatinib arm did not receive study treatment and was excluded from analyses. 42.5% and 34.8% of pts in the pyrotinib and lapatinib arm had no prior chemo for metastatic disease, 41.8% and 49.2% had one prior line, and 15.7% and 15.9% had two lines. At the planned interim analysis, the median PFS was 12.5 months (95% CI 9.7–not reached) with pyrotinib plus capecitabine vs 6.8 months (95% CI 5.4–8.1) with lapatinib plus capecitabine (HR 0.39 [95% CI 0.27–0.56]; P<0.0001), which met the criterion for statistical significance (≤0.0066). Among trastuzumab-resistant pts, prolonged PFS with pyrotinib plus capecitabine was also observed (12.5 months [95% CI 6.9 to not reached] vs 6.9 months [95% CI 5.4 to not reached]; HR 0.60 [95% CI 0.29 to 1.21]). Benefits in objective response rate, clinical benefit rate, and duration of response with pyrotinib plus capecitabine were also indicated (Table). The most common grade ≥3 adverse events were diarrhea (30.6% vs 8.3% in the pyrotinib vs lapatinib arm) and hand-foot syndrome (16.4% vs 15.2%). **Conclusions:** In pts with HER2+ MBC after trastuzumab and chemo, pyrotinib plus capecitabine achieved a significant better PFS than lapatinib plus capecitabine, with manageable toxicity, verifying the phase 2 findings. Clinical trial information: NCT03080805. Research Sponsor: Jiangsu Hengrui Medicine.

1004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A randomized, open-label, phase III trial of pertuzumab retreatment in HER2-positive, locally advanced/metastatic breast cancer patients previously treated with pertuzumab, trastuzumab, and chemotherapy: The Japan Breast Cancer Research Group-M05 (PRECIOUS) study. *First Author: Yutaka Yamamoto, Department of Breast and Endocrine Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan*

Background: Patients with HER2-positive locally advanced/metastatic breast cancer (LA/MBC) previously treated with pertuzumab (P)-containing regimens have few therapeutic options. The efficacy of P re-treatment combined with trastuzumab (T)+chemotherapy was examined in such patients. **Methods:** Patients previously treated with P-containing regimens as 1st/2nd-line treatment for LA/MBC were randomly assigned 1:1 to two groups (P+T+chemotherapy based on physicians' choice (C) (PTC), and T+C (TC)), stratified by estrogen receptor status, previous P treatment duration, number of previous chemotherapy regimens, and site of metastasis. The primary endpoint was investigator-assessed progression-free survival (PFS). Secondary endpoints included PFS by independent review, PFS in patients treated with T-DM1 as the latest regimen (PFS after T-DM1), objective response rate (ORR), overall survival (OS), safety, and health-related quality of life (HRQoL). **Results:** Of the 219 pts enrolled, 217 (108 PTC, 109 TC) were included in the intent-to-treat analysis. At the data cutoff (July 31, 2019), PFS and OS events were 178 (82.0%) and 84 (38.7%), respectively. Median follow-up time was 14.3 months (mo). Investigator –assessed PFS was significantly better in the PTC group (median PFS 5.7 vs. 4.3 mo; HR=0.713 [95%CI, 0.529-0.961]; log-rank test p=0.025). Median PFS by independent review (4.6 vs. 4.0 mo; HR=0.740 [95%CI, 0.552–0.993]; log-rank test p=0.0428) and median PFS after T-DM1 (5.7 vs. 4.4 mo; HR=0.716 [95%CI, 0.511-1.002]; log-rank test p=0.0428) were also significantly better in the PTC group. OS tended to be longer in the PTC group, though further follow-up is needed (median 28.7 vs. 23.3 mo; HR=0.695, [95%CI, 0.451-1.073], p=0.099). The ORR with measurable disease (PTC (n=91) 20.2% vs. TC (n=92) 24.7%) did not differ between the groups. The serious adverse event rate did not differ between the groups (18.1% vs. 21.1%). There were no new safety signals included cardiac events in the groups. In the comparison of HRQoL by time to deterioration analysis, there was no significant difference between the groups in FACT-B TOI (PTC 2.8 mo vs. TC 4.3 mo; HR=1.27, p=0.2289). **Conclusions:** P re-treatment as 3rd or 4th-line chemotherapy should be considered a new standard treatment option for patients with HER2-positive LA/MBC previously treated with P. Clinical trial information: NCT02514681. Research Sponsor: Chugai Pharmaceutical.

1005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Tucatinib versus placebo added to trastuzumab and capecitabine for patients with previously treated HER2+ metastatic breast cancer with brain metastases (HER2CLIMB). *First Author: Nancy U. Lin, Dana-Farber Cancer Institute, Boston, MA*

Background: Tucatinib (TUC) is an investigational, highly selective HER2 kinase inhibitor. HER2CLIMB (NCT02614794) showed clinically meaningful and statistically significant improvements in overall survival (OS) and progression free survival (PFS) in all pts, prolongation of PFS in pts with brain metastases (BM), and objective response rate (ORR) when TUC was added to trastuzumab (T) and capecitabine (C). Primary methods and outcomes have been reported previously (Murthy NEJM 2019). We report the results of exploratory efficacy analyses in pts with BM. **Methods:** All pts with HER2+ metastatic breast cancer (MBC) enrolled in HER2CLIMB had a baseline brain MRI. Pts with BM were eligible and classified as untreated, treated stable, or treated and progressing. Pts were randomized 2:1 to receive TUC or placebo, in combination with T and C. Efficacy analyses in pts with BM at baseline were performed by applying RECIST 1.1 to the brain based on investigator evaluation. CNS-PFS (progression in the brain or death) and OS were evaluated in BM pts overall. Intracranial (IC) confirmed ORR (ORR-IC) and IC duration of response (DOR-IC) were evaluated in BM pts with measurable IC disease. After isolated brain progression, pts could continue study therapy after local treatment until second progression, and time from randomization to second progression or death was evaluated. **Results:** Overall, 291 pts (48%) had BM at baseline: 198 (48%) in the TUC arm and 93 (46%) in the control arm. There was a 68% reduction in risk of CNS-PFS in the TUC arm (HR: 0.32; 95% CI: 0.22, 0.48; $P < 0.0001$). Median CNS-PFS was 9.9 mo in the TUC arm vs 4.2 mo in the control arm. Risk of death overall was reduced by 42% in the TUC arm (OS HR: 0.58; 95% CI: 0.40, 0.85; $P = 0.005$). Median OS was 18.1 mo vs 12.0 mo. ORR-IC was higher in the TUC arm (47.3%; 95% CI: 33.7, 61.2) vs the control arm (20.0%; 95% CI: 5.7, 43.7). Median DOR-IC was 6.8 mo (95% CI: 5.5, 16.4) vs 3.0 mo (95% CI: 3.0, 10.3). In pts with isolated brain progression who continued study therapy after local treatment (n = 30), risk of second progression or death was reduced by 67% (HR: 0.33; 95% CI: 0.11, 1.02), and median PFS from randomization was 15.9 mo vs 9.7 mo, favoring the TUC arm. **Conclusions:** In pts with heavily previously treated HER2+ MBC with BM, TUC in combination with T and C doubled the ORR-IC, reduced risk of IC progression or death by two thirds and reduced risk of death by nearly half. If approved, TUC in combination with T and C has the potential to become a new standard of care in pts with HER2+ MBC with and without BM. Clinical trial information: NCT02614794. Research Sponsor: Seattle Genetics.

1006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Alpelisib (ALP) + fulvestrant (FUL) in patients (pts) with *PIK3CA*-mutated (mut) hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (ABC) previously treated with cyclin-dependent kinase 4/6 inhibitor (CDKi) + aromatase inhibitor (AI): BYLieve study results. *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: *PIK3CA* mutations (mut) occur in ~40% of pts with HR+, HER2– ABC and are associated with poor prognosis and resistance to treatment (tx). ALP, a PI3Kα inhibitor, plus FUL demonstrated efficacy in the phase 3 SOLAR-1 trial of HR+, HER2– *PIK3CA*-mut ABC. Little clinical data and few prospective studies are available to inform tx decisions for pts with HR+, HER2– *PIK3CA*-mut ABC in the post-CDKi setting. BYLieve is the first trial evaluating ALP + endocrine therapy (ET; FUL or letrozole) in pts with HR+, HER2– *PIK3CA*-mut ABC who progressed on/after prior therapy, including CDKi. In this ongoing phase 2, open-label, noncomparative study, 112 pts with centrally confirmed *PIK3CA* mut in tumor tissue are enrolled in each cohort per immediate prior tx of CDKi + AI, CDKi + FUL, or systemic chemo or ET. Enrollment is complete in prior CDKi + AI and CDKi + FUL cohorts and ongoing in prior systemic chemo or ET cohort. We report on the cohort of pts with CDKi + AI as immediate prior tx. **Methods:** Pts received ALP 300 mg/day + FUL 500 mg Q28D + C1D15. Primary endpoint was proportion of pts alive without disease progression at 6 mo per local assessment; 2-sided 95% confidence intervals (CI) were calculated using Clopper and Pearson (1934) exact method. Evidence of clinically meaningful tx effect was defined as the lower bound of the 95% CI > 30%. Safety was assessed in all patients; AEs presented by preferred term. **Results:** 127 pts whose immediate prior tx was CDKi + AI were enrolled, of whom 121 had centrally confirmed *PIK3CA* mut; median follow-up was 11.7 mo. Primary endpoint was met: proportion of pts without disease progression at 6 mo was 50.4% (95% CI, 41.2-59.6). Most frequent all-grade AEs were diarrhea (60%), hyperglycemia (58%), nausea (46%), fatigue (29%), decreased appetite (28%), and rash (28%). Most frequent grade ≥3 AEs included hyperglycemia (28%), rash (9%), and rash maculopapular (9%). Incidence of AEs leading to discontinuation was low; most frequent AEs leading to discontinuation were rash (5 pts, 3.9%), colitis, hyperglycemia, urticaria, and vomiting (2 pts, 1.6% each). **Conclusions:** With follow-up still ongoing, BYLieve shows in a large number of pts that ALP + FUL demonstrates clinically meaningful efficacy and manageable toxicity post CDKi tx. Building on findings from SOLAR-1, BYLieve further supports use of ALP + FUL for HR+, HER2– *PIK3CA*-mut ABC. Clinical trial information: NCT03056755. Research Sponsor: Novartis Pharmaceuticals Corporation.

1007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

PARSIFAL: A randomized, multicenter, open-label, phase II trial to evaluate palbociclib in combination with fulvestrant or letrozole in endocrine-sensitive patients with estrogen receptor (ER)[+]/HER2[-] metastatic breast cancer. *First Author: Antonio Llombart-Cussac, Hospital Arnau de Vilanova, Universidad Catolica, Medica Scientia Innovation Research (MedSIR), Valencia, Spain*

Background: The CDK4/6 inhibitor palbociclib (P) in combination with letrozole (L) has become a standard first-line treatment for patients (pts) with luminal metastatic breast cancer (MBC) (PALOMA-1 & 2 trials). Meanwhile, the anti-estrogen fulvestrant (F) showed to be superior to anastrozole in the same population (FALCON trial). We aimed to identify the best endocrine agent to combine with P in this first-line scenario. **Methods:** A total of 486 pts with ER [+]/HER2[-] MBC with no prior therapy in the advanced setting and endocrine sensitive criteria (relapse > 12 months [mo] after the end of adjuvant endocrine therapy or diagnosed with "de novo" metastatic disease) were randomly assigned (1:1 ratio) to receive P (oral 125 mg/day [d]; 3 wks on/1 wk off) plus F 500 mg/d (I.M Days 0, 14, 28, and then every 28 d) or PL (oral 2.5 mg/d). Pts were stratified by visceral involvement and type of disease presentation ("de novo"/recurrent). Primary endpoint was investigator-assessed progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), clinical benefit rate (CBR), and safety. 254 events were needed with 80% power to detect a hazard ratio (HR) ≤0.7 in favor of PF (2-sided $\alpha = 0.05$). **Results:** By March 9th, 2020, 256 PFS events occurred. Pts characteristics were well balanced. Median age was 62 years (range: 25–90), 56.6% were ECOG 0, 40.7% had "de novo" metastatic disease, 48% had visceral disease, and 43.6% with ≥3 organ sites involved. At median follow-up of 32 mo, median PFS was 27.9 mo (95% confidence interval [CI], 24.2-33.1) with PF and 32.8 mo (95% CI, 25.8-35.9) with PL (HR: 1.1; 95% CI, 0.9-1.5; P = 0.321). No differences were observed for pts with or without visceral involvement (HR: 1.3 and HR: 0.97 respectively, interaction P = 0.275), and for "de novo" or recurrent metastatic disease (HR: 1.1 and HR: 1.1 respectively, P = 0.979). The 4-year OS rate was 67.6% in PF and 67.5% in PL arm (HR: 1; 95% CI, 0.7-1.5; P = 0.986). No differences were observed in ORR or CBR between arms. Grade ≥3 adverse events were similar in both arms, being neutropenia and leukopenia the most frequent. No treatment-related deaths were reported. **Conclusion:** This study was not able to identify an improvement in PFS for PF over PL in patients with endocrine-sensitive ER[+]/HER2[-] MBC. As both arms demonstrated comparable 4 years-OS, PF is a reasonable alternative to PL in this setting. Clinical trial information: NCT02491983. Research Sponsor: Pfizer.

1008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized trial of a collaborative palliative and oncology care intervention to improve communication about end-of-life care in patients with metastatic breast cancer. *First Author: Jennifer S. Temel, Massachusetts General Hospital, Boston, MA*

Background: Studies have demonstrated the benefits of early, integrated palliative care in improving quality of life (QOL) and end-of-life (EOL) care for patients with poor prognosis cancers. However, the optimal timing and outcomes of delivering palliative care for those with advanced cancers that have longer disease trajectories, such as metastatic breast cancer (MBC), remains unknown. We tested the effect of a collaborative palliative and oncology care model on communication about EOL care in patients with MBC. **Methods:** Patients with MBC and clinical indicators of poor prognosis (N=120) were randomized to receive collaborative palliative and oncology care or usual care between 05/02/2016 and 12/26/2018. The intervention entailed five structured palliative care visits, including a joint visit with oncology when possible, which focused on symptom management, coping, prognostic awareness, decision-making, and planning for EOL. The primary outcome was documentation of EOL care discussions in the electronic health record. Patients also completed questionnaires at baseline and 6, 12, 18, and 24 weeks regarding communication with clinicians about EOL care, QOL, and mood symptoms. **Results:** The sample included only women (100.0%) who mostly identified as white (87.5%), with a mean age of 56.91 years (SD=11.24). The rate of EOL care discussions documented in the health record was higher among intervention patients versus those receiving usual care (67.2% vs 40.7%, p=0.006), including a higher completion rate of a Medical Orders for Life Sustaining Treatment form (39.3% vs 13.6%, p=0.002). Intervention patients were also more likely to report discussing their EOL care wishes with their doctor compared to usual care patients (OR=3.10, 95% CI: 1.21, 7.94, p=0.019). Study groups did not differ in reported QOL or mood symptoms. **Conclusions:** This novel collaborative palliative care intervention significantly improved communication and documentation regarding EOL care for women with MBC. Further work is needed to examine the effect of this care model on healthcare utilization at the end of life. Research Sponsor: Pfizer.

1009 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Pooled ctDNA analysis of the MONALEESA (ML) phase III advanced breast cancer (ABC) trials. *First Author: Fabrice Andre, Gustave Roussy Université Paris Sud, Villejuif, France*

Background: Biomarker analyses have been presented separately for each Phase III ML trial, which tested efficacy and safety of ribociclib (RIB) with different endocrine therapy (ET) combination partners as first- or second-line treatment for hormone receptor–positive, HER2-negative (HR+/HER2−) ABC. Here, using the largest pooled biomarker dataset of a CDK4/6 inhibitor in ABC to date, we identify potential biomarkers of response or resistance to RIB across ML trials. **Methods:** Baseline ctDNA from 1503 patients (pts) enrolled in ML-2, 3, and 7 was assessed using next-generation sequencing with a targeted panel of 557 genes. Genes with an alteration frequency ≥2% and in ≥15 pts per treatment arm were included (83 genes). Genetic alteration was defined as presence of a mutation, short insertion/deletion, or copy number alteration. Cox proportional hazard model of progression-free survival (PFS) was fit with gene-by-treatment interaction. Genes with interaction $P < 0.10$ and genes of interest were investigated. **Results:** Pts with alterations in *FRS2* and *PRKCA* (treatment interaction $P < 0.05$) as well as *MDM2, ERBB2, AKT1, and BRCA1/2* ($P > 0.05$ but considered actionable) had a trend for increased PFS benefit of RIB vs PBO (Table). Pts with alterations in *CHD4, BCL11B, ATM*, or *CDKN2A/2B/2C* derived little to no added PFS benefit with RIB vs PBO (*P* interaction < 0.10; hazard ratio [HR] > 0.80). Data on genes implicated in the literature as potential mechanisms of resistance to ET and/or CDK4/6 inhibition (*ESR1, PTEN, FAT1, RB1*, and *NF1*) will be presented. **Conclusions:** Results of this pooled analysis of the ML-2, 3, and 7 trials, the largest biomarker analysis of any CDK4/6 inhibitor in ABC, revealed several potential biomarkers of response (*FRS2, MDM2, PRKCA, ERBB2, AKT1*, and *BRCA1/2*) or resistance (*CHD4, BCL11B, ATM*, or *CDKN2A/2B/2C*) to RIB. Clinical trial information: NCT01958021; NCT02422615; NCT02278120. Research Sponsor: Novartis.

Prognostic impact of ESR1 mutations in ER+ HER2- MBC patients prior treated with first line AI and palbociclib: An exploratory analysis of the PADA-1 trial. *First Author: Francois Clement Bidard, Centre René Huguenin, Saint Cloud, France*

Background: The question of which is the best endocrine partner to CDK4/6 inhibitors in first line for ER+ HER2- metastatic breast cancer (MBC) remains open. *ESR1* mutations might be of paramount importance, as they confer resistance to AI but not to SERD. In pts treated with first line palbociclib-AI combination (PADA-1 trial, NCT03079011), we investigated *ESR1mut* detection rate at inclusion, prior to any therapy, and their prognostic impact. **Methods:** The PADA-1 phase 3 trial (NCT03079011, UCBG-GINECO) evaluates the utility of monitoring the onset of *ESR1mut* in cell-free DNA (with a ddPCR assay [Jeannot *et al*, Oncogene 2020]) of pts receiving AI-palbociclib in first line. Included pts had no prior therapy for MBC and no overt resistance to AI. **Results:** N = 1017 ER+ HER2- MBC pts were included in 22 months from 04/2017 and had their cfDNA tested for *ESR1mut* at inclusion and during therapy. N = 33/1017 pts had a detectable circulating *ESR1mut* at inclusion (3.2%, 95%CI [2.2;4.5]), *ESR1mut* positivity being associated with a prior exposure to AI in the adjuvant setting ($p < 0.01$). N = 1 pt died after 1 month on treatment. In N = 25/32 evaluable pts (78%), *ESR1mut* became undetectable in cfDNA (AF < 0.1%) within the first 5 months on treatment, with a median time to *ESR1mut* 'clearance' of 34 days. Among these 25 pts, 14 pts (56%) had *ESR1mut* detected again during therapy; 2 pts (8%) experienced a progression with no *ESR1mut* detected; the remaining 9 patients (36%) were still both *ESR1mut* -free and progression-free at time of analysis. With a median FU time of 12.4 months (range: 0-25.3m) under AI-palbociclib, the 33 ESR1mut-positive pts had a shorter PFS (median: 17.5mo, 95%CI[10.5-NR]) than the 984 ESR1mut-negative pts (median not reached), with an estimated HR = 2.8 [1.6;5.0]. Updated data will be presented at the meeting. **Conclusions:** *ESR1mut* are rarely detected in the cfDNA of ER+ HER2- MBC patients with no overt resistance to AI. The quick 'clearance' of *ESR1mut* under treatment and the observed 17.5 months-long median PFS both suggest that the AI-palbociclib combination retain a clinical activity in this population. *ESR1mut*-positivity prior was however associated with a significantly shorter PFS, suggesting that *ESR1mut* positivity at baseline could accelerate the onset of resistance to AI-palbociclib. These findings may put into perspective the incoming results of the PARSIFAL trial. Clinical trial information: NCT03079011. Research Sponsor: Pfizer.

1011 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

A multiparameter classifier to predict response to lapatinib plus trastuzumab (LT) without chemotherapy in HER2+ breast cancer (BC). *First Author: Jamunarani Veeraraghavan, Baylor College of Medicine, Houston, TX*

Background: Several trials have shown 25-30% pathologic complete response (pCR) rates in patients with HER2+ BC treated with LT therapy (+ endocrine therapy if ER+), but no chemotherapy (CTX). We hypothesize that a multiparameter classifier, comprised of HER2 gene and protein levels, intratumor heterogeneity (ITH), HER2-enriched (E) subtype, and *PIK3CA* mutation status can identify patients whose tumors are "addicted" to HER2 signaling and are likely to achieve pCR from a CTX-sparing de-escalation strategy. **Methods:** Baseline specimens from 2 trials (TBCRC023 [NCT00999804] and PAMELA [NCT01973660]) of neoadjuvant CTX-sparing LT (+ endocrine therapy if ER+) in HER2+ BC were used. HER2 protein and ITH (scored for % 3+ by IHC), and gene amplification (HER2:CEP17 ratio and copy number (CN) by CISH) were measured on the same slide by the dual gene protein assay (GPA). HER2-E and *PIK3CA* mutation status were assessed by research-based PAM50 and MSK-IMPACT platforms, respectively. A decision tree algorithm was used to determine the GPA cutoffs and to construct the classifier of response (by pCR) in TBCRC023, which was then validated in PAMELA. **Results:** Of the evaluable patients from TBCRC023 (N = 130) and PAMELA (N = 151), GPA data were available for 121 and 94 cases, respectively. Both cohorts exhibited similar distributions for HER2 ratio, CN, and % 3+, and a strong correlation between HER2 ratio and CN ($R > 0.92$). In TBCRC023, 73 cases had data from GPA, PAM50, and IMPACT, of which 15 had pCR. Recursive partitioning identified cutoffs of HER2 ratio > 4.6 and % 3+ > 97.5% in both the GPA data cohort (N = 121) and complete data cohort (N = 73). With PAM50 and IMPACT data, the model added HER2-E and *PIK3CA* wild-type (wt). For practical reasons, the classifier was locked as HER2 ratio ≥ 4.5 AND % 3+ ≥ 90% AND *PIK3CA*-wt AND HER2-E, which yielded a PPV of 55% and NPV of 94%. Validation in PAMELA using 45 cases with data for all 3 assays yielded PPV of 44% and NPV of 82%. 29 TBCRC023 cases without IMPACT data could be predicted to be non-pCR, of which 26 were correct (NPV = 89%). In PAMELA, 66 additional cases could be predicted to be non-pCR, of which 54 were correct (NPV = 81%). **Conclusions:** We have constructed a multiparameter classifier that can predict pCR with targeted therapy alone that compare to pCR rates of CTX + dual anti-HER2 in unselected patients. Prospective validation in a clinical trial is warranted. Research Sponsor: Department of Defense Breast Cancer Research Program, NCI-SPORE, TBCRC (BCRF and Komen), Ventana.

Association of tumor mutational burden (TMB) and clinical outcomes with pembrolizumab (pembro) versus chemotherapy (chemo) in patients with metastatic triple-negative breast cancer (mTNBC) from KEYNOTE-119. *First Author: Eric P. Winer, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: In the randomized, open-label, phase 3 KEYNOTE-119 study (NCT02555657), OS was not significantly different with pembro monotherapy versus chemo in second- or third-line settings for mTNBC; however, the pembro treatment effect increased with increasing PD-L1 enrichment. We evaluated the association of TMB with efficacy of pembro monotherapy versus chemo in patients with previously treated mTNBC. **Methods:** Patients with centrally confirmed TNBC and 1 or 2 prior systemic treatments for metastatic disease were enrolled. Patients were randomly assigned 1:1 to pembro 200 mg Q3W or single-agent chemo per investigator's choice of capecitabine, eribulin, gemcitabine, or vinorelbine. Association of TMB, as measured by FoundationOne CDx (Foundation Medicine), with response was an exploratory objective evaluated using receiver operator characteristic (ROC) analysis, logistic regression (ORR), and Cox regression (OS; PFS) within treatment arms; estimates of efficacy based on TMB cutpoint used a prespecified cutpoint of 10 mut/Mb. **Results:** TMB data were available for 253/601 (42.1%) treated patients (pembro, n = 132; chemo, n = 121); baseline characteristics were similar to that of the overall study population. One-sided *P* values for the association of TMB and clinical outcomes in pembro-treated patients were 0.154 for ORR, 0.014 for PFS, and 0.018 for OS; the area under the ROC curve ([AUROC] 95% CI) for predicting ORR was 0.58 (0.43-0.73). Two-sided *P* values for the association of TMB and clinical outcomes in chemo-treated patients were 0.114 for ORR, 0.478 for PFS, and 0.906 for OS; AUROC (95% CI) was 0.43 (0.27-0.59). Twenty-six patients had TMB ≥10 mut/Mb. Thus, the prevalence of TMB ≥10 mut/Mb was ~10%. Outcomes based on TMB cutpoint are reported in the Table. **Conclusions:** Data from this exploratory analysis from KEYNOTE-119 suggest a potential positive association between TMB and clinical benefit with pembro but not chemo in patients with mTNBC. Although precision is limited by sample size and the number of patients with TMB ≥10 mut/Mb, ORR and HRs for OS suggested a trend towards increased benefit with pembro versus chemo in patients with TMB ≥10 mut/Mb. Clinical trial information: NCT02555657. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

	TMB ≥10, pembro (n = 14)	TMB ≥10, chemo (n = 12)	TMB < 10, pembro (n = 118)	TMB < 10, chemo (n = 109)
ORR, % (95% CI)	14.3% (4.0-39.9)	8.3% (0.4-35.4)	12.7% (7.9-19.9)	12.8% (7.8-20.4)

Results of ENCORE 602 (TRIO025), a phase II, randomized, placebo-controlled, double-blinded, multicenter study of atezolizumab with or without entinostat in patients with advanced triple-negative breast cancer (aTNBC). *First Author: Joyce O'Shaughnessy, Baylor Charles A. Sammons Cancer Center, US Oncology and Texas Oncology, Dallas, TX*

Background: Chemotherapy remains as the only standard treatment option for aTNBC in second and subsequent lines. Entinostat (ENT) is an oral, class I-selective histone deacetylase inhibitor, that has shown antitumor activity in preclinical models of TNBC when combined with immune checkpoint blockade. ENCORE 602 evaluated the efficacy and safety of atezolizumab (ATEZO) + ENT vs ATEZO + placebo (P) in patients (pts.) with pretreated aTNBC. **Methods:** Pts. with previously treated aTNBC (PD-1/PD-L1 inhibitors naïve) were randomized 1:1 to receive ATEZO (1200 mg IV Q3W) + ENT (5 mg PO QW) or ATEZO+P. Treatment continued until unequivocal progressive disease or unacceptable toxicity. The primary endpoint was PFS as determined by the investigators using RECIST 1.1. The hypothesis was that the combination would improve median PFS by 3 months (hazard ratio = 0.57). Sixty events (from 70 pts.) would provide 80% power with 1-sided significance level of 0.1. Secondary endpoints were PFS per immune-related RECIST (irRECIST), ORR, clinical benefit rate (CBR), Overall Survival (OS), and safety. **Results:** 81 pts. were enrolled, median age 56 years (range 29-87), 69% received 1 prior line of therapy and 31% > 1 line. No significant difference in PFS per RECIST 1.1 was observed between ATEZO+ENT and ATEZO+P (median PFS 1.68 and 1.51 months, respectively [p = 0.64; HR 0.89, 95% CI: 0.53-1.48]), nor in any of the secondary efficacy endpoints (median PFS per irRECIST 1.68 vs 1.54 months; ORR 10.0% vs 2.4%; CBR 37.5% vs 31.7%; median OS 9.8 vs 12.4 months, respectively). Frequency of treatment-emergent adverse events (TEAEs), SAEs, discontinuations due to TEAE and TEAE with outcome death were higher in the ENT+ATEZO arm. **Conclusions:** In pts. with previously treated aTNBC, median PFS was not prolonged when ENT was added to ATEZO compared to ATEZO and placebo, and the combination resulted in greater toxicity. Clinical trial information: NCT02708680. Research Sponsor: Syndax Pharmaceutical Inc.

A phase Ib/II study of eribulin (ERI) plus pembrolizumab (PEMBRO) in metastatic triple-negative breast cancer (mTNBC) (ENHANCE 1). *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: As monotherapies, both ERI (a chemotherapeutic microtubule inhibitor) and PEMBRO (a programmed death [PD]-1 blocking immunotherapy) have shown promising antitumor activity in mTNBC. Emerging data suggest that the addition of immunotherapy to traditional chemotherapy holds promise for mTNBC. This open-label, single-arm, phase 1b/2 study evaluated the safety and efficacy of ERI + PEMBRO in mTNBC. **Methods:** Patients (pts) with mTNBC and ≤2 prior systemic anticancer therapies for metastatic disease were enrolled and stratified by prior number of therapy (Stratum 1, 0; Stratum 2, 1–2). Pts received IV ERI 1.4 mg/m^2 on day (d)1 and d8 and IV PEMBRO 200 mg on d1 of a 21-d cycle. The primary objectives were safety and objective response rate (ORR per RECIST 1.1 by independent imaging review). Assessments also included efficacy outcomes by PD ligand-1 (PD-L1) expression status; PD-L1+ was defined as a combined positive score ≥1 using the PD-L1 IHC 22C3 pharmDx. **Results:** As of data cutoff (July 31, 2019), 167 pts (Stratum 1, n=66; Stratum 2, n=101) were enrolled and treated. No dose-limiting toxicities were observed. The most common treatment-emergent adverse events were fatigue (66%), nausea (57%), peripheral sensory neuropathy (41%), alopecia (40%), and constipation (37%). No deaths were considered treatment related. The overall ORR was 23.4% (95% CI: 17.2–30.5). Efficacy outcomes by PD-L1 status (PD-L1+, n=74; PD-L1-, n=75) and stratum are presented (table). **Conclusions:** ERI + PEMBRO has activity in pts with mTNBC. There was a trend toward more robust activity for the combination among patients with PD-L1+ tumors compared to PD-L1- tumors in the first-line setting (Stratum 1); whereas, in the later-line setting (Stratum 2) similar survival outcomes were observed among the PD-L1+ and PD-L1- pts. ERI + PEMBRO shows promise for mTNBC with efficacy that appears greater than historical reports of either agent alone. Clinical trial information: NCT02513472. Research Sponsor: This work was supported by Eisai Inc., Woodcliff Lake, NJ, USA; and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Randomized phase III trial of eribulin (E) versus standard weekly paclitaxel (P) as first- or second-line therapy for locally recurrent or metastatic breast cancer (MBC). *First Author: Minetta C. Liu, Mayo Clinic, Rochester, MN*

Background: The ph III EMBRACE trial of E vs physician's choice of tx led to FDA approval of E as ≥3rd-line tx for MBC pts with prior exposure to anthracyclines/taxanes. The ph III BOLD 301 trial of E vs capecitabine in advanced BC treated with anthracyclines/taxanes showed a nonsignificant trend to improved median OS for all pts; pre-planned analysis by HER2 status revealed a nominally significant benefit for HER2- pts. **Methods:** RU011201I is an investigator initiated ph III trial with 1:1 randomization to E (1.4 mg/m2 D1,8 q21days) vs P (90 mg/m2 D1,8,15 q28days) within strata defined by (neo)adjuvant taxanes (yes/no), HR status (+/-), and line of tx (1st/2nd). Pts had measurable or non-measurable disease by RECIST v1.1; new or progressive mets; peripheral neuropathy (PN) gr<2; ≤1 prior chemotx regimens for advanced or MBC. Asymptomatic brain mets with stable MRIs for >3 mos were allowed. (Neo)adjuvant taxanes were allowed if >12 mos between tx completion and disease recurrence. Radiographic studies occur q12wks. Survival data are collected q12wks after the Off-Tx Visit. Pts reported side effects weekly; post-baseline symptomatic AE rates worse than baseline were compared between arms using Fisher's exact tests. We report clinical outcomes and the primary objective related to PRO-CTCAE use. **Results:** 201 pts enrolled 3/2014 - 5/2018 with 33.8 mos median f/u; 3 are on tx as of 2/20/20 (1E, 2P). Pt characteristics were the same between E vs P: median age 62 yrs (range 27-85); 42% prior taxane; 78% ER+; 70% starting 1st line tx. Baseline lesion distribution was similar except for lung mets (37E, 53P). No difference was seen between E vs P in PFS (5.7 vs 5.9 mos; P=0.72), OS (18.1 vs 16.4 mos; P=0.75), TTF (5.3 vs 4.9 mos; P=0.82), DOR (10.8 vs 12.3 mos; P=0.84), or number of metastatic events (55 vs 54). 37E and 36P pts required ≥1 dose reduction. Hematologic toxicities ≥ gr 3 were higher with E (40 vs 22%). PN events were similar: 56 vs 58 total, 4 vs 7 motor, 52 vs 51 sensory. Median duration of PN and median time to 1st PN event were 74 vs 140 and 56 vs 41 days. Worsened numbness/tingling severity and other pt-reported AE rates were similar, but worsened numbness/tingling interference (63% vs 78%, P=0.04) and vomiting frequency (35% vs 57%, P=0.005) were lower with E. **Conclusions:** Clinical outcomes were equivalent with E vs P as 1st/2nd line tx for HER2- advanced BC. The nature and severity of PN were similar between arms, but time of onset, duration, and interference with daily living favor E. E may be a suitable treatment option in this setting. Clinical trial information: NCT02037529. Research Sponsor: Eisai.

Phase II trial of bicalutamide in combination with palbociclib for the treatment of androgen receptor (+) metastatic breast cancer. *First Author: Ayca Gucalp, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Genome-wide transcriptional analysis has identified a unique subset of androgen receptor (AR) +, estrogen receptor (ER)/progesterone receptor (PR)-breast cancer (BC). The functional role of AR was confirmed initially in preclinical models demonstrating that androgen-driven growth could be abrogated by anti-androgen therapy. TBCRC011 established the safety and efficacy of inhibiting AR with bicalutamide (B) in patients (pts) with AR+/ER/PR- metastatic BC (MBC) with a median progression free survival (PFS) of 12 weeks (wks) (95% CI, 11–22 wks). In preclinical data, palbociclib (P) has been shown to reduce growth of AR+/ER/PR- MDA-MB-453 BC cells. It has been shown that AR+ triple negative BC (TNBC) expresses a luminal profile and has intact Rb protein, the target of P activity. We conducted this Phase I/II trial of the AR inhibitor B in combination with the CDK4/6 inhibitor P in pts with AR+/ER/PR/HER2- BC (NCT02605486) to test the hypothesis that androgen blockade, paired with CDK4/6 inhibition would have increased efficacy in pts with androgen-dependent BC. **Methods:** Postmenopausal pts with AR+ TN MBC defined as IHC ≥ 1% nuclear staining (DAKO, Clone AR441 (5/2016-11/2016) then Ventana AR SP107 (11/2016-6/2018), ECOG ≤2, measurable/non-measurable disease were eligible for enrollment. Any number of prior regimens was permitted. Pts received B 150 mg daily and P 125 mg daily 3 wks on 1 wk off. Pts were evaluated for toxicity every 2-4 wks and for response every 8-12 wks. Primary endpoint: 6 month (mo) PFS. Secondary endpoints: clinical benefit rate, toxicity, correlative studies to better characterize AR+ TNBC. A Simon 2-stage minimax design that discriminates between 6 mo PFS rates of 20% and 40% was used. If ≥ 11/33 pts were PF at 6 mo then B+P would warrant further study. **Results:** As of 1.1.20 33 pts were enrolled on study with median (med) age 67 (42-79), performance status 0 (0-1). Number of pts with visceral metastases: 20, measurable disease: 22. AR% 1-9: 3, 10-50: 6; 51-100: 24. Med prior lines for MBC: 3 (0-9). Best response: (31 evaluable pts): 11 pts PF at 6mo: 10 SD > 6mo, 1 PR. Med wks on study: 14 (2-101). Toxicity > 10% grade >3 related: Number of pts with leukopenia: 21, neutropenia: 21, lymphocytopenia: 6, thrombocytopenia: 3. One pt with febrile neutropenia. One death due to disease progression within 30 days off study. **Conclusions:** In this selected subset of pts with AR+ TN MBC, this study met its prespecified endpoint with 11 pts PF at 6 mo on B 150 mg + P 125 mg. B+P has been well tolerated with no unexpected toxicity observed. Clinical trial information: NCT02605486. Research Sponsor: Pfizer.

Exploring impact of mutations in non-*BRCA* DNA damage response (DDR) and non-DDR genes on efficacy in phase III EMBRACA study of talazoparib (TALA) in patients (pts) with germline *BRCA1/2* mutated (g*BRCA*m) HER2-negative (HER2-) advanced breast cancer (ABC). *First Author: Jennifer Keating Litton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Loss-of-function mutations in genes encoding components of the homologous recombination DNA damage response (DDR) machinery, notably *BRCA1/2*, are associated with tumor sensitivity to poly(ADP-ribose) polymerase inhibitors (PARPi). In EMBRACA, the PARPi TALA showed an improvement in progression-free survival (PFS) (HR [95% CI] 0.54 [0.41-0.71], $P < 0.001$) vs physician's choice of chemotherapy (PCT) in g*BRCA*m HER2− ABC. **Methods:** Baseline tumor tissue from 308 pts (71%; intent-to-treat) was sequenced using the FoundationOne CDx panel. Mutations summarized below were known/likely pathogenic single-nucleotide variants, insertions, deletions, or rearrangements. Best tumor response (BOR) was using RECIST 1.1 by Investigator (confirmation of CR or PR not required). **Results:** 296/308 (96%) of evaluable pts exhibited ≥1 tumor *BRCA* mutation, with 7 of the remaining 12 exhibiting *BRCA* copy number alterations deemed pathogenic. Mutations in other genes implicated in DDR and/or potential sensitization to PARPi were rare, with mutations detected in *BARD1, CDK12, FANCG, STAG2* (each 0.3%), *ATR, BRD4, FANCC, PALB2, RAD51B* (0.6%), *ATM, BRIP1* (1.0%), *NBN* (1.3%), *CHEK2, FANCA* (1.6%), and *ARID1A* (2.3%). No association was observed between total number of DDR mutations, including *BRCA1/2*, and best tumor response (BOR) [odds ratio of 1 vs ≥2 DDR mutations (95% CI): TALA, 0.76 (0.31-1.87), $P = 0.55$; PCT, 0.98 (0.27-3.51), $P = 0.97$]. *TP53* and *PIK3CA* were the most commonly mutated non-*BRCA* genes in *BRCA*m tumors (52.0 and 10.8%, respectively). *TP53* mutations were more prevalent in *BRCA1*m vs *BRCA2*m tumors (85.2 vs 24.8%). *PIK3CA* mutations were more prevalent in *BRCA2*m vs *BRCA1*m tumors (15.9 vs 5.2%). With TALA, PFS was significantly shorter in pts with *TP53* mutations than without [HR (95% CI) 1.693 (1.186-2.418), $P = 0.0033$]. A similar, non-significant, trend was evident with PCT [HR (95% CI) 1.439 (0.859-2.411), $P = 0.1614$]. *PIK3CA* mutational status had no impact on PFS in either arm. **Conclusions:** Selection based on g*BRCA* mutational status is appropriate to identify HER2− ABC pts with potential for clinical benefit from TALA, with the total number of tumor mutations in *BRCA1/2* and other DDR genes not impacting response (within the g*BRCA*m subset). *TP53* mutations were associated with shorter PFS, likely reflecting the worse outcomes observed in g*BRCA1*m patients. Additional correlative analyses are ongoing. Clinical trial information: NCT01945775. Research Sponsor: Pfizer Inc.

1019 Poster Discussion Session; Displayed in Poster Session (Board #104), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Clinical efficacy and molecular effects of lenvatinib (Len) and letrozole (Let) in hormone receptor-positive (HR+) metastatic breast cancer (MBC). *First Author: Joline Si Jing Lim, National University Cancer Institute, Singapore, Singapore*

Background: Preclinical studies show cross talk between RET and estrogen receptor, with at least additive treatment (Tx) effect of Len, a RET inhibitor, with Let. Our previous work concluded a recommended phase 2 dose (RP2D) of Len 14mg daily and Let 2.5mg daily (Lim, ASCO 2019). We present efficacy data from dose escalation and expansion cohorts. **Methods:** Safety, tolerability and efficacy data of MBC patients in both dose escalation (Len dose level 1 [DL]:20mg, DL -1:16mg and DL -2:14mg) and expansion (Len 14mg) cohort of this phase Ib/II study of combination Len+Let study was analysed. Patients were treated with single-agent Len for 2 weeks, followed by Len+Let until disease progression (PD). Serial tumor biopsies at baseline, after Len alone, 4 weeks post Len+Let, and upon PD, were sequenced for 440 genes with the ACTOnco+ platform. **Results:** A total of 33 pts (DL1 6pts, DL-1 6pts, DL-2 + expansion 21pts) with median 5 lines of prior Tx (range 0-11) were enrolled; 87.9%, 75.8%, and 75.8% had prior endocrine therapy (ET), ET+CDK4/6 inhibitor (i), and chemotherapy (CT) respectively. Objective response rate (ORR), disease control rate (DCR) ≥6 months (m), median duration of response (DOR), and percentage progression-free (PPF) at 12m were 33.3%, 45.5%, 11.5m (range 6.3-22.4), and 27.2% respectively. Among patients who previously progressed on CDK4/6i (n = 25), ORR, DCR ≥6m, median DOR, and PPF at 12m were 24.0%, 40.0%, 13.7m (range 6.3-18.2), and 12.0% respectively. Of note, 3/25 (12%) patients had durable response to Len+Let lasting ≥12m, despite having only modest PFS on ET+CDK4/6i (3, 7, and 12 months respectively). Most frequent all-grade toxicities (tox) were HTN (n = 15, G3:15), hypothyroidism (n = 20, G3:0) and fatigue (n = 13, G3:2), with no G4/5 tox. No new toxicity signals were observed compared to dose escalation phase. Pre-treatment tumor molecular profiling showed responders to be more likely to harbor NEFH, USH2A and PTCH1 mutations, while non-responders were more likely to carry PIK3R1, APC and PALB2 mutations. Sequencing of serial biopsies showed downregulation of BRD4, PTCH1, KIT, NTRK1 and CREBBP after Len treatment. **Conclusions:** Len+Let showed significant anti-tumor activity with meaningful duration of response, even in pts who failed prior CT or ET+CDK4/6i. The results support further investigation in randomized studies. Tumor profiling identified mutations associated with response and insights on molecular effects of lenvatinib. Clinical trial information: NCT02562118. Research Sponsor: National Medical Research Council, Singapore, Pharmaceutical/Biotech Company.

Comparison of StemPrintER, a novel biology-based genomic predictor of distant recurrence in breast cancer, with Oncotype DX in the TransATAC cohort. *First Author: Salvatore Pece, European Institute of Oncology, Milan, Italy*

Background: Accurate prediction of distant metastasis (DM) in early stage ER+/HER2- breast cancer (BC) patients is vital to avoid over/under-treatment with adjuvant chemotherapy (CT). The OncotypeDX Recurrence Score (RS) is a widely used tool to assist clinical decision-making for CT. The StemPrintER Risk Score (SPRS) is an alternative genomic predictor based on the biology of cancer stem cells that predicts recurrence risk in ER+/HER2- BCs (Pece S. *et al.*, EBioMedicine 2019). Here, we analyze the prognostic value of SPRS in the TransATAC cohort of post-menopausal ER+/HER2- BC patients, and compare the prognostic information provided by SPRS and RS for 10-year risk of DM. **Methods:** The likelihood χ^2 ($LR\chi^2$) and Kaplan-Meier survival analyses were used to assess prognostic information provided by SPRS, RS and the clinical treatment score (CTS) in 818 TransATAC patients treated with anastrozole or tamoxifen for 5 years. Comparative analyses were made for DM risk over the 10-year follow-up, as well as in the early (0-5 years) or late (5-10 years) interval, according to nodal status. **Results:** Used as a continuous variable, SPRS was an independent predictor of DM in years 0-10 among all patients when adjusted for clinical parameters as expressed by the CTS [HR=1.43 (1.18-1.73), $P<0.0001$], as well as in node-negative [HR=1.51 (1.17-1.94), $P=0.001$] but not node-positive (N1-3) patients [HR=1.29 (0.95-1.75), $P=0.11$]. A predefined SPRS cut-off was used to stratify patients into low *vs.* high risk groups [LOW: N=454, 10-year DM rate=5.8%; HIGH: N=364, 10-year DM rate=21.9%; $HR_{HIGH\ vs.\ LOW}$=2.96 (1.85-4.73); $P<0.0001$]. SPRS outperformed RS in providing prognostic information for 10-year DM risk (SPRS: HR=1.79, $P<0.0001$, $LR\chi^2$=33.4; RS: HR=1.52, $P<0.0001$, $LR\chi^2$=22.1), with even greater differences in late DM prediction in N0 patients. SPRS also provided more prognostic information than RS to CTS ($\Delta LR\chi^2$: SPRS+CTS *vs.* CTS= 14.9; RS+CTS *vs.* CTS= 9.7). **Conclusions:** In ER+/HER2- TransATAC BC patients, SPRS was highly prognostic for DM and was superior to RS in providing additional prognostic information to conventional clinicopathological parameters. Research Sponsor: Italian Association for Cancer Research (AIRC), Cancer Research UK (CRUK).

1022 Poster Discussion Session; Displayed in Poster Session (Board #107), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Prognostic and predictive value of ESR1 mutations in postmenopausal metastatic breast cancer (MBC) patients (pts) resistant to aromatase inhibitors (AI), treated with palbociclib (PAL) in combination with endocrine therapy (ET) or capecitabine (CAP) in the PEARL study. *First Author: Miguel Martin, Instituto de Investigación Sanitaria Gregorio Marañón, Universidad Complutense, CIBERONC, Madrid, Spain*

Background: Prior retrospective data has shown *ESR1* mutation is an acquired resistant mechanism to AI. However, little is known about ist prognostic and predictive value to endocrine-based therapy and chemotherapy. PEARL study compared PAL+ET vs CAP in AI resistant patients. Here we wxplored prospectively the *ESR1* mutational status based on updated PFS and OS. **Methods:** PEARL is a phase 3 study with 2 subsequent cohorts: cohort 1 with 296 pts randomized to PAL+Exemestane (EXE) vs CAP and cohort 2 with 305 pts randomized to PAL+ Fulvestran (FUL) vs CAP. *ESR1* hotspot mutations were analyzed in circulating free DNA at baseline by digital PCR. Cox regresion analysis for PFS and OS were performed. Adjusted hazard ratios (aHR) and interaction test between treatment and *ESR1* status were calculated. **Results:** *ESR1* mutational status was assessed in 557 pts, 91% and 94% treated with CAP and PAL+ET, respectively; 164 (29%) had *ESR1* mutations. Characteristics between *ESR1* wild-type (WT) and mutated pts were balanced except for ECOG, prior sensitivity to ET, treatment line, prior AI for metastatic disease and time from first metastatic diagnosis to randomization. Median follow-up was 22.5 months (m). Median PFS was 9.6 vs. 7.5 m (HR: 1.06 [0.88 - 1.28], p = 0.522) and median OS was 30.2 vs 30.3 (HR: 0.99 [0.78 - 1.26] p = 0.934), for CAP vs. PAL+ET, respectively. No interaction was seen between treatment arm and ESR1 status either for PFS (p = 0.538) or OS (p = 0.957). **Conclusions:** In luminal MBC, *ESR1*-mutated pts had poorer OS than *ESR1*-WT pts regardless of treatment received. Clinical trial information: NCT02028507. Research Sponsor: Pfizer and AstraZeneca.

A phase Ib study to evaluate the oral selective estrogen receptor degrader GDC-9545 alone or combined with palbociclib in metastatic ER-positive HER2-negative breast cancer. *First Author: Elgene Lim, St. Vincent's Hospital, University of New South Wales, Darlinghurst, Australia*

Background: GDC-9545 is a potent, orally available, selective estrogen receptor degrader developed for the treatment of ER-positive (ER+) breast cancer alone or combined with CDK4/6 inhibitors. A first-in-human study evaluated 10-250 mg GDC-9545; tolerability, pharmacokinetic (PK), pharmacodynamic (PD), and clinical results support expansion cohorts at ≥30 mg (Jhaveri et al., 2019). **Methods:** This study evaluated PK, PD, and efficacy of GDC-9545 alone and combined with palbociclib, ± LHRH agonist. Eligible patients (pts) had ER+ (HER2-) metastatic breast cancer (MBC) with ≤ 2 prior therapies in the advanced or metastatic setting. No prior treatment with CDK4/6 inhibitor was allowed in pts receiving palbociclib. **Results:** Eight-five pts were enrolled in 2 cohorts: GDC-9545 100 mg given once daily ± LHRH agonist (Cohort A), and GDC-9545 100 mg +125 mg palbociclib on a 21 day on/7 day off schedule ± LHRH agonist (Cohort B). Of the 39 pts in Cohort A, adverse events (AE) occurring in ≥10% of pts were fatigue, cough, back pain, pain in extremity, and arthralgia. Related AEs were generally Grade (G) 1-2; there were 3 related G3 AEs of fatigue, transaminase increased, and diarrhea. Two pts had GDC-9545 reduced, one due to G3 diarrhea and another due to G3 transaminitis. Of the 46 pts in Cohort B, AEs in ≥10% of pts were neutropenia, fatigue, bradycardia, diarrhea, constipation, dizziness, nausea, anemia, asthenia, thrombocytopenia, pruritus, and visual impairment. Twenty-six (57%) pts had G≥3 AEs. G≥3 neutropenia was reported in 23 (50%) pts. One pt had palbociclib reduced due to G3 febrile neutropenia. Eleven (13%) of 85 pts had G1 asymptomatic bradycardia considered related to GDC-9545. No pts in either cohort discontinued study treatment due to AEs. PK analysis and clinical data demonstrate no clinically relevant drug-drug interactions between GDC-9545 and palbociclib. Reduced ER, PR, and Ki67 levels, and an ER activity signature, were observed in paired pre- and on-treatment biopsies (n = 12). Eighteen of 33 pts in Cohort A had either confirmed partial responses or were on study 24 weeks (clinical benefit rate 55%). Clinical benefit was observed in pts with prior fulvestrant treatment and with detectable ESR1 mutations at enrollment. Clinical benefit data for both cohorts are anticipated to be mature in April 2020. **Conclusions:** GDC-9545 was well-tolerated as a single agent and in combination with palbociclib with encouraging PK, PD, and anti-tumor activity in ER+ MBC to support Phase III development. Clinical trial information: NCT03332797. Research Sponsor: Genentech, Inc.

A phase I dose escalation and expansion study of the next generation oral SERD AZD9833 in women with ER-positive, HER2-negative advanced breast cancer. *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN*

Background: AZD9833 is an oral selective estrogen receptor (ER) antagonist and degrader (SERD) that has shown antitumor efficacy in a range of preclinical models of breast cancer. **Methods:** SERENA-1 (NCT03616587) is an ongoing Phase 1, open-label study in pre- and post-menopausal women, after ≥1 endocrine therapy and ≤2 prior chemotherapies for ER+ HER2- advanced breast cancer (ABC). The primary objective is to determine the safety and tolerability of AZD9833 once daily (QD), with dose-limiting toxicities (DLTs) in 28d defining the maximum tolerated dose. Secondary objectives include pharmacokinetics and anti-tumor response. Pharmacodynamic (PD) analysis includes ER modulation in paired tumor biopsies and ctDNA dynamic changes. **Results:** At 20 January 2020: 60 patients were treated (median prior therapies 5 (1–9); prior fulvestrant (Fv) 82%; prior CDK4/6i 68%) across five doses; 25 mg QD n=12, 75 mg QD n=12, 150 mg QD n=13, 300 mg QD n=13, 450 mg QD n=10. AZD9833 exposure was dose proportional after multiple doses, with a median terminal t1/2 of 12h. Treatment-related AEs experienced by ≥10% of patients were visual disturbances (53%; 91% G1, 6% G2, 3% G3), bradycardia/sinus bradycardia (45%; 93% G1, 7% G2), nausea (18%; 46% G1, 55% G2), fatigue (13%; 38% G1, 63% G2), dizziness (10%; 83% G1, 17% G3) vomiting (10%; 50% G1, 33% G2, 17% G3), and asthenia (10%; 67% G1, 33% G2). Three patients experienced DLTs: G3 QTcF prolongation (300 mg); G3 vomiting (450 mg); and a combination of G2 visual disturbance, G2 headache and G2 gait disturbance (450 mg). DLTs resolved with dose reduction. No G4 or 5 AEs were reported. Efficacy data are presented in the table below; objective response rate (ORR) and clinical benefit rate (CBR) at 24 weeks. Clinical trial information: NCT03616587. ER signalling pathway modulation was observed in all dose cohorts. In patients where clinical responses occurred and paired biopsies obtained, 98% reduction in Ki67 was measured. Updated data will be presented. **Conclusions:** AZD9833 has an encouraging efficacy and dose-dependent safety profile. Evidence of clinical benefit and target engagement was observed at all dose levels in women with ER+ ABC, including patients pre-treated with CDK4/6i and Fv, and those with *ESR1* mutations. A Phase 2 study comparing efficacy and safety of three doses AZD9833 vs Fv is planned (NCT04214288). Research Sponsor: AstraZeneca.

International retrospective cohort study of locoregional and systemic therapy in oligometastatic breast cancer (OLIGO-BC1). *First Author: Takayuki Ueno, Breast Oncology Center, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Systemic therapy is the standard care in metastatic breast cancer (BC). However, retrospective studies demonstrated survival benefits of locoregional and systemic (combination) therapy in oligometastatic BC. To clarify it, the Federation of Asian Clinical Oncology conducted an international retrospective cohort study (OLIGO-BC1) (UMIN No.000030047). **Methods:** Oligometastatic BC patients diagnosed from 2007 to 2012 were registered. "Oligometastases" is defined as low volume metastatic disease with limited number and size of metastatic lesions up to five and not necessarily in the same organ by the ABC guidelines. Overall survival (OS) from the diagnosis of oligometastases was the primary endpoint and compared between combination and systemic therapy using a log-rank test. Assuming the 5-year OS of 50% and 40%, respectively, 698 patients were required to achieve 80% power to detect the superiority of combination therapy, at a two-sided significance level. A multivariable Cox regression model with stratification by country was performed to estimate hazard ratio (HR) for therapy and other risk factors. **Results:** While 1,262 cases had been registered from February 2018 to May 2019, 1,200 remained for analysis after exclusion of unavailable cases. Among them, 573, 529 and 98 cases were registered from China, Japan and Korea, respectively. Luminal BC was recorded in 526 cases (44%), luminal-HER2 BC in 189 (16%), HER2 BC in 154 (13%), triple-negative BC in 166 (14%) and others in 165 (13%). One oligometastatic BC was found in 578 cases, 2 in 289, 3 in 154, 4 in 102 and 5 in 77. Bone metastases were recorded in 301 cases, visceral metastases in 387, locoregional recurrence in 25, local recurrence in 83 and multiple metastatic sites in 404. Combination therapy was performed in 595 cases and systemic therapy in 404. At median follow-up of 4.9 years, 5-year OS was 59.6% and 41.9%, respectively ($p < 0.01$). An adjusted HR was 0.61 (95% CI: 0.51, 0.74). Type of systemic therapy, younger age, ECOG performance status 0, stage I BC, non-triple negative subtype, fewer metastatic sites, local recurrence and longer disease-free interval were significantly favorable prognostic factors. Discussions: Oligometastatic BC under some conditions seems to be curable. Taken together with recent molecular targeted therapy, locoregional therapy will be advantageous to conquer it. **Conclusions:** Combination therapy is a promising strategy for patients with oligometastatic BC. Research Sponsor: Federation of Asian Clinical Oncology.

Genomic mapping to identify mutations in RYR2 and AHNAK in basal-like breast tumors expressing PD-L1. *First Author: Francisco J Cimas, Translational Oncology Laboratory, CRIB-UCLM, Albacete, Spain*

Background: Basal-like breast cancer is a specific subtype of breast tumors with limited therapeutic options. Although treatment with the anti-PD-L1 antibody atezolizumab has recently shown clinical activity in this setting, not all patients do respond even expressing high levels of PD-L1. In the present article we explored the presence of mutations in breast cancer tumors with high expression of PD1 and PD-L1 with the aim to identify molecular correlates associated with outcome. **Methods:** We used RNA-seq and mutational data from 971 breast cancer patients using the TCGA dataset, to identify mutations in patients with high levels of PD1 and PD-L1. Data analysis was performed using DESeq R and MAFTools Bioconductor packages. Transcriptomic signatures from the identified mutations were associated with outcome using the Kapplan-Meyer Plotter tool. We correlated the identified transcripts with immune populations using TIMER online tool and correlation between genes with Cancertool online platform. **Results:** We identified co-occurrent mutations in RYR2 and AHNAK in 8% and 5% of basal like tumors, respectively, in patients with high levels of PD1 and PD-1. The transcriptomic signature of these mutations conferred good prognosis for relapse free survival (RFS) and overall survival (OS). CXCL9 for RYR2 and GBP5, C1QA, IL2RG, CSF2RB and IDO1 for AHNAK were the most relevant genes identified in these signatures. Expression of CXCL9, GBP5, IL2RG and IDO1 correlated with the presence of immune cell populations mainly dendritic cells. This signature, including CXCL9, GBP5, C1QA, IL2RG, CSF2RB and IDO1 classified patients with favorable RFS (HR 0.27 CI 0.2-0.30; p = 1.1e-16) and OS (HR 0.18 CI 0.09-0.34; p = 6.8e-9). This signature showed a stronger prediction capacity compared with already described immunologic signatures. Finally we identify that LAG3 was the only gene commonly present in both signatures and correlated positively with the expression of PD1 and PD-L1. **Conclusions:** We describe two novel mutations which transcriptomic signatures associated with favorable outcome in basal-like tumors that express elevated levels of PD1 and PD-L1. Future studies should be performed to confirm the role of these mutations and signatures in relation with clinical activity of PD1/PD-L1 inhibitors. Circulating tumor DNA (ctDNA) to evaluate stage III and stage IV metastatic breast cancer (MBC), describe tumor heterogeneity, and outcome. *First Author: Qiang Zhang, Northwestern University, Department of Medicine, Division of Hematology/Oncology, Lurie Cancer Center, Chicago, IL*

Background: MBC is a challenging clinical condition treated with palliative intent due to tumor heterogeneity. We reported in 2019 ASCO that the correlation of HER2 and ESR1 mutations of ctDNA with CTCs results in worse prognosis in MBC. Here we reported that ctDNA mutations is a key point which is different between Stage III and Stage IV, and it would be helpful to evaluate the MBC metastasis and outcome. **Methods:** This study included 33 Stage III and 204 Stage IV MBC patients who received systemic treatments at NMH (2016-2019). Plasma ctDNA before treatment was isolated from patients and then was analyzed by Guardant 360 Health NGS-based assay for a 73 genes panel for genomic alterations including single nucleotide variants, insertions/deletions, gene fusions/rearrangements and copy number variations. Causal Inference with Ensembel Learning was used for statistical analyses. **Results:** Among stage III patients, 40% are luminal, 44% are $HER2^+$ and 16% are TNBC, while in stage IV 50% patients are luminal, 20% are $HER2^+$ and 30% are TNBC. The major differences in ctDNA between two stages lie in several genes including *PIK3CA, ERBB2* and *KRAS*. On the top of the list is PIK3CA, which is detected in 2 out of 33 stage III patients (1 luminal, 1 $HER2^+$) (6.06%) in baseline, each of them carries 1 mutation on PIK3CA (E542K, E545G). In 43 out of 204 stage IV patients (21.57%) who carry this gene, 15 show 1 amplification, 34 have 1 mutation (mainly H1047R, E542K, E545K and H1047L), 11 have 2 mutations (E542K/E726K, D454N/D1029N, E545K/D1017H, E545K/L287L, H1047R/E453K, H1047R/N426S and P539R/H1047R), and 1 has 3 mutations (E542Q/D454N/D1029N and E545K/E726K/R93Q). On treatment effects, PIK3CA is found to be very detrimental on prognosis and on its effects on the treatment outcome. Patients without any mutation in PIK3CA live 2.65 times longer than those with more than one mutations on PIK3CA (p-value = 4.47e-06, CI = [1.731, 3.926]). PIK3CA, ESR1, TP53 and ARID1A are found to significantly affect liver metastasis when RET, FBXW7, ERBB2, CCND2, BRAF and MET are found to be associated with lung metastasis for both stages. EGFR, KIT and ARID1A are associated with CNS metastasis. **Conclusions:** We elucidated that ctDNA mutations on PIK3CA and other genes dramatically increased in Stage IV patients compared to Stage III patients which provides a new insight on the Stage III and Stage IV MBC determination. New set of genes especially PIK3CA are identified to correlate with metastasis and affect the outcome which may also be reliably used to monitor the response to therapy. 1029 Poster Session (Board #114), Fri, 8:00 AM-11:00 AM

Prognostic and predictive effects of circulating and disseminated tumor cells in breast cancer: A National Cancer Database (NCDB) analysis. *First Author: Nadeem Bilani, Cleveland Clinic Florida, Weston, FL*

Background: Alongside other biomarkers, circulating tumor cells (CTCs) and disseminated tumor cells (DTCs) could contribute to our growing understanding of the breast cancer (BC) "liquid biopsy". This study evaluated 1) clinicopathologic factors associated with CTCs and DTCs, 2) the prognostic value of CTCs and DTCs by disease stage, 3), the efficacy of chemotherapy by CTC and DTC status. **Methods:** We conducted a retrospective analysis of BC using the 2004-2016 National Cancer Database (NCDB). The NCDB defines CTCs as isolated tumor cells (ITCs) found in the blood (using assays such as reverse transcriptase polymerase chain reaction or immunohistochemistry) distant from the breast. DTCs are ITCs found in the bone marrow or other non-regional tissues. To evaluate variables associated with CTCs or DTCs, we used chi-squared and Wilcoxon rank-sum tests (univariate), followed by multivariate logistic regression. Consequently, we included CTC or DTC status in a multivariate, stage-by-stage Cox regression analysis for overall survival (OS). After adjusting for receptor status and staging, we used the Kaplan-Meier method to explore chemotherapy efficacy in CTC- or DTC-positive vs. CTC- or DTC-negative subsets. **Results:** 4,846 cases reported CTC-status, 1,454 (21.1%) of which were positive. 4,993 cases reported DTC-status, 1,400 (20.3%) of which were positive. Factors associated with positive CTC status were HER2-positivity, progesterone receptor-positivity, lobular histology and N-staging. Factors associated with positive DTC status were being White, HER2-positivity, lobular histology and N-staging. Positive CTC-status was associated with poor OS overall in late-stage (III and IV) (HR 1.477, 95% CI: 1.129-1.931, p = 0.004) but not early-stage BC (0, I, II) (p = 0.110) disease. DTC-status was not associated with OS in early-stage or late-stage subsets. In hormone receptor (HR)-positive disease, chemotherapy was associated with better OS when CTC-status was also positive both in early-stage (p = 0.003) and late-stage (p = 0.023) disease. In a subset of the same BC subtype with negative CTC-status, however, chemotherapy conferred no survival benefit (p = 0.638 for early-stage, p = 0.501 for late-stage). DTC status was not a significant predictor of chemotherapy efficacy in early or late-stage, HR+ disease. **Conclusions:** This study suggests that CTC-status is a stronger prognostic factor at later stages of BC; yet it can also help guide management of early-stage disease as it appears predictive for chemotherapy benefit. Research Sponsor: None.

1030 Poster Session (Board #115), Fri, 8:00 AM-11:00 AM

The contribution of clinical subtype to survival differences among patients with de novo and recurrent metastatic breast cancer (dMBC). *First Author: Danielle Marie File, University of North Carolina, Chapel Hill, NC*

Background: Patients with de novo metastatic breast cancer (dMBC) have superior median overall survival (mOS) compared to recurrent metastatic breast cancer (rMBC). Whether patient characteristics, prior treatment, tumor stage and innate biological differences contribute to this observation is unknown. **Methods:** Clinical and pathological data from patients diagnosed with MBC from 2011 to 2017 at the University of North Carolina (UNC) was obtained from the prospective UNC Metastatic Breast Cancer Clinical Database (223 dMBC, 607 rMBC). Only patients with known survival status were included. Subtype was determined by hormone receptor (HR) and HER2 staining of the primary tumor. Pathologic staging results were used when available, otherwise clinical staging was used. Patient and tumor characteristics were compared using chi-square testing, and survival outcomes by Cox proportional hazards modeling. **Results:** 26.9% of patients with MBC presented with dMBC, with significant variation in the ratio of dMBC to rMBC across subtypes. In particular, there were more cases of HER2+ dMBC than rMBC (26.9% vs 14.0%) and fewer cases of triple negative dMBC (20.6% vs 35.3%)(p-value < 0.001). Nearly half of all cases of HR-/HER2+ MBC were de novo (48.2%). dMBC was significantly associated with older age ($p = 0.002$), lower grade ($p = 0.027$), higher T and N stage ($p < 0.001$) and African American race (30% vs 22%, $p = 0.022$). There was no significant difference in proportion of patients with visceral metastatic disease or in number of metastatic sites at diagnosis. Median follow up was 39 months in both cohorts. mOS was 12 months greater in dMBC than rMBC (34m vs 22m, $p < 0.001$). These differences were significant across all subtypes except HR+/HER2+. The difference in mOS between dMBC and rMBC was greatest in the HR-/HER2+ subgroup (45m vs 15m, $p = 0.006$). In multivariable analysis, dMBC remained associated with improved survival (adjusted hazard ratio 0.59, $p < 0.001$) independent of variables including age, race, subtype, grade and number of metastatic sites at diagnosis. **Conclusions:** Patients with dMBC have significantly better prognosis than those with rMBC. This improved outcome is in part due to subtype variation, with more triple negative and fewer HER2+ tumors in rMBC, however these differences largely remained when stratified by subtype. In multivariable analysis, de novo presentation of MBC remained an independently significant contributor to longer survival. Further investigation should focus on biologic differences between dMBC and rMBC. Research Sponsor: John William Pope Foundation.

1031 Poster Session (Board #116), Fri, 8:00 AM-11:00 AM

Identification of pathogenic *ROS1* alterations in cell-free DNA (cfDNA) from patients with breast cancer. *First Author: Jeremy Meyer Force, Duke University Medical Center, Durham, NC*

Background: ROS1 is an important proto-oncogene involved in the development of various cancers for which we have FDA approved therapies. While activation of the *ROS1* tyrosine kinase receptor has been reported in 1-2% of lung cancers, the frequency and type of *ROS1* alterations in breast cancer have not been fully explored. We previously described the incidence of *ROS1* alterations from breast cancer tissue. The purpose of this study was to identify the incidence of *ROS1* genomic alterations occurring in cfDNA from patients with breast cancer. **Methods:** We queried 16,053 breast cancer samples from the Guardant Health breast cancer database between June 2015 - October 2019 to identify the incidence of *ROS1* alterations detected in cfDNA in breast cancer. We identified fusion partner genes and classified each alteration type into the following categories: fusion, single nucleotide variants (SNVs), and indels. Radical amino acid changes occurring at conserved regions across the *ROS1* gene were identified. *In vitro* analyses were used to investigate the effect of *ROS1* nonsynonymous mutations on the ROS1 protein. We made associations with *ROS1* alterations and co-occurring mutated genes. **Results:** Nonsynonymous *ROS1* alterations from the Guardant Health breast cancer database were found in 162 samples from 142 patients in the 16,053-patient cohort (1%). Alterations found included: 1 (0.6%) *ROS1-SLC35F1* fusion, 155 (95.7%) SNVs, and 6 (3.7%) indels. Of the 155 SNVs, we identified 23 (14.8%) mutations occurring in the *ROS1* kinase, of which, 20 (12.9%) occurred at highly conserved regions and 15 (9.6%) harbored radical amino acid changes. The top 5 co-occurring mutations in samples with *ROS1* alterations were *TP53* (50%), *PIK3CA* (44%), *ESR1* (27%), *EGFR* (21%), and *FGFR1* (18%). **Conclusions:** A modest incidence of *ROS1* genomic alterations occurs in cfDNA from patients with breast cancer. New somatic alterations in the *ROS1* gene were identified from Guardant Health that were not detected in publicly available databases. A portion of mutations occurred at highly conserved regions across the *ROS1* gene suggesting these may be more actionable than currently recognized. *In vitro* analyses of *ROS1* gene activation from these newly discovered somatic alterations are being investigated with results to be reported. Co-occurring mutations reveal a unique genotype associated with *ROS1* alterations that may play a biologic role in ROS1-mediated pathogenesis. 1032 Poster Session (Board #117), Fri, 8:00 AM-11:00 AM

Organ specificity dictates tumor immune infiltration and composition in metastatic breast cancer; lessons from a rapid autopsy tissue collection study. *First Author: Colt Egelston, City of Hope, Duarte, CA*

Background: Immune composition in the tumor microenvironment (TME) of patient tumors has proven to play a central role in the propensity of tumors to metastasize and respond to therapy. Evidence has suggested that the metastatic TME is immune aberrant, however limited sample size and numbers has made assessment of the immune TME in the development of multi-organ metastases difficult. Here we utilize a rapid autopsy tissue collection protocol to assess the infiltration and composition of the immune TME in numerous metastatic tissue sites, paired disease-free tissue sites, and the associated tissue draining lymph nodes. **Methods:** Post-mortem tissues were collected from six metastatic breast cancer patients shortly after death through City of Hope's "Legacy Project for Rapid Tissue Donation" Program. The average post mortem interval (PMI) for tissue collection was 6 hours. Collected specimens include metastatic lesions and paired non-cancer samples from every cancer-involved organ, disease-free specimens from non-involved major organs, distant and tumor-draining lymph nodes (both cancer-infiltrated and disease free), as well as blood. Immediately following collection, specimens were processed into single cell suspension for flow cytometry. Over 80 immune cell phenotypes were assessed, including CD8+ and CD4+ T cell subsets, B cell subsets, natural killer (NK) cells, tumor associated macrophages (TAMs), dendritic cell subsets, and other cells. **Results:** Tumor infiltrated tissues were found to have comparable immune cell densities and composition compared to paired disease-free tissues of the same organ type. However, immune cell densities in metastatic tissues and disease-free tissues were significantly different between organ types, with lung immune infiltration consistently being greater than liver tissues. Differences in immune composition between tissue sites were also observed. Notably, liver tissues favored the presence of central memory CD8+ T cells, while lung tissues favored the presence of CD8+ tissue resident memory T cells. Relative to disease-free lung tissues, tumor infiltrated lungs contained diminished frequencies of CD8+ tissue resident memory T cells and altered B cell phenotypes. **Conclusions:** These data suggest that immune monitoring and trafficking of metastatic tissues site is dictated by organ type, which can be altered in composition by tumor infiltration. Further studies such as these may reveal organ-specific mechanisms of response to therapeutic interventions. Research Sponsor: Waisman Foundation.

1033 Poster Session (Board #118), Fri, 8:00 AM-11:00 AM

Predictor of trastuzumab-induced cardiotoxicity in breast cancer (BC) patients: HER2/neu 655 polymorphisms, biochemical and clinical features. *First Author: Isabel Blancas, Oncology Department, San Cecilio University Hospital, Granada, Spain*

Background: The introduction of trastuzumab in the treatment scheme of the HER2 BC patients has improved the evolution of the disease. Nevertheless, some of this patients develop cardiotoxicity. We studied some of our population of HER2 positive BC patients treated with trastuzumab trying to find predictors for developing cardiotoxicity, specifically the association of the HER2 Ile655Val A>G polymorphism with trastuzumab-induced cardiotoxicity and with survival and some biochemical and clinical features. **Methods:** For the study breast cancer patients were recruited from San Cecilio University Hospital in Granada (Spain) who were treated with trastuzumab. HER2 Ile655Val A>G polimorphism was performed in 93 patients using Taqman SNP technology. We analyzed the relation of polymorphisms with disease free survival (DFS) and overall survival (OS). We also could asses 66 patients who had biochemical measurement of NTpro BNP during the treatment with trastuzumab and cardiovascular risk factors including diabetes, hypertension, smoking, hypercholesterolemia and body mass index (BMI). Cardiotoxicity was defined as a $\geq$ 10% decrease of the left ventricular ejection fraction (LVEF) from baseline, a LVEF below 40% or any clinical manifestation of heart insufficiency. NT-proBNP cut-off points were considered to stablish normal or abnormal values adjusted by patient age. **Results:** Genotype frequencies of HER2/neu 655 met Hardy-Weinberg equilibrium ($p = 0.363$). Logistic regression analysis adjusted by hormonal status and anthracycline treatment showed higher cardiotoxicity risk for AG vs AA Her2-Ile655 polimorphism (OR = 3.00, CI95% 1.07-8.41, $p = 0.037$) or for AG vs AA+GG Her2-Ile655 polimorphism (OR = 3.21, CI95% 1.15-8.96, $p = 0.026$). We did not find association between HER2neu Ile655Val polymorphism and DFS or OS. NT-proBNP baseline higher than the range (OR 5.9, 95% CI 1.2 - 28.5, $p = 0.028$) and diabetes mellitus (OR 22.0, 95% CI 5.7 - 85.4, $p = 0.000$) were found to be related with the development of cardiotoxicity. **Conclusions:** HER2-Ile655 A>G polymorphism is significantly associated with higher risk of trastuzumab-induced cardiotoxicity but it is not correlated with DFS neither OS. Diabetes or baseline high NT-proBNP levels are predictors for the development of trastuzumab-induced cardiotoxicity. These parameters should be considered for a closer follow up and for preventive actions as accurate glycaemic control for patients who will receive trastuzumab. 1035 Poster Session (Board #120), Fri, 8:00 AM-11:00 AM

Detection of actionable gene mutations in breast cancer by amplicon-based next-generation sequencing liquid biopsy. *First Author: Jing Shan Lim, Lucence Diagnostics, Singapore, Singapore*

Background: The PI3K-inhibitor, alpelisib, was approved for the treatment of hormone receptor (HR)-positive, HER2-negative breast cancers with *PIK3CA* mutations based on findings from the SOLAR-1 trial. *PIK3CA*-positivity in tumor tissue was 29% (341/1172), but was only 15% (177/1172) in plasma cell-free DNA (cfDNA). The lower mutation detection rate observed in cfDNA may limit the clinical application of liquid biopsy in breast cancer. Amplicon-based next-generation sequencing (NGS) approach may confer improved sensitivity, allowing more effective profiling. We conducted a study to evaluate the use of this technology. **Methods:** Plasma cfDNA from 113 breast cancer patients (82.3% metastatic) underwent real-world testing in a CAP and ISO15189 accredited central laboratory. We analysed genetic alterations in cfDNA using an amplicon-based NGS technology. The presence of *PIK3CA* and other mutations relevant to breast cancer were correlated to molecular subtypes and treatment histories. **Results:** At least one mutation was detected in 70.8% of cases. Mutations were more frequent in metastatic cases (77.4%) compared to non-metastatic cases (27.3%). Across all patients, mutations in *PIK3CA* (33.6%), *TP53* (32.7%), *ESR1* (22.1%), *GATA3* (7.1%) and *ERBB2* (7.1%) were most frequently detected, in accordance with tumor tissue genotyping studies. *PIK3CA* mutations were more common in HR+ HER2- patients (44.4% vs 28.6% of other patients). Among *PIK3CA*-mutant cases, multiple *PIK3CA* mutations were present in 18.4% of cases, and hotspot mutations H1047R (34.2%), E542K (26.3%) and E545K (15.8%) were most frequent. An association was seen between *PIK3CA* mutation and prior treatment with CDK4/6 inhibitors (palbociclib, ribociclib) or mTOR inhibitor (everolimus), with 58% of *PIK3CA*-mutant cases having received these treatment previously compared to only 20% of *PIK3CA*-wild type (wt) cases. In addition, 75% of previously treated *ESR1*-mutant cases had specifically received hormonal treatment, compared to 60 % of *ESR1*-wt cases that received any treatment. **Conclusions:** We report similar *PIK3CA* mutation frequencies (~30%) with amplicon-based NGS on cfDNA compared to tumor tissue testing in breast cancer. Importantly, other driver mutations were also observed at similar frequencies as external tissue studies, implying high sensitivity as the primary reason for performance. This supports the clinical utility of an amplicon-based NGS-based approach to liquid biopsy for the sensitive detection of actionable mutations in breast cancer. 1036 Poster Session (Board #121), Fri, 8:00 AM-11:00 AM

Trastumab deruxtecan for HER2-positive metastatic breast cancer: DESTINY-Breast01 subgroup analysis. *First Author: Shanu Modi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Trastuzumab deruxtecan (T-DXd; DS-8201) is an antibody-drug conjugate composed of an anti-HER2 antibody, a cleavable linker, and a cytotoxic topoisomerase I inhibitor. In the pivotal DESTINY-Breast01 trial, efficacy of T-DXd in HER2-positive metastatic breast cancer (mBC) was demonstrated, with an objective response rate (ORR) of 60.9% and median progression-free survival (mPFS) of 16.4 months. **Methods:** DESTINY-Breast01 was a single-group, open-label, multicenter, phase II trial of 184 patients with HER2-positive mBC previously treated with trastuzumab emtansine (T-DM1) who received T-DXd at 5.4 mg/kg. Multivariate analysis using logistic regression models (ORR) and Cox proportional hazards models (duration of response [DOR], mPFS) explored 15 relevant clinical predictor variables. Circulating tumor DNA (ctDNA) was collected prior to the first dose, every 3 cycles of treatment, and at the end of treatment. Sequencing was done via GuardantOMNI (Guardant Health) for single-nucleotide variation/insertion and deletion, amplification, and fusion of ≈ 500 genes. **Results:** Efficacy in all evaluated clinical subgroups was similar to the overall ORR 60.9% and mPFS 16.4 months with ranges from ORR 46.4%-74.5% and mPFS 12.3-18.1 months. Variables associated with improved ORR, DOR, or mPFS included hormone receptor positive status, fewer prior treatment regimens (continuous variable), pertuzumab given in the first or second line, and normal renal and hepatic function. Variables that did not impact efficacy outcomes compared to the overall population include age, race, region, ECOG PS, HER2 IHC 3+ status, progesterone receptor status, best response to T-DM1, time since diagnosis, and history of brain metastases. In 48 subjects with progression as of data cut date, metastases were most commonly observed in the liver, lung, and lymph nodes. Only 8% (4 of 48) had progression involvement in the brain upon disease progression. Decrease of ERBB2 copy number in ctDNA was seen on treatment and correlated with clinical response. Additional changes in molecular markers on treatment and following progression will be described. **Conclusions:** T-DXd demonstrated strong efficacy in all clinical subgroups analyzed. Further exploration of both clinical and molecular variables to determine biomarkers of efficacy may be warranted. Clinical trial information: NCT03248492. Research Sponsor: Daiichi Sankyo, Inc.

1037 Poster Session (Board #122), Fri, 8:00 AM-11:00 AM

Clinical activity of MCLA-128 (zenocutuzumab) in combination with endocrine therapy (ET) in ER+/HER2-low, non-amplified metastatic breast cancer (MBC) patients (pts) with ET-resistant disease who had progressed on a CDK4/6 inhibitor (CDK4/6i). *First Author: Barbara Pistilli, Gustave Roussy, Villejuif, France*

Background: MCLA-128 (zenocutuzumab) is an ADCC-enhanced humanized bispecific antibody targeting HER2 and HER3 and potently blocking HER3-ligand induced receptor dimerization. Upregulation of Her2:Her 3 pathway is a means of resistance to ET in HR+ breast cancer, indicating a potential role for MCLA-128. In preclinical studies, the combination of MCLA-128 with ET in breast cancer xenografts outperformed single drug treatments. The current study explores the use of MCLA-128 to rescue pts with ET-resistant MBC who have progressed on a CDK4/6i. **Methods:** This phase II, open-label trial planned for up to 40 evaluable women with HR+, HER2 low (IHC 1+/IHC 2+ with negative FISH) MBC, who had progressed on a CDK4/6i and up to 3 lines of ET, who had received ≤ 2 chemotherapy regimens in the metastatic setting. Pts received MCLA-128 (750 mg, 2h IV, flat dose) q3w combined with last ET on which the pt had previously progressed immediately prior to study entry. Disease control rate (DCR; RECIST 1.1, per investigator), best overall response (BOR), overall response rate (ORR), safety, and PK, are evaluated. Data cut off was 14Nov2019. **Results:** 48 pts were treated, all of whom had progressed on a CDK4/6i. Pts had received a median 2 prior ET lines (range 1-5) and 1 line (range 1-3) of chemotherapy. Pts had a median number of 3 metastatic sites (range 1-6) and 42 (88%) had visceral involvement. Among 42 pts evaluable for efficacy, DCR was 45% (90% CI 32-59) with 2 pts having unconfirmed PR and 19 pts SD as BOR. Common related AEs (all grades; G3-4) were asthenia/fatigue (27%; 2%), diarrhea (25%; 0), nausea (21%; 0). No clinically significant LVEF decline was seen. At the end of cycle 1, mean trough level of MCLA-128 was 15.5 μg/mL, and mean terminal half-live was 102 h (n = 19-21). Data on the primary endpoint, clinical benefit rate at 24 weeks, and biomarkers will be provided. **Conclusions:** The addition of MCLA-128 to the last line of ET showed clinical activity after ET+CDK4/6i failure and a favorable safety profile. Clinical trial information: NCT03321981. Research Sponsor: Merus NV.

1038 Poster Session (Board #123), Fri, 8:00 AM-11:00 AM

Addition of endocrine therapy to dual anti-HER2 targeted therapy in initial treatment of HER2+/HR+ metastatic breast cancer. *First Author: Matthew Loft, The Walter and Eliza Hall Institute of Medical Research, Melbourne, VIC, Australia*

Background: The combination of dual anti-HER2 targeted therapy and chemotherapy is the current first line standard of care for HER2+ metastatic breast cancer. Endocrine therapy (ET) is the backbone of treatment in hormone receptor positive (HR+) disease, but the role of the addition of endocrine therapy following chemotherapy in HER2+/HR+ disease remains unclear as pivotal first line clinical trials excluded endocrine therapy use. **Methods:** Data from a multi-site community cohort of consecutive HER2+ metastatic breast cancer patients diagnosed between 1 January 2012 and 31 August 2019 was examined. Patients were treated at clinician discretion. The subset of patients eligible for this analysis were those that were HR+ and had received first line dual anti-HER2 targeted therapy. **Results:** Of 132 eligible patients included in the analysis, 78 (59.1%) received endocrine therapy and 54 (40.9%) did not. Median follow up was 25.9 months. There were no significant differences between the two groups based on age, performance status, previous therapy or de novo disease (Table), however, patients with bone metastases were more likely to receive ET in conjunction with first line dual anti-HER2 therapy (71% vs 52%, $p = .043$). The addition of ET was associated with improved progression free (HR 2.1, 95% CI 1.2-3.5, $p = 0.007$) and overall survival (HR 2.7, 95% CI 1.2-5.5, $p = 0.007$) in multivariate analysis. No increase in serious adverse events was noted although endocrine therapy related toxicities were not specifically collected. **Conclusions:** In this real-world series, the addition of ET to first line dual anti-HER2 therapy in HER2+/HR+ metastatic breast cancer was associated with improved progression free and overall survival. Further research is required to validate these findings and examine the role of CDK4/6 inhibitors in this disease, but may provide reassurance to clinicians considering ET in this clinical context. Research Sponsor: None.

1039 Poster Session (Board #124), Fri, 8:00 AM-11:00 AM

A phase I dose escalation study evaluating the safety and tolerability of a novel anti-HER2 antibody-drug conjugate (PF-06804103) in patients with HER2-positive solid tumors. *First Author: Funda Meric-Bernstam, MD Anderson Cancer Center, Houston, TX*

Background: PF-06804103 is an anti-HER2 immunoglobulin G1 antibody-drug conjugate (ADC), comprising an anti-HER2 monoclonal antibody conjugated with a cleavable linker to the cytotoxic agent Aur0101. PF-06804103 demonstrated strong activity in low to high HER2-expressing preclinical tumor models. In this study, the safety and tolerability of PF-06804103 was assessed in patients with advanced breast cancer (BC) or gastric cancer (GC). **Methods:** This multi-center, open-label, first-in-patient, phase I study (NCT03284723) has two parts: dose escalation (Part 1) and dose expansion (Part 2). In Part 1, groups of adult patients (pts) with HER2+ BC or HER2+ GC, who are resistant or intolerant to standard therapy or for which no standard therapy is available, received PF-06804103 intravenously once every 21 days (Q3W); dosage was escalated per cohort. Primary objectives were to evaluate the safety and tolerability of PF-06804103, characterize its dose-limiting toxicities (DLTs), and determine the recommended phase 2 dose. Response was assessed using RECIST v1.1. Objective response rate (ORR) was calculated for response-evaluable pts with target lesions at baseline and ≥1 post-baseline assessment (including unconfirmed responses). **Results:** A total of 35 pts (BC: n = 20; GC: n = 15) received PF-06804103 at escalating dose levels (0.15 mg/kg: n = 2; 0.5 mg/kg: n = 2; 1.2 mg/kg: n = 2; 2 mg/kg: n = 4; 3 mg/kg: n = 10; 4 mg/kg: n = 9; 5 mg/kg: n = 6). The median (range) number of prior therapies was 6 (3–18) and 3 (1–6) for BC and GC groups, respectively (all pts had prior HER2-targeted therapy). The 3 most common, drug-related adverse events (any grade) were alopecia (n = 17, 48.6%), fatigue (n = 15, 42.9%), and neuropathy (n = 9, 25.7%). DLTs (mostly grade 3) occurred in 3 pts and included arthralgia, neuropathy, myalgia, fatigue, and osteomuscular pain. Preliminary ORR in the patients treated with doses ≥3mg/kg was 52.4% (11/21). **Conclusions:** The PF-06804103 ADC demonstrated manageable toxicity and promising anti-tumor activity in this small, heavily pretreated study population. Clinical trial information: NCT03284723. Research Sponsor: Pfizer.

1040 Poster Session (Board #125), Fri, 8:00 AM-11:00 AM

SOPHIA analysis by chemotherapy (Ctx) choice: A phase III (P3) study of margetuximab (M) + Ctx versus trastuzumab (T) + Ctx in patients (pts) with pretreated HER2+ metastatic (met) breast cancer (MBC). *First Author: Santiago Escrivá, Medical Oncology Department, Vall d'Hebron University Hospital. Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Despite advances, pretreated HER2+ MBC remains incurable with ongoing need for new therapies. Investigational M has similar HER2 binding and antiproliferative effects as T. Relative to T, M Fc engineering increases binding affinity for both variants of activating Fc receptor (FcR) CD16A and decreases affinity for inhibitory FcR CD32B, coordinately activating innate and adaptive immunity. In a Phase 3 (P3) trial, M prolonged PFS over T (Table). Second interim OS results from Sept 2019 also favor M (hazard ratio [HR], 0.89; 95% CI 0.69–1.13; nominal *P*=0.326). **Methods:** SOPHIA (NCT02492711), an open-label P3 trial, enrolled pts with HER2+ MBC after pertuzumab and 1–3 lines of prior treatment (Tx) for MBC. Randomization was 1:1 to M (15 mg/kg IV q3w + Ctx) or T (6 [8 for loading dose] mg/kg IV q3w + Ctx), stratified by met sites (≤2, >2), lines of Tx for met disease (≤2, >2), and Ctx choice, including capecitabine (Cap), eribulin (Eri), gemcitabine (Gem), or vinorelbine (Vin). Primary endpoints were central blinded PFS and OS, assessed sequentially using the stratified log-rank test. **Results:** Investigator chemotherapy choices and results by chemotherapy are shown in the table. Subjects receiving Eri and Gem had the lowest PFS hazards ratios (HRs), favoring M over T, although no statistical significance of individual chemotherapy subgroups was seen. There was variable toxicity among Ctx subgroups, and fewer subjects receiving Cap had Ctx related Grade 3 or higher (>=Gr 3) AEs. In this unblinded study, more subjects on M than T in all subgroups discontinued Ctx while continuing study antibody. **Conclusions:** In combination with chemotherapy in pretreated HER2+ MBC, M improved PFS over T. Safety was manageable in all Ctx subgroups. Differences among HRs for chemotherapy subgroups may be driven by selection bias and/or sensitivity differences. Clinical trial information: NCT02492711. Research Sponsor: MacroGenics.

1041 Poster Session (Board #126), Fri, 8:00 AM-11:00 AM

Preliminary safety, efficacy and pharmacokinetics (PK) results of KN026, a HER2 bispecific antibody in patients (pts) with HER2-positive metastatic breast cancer. *First Author: Dongmei Ji, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: KN026 is a novel bispecific antibody that simultaneously binds to two distinct HER2 epitopes, the same domains as trastuzumab (ECD4) and pertuzumab (ECD2). It blocks ligand-dependent and independent tumor growth and enhances HER2 receptor internalization. In preclinical studies, KN026 showed activity in trastuzumab plus pertuzumab resistant tumor cell lines. This first-in-human study evaluated the safety/tolerability, pharmacokinetics (PK), and preliminary efficacy of KN026 monotherapy. **Methods:** This dose-escalation and expansion study enrolled Chinese patients (pts) with metastatic breast cancer who have failed prior anti-HER2 therapy. All pts intravenously received KN026 monotherapy at ascending dose of 5 mg/kg (QW), 10 mg/kg (QW), 20 mg/kg (Q2W) or 30 mg/kg (Q3W). Dose limiting toxicity (DLT) evaluation period was 28 days for QW and Q2W, and 21 days for Q3W. Efficacy evaluation was performed by RECIST 1.1 every 6 weeks and safety assessment according to CTCAE v 4.03. **Results:** As of the Jan, 22, 2020, 63 pts [median age: 54 years (31~69)] enrolled and 62 pts were included in the efficacy analysis. 41 pts remained on treatment and 22 pts discontinued treatment due to disease progression (n = 21) and adverse events (n = 1). The median treatment duration was 12 weeks (range: 4~62 weeks). Median prior lines of therapies are 3 (range: 1~15), and median prior lines of HER2 target therapies are 2 (range: 1~12). No DLTs were observed. Treatment-related AEs (TRAEs) occurred in 49 pts and 4 pts experienced 4 grade 3 TRAE (hypertension, infusion related reaction, transaminases increased and ventricular arrhythmia). The common (≥ 10%) TRAE were pyrexia (23.8%), diarrhea (19.0%), aspartate aminotransferase increased (15.9%), neutrophil count decreased (11.1%) and white blood cell count decreased (11.1%). The objective response rate at recommended Phase 2 dose levels (n = 56) was 32.1% (95% CI 20.3, 46.0) and disease control rate 76.8% (95% CI 63.6, 87.0). Pharmacokinetic analysis showed exposure (C_{max} and $AUC_{0\text{-}t}$) of KN026 increased by dose. The recommended Phase 2 dose (RP2D) were 20 mg/kg Q2W and 30 mg/kg Q3W. **Conclusions:** KN026 is well tolerated and has demonstrated encouraging anti-tumor activity in HER2-positive breast cancer patients who have failed standard anti-HER2 therapies. The recommended Phase 2 dose (RP2D) of KN026 were 20 mg/kg Q2W and 30 mg/kg Q3W. Phase II trials in various HER2-positive and HER2-low/intermediate solid tumors are currently ongoing. Clinical trial information: NCT03619681. Research Sponsor: Alphamab (Australia) Co Pty Ltd.

1043 Poster Session (Board #128), Fri, 8:00 AM-11:00 AM

Management of adverse events in patients with HER2+ metastatic breast cancer treated with tucatinib, trastuzumab, and capecitabine (HER2CLIMB). *First Author: Alicia Frances Clare Okines, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Tucatinib (TUC) is an investigational TKI, highly selective for HER2 without significant inhibition of EGFR. HER2CLIMB is a randomized trial of TUC vs placebo in combination with trastuzumab and capecitabine in patients (pts) with HER2+ breast cancer (NCT02614794, Murthy NEJM 2019). The most common G ≥3 adverse events (AEs) with higher incidence on the TUC arm (diarrhea, palmar-plantar erythrodysesthesia syndrome [PPE], and elevated liver enzymes) are described herein. **Methods:** Given that pts on the TUC arm had a longer duration of tx than those on the control arm, time-at-risk exposure-adjusted incidence rates of diarrhea, AST, ALT, and PPE were calculated as the number of pts with an event divided by the total exposure time-at-risk of an initial occurrence of the event among pts in the tx group. Time-to-event analyses were conducted for AST/ALT/bilirubin (in aggregate), diarrhea, and PPE. **Results:** Diarrhea and elevated AST/ALT/bilirubin on both the TUC and control arms were primarily G1/2 and manageable with dose modifications, and in some cases of diarrhea, with antidiarrheal tx. Median time to diarrhea onset was shorter on the TUC arm compared to control. For AST/ALT/bilirubin and PPE, median time to first onset was Cycles 1 and 2. On the TUC arm, antidiarrheals were used in 49.7% of cycles in which diarrhea was reported (39.8% on the control arm), and when used, the median duration of use on each arm was 3 days per cycle. Prophylactic antidiarrheals were not required per protocol. When adjusted for exposure (time-at-risk exposure-adjusted incidence rate per 100 person-years), the difference in G ≥3 events between tx arms becomes similar for diarrhea and PPE (21 vs 17 and 21 vs 19). The difference in G ≥3 events between arms is reduced for AST and ALT (7 vs 1 and 8 vs 1). **Conclusions:** TUC with trastuzumab and capecitabine was well-tolerated. Rates of G ≥3 diarrhea and PPE were similar between tx arms. Elevated liver enzymes were higher on the TUC arm, but were transient and reversible. Discontinuation of TUC due to AEs was rare. Clinical trial information: NCT02614794. Research Sponsor: Seattle Genetics, Inc.

Peripheral endothelial function changes during HER2-directed therapy differ based on whether or not a patient receives anthracycline. *First Author: Antonious Ziad Hazim, Mayo Clinic, Rochester, MN*

Background: Trastuzumab is well-demonstrated to be associated with cardiotoxicity (typically reduced ejection fraction), most commonly in patients who also receive anthracycline. The vascular effects of trastuzumab and anthracycline are understudied; we aimed to compare change in endothelial function during and after trastuzumab and to assess how anthracycline receipt affects this. **Methods:** This is an observational prospective study of women with newly diagnosed HER2-positive breast cancer. All participants underwent baseline evaluation of endothelial function testing by use of the EndoPAT2000 device approximately every three months over the subsequent 18 months after the initiation of HER2-directed therapy +/- anthracycline. The primary endpoint was change in endothelial function over time using the reactive hyperemia index (RHI). Framingham Risk Score (FRS) and lower RHI are both known to be independent predictors of future cardiovascular events in the general population. RHI deterioration was defined as a 20% reduction from baseline RHI to any available follow-up RHI assessment. Univariate analyses assessed if age, FRS, baseline RHI, and RHI deterioration differed between recipients and non-recipients of anthracycline using the Wilcoxon test. A multivariate logistic model evaluated FRS, age, and anthracycline receipt as possible independent predictors of RHI deterioration. **Results:** Among 38 eligible patients who consented and completed baseline assessments in addition to at least one follow-up assessment, 17 (45%) subsequently received anthracycline. 145 total follow-up RHI assessments were available overall (5 per patient on average). There were no differences between recipients and non-recipients of anthracyclines with regard to age [mean 49 years (SD 12) vs 53 years (SD 11); p=0.25], baseline FRS [mean 1.0 (SD 1.0) vs 1.5 (SD 1.4); p= 0.28] or baseline RHI [mean 2.4 (SD 0.6) vs 2.1 (SD 0.7); p=0.09]. RHI deterioration was more common for anthracycline recipients (mean 43% vs 21%; p=0.004), and in the multivariate model, anthracycline use was the only independent predictor of RHI deterioration (odds ratio: 2.8; 95% confidence interval: 1.35-6.07; p=0.006). **Conclusions:** This study suggests that endothelial dysfunction is more common after combined anthracycline and HER2-directed therapy than after HER2-directed therapy alone. RHI should be further studied as a possible early biomarker of cardiovascular toxicity in patients receiving treatment for breast cancer. Interstitial lung disease in Japanese patients with HER2-expressing metastatic breast cancer receiving trastuzumab deruxtecan. *First Author: Masaya Hattori, Department of Breast Oncology, Aichi Cancer Center, Nagoya, Japan*

Background: Trastuzumab deruxtecan (T-DXd) is a new potent HER2-targeting antibody-drug conjugate in patients with HER2-expressing breast cancer. Interstitial lung disease (ILD), including fatal cases, have been reported in patients receiving T-DXd, which have indicated high incidence in Japanese patients. In this study, we aimed to characterize the severity, management, and the time course of ILD in Japanese patients receiving T-DXd. **Methods:** Patients with HER2-expressing metastatic breast cancer who developed ILD during treatment with T-DXd in our hospital were included in this study. We reviewed clinical charts and assessed CT images. ILD was graded according to the Common Terminology Criteria for Adverse Events (version 4.0). **Results:** A total of 10 patients (38.5%) of 26 metastatic breast cancer patients who received T-DXd in our hospital developed ILD during their treatment with T-DXd. Of the 10 patients with a median age of 55 years, 8 were with HER2-positive tumors and 2 were with low HER2-expressing tumors. All HER2-positive patients were previously treated with trastuzumab, pertuzumab and T-DM1. Four patients received the dose with 5.4 mg/kg, 3 with 6.4 mg/kg, 2 with 4.4 mg/kg, and 1 with 7.4 mg/kg. Median time to ILD onset was 7.6 months (range, 1.7-19.8). Severity of ILD was grade 1 in 7 patients, grade 2 in one patient, grade 3 in one patient and grade 5 in one patient. All patients with grade $\geq$2 ILD received corticosteroids. T-DXd was interrupted in all cases after the diagnosis of ILD and was re-administered in one case after recovery. In the fatal case, T-DXd was continued after the appearance of small reticular opacities without symptoms. In some cases, sustained off-treatment responses for more than 6 months after interruption was observed. **Conclusions:** T-DXd-induced ILD in Japanese breast cancer patients mostly occurred asymptomatically and improved by T-DXd interruption and/or steroid administration. Careful radiographic monitoring and, in case with ILD is suspected, prompt ILD management with interruption of T-DXd should be considered. Research Sponsor: None.

1046 Poster Session (Board #131), Fri, 8:00 AM-11:00 AM

A phase Ib study of pembrolizumab (pembro) plus trastuzumab emtansine (T-DM1) for metastatic HER2+ breast cancer (MBC). *First Author: Adrienne Gropper Waks, Dana-Farber Cancer Institute, Boston, MA*

Background: Preclinical evidence suggests treatment (tx) with T-DM1 plus an anti-PD1 antibody triggers antitumor immunity. We conducted a phase 1 trial to determine the safety and explore the efficacy of T-DM1 plus pembro. **Methods:** Eligible patients (pts) had MBC previously treated with trastuzumab (H) and taxane (T), were T-DM1-naïve, and received >1 prior line of tx for MBC or developed recurrence within 6 months (mo) of adjuvant tx. A dose de-escalation (esc) design was used with 6 pts in the dose-finding cohort, followed by an expansion (exp) cohort at the recommended phase 2 dose (RP2D), with mandatory baseline biopsies (bx). The primary endpoint was safety and tolerability. Secondary endpoints included objective response rate (ORR), progression-free survival (PFS), and clinical benefit rate (CBR: complete response + partial response + stable disease >24 weeks). Associations between immune biomarkers and tx response were explored. **Results:** 20 pts started protocol tx (6 in dose de-esc cohort; 14 in exp cohort). Median follow-up was 23.5 mo. Pts had median age 54 yrs and median 1 line of prior MBC tx (range 0-2); 100% had received prior T, H, and pertuzumab. There were no dose-limiting toxicities in the dose de-esc cohort; thus full doses of T-DM1 (3.6 mg/kg q21 days) and pembro (200 mg q21 days) were the RP2D. 85% of pts experienced tx-related adverse events (AEs) > grade (gr) 1; 20% of pts experienced gr3 AEs. There were no gr>4 AEs. Gr3 AEs were fatigue; AST increase; ALT increase; pneumonia; pneumonitis; oral mucositis; and vomiting, each in 1 pt. 17 pts had baseline bx; 6 pts had repeat bx after 1 tx cycle. Efficacy results, overall and by PD-L1 Combined Positive Score (CPS; 22C3 staining) and tumor-infiltrating lymphocyte (TIL) status, are shown in the table. Tumors' antigen presentation will be explored through HLA/dendritic cell marker staining and immune signatures by RNA sequencing. **Conclusions:** T-DM1 plus pembro was safe and tolerable. The regimen demonstrated clinical activity. Further exploration of immune-related predictive biomarkers is warranted. Clinical trial information: NCT03032107. Research Sponsor: Merck.

Targeted next generation sequencing to expand *HER2* status detection: Implication for newer *HER2*-directed agents. *First Author: Ning Liao, Guangdong Provincial People's Hospital, Guangzhou, China*

Background: Establishment of *ERBB2* (*HER2*) amplification status in breast carcinoma (BC) and gastric carcinoma (GC) is essential for treatment selection, but no anti-*HER2* therapies have been approved for tumors with low level of *HER2* expression. The clinical trial (NCT02564900) was initiated to evaluate the safety and efficacy of trastuzumab deruxtecan (DS-8201a) in BC patients with lower *HER2* expression by current methods. This study aims to validate NGS-based detection for *HER2* low expression. **Methods:** 275 BC and 425 GC were collected and subjected to NGS for genomic alteration detection. The testing was carried out by a College of American Pathologists (CAP) accredited and Clinical Laboratory Improvement Amendments (CLIA) certified laboratory, Shanghai, China. Protein expression was analyzed by using IHC. FISH was carried out on 108 samples, including 63 BC and 45 GC. To set up NGS cutoff, FISH was performed on additional 34 samples. Sensitivity, specificity and accuracy were evaluated based on FISH as a gold-standard reference. **Results:** In BC, the expression level of *HER2* protein detected by IHC was overall IHC 0 in 28.7%, 1+ in 18.9%, 2+ in 27.3% and 3+ in 25.1%, respectively, while in GC, the expression level was 60.7%, 18.6%, 14.8% and 5.9%, respectively. Log2ratio was used to assess *ERBB2* amplification status detected by NGS. According to the FISH results of 34 other samples with high sensitivity (98%) and specificity (100%), the threshold was determined as 0.5. 8 and 10 samples of IHC 1+/2+ met the cutoff in BC and GC, respectively. In 63 BC, there were 17 positive and 46 negative by FISH. According to the threshold, the sensitivity and specificity of NGS detection was 94.1% and 97.8%, respectively. The proportion of samples with IHC 2+ that couldn't determine NGS *ERBB2* status was 49.2%. However, except for false positive and false negative, the NGS results were concordant with FISH. In 45 GC, there were 5 positive and 40 negative by FISH. The specificity and sensitivity was 97.5% and 40%, respectively. In 4 samples with IHC 2+, 2 of them were discordant with the results of NGS and FISH. All IHC 1+ didn't meet the cutoff of NGS and was FISH negative in 108 samples. The accuracy of NGS in *ERBB2* detection was 96.8% and 91.1% for BC and GC, respectively. **Conclusions:** Our data indicated that the NGS-based detection of *ERBB2* amplification had high sensitivity, specificity and accuracy. In samples with IHC 1+/2+, the results of NGS detection were high concordant with FISH detection. Research Sponsor: None.

1048 Poster Session (Board #133), Fri, 8:00 AM-11:00 AM

Pyrotinib plus capecitabine for HER2-positive, trastuzumab-resistant metastatic breast cancer: A pooled analysis of three randomized controlled trials. *First Author: Zefei Jiang, The Fifth Medical Center of Chinese PLA General Hospital, Beijing, China*

Background: Trastuzumab is the most widely used anti-HER2 agent in patients (pts) with HER2-positive breast cancer, both in (neo)adjuvant and metastatic settings; however, drug resistance is inevitable. This pooled study aimed to investigate the efficacy of pyrotinib plus capecitabine in pts with HER2-positive, trastuzumab-resistant relapsed or metastatic breast cancer. **Methods:** Data were derived from three randomized controlled trials, including a phase II (NCT02422199) and the PHOEBE phase III (NCT03080805) study comparing pyrotinib plus capecitabine vs lapatinib plus capecitabine and the PHENIX phase III (NCT02973737) study comparing pyrotinib plus capecitabine vs placebo plus capecitabine. Pts with trastuzumab-resistant disease were included in the analyses, including 39 pts who had relapsed within six months after adjuvant trastuzumab and 57 pts who had progressed within three months of trastuzumab treatment for metastatic disease. The pooled tumor response data (per blinded independent central review) were reported herein. **Results:** In the pooled analysis of all three studies, 63 pts received pyrotinib plus capecitabine. Among them, 28 (44.4%) pts had disease progression or died. The median progression free survival (PFS) was 12.4 months (95% CI, 6.9 to not reached). In total, 40 pts (63.5% [95% CI, 50.4% to 75.3%]) achieved objective response, and the estimated median duration of response (DoR) was 11.1 months (95% CI, 6.9 to not reached). In the pooled analysis involving the phase II and PHOEBE phase III, 43 pts were treated with pyrotinib plus capecitabine and 33 pts with lapatinib plus capecitabine. In total, 18 (41.9%) pts with pyrotinib plus capecitabine and 17 (51.5%) pts with lapatinib plus capecitabine had disease progression or died. The PFS tended to be prolonged with pyrotinib plus capecitabine vs lapatinib plus capecitabine (median, 12.4 months [95% CI, 6.9 to not reached] vs 6.9 months [95% CI, 5.5 to not reached]; hazard ratio, 0.62 [95% CI, 0.31 to 1.24]; p=0.0864). The objective response rate was 67.4% (95% CI, 51.5% to 80.9%) with pyrotinib plus capecitabine compared with 54.5% (95% CI, 36.4% to 71.9%) with lapatinib plus capecitabine. The estimated median DoR was 11.1 months [95% CI, 6.9 to not reached] vs not reached [95% CI, 4.2 months to not reached], respectively. **Conclusions:** Pyrotinib plus capecitabine showed favorable efficacy in pts with HER2-positive, trastuzumab-resistant relapsed or metastatic breast cancer. This combination could be a treatment option for this population. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

1049 Poster Session (Board #134), Fri, 8:00 AM-11:00 AM

A first in-human study of A166 in patients with locally advanced/metastatic solid tumors which are HER2-positive or HER2-amplified who did not respond or stopped responding to approved therapies. *First Author: Yongheng Liu, Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd., Chengdu, China*

Background: HER2 is an effective therapeutic target for breast and gastric cancer. A166 is an antibody-drug conjugate composed of a novel cytotoxic drug site-specifically conjugated to transtuzumab sequence via a stable protease-cleavable valine citrulline linker. **Methods:** This was a single arm, open-label, multicenter, dose escalating Phase 1 first-in-human study of A166 as monotherapy in solid tumor patients. Dose escalation and MTD identification was directed using a Bayesian logistic regression model with overdose control. The following dose levels were evaluated in this study: 0.3, 1.2, 3.6, 4.8 mg/kg. (ClinicalTrials.gov NCT03602079) **Results:** As of November 1, 2019 35 pts have completed the DLT evaluation period across 4 dose levels. Overall, A166 had an acceptable toxicity profile with no unexpected toxicities related to the study drug. No adverse events recorded met the protocol specified definition of a dose limiting toxicity at any studied dose level. Most frequently (≥10%) occurring TEAEs include were Keratitis, Decreased appetite, Dry eye, Vision blurred etc. Overall incidence of ophthalmic toxicities in the 3.6 mg/kg cohort was 80% and in the 4.8 mg/kg cohort it was 83%. Among the 27 patients evaluable for efficacy, best response was progression of disease in 11 patients (41%), stable disease in 9 patients (33%) and partial response in 7 patients (26%), for the total disease control rate of 59%.Responses were seen only at the dose levels of 3.6 mg/kg and 4.8 mg/kg. **Conclusions:** A166 demonstrated clinically meaningful efficacy in heavily pretreated patients with relapsed or refractory advanced solid cancers. The achievement of an ORR of 36% at efficacious dose levels and up to 100% in HER2 positive patients regardless of histology (2 CRC, 1 BC and 1 NSCLC) at the highest studied dose level exceed Clinical trial information: NCT03602079. 1050 Poster Session (Board #135), Fri, 8:00 AM-11:00 AM

Patient-matched tissue and liquid biopsies identify shared and acquired genomic alterations in breast cancer. *First Author: Ethan Sokol, Foundation Medicine, Inc., Cambridge, MA*

Background: Liquid biopsy-based comprehensive genomic profiling (CGP) is a minimally invasive approach to potentially identify truncal driver alterations and mechanisms of acquired resistance. However, there are limited data comparing solid tissue and plasma biopsies from the same patient in breast cancer. **Methods:** CGP was performed on matched tumor tissue and plasma samples from 444 patients with breast cancer (Foundation Medicine, Inc.) to identify short variant mutations and rearrangements in at least 62 genes. ER/PR/HER2 status was abstracted for a subset of patients (n = 273). Patients were primarily ER+/HER2- (58%) with fewer HER2+ (16%) and TNBC (25%). **Results:** Samples were temporally heterogeneous with a median time between matched tissue-plasma collection of 276 days (interquartile range 45 - 650). Positive percent agreement (PPA) to tissue biopsy was 81.5% with higher PPA for collection interval ≤1y v > 1y (82.5% v 76.5%). PPA was highest in known truncal driver genes (*AKT1*, *PTEN*, *BRCA2*, *BRCA1*, *TP53*, *PIK3CA*: 85-89% PPA). PPA of tissue to liquid biopsy was 50.5% with strong time dependence (62.4% ≤1y, 37.9% > 1y), presumably due to intervening therapies. Acquired alterations in liquid biopsy were primarily known resistance mechanisms (*ESR1*, *NF1*, *ERBB2*, *PIK3CA*, *PTEN*, *TP53*, *BRCA1*, and *BRCA2*), were often polyclonal, associated with longer collection intervals, and exhibited higher prevalence in the ER+/HER2- subtype (62% ER+/HER2-, 33% HER2+, 42% TNBC). Acquired alterations significantly enriched in ER+ cases included *ESR1, NF1, ERBB2* and *TP53*. For *PIK3CA*, a PPA of 84.6% was observed with solid as baseline and 79.1% with liquid as baseline; prevalence was similar (36.5% solid, 35.6% liquid). Alpelisib companion diagnostic alterations (CDx) had a similar PPA (84.0% solid, 83.3% liquid). Overall percent agreement (OPA) for PIK3CA CDx in paired samples was 91.4% (406/444). When acquired *PIK3CA* alterations are observed they tend to be subclonal, co-occur with shared *PIK3CA* alterations, and consist of rare alterations (E726K, E453K, M1043I). **Conclusions:** While high PPA to tissue was observed for alterations in truncal driver genes, acquired alterations observed in plasma were frequently polyclonal, often identify potential mechanisms of therapeutic resistance and are, in part, a function of time and intervening treatments relative to tissue CGP. These results demonstrate high PPA to tissue suggesting that liquid biopsy has clinical validity in identifying truncal alterations and can also identify acquired alterations in breast cancer. 1051 Poster Session (Board #136), Fri, 8:00 AM-11:00 AM

A phase Ib study of abemaciclib in combination with pembrolizumab for patients with hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) locally advanced or metastatic breast cancer (MBC) (NCT02779751): Interim results. *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Abemaciclib is an orally administered, selective small molecule cyclin-dependent kinase (CDK)4 and 6 inhibitor, approved to treat HR+, HER2- MBC patients (pts) on a continuous twice daily dosing schedule as monotherapy or in combination with an aromatase inhibitor as initial endocrine based therapy or in combination with fulvestrant. Abemaciclib monotherapy increased tumor immunogenicity and synergized with anti-PD-1 to boost antitumor efficacy in murine models. Here we report safety and antitumor activity of abemaciclib plus pembrolizumab in HR+, HER2- MBC pts. **Methods:** This multicenter, nonrandomized, open-label, multi-cohort phase Ib study of abemaciclib plus pembrolizumab enrolled a cohort of endocrine resistant HR+, HER2- MBC pts who had received 1 or 2 prior chemotherapy regimens for MBC. No prior CDK4/6 inhibitor was allowed. Patients received 150mg abemaciclib orally every 12 hours plus pembrolizumab 200mg IV on day 1 every 21 days. Primary objective was to characterize safety of the abemaciclib plus pembrolizumab combination. Secondary objectives included objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Results:** Of 28 pts enrolled, 15 (54%) received 1 line and 10 (36%) 2 lines of prior systemic chemotherapy in the locally advanced/metastatic setting. Safety of the combination was generally consistent with known side effects of abemaciclib and pembrolizumab and was generally manageable. Grade 3/4 adverse events in >2 pts included neutropenia (8 pts/29%), AST increase (5 pts/18%), diarrhea, and ALT increase (3 pts/11% each). Eight pts had confirmed partial response (29% ORR), and disease control rate (complete response [CR]+partial response [PR]+stable disease [SD]) was 82%. Clinical benefit rate (CR+PR+SD persisting for ≥6 months) was 46%. Median PFS and OS were 8.9 months (95% CI 3.9, 11.1) and 26.3 months (95% CI 20.0, 31.0), respectively. **Conclusions:** Combination of abemaciclib plus pembrolizumab demonstrated a generally tolerable safety profile with numerically higher rate of transaminase elevations than reported for the individual treatments. Compared to historical data for abemaciclib monotherapy in a similar pt population, a numerically higher but not obviously different ORR, PFS, and OS was observed. Clinical trial information: NCT02779751. Research Sponsor: Eli Lilly and Company.

1052 Poster Session (Board #137), Fri, 8:00 AM-11:00 AM

Biomarker analysis from a phase I study using gedatolisib+palbociclib+hormone therapy in ER+/HER2- metastatic breast cancer (mBC). *First Author: Robert Wesolowski, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Endocrine therapy with a CDK4/6 inhibitor (CDKi) is standard of care (SOC) for patients (pts) with estrogen-receptor-positive (ER+) metastatic breast cancer (mBC). Resistance to therapy may arise from mutations in ESR1, PIK3CA, and activation of receptor tyrosine kinase signaling pathways. In this study, gedatolisib (G), a PI3KCA/mTOR inhibitor, was added to a CDKi (palbociclib, P) + letrozole (L) or fulvestrant (F) for treatment of pts with ER+/HER2- mBC. **Methods:** This phase 1b study (NCT02684032) comprises a dose escalation phase evaluating the dose-limiting toxicity and maximum tolerated dose of G+P+L/F and a dose expansion phase assessing the objective response rate of G+P+L/F, compared with historical data for P+L or P+F. Response was assessed using RECIST v1.1. Genomic and transcriptomic analyses were performed on archival pt tumor biopsies. Longitudinal plasma ctDNA analysis was performed on samples taken at baseline, on-treatment, and end-of-treatment. Unsupervised data analysis was conducted. **Results:** Genomic information was available for 25 of 35 pts with measurable disease (G+P+L: 11; G+P+F: 14). No relationship was observed between responses (1 complete response [CR] and 11 partial responses [PR]) and baseline PIK3CA pathway alterations. Pt tumor tissue analysis (n = 25) confirmed pts with FGF3/4/19 amplification (n = 4) had larger changes in tumor size in response to G+P+L/F (p = 0.029). Of the 6 pts with an ESR1 mutation, 1 pt with an ESR1 Y537S mutation exhibited a partial response (PR) to G+P+L. Longitudinal plasma ctDNA analysis (73-gene panel) revealed that decreases in PIK3CA and PTEN were most associated with clinical response. Plasma sample analysis (n = 21) showed that pts with somatic alterations in EGFR (n = 4) had a greater response to therapy (p = 0.066), compared with pts without somatic EGFR alterations. Transcriptomic profiling also revealed responsive patients had higher levels of EGFR expression. Pts exhibiting CR/PR had a lower somatic tumor mutation burden at Cycle 5 Day 1 compared with baseline (p = 0.0013). **Conclusions:** The addition of G to SOC endocrine + CDKi therapy may help overcome resistance due to activation of FGFR or EGFR signaling pathways and the ESR1 Y537S mutation. Somatic frequency changes of PI3K pathway alterations were most correlated with clinical response. Genomic data analysis from dose expansion samples is currently ongoing. Clinical trial information: NCT02684032. Research Sponsor: Pfizer.

1053 Poster Session (Board #138), Fri, 8:00 AM-11:00 AM

Acquired RB1 mutations in estrogen receptor-positive (ER+) clinically advanced and metastatic breast cancer (MBC). *First Author: Kimberly McGregor, Foundation Medicine, Cambridge, MA*

Background: Prior to use of cell cycle inhibitor drugs such as palbociclib, mutations in the retinoblastoma cell cycle inhibitory gene (*RB1*) were extremely uncommon. To assess recent descriptions of *RB1* mutations in MBC as treatment related, we compared primary untreated ER+ breast cancer samples from patients who developed MBC with ER+ MBC metastasis biopsies in post-primary treatment patients. **Methods:** Extracted DNA from 15 untreated primary breast tumors (PBx) and 36 treated metastatic MBC tumors (MBx) were sequenced by hybrid capture genomic profiling to evaluate all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on up to 1.1 Mbp of sequenced DNA. PD-L1 expression was determined by IHC (Dako 22C3). **Results:** The age distribution, GA per tumor, *CDH1* and *ERBB2* GA frequencies were similar in PBx and MBx. GA in *ESR1* ($P < 0.0008$), classically associated with acquired hormonal therapy resistance, and *PIK3CA* ($p < 0.11$) were increased in the MBx vs the PBx samples. *RB1* GA were more frequent in the MBx samples (11%) than the pre-treatment PBx samples (0%, $P < 0.31$). GA not associated with targeted therapy programs were similar in both groups. In addition to low frequencies of *ERBB2* amplification in the ER+ tumors, the most frequent potentially targetable GA identified in both PBx and MBx included GA in *FGFR1* and *NF1*. *BRCA1* GA were identified in the MBx group only. Biomarkers of potential immunotherapy benefit including MSI status, TMB levels and PD-L1 IHC staining were at similarly low levels in both groups. Additional cases are being identified to expand the cohort sizes for final presentation. **Conclusions:** In addition to the well-known acquisition of hormonal therapy resistance mutations in *ESR1* and *PIK3CA* in ER+ MBC, this study also supports the acquisition of *RB1* mutations when post-treatment metastasis biopsies are sequenced rather than pre-treatment primary tumors. This increase in *RB1* mutation identification is associated with exposure of the tumors to anti-cell cycle drugs such as palbociclib in the treated but not the untreated cohort. Overall survival (OS) in patients (pts) with advanced breast cancer (ABC) with visceral metastases (mets), including those with liver mets, treated with ribociclib (RIB) plus endocrine therapy (ET) in the MONALEESA (ML) -3 and -7 trials. *First Author: Denise A. Yardley, Sarah Cannon Research Institute and Tennessee Oncology PLLC, Nashville, TN*

Background: In the Phase III ML-3 (NCT02422615) and ML-7 (NCT02278120) trials, RIB + ET demonstrated a significant OS benefit (ML-3: HR, 0.72, P = 0.00455; ML-7: HR, 0.71, P = 0.00973) over placebo (PBO) + ET in pts with HR+/HER2- ABC (Im et al. *N Engl J Med.* 2019; Slamon et al. *N Engl J Med.* 2019). The presence of visceral mets generally portends a poor prognosis, which is especially poor in pts with liver mets (He et al. *Ann Oncol.* 2019). Here we report OS in pts with visceral mets with a focus on those with liver mets in ML-3 and ML-7. **Methods:** In ML-3, postmenopausal pts were randomized 2:1 to receive RIB + fulvestrant (FUL) or PBO + FUL as first- (1L) or second-line (2L) treatment. In ML-7, premenopausal pts were randomized 1:1 to receive RIB + ET or PBO + ET (this analysis included only pts who received an NSAI as ET partner to match approved indication). **Results:** Visceral mets were identified in 293 pts (60.5%) in the RIB arm and 147 (60.7%) in the PBO arm in ML-3 and 150 (44.8%) and 142 pts (42.1%), respectively, in ML-7. In ML-3, the median age of pts with visceral mets was 63 and 65 years in the RIB and PBO arms, and in ML-7 it was 42.5 and 45.0 years, respectively. In ML-3, 214 pts with visceral mets received 1L therapy (RIB, n = 137; PBO, n = 77), while 219 pts received 2L therapy or had early relapse (RIB, n = 151; PBO, n = 68). Lung and liver were the most common sites of visceral mets for pts in ML-3 (49.8% and 44.8%, respectively) and ML-7 (51.4% and 58.2%, respectively). OS HRs in pts with visceral mets were consistent with the benefit in the overall pt populations and suggested a particularly substantial OS benefit in pts with liver mets (HR for liver mets group in ML-3, 0.629 [95% CI, 0.421-0.942]; HR in ML-7, 0.531 [95% CI, 0.321-0.877]; Table). No new safety signals were observed. **Conclusions:** Approximately half of the pts in ML-3 and ML-7 had visceral mets. The OS data in these pts are consistent with the benefit observed with RIB in the overall populations of each trial. In pts with liver mets, a group with an especially poor prognosis, RIB + ET demonstrated a substantial OS benefit compared with PBO + ET. Clinical trial information: NCT02422615; NCT02278120. Research Sponsor: Novartis Pharmaceuticals Corporation.

1055 Poster Session (Board #140), Fri, 8:00 AM-11:00 AM

Updated results from the phase IIIb complement-1 study of ribociclib (RIB) plus letrozole (LET) in the treatment of HR+, HER2-advanced breast cancer (ABC). *First Author: Michelino De Laurentiis, Istituto Nazionale Tumori "Fondazione G.Pascale-IRCCS, Naples, Italy*

Background: Real-world evidence is important as it complements data from randomized controlled trialse report updated results from CompLEEment-1, a Phase IIIb trial evaluating RIB+LET in an expanded population, the largest CDK4/6i trial in ABC to date. **Methods:** Patients (pts) with HR+, HER2– ABC, ≤ 1 line of prior CT and no prior ET for ABC received RIB+LET. Study design has been reported previously (De Laurentiis, et al. ASCO 2019). Primary endpoints were safety and tolerability. **Results:** 3,246 pts received ≥ 1 dose of study treatment. Median duration of follow-up was 25.4 months (mos) (15 additional mos since interim analysis [De Laurentiis, et al. ABC5 2019]). Median treatment exposure was 17.8 mos. Baseline characteristics indicated a diverse population, including men (1.2%), premenopausal women (22.2%), and pts aged ≥ 70 years (19.5%); 112 (3.5%) pts had an ECOG PS of 2, 194 (6.0%) pts received prior CT for ABC, and 51 (1.6%) pts had stable CNS lesions. The most common adverse events (AEs) were neutropenia (61.1%), nausea (35.9%), and fatigue (23.4%). Grade 3/4 hematologic abnormalities (> 5.0 %) were decreased neutrophils (54.8%), leukocytes (25.9%), and lymphocytes (12.6%). Grade 3/4 biochemical abnormalities (> 5.0 %) were increased ALT (9.1%) and AST (6.7%). An increase of > 60 ms in QTcF interval from baseline occurred in 189 (5.9%) pts, while post-baseline QTcF of > 480 to ≤ 500 ms and > 500 ms occurred in 59 (1.8%) and 42 (1.3%) pts, respectively. Treatment-related AEs led to treatment discontinuation in 418 (12.9%) pts. Of 74 (2.3%) on treatment deaths, 38 (1.2%) were due to breast cancer. Median time to progression was 27.1 mos (95% CI, 25.7-NE), overall response rate was 43.6% (95% CI, 41.5-45.8%), and clinical benefit rate was 69.1% (95% CI, 67.1-71.1%) for pts with measurable disease at baseline. **Conclusions:** This analysis confirms the safety and efficacy of RIB+LET in a large, diverse cohort of pts with HR+, HER2– ABC (with no previous ET for ABC), closely resembling real-world clinical practice. Safety and efficacy data were consistent with those observed in the MONALEESA trials, supporting the use of RIB+LET in the first-line setting. NCT02941926. Clinical trial information: NCT02941926. 1056 Poster Session (Board #141), Fri, 8:00 AM-11:00 AM

The efficacy of first-line chemotherapy in endocrine-resistant hormone receptor-positive (HR+), human epidermal growth factor receptor 2- negative (HER2-) metastatic breast cancer (MBC). *First Author: Sudpreeda Chainitikun, Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Combinations of endocrine therapy (ET) and targeted therapy (CDK4/6 or mTOR inhibitors) are standard of care for HR+/HER2- MBC. When ET is not effective, chemotherapy is commonly used. However, clinical outcomes of chemotherapy in the endocrine-resistant setting are limited. We hypothesized that clinicopathological baseline and prior ET factors determine chemotherapy's efficacy. We sought to identify predictive factors and the compare efficacies of chemotherapy agents in endocrine-resistant MBC. **Methods:** We conducted a retrospective study of patients with HR+/HER2- MBC who received chemotherapy after progression on ET with or without targeted therapy at MD Anderson Cancer Center from 1999-2017. We collected baseline clinicopathological and all treatment data. The primary endpoint was time to treatment failure (TTF) of first-line chemotherapy for MBC. We performed univariate and multivariate analyses using the Cox proportional hazard model. Kaplan-Meier methods were used to analyze TTF. **Results:** In the 1,258 patients analyzed, the mean age was 55.3 years (range 21-91). Forty-five patients (3.6%) had inflammatory breast cancer (IBC). Three hundred ninety patients (31%) received previous targeted therapy: 264 with CDK4/6 inhibitor, 205 with mTOR inhibitor, and 79 with both. The most frequent chemotherapy agents were capecitabine (48.9%) and taxanes (paclitaxel, nab-paclitaxel, or docetaxel; 28.6%). After adjustment for all factors in a multivariate model, IBC and prior exposure to a CDK4/6 inhibitor were significantly associated with shorter TTF. Previous treatment with a CDK4/6 inhibitor had the strongest negative effect on chemotherapy TTF regardless of ET duration (adjusted hazard ratio [HR] 1.84; 95%CI 1.49-2.27; $p < 0.001$). Capecitabine had significantly longer median TTF than taxanes regardless of whether patients had prior exposure to taxanes in (neo) adjuvant setting (6.1 vs 4.9 months; HR 0.64; 95%CI 0.55-0.75; $p < 0.001$). Conversely, the median TTF for taxanes was shorter in patients who received prior (neo)adjuvant taxanes than in those who did not (4.5 vs 5.1 months). **Conclusions:** Previous exposure to CDK4/6 inhibitor had a negative predictive effect for the efficacy of chemotherapy. Capecitabine had the best efficacy against endocrine-resistant breast cancer. Research Sponsor: Morgan Welch Inflammatory Breast Cancer Research Program.

1057 Poster Session (Board #142), Fri, 8:00 AM-11:00 AM

Integration of the stem cell biology-based genomic tool, StemPrintER, with clinicopathological parameters for the prediction of distant recurrence in ER+/HER2- breast cancer (BC) patients. *First Author: Salvatore Pece, European Institute of Oncology, Milan, Italy*

Background: The StemPrintER risk score (SPRS) is a 20 gene-based predictor that estimates the "degree of stemness" of the primary tumor and provides additional prognostic information regarding distant metastasis (DM) risk in early stage ER+/HER2- breast cancer (BC) patients beyond that obtained from standard clinicopathological parameters. Here we describe a further refined model, that combines prognostic information from SPRS with tumor size (pT) and nodal status (pN), termed SPARE (SPRS for Personalized Adjuvant therapy in Receptor-Expressing patients). SPARE was compared to the clinical treatment score (CTS) for 10-year risk of DM in a consecutive-retrospective ER+/HER2- BC patient cohort (n=1,827) with 15-year complete follow-up from the European Institute of Oncology (IEO) in Milan. **Methods:** The SPARE model was developed in patients randomly assigned to a training set (n=609), using the ridge-penalized Cox regression, and tested in an independent validation set (n=1,218). Likelihood χ^2 ($LR\chi^2$) and Kaplan-Meier survival analysis were used to compare the prognostic information from SPARE and CTS (based on age, pN, pT, endocrine treatment). Comparative analyses were made for the DM risk over the 10-year follow-up, as well as in the early (0-5 years) or late (5-10 years) interval, according to nodal status. **Results:** SPARE outperformed CTS in providing prognostic information for 10-year DM risk ($LR\chi^2$: SPARE = 141.2, $P<0.0001$; CTS=118.1, $P<0.0001$), with even greater differences in node-negative patients ($LR\chi^2$: SPARE=47.6, $P<0.0001$; CTS=27.5, $P<0.0001$) and in 1-3 node-positive patients ($LR\chi^2$: SPARE=30.6, $P<0.0001$; CTS=15.1, $P<0.0001$). When reciprocally adjusted for each other, SPARE added prognostic information to CTS ($\Delta LR\chi^2$: CTS+SPARE *vs.* CTS = 25.2; $P<0.0001$), while CTS did not provide any statistically significant information to SPARE (SPARE+CTS *vs.* SPARE = 2.1, $P=0.14$). Using predefined cut-offs to stratify chemo-naïve patients clinically estimated at low recurrence risk, SPARE identified low, intermediate and high risk patients based on their annual rate of DM in the early (low, 0.2%, intermediate, 0.8%, high, 3.3%) and late (low, 0.3%, intermediate, 0.9%, high, 1.6%) interval. **Conclusions:** SPARE represents a more refined clinical tool, compared to standard clinicopathological parameters, that could be used for personalized therapeutic decision making in ER+/HER2- BC patients. Research Sponsor: Italian Association for Cancer Research (AIRC).

1059 Poster Session (Board #144), Fri, 8:00 AM-11:00 AM

Cell-free DNA comparative analysis of hormone receptor-positive, first-line metastatic breast cancer genomic landscape in the United States and China. *First Author: Huiping Li, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Breast Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Metastatic breast cancer (MBC) is a heterogeneous disease associated with known somatic mutations of variable biological value in different subtypes. Furthermore, the clinical evolution of the disease demonstrates clonal evolution resulting in disease resistance more accurately detected using blood-based sequencing. Few studies have explored differences in genomic features of tumors across populations. Here, we performed circulating tumor DNA (ctDNA) sequencing to compare the genomic landscape of patients with hormone-receptor positive MBC at time of first recurrence or *de-novo* metastatic diagnosis in the United States (US) and China. **Methods:** Twenty-three US patients from Northwestern University and 65 Chinese patients from Peking University had ctDNA sequencing from plasma performed using the harmonized CLIA-certified, 152-gene PredicineCARE assay in laboratories in the US and China, respectively. The data analysis was conducted in China. Institutional Review Boards at each site approved the study. Fisher's exact test was performed to compare mutational frequencies across populations. **Results:** Median age of patients at MBC diagnosis was 51 in the US cohort and 55 in the Chinese cohort. 87% of US patients and 82% of Chinese patients had received prior therapy for primary breast cancer, including endocrine therapy. Mutations were detected in 17 of 23 (74%) US patients and 59 of 65 (91%) Chinese patients. CNAs were observed in 57% of US patients and 58% of Chinese patients. The most common mutations detected in US patients were *TP53* (26%), *PIK3CA* (22%), *AKT1* (22%), *CDH1* (17%), *PTEN* (13%), and *ESR1* (9%) vs. *PIK3CA* (46%), *TP53* (35%), *ESR1* (12%), and *BRCA2* (11%) in Chinese patients. Frequency of *AKT1* and *CDH1* mutations were significantly higher in the US population ($P < 0.05$), while *PIK3CA* mutations were higher in the Chinese population ($P < 0.05$). CNA gains in CCND3 and CDK4 were significantly higher in the US cohort, and FGFR1 was significantly more common in the Chinese cohort (all $P < 0.05$). **Conclusions:** To our knowledge, this is a first cross-regional comparison study in HR+ MBC patients in the US and China using a harmonized cfDNA NGS platform. At a population level, there were notable differences observed in somatic variants in two cohorts. Future sequencing efforts and clinical trials should include patients of diverse ethnic backgrounds to explore the impact of differences in genomic landscape on probability of benefit from treatments. A larger validation cohort is required to confirm these findings. Research Sponsor: National Natural Science Foundation of China.

1060 Poster Session (Board #145), Fri, 8:00 AM-11:00 AM

Meta-analysis of cyclin-dependent kinase (CDK) 4/6 inhibitors with endocrine therapy versus endocrine therapy alone on progression-free survival (PFS) and overall survival (OS) for metastatic breast cancer (MBC). *First Author: Ranju Kunwor, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: CDK 4/6 inhibitors with Endocrine therapy (ET) are the preferred first line treatment for Hormone Receptor positive and Human Epidermal Growth factor receptor 2 negative (HR+/HER2-) MBC. Over the last few years multiple trials have shown benefit in PFS. Only two studies evaluating Ribociclib and Abemaciclib showed an OS benefit while no statistically significant OS benefit has been reported in any of the studies evaluating Palbociclib raising the possibility that this benefit may be drug specific rather than applicable to all CDK 4/6 Inhibitors. This updated meta-analysis of randomized controlled trials (RCTs) aims to assess the PFS and OS of all three CDK 4/6 inhibitors in HR+/HER2- MBC. **Methods:** We performed a systematic search for RCTs using Cochrane Library, PubMed, Embase, and Web of Science. Only the phase II and III RCTs comparing CKD 4/6 inhibitors plus ET with ET alone were eligible for this meta-analysis. The pooled analysis of Hazard Ratio (HR) was performed with Review Manager 5.3 using random effect model. **Results:** A total of 8 RCTs including 4338 patients with HR+/HER2- MBC were included in this meta-analysis (table). The pooled HR for PFS was 0.55 (95% confidence interval (CI), 0.50-0.59; $P < .00001$) and the pooled HR for OS was 0.75 (95% CI, 0.68-0.84; $P < .00001$). **Conclusions:** The result of our meta-analysis confirms the previously reported PFS benefit from CDK 4/6 inhibitors plus ET and shows an OS benefit when including RCTs of all 3 CDK 4/6 inhibitors for the treatment of HR+/HER2- MBC. Research Sponsor: None.

List of included RCTs.

1061 Poster Session (Board #146), Fri, 8:00 AM-11:00 AM

MONARCH 2: Subgroup analysis of patients receiving abemaciclib + fulvestrant as first- and second-line therapy for HR+, HER2- advanced breast cancer. *First Author: Patrick Neven, Hospital Gasthuisberg, Leuven, Belgium*

Background: In MONARCH 2 (M2), abemaciclib (A), an oral selective cyclin dependent kinase 4 & 6 inhibitor, + fulvestrant (F) demonstrated statistically significant improvements in progression-free survival (PFS) and overall survival (OS) compared to placebo (P) + F in hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) advanced breast cancer (ABC). Numerically more pronounced PFS & OS improvement was noted in subgroups (Sub) with visceral (V) disease and primary endocrine resistance. Here we report efficacy data for M2 with respect to 1L and 2L Sub (last line of endocrine therapy [ET] in (neo)adjuvant and metastatic setting, respectively). **Methods:** M2 (NCT02107703) was a global, randomized, double-blind Phase 3 trial of A+ F (N = 446) or P + F (N = 223) in women with ET resistant (ETR) HR+, HER2- ABC regardless of menopausal status. Patients (pts) were stratified by site of metastasis (V, bone-only, or other) and resistance to prior ET (primary vs secondary). Exploratory Sub analyses of PFS and OS were conducted among pts in the ITT population with 1L vs 2L. Hazard ratios (HR) were estimated using Cox models with a test of interactions of Sub with treatment performed. **Results:** At data cut-off (June 20th, 2019), the effect of A + F vs P + F was consistent across 1L (N = 265/133) and 2L (N = 170/86) Sub, with no statistically significant interaction for PFS (p = 0.341) or OS (p = 0.265). For 1L pts, improvements in PFS (HR: 0.57; 95% CI:0.45, 0.73) and OS (HR: 0.85; 95% CI:0.64, 1.14) were observed. Similar efficacy results were observed for 2L pts (PFS: HR: 0.48; [95% CI: 0.36, 0.64]; OS HR: 0.66 [95% CI: 0.46, 0.94]). The numerically largest effects in the 1L population were noted in pts with less favorable prognostic factors such as primary ETR (PFS: HR 0.40 [95% CI: 0.26, 0.63]; OS: HR 0.58 [95% CI:0.35, 0.97]) and V disease (PFS: HR 0.54 [95% CI: 0.39, 0.73]; OS: HR 0.82 [95% CI: 0.57, 1.17]). **Conclusions:** The statistically significant benefit observed in the M2 study was observed across 1L and 2L patients. In 1L patients (A+F Arm), improvements were observed for PFS and OS with the most pronounced effects noted in patients with less favorable prognostic factors. Clinical trial information: NCT02107703. Research Sponsor: Eli Lilly and Company.

1062 Poster Session (Board #147), Fri, 8:00 AM-11:00 AM

A phase II trial of cabozantinib in hormone receptor-positive breast cancer with bone metastases. *First Author: Jing Xu, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: We assessed the antitumor activity of cabozantinib, a potent multireceptor oral tyrosine kinase inhibitor with activity against MET, RET, VEGFR2, and AXL, in patients with hormone-receptor positive (HR+) breast cancer with bone metastases. **Methods:** In this single-arm multicenter phase II study, patients with HR+, HER2- metastatic breast cancer and ≥ 1 prior line of therapy received an initial starting dose of 100 mg cabozantinib, later reduced to 60 mg per day. The primary endpoint was bone scan response rate determined by independent central review and defined as percent change of bone scan area from baseline. The target bone scan response rate was 30% compared to a null response rate of 10%. Secondary endpoints included objective response rate (ORR) by RECIST v1.1, progression free (PFS) and overall survival (OS). Bone scan and CT were obtained every 12 weeks. **Results:** Among 52 enrolled patients, median age was 55, and 54% and 42% had > 2 lines prior endocrine and chemotherapy, respectively and 18 (35%) had bone-only disease. 20 (38%) experienced a partial bone scan response and 6 (12%) had stable disease (SD). 16 (31%) patients discontinued study prior to week 12 assessment for early clinical progression or toxicity, and three (6%) had missing follow-up scans. Best extra-osseous overall response revealed SD in 26 (50%), but no objective responses. In 25 patients with bone scan disease control at 12 weeks, only 3 (12%) developed extra-osseous progression. Median PFS was 4.3 months (90% CI 2.8 - 5.5) and OS was 19.6 months (90% CI 18.0 – 26.8). In a landmark analysis, patients with bone scan disease control at 12 weeks had longer OS (median 24.2 months, 90% CI 16.4 – 31.7) than those without (median OS 13.3 months, 90% CI 9.5 – 18.2), with a hazard ratio of 0.37 (90% CI 0.21 – 0.65). Most common grade 3 or 4 toxicities were hypertension (10%), anorexia (6%), diarrhea (6%), fatigue (4%) and hypophosphatemia (4%). Dose reduction or delay occurred in 42 (81%) patients. **Conclusions:** This study met its primary endpoint with bone scans improved in 38% of patients with metastatic HR+ breast cancer and remained stable in an additional 12% with cabozantinib treatment. Bone scan response correlated with improved OS. This is the first reported study in breast cancer to use bone scan response as a primary endpoint. Further studies with cabozantinib in HR+ breast cancer and additional validation of bone scan response as a surrogate for clinical benefit in breast cancer are warranted. Clinical trial information: NCT01441947. Research Sponsor: Exelixis, Inc, Conquer Cancer Foundation of the American Society of Clinical Oncology.

1063 Poster Session (Board #148), Fri, 8:00 AM-11:00 AM

Prevalence and characterization of dermatologic adverse events related to alpelisib (BYL719) in breast cancer patients. *First Author: Dulce M. Barrios M.S, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Rash develops in approximately 50% of breast cancer patients receiving alpelisib, often requiring dose modifications. Herein, we describe the characteristics of alpelisib-related dermatologic adverse events (dAEs). **Methods:** A single center retrospective analysis was conducted via review of electronic medical records. We collected clinical, laboratory and management data relevant to patients treated with alpelisib for advanced breast cancer under four different randomized clinical trials or post approval by regulatory agencies from 6/1/2013 to 7/31/2019. Type and severity of dAEs was recorded using the Common Terminology Criteria for Adverse Events version 5.0 (CTCAE v5.0). **Results:** A total of 102 patients (mean age 56 years, range 27-83) receiving alpelisib from 200 to 350 mg daily, most frequently in combination with endocrine therapy (79, 77.5%) were included. We identified 41 (40.2%) patients with all-grade rash [CTCAE grade 1/2 = 22 (21.6%); CTCAE grade 3 = 19, (18.6%)] distributed primarily along the trunk (18, 78%) and developing, on average, within 12.8 +/- 1.5 days of treatment initiation (n = 38). Mean duration of rash was 7.1 +/- 3.8 days; and no grade 4 dAEs were observed. Of 29 patients with documented morphology of alpelisib-related dAEs, the majority (26, 89.7%) had maculopapular rash. Thirteen (68%) of 19 patients with any-grade rash and report of any associated symptoms had pruritus (7, 36%) or burning pain (6, 32%). All-grade dAEs correlated with an increase in serum eosinophils from 2.7% to 4.4% ($p < 0.05$), and prophylaxis with non-sedating antihistamines (n = 43) was correlated with a reduction of grade 1/2 rash onset (OR 0.39, p = 0.09). Sixteen (84.2%) of 19 patients with grade 3 dAEs had interruption of alpelisib, followed by management with antihistamines, topical and/or systemic corticosteroids. We did not observe rash recurrence in 12 (75%) of these 16 patients who re-initiated therapy; and the majority (9, 56.3%) were re-challenged *without* a dose reduction. **Conclusions:** Pruritus and increased blood eosinophils occur with maculopapular rash within the first two weeks of initiating alpelisib and persists for approximately seven days. To reduce onset of grade 1/2 rash, non-sedating antihistamines (i.e. cetirizine) are recommended during the first eight weeks. While grade 3 rash leads to interruption of alpelisib, dermatologic improvement is evident with systemic corticosteroids; and most patients can resume therapy at a maintained or reduced dose upon re-challenge. Research Sponsor: U.S. National Institutes of Health.

1064 Poster Session (Board #149), Fri, 8:00 AM-11:00 AM

The effect of neutropenia on patient-reported functioning and quality of life (QOL) among palbociclib participants of the MADELINE study. *First Author: David Richardson, RTI Health Solutions, Research Triangle Park, NC*

Background: MADELINE is an observational, multicenter study of women with HR+/HER2- advanced or metastatic breast cancer who were followed for 6 months to evaluate patient reported QOL after initiating palbociclib combination therapy or other approved treatment in the US. A novel mobile application was developed to capture PROs for QOL at daily, weekly, monthly/cycle-based intervals for up to 6 months. QOL measures were evaluated to determine if palbociclib-treated patients experiencing episodes of neutropenia had associated decreases in QOL compared to patients without episodes of neutropenia. **Methods:** Patients completed the SF-12 and CES-D-10 at baseline and each cycle. Change from baseline was assessed using mean scores and mixed-effects models. Daily pain and fatigue severity were measured on an 11-point scale (0-10, 10 being worst possible pain/fatigue) and averaged to create weekly scores. Patients indicated weekly how breast cancer or its treatment interfered with family/social life, productivity, physical activity and energy on a 5-point scales (from not at all to a great deal). Demographic and clinical data including adverse events were recorded in an eCRF. **Results:** 25 sites contributed 139 patients (median [range] age 60 [34, 82]; white: 83%; ECOG 0-1: 87%). During the 6-month follow up period, 45% of patients experienced ≥1 neutropenia event (grade 1-4: 17%, 27%, 24%, 2%) and 11% had an event resulting in a dose change. Least-square (LS) mean change from baseline to end of study for the SF-12 Physical/Mental Component summaries (PCS/MCS) and the CES-D-10 showed no association between neutropenia and decreased QOL. Daily pain/fatigue was relatively stable for those with neutropenia (cycle 1, week 1: 2.8 [1.95] and 1.8 [0.95]; cycle 6, week 1: 2.4 [1.95] and 2.3 [1.59]) and those without (cycle 1, week 1: 2.2 [2.46] and 2.8 [2.39]; cycle 6, week 1: 1.6 [2.29] and 2.4 [2.22]). There was no significant change for impact of breast cancer or treatment across cycles. **Conclusions:** Patients with neutropenia did not experience decreased QOL compared to patients without neutropenia nor did patients as a whole experience numerically or clinically meaningful decrease in QOL throughout the follow up period. Daily PROs collected suggest a low level of pain/fatigue that did not change substantially over time. Research Sponsor: Pfizer, Inc.

1065 Poster Session (Board #150), Fri, 8:00 AM-11:00 AM

Combination of fulvestrant and chemotherapy in ESR1 Y537S mutant breast cancer cells and potential synergy mechanism related to p53 wildtype. *First Author: Wen Ma, Dana-Farber Cancer Institute, Boston, MA*

Background: The acquisition of ligand-independent ESR1 mutations during endocrine therapy in metastatic ER+ breast cancer is a common mechanism of resistance to endocrine treatment, particularly aromatase inhibitors, and found in more than 30% of patients with metastatic ER+ breast cancer. Our recent work showed that the ER mutations confer resistance to currently available endocrine treatments while promoting an aberrant ER transcriptional activity that drives metastases. These results underscore the importance of targeting the ESR1 mutations even after the development of endocrine resistance. We hypothesized that during chemotherapy treatment, the ESR1 mutations remain an important driver of tumor growth and metastases and therefore drugs targeting the ESR1 mutation could enhance the efficacy of chemotherapy. In this study we investigated the combination of chemotherapy with the selective estrogen receptor degrader in the presence of WT and mutant ER. **Methods:** We performed synergy studies testing the combination of fulvestrant with chemotherapy treatments commonly used in ER+ metastatic breast cancer including 5FU (representing capecitabine), adriamycin and paclitaxel using MCF7 and T47D breast cancer cell lines engineered to express doxycycline inducible Y537S-ESR1 mutation. **Results:** We found that in MCF7 cells the combination of chemotherapy and fulvestrant was synergistic and the synergy was augmented with the induction of the Y537S mutation. In contrast, there was no synergy in T47D cells that harbor a P53 mutation. We confirmed that the synergistic activity of fulvestrant with chemotherapy is dependent on P53 by generating P53 knock-out MCF7 cells using CRISPR-cas9. Additionally, cell cycle and apoptosis analyses showed that the synergistic activity was mainly due to increased effects on G1 arrest rather than apoptosis. **Conclusions:** Our study indicates that chemotherapy and fulvestrant are synergistic in ER+ breast cancer and the synergy is increased in the presence of the Y537S ESR1 mutation and is dependent on P53 activity. These results support a clinical trial testing the addition of fulvestrant or other novel selective estrogen receptor degraders in patients with metastatic ER+ breast cancer who are starting chemotherapy treatment. Research Sponsor: U.S. National Institutes of Health.

1066 Poster Session (Board #151), Fri, 8:00 AM-11:00 AM

Phase Ib trial to evaluate safety and anti-tumor activity of the AKT inhibitor, ipatasertib, in combination with endocrine therapy and a CDK4/6 inhibitor for patients with hormone receptor positive (HR+)/HER2 negative metastatic breast cancer (MBC) (TAKTIC). *First Author: Seth Andrew Wander, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: The cyclin-dependent kinase 4/6 inhibitors (CDK4/6i), with an anti-estrogen, are the standard of care for HR+/HER2- MBC. Insights from patient biopsies and preclinical analysis suggest that AKT1 activation can provoke CDK4/6i resistance. We hypothesized that targeting AKT1 following CDK4/6i progression may provide clinical benefit. **Methods:** TAKTIC is an open-label phase Ib trial exploring the combination of the AKT1 inhibitor, ipatasertib (ipat), with an aromatase inhibitor (Arm A), fulvestrant (Arm B), or the triplet combination (Arm C) of fulvestrant + ipat + palbociclib (palbo). The primary objective is to evaluate the safety and tolerability of ipat in combination with endocrine therapy +/- CDK4/6i. Key inclusion criteria include unresectable HR+/HER2- MBC; at least 1 prior therapy for MBC including any CDK4/6i; up to 2 prior lines of chemotherapy for MBC (no limit on prior endocrine therapy). Here, we present an interim analysis from the triplet combination (Arm C). **Results:** As of 1/31/2020, 25 pts have enrolled, including 12 on Arm C, all of whom received prior CDK4/6i (median no of prior lines = 5.5, range 2-7). Along with fulvestrant, 3 pts received ipat at 200mg + 125mg palbo, 7 pts received 300mg + 125mg palbo, and 2 pts received 400mg + 100mg palbo. To date, 8/12 pts remain on treatment including 2 with partial response, 3 with stable disease, 3 with restaging studies pending and 4 with progressive disease. The triplet combination was well tolerated. Grade 3 toxicities included reduced WBC (8/12), reduced neutrophil count (11/12), reduced lymphocyte count (2/12) and single instances of transaminitis, rash, and reduced platelet count. The only grade 4 toxicity was reduced neutrophil count (4/12). There were no DLTs observed and no discontinuations due to toxicity. Mean steady state pharmacokinetic parameters for ipat were similar to historical data from single agent trials suggesting that combined treatment with palbo + fulvestrant did not affect the pharmacokinetics of ipat. Updated analysis will be presented at the meeting. **Conclusions:** The triplet combination of endocrine therapy with CDK 4/6i and AKTi appears to be well tolerated in heavily pre-treated pts, with a subset demonstrating signs of clinical benefit. The trial demonstrates how insights into the molecular mechanisms of CDK4/6i resistance could be leveraged into actionable therapeutic regimens for HR+/HER2- MBC. Clinical trial information: NCT03959891. Research Sponsor: Genentech, Inc.

1067 Poster Session (Board #152), Fri, 8:00 AM-11:00 AM

Serum biomarkers of inflammation (ferritin, IL-8, TNFR1) and outcomes in BOLERO-2, a phase III trial of HR+/HER2- metastatic breast cancer treated with everolimus (mTOR inhibitor). *First Author: Suhail M. Ali, Lebanon VAMC, Lebanon, PA*

Background: Everolimus (EVE) plus exemestane (EXE) doubled PFS while maintaining quality of life versus EXE alone in postmenopausal hormone receptor-positive (HR^+), HER2-negative metastatic breast cancer (MBC) (BOLERO-2 phase 3; NCT00863655). Here we investigated several serum biomarkers of inflammation: ferritin, interleukin-8 (IL-8), and tumor necrosis factor receptor 1 (TNFR1). Both higher IL-8 (ASCO 2018, #3025) and TNF (Nature 569:428-32, 2019) have been reported to be associated with worsened outcome to immune checkpoint inhibitors (ICI), and IL-8- and TNF-targeted therapies combined with ICIs are in phase I trials. We evaluated the prognostic/predictive ability of serum ferritin, IL-8, and TNFR1 to everolimus in BOLERO-2. **Methods:** Serum biomarkers were determined on pretreatment serum samples using the ELLA immunoassay platform (ProteinSimple, San Jose, CA). Cox-proportional hazards model was used to assess the efficacy of EVE, and the prognostic and predictive effect on PFS and OS. **Results:** Pretreatment serum biomarker levels were determined in 510 patients (70 %) of 725 BOLERO-2 patients randomized 2:1 to EVE+EXE or EXE). Serum levels (25%, 50%, 75%) were: ferritin (68.9, 125.5, 253.1 ng/ml); IL-8 (14.5, 19.4, 27.7 pg/ml); and TNFR1 (1205, 1470, 1868 pg/ml). Ferritin correlated significantly with TNFR1 ($r=0.45$, $p<0.0001$), while IL-8 correlated weakly with TNFR1 ($r=0.10$, $p=0.023$). Higher levels of all 3 biomarkers were prognostic for significantly shorter PFS and OS (table). But no biomarkers were predictive: everolimus was efficacious regardless of the 3 biomarker levels ($p>0.05$). **Conclusions:** High levels of serum ferritin, IL-8, and TNFR1 were significantly associated with shorter PFS and OS in HR+/HER2- MBC patients. Everolimus had superior outcomes compared to placebo, regardless of serum biomarker level. These 3 significant prognostic biomarkers are all associated with increased inflammatory processes through different pathways. Anti-inflammatory therapy targeted against these biomarkers should be evaluated based on serum level as potential combination therapy with everolimus or CDK 4/6 inhibitors in HR+ MBC. Research Sponsor: Novartis.

1068 Poster Session (Board #153), Fri, 8:00 AM-11:00 AM

Pazopanib (PZ) plus endocrine therapy as treatment for hormone resistant advanced breast cancer (ABC). *First Author: Ozge Gumusay, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, CA*

Background: A major limitation of endocrine therapy in hormone receptor positive (HR+) ABC is the development of resistance. Preclinical data suggests that higher levels of vascular endothelial growth factor (VEGF) are associated with endocrine therapy resistance. We conducted a phase II trial to evaluate the clinical benefit (CB) of PZ, a VEGF receptor tyrosine kinase inhibitor (TKI) combined with nonsteroidal aromatase inhibitors (NSAIs) in pts with ABC resistant to NSAIs. **Methods:** Eligibility included postmenopausal women with HR+ ABC and progressive disease (PD) after at least one month of NSAIs. Treatment was PZ 800 mg/day plus either letrozole or anastrozole. The primary endpoint was clinical benefit rate at 12 weeks (CBR12, wks). Secondary endpoints were PFS and safety. A CBR of 20% was considered a clinically meaningful comparison to the expected CBR of $< 5\%$ with continued NSAIs after PD. Using a 2-stage design, stable disease in at least 1 of the first 13 pts allowed continued enrollment to a planned 28. **Results:** 32 pts were enrolled; 28 are evaluable for study endpoints and all patients completed the study. The median age was 58 years (range: 41-77). Pts were heavily pre-treated, with a median of 2 prior hormone therapies (range 1-6) and 1 prior chemotherapy (range 0-8). 8 pts (28.6%) stopped treatment due to adverse events (AE) including hypertension (HTN), fever, transaminitis, nausea, vomiting, rash, hand foot syndrome and pulmonary embolism (PE); 6 pts progressed before wk 12. CBR12 was 46.4% (12 SD, 1 PR); CBR24 was 25% (5 SD, 2 PR). Median PFS was 20 wks (95% CI 11-48, and median PFS for pts with CBR12 was 24 wks. 7 pts had PFS $>$ 6 months (24, 32, 36, 36, 48, 184 and 274 wks); 2 pts had PFS $>$ 3 years (184 and 274 weeks). The most common grade 1/2 AE were nausea (48.2%), fatigue (33.3%), diarrhea (29.6%), back pain (22.2%), and arthralgias (22.2%). Grade 3/4 AEs included HTN (3/28; 11.1), transaminitis (3/28; 11.1%), headache (2/28; 7.4), heart failure, vertigo, nausea, oral pain, vomiting, fever, fatigue, and hypokalemia (one patient each: 3.7%). **Conclusions:** The addition of PZ to NSAIs resulted in a CBR12 of 46.4%, and a CBR24 of 25% in pts with heavily pre-treated ABC resistant to NSAIs. These results support clinical efficacy of antiangiogenic TKI in HR+ ABC, and suggest benefit in hormone resistant disease. Expected toxicities resulted in early discontinuation in 28.6%, which limited drug exposure. Clinical trial information: NCT 01466972. Research Sponsor: GSK/Novartis.

1069 Poster Session (Board #154), Fri, 8:00 AM-11:00 AM

***PIK3CA* mutation status and progression-free survival in advanced hormone receptor positive (HR+)/ human endocrine receptor negative (HER2–) metastatic breast cancer (mBC): A meta-analysis of published clinical trials.** *First Author: James Signorovitch, Analysis Group, Inc., Boston, MA*

Background: Approximately 40% of HR+/HER2- mBC patients harbor *PIK3CA* mutation. Associations between *PIK3CA* mutation status and clinical outcomes among patients with HR+/HER2- mBC have been heterogeneous across clinical trials. We synthesized available evidence from clinical trials to estimate the association between *PIK3CA* status and progression-free survival (PFS) using a meta-analysis adjusting for study design differences. **Methods:** Randomized clinical trials reporting PFS stratified by *PIK3CA* status in HR+/HER2- mBC were identified via a systematic literature review. Trial arms receiving *PIK3CA* targeted therapies were excluded. Median PFS, 6-, 12- and 18-month PFS rates, and data on trial design features were extracted. Associations between *PIK3CA* status and PFS were estimated adjusting for study follow-up duration, *PIK3CA* testing method (ctDNA vs tissue) and study treatment using multi-level random effects meta-regression. **Results:** The analyzed data included 3,238 patients from 33 study arms across 11 trials (*PIK3CA* mutated (MT): 1,386, wild type (WT): 1,852). *PIK3CA* mutation was overall associated with shorter median PFS (difference [95% CI] (months): -2.15 [-4.14, -0.15]) with substantial heterogeneity across studies ($I^2 = 98.34\%$). The direction of this association was robust to adjustment for study treatment (-1.27 [-2.22, -0.32]). The association was stronger for ctDNA testing (-2.16 [-3.65, -0.66]; N (total patients): 1,876) than for tissue testing (-0.65 [-2.2, 0.91]; N: 998). Findings were similar for 6-month PFS rates (absolute rate difference -9.17% [-14.22, -4.12], N: 3,179; MT: 1,366, WT: 1,813). Associations were directionally consistent but not statistically significant at 12 months (N = 2,487; MT: 1,056, WT: 1,431) and 18 months (N = 1,745; MT: 811, WT: 934), potentially due to the decreasing precision towards the tails of the PFS curves and significant heterogeneity across studies. **Conclusions:** Pooling evidence across multiple studies, *PIK3CA* mutation was associated with shorter PFS, especially when ctDNA testing was used. These findings suggest a negative prognostic value of *PIK3CA* mutation in patients with HR+/HER2- mBC. Research Sponsor: Novartis.

1070 Poster Session (Board #155), Fri, 8:00 AM-11:00 AM

Phase I/II study of SAR439859, an oral selective estrogen receptor degrader (SERD), in estrogen receptor-positive (ER+)/human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (mBC). *First Author: Mario Campone, Institut de Cancérologie de l'Ouest, René Gauducheau, St Herblain, France*

Background: SERDs competitively antagonize and degrade the ER and can block signaling in ER-dependent tumors resistant to standard endocrine therapy (ET). This study (NCT03284957) investigates SAR439859, a potent oral SERD, in ER+/HER2- mBC. We present pooled dose escalation/expansion (Part A/B) data for SAR439859. **Methods:** Postmenopausal patients (pts) with ER+/HER2- mBC treated for ≥ 6 mos with prior ET received SAR439859 ≥ 150 mg QD (Part A) or 400 mg QD (Part B). Chemotherapy and targeted therapy in the advanced setting were allowed. Objective response rate (ORR; RECIST v1.1), clinical benefit rate (CBR; complete or partial response [PR] or stable disease [SD] ≥ 24 weeks), safety, and pharmacokinetics (PK) were assessed. **Results:** Pts (n = 62; Part A, 13; Part B, 49) had a median age of 63 yrs (range 37–88) and ECOG PS 0 (59.7%) or 1 (40.3%); 93.5% had visceral disease. All had prior ET, 74.2% had prior targeted therapy and 48.4% had ≥ 3 prior lines in the advanced setting. 61.3% of pts had treatment-related adverse events (TRAEs), all grade 1–2. Most frequent: hot flush (16.1%), constipation, arthralgia (both 9.7%), decreased appetite, vomiting, diarrhea, nausea (all 8.1%), fatigue (6.5%). No pts discontinued due to AEs. CBR was 35.6% overall, with antitumor activity irrespective of *ESR1* mutation status (Table). In pts with no prior SERD, CDK4/6 or mTOR inhibitors (n = 14), ORR was 21.4% and CBR 64.3%. PK data for Part B and *ESR1* mutation data will be provided. **Conclusions:** SAR439859 had a favorable safety profile with limited TRAEs. In these heavily pre-treated pts (prior targeted therapy in 74.2%), ORR and CBR were similar to historical fulvestrant performance in pts with no prior targeted therapy. Encouraging ORR and CBR in pts with no prior SERD, CDK4/6 or mTOR inhibitors (n = 14; ORR 21.4%; CBR 64.3%) supports SAR439859 development in earlier lines of therapy. Clinical trial information: NCT03284957. Research Sponsor: Sanofi.

1071 Poster Session (Board #156), Fri, 8:00 AM-11:00 AM

A phase II study of rh-endostatin in combination with chemotherapy in human epidermal growth factor receptor 2 (HER-2) negative advanced breast cancer (ABC). *First Author: Yuan Huang, Institute of Cancer and Basic Medicine (ICBM), Chinese Academy of Sciences, Department of Breast Medical Oncology, Cancer Hospital of the University of Chinese Academy of Sciences, Department of Breast Medical Oncology, Zhejiang Cancer Hospital, Hangzhou, China*

Background: There is an urgent need to improve the efficacy of chemotherapy for HER-2 negative patients (pts) who lack anti-HER-2 therapies. Rh-Endostatin (endostar), a recombinant human endostatin, is a potent inhibitor of angiogenesis. This single-arm multicenter phase 2 study was designed to assess the efficacy and safety of endostar combined with chemotherapy in HER-2 negative ABC. **Methods:** Eligible pts had HER-2 negative inoperable locoregionally recurrent or metastatic breast cancer and an ECOG PS of 0 or 1. Pts with either measurable or nonmeasurable disease were eligible. Endostar (15 mg/m^2, continuous infusion, day 1-7) plus chemotherapy were administered every 21 days until disease progression, intolerable toxicity or other reasons. Chemotherapy regimens were selected by investigators based on clinical decision. Primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR) and adverse events (AEs). **Results:** From August 2016 to December 2019, 40 female pts were enrolled in 3 centers. The median age was 52. Ten pts were previously untreated and 30 pts had at least 1 line of chemotherapy for advanced disease. 31 pts were triple negative BC (TNBC) and 9 pts were hormonal receptor positive (HR+). Platinum combined with paclitaxel or gemcitabine were administered with endostar in 55% of pts. Others received paclitaxel or gemcitabine combined with endostar. 12 pts achieved a best response of partial response (PR) and 13 pts had stable disease (SD). Among 30 pts with measurable disease, ORR was 40% and DCR was 83%. The ORR for patients treated as the first-line therapy was 75% while as the second line or beyond was 27%. For TNBC and HR+ BC pts, the ORR was 46% and 17% respectively. Median PFS was not reached after a median follow-up of 7.6 months. The most common Grade 3/4 AEs observed during this study were neutropenia (10%), leukopenia (10%) and thrombocytopenia (5%). **Conclusions:** Endostar combined with chemotherapy was effective and well tolerated for the treatment of HER-2 negative ABC, especially TNBC. Its efficacy and safety could be further studied in randomized trials. Clinical trial information: NCT03907098. Research Sponsor: Simcere.

1072 Poster Session (Board #157), Fri, 8:00 AM-11:00 AM

Preliminary safety and efficacy of GX-I7, a long-acting interleukin-7, in combination with pembrolizumab in patients with refractory or recurrent metastatic triple negative breast cancer (mTNBC): Dose escalation period of Phase Ib/II study (KEYNOTE-899). *First Author: Joohyuk Sohn, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Pembrolizumab monotherapy did not significantly improve OS as 2nd and 3rd-lines treatment for mTNBC compared to standard chemotherapy in phase III study (KEYNOTE-119) leading to high unmet needs of effective treatment. Recent studies showed that higher lymphocyte count is an independent factor which correlates with better response to checkpoint blockade in cancer patients. GX-I7, a long-acting interleukin-7, could potentially provide synergistic anti-tumor efficacy with pembrolizumab by increasing number of T cells both in tumor microenvironment (TME) and peripheral blood (PB). **Methods:** This is an open-label, phase Ib/II study in patients with refractory or recurrent TNBC who failed from standard chemotherapy in the metastatic setting, with ≤3rd-lines of previous chemotherapy. The dose escalation phase adopted the 3+3 design. The GX-I7 doses were administered IM q9w or q12w, with or without cyclophosphamide pre-conditioning depending on the allocation, and in combination with pembrolizumab 200 mg IV q3w. The objectives were dose limiting toxicities (DLTs), safety, pharmacodynamic markers including lymphocyte increase and RP2D. **Results:** As of January 30, 2020, GX-I7 and pembrolizumab were exposed to 24 patients (median age 46.0 years [29-75], ECOG PS 1 [58.3%], median cycle no. 3 [1-9]). Treatment was discontinued in 13 (54.2%), majority due to PD and 11 patients are ongoing. No DLTs were reported in all dose groups. Treatment related AEs occurred in 91.7% of patients with grade 1-2 and 9.1% with grade 3 (no grade 4). Common AEs were injection site reaction (39.0%) and fever (13.0%), which were easily managed. Grade 3 toxicity were AST/ALT elevation and infusion related reaction, reported from 1 patient each (4.2%). GX-I7 induced dose-dependent lymphocyte proliferation in PB, with approximately 4-folds increase in high doses. 17 patients were evaluable; confirmed objective responses from ongoing patients included one partial response (5.9%), 2 stable disease (11.8%) and 1 durable unconfirmed PD (5.9%). **Conclusions:** GX-I7 in combination with pembrolizumab was well tolerated, with no DLTs reported. There was no apparent increase of immune-related AEs with the addition of GX-I7. Pharmacodynamics data support proof of mechanism and it warrants further clinical studies. Clinical trial information: NCT03752723. Research Sponsor: Korea Drug Development Fund, Pharmaceutical/Biotech Company.

1073 Poster Session (Board #158), Fri, 8:00 AM-11:00 AM

Dual anti-CTLA-4 and anti-PD-1 blockade in metaplastic carcinoma of the breast: Dart (SWOG S1609, Cohort 36). *First Author: Sylvia Adams, New York University Cancer Institute, New York, NY*

Background: Immune checkpoint blockade, specifically anti-CTLA-4 and anti-PD-1-directed approaches, has improved outcomes in various tumors and is being tested in SWOG S1609 in rare solid tumors (DART=Dual Anti-CTLA-4 & Anti-PD-1 blockade in Rare Tumors). Metaplastic breast cancer (MpBC) is a rare subtype of breast cancer with poor response to cytotoxics and median survival of < 1 year for metastatic disease. A MpBC stratum was added based on promising activity of immunotherapy in a patient with MpBC (Adams, npj Breast Cancer 2017). Here, we report the MpBC cohort of S1609 DART. **Methods:** In this prospective, open-label, multicenter phase II trial patients received ipilimumab (1mg/kg q6 weeks) plus nivolumab (240mg intravenously every 2 weeks). Eligibility for cohort 36 required histologically confirmed MpBC, measurable disease, and ECOG PS 0-2. Prior anti-CTLA4 or anti-PD-1/PD-L1 treatment (but not both) was permitted as well as treated brain metastases. The primary endpoint was overall response rate (ORR, confirmed CR, PR) by RECIST v1.1; 2 or more responses in 16 patients was considered a success. Secondary endpoints: toxicity (CTCAE v4.0), PFS and ORR by immune-related RECIST (iRECIST), overall survival (OS). Biomarker analyses are ongoing. **Results:** Nineteen patients were registered to the cohort and seventeen eligible patients received therapy. The median age was 60 (range 26-85), most tumors were high grade, triple negative and had a high ki67 (median 87%), median prior therapy = 2 lines. The ORR was 12% (RECIST 1.1) and 18% (iRECIST), with ongoing responses at 23, 18 and 11 months, respectively; SD was seen in 24%, none $>$ 6 months (Table). Median OS was 12 months. AEs were observed in 11 patients (65%), with 3 patients (18%) having Grade 3/4 AEs and 1 patient with a fatal AE (myocarditis). The most common toxicities were LFT abnormalities and fatigue. **Conclusions:** Cohort 36 met its primary endpoint: ipilimumab plus nivolumab was clinically active in advanced MpBC, with durable responses observed in 3/17 patients. Further investigation of this combination is warranted. Clinical trial information: NCT02834013. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Metaplastic breast cancer (n=17)	RECIST 1.1	iRECIST

1074 Poster Session (Board #159), Fri, 8:00 AM-11:00 AM

Evaluation of DNA repair biology signatures to predict specific carboplatin (C) versus docetaxel (D) benefit in advanced triple-negative breast cancer (aTNBC). *First Author: Holly Tovey, Clinical Trials and Statistics Unit, The Institute of Cancer Research, London, United Kingdom*

Background: In the Triple Negative Trial we observed no improved response rate (RR) to C over D in aTNBC [Tutt et al, Nat Med 2018], but we did in *BRCA1/2* mutated (mut) patients (pts). We hypothesise tumors with other aberrant DNA damage response (DDR) characteristics having higher RR to DNA damage inducing C than D. **Methods:** We tested the predictive value of DDR process related gene expression signatures (PARPi7, chromosomal instability CIN70, TP53 & DDR Deficiency (DDRD)) on 192 treatment naïve primary tumours (PT) by total RNA-sequencing. Odds ratio (OR) for RR are reported. Paired PT & recurrent (REC) signature scores were compared. **Results:** Unexpectedly, high DDRD and PARPi7 were associated with higher RR to D than C (p =0.01 & 0.06). No effect was observed for CIN70 or *TP53* signature. To assess whether the unexpected results were due to biological changes 12 PT-REC pairs were available from pts who received chemotherapy (CT) between PT & REC. CIN70 increased from PT to REC, DDRD (non-significantly) & PARPi7 decreased. 4/5 *TP53* wildtype classified PT samples classified as mut in REC. The *BRCA1/2* & DDRD-treatment interactions only held in pts who received CT before trial entry (table). The PARPi7-treatment interaction only held in CT naïve pts. In CT naïve pts, high CIN70 tumors suggested higher C RR as hypothesized. Restricted to the 149 PAM50 basal-like pts, results were non-significant but similar trends seen. **Conclusions:** In this trial of aTNBC, DDRD high pts with prior CT had better RR to D than C. A possible explanation for this unexpected result is selective pressure of adjuvant DNA damaging CT and selection for relative taxane sensitivity in those who recur despite a high DDRD score. The hypothesised CIN70 treatment interaction was observed in CT naïve pts. Our results suggest care is required in application of signatures to initial diagnostic material when predicting response to DNA damaging agents at REC particularly in pts with prior CT. Research Sponsor: Cancer Research UK and Breakthrough Breast Cancer.

RNA sequencing analysis and T-cell receptor repertoire in triple-negative breast cancer (TNBC). *First Author: Ju Won Kim, Korea University Anam Hospital, Seoul, South Korea*

Background: Triple negative breast cancer (TNBC) is defined by the lack of two hormone receptors (HR) and human epidermal growth factor receptor 2 (HER2), and well known to have poor prognosis. In this study, we conducted a RNA sequencing including T-cell receptor (TCR) repertoire analysis to develop prognostic biomarker in patients with TNBC. In addition, genes and signaling pathways that correlated with selected biomarker were also investigated. **Methods:** Total of 78 tumor tissues from TNBC patients were participated for RNA-seq (IIlumina Hiseq) analysis. Groups of significant genes were selected by differentially expressed genes (DEGs) analysis, whose expression levels differed more than 1.5 times between patients and normal, or early stage and advanced stage TNBC. Transcript expression levels for prognostic biomarker were analyzed based on R v3.4.3. Using CBS ProbePINGS, a genomic big data analytics platform, we evaluated druggable pathways and protein-protein interaction (PPI). The Interaction Frequency Ratio Score (IFRS) was calculated by investigating highly interactive pathways, and the drugs were matched to patients. TCR repertoire analysis was performed by MiXCR. **Results:** Ten candidate gene signatures were selected based on RNA sequencing data of each sample. Cross-validation through machine learning showed that the accuracy of the first-ranked signature was 92.3%, the second was 92.0%, and the third was 90.3%. The accuracy of 4^{th} to 6^{th} was 88.7%, and the accuracy of 7^{th} to 10^{th} was over 88.0%. Cross-validated gene signature, age, and TNM staging showed significant discriminant power under univariate Cox regression analysis ($p < 0.05$). In the CBS ProbePINGS, human papillomavirus infection, MAPK pathway, and tumorigenesis pathway were correlated with cell signaling. CDK2, FN1, and JUN genes were highly interactive each other. In addition, the drug matching result according to IFRS value suggested imatinib and regorafenib could be possible candidates. TCR repertoire analysis presented that number of clonecount was lower in recurrent or metastatic TNBC than early stage cancer. **Conclusions:** This study revealed a specific gene signatures that can accurately determine recurrence and metastasis in patients with TNBC based on RNA sequencing analysis. TCR repertoire analysis and CBS ProbePINGS could be valuable method in treatment selection Research Sponsor: None.

1076 Poster Session (Board #161), Fri, 8:00 AM-11:00 AM

A phase Ib trial of the cyclin-dependent kinase inhibitor dinaciclib (dina) in combination with pembrolizumab (P) in patients with advanced triple-negative breast cancer (TNBC) and response correlation with MYC-overexpression. *First Author: Amy Jo Chien, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Increased expression of the MYC transcriptional oncogene is found in about 70% of TNBC and is associated with poor prognosis. In MYC-overexpressing TN xenografts, CDK1 inhibition with dina results in synthetic lethality, and attenuates distant metastasis. In syngeneic models, the combination of dina with anti-PD1 therapy is synergistic and increases immune cell tumor infiltration and activation. **Methods:** Patients (pts) with advanced TNBC received dina IV day 1 and 8 in combination with fixed dose P 200 mg once every 21 days. Dina was dose escalated using a toxicity probability interval design targeting a dose limiting toxicity (DLT) rate of 25%. Evaluable disease and pre-treatment metastatic biopsies were required. After 17 pts were enrolled, eligibility was amended to require $\leq$2 lines of prior chemotherapy, and LDH $\leq$1.5x normal. MYC IHC was performed on baseline tumor biopsies and correlated with clinical response using Welch's unequal variances t-test. **Results:** 32 pts were enrolled (median age 53, median 2 prior lines of therapy, 13 pts (41%) had disease which was previously ER+). 18 pts were enrolled in the dose escalation phase with no observed DLTs; 33 mg/m2 was determined to be the recommended phase 2 dose (RP2D). 14 additional patients were enrolled in dose expansion at 33 mg/m2, completing trial accrual. Grade $\geq$3 adverse events (AEs) in all pts included neutropenia (ntp) (37.5%), febrile ntp (12.5%), fatigue (12.5%), transaminitis (3.2%), and neuromuscular weakness (3.2%). Most common all grade AEs included fatigue (63%), diarrhea (63%), nausea (63%), and ntp (53%). Possible immune-related AEs included sinusitis (4 pts), hemolytic anemia (1 pt), pneumonitis (1 pt), rash (2 pts), neuromuscular weakness (1 pt), and transaminitis (1 pt). Of the 29 patients evaluable for response, 1 pt (3.4%) had a CR, 4 pts (13.8%) had a PR, and 6 pts (20.6%) had SD. MYC IHC staining on baseline metastatic tumor biopsies in 19 pts correlated significantly with clinical response. Additional biomarker testing will be reported. **Conclusions:** The RP2D of dina given in combination with standard dose P is 33 mg/m2 on D1, 8 of a 21-day cycle. Toxicities were generally manageable and non-overlapping. In exploratory analysis, greater MYC IHC staining correlated significantly with response to study therapy. Clinical trial information: NCT01676753. Research Sponsor: Merck, U.S. National Institutes of Health.

1077 Poster Session (Board #162), Fri, 8:00 AM-11:00 AM

Preliminary efficacy data of triple-negative breast cancer cohort of NCI 9881 study: A phase II study of cediranib in combination with olaparib in advanced solid tumors. *First Author: Navid Hafez, Yale University School of Medicine, New Haven, CT*

Background: Cediranib, a pan-vascular endothelial growth factor receptor tyrosine kinase inhibitor, suppresses expression of *BRCA1, BRCA2*, and *RAD51* and increases sensitivity of tumors to poly-(ADP-ribose) polymerase (PARP) inhibitors *in vitro*. Olaparib, a PARP inhibitor, demonstrates clinical efficacy in patients with germline *BRCA1/2* mutations and HER2-negative metastatic breast cancer. We therefore tested the anti-tumor activity of the combination of cediranib and olaparib in patients (pts) with metastatic triple-negative breast cancer (TNBC). **Methods:** This multi-institutional, two-stage, phase II study enrolled patients with metastatic TNBC previously treated with a minimum of one prior line of systemic therapy in the advanced setting. Patients were treated with cediranib 30mg po daily plus olaparib 200mg po BID until disease progression or unacceptable toxicity. The primary endpoint was objective response rate by RECIST v1.1. Baseline tumor biopsies were obtained for biomarker analyses. **Results:** Baseline characteristics of the 37pts enrolled are summarized below. The overall objective response rate was 14% (95% CI: 0.025, 0.2453). Median duration of response was 2.0 months (mos) with a range of 1.8 to 6.3 mos. Disease control rate ((# of pts with CR, PR or SD)/(# of evaluable pts)) was 81% (95% CI: 0.6846, 0.937). Median PFS was 3.7 mos (95% CI: 2.1, 4.3). Grade 3/4 adverse events (G3/4 AEs), irrespective of attribution, occurred in 25 of 38 (66%).G3/4 AEs occurring in $>$ 5% of pts were hypertension (24%) and dyspnea (11%), diarrhea (8%) vomiting (8%). **Conclusions:** The cediranib/olaparib combination resulted in promising objective responses in 14% of biomarker-unselected patients with heavily pre-treated, metastatic TNBC. The regimen required prompt initiation of antihypertensives, but AEs were overall manageable. Analyses of mutation status in homologous recombination DNA repair genes are ongoing and will be correlated with clinical outcome. Clinical trial information: NCT02498613. Research Sponsor: U.S. National Institutes of Health.

	Total N = 37, Median (range)
Age	49 (32-68)

1078 Poster Session (Board #163), Fri, 8:00 AM-11:00 AM

Translational relevance of androgen receptor immunohistochemistry scoring systems for data harmonization in triple negative breast cancer (TNBC). *First Author: Suhail Sayeed Mufti, HealthCare Global Enterprises Ltd, Bangalore, India*

Background: Androgen receptor (AR) expressing triple negative breast cancer (TNBC) is a sub-set of TNBC with an evolving prognostic and predictive behaviour. AR immunohistochemical threshold for positivity has not been standardized and a wide range of cut-offs have been used across studies ($>$ 0% to 75%). In this study we explored AR immunohistochemistry thresholds in relation to disease free survival (DFS) and clinical outcomes in non-metastatic TNBC using the Allred and H-Score systems. Increasing interest in AR as a therapeutic target for TNBC and the use of digital tissue image analysis makes it important to standardize AR immunohistochemistry reporting. **Methods:** 100 FFPE (formalin-fixed paraffin-embedded) tumour blocks were retrieved for non-metastatic TNBCs diagnosed between January 2015 and May 2017 and immunostained using AR441 (IgG1) mouse monoclonal antibody. Clinical follow-up ranged from 59 to 31 months and DFS was calculated. Cut-off scores were explored using *Evaluate Cutpoints* (*R maxstat* package) and *X-tile* software. The score with maximum split in DFS (based on log-rank statistics and lowest p-value) was chosen as the cut-off. Descriptive and survival statistics was performed. **Results:** The median age was 51 (SD 11.262; range 28 to 82) years. Using *Evaluate Cutpoints* $\geq$3 was found as the threshold for AR by Allred Score. 36% cases were AR positive using Allred score (HR 0.508; CI 0.234 - 1.11; p-value 0.08). Using *Evaluate Cutpoints* $\geq$30 was found as the threshold for AR by H-Score (HR 0.624, CI 0.306 - 1.27; p-value 0.19). 35% cases were AR positive using H-Score. *X-tile* analysis also found the cut-offs as $\geq$3 and $\geq$30 for Allred and H-Score respectively ($p < 0.05$). A significant correlation was seen between the two scoring systems (Pearson Correlation 0.935; $p < 0.01$). A significantly higher number of grade III TNBCs were AR negative (n = 55/76) compared to grade II (n = 9/24) (p = 0.002). Cut-off for Ki67 was 75 (HR 1.61, CI 0.85-3.04, p-value 0.141) with a significantly higher number of AR negatives in the Ki67$\geq$75 group (21/26; $p < 0.05$). The overall median DFS was 51.9 months. There was no significant difference in DFS for the AR negative (median: 47.4 months; mean: 39.39 months) and AR positive (Median survival not reached; mean: 41.3 months) groups(p = 0.23). **Conclusions:** AR immunohistochemistry cut-offs using the Allred ($\geq$3) and H-Score ($\geq$30) are close to the ones used for ER/PR immunohistochemistry as per ASCO/CAP guidelines, making a strong case for universal application of these systems for harmonization of AR data. Frequency of brain metastases in patients with locally advanced triple negative breast cancer after neoadjuvant platinum-based chemotherapy: Impact of *BRCA1/2* mutations. *First Author: Elena Glazkova, N.N. Blokhin National Medical Research Center of Oncology, St. Petersburg, Russian Federation*

Background: patients with triple negative breast cancer has poor survival outcomes. Achievement of pathological complete response (pCR) after neoadjuvant chemotherapy can significantly improve survival of these patients, however some patients will relapse even after pCR. **Methods:** we reviewed prospectively-maintained outcomes database of N.N. Blokhin NMRCO. We extracted information about patients with locally advanced non-metastatic (stage IIIA-IIIC) triple negative breast cancer who were treated with neoadjuvant platinum based chemotherapy in 2014-2018 years. All included patients were tested for the presence of *BRCA1/2* mutation with whole-exome next-generation sequencing or for "founder" hot-spot mutations. **Results:** we identified 80 patients who received neoadjuvant treatment with various platinum-based regimens. Pathological complete response rate was 62.5%. *BRCA*-mutations was found at 22 (27.5%) patients. Median follow-up time was 35.6 months (17.0 – 61.3). 2-year DFS was 77.3%, and 3-year DFS was 70.0%, there was significant differences in DFS in patients, who achieved and patients with residual tumor – 85,2% vs 64,3% (p=0,028). 2-year OS was 91%, 3-year OS was 78,5%. 18 patient had disease progression, the most common sites of disease progression were brain (9 [50.0%]), lungs (5 [27.8%]), 3 (16.7%) patients had locoregional relapses and 1 (5,6%) liver metastases. We separately analysed characteristics of patients with brain metastases (table). There were no significant differences in tumour pathologic response and patient age. All patients, who relapced after pCR, had brain metastases. We also found, that 7 of 9 patients with brain metastases had different *BRCA* mutations. Brain metastases developed in 40,9% (9/22) of patients with *BRCA1* mutations and 3,4% (2/58) of patients with wild type *BRCA1* (p<0,00001). **Conclusions:** *BRCA1* mutation is significant prognostic factor for brain metastases development in locally advanced triple negative breast cancer. Research Sponsor: None.

Disparities in the receipt of National Comprehensive Cancer Network (NCCN) guideline adherent care in triple-negative breast cancer (TNBC) by race/ethnicity, socioeconomic status, and insurance type. *First Author: Chimezie Ubbaonu, University of California, Irvine, CA*

Background: Breast cancer is the most commonly diagnosed cancer in women in the United States and the second leading cause of cancer mortality in women.TNBC is more likely to present at an earlier age with more advanced and aggressive disease. The overarching goal of treatment recommendations listed in the National Comprehensive Cancer Network (NCCN) guidelines are to improve patient outcomes. Here we examine factors which may contribute to NCCN guideline adherence. **Methods:** This was a retrospective cohort study of women with triple negative breast cancer using data from the California Cancer Registry (CCR) between 2004-2016 (with follow-up through 11/2018). Indicators for concordance with NCCN guidelines for TNBC was used as the dependent variable in the analysis. A multivariable logistic regression was used to determine the effects of independent variables on adherence to NCCN guidelines. Odds ratios and 95% Confidence Intervals (CI) were calculated. Non-Hispanic Whites, having medical insurance and highest socioeconomic status (SES) were set as references values in the regression models. Disease specific survival was calculated using the Cox regression analysis. **Results:** A total of 16,858 women were included in this study, 32.5% (n = 5,472) received NCCN adherent care ($p < 0.0001$). Non-Hispanic Blacks (NHB) and Hispanic patients were less likely to receive guideline adherent care (respectively, OR 0.87, 95%CI 0.79-0.95 and OR 0.87, 95%CI 0.79-0.95). Patients of lowest and lower-middle socioeconomic status (SES) were less likely to receive NCCN guideline adherent care (respectively, OR 0.77, 95%CI 0.68-0.87 and OR 0.88, 95%CI 0.79-0.98). Overall, non-adherent care was associated with an increased disease-specific mortality (HR 1.21, 95%CI 1.11-1.31, $p < 0.0001$). Hazard ratios were calculated after adjusting for adherent care and NHB patients had an increased disease-specific mortality (HR 1.28, 95%CI 1.16-1.42, $p < 0.0001$) in addition to patients with Medicare or Medicaid payer status (respectively, HR 1.20, 95%CI 1.08-1.34, $p < 0.001$ and HR 1.29, 95%CI 1.15-1.43, $p < 0.0001$). **Conclusions:** A significant portion of TNBC patients in California continue to receive non-guideline adherent care. Non-Hispanic black patients and lower SES quintile groups were less likely to receive guideline adherent care. Patients with non-adherent care had worse disease specific survival compared to recipients of NCCN-adherent care. Research Sponsor: None.

1082 Poster Session (Board #167), Fri, 8:00 AM-11:00 AM

Induction bevacizumab, etoposide and cisplatin followed by whole brain radiotherapy (WBRT) versus WBRT alone in breast cancer with untreated brain metastases: Results of a randomized phase II A-PLUS trial. *First Author: Yen-Shen Lu, National Taiwan University Hospital, Taipei, Taiwan*

Background: Our previous study (*Clin Cancer Res.* 2015;21(8):1851) demonstrated that bevacizumab preconditioning followed by etoposide and cisplatin (BEEP) is a highly effective treatment for breast cancer (BC) patients (pts) with brain metastases (BM) progressing from WBRT. We conducted a randomized phase II study A-PLUS (NCT02185352) to test whether using BEEP as an induction therapy could enhance the efficacy of WBRT and provide systemic control. **Methods:** BC pts with measurable BM not suitable for surgery/radiosurgery and had not received WBRT were randomized (2:1) to experimental arm: induction BEEP for 3 cycles (~2 months [ms]) followed by WBRT or control arm: upfront WBRT. The BEEP regimen consists of bevacizumab 15 mg/kg on day 1, and etoposide 70 mg/m^2/day on days 2-4, cisplatin 70 mg/m^2 on day 2, followed by prophylaxis GCSF, every 21 days. After WBRT in both arms, pts received treatment of physician's choice except BEEP until BM progression. Stratification was based on the Graded Prognostic Assessment score. Primary endpoint was brain-specific progression free survival (BS-PFS) based on RECIST 1.1, with a total of 108 pts, power of 0.8 at the 2-sided α level of 0.2. **Results:** Of 112 enrolled pts, 74 were in experimental arm and 38 in control arm. Baseline patient characteristics were generally balanced between arms. With median follow up of 28.7 ms, median BS-PFS was 8.1 vs. 6.5 ms (p= 0.146; HR 0.71 [95% CI 0.44-1.13]), which met the primary endpoint (pre-defined α level of 0.2). Results of preplanned analysis included: 2-month brain-specific objective response rate of BEEP alone vs. WBRT was 41.9% vs. 52.6% (p= 0.613); 8-month BS-PFS rate was 48.7% vs. 26.3% (p= 0.027); median PFS was 6.4 vs. 4.7 ms (p= 0.071; HR 0.67 [95% CI 0.43-1.04]), and extra-BM PFS was 7.9 vs. 5.0 ms (p= 0.141; HR 0.71 [95% CI 0.46-1.12]). Median overall survival was 15.6 vs. 13.6 ms (p= 0.855; HR 0.96 [95% CI 0.59-1.55]), with 31.6% of pts in control arm received BEEP regimen treatment after BM progression. The most common all-grade adverse events (AEs) in experimental arm were neutropenia (30.2%), nausea (27.9%), anemia (27.4%), and leukopenia (24.2%). Most AEs were mild to moderate in severity. Two pts discontinued BEEP treatment due to grade 4 nephrotoxicity and grade 3 infection, respectively. **Conclusions:** BEEP as induction treatment followed by WBRT for BC pts with BM may improve control of both BM and systemic disease. Further validation by a phase III study is necessary. Clinical trial information: NCT02185352. Research Sponsor: Roche Products Ltd., Other Foundation, Other Government Agency, Pharmaceutical/Biotech Company.

1084 Poster Session (Board #169), Fri, 8:00 AM-11:00 AM

The landscape of genomic alterations detected in serial circulating tumor DNA (ctDNA) in clinical progressive metastatic breast cancer. *First Author: Saya Jacob, Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Metastatic breast cancer (MBC) is associated with genomic evolution, representing a challenge at clinical progression. While tissue and blood next-generation sequencing (NGS) allows for the baseline detection of alterations, non-invasive longitudinal assessment of ctDNA can provide a tool for monitoring tumor evolution. We characterized genomic changes using serial ctDNA testing in patients with clinical progression. **Methods:** Patient data was obtained under an IRB-approved protocol and ctDNA was collected at Northwestern University between 2015-2019. All ctDNA samples were analyzed using the Guardant360 NGS assay. Of 255 patients with MBC, 86 had at least two serial ctDNA collections with the second collection drawn at first progression (P1) by imaging and clinical assessment. Participants were followed until second clinical progression (P2). We analyzed type of alterations, mutant allele frequency (MAF), number of alterations (NOA), and sites of disease on imaging in close proximity to ctDNA evaluation. Matched pairs variations in MAF and NOA at P1 and P2 were tested through Wilcoxon test. **Results:** We identified 44 HR+, 20 HER2+ and 22 TNBC cases. Median lines of therapy were 3 (interquartile range (IQR): 1-6) for HR+, 3 (IQR: 1-5) for HER2+, and 2 (IQR: 1-4) for TNBC. The most likely alterations between baseline to P1 were *TP53* ($p < 0.0075$), *PIK3CA* ($p < 0.0126$), *AR* ($p < 0.0126$), *FGFR1* ($p < 0.0455$) and *ESR1* ($p < 0.0143$). In the HR+ subset, *ESR1* was statistically more likely at P1. *ESR1* at P1 was also associated with development of new liver lesions ($p < 0.0320$). *ERBB2* mutation at P1 was associated with new lung ($p < 0.0050$) or bone lesions ($p < 0.0030$). Increase in NOA was observed between baseline and P1 ($p < 0.0001$), P1 and P2 ($p < 0.0001$), and baseline to P2 ($p < 0.0004$). MAF was increased between baseline and P2 ($p < 0.0480$). **Conclusions:** Serial ctDNA testing identified resistance alterations (*TP53, PIK3CA, AR, ESR1, FGFR1),* with some mutations indicating new sites of disease (*ESR1, ERBB2*). Heterogeneity of ctDNA was significantly associated with progressive disease. Prospective evaluation of the impact of serial ctDNA testing on treatment decisions is needed to expand the role of precision medicine in MBC. Research Sponsor: None.

	Baseline	P1	P2
NOA	4 (IQR: 1-6)	5 (3-8)	6 (4-10)
MAF	3.3 (IQR:0.3-11.4)	3.6 (0.8-15.4)	5.0 (0.5-14)
Cases with NOA Increase from Baseline		**58% ($p < 0.0001$)**	**81% ($p < 0.0004$)**
Cases with MAF Increase from Baseline		55% ($p < 0.2390$)	**65% ($p < 0.0480$)**
New Alterations		***TP53, PIK3CA, AR, FGFR1, ESR1***	
New Metastases		***ESR1*: Liver** ***ERBB2*: Lung, Bone**	

1085 Poster Session (Board #170), Fri, 8:00 AM-11:00 AM

Metastatic behavior of mixed invasive ductal lobular carcinoma (mIDC/ILC). *First Author: Azadeh Nasrazadani, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Mixed invasive ductal lobular carcinoma (mIDC/ILC) is a poorly described subtype of invasive breast cancer, characterized by its composition of both ductal and lobular histopathology. It is unclear if individual or both components drive metastasis. Literature is sparse regarding sites of metastatic spread of this elusive subtype of invasive breast cancer. **Methods:** Cohorts of patients with mIDC/ILC, invasive ductal carcinoma (IDC), and invasive lobular carcinoma (ILC) were identified from the UPMC Network Cancer Registry. Among these, 46 patients with mIDC/ILC, 1,131 patients with IDC, and 145 patients with ILC seen at UPMC Magee Women's Hospital from 1990 – 2017 were found to have developed distant metastasis during the course of their disease. The metastatic pattern of spread was compared between the cohorts. Formalin-fixed, paraffin-embedded patient samples from the metastatic sites of a portion of the mIDC/ILC cases (n = 19) was acquired and evaluated by H&E staining. **Results:** Patients with IDC were more likely than patients with ILC to have metastasis to the liver ($p = 0.001$) and lung ($p < 0.001$), and less likely to have metastasis to the peritoneum ($p < 0.001$). Patients with mIDC/ILC were more likely than patients with IDC to have peritoneal metastasis ($p = 0.01$), similar to patients with ILC. Compared to patients with ILC, patients with mIDC/ILC were more likely to have liver metastasis ($p = 0.001$), similar to patients with IDC. Evaluation of the metastatic lesions originating from mIDC/ILC displayed a spectrum of histopathology including mixed histology (n = 3), pure IDC (n = 3), pure ILC (n = 5), and indeterminate lesions with features of both IDC and ILC (n = 6). Two cases were uninterpretable due to significant crush artifact. Metastatic mIDC/ILC lesions with retained mIDC/ILC histology were found in vertebral, pleural, and skin tissues. Metastatic mIDC/ILC lesions with IDC histology were found in a cerebellar, liver, and chest wall lesion; whereas, those with ILC histology were found in bowel, omental fat, ovary, bone, and sacrum. Indeterminate histology metastatic lesions were found at liver, chest wall, cerebellar, and bone sites. **Conclusions:** mIDC/ILC metastasizes to a range of distant sites with a higher preference to the liver and peritoneum as compared to ILC and IDC, respectively. Metastatic lesions arising from mIDC/ILC tumors showed a spectrum of histologies, including mIDC/ILC, IDC, ILC and indeterminate lesions with features of both IDC and ILC. Ongoing genomics studies will provide further insight into development of metastases from mIDC/ILC tumors. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

1086 Poster Session (Board #171), Fri, 8:00 AM-11:00 AM

Outcomes for black versus white women with stage IV breast cancer enrolled on investigator-initiated clinical trials at Emory. *First Author: Princess Ekpo, Emory University, Atlanta, GA*

Background: Black women are 40% more likely to die from their breast cancer compared to White women. Inadequate representation of Blacks in clinical trials may contribute to health care inequity. Emory's Winship Cancer Institute (WCI) in Atlanta serves a significant Black population and has a unique opportunity to engage these underrepresented patients in clinical trials. We aimed to assess clinical outcomes in Black versus White women with metastatic breast cancer (MBC) enrolled on investigator-initiated clinical trials (IITs) at Emory. **Methods:** Black and White women with MBC enrolled on IITs conducted at WCI between 1/2009 and 1/2019 were retrospectively evaluated. Descriptive statistics were generated for all patient characteristics. Univariate analyses and a multiple logistic regression model were used to assess the effect of age and race on clinical response, length of time on trial, number of therapy lines prior to trial enrollment, and toxicity on trial. Overall survival was assessed using Kaplan Meier analysis. **Results:** Sixty-two women with MBC were included [White, n = 41 (66%), and Black, n = 21 (34%), p = 0.55]. Over 90% of women were enrolled on phase II clinical trials and received targeted therapy. Mean age at clinical trial consent was 53.2 and 55.9 years in Black and White women, respectively (p = 0.36). While the majority of women had hormone-receptor positive disease, a higher percentage of Blacks had triple negative breast cancer (29% vs. 17% in Whites, p = 0.39). Black women had fewer lines of systemic therapy prior to trial enrollment (2.86 vs. 4.3, respectively, p = 0.017) and were enrolled on trial for less time than White women (5.67 mo vs. 7.83 mo, respectively, p = 0.22). There were no differences in toxicity rates among patients enrolled on IITs based on race. Black women were more likely to have progressive disease (PD) on trial (45% in Blacks vs. 20% in Whites, p = 0.05). While there was no significant difference in overall survival (p = 0.482), there was a trend towards shorter survival in Black women (51.3 mos vs. 64 mos, respectively). **Conclusions:** Black women with MBC who enrolled on IIT trials at Emory had worse treatment response and a trend towards poorer survival compared to White women. More research is needed to determine whether this is due to adverse biology. These results reinforce the need for exploration of biomarkers of response by race and ethnicity and improved representation of Blacks in clinical trials to inform real world efficacy. Real-world clinical effectiveness and safety of olaparib monotherapy in HER2-negative gBRCA-mutated metastatic breast cancer: Phase IIIb LUCY interim analysis. *First Author: Karen A. Gelmon, Department of Medical Oncology, BC Cancer, Vancouver, BC, Canada*

Background: OlympiAD (NCT02000622) demonstrated the benefit of olaparib over standard of care in patients (pts) with HER2-negative (HER2-) metastatic breast cancer (MBC) and germline *BRCA* mutations (gBRCAm). LUCY (NCT03286842) aimed to provide additional data on the real-world effectiveness and safety of olaparib monotherapy in this setting. **Methods:** This Phase IIIb, open-label, single-arm study of olaparib 300 mg twice-daily, enrolled pts with HER2- gBRCAm MBC who had received a taxane and/or anthracycline in the (neo)adjuvant/metastatic setting, and ≤2 lines of chemotherapy for MBC. Hormone receptor-positive (HR+) pts had progressed on prior endocrine therapy (ET), and further ET was considered unsuitable. Primary endpoint: investigator-defined progression-free survival (PFS). Secondary endpoints: overall survival, time to first subsequent therapy or death (TFST), and investigator-assessed clinical response rate (CRR). The interim analysis was planned after 160 PFS events. **Results:** From Oct 2018-Sept 2019, 252 pts were enrolled (160 sites, 15 countries; mean age 46.2 [range 22-75] years; 73.4% ECOG PS 0). Median total treatment duration: 7.9 months (mo; range 0.2-20.0). Median PFS: 8.1 mo (95% confidence interval [CI] 6.9, 8.7; 166 events [65.9%]). Clinical trial information: NCT03286842. Median TFST: 9.7 mo (95% CI 8.7, 11.1). CRR: 48.6% (95% CI 42.2, 55.0). Adverse events (AEs) in >20% of pts (all grades): nausea, anemia, asthenia, vomiting, and fatigue. 24.6% of pts reported a grade ≥3 AE, including anemia (n=33 [13.1%]). 4.4% of pts had an AE leading to treatment discontinuation. **Conclusions:** Interim results in this real-world population of pts with HER2- gBRCAm MBC were consistent with the OlympiAD study, and support olaparib as a chemotherapy-free alternative treatment for pts with gBRCAm advanced BC. Research Sponsor: This study was sponsored by AstraZeneca and is part of an alliance between AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA (MSD).

	Subgroup (%)	Events, n (%)	Median PFS, mo	95% CI

Clinical predictors of long-term response to capecitabine in metastatic breast cancer (MBC). *First Author: Deirdre Kelly, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Select patients (pts) with metastatic breast cancer (MBC) treated with capecitabine (cape) experience long-term disease control. We aimed to evaluate the clinical and biological predictors of long-term response. **Methods:** Pts receiving cape monotherapy for breast cancer from 01/2006 to 01/2016 at Princess Margaret Cancer Centre in Toronto, Canada (N = 352) or Alberta, Canada (N = 798) were identified through central pharmacy records. A median time-to-progression (MTTP) 3-fold higher (19.3 months) than those seen in published studies for patients treated with cape monotherapy at 1000mg/m2 was applied to select for pts with long-term response. MBC pts meeting these criteria were identified through chart review, with collection of clinical, pathological, and survival outcomes in addition to oncologist assessed (o) best response (eg: oCR, oPR, oSD) by radiology report review. Descriptive statistics, Kaplan-Meier and Cox-regressions were applied. **Results:** Overall, 41 (4%) pts met long-term response criteria. Median age of the study cohort was 62 (range 40-80), with 39% metastatic at diagnosis and 76% post-menopausal. At initiation of cape, a majority of pts were HR positive (85%), with an LDH < ULN (56%), and had bone (83%) or visceral (63%) metastases. Only 1 (2%) patient was HER2+. In the metastatic setting, most patients were chemotherapy-naive (83%) and had received 0-1 lines of hormonal therapy (61%). Median treatment duration with cape was 2.2 years (range 1.7-5.7) with 37% of pts having ≥40 cycles (range 22-94). Visceral (49%), bone (34%), and lymph nodes (24%) were the most common sites of progression, with 41% requiring 1 dose reduction and 27% requiring 2 dose reductions of cape. Overall response rate was 56% (oCR = 2%, oPR = 54%) with 44% having oSD as best response. Median follow-up was 6.8 years (95% CI: 5.5-8.2). Median PFS was 2.3 years (2.0-2.6), with a median OS of 3.8 years (2.9-4.6). 5 patients (12%) remained alive at data-cutoff, and 1 (2%) remained on treatment after 94 cycles of cape. **Conclusions:** Clinical features associated with long-term response on cape include HR positive, HER2 negative postmenopausal patients with bone predominant metastasis who have received 0-2 lines of prior hormone therapy and 0-1 lines of chemotherapy in the metastatic setting. This is the largest reported analysis of MBC patients with prolonged responses to cape. In the absence of randomized controlled trials; real-world evidence could aid clinicians in the optimal patient selection for treatment with cape. Research Sponsor: None.

Mutation profile differences in younger and older patients with advanced breast cancer using circulating tumor DNA (ctDNA). *First Author: Katherine Clifton, Washington University School of Medicine, St. Louis, MO*

Background: Although the noninvasive nature of ctDNA testing is attractive in an older adult population, less is known regarding the mutation profiles of ctDNA in the older adult breast cancer population as this population is often excluded from studies. Previous tissue testing has shown differences in mutation profiles between older and younger adults with breast cancer. The objective of this study is to assess differences in mutation profiles in the older and younger adult breast cancer population using a ctDNA assay. **Methods:** Patients (pts) with advanced breast cancer underwent molecular profiling using a plasma-based ctDNA NGS assay (Guardant360) between 5/2015-10/2019 at Siteman Cancer Center. Clinicopathological histories were obtained from the medical record. The results of a multicenter database of pts with advanced breast cancer who had undergone molecular profiling using Guardant360 were obtained. Associations between mutations and age were measured using a Fisher's exact test. **Results:** In the single institution cohort, of the 214 patients who underwent testing, 148 (69.16%) were < 65 and 66 (30.84%) ≥ 65 years-old. The most frequently mutated genes in age < 65 pts were *TP53* (48.65%), *PIK3CA* (35.81%), and *ESR1* (30.41%) while the most frequently mutated genes in age≥65 pts were *PIK3CA* (56.06%), *TP53* (51.52%), *ESR1* (25.76%), and *ATM* (21.21%). *ATM, BRAF* and *PIK3CA* mutations were found more frequently in age≥ 65 pts with ER+ HER2- breast tumors ($p < 0.01$). *MYC* and *ESR1* mutations were not significantly associated with age, overall or within subtype. Overall ctDNA resulted in change in management in 19.8% pts (40/202). In the larger multicenter cohort, of the 8803 pts who underwent testing, 5367 (61.0%) were < 65 and 3417 (38.8%) ≥ 65 years-old. *ATM, ESR1* and *PIK3CA* mutations were more common in age≥65 pts ($p < 0.0001$) and *MYC* mutations were less common in age≥65 pts ($p < 0.0001$). **Conclusions:** This study found that ctDNA is a feasible, attractive alternative to traditional biopsies and may identify actionable mutations in older adults with breast cancer. When controlling for subtype, results from a single institution were similar to the larger multicenter cohort showing *ATM* and *PIK3CA* were more common in the older adult population. This data suggests there may be additional molecular differences between breast cancer in older compared to younger adults that warrants further investigation. 1090 Poster Session (Board #175), Fri, 8:00 AM-11:00 AM

Systemic therapy for patients with breast cancer and one to three brain metastases (BM). *First Author: Zaid A Soomro, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite advances in systemic therapies and improved overall survival of metastatic breast cancer (MBC) patients, the development of brain metastases (BMs) remains a challenging complication that affects quality of life and increases morbidity and mortality. Current clinical practice guidelines recommend local treatment of BMs without changing systemic therapy (CST) in patients with stable systemic disease. **Methods:** We retrospectively investigated the impact of CST (when applicable as per treating physician's discretion) after diagnosis of the initial 1-3 BMs on the patient's progression-free survival time (PFS), defined as time to death, to a second BMs or to extracranial metastases. All MBC patients with 1 to 3 BMs only (without extracranial disease) treated at our institution between 2002 and 2017 were identified. For each patient, full information on follow-up and administered therapies were mandatory for inclusion. Hazard ratios (HR) were calculated using the Cox proportional hazard model. We also computed the restricted mean survival time (RMST) up to 5 years of follow-up. **Results:** Among the 2645 patient with BM treated at our institution, 80 were included for analysis. In regards to primary BMs management in patients, 46 of 80 (57%) were treated by radiation therapy, 6 of 80 (7.5%) underwent surgical resection, and 28 of 80 (35%) were managed by a combination of surgery and radiation therapy. All patients had staging imaging documenting lack of extracranial metastases at the time of local therapy of BMs. Following the primary management of BM, we observed that providers changed systemic therapy in 32 of 80 (40%), defined as the CST group. CST included both initiation of therapy in 16 of 80 (20%) and switching of adjuvant therapy in 16 of 80 (20%). Median PFS among CST was 7.7 months vs. 7.2 months among no CST (HR = 0.855, 95% confidence interval (CI) 0.53-1.38, p = 0.52). 5-year RMST for the CST group was 16.6 months vs. 12.8 months in no CST group. The difference of 3.8 months (95% CI 4.3-11.8) was not statistically significant. **Conclusions:** Patients with 1-3 BMs without extracranial disease had a median PFS close to 7.5 months after local therapy. Consistent with current standard of care of maintaining the same systemic therapy approach upon developing isolated BMs, our findings did not demonstrate a significant difference in PFS between patients who experienced a change in systemic therapy compared to those who did not. 1091 Poster Session (Board #176), Fri, 8:00 AM-11:00 AM

Veliparib (V) monotherapy (monoTx) following combination therapy with V + carboplatin/paclitaxel (CP) in patients with g*BRCA*-associated advanced breast cancer: Exploratory results from BROCADE3. *First Author: Hyo S. Han, Moffitt Cancer Center, Tampa, FL*

Background: In BROCADE3 (NCT02163694), addition of PARP inhibitor V to CP resulted in improved progression-free survival (PFS) (HR 0.71 [95% CI 0.57−0.88], p=0.002) in patients (pts) with advanced HER2-negative breast cancer and g*BRCA1/2* mutation. A subset of pts transitioned to V/placebo (PL) monoTx at an intensified dose/schedule after CP discontinuation prior to progression (investigator discretion). Here, we evaluate the impact of this transition on efficacy and safety. **Methods:** Pts were randomized 2:1 to CP with V (n=337) or PL (n=172). V (120 mg po BID) or PL was given on Days (D) −2 to 5, C (AUC 6) on D1, and P (80 mg/m^2) on D1, 8, and 15 (21-day cycles). Pts who transitioned to monoTx received V/PL 300-400mg BID daily until progression. A Cox model with a time varying covariate indicating transition from V/PL with CP to V/PL monoTx was fit to estimate treatment effect during combination and monoTx phases. PFS by cycles of CP prior to monoTx and AEs during monoTx are summarized. **Results:** A subgroup of 136 (40%) and 58 (34%) pts on the V and PL arms, respectively, received monoTx. When a Cox model with a time-varying covariate was fit for PFS (per investigator), the nominal P-value for treatment by covariate interaction was 0.038. The HRs (95% CI) for V vs PL during combination therapy and monoTx were 0.81 (0.62–1.06) and 0.49 (0.33–0.73). The Table summarizes PFS by cycles of C and/or P prior to monoTx. Common AEs (>20% of pts) during V or PL monoTx were nausea (52%/10%), fatigue (23%/12%), headache (21%/17%), and diarrhea (21%/9%). Seizures (2.2%/0%) were reported during monoTx. Rates of cytopenias for V or PL monoTx were: anemia 12%/14%; neutropenia 13%/12%; and thrombocytopenia 10%/5%. **Conclusions:** These analyses suggest that pts treated with V + CP derive benefit from both combination therapy as well as V monoTx after CP discontinuation. Pts receiving V monoTx after ≤ 6 cycles of VCP experienced a similar benefit to those who transitioned to monoTx after 7–12 cycles of VCP, suggesting that V maintenance therapy may be suitable following a limited duration of combination therapy. Clinical trial information: NCT02163694. Research Sponsor: AbbVie.

Median PFS (investigator-assessed) in pts who received V/PL monoTx.

Cycles of C and/or P before monoTx	V + CP Events, n/N at risk (%)	PL + CP	V + CP Median PFS, mo (95% CI)	PL + CP	HR (95% CI)
≤6	15 / 27 (56)	12 / 13 (92)	18.4 (12.5, -)	12.8 (6.2, 14.7)	0.38 (0.16, 0.88)
7–12	39 / 62 (63)	21 / 27 (78)	18.9 (15.1, 22.3)	13.3 (10.6, 19.7)	0.54 (0.31, 0.95)
Any	70 / 136 (52)	45 / 58 (78)	25.7 (20.5, -)	14.6 (12.8, 19.7)	0.49 (0.34, 0.73)

Diagnostic yield and clinical utility of germline genetic testing following somatic testing in breast cancer patients. *First Author: Stephen E Lincoln, Invitae, San Francisco, CA*

Background: Germline genetic testing is recommended for breast cancer patients with specific presentations or family histories. Separately, tumor DNA sequencing is increasingly used to inform therapy, most often in patients with advanced disease. Recent NCCN and ESMO guidelines recommend germline testing following somatic testing, under specific circumstances and for specific genes. We examined the utility of germline findings in patients referred for both test modalities. **Methods:** We reviewed somatic and germline mutations in a consecutive series of patients who: (a) had a current or previous breast cancer diagnosis, (b) were referred for germline testing, and (c) previously received tumor sequencing. Diverse reasons for germline testing included: a tumor finding of potential germline origin, treatment or surgical planning, personal or family history, and patient concern. **Results:** 227 patients met study criteria of whom 88 (39%) harbored a pathogenic germline variant (PGV) in a high or moderate risk cancer predisposition gene. Mutations in certain genes were most likely to be of germline origin, and most PGVs were potentially actionable (Table). 13% of PGVs were not reported by tumor tests as either germline or somatic findings, usually a result of tumor test limitations. Of note, 27 of the patients with PGVs (31%) had these variants uncovered only after presenting with a second, possibly preventable, malignancy. **Conclusions:** Germline testing following tumor sequencing often yielded findings that may impact care. Indeed, the 39% PGV rate we observed suggests that such testing may be underutilized. We observed actionable PGVs missed by somatic tests, PGVs uncovered in patients' second malignancies, and PGVs not within germline reflex testing criteria. These results reinforce the utility of germline testing separate from somatic testing in appropriate patients. Research Sponsor: None.

Somatic and germline findings by gene. Genes with no germline findings are not shown.

Gene	Total Findings	#Germline (%Total)	ESMO Criteria	Potential Utility
BRCA1/2	119	53 (45)	Yes	MG,PT,CT
TP53	53	4 (8)	No *	MG,CT
ATM	18	9 (50)	No	MG,CT
PTEN	15	1 (7)	No	MG,CT
CHEK2	12	8 (67)	No	MG,CT
PALB2	11	9 (82)	Yes	MG,CT
Other	15	4 (26)	No *	MG

*ESMO criteria for TP53 and RB1 require age < 30 -- our *TP53/RB1* PGV-positive patients were older. Abbreviations: ESMO: Germline test recommended (PMID 31050713). Utility: PGVs associated with management guidelines (MG), approved precision therapies (PT) or clinical trial eligibilities (CT). Other genes: *RB1, CDKN2A, BRIP1*.

1093 Poster Session (Board #178), Fri, 8:00 AM-11:00 AM

Efficacy and safety of liposomal mitoxantrone (Lipo-MIT) in advanced breast cancer (ABC): A randomized, open label, active-controlled, single-center, phase II clinical trial. *First Author: Leiping Wang, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Anthracyclines are associated with cardiotoxicity and myelosuppression in breast cancer (BC) patients. A new drug delivery system, liposomal preparation has shown higher anti-cancer effect and lower toxicity due to modified drug release and particle shape. This trial aimed to evaluate the efficacy and safety of Lipo-MIT in ABC. **Methods:** This is a randomized, open label, active-controlled, single-center, phase II clinical trial. Eligible patients were randomized in a ratio of 1:1 to receive Lipo-MIT or mitoxantrone hydrochloride injection (MIT) intravenously. The dosage was 20 mg/m^2 for Lipo-MIT and 14 mg/m^2 for MIT, once every four weeks (i.e., one treatment cycle). The primary endpoint was objective response rate(ORR). The secondary endpoints were progression free survival (PFS) and safety. **Results:** From Oct 2015 through Jul 2017, 60 patients were randomized to Lipo-MIT group (n = 30) or MIT group (n = 30). The Median (Q1,Q3) age was 56.0 (41.0,62.0) years in Lipo-MIT group and 54.5 (44.0,62.0) years in MIT group. Nineteen patients in Lipo-MIT group and 23 in MIT group received < 4 cycles of treatment, 11 patients in Lipo-MIT group and 7 in MIT group were treated for 4 or more cycles. When Lipo-MIT group was compared with MIT group, ORR was 13.3% (4/30) and 6.7% (2/30), disease control rate (PR+SD) was 50% (15/30) and 30% (9/30), median PFS was 2.30 (95% CI: 1.74-3.91) and 1.86 (95% CI: 1.74-2.40) months (P> 0.05). Lipo-MIT showed significantly lower incidence of all-grade white blood cell decreased (86.7% vs 96.7%), neutrophil count decreased (80.0% vs 96.7%), conjugated bilirubin increased (53.3% vs 56.7%), aspartate aminotransferase increased (40.0% vs 53.3%), and troponin T increased (3.3% vs 36.7%) than MIT, but higher incidence of anemia (76.7% vs 46.7%), skin hyperpigmentation (66.7% vs 3.3%), and platelet count decreased (56.7% vs 53.3%) than MIT. **Conclusions:** Lipo-MIT provided numerically better ORR, DCR, and PFS than MIT in ABC. Lower incidence of troponin T increased might suggest lower cardiotoxicity of Lipo-MIT. It is worthwhile to further explore the clinical utility of Lipo-MIT in ABC. Clinical trial information: NCT02596373. Research Sponsor: CSPC ZhongQi Pharmaceutical Technology Co., Ltd., shijiazhuang, China.

1094 Poster Session (Board #179), Fri, 8:00 AM-11:00 AM

Comparison of the cell-free DNA genomics in patients with metastatic breast cancer (MBC) who develop brain metastases versus those without brain metastases. *First Author: Neelima Vidula, Massachusetts General Hospital, San Francisco, CA*

Background: The genomics of patients with metastatic breast cancer (MBC) who develop brain metastases (BM) is not well understood given the difficulty in obtaining brain tumor for genotyping. We compared tumor genotyping results via cell-free DNA (cfDNA) collected at MBC diagnosis in patients who developed BM after MBC diagnosis with those who did not develop BM (non-BM). **Methods:** Patients at an academic institution who had cfDNA testing (Guardant 360/Next generation sequencing, 73 gene assay) at MBC diagnosis between 1/2016-12/2017, with ≥ 6 months of follow-up post testing, were identified. A chart review was done to identify tumor subtype, demographics, cfDNA results, and development of BM at or after MBC diagnosis. Pearson's chi-squared and Wilcoxon rank sum tests were used to determine differences in clinical and cfDNA characteristics in BM vs. non-BM ($p<0.05$ for statistical significance). **Results:** CfDNA results were available for 49 patients, of whom 13 (27%) developed BM (4 with BM at MBC diagnosis). The median time to BM development was 11 months. While patients with BM were younger at MBC diagnosis than non-BM (median age BM 53 vs. non-BM 61, p=0.05), they had similar subtype (BM vs. non-BM: HR+/HER2- 62% vs. 69%, HER2+ 8% vs. 14%, TNBC 23% vs. 17%, unknown 8% vs. 0%, p=0.3), de-novo vs. recurrent disease (BM vs. non-BM: de-novo 8% vs. 14%, recurrent 92% vs. 86%, p=0.6), and visceral disease (BM vs. non-BM: 77% vs. 56%, p=0.2) distributions. All patients with BM had ≥1 detectable cfDNA mutation vs. 88% of non-BM. While the median mutant allele frequency of the most common mutation was similar in BM vs. non-BM (2.4% vs. 3.7%, p=0.5), the mutation pattern varied. Patients with BM more often had mutations in *BRCA1* (15% vs. 3%, p=0.1), *APC* (15% vs. 0%, p=0.02), and *CDKN2A* (15% vs. 0%, p=0.02), compared to non-BM. In 4 patients with BM at MBC diagnosis, mutations in *APC* (50%), *CDKN2A* (50%), and *BRCA 1/2* (25%) were noted; 1 had coexisting *APC* and *BRCA1/2* mutations and another had coexisting *APC* and *CDKN2A* mutations. **Conclusions:** Patients with MBC who develop BM may have different cfDNA genomics, particularly *BRCA1*, *APC*, and *CDKN2A* mutations. Further research is needed to determine the predictive value of cfDNA at MBC diagnosis in the identification of patients at higher risk of developing BM. Research Sponsor: None.

CfDNA mutations.

Mutation	BM (n=13)	Non-BM (n=36)	p-value
TP53	54%	39%	0.4
PI3KCA	31%	39%	0.6

1095 Poster Session (Board #180), Fri, 8:00 AM-11:00 AM

A phase I study of SHR6390, a cyclin-dependent kinase 4/6 inhibitor in patients with advanced breast cancer (ABC). *First Author: Pin Zhang, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: SHR6390 is a novel inhibitor of cyclin-dependent kinase 4/6 (CDK 4/6). This study was conducted to evaluate the tolerability, pharmacokinetics, safety, and preliminary antitumor activity of SHR6390 in patients (pts) with advanced breast cancer (ABC). **Methods:** In this open-label, single-arm phase I study, pts who had failed standard therapy were enrolled to receive oral SHR6390 in 3 + 3 dose-escalation pattern at doses of 25−175 mg. Eligible pts were given a single-dose of SHR6390 in week 1, followed by once daily continuous doses for three weeks, and one week off in 28-day cycle. Based on the tolerability, pharmacokinetics, and activity data revealed from the dose-escalation phase, three dose cohorts were selected to expand to 8−10 pts. The primary endpoints were maximum tolerated dose (MTD) and pharmacokinetics. **Results:** Between Apr 15, 2016 and Dec 21, 2018, 40 pts were enrolled. All pts were diagnosed of hormone receptor positive and HER2-negative ABC. 45.0% of pts had at least three prior chemotherapies and 55.0% had at least two prior endocrine therapies. SHR6390 100 mg, 125 mg, and 150 mg cohorts were expanded to 10 pts, respectively. No dose limiting toxicity was observed and the MTD was not reached. Adverse events (AEs) of grade ≥3 were observed in 22 (55.0%) of 40 pts, being neutropenia (52.5%), leukopenia (35.0%), thrombocytopenia (5.0%), and hypertension (2.5%). No serious AEs were reported. At the doses of 50−175 mg, median time to peak concentration was 2.5−4.0 h, and mean terminal half-life was 40.3−51.4 h with single-dose SHR6390. Following multiple dosing, steady state SHR6390 was observed on day 8. The steady state areas under the concentration and peak concentration increased slightly greater than the increase rate of dose, with steady state C_{max} at day 21 of 41.1, 53.4, 87.0, 115.0, 126.0, and 155.0 ng/mL in 50, 75, 100, 125, 150, and 175 mg cohorts, respectively. The disease control rate was 62.5% (25/40, 95% CI 45.8% to 77.3%). Two pts (5%, one in 125 mg, one in 150 mg cohort) achieved partial response, with responses lasting 169 and 356+ days, respectively. **Conclusions:** SHR6390 showed acceptable safety profile and dose-dependent plasma exposure in pts with ABC. The recommended phase II dose was 150 mg. Preliminary evidence of clinical activity was observed, warranted further study. Clinical trial information: NCT02684266. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

1096 Poster Session (Board #181), Fri, 8:00 AM-11:00 AM

The incidence and impact of brain metastasis in patients with hereditary *BRCA1/2* mutated invasive breast cancer in a prospectively followed cohort. *First Author: Haven Garber, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Previous reports suggest the incidence of brain metastasis is higher in patients with hereditary *BRCA1* mutations compared to *BRCA1* noncarriers among breast cancer patients who develop recurrent disease. PARP inhibitors are now standard therapies for metastatic breast cancer patients with germline *BRCA1* or *BRCA2* mutations (*gBRCA1/2*) based on their efficacy in treating systemic disease. However, as management of systemic disease improves, a concern is that patients with hereditary *BRCA* mutations may experience higher rates of disease progression in the CNS. We aimed to estimate the incidence of brain metastasis in breast cancer patients with *gBRCA1/2* using a prospectively maintained *gBRCA* database and to assess the impact of brain metastasis on survival. **Methods:** To determine incidence, we queried a prospectively maintained electronic database that included patients referred to the MDACC genetics department and who underwent *gBRCA1/2* testing. We identified patients with stage I-III invasive breast cancer who were treated between 2000-2017 and assessed for disease recurrence and brain metastasis. To expand our cohort for descriptive characteristics (separate from the incidence analysis), we queried the Breast Medical Oncology database for patients with brain metastasis who had undergone *BRCA1/2* testing outside the genetics department or at outside institutions. **Results:** Of 474 patients with Stage I-III breast cancer and *gBRCA1*, 77 (16.2%) developed distant metastasis (median f/u: 9.1 years). Of these patients, 34/77 (44.2%) developed brain metastasis. In comparison, 42 of 318 (13.2%) of *gBRCA2* patients with Stage I-III breast cancer developed distant recurrence (median f/u: 8.4 years), and 7/42 (16.7%) experienced brain metastasis. In *gBRCA1* patients with brain metastasis, 45/48 (83.8%) had triple negative disease, and the median time from diagnosis to brain metastasis was 2.45 years. The brain was among the initial sites of disease recurrence in 24/48 (50%) of *gBRCA1* patients. For *gBRCA1* patients with distantly recurrent disease, median OS from diagnosis was 3.19 years for patients with brain metastasis vs. 5.37 years for patients without brain mets (HR 0.54; 95% CI 0.34 to 0.85; $P = 0.0082$). **Conclusions:** Brain metastasis is frequent among breast cancer patients with recurrent disease and hereditary *BRCA1* mutations. Development and testing of agents with intracranial activity is critical for improving long-term outcomes in *gBRCA1* patients with metastatic breast cancer. 1097 Poster Session (Board #182), Fri, 8:00 AM-11:00 AM

Veliparib (V) monotherapy after progression on placebo (PL) + carboplatin/paclitaxel (CP) in patients with advanced HER2-negative g*BRCA*-associated breast cancer: Crossover outcomes and exploratory biomarker analyses in BROCADE3. *First Author: Shannon L Puhalla, University of Pittsburgh Medical Center Cancer Centers, Pittsburgh, PA*

Background: In BROCADE3 (NCT02163694), addition of the PARP inhibitor (PARPi) V to CP improved PFS in patients (pts) with g*BRCA*-associated advanced breast cancer (hazard ratio 0.71 [95% CI 0.57–0.88], p = 0.002). Reversion mutations may account for resistance to platinum-based CT and PARPi. Efficacy, safety, and exploratory biomarker analyses for pts randomized to PL + CP who received crossover (Cx) V monotherapy after progression are reported. **Methods:** 513 total pts were randomized 2:1 to V + CP or PL + CP. V/PL, C, and P could be discontinued independently prior to progression, leading to varying platinum-free intervals at the time of progression. After progression, pts in the PL + CP arm could receive open-label Cx V monotherapy (300–400 mg BID continuous), beginning within 60 d of progression and continuing to second progression. Adverse events (AEs) and activity during Cx V were assessed. Exploratory analysis of *BRCA* reversion mutations restoring *BRCA1/2* protein function that emerged during PL + CP treatment was performed on plasma circulating tumor DNA using targeted-amplicon next generation sequencing. **Results:** At data cutoff, 75 pts initially randomized to PL + CP had ≥1 dose of Cx V. Mean (range) duration of Cx V was 154 d (2–966). Activity during Cx V is in the Table. Mean (range) platinum-free interval at time of first dose of Cx V was 3.1 mos (0.4–10.9) vs 8.1 mos (1.0–34.9) in pts who had progressed vs had not progressed by 24 wks after first dose of Cx V. *BRCA* reversion analysis was completed for 18 Cx pts. Reversion mutations were identified in 1/18 pts (5.6%). This patient had Cx V duration of 19 d and had progressed by 24 wks. *BRCA* reversion analysis on additional Cx pts will be presented. Most common AEs during Cx V were nausea (61%), vomiting (29%), fatigue (24%), and diarrhea (21%). Any grade anemia, neutropenia, and thrombocytopenia occurred in 7%, 15%, and 7% of pts. Three pts (4%) experienced a convulsion event. **Conclusions:** Platinum-free interval may influence efficacy of subsequent PARPi. Impact of *BRCA* reversion mutations warrants further evaluation. Cross-resistance may limit PARPi efficacy after platinum failure. Clinical trial information: NCT02163694. Research Sponsor: AbbVie.

Trends of skeletal related events in patients with breast cancer metastasized to bone. *First Author: Prasanth Lingamaneni, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Up to three-quarters of women with advanced breast cancer develop bone metastases, predisposing to Skeletal Related Events (SRE), which are associated with a significant health care burden, poor prognosis, loss of functional independence and a decrease in quality of life. We performed a retrospective analysis on predictors of SRE in this population. We also evaluated temporal trends of outcomes and resource utilization in those with SRE. **Methods:** Adult breast cancer patients with metastases to bone, admitted from January 2012 to September 2015 were identified from the Nationwide Inpatient Sample database. Based on previous studies, SRE was defined by using ICD-9 codes for pathologic fracture, spinal cord compression, necessity for radiation to bone or surgery to bone. Multivariable analysis of predictors of SRE in patients with breast cancer metastatic to bone, as well as mortality in the SRE group were performed. Temporal trends of resource utilization across the years were evaluated. **Results:** A total of 143,455 patients with breast cancer with metastases to bone were identified, of which 17.2% had SRE. Patients with SRE had a mean age of 66 years and were predominantly white (70.2%). After adjusting for confounders, African Americans and Hispanics were less likely than Whites to develop SRE. On multivariable analysis, only comorbidity burden (in the form of high Charlson comorbidity index) predicted inpatient mortality. Rates of SRE in breast cancer patients with bone metastases did not change over the years (17.2% to 17.1%). Inpatient mortality of patients with SRE remained stable (3.76% to 3.79%). There was a statistically significant increase in surgical intervention (43.4% to 47.7%, $p<0.01$) and decrease in radiation to bone (25.7% to 19.7%, $p<0.001$) over time. Length of hospital stay and total hospital charges, after adjusting for inflation, remained largely unchanged. **Conclusions:** Incidence of SRE, inpatient outcomes and health care costs remained stagnant in those with metastatic breast cancer between 2012 and 2015, despite the advent of novel bone-targeted agents. There has been an increased trend towards surgical intervention and less utilization of local radiation over time. Research Sponsor: None.

Predictors of SRE in breast cancer patients with bone metastases.

Predictor	Adjusted OR (95% CI)	P-value
Age (per year increase)	1.008 (1.005-1.011)	**<0.001**
African American	0.86 (0.80-0.94)	**<0.01**
Hispanic	0.88 (0.77-0.99)	**0.04**

Surgery at primary and metastatic sites for stage IV breast cancer (BC): A National Cancer Database (NCDB) analysis. *First Author: Nadeem Bilani, Cleveland Clinic Florida, Weston, FL*

Background: There is no clear evidence of a survival benefit of primary tumor resection in patients with stage IV breast cancer (BC). This large study evaluated factors associated with undergoing primary tumor resection, and whether resection at the primary site, or distant site resection (metastasectomy), was associated with better overall survival (OS). **Methods:** This retrospective analysis of stage IV BC cases used the 2004-2016 National Cancer Database (NCDB) population. To evaluate variables associated with primary tumor resection, we used univariate analyses (chi-squared and Wilcoxon rank-sum test), followed by multivariate logistic regression. Consequently, we conducted multivariate Cox regression survival analyses on the following groups: 1) all stage IV BC patients; 2) a subset of those with only 1 site of metastasis; and 3) another subset with metastasis to > 1 distant site. **Results:** A total of 54,871 stage IV BC patients were included in this analysis. From this, we analyzed a subset with only 1 distant site involved (n = 30,480) and another subset with multiple secondary sites (n = 17,344). In total, 15,661 patients underwent surgery at the primary site: 11,451 (73.1%) were non-Hispanic white; 2479 (15.8%) were non-Hispanic black; 981 (6.3%) were Hispanic and 484 (3.1%) were Asian. Variables associated with undergoing resection of the primary tumor were: age, race, Charlson/Deyo score, insurance and facility type, involved breast quadrant, receptor status, N-staging, extent of metastasis and year of diagnosis. Survival analysis of all stage IV patients showed that both lumpectomy (HR 0.59, 95% CI: 0.57-0.62, $p < 0.0001$) and mastectomy (HR 0.62, 95% CI: 0.60-0.64, $p < 0.0001$) were associated with better OS when compared to no surgery. The statistical effect was larger in the subgroup with metastasis to 1 site, but still significant in the subgroup with multiple metastatic sites. Distant site resection also yielded a survival benefit compared to no metastasectomy across all 3 groups. In the subgroup with metastasis to only 1 site, metastasectomy was associated with better OS when the metastatic site was liver (HR 0.60, 95% CI: 0.43-0.82, p = 0.0018), lung (HR 0.47, 95% CI: 0.37-0.61, $p < 0.0001$), and brain (HR 0.70, 95% CI: 0.55-0.88, p = 0.0022). **Conclusions:** Across all 3 patient subgroups, primary tumor resection (lumpectomy or mastectomy) and metastasectomy were associated with improved OS. Additional stratified analysis in the subgroup with only 1 metastatic site showed benefit of metastasectomy when that site was the lung, liver or brain. Research Sponsor: None.

TPS1100 Poster Session (Board #185), Fri, 8:00 AM-11:00 AM

Trastuzumab deruxtecan (T-DXd; DS-8201) in combination with pembrolizumab in patients with advanced/metastatic breast or non-small cell lung cancer (NSCLC): A phase Ib, multicenter, study. *First Author: Hossein Borghaei, Fox Chase Cancer Center, Philadelphia, PA*

Background: T-DXd is an antibody-drug conjugate composed of an anti-HER2 antibody, cleavable tetrapeptide-based linker, and potent topoisomerase I inhibitor. In a phase II trial in patients (pts) with heavily pretreated, metastatic HER2+ breast cancer (BC), T-DXd had a confirmed objective response rate (cORR) of 60.9% (112/184) and median progression-free survival (PFS) of 16.4 mo (Modi *N Engl J Med* 2019); these results led to the recent FDA approval for HER2+ unresectable or metastatic BC after $\geq$ 2 prior anti-HER2 based regimens. For HER2-low BC and HER2-expressing/mutated NSCLC, no HER2-directed therapies have been approved. In a phase I trial of T-DXd in pts with HER2-low BC or HER2-expressing/mutated NSCLC, cORR was 44.2% (19/43) (Modi SABCS 2018), and 55.6% (10/18) (Tsurutani *Thorac Oncol* 2018), respectively. In preclinical models, T-DXd combined with an anti–PD-1 antibody was more effective than monotherapy with either agent (Iwata *Mol Cancer Ther* 2018). Here we describe a phase Ib study of T-DXd in combination with pembrolizumab in pts with locally advanced/metastatic HER2-expressing BC or HER2-expressing/mutated NSCLC (DS8201-A-U106; NCT04042701). **Methods:** This is an open-label, multicenter, nonrandomized, multidose, 2-part study in adult (aged $\geq$18 y) pts in the United States and Europe. In part 1 (dose escalation), pts received T-DXd 3.2 or 5.4 mg/kg IV q3w and pembrolizumab 200 mg IV q3w to determine the recommended dose for expansion (RDE). The RDE will be given to 4 cohorts (part 2): 2 cohorts with BC (HER2+ [IHC 3+ or IHC 2+/ISH+] with progression on prior T-DM1; and HER2-low [IHC 1+ or IHC2+/ISH-] with progression on prior standard treatments) and 2 cohorts with NSCLC (anti–PD-1, –PD-L1, and -HER2 treatment naive either HER2-expressing [IHC $\geq$ 1+] or HER2-mutated). Enrollment began in February 2020 with approximately 115 to 133 pts planned to be enrolled at 5 sites for part 1 and expanding to 25 sites for part 2. The primary endpoint in part 1 is dose-limiting toxicities. The part 2 primary efficacy endpoint is cORR by independent central review (ICR) per RECIST 1.1. Additional endpoints include duration of response, disease control rate, and progression-free survival by ICR, overall survival, safety, and pharmacokinetics. Clinical trial information: NCT04042701. Research Sponsor: Daiichi Sankyo, Inc.

TPS1101 Poster Session (Board #186), Fri, 8:00 AM-11:00 AM

First-in-human phase I study of anti-HER2 ADC MRG002 in patients with relapsed/refractory solid tumors. *First Author: Jin Li, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China*

Background: MRG002 is an antibody drug conjugate (ADC) composed of a humanized anti-HER2 IgG1 monoclonal antibody conjugated to a microtubule disrupting agent monomethyl auristatin E (MMAE). MRG002 is presently being investigated in an ongoing phase I study for safety, tolerability, pharmacokinetics (PK), and preliminary antitumor activity in patients (pts) with solid tumors. **Methods:** MRG002 is evaluated as monotherapy for the treatment of pts with confirmed HER2 positive locally advanced or metastatic cancers, including breast cancer (BC), gastric cancer (GC), salivary gland cancer (SGC) and others. The primary objective is to determine the maximum tolerated dose (MTD) and a recommended phase II dose (RP2D). Secondary objectives include evaluation of PK, tumor response, and immunogenicity. In the dose escalation phase with "3+3" design, approximately 24 pts will be enrolled to identify MTD. The starting dose of MRG002 is 0.3 mg/kg, followed by 0.6, 1.2, 1.8, 2.2, 2.6, and 3.0 mg/kg. In the dose expansion phase, about 50 pts with HER2 positive advanced cancers will be enrolled to further evaluate the safety, antitumor activity, and PK at an appropriate confirmed dose. In this phase I study, each pt receives single agent MRG002 once every 3 weeks (Q3W) for a maximum of 8 treatment cycles. Pts with BC and GC should have HER2 positive advanced solid tumors per College of American Pathologists (CAP) guidelines. For other cancers, pts must have IHC status of 2+ or 3+, regardless of FISH results. Pts should have either failed or are ineligible for standard treatments. All pts must have at least 1 measurable lesion per RECIST 1.1. ECOG should be 0-1, and bone marrow, hepatic, renal, cardiac functions should be adequate. Observations include adverse events (AEs), dose-limiting toxicity (DLT), and antitumor activity, which is assessed every two treatment cycles. Further clinical trial details can be found on chinadrugtrials.org.cn (CTR20181778). Enrollment is ongoing since November 2018. Clinical trial information: CTR20181778. Research Sponsor: Shanghai Miracogen Inc.

TPS1102 Poster Session (Board #187), Fri, 8:00 AM-11:00 AM

Trial in progress: A phase II open-label, randomized study of PARP inhibition (olaparib) either alone or in combination with anti-PD-L1 therapy (atezolizumab) in homologous DNA repair (HDR) deficient, locally advanced or metastatic non-HER2-positive breast cancer. *First Author: Patricia LoRusso, Yale University School of Medicine, New Haven, CT*

Background: While immunostimulatory therapies have shown great success, a major challenge remains identification of mechanisms to effectively treat the majority of patients with so-called "non-inflamed" tumors lacking marked lymphocyte infiltration and PD-L1 expression. The DNA repair proficiency of a tumor may impact its potential for immune recognition and sensitivity to immune checkpoint blockade. Preclinically, PARP inhibition in HDR-deficient tumors has been shown to trigger antitumor immunity through a STING-dependent antitumor immune response. Effects of PARP inhibitors were augmented when combined with PD-1 blockade. We hypothesize that enhanced DNA damage and cell death induced by PARP inhibition in tumors with homology directed repair (HDR) deficiency will enhance adaptive anti-tumor immune responses and increase sensitivity to PD-1 axis blockers. **Methods:** This is a randomized, open-label phase II clinical trial exploring the PARP inhibitor olaparib either alone or in combination with the anti-PD-L1 human monoclonal antibody atezolizumab in BRCA1/2 mutated locally advanced or metastatic non-HER2-positive breast cancer. HDR deficiency is defined as the presence of deleterious BRCA 1/2 mutations. Randomization occurs in a 1:1 fashion to two arms: (1) olaparib 300 mg PO bid continuously in 21-day cycles or (2) olaparib 300 mg PO bid continuously in combination with atezolizumab 1200 IV every 3 weeks in 21-day cycles. Patients undergo baseline evaluations and pre-treatment biopsy within 2 weeks of starting therapy. Repeat biopsies are required at the time of first tumor assessment scan (6 weeks from the start of treatment) and in the event of disease progression. Correlative studies, including detailed analysis of the genomic profile and tumor immune contexture, will be performed at each biopsy time point. The primary objective is to compare progression free survival between the study arms. If progression occurs on the olaparib monotherapy arm, cross-over to the combination arm is allowed. This study began enrolling in August 2018; 47 of the planned 72 patients have been registered. Clinical trial information: NCT02849496. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

TPS1103 **Poster Session (Board #188), Fri, 8:00 AM-11:00 AM**

A phase I dose-escalation trial of alpha-tocopheryloxyacetic acid and concurrent trastuzumab in patients with treatment refractory HER2+ metastatic breast cancer. *First Author: William R Gwin, University of Washington, Seattle, WA*

Background: Metastatic HER2+ breast cancer, while initially responsive to trastuzumab, pertuzumab, and TDM-1, eventually progresses. The FDA recently approved trastuzumab deruxtecan, showing benefit in progression free survival but not in overall survival to date. Thus, additional therapies are needed for patients who progress on these HER2 directed agents. In metastatic HER2+ breast cancer, HER2-specific Th1 immune responses and higher CD4+ Th1 and CD8+ TIL levels are associated with a survival benefit. As this Type 1 immunity occurs in a minority of patients, additional immune modulation is needed. Alpha-tocopheryloxyacetic acid (α-TEA) has been reported to augment Type 1 immunity through increasing activated effector memory CD4+ and CD8+ T cells and decreasing immune suppressive CD4+CD25+ regulatory T cells in the tumor microenvironment. When given concurrently with an anti-HER2 antibody (7.16.4) in a pre-clinical tumor model, α-TEA synergized with 7.16.4 to induce tumor regression. We hypothesize that α-TEA and trastuzumab combination therapy in metastatic HER2+ breast cancer will be well tolerated, induce a clinical response, and augment anti-tumor Th1 immunity. **Methods:** *Trial Design*: Phase I dose escalation trial of α-TEA in combination with trastuzumab. Patients with metastatic HER2+ breast cancer will receive one of four doses sequentially of α-TEA: 0.6 mg/kg, 1.2 mg/kg, 2.4 mg/kg, and 4.8 mg/kg. Toxicity is assessed at baseline and through end of study. Blood and tumor tissue will be collected for immunologic monitoring and evaluation. Clinical response will be evaluated according to RECIST 1.1. *Eligibility:* Patients with progressive metastatic HER2+ breast cancer who have previously progressed on trastuzumab/pertuzumab and TDM-1. *Specific Aims*: Determine: (1) safety of four escalating doses of α-TEA with concurrent trastuzumab, (2) clinical response rate of α-TEA with concurrent trastuzumab (3) if concurrent α-TEA and trastuzumab increases activated effector memory CD4+ and CD8+ T cells, and (4) if concurrent α-TEA and trastuzumab increase the number of HER2-specific T cells. *Statistical Methods*: (1) The sample size of 24 and cohort size of 6 are determined by simulation experiments and practical consideration, (2) clinical response will be evaluated; overall PFS and OS will be calculated, (3) activated effector memory CD4+ and CD8+ T-cells will be analyzed (4) HER2-specific IFN-g/IL-10 ratios will be evaluated. *Targeted Accrual:* Twenty-four (24) patients. Clinical trial information: NCT04120246. Research Sponsor: Veana Therapeutics, Inc.

TPS1104 **Poster Session (Board #189), Fri, 8:00 AM-11:00 AM**

SGNLVA-001: A phase I open-label dose escalation and expansion study of SGN-LIV1A administered weekly in breast cancer. *First Author: Heather Christine Beckwith, Univ of Minnesota, Minneapolis, MN*

Background: LIV-1 is a highly prevalent transmembrane protein in breast cancer cells. Ladiratuzumab vedotin (LV), SGN-LIV1A, is an investigational antibody-drug conjugate (ADC) that targets LIV-1 via a humanized IgG1 monoclonal antibody conjugated to monomethyl auristatin E (MMAE) by a protease-cleavable linker. LV is internalized when it binds LIV-1 on cell surfaces and MMAE is released, which binds tubulin and induces apoptosis. LV has been shown to be active and tolerable in metastatic breast cancer (mBC) at a recommended dose of 2.5 mg/kg every 21 days (Modi 2017). More frequent, fractionated dosing has improved the activity and/or safety of other ADCs. Thus, this study is actively accruing subjects with metastatic triple negative breast cancer (mTNBC; estrogen receptor (ER)/progesterone receptor (PR)/human epidermal growth factor receptor 2 (HER2) receptor-negative) and endocrine-resistant ER+ or PR+ (hormone receptor [HR+])/HER2-negative mBC to test weekly dosing of LV (Days 1, 8, and 15 of every 3-week cycle). **Methods:** This study is enrolling up to 82 subjects (42 HR+/HER2-negative and 40 mTNBC) into dose escalation and dose expansion cohorts (NCT01969643). Eligible subjects are females $\geq$18 years old with pathologically and radiologically confirmed metastatic HR+/HER2-negative or mTNBC with at least 1 measurable lesion per RECIST v1.1. Subjects with HR+/HER2-negative disease must have received no more than 1 prior line of cytotoxic chemotherapy in the locally advanced (LA)/mBC setting, either as single agent or combination therapy. Subjects with mTNBC must have received 1 prior line of cytotoxic chemotherapy in the LA/mBC setting. Progression within 6 months of completion of neoadjuvant or adjuvant therapy is considered an LA/mBC regimen. Subjects must have adequate organ function, ECOG status of $\leq$1, and no $\geq$ Grade 2 peripheral neuropathy. Subjects with brain lesions must have received definitive treatment of the lesions. Prior therapy with MMAE-containing agents is not allowed. Dose escalation follows the modified toxicity probability interval method (Ji 2010). Dose expansion cohorts will provide data about activity and tolerability. Tumor assessments will be conducted every 2 cycles per RECIST v1.1 and all subjects will be followed for safety. Pharmacokinetics and markers of pharmacodynamics will be assessed. Primary safety endpoint is the incidence of adverse events and dose-limiting toxicities. Key efficacy endpoints include confirmed overall response rate, duration of response, and progression-free survival. Clinical trial information: NCT01969643. Research Sponsor: Seattle Genetics Inc.

TPS1105 **Poster Session (Board #190), Fri, 8:00 AM-11:00 AM**

A phase II trial of nivolumab (NIVO) + abemaciclib (ABE) or palbociclib (PAL) + anastrozole (ANA) in postmenopausal women and men with estrogen receptor (ER)+/human epidermal growth factor 2 (HER2)- primary breast cancer (BC): CheckMate 7A8. *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Cyclin-dependent kinase 4/6 (CDK 4/6) inhibition coupled with ER signaling blockade is an efficient treatment approach for patients (pts) with metastatic hormone receptor-positive, HER2− BC. Preclinical data suggest synergistic activity of CDK 4/6 inhibition and PD-1 blockade; in a syngeneic mouse tumor model, improved efficacy and complete tumor regression were observed with phased administration of ABE + PD-L1 therapy. **Methods:** CheckMate 7A8 (NCT04075604) is a randomized, noncomparative, multicenter, phase 2 study evaluating (NIVO) + PAL + ANA in postmenopausal pts with ER+, HER2− primary BC. After determining safe doses for NIVO combination regimens in the safety run-in phase, pts will be randomized in a 4:4:3 ratio to 1 of 3 treatment arms (Table) stratified by PD-L1 expression, node status and tumor size. Following treatment, all pts will undergo surgery and safety follow-up. Eligible pts are postmenopausal women and men with newly diagnosed, untreated, histologically confirmed ER+, HER2− BC with primary tumor $\geq$ 2 cm; suitable for neoadjuvant endocrine monotherapy and surgery; ECOG PS of 0–1; have baseline tumor tissue available; willing to undergo on-treatment research biopsy and tissue collection at surgery. Primary endpoints are number of pts with occurrence of dose-limiting toxicity (safety run-in phase) and residual cancer burden 0–I rate by central assessment at time of definitive surgery (randomized phase). Secondary endpoints include safety and tolerability, pathologic complete response, objective response rate and breast-conserving surgery rate. Key exploratory endpoints include biomarkers indicative of pharmacodynamic changes and potentially predicting treatment sensitivity. Interim analyses are planned. The study is currently enrolling. Clinical trial information: NCT04075604. Research Sponsor: Bristol-Myers Squibb.

Treatment arms in the safety run-in and randomized phases.

Safety run-in phase	NIVO + PAL 3 wks on 1 wk off + ANA × 5 cycles
Randomized phase	
Arm A	NIVO + PAL 3 wks on 1 wk off + ANA × 5 cycles
Arm B	PAL 3 wks on 1 wk off + ANA × 1 cycle then NIVO + PAL 3 wks on 1 wk off + ANA × 4 cycles
Arm C	PAL 3 wks on 1 wk off + ANA × 5 cycles
	ANA, 1 mg orally once daily; NIVO, 480 mg intravenously every 4 wks; PAL, 125 mg orally once daily

TPS1106 **Poster Session (Board #191), Fri, 8:00 AM-11:00 AM**

[OPTIMAL 3] A phase III trial to evaluate the efficacy and safety of DHP107 (Liporaxel, oral paclitaxel) compared to Taxol (IV paclitaxel) as first line therapy in patients with recurrent or metastatic HER2 negative breast cancer (BC) (NCT03315364). *First Author: Sung-Bae Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Paclitaxel is a microtubule-stabilizing drug used for various cancers including breast cancer (BC) and gastric cancer (GC). DHP107 is an oral paclitaxel solution formulated with non-toxic excipients using DH-LASED technology, which doesn't require pre-treatment. DHP107 demonstrated comparable efficacy and safety to IV paclitaxel for patients with advanced GC (Ann Oncol 2018), and was market approved as the first oral paclitaxel in 2016 for GC in Korea. In previous OPTIMAL phase II study, the primary endpoint objective response rate (ORR) was 54.5% in HER2 negative metastatic BC (MBC) patients and 44.4% in triple negative BC (TNBC) patients. Disease control rate (DCR) was 90.9% by the investigators' assessment. Toxicity was manageable (2019 ESMO). OPTIMAL phase III is being conducted in Korea, China and Eastern Europe based on this result and another phase II study (OPERA) is being performed in USA. **Methods:** OPTIMAL 3 study is a multinational, multi-center, randomized and open-label trial enrolling HER2 negative (HR+/HER2- or TNBC) recurrent or metastatic BC patients. Patients are randomized to either study (DHP107) or control group (IV paclitaxel) in a 1:1 ratio and stratified by disease free interval (DFI$\leq$48 weeks vs >48 weeks), visceral metastasis status (visceral vs non-visceral) and country. Patients are administrated with DHP107 (200mg/m^2 p.o. bid) or IV paclitaxel (80mg/m^2 infused) on D1, 8, 15, q4wks. Tumor assessments are performed on every 8 weeks ($\pm$7 days) from C1D1 until disease progression (RECIST V1.1). Key inclusion & exclusion criteria are hormone receptor (ER/PR) positive or negative, HER2 negative, ECOG performance status $\leq$1 and no prior chemotherapy in recurrent or metastatic disease. The primary endpoint is progression free survival (PFS). Secondary endpoints include ORR, overall survival (OS), time to treatment failure (TTF), DCR, quality of life (QoL) and safety. Total target number of patients is 476 with an estimated 10% drop-out rate. The test is based on non-inferiority hypothesis (HR=1.33) with 80% power. The primary endpoint will be analyzed using a one-sided test at a 2.5% significance level, and other endpoints will be analyzed using a two-sided test at a 5% significance level, with 95% confidence interval. The first subject was enrolled in Jan 2019 and recruitment is ongoing and is expected to be completed in Dec 2020. Final results of this study will be announced by the end of 2022. Clinical trial information: NCT03315364. Research Sponsor: DAEHWA Pharmaceutical Co,.Ltd.

TPS1107 **Poster Session (Board #192), Fri, 8:00 AM-11:00 AM**

Phase II trial of SAR439859 vs endocrine monotherapy in pre- and postmenopausal, estrogen receptor-positive (ER+)/human epidermal growth factor receptor 2-negative (HER2-), locally advanced or metastatic breast cancer (BC) with prior exposure to hormonal therapies. *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Endocrine therapy (ET) targeting ER signaling is the mainstay of care for ER+ metastatic BC. There remains an unmet need in patients (pts) whose tumors become resistant to currently available ET. Selective ER degraders (SERDs) were developed to overcome resistance to existing ER-directed therapies by both competitively antagonizing and degrading ERs, while exploiting continued dependence of the tumor on ER signaling. SAR439859 is a potent SERD with robust preclinical ER degrading activity. In a Phase I dose escalation trial, SAR439859 demonstrated a favorable safety profile with no dose-limiting toxicities across all doses (20–600 mg QD). ER occupancy generally exceeded $>$ 87% with plasma concentrations $>$ 100 ng/mL. Overall response rate was 6.3% and clinical benefit rate was 50% (Campone. SABCS 2019. P5-11-02). The recommended Phase II monotherapy dose was 400 mg QD. **Methods:** This international, prospective, open-label, randomized Phase II study (NCT04059484; ACT16105) assesses safety and efficacy of SAR439859 in pts with ER+ ($>$ 1%)/HER2- metastatic or locally advanced BC progressing on $\geq$ 6 months of continuous ET (0–2 lines in the metastatic setting). Prior CDK inhibitors are allowed. Exclusion criteria include Eastern Cooperative Oncology Group performance status (ECOG PS) $\geq$ 2, life expectancy $<$ 3 months, $>$ 1 chemotherapy or targeted therapy in the metastatic setting, concomitant illness and factors potentially affecting SAR439859 absorption. Pts are randomized 1:1 to SAR439859 400 mg QD orally or physician's choice of endocrine monotherapy (fulvestrant, tamoxifen, aromatase inhibitor). Pts receive 28-day cycles until unacceptable toxicity, progression, death, investigator decision or pt request. Stratification factors include visceral metastases, prior CDK4/6 inhibitors, and ECOG PS. Primary endpoint is progression-free survival (RECIST v1.1). Secondary endpoints include overall survival, response rate, duration of response, clinical benefit, pharmacokinetics, quality of life and safety. Target enrollment: n = 282; current enrollment: n = 9. Funding: Sanofi Clinical trial information: NCT04059484. Research Sponsor: Sanofi.

TPS1108 **Poster Session (Board #193), Fri, 8:00 AM-11:00 AM**

Phase II preoperative window study of SAR439859 versus letrozole in postmenopausal women with newly diagnosed estrogen receptor-positive (ER+)/human epidermal growth factor receptor 2-negative (HER2-) breast cancer. *First Author: Mario Campone, Institut de Cancérologie de l'Ouest, René Gauducheau, St Herblain, France*

Background: Endocrine therapy targeting ER signaling is the standard of care for women with ER+ breast cancer. Selective ER degraders (SERDs) block ER signaling through dual competitive antagonism and receptor degradation. SAR439859, a potent, oral SERD, is in clinical development for ER+/HER2- breast cancer. This study is a 14-day preoperative non-therapeutic 'window of opportunity' trial to assess the direct effects of SAR439859 on tumor cell proliferation by evaluating the pharmacodynamic activity of SAR439859 in ER+/HER2- breast cancer. **Methods:** This international, open-label, Phase II randomized study (NCT04191382; ACT16106) evaluates SAR439859 at two dose levels versus the aromatase inhibitor letrozole by assigning 126 preoperative patients 1:1:1 to receive SAR439859 400 mg/day, SAR439859 200 mg/day or letrozole 2.5 mg/day. SAR439859 dosing is based on an ongoing Phase I/II study (NCT03284957; TED14856) in metastatic breast cancer (Campone. SABCS 2019. P5-11-02). Postmenopausal women with ER+/HER2- breast cancer indicated for immediate surgery (Stage I, Stage II or operable Stage III), Eastern Cooperative Oncology Group performance status 0–1 and Ki67 levels of $\geq$ 15% are eligible. Exclusion criteria include disorders potentially affecting absorption of SAR439859 or letrozole, and any prior therapy for breast cancer. Patients receive study treatment for 14 days, with the last dose given on the day before surgery. Paired tumor biopsies for assessment of biomarkers are performed at baseline and during surgery. The primary study endpoint is change in Ki67, a predictor of treatment benefit and long-term survival outcomes, after 14 days of treatment compared with baseline. Secondary endpoints include proportion of patients with $\geq$ 50% decrease in Ki67, ER expression to assess degradation, and safety. Pharmacokinetics of SAR439859, additional tumor markers, genomic mutation profile, Preoperative Endocrine Prognostic Index and pathological Complete Response will also be assessed. The study is currently recruiting; target enrollment: n = 126. Clinical trial information: NCT04191382. Research Sponsor: Sanofi.

TPS1109 **Poster Session (Board #194), Fri, 8:00 AM-11:00 AM**

A phase III trial of capivasertib and paclitaxel in first-line treatment of patients with metastatic triple-negative breast cancer (CAPItello290). *First Author: Peter Schmid, Barts Cancer Institute, Centre for Experimental Cancer Medicine, London, United Kingdom*

Background: Therapeutic options for patients with metastatic triple-negative breast cancer (TNBC) are limited to sequential chemotherapy, although recent advances with novel agents have been made for specific subgroups (PD-L1 inhibitor atezolizumab in combination with nab-paclitaxel in patients with PD-L1-positive tumors and PARP inhibitors in patients with germline BRCA mutations). The PI3K/AKT/PTEN signaling pathway is often activated in TNBC, mainly through activating mutations in *PIK3CA* or *AKT1* and/or inactivating alterations in PTEN. The phase II PAKT study (NCT02423603) demonstrated that addition of the oral AKT inhibitor capivasertib to first-line paclitaxel resulted in significantly longer progression-free survival (PFS) and overall survival (OS) in patients with advanced TNBC, especially in patients with PIK3CA/AKT1/PTEN-altered tumors (Schmid et al, 2019). This phase III trial (NCT03997123) will further evaluate the efficacy and safety of capivasertib in combination with paclitaxel in first-line treatment of patients with metastatic TNBC in an unselected population and will also explore potential predictive markers of sensitivity to the combination of paclitaxel and capivasertib. **Methods:** Eligible patients for this double-blind, randomized, placebo-controlled trial must have metastatic TNBC or locally advanced disease not amenable to resection with curative intent. Patients must be candidates for single-agent taxane therapy and have received no prior systemic therapy for locally advanced inoperable or metastatic disease. Prior chemotherapy in the (neo)adjuvant setting must be completed $\geq$12 months prior to enrollment. Patients will be randomized 1:1 to paclitaxel 80 mg/m^2 (days 1, 8 and 15) with either capivasertib 400 mg twice daily or placebo (days 2–5, 9–12 and 16–19) every 28 days, until objective radiologic disease progression as defined by RECIST 1.1, unacceptable toxicity or death. Stratification factors will be prior adjuvant chemotherapy, visceral versus non-visceral disease, and geographic region. Post-randomization central testing of tumor tissue (collected prior to enrollment) will be carried out to identify predictive markers of sensitivity to treatment. The primary endpoints of this study are PFS and OS. Secondary endpoints include safety and tolerability, time to second progression or death, objective response rate, duration of response, and clinical benefit rate. Enrollment for this study started in May 2019. Clinical trial information: NCT03997123. Research Sponsor: AstraZeneca.

TPS1110 **Poster Session (Board #195), Fri, 8:00 AM-11:00 AM**

First-in-human phase I/Ib multicenter, open-label dose escalation study to assess safety and tolerability of PMD-026 in patients with metastatic breast cancer with expansion in metastatic triple negative breast cancer. *First Author: Muralidhar Beeram, START, San Antonio, TX*

Background: Metastatic triple negative breast cancer (mTNBC) has a poor prognosis with limited durable treatment options. RSK (P90 ribosomal S6 kinase) is a signaling protein at the convergence point of PDK-1 and MAPK signaling pathways. RSK1-3 phosphorylates transcription factors, including Y-box binding protein-1 (YB-1), thereby inducing drug resistance and cancer growth genes. Phosphorylated YB-1 is involved in tumor cell survival, proliferation, and drug resistance. In human breast tumor samples, RSK2 protein is expressed across all breast cancer subtypes (TNBC, ER+ and HER2+) and is associated with poor overall survival. Expression of RSK2 is found in approximately 87% of mTNBC tumors and of those tumors approximately 41% have very high expression of RSK2. PMD-026 is a potent, oral, small molecule RSK inhibitor with high selectivity for RSK2. Preclinical *in vivo* studies have demonstrated activity both as a single agent and in combination with standard of care therapies. Further, a CAP/CLIA certified IHC method has been developed with Roche to determine tumor expression of RSK2. **Methods:** This single-arm, open-label, first-in-human, phase I/Ib study evaluates the safety and efficacy of single agent PMD-026 in patients with metastatic breast cancer for whom standard therapies are no longer effective. During dose escalation, the study utilizes an accelerated titration design with single patient cohorts until the occurrence of DLT or Grade 2+ toxicity; then reverts to 3+3 design to define the maximally tolerated dose (MTD) and recommended phase II dose (RP2D). The dose expansion portion will enroll approximately 20 patients with mTNBC. Patients are dosed orally once daily in 21-day cycles with measures to adapt the dosing schedule based on the pharmacokinetic (PK) data, as needed. Tumor tissue is required for all enrolled patients; RSK2 expression will be retrospectively correlated with clinical outcomes. The primary objectives are to determine safety and tolerability of PMD-026, determine the MTD, define a RP2D, and assess anti-tumor activity of PMD-026 in patients with TNBC. Secondary objectives are to evaluate PK, time to response, mTNBC subtyping using NanoString, and duration of response of PMD-026. To date, cohorts 1 and 2 have been completed without DLT. Enrollment to cohort 3 began in January 2020. Clinical trial information: NCT04115306. Research Sponsor: Phoenix Molecular Designs.

TPS1111 Poster Session (Board #196), Fri, 8:00 AM-11:00 AM

CONTESSA TRIO: A multinational, multicenter, phase (P) II study of tesetaxel (T) plus three different PD-(L)1 inhibitors in patients (Pts) with metastatic triple-negative breast cancer (TNBC) and tesetaxel monotherapy in elderly pts with HER2-metastatic breast cancer (MBC). *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Chemotherapy treatments with robust efficacy that preserve quality of life are needed. T is a novel, oral taxane that has potential advantages over currently available taxanes, including: oral administration with a low pill burden and once every 3 week (Q3W) dosing; no observed hypersensitivity reactions; preclinical evidence of central nervous system (CNS) penetration; and improved activity against chemotherapy-resistant tumors. More than 600 pts have been treated with T in clinical studies. T had robust monotherapy activity in a P2 study in 38 pts with HER2-, HR+ MBC, with a confirmed objective response rate (ORR) per RECIST 1.1 of 45%. **Methods:** CONTESSA TRIO is a 2-cohort, multinational, multicenter, P2 study. In Cohort 1, 90 pts (potential expansion to up to 150 pts) with metastatic TNBC who have not received prior chemotherapy for advanced disease will be randomized 1:1:1 to receive T at 27 mg/m^2 Q3W plus either: (1) nivolumab at 360 mg Q3W; (2) pembrolizumab at 200 mg Q3W; or (3) atezolizumab at 1,200 mg Q3W. Nivolumab and pembrolizumab (PD-1 inhibitors) and atezolizumab (a PD-L1 inhibitor) are approved for the treatment of multiple types of cancer; atezolizumab, in combination with nab-paclitaxel, was recently approved in the US for the treatment of metastatic TNBC. The dual primary endpoints for Cohort 1 are ORR and progression-free survival (PFS). A sample size of 30 pts in each PD-(L)1 inhibitor treatment group has approximately 70% power to detect an ORR difference of $\geq$ 35% between the treatment group with the highest ORR and the treatment group with the lowest ORR. Secondary endpoints include duration of response (DoR) and overall survival (OS). Efficacy results for each of the 3 PD-(L)1 inhibitor combinations will be assessed for correlation with the results of each of the 3 approved PD-L1 diagnostic assays. CONTESSA TRIO is the first randomized clinical study to compare 3 approved PD-(L)1 inhibitors. In Cohort 2, 40 elderly pts (potential expansion to up to 60 pts) with HER2- MBC who have not received prior chemotherapy for advanced disease will receive T monotherapy at 27 mg/m^2 Q3W. The primary endpoint for Cohort 2 is ORR. A sample size of 40 will allow the ORR to be estimated with a maximum standard error of $<$ 8%. Secondary endpoints include PFS, DoR and OS. Pts with CNS metastases are eligible for both cohorts. The study was initiated in March 2019. Clinical trial information: NCT03952325. Research Sponsor: Odonate Therapeutics, Inc.

TPS1112 Poster Session (Board #197), Fri, 8:00 AM-11:00 AM

A phase II trial of atezolizumab (anti-PD-L1) with carboplatin in patients with metastatic triple-negative breast cancer (mTNBC). *First Author: Eric Michael Lander, Vanderbilt University Medical Center, Nashville, TN*

Background: Patients with metastatic triple negative breast cancer (mTNBC) have limited treatment options. Recent studies with a PD-L1 inhibitor and taxane based chemotherapy have demonstrated an increase in median progression free survival (PFS) in mTNBC. While taxanes target microtubules, platinum agents directly alkylate DNA and may generate additional neoantigens to enhance anti-tumor immunity via immune checkpoint inhibition. In this study, we are evaluating the combination of carboplatin with and without atezolizumab in patients with mTNBC. Serial biopsies are poised to help elucidate biological differences in responders and nonresponders. As optimal timing of adding checkpoint inhibition to chemotherapy is debatable, the randomized, crossover design will give insight into whether priming mTNBCs with DNA damaging chemotherapy results in cellular and immune changes that lead to a greater likelihood of response. **Methods:** This is a randomized phase II multicenter study at seven sites within the Translational Breast Cancer Research Consortium (TBCRC). Patients with mTNBC, ECOG 0-1, and 0-1 prior regimens for mTNBC are eligible. 106 patients will be randomized 1:1 to receive atezolizumab 1200 mg plus carboplatin AUC 6 (n = 53; Arm A) or carboplatin AUC 6 alone (n = 53; Arm B) every 3 weeks until intolerable toxicity or disease progression occurs. Patients receiving carboplatin alone have the option to cross over to atezolizumab upon progression (Arm Bx). Patients will undergo clinical assessment every cycle, and tumor assessment every 3 cycles with CT scan of the chest, abdomen, and pelvis and bone scan. Core biopsies of a metastatic lesion are performed at baseline and at progression. The primary endpoint is median progression free survival (PFS) with 95% confidence intervals based on RECIST 1.1. The sample size of 106 with 1:1 randomization is powered to detect a 1.5-month difference in PFS between arms (α = 0.10, β = 0.20). Secondary endpoints include overall response rate (ORR), duration of response (DOR), clinical benefit rate, and overall survival. The PFS, ORR, and DOR will also be measured by irRECIST to account for delayed effects of atezolizumab on tumor burden. The quantification of tumor infiltrating lymphocytes (TILs) will study the prognostic effects of TILs on PFS in patients receiving atezolizumab. Biopsy-derived PD-L1 expression by IHC and RNA-seq will assess treatment-induced changes, define triple-negative subtypes, and evaluate for resistance mechanisms. To date, 89 of 106 patients are enrolled. Clinical trial information: NCT03206203. Research Sponsor: Genentech, Conquer Cancer Foundation of the American Society of Clinical Oncology, Translational Breast Cancer Research Consortium; SPORE.

TPS1113 Poster Session (Board #198), Fri, 8:00 AM-11:00 AM

Phase II trial of a PARP inhibitor in somatic *BRCA* mutant metastatic breast cancer. *First Author: Neelima Vidula, Massachusetts General Hospital, San Francisco, CA*

Background: Poly(ADP-ribose) polymerase (PARP) inhibitors are now approved for patients with germline *BRCA1/2* mutated HER2 negative metastatic breast cancer (MBC). However, germline *BRCA1/2* mutations only account for 5-10% of breast cancer. We previously demonstrated that a subset of MBC may harbor somatic *BRCA1/2* mutations detectable by cell-free DNA (cfDNA) (Vidula, SABCS, 2017). We hypothesize that somatic *BRCA1/2* mutant MBC may also respond to PARP inhibition, similar to ovarian cancer, where PARP inhibition is efficacious in both somatic and germline tumors (Oza, 2017). **Methods:** This single arm, open label, phase II clinical trial is evaluating the efficacy of talazoparib, a PARP inhibitor, in 30 patients with somatic pathogenic *BRCA1/2* mutant MBC identified by cfDNA. Patients may have triple-negative disease with receipt of at least 1 prior chemotherapy regimen, or hormone receptor positive, HER2 negative disease with at least 1 prior hormone therapy for MBC. Patients may have received a prior platinum, in the absence of progression on platinum chemotherapy. Patients must not have a known germline *BRCA1/2* mutation. Patients will be treated with talazoparib 1 mg daily until progression, unacceptable toxicity, or withdrawal of consent, with clinical exams monthly, scans (CT chest, abdomen, and pelvis, and bone scan as appropriate) every 3 months, and serial cfDNA collected monthly. The primary endpoint is progression-free survival, as defined by RECIST 1.1. Subjects are enrolled in a 2-stage design, which provides 80% power to demonstrate that treatment is associated with "success" (PFS $>$ 12 weeks) in ^{3} 53% patients (4% alpha). Additional endpoints include objective response rate and toxicity (per NCI CTCAE version 5.0). Correlative endpoints include determining changes in *BRCA1/2* mutant allele fraction, genomic evolution including emergence of *BRCA* reversion mutations, and the impact of biomarker changes on outcomes. This trial is currently enrolling patients at the Massachusetts General Hospital. Successful completion of this study may help expand the patient population that is able to benefit from PARP inhibition. Clinical trial information: NCT03990896. Research Sponsor: Pfizer Aspire Award.

TPS1114 Poster Session (Board #199), Fri, 8:00 AM-11:00 AM

Immunotherapy and chemotherapy combination for chest wall disease: TBCRC 044 trial. *First Author: Neelima Vidula, Massachusetts General Hospital, San Francisco, CA*

Background: Immunotherapy combined with chemotherapy is being studied in metastatic breast cancer, and may have durable outcomes. Chest wall recurrence represents a difficult to treat subtype of breast cancer with a poor prognosis, with lymphovascular invasion in the primary tumor a significant risk factor. Given the inflammatory nature of this disease and the association of programmed cell death 1 (PD-1) expression with lymphovascular invasion, we hypothesized that the combination of pembrolizumab, an anti-PD-1 antibody, with carboplatin may be effective as treatment for breast cancer chest wall recurrences. **Methods:** This randomized phase II study is enrolling 84 patients with breast cancer involving the chest wall, who may also have distant metastases. Patients receive treatment with pembrolizumab 200 mg and carboplatin AUC 5 every 3 weeks for 6 cycles (Arm A, n = 56) followed by maintenance pembrolizumab +/- carboplatin (Arm Ax), or carboplatin AUC 5 every 3 weeks for 6 cycles (Arm B, n = 28) with an option to cross-over to pembrolizumab +/- carboplatin on progression (Arm Bx). Patients with all disease subtypes, triple-negative, hormone receptor positive/HER2- after 2 prior lines of hormone therapy, and HER2+ disease (with the option to continue trastuzumab) are eligible, with no limit on the number of prior therapies. Prior platinum chemotherapy is allowed in the absence of overt disease progression. Patients undergo clinical assessment with every cycle of treatment including chest wall photography, scans (CT chest, abdomen, and pelvis) every 2 cycles, and have peripheral blood and chest wall biopsies collected at baseline and the start of cycle 3 for correlative studies. The primary endpoint is the disease control rate in the chest wall and distant sites at 18 weeks of treatment based on RECIST 1.1. The study is powered to determine a 20% difference in disease control between arms (hazard ratio 0.52, α = 0.10, β = 0.20). Additional endpoints include response by tumor programmed death ligand 1 (PD-L1) status and irRECIST, progression-free survival, and toxicity. Chest wall tumor samples will be analyzed for changes in tumor immune composition, and PD-L1 and MYC oncogene expression, based on preclinical data to suggest that PD-L1 may be upregulated by MYC. Peripheral blood samples will be evaluated for changes in PD-L1 expression, cell-free DNA, and circulating tumor cells with treatment. The study is enrolling patients at 7 sites within the Translational Breast Cancer Research Consortium (TBCRC), with current enrollment of 38/84 patients. Clinical trial information: NCT03095352. Research Sponsor: Grants from Merck, UCSF Breast Oncology Development Grant.

TPS1115 Poster Session (Board #200), Fri, 8:00 AM-11:00 AM

B-TREUH: A single-arm phase II pilot study of euthyroid hypothyroxinemia in metastatic breast carcinoma. *First Author: Shruti Trehan, Aultman Hosp Cancer Ctr, Canton, OH*

Background: It is estimated that there are approximately 155,000 people living with metastatic breast cancer in the US. Studies exploring the connection between hypothyroidism or hyperthyroidism and breast cancer have yielded varying results with up to 33% prevalence of thyroid disease in these patients. L-thyroxine (T4) is the most commonly prescribed agent in the US to manage hypothyroidism. However, there are data suggesting that T4 is a pro-oncogenic agent with proposed mechanisms such as stimulation of mitogenesis, angiogenesis, resistance to apoptosis. In addition, T4 May counter anti-PDL-1 and radiation effects. Triiodothyronine (T3), which is deiodinated form of T4 and also commercially available, is felt to be less oncogenic and less mitogenic. Therefore, exogenous supplementation of T3 would decrease the T4 levels creating the desired state of EUTHYROID HYPOTHYROXINEMIA. The study hypothesizes that replacing L-thyroxine (T4) with Triiodothyronine (T3) in hypothyroid patients with metastatic breast carcinoma, while they simultaneously continue to receive standard systemic therapy, with titrating T3 dose to achieve a state of Euthyroid Hypothyroxinemia would result in improved disease outcomes. **Methods:** Eligible participants are adults with metastatic breast carcinoma with estimated life expectancy of $>$ 3months, hypothyroidism, and with normal TSH on L-thyroxine (T4). Following consent, participants will discontinue L-thyroixne (T4) and initiate Triiodothyronine (T3) dose based on current T4 dose after an appropriate washout period. Drug titration will be in accordance with thyroid function testing to maintain levels of free T4 at $<$ 50% normal range. The treatment period will continue for 9 months with periodic assessment of disease status, quality of life (FACT-B) and laboratory measures. The primary endpoint is the progression free survival at 12 months while the secondary endpoints are prevalence of hypothyroidism in the cohort, overall survival, quality of life, and duration of time to achieve the Euthyroid Hypothyroxinemia state. Given many uncertainties to calculate power precisely, the sample size is estimated to be approximately 30 patients. Clinical trial information: NCT03787303. Research Sponsor: None.

1500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Targeted therapy based on germline analysis of tumor-normal sequencing (MSK-IMPACT) in a pan-cancer population. *First Author: Zsofia Kinga Stadler, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor mutational profiling for identification of somatic alterations for targeted treatment is increasingly being performed in advanced cancer patients (pts). We sought to assess the clinical utility of germline mutation profiling for targeted therapeutic interventions in a pan-cancer patient population. **Methods:** All pts who had germline genetic testing through a prospective protocol via a next-generation sequencing panel (MSK-IMPACT) were identified (N=11,975) from 2015-5/2019. The medical record of pts with likely pathogenic/pathogenic germline (LP/P) alterations in genes with known therapeutic targets were reviewed to identify germline-targeted treatment either in a clinical or research setting. **Results:** We identified 2,043 (17.1%) pts who harbored LP/P variants in a cancer predisposition genes including 777 (6.5%) in genes with potentially targetable therapeutic implications: 416 *BRCA1/2,* 149 DNA mismatch repair genes (Lynch syndrome, LS), 122 *ATM*, 45 *PALB2*, 26 *RAD51C/D*, 7 *RET*, 4 *TSC*, 3 *PTCH1*, 2 *ALK*, 1 *EGFR*, 1 *MET* and 1 *KIT*. Of those with advanced disease (n=554), 45.3% received targeted therapeutic treatment (Table) including 50.9% BRCA1/2, 58.3% LS (67.4% of microsatellite-high LS cases), 41.7% *PALB2*, 36.8% RAD51C/D and 19.3% *ATM* carriers. Of patients receiving a poly (ADP-ribose) polymerase inhibitor (PARP-I) in the setting of a *BRCA1/2* mutation, 55.1% had breast or ovarian cancer; however, 44.8% had other tumors, including pancreas, prostate, bile duct, gastric, wherein the drug was given in a research setting. Among *PALB2* pts receiving PARP-Is, 53.3% (8/15) had breast or pancreas cancer; 46.7% had cancer of the prostate, ovary or unknown primary. **Conclusions:** In our pan-cancer analysis, 6.5% of pts harbored a targetable germline variant highlighting the importance of germline analysis in advanced cancer pts for selection of both FDA-approved treatments and clinical trial participation with germline-targeted therapeutics. Research Sponsor: Internal MSK Funding.

Gene(s) with potential targetable therapy	Drug Class	% of advanced cancer patients receiving targeted therapy
BRCA1, BRCA2	PARP-I	50.9% (165/324)
Lynch syndrome (*MLH1, MSH2, MSH6, PMS2, EPCAM*)	Checkpoint-inhibitors	58.3% (42/72) (irrespective of MSI) 67.4% (29/43) (MSI-High)
ATM	PARP-I	19.3% (17/88)
PALB2	PARP-I	41.7% (15/36)
RAD51C, RAD51D	PARP-I	36.8% (7/19)
RET	Tyrosine kinase inhibitor	60% (3/5)
TSC	mTOR inhibitor	0% (0/3)
PTCH1	Hedgehog-signaling inhibitor	33.3% (1/3)
ALK	ALK kinase inhibitor	0% (0/2)
EGFR	EGFR inhibitor	100% (1/1)
MET	MET kinase inhibitor	0% (0/1)

1501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Tumor/normal genomic profiling in patients with metastatic solid tumors identifies pathogenic germline variants of therapeutic importance. *First Author: Erin Frances Cobain, University of Michigan, Ann Arbor, MI*

Background: Tumor molecular profiling via next-generation sequencing (NGS) is routinely utilized to direct patients toward clinical trials of targeted therapeutics. NGS testing of paired tumor/normal samples identifies incidental pathogenic germline variants (PGVs), having potential implications for patients and their families. **Methods:** From 2011-2018, 1,015 patients with metastatic, refractory solid tumors underwent targeted (1700 genes) exome and transcriptome sequencing of matched tumor/normal samples through the Michigan Oncology Sequencing program. Identified PGVs that conferred increased cancer risk or were associated with certain autosomal recessive conditions were reported to the treating oncologist. Chart reviews were conducted every 3 months to assess whether PGV identification impacted treatment decision making. **Results:** 169 PGVs were identified in 160 unique patients (15.8% of cohort). 69 PGVs (41%) harbored a clear somatic second hit event in the tumor. PGVs associated with defects in double-strand DNA repair (*BRCA1, BRCA2, ATM, PALB2, BRIP1)* or DNA mismatch repair (*MLH1, MSH2 and PMS2*) were identified in 49 patients (5% of cohort, 31% of patients with PGVs), 37 of which had not previously been identified. 14 PGVs in DNA double-strand repair and 7 PGVs in DNA mismatch repair were identified in cancer types not commonly associated with hereditary breast ovarian cancer or Lynch syndromes, including cancers of unknown primary origin and sarcomas. 7 patients received a PARP inhibitor (PARPi), 3 patients received an immune checkpoint inhibitor (ICI) and 1 patient received both PARPi and ICI therapy on the basis of a PGV in DNA repair. 6 patients achieved clinical benefit, defined as time on treatment $\geq$ 6 months. A patient with cancer of unknown primary origin and PGV in MSH2 achieved exceptional response to ICI therapy, with complete response ongoing and lasting 23 months. **Conclusions:** Targeted NGS of matched tumor/normal samples identified PGVs in about 1 in every 6 patients with metastatic solid tumors. Approximately 40% of PGVs are associated with a somatic second hit in the tumor, supporting their role in tumor pathogenesis. Unexpected PGVs with therapeutic implications are identified in patients with diverse cancer types, providing opportunities to use targeted therapies with potential for significant clinical benefit. Given this finding, testing for PGVs in DNA repair genes should be considered in all patients with metastatic solid tumor malignancies. 1502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Characterization of patients with multiple primary tumors. *First Author: Karen Anne Cadoo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: 17% of patients (pts) with a cancer diagnosis in the U.S. have a prior malignancy. We sought to characterize pts with multiple (≥2) primary cancers (MPC) & identify potential drivers of cancer risk to guide management. **Methods:** Pts prospectively consented (1/2013-2/2019) to tumor-normal sequencing via custom targeted NGS panel. A subset consented to testing of >76 germline cancer predisposition genes. IARC 2004 rules for defining MPC were applied.Age adjusted gender specific standardized incidence ratios (SIR) for cancer event combinations occurring in at least 5pt were calculated using R statistical package. **Results:** Of 24417 pts sequenced, 4341 had MPC (18%). (Table) 3465 (80%) had 2, 4% had >4 cancers. Cancer pairs where SIR of 2nd cancer was higher than expected included: colon-colon, prostate-pancreas, bladder-prostate in men & lung-lung, breast-pancreas, thyroid-pancreas in women. 1580 (36%) pts had germline testing; 324 (21%) had 361 pathogenic/likely pathogenic (P/LP) variants (vts). Of these, 157 (48%), 66(20%), pts had high, moderate penetrance vts. The remainder had low penetrance, recessive or vts of uncertain utility. Of pts with high penetrance vt, 132 (84%) had at least one tumor type concordant with germline findings. **Conclusions:** 18% of pts in this cohort had MPC. There was a significant excess over expected incidence in some cancer combinations. Of pts with germline testing, 21% had a P/LP vt, with most (69%) being high or moderate penetrance. Assessment for loss of heterozygosity in tumor & germline sequencing of the full MPC cohort is ongoing. Research Sponsor: Robert and Kate Niehaus Center for Inherited Cancer Genomics.

1503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Performance of the IBIS/Tyrer-Cuzick (TC) Model by race/ethnicity in the Women's Health Initiative. *First Author: Allison W. Kurian, Stanford School of Medicine, Stanford, CA*

Background: The TC model, a breast cancer (BC) risk assessment tool based on family cancer history, reproductive and lifestyle factors is used to guide BC screening and prevention. TC was developed and validated largely in non-Hispanic White (NHW) women. We evaluated the calibration and discrimination of TC version 7.02 among racially/ethnically diverse post-menopausal women enrolled in the Women's Health Initiative (WHI) clinical trials or observational study. **Methods:** WHI enrolled post-menopausal women from 1993-1998 and followed them prospectively for BC incidence. We included women aged ≤80 years at enrollment with no prior BC or mastectomy and with data required for TC, including weight, height, ages at menarche, first birth and menopause, menopausal hormone therapy use and family history of breast or ovarian cancer in first or second-degree relatives. Calibration was assessed by the ratio of observed BC cases to the number expected by TC (O/E), with expected cases calculated as the sum of cumulative hazards. We tested for differential discrimination by race/ethnicity (NHW, African American, Hispanic, Asian/Pacific Islander, Native American, other) using Cox regression. Time to BC was modeled using age, race/ethnicity, TC estimate (transformed by log of relative lifetime risk), and a term for interaction between race/ethnicity and TC estimate. **Results:** During the follow-up period (median 18.9 years, maximum 23.4 years), 6,836 new BC cases were diagnosed among 91,893 women. TC was well-calibrated overall (O/E 0.95) in NHW and African Americans, but over-estimated risk for Hispanics (O/E 0.75, Table). Results suggested good calibration for Asian/Pacific Islanders and Native Americans, but sample sizes were small. Discrimination did not differ significantly by race/ethnicity (two-sided p-value for interaction = 0.33). **Conclusions:** TC provided similar risk discrimination among post-menopausal women of different racial/ethnic groups over nearly 20 years of follow-up; however, it overestimated risk for Hispanics. Future studies in diverse populations are warranted, with need for a more accurate breast cancer risk assessment tool for Hispanics. Research Sponsor: Myriad Genetics, U.S. National Institutes of Health.

Race/Ethnicity	N	Observed (O) BC cases	Expected (E) BC cases	Calibration (O/E Ratio) (95% CI)
NHW	80,260	6133	6408.6	0.96 (0.93-0.98)
African American	5903	373	411.0	0.91 (0.82-1.00)

1504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Comprehensive breast cancer (BC) risk assessment for CHEK2 carriers incorporating a polygenic risk score (PRS) and the Tyrer-Cuzick (TC) model. *First Author: Shannon Gallagher, Myriad Genetics, Inc., Salt Lake City, UT*

Background: Women with pathogenic variants in the moderate penetrance *CHEK2* gene have on average an estimated > 20% lifetime risk for breast cancer, thereby meeting an established threshold for more aggressive screening, including consideration of breast magnetic resonance imaging (MRI). However, we previously showed that *CHEK2* penetrance is modified by an 86-SNP PRS. *CHEK2* risk is further modified by family history (FH) and other TC model variables. Here, we describe development of a comprehensive risk prediction model for women of European ancestry to more precisely estimate risk by incorporating *CHEK2*, PRS and TC V7.02. The number of *CHEK2* carriers with low (< 20%), moderate (20%-50%) and high (> 50%) remaining lifetime risk based on the combined model was examined in an independent study cohort. **Methods:** This IRB-approved study included de-identified clinical records from 358,471 women of European ancestry who were tested clinically for hereditary cancer risk with a multi-gene panel. Model development was based on analysis of *CHEK2* PV carriers (*N*= 4,331) and women negative for BC gene PV (*N* =353,681) who were tested between September 2013 and July 2019. Risk estimates incorporating *CHEK2*, PRS and TC were calculated using a fixed-stratified (FS) method that accounts for correlations between risk factors in a manner equivalent to multivariable co-estimation. Risk stratification was assessed in an independent cohort of *CHEK2* carriers (*N*= 459) who were tested after July 2019 and not included in model development. **Results:** We detected significant correlation of *CHEK2* status with FH ($p = 4.1 \times 10^{-17}$) and of PRS with FH among *CHEK2* carriers ($p = 1.7 \times 10^{-5}$). For these factors, joint effects were co-estimated using the FS method. In an independent cohort, 24.0% of *CHEK2* carriers were categorized as low risk (< 20%), and 62.6% were categorized as moderate risk (20-50%). For 13.4% of *CHEK2* carriers, risk estimation incorporating PRS and TC generated BC risks of greater than 50%, consistent with genes recognized as highly penetrant. **Conclusions:** In *CHEK2* PV carriers, comprehensive risk assessment could inform individualized decision-making and may lead to improved targeting of screening and prevention strategies. Research Sponsor: Myriad Genetics.

1505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

BARCODE 1: A pilot study investigating the use of genetic profiling to identify men in the general population with the highest risk of prostate cancer to invite for targeted screening. *First Author: Ros A. Eeles, Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Genetic profiling could be used to target population screening for prostate cancer (PrCa). Approximately 170 single nucleotide polymorphisms (SNPs) have been identified that associate with PrCa development. Although these confer a low to moderate risk of PrCa, the risk is cumulative with increasing number of risk alleles. BARCODE1 is the first study to prospectively investigate the use of a genetic profile in PrCa screening in the UK general population. **Methods:** A custom Eurek Genomics (EG) SNP assay was developed. Healthy males aged 55-69 were invited to participate via their General Practitioners (GPs). Saliva samples were collected via mailed collection kits. After DNA extraction, genotyping was conducted using the EG assay and a polygenic risk score (PRS) was calculated for each participant. The PRS was calculated using the sum of the weighted alleles for 130 risk loci. Men in the top 10% of the genetic risk profile were invited for prostate MRI and biopsy at the Royal Marsden Hospital (RMH) in London. **Results:** Invitation letters were sent to 1434 men; overall uptake was 26% (range 13%-47%). 87% of responders were eligible for study entry. DNA was extracted from 303 samples and genotyped. Data were available for 285 men following QC. Mean PRS was 10.33 with a standard deviation of 0.64; twenty-five participants with a PRS above the 90^{th} centile were identified for screening with MRI and prostate biopsy. Of these men (after exclusions due to medical comorbidity/invitations declined) 9 out of 20 had an abnormal MRI (45%) and 18 men underwent biopsy with 7 diagnoses of PrCa (38.8%). All cancers were low-risk with a mean PSA of 1.8 and were managed with Active Surveillance (AS). There were two adverse events following biopsy, both simple lower urinary tract infections managed with oral antibiotics. Average duration of follow-up is 4.5 months (range 1-11). **Conclusions:** Successful completion of recruitment has shown this community study to be feasible, with an average uptake of 26%. Approximately 70 GP sites have been identified to allow a transition to the full BARCODE-1 study which will recruit 5000 men. The use of genetic profiles to guide PrCa screening is attractive; it requires a one-off test utilising germline DNA which can be assessed for risk loci which are constant, unlike PSA which fluctuates. The results of the BARCODE1 study will be important in defining the role of genetic profiling in targeted PrCa population screening. Research Sponsor: European research council.

1506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results from MAGENTA: A national randomized four-arm noninferiority trial evaluating pre- and post-test genetic counseling during online testing for breast and ovarian cancer genetic risk. *First Author: Elizabeth M. Swisher, University of Washington School of Medicine, Seattle, WA*

Background: Hereditary breast and ovarian cancer (HBOC) is preventable when genetic risk is identified. We aimed to test whether pre and/or post-test genetic counseling is needed to optimally deliver online accessible genetic testing. **Methods:** MAGENTA (Making GENetic Testing Accessible) is a four-arm non-inferiority trial evaluating electronic genetic education and results delivery alone or combined with pre-test only, or post-test only telephone genetic counseling compared to mandatory pre- and post-test counseling (control arm) in women at risk of HBOC (NCT02993068). Regardless of assigned arm, all subjects with a pathogenic mutation received post-test telephone counseling. All subjects were enrolled electronically as part of either a family history cohort (FHC) or a cascade cohort (CC, known familial mutation). The primary outcome was cancer risk distress at 3 months and the trial was powered for the FHC. Secondary outcomes included completion of testing (i.e., received results), anxiety, depression, quality of life, and decisional regret, all measured by standardized scales. **Results:** Enrollment is complete and a total of 3,822 participants were randomized, 3,111 in FHC and 711 in CC. Participants were enrolled from all 50 states, but most were white/non-Hispanic (88%). Among participants that completed genetic testing, 173 (7.2%) had a mutation in a breast or ovarian cancer gene, with 114 (5.7%) of FHC and 59 (14.2%) of CC. In the primary intention-to-treat analysis of FHC, each of the three experimental arms was non-inferior to the control arm for distress at 3 months ($p < 0.025/3 = 0.0083$). In the CC, no and pre-test only counseling were also non-inferior ($p < 0.025/3 = 0.0083$). Distress was lowest in the arm with neither pre nor post-test counseling. Overall, 318 (18%) participants had very high distress at three month follow-up, and this rate was not significantly different across arms. Anxiety, depression and decisional regret did not have statistically significant differences across arms at follow-up. Test completion was highest in the no counseling arm (86.4%) and lowest in the control arm (60.6%). **Conclusions:** Electronic genetic education and results release without genetic counseling was non-inferior with regard to patient distress and was associated with higher test completion and lower distress. These results support use of a genetic testing paradigm providing individualized genetic counseling only for patients with positive test results. Clinical trial information: NCT02993068. Research Sponsor: Stand up to Cancer.

1507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A randomized controlled trial of video-education or in-person genetic counseling for men with prostate cancer (ProGen). *First Author: Huma Q. Rana, Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Approximately 10% of men with advanced prostate cancer (PC) have pathogenic/likely pathogenic variants (PV) in cancer susceptibility genes and their identification may lead to targeted therapy. Genetic testing (GT) can also guide cancer surveillance and prevention for family members. While GT is recommended for men with potentially lethal PC, traditional testing models are strained, and access limited. The ProGen study examined a novel pretest model aimed at providing access to GT while promoting informed consent. **Methods:** Inclusion criteria were: potentially lethal PC (metastatic, localized with Gleason score ≥8, rising/persistent PSA after local therapy), diagnosis age ≤ 55 years, prior malignancy, family history suggestive of a PV and/or at oncologist's discretion. Consented subjects from 3 sites were randomized 3:1 to video education (VE) or in-person genetic counseling (GC). Subjects who consented to GT had 67 genes analyzed (Ambry, USA) with results disclosed by telephone by a genetic counselor. Outcomes included GT uptake, PV prevalence, and survey measures of satisfaction, distress, genetics knowledge, family communication, and impact on cancer care (obtained at the time of intervention, and at 1, 4, and 12 months after result disclosure). Two-sided Fischer exact tests were used for between-arm comparisons. **Results:** Over a 2-year period: 662 subjects were randomized, VE or GC were completed by 604 subjects (VE: 93.1%, GC: 88.8%) of whom 596 subjects (VE:98.9%, GC:97.9%) consented to GT. To date, 591 subjects have completed GT (VE: 99.3%, GC: 98.6%). At the time of intervention, most subjects agreed or strongly agreed that their assigned arm was useful (VE: 95%, GC: 88%). Differences were not statistically significant. Notably, 84 PV were identified in 78 subjects (13.2%), with *BRCA1/2* PV accounting for 32% of subjects with a positive result (*BRCA2*:21, *BRCA1*:4). **Conclusions:** In this randomized trial, both novel VE and traditional GC yielded high GT uptake without significant differences in outcome measures of acceptability and satisfaction. VE enabled access to critical GT results while maintaining the core tenants of informed consent. PV were found in 13.2% of subjects, 32% of whom had *BRCA1/2* PV. Analysis of collected survey data to inform strengths and limitations of VE as compared with pretest GC will be presented. Clinical trial information: NCT03328091. Research Sponsor: 2018 Medical Oncology Department Award.

1508 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Uptake of oophorectomy in women with findings on multigene panel testing: Results from the Prospective Registry of Multiplex Testing (PROMPT). *First Author: Susan M. Domchek, University of Pennsylvania, Philadelphia, PA*

Background: With the expansion of multigene panel testing for cancer susceptibility, increasing numbers of patients are identified with pathogenic/likely pathogenic variants (P/LP V) in genes which do not have a clearly actionable increased risk of ovarian cancer (OC) (lifetime risk of OC >5%). However, there is concern that patients and/or providers may ascribe OC risk to such genetic findings with the potential for unnecessary oophorectomy (ooph). **Methods:** The Prospective Registry of Multiplex Testing (PROMPT) is an online registry for individuals with a genetic alteration detected on multiplex panel testing for cancer susceptibility. Participants self-enroll and complete baseline and annual follow-up questionnaires. PROMPT has enrolled 7388 participants (6936; 93.9% women) since September 2014. **Results:** 1566 women in the PROMPT registry reported ooph, the indications for which were reported as either cancer treatment (n=481, 30.7%) or benign disease (n=432, 27.6%). An additional 186 (12.8%) reported PV in genes associated with lifetime OC risk >5% (*BRCA1, BRCA2, RAD51C, RAD51D, BRIP*, or Lynch syndrome genes). The remaining 467 did not have guideline based indications for ooph due to OC risk and are described further here. 92 (19.7%) had a variant of uncertain significance (VUS) in genes associated with OC, 241 (51.6%) had a personal history of breast cancer (BC) and no VUS in OC genes, and 119 (25.5%) had no personal history of BC and no VUS in OC genes. The majority of women had no family history (FH) of OC in first or second degree relatives (Table). Most ooph occurred prior to age 50. Of the 405 women with *CHEK2* P/LP, 11.4% reported ooph (59% under age 50 when age known), as did 13.2% (of 228) with *CHEK2* VUS, 8.8% (of 261) with *ATM* P/LP (66.7% under age 50), and 8.3% (of 387) with *ATM* VUS. In addition, of the 184 women with *PALB2* P/LP, 14.1% reported ooph (35.3% under age 50) as did 11.6% (of 198) with *PALB2* VUS. Of those who reported provider discussions, 47.2% stated "my provider recommended this" (including >60% in the OC gene VUS group) and an additional 25.2% stated "my provider presented this as an option, but not a requirement". In those with no FH of OC, 45.8% stated that their provider recommended ooph. **Conclusions:** 10-15% of women with PV/VUS in genes not associated with a high risk of OC reported ooph without a clear indication. Research Sponsor: Komen, Breast Cancer Research Foundation.

Underwent ooph	No reported FH OC	Ooph <50
VUS in gene associated with OC N=92	68.1%	51.5%
Personal history BC (no OC VUS) N=241	85.0%	58.7%
No BC, no OC VUS N=119	56.2%	73.0%

Vitamin D supplements and marine omega-3 fatty acids and development of advanced cancer. *First Author: Paulette Chandler, Brigham and Women's Hospital/Harvard Medical School, Boston, MA*

Background: Epidemiologic data suggest that vitamin D supplementation may reduce cancer mortality. We tested whether vitamin D and/or omega-3 supplementation reduces the incidence of advanced stage cancer at diagnosis or lethal cancer, and whether body mass index (BMI) modifies these associations. **Methods:** The VITamin D and OmegA-3 TriaL (VITAL) is a randomized, placebo-controlled, 2x2 factorial trial of vitamin D3 (cholecalciferol, 2000 IU/day) and marine omega-3 fatty acids (1 g/day) that enrolled men aged ≥50 years and women aged ≥55 years free of cancer and cardiovascular disease at baseline. For this particular analysis, the primary outcome is a composite of metastatic and fatal invasive total cancer. Secondary analyses included examination of BMI (<25, 25-<30, and >= 30 kg/m^2) as effect modifiers of the observed associations. **Results:** VITAL randomized 25,871 participants, among whom 1,617 were diagnosed with invasive cancer over a median 5.3 year intervention period. No significant differences by treatment arm (vitamin D vs placebo: hazard ratio [HR]=0.96; 95% confidence interval, 0.88-1.06; p=0.47; omega-3 vs placebo; HR 1.03 [0.93-1.13]; p=0.56) were observed. However, a significant reduction in advanced cancers (metastatic or fatal) was found for those randomized to vitamin D, compared to placebo (226 assigned to vitamin D and 274 to placebo; HR 0.83 [0.69-0.99]; p=0.036). There was no difference by omega-3 assignment (246 assigned to omega-3 and 254 to placebo: HR 0.97 [0.81-1.15], p=0.72). When stratified by BMI, there was a significant reduction for the vitamin D arm in incident metastatic or fatal cancer among those with normal BMI (BMI<25: HR 0.62 [0.45-0.86], but not among those who were overweight or obese (BMI 25-<30: HR 0.89 [0.68-1.17]; BMI >=30: HR 1.05 [0.74-1.49]); p for interaction by BMI =0.03. There was no effect modification by BMI noted for the omega 3 arm. **Conclusions:** In a randomized clinical trial, supplementation with vitamin D, but not omega-3s, reduced incidence of advanced (metastatic or fatal) cancer in the overall cohort, with strongest risk reduction in normal weight individuals. Further research is needed to understand these findings. Clinical trial information: NCT01169259. Research Sponsor: U.S. National Institutes of Health.

Complete human papillomavirus vaccination coverage over a 13-year period in a large population of privately insured U.S. patients. *First Author: Yull Edwin Arriaga, University of Texas Southwestern Medical Center, Dallas, TX*

Background: In the US, Human Papillomavirus (HPV) vaccination coverage is low, particularly in adolescents aged 13-15 years with respect to the Healthy People 2020 goal of 80%. There has been variability in the definition of measuring vaccination coverage in published studies. We examined complete HPV vaccination coverage in a population of privately insured individuals in the US. **Methods:** This retrospective study used IBM MarketScan Commercial Database, years 2006 to 2018. Inclusion criteria were ages 9 to 45 years and continuous enrollment from age 9 years or from 2006. Complete HPV vaccination coverage was defined as receipt of 2 doses (age 9-15 years) or 3 doses (age 16-45 years) within 12 months and stratified by year, demographics, and US region. Mean vaccination costs per dose were summarized by vaccine brand and health plan type. **Results:** The table summarizes complete HPV vaccination coverage by selected age groups for 2006 (n=12,221,938), 2010 (n=4,692,633), 2014 (n=2,808,132), and 2018 (n=1,662,148). From 2017 to 2018, the percentage of members who received HPV vaccine increased; for females ages 13-15 by 1% and 16-17 by 5% while for males ages 13-15 by 6% and 16-17 by 15%. In 2018, by region, the highest coverage was in females aged 18-26 at 53% and males aged 16-17 at 43% in the Northeast, and mean cost for each brand was $120 (-6% from 2017), $165 (-3%) and $220 (+5%) for Cervarix (n=151), Gardasil (n=8,201) and Gardasil 9 (n=139,356), respectively. The rate of utilization of Gardasil 9 increased from 33% (2015) to 94% (2018) of all vaccines. The lowest mean HPV vaccine cost by health plan type and brand was with Point-of-Service (POS) and Cervarix at $106, and the highest was with POS with Capitation and Gardasil 9 at $243. **Conclusions:** In a commercially insured US population, complete HPV vaccination coverage was lower than the Healthy People 2020 goal, but increased over time. Coverage varied according to health plan type and by region. In 2018, Gardasil 9 had the highest mean cost but was the most utilized vaccine, which may be related to broader coverage of HPV types. This study was limited by the transient nature of member enrollment and complexity of measuring complete vaccination coverage. These results should inform policy makers and practicing clinicians about the gap in vaccination coverage. Research Sponsor: IBM Watson Health.

Complete HPV vaccination coverage by year, sex, and age.

		Vaccination Coverage (%) by Year

Smoking cessation (SC) and lung cancer (LC) outcomes: A survival benefit for recent-quitters? A pooled analysis of 34,649 International Lung Cancer Consortium (ILCCO) patients. *First Author: Aline Fusco Fares, Princess Margaret Hospital, Toronto, ON, Canada*

Background: Tobacco smoking profoundly impacts LC risk; however, data are limited as to what extent SC prior to diagnosis impacts LC overall survival (OS) and lung cancer specific survival (LCSS). LC screening offers a possible teachable moment, but there is uncertainty of SC benefits after a lifetime of smoking. We use the ILCCO database to answer if SC prior to LC dx is associated with better OS and LCSS, considering time since smoking cessation (TSSC). **Methods:** Using individual data, analysis was performed on 17 ILCCO studies with available TSSC to estimate survival using univariable analysis and models of stage-adjusted and cumulative smoking-adjusted multivariable analysis. Adjusted Hazard Ratios (aHR) from Cox models, cubic spline smooth curves and Kaplan-Meier curves were created. Sensitivity analysis was performed for TSSC and LCSS on 13 studies. **Results:** Of 34649 patients, 14322 (41%) were current smokers 14273 (41%) ex-smokers and 6054 (18%) never smokers at diagnosis. We confirmed that ex-smokers (aHR 0.88 CI 0.86-0.91) and never smokers (aHR 0.76 CI 0.73-0.8) improved OS compared to current smokers. Amongst ex-smokers, < 2y TSSC (aHR 0.88 CI 0.82-0.94), 2-5y TSSC (aHR 0.83 CI 0.77-0.90) and > 5y TSSC (aHR 0.8 CI 0.76-0.84) had improved OS compared to CS. Sensitivity analysis showed a trend towards improved LCSS survival for < 2y TSSC (aHR 0.95 CI 0.86-1.05) and 2-5y TSSC (aHR 0.93 CI 0.83-1.04), whereas > 5y TSSC significantly improved LCSS by 15% (aHR 0.85 CI 0.78-0.92). To mimic the LC screening participants, in analysis of > 30 pack-years individuals, associations were strikingly strong: < 2y TSSC had improved OS by 14% (aHR 0.86 CI 0.80-0.93); 2-5y TSSC by 17% (aHR 0.83 CI 0.76-0.90); and > 5 TSSC by 22% (aHR 0.78 CI 0.74-0.83), compared to current smokers; for < 30 packs-years, a trend towards better OS was observed for < 2y TSSC (aHR 0.95 CI 0.92-1.02) and 2-5y TSSC (aHR 0.86 CI 0.74-1.01), whereas > 5y TSSC improved OS by 23% (aHR 0.77 CI 0.72-0.82). **Conclusions:** Among ex-smokers, the risk of overall death was reduced by 12% on < 2y TSSC, 17% on 2-5y TSSC and 20% > 5y TSSC, whereas for LCSS, the benefit was significant only for > 5y TSCC, compared to current smokers at time of diagnosis. Here we demonstrate that convincing screening participants to quit smoking at any point of their trajectory, even just prior to dx such as < 2y TSSC, improved OS, and LCSS benefit was present beyond 5y of quitting. These relationships are independent of pack-years, age, across all stages and other prognostic variables. The impact of poly ADP ribose polymerase (PARP) inhibitors on clonal hematopoiesis. *First Author: Kelly L Bolton, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Poly (ADP-ribose) polymerase (PARP) inhibitors are an important new class of anti-cancer therapies. Therapy-related myeloid neoplasia (tMN) has been reported following PARPi therapy, and is associated with adverse outcomes. Further insight is required into the risk of tMN conferred by PARPi therapy, independent of germline genetic background and prior therapy. We have shown that oncologic therapy selects for acquired mutations in the blood (clonal hematopoiesis; CH) particularly those in the DNA damage response pathway (DDR) including *PPM1D*, *TP53* and *CHEK2* and that CH confers an increased risk of tMN. We hypothesized that characterization of the relationship between CH and PARPi therapy provides insight into its potential for leukemogenesis and may offer opportunities for tMN prevention. **Methods:** We assessed for CH in the blood of 10,156 cancer patients, including 54 who received PARPi therapy, 5942 who received another systematic therapy or radiation therapy and 4160 untreated prior to blood draw. **Results:** Patients exposed to PARPi therapy were more likely to have CH (33%) compared to those exposed to other systemic therapies or radiation (18%) or untreated patients (16%). This was particularly pronounced for DDR CH; 25% of PARPi treated patients had DDR CH compared to 2% of untreated patients. In a multivariable model accounting for demographics, exposure to chemotherapeutic agents, radiation therapy and germline *BRCA* mutation status, exposure to PARPi conferred an increased risk of DDR CH (OR = 3.6, 95% CI 1.5-8.5, p = 0.004). This effect was attenuated after accounting for cumulative exposure to therapy (OR = 2.8, 95% CI 0.97-8.2, p = 0.06) suggesting a multifactorial contribution to the enrichment of CH following PARPi therapy. To characterize this further we performed a prospective collection of patients with CH over a median follow-up time of 58 months. During the follow-up period, 17 patients received PARPi, 360 received cytotoxic therapies or radiation and 232 were untreated or received targeted therapies. The growth rate of DDR CH was significantly higher among those who were exposed to PARPi (median, +2.8% increase in VAF per year) compared to untreated patients (+0.08% per year, p = 0.02) and those exposed to other cytotoxic therapies (+1% per year, p = 0.04). **Conclusions:** Taken together our data suggests that PARPi therapy promotes the expansion of DDR CH. Future studies should examine the potential of CH to identify individuals at high risk of tMN following PARPi therapy and to develop therapies aimed to prevent tMN in patients with CH. Clinical conundrums: Developing a strategy for discerning TP53-associated chip and coherent clinical care. *First Author: Jeffrey N. Weitzel, City of Hope, Duarte, CA*

Background: Germline *TP53* mutations are associated with Li-Fraumeni syndrome (LFS). However, approximately 20% of commercial laboratory multigene panel test (MGPT)-detected pathogenic *TP53* variants represent aberrant clonal expansion (ACE), rather than a germline finding, and are often detected in individuals that lack classic features of LFS. Clonal hematopoiesis (CH) is a form of ACE, and in the absence of an abnormal hemogram is termed Clonal hematopoiesis of indeterminate potential (CHIP). CHIP is often associated with a pathogenic variant (PV) in hematopoietic pathway gene(s) at a variant allele frequency (VAF) less than expected for a heterozygous germline finding. The prevalence increases with age and exposure to chemotherapy. The presence of a skewed VAF is usually noted in a comment on a genetic test result, however, clinicians without genetic training often lack understanding of the comment and need strategies to discern the difference between germline findings, CHIP, and post-zygotic mosaicism. Our studies illuminate possible strategies for discernment for clinicians. **Methods:** Among 113 cases with MGPT-detected *TP53* PVs, enrolled in the Clinical Cancer Genomics Community Research Network registry, we obtained additional tissues, family history and complete blood count (CBC) reports on 42 cases. DNA extracted from formalin fixed paraffin embedded (FFPE) tumor/normal tissues, blood, saliva, eyebrow plucks, was analyzed using a previously validated custom myeloid and CH gene (n = 79) amplicon-based QIAseq panel. PVs with VAF $>$ 2% were included in analyses. **Results:** Germline status was confirmed for 6 cases (one with a CH PV), post-zygotic mosaicism was supported for 5 cases and 2 were indeterminant. 12 had results supporting ACE/CH, with additional CH-associated PV(s) identified in 5/12 (41%); n = 2 of each *TET2*, *ATM*, *TP53*; and increasing VAF over time for the driver *TP53* PV was noted in 2. Of these 2 one was identified to have a hematopoietic malignancy identified through analysis of the CBCs and bone marrow biopsy in parallel with the increasing VAF. Additional results are pending for 7 cases. **Conclusions:** With the use of our multi-tissue NGS strategy, serial sampling of suspected ACE/CH cases, family history and CBC analyses we were able to discern the status of most *TP53* genetic findings. This work has direct translational impact, refining risk estimation and improving the clinical care of patients with *TP53* PVs, while avoiding unnecessary LFS-related care and enabling appropriate care for those with ACE. Research Sponsor: U.S. National Institutes of Health.

Genetic counseling referrals after next generation sequencing testing. *First Author: Rafael Gonzalez, Duke University Health System, Durham, NC*

Background: Next generation sequencing (NGS) testing of tumor tissue or blood is performed to identify 'actionable' mutations that might guide patient care. NGS testing might incidentally identify germline mutations associated with cancer syndromes. No distinction is made between germline and somatic alterations on NGS reports, thus confirmatory germline testing is required. In this quality improvement (QI) initiative, we evaluated the frequency of referrals to genetic counseling (GC) for patients with potentially heritable germline mutations identified through NGS testing. **Methods:** We generated a list of high-risk mutations (HRMs) which merit GC referral based on NCCN guidelines. NGS test results for 3,400 consecutive patients with solid tumor malignancies were reviewed by the molecular tumor board from 1/2014-9/2019 and were screened for pathogenic HRMs. Basic demographic, oncologic, and GC data were retrospectively abstracted for each patient. The outcomes of interest were the frequency of HRMs identified through NGS testing, the proportion of patients subsequently referred to GC, and the proportion of patients ultimately diagnosed with a hereditary cancer syndrome. **Results:** 472 individual patients (14%) had NGS testing with one or more HRM identified; 465 patients were evaluable which corresponded to 519 HRMs that were included in the analysis (Table). Malignancies included were gastrointestinal 199 (42.8%), lung 83 (17.8%), genitourinary/renal 56 (12.0%), breast 49 (10.5%), gynecologic 35 (7.5%), and other 43 (9.2%). 75 (16.1%) patients had germline testing prior to NGS testing. Of those patients without prior germline genetic testing, 62 (15.9%) were referred to GC, and 19 (4.9%) patients were diagnosed with a hereditary cancer syndrome. **Conclusions:** Tumor NGS testing identifies HRMs that may represent an undiagnosed heritable germline mutation. Providers ordering NGS tests should review results for HRMs, refer to GC when appropriate, and offer confirmatory germline testing for patients and their families. Research Sponsor: None.

The prevalence of germline mutations among patients with solid tumors with genomic alterations identified on tumor testing: Results from a tertiary care academic center molecular tumor board. *First Author: Catherine Watson, Duke University, Durham, NC*

Background: The proportion of germline versus somatic mutations identified on genomic tumor testing of solid malignancies is not well characterized. We compared somatic and germline testing results in patients with breast, ovarian, pancreatic or prostate cancer with a genomic alteration identified on tumor testing. **Methods:** Retrospective chart review was performed using a tertiary care academic center's database of somatic tumor testing results obtained via FoundationOne and Guardant testing. Patients with breast, ovarian, pancreatic or prostate cancer who had a genomic alteration identified on tumor testing, including pathogenic and VUS variants, in *BRCA1*or *BRCA2*,*CHEK2*, *ATM*, *BRIP1*, *RAD51-C*,*RAD51D*, *PALB2*and *CDH1*and who had also received germline testing were identified. Analysis was performed to assess prevalence of germline results. The association between mutant allele fraction (MAF) and germline mutation status was also assessed. **Results:** Results: 124 patients with breast, ovarian, pancreatic or prostate cancer were identified who had a genomic alteration of interest also tested for via germline testing. 54 (32.5%) of tumor mutations were also identified on germline testing. Proportion of genomic results that were germline was wide, ranging from 0-85.7% depending on the gene and variant classification (Table). Germline mutations were present in 36.4% of breast, 25% of ovarian, 53.3% of pancreatic, and 20.9% of prostate cancer patients who had a tumor alteration present. Alterations that were found to be concordant in both somatic and germline testing had an average MAF of 0.54, and alterations identified on somatic testing only had an average MAF of 0.30. **Conclusions:** Our findings suggest that approximately one-third of genomic alterations on tumor testing will be of germline origin. However, concordance rates may be gene and variant dependent. Higher MAF may be associated with germline alteration status, but further evaluation is needed. Thus, while information provided by genomic tumor testing may be suggestive of a correlating germline mutation, no single alteration type or MAF value is reliably predictive. Research Sponsor: None.

The impact of tumor NGS testing on hereditary cancer risk assessment and population management in an integrated community health care system. *First Author: Sachdev P. Thomas, Kaiser Permanente, Dept of Medical Oncology, Vallejo, CA*

Background: Next-generation sequencing (NGS) for tumor molecular profiling is used in Oncology to identify 'actionable alterations' for clinical trials or on/ off-label therapy. Tumor NGS can also reveal potentially heritable germline mutations. The frequency of such incidental germline mutations has been estimated to be 4-15%. The 2015 ASCO Statement supports communication of medically relevant incidental germline findings from somatic mutation profiling to patients (PTS). The impact of tumor NGS testing on hereditary cancer risk assessment programs in the context of a wider population management strategy is unknown. We sought to evaluate this within our Kaiser Permanente Northern California (KPNC) population with ready access to tumor NGS and an ongoing hereditary cancer risk assessment program. **Methods:** Kaiser Permanente Northern California (KPNC) is part of a large, integrated health care system. NGS at KPNC is performed in collaboration with STRATA Oncology, a precision oncology partnership. All NGS results are reviewed by a multidisciplinary KPNC Genomic Oncology Committee (GOC)which also includes genetic counselors and pathologists. We examined all NGS reports between November 2017 through December 2019 to determine the types of cancers tested, number with a possible germline mutation and number referred for genetic counseling and testing (GCT). **Results:** 4,825 PTS with advanced cancer underwent STRATA NGS testing. A total of 207 PTS (4.3%) were identified as potential germline mutation carriers, all 207 were recommended for GCT referral. Of these, 92 (45.0%) separately met 2020 NCCN Criteria for Genetic/Familial High-Risk Assessment (2020NG/FA), prior to tumor NGS; 115 (53.6%) did not and 3 (1.4%) had insufficient information. The cancers most frequently meeting NCCN criteria were pancreatic, breast and colon. Of the 92 PTS who met 2020NG/FA, 60 (65%) underwent GCT and 34 (57%) were confirmed to have a germline mutation. Of the 115 PTS that did not meet 2020NG/FA, 47 (41%) underwent GCT and 19 (40%) were confirmed to have a germline mutation. Overall germline mutations were confirmed in 16.5% of patients who did not meet 2020NG/FA and 37% who did. **Conclusions:** In our community-based integrated healthcare system, systematic review of next-generation sequencing results by an expert GOC led to more robust identification of germline mutation carriers and navigated them to appropriate GCT. Ongoing work will clarify data on cascade testing. We are currently developing automated workflows for GCT. Research Sponsor: None.

Expanding the diagnostic yield of germline genetic testing in cancer patients using deep learning. *First Author: Saud H Aldubayan, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: Germline genetic analysis is an essential tool for implementing precision cancer prevention and treatment. However, only a small fraction of cancer patients, even those with features suggestive of a cancer-predisposition syndrome, have detectable pathogenic germline events, which may in part reflect incomplete pathogenic variant detection by current gold-standard methods. Here, we leveraged deep learning approaches to expand the diagnostic utility of genetic analysis in cancer patients. **Methods:** Systematic analysis of the detection rate of pathogenic cancer-predisposition variants using the standard clinical variant detection method and a deep learning approach in germline whole-exome sequencing data of 2367 cancer patients (n = 1072 prostate cancer, 1295 melanoma). **Results:** Of 1072 prostate cancer patients, deep learning variant detection identified 16 additional prostate cancer patients with clinically actionable pathogenic cancer-predisposition variants that went undetected by the gold-standard method (198 vs. 182), yielding higher sensitivity (94.7% vs. 87.1%), specificity (64.0% vs. 36.0%), positive predictive value (95.7% vs. 91.9%), and negative predictive value (59.3% vs. 25.0%). Similarly, germline genetic analysis of 1295 melanoma patients showed that, compared with the standard method, deep learning detected 19 additional patients with validated pathogenic variants (93 vs. 74) with fewer false-positive calls (78 vs. 135) leading to a higher diagnostic yield. Collectively, deep learning identified one additional patient with a pathogenic cancer-risk variant, that went undetected by the standard method, for every 52 to 67 cancer patients undergoing germline analysis. Superior performance of deep learning, for detecting putative loss-of-function variants, was also seen across 5197 clinically relevant Mendelian genes in these cohorts. **Conclusions:** The gold-standard germline variant detection method, universally used in clinical and research settings, has significant limitations for identifying clinically relevant pathogenic disease-causing variants. We determined that deep learning approaches have a clinically significant increase in the diagnostic yield across commonly examined Mendelian gene sets. Deep learning to identify high-risk smokers for lung cancer screening from chest radiographs. *First Author: Vineet Raghu, Cardiovascular Imaging Research Center (CIRC), Department of Radiology, Massachusetts General Hospital & Harvard Medical School, Boston, MA*

Background: Appearance on chest radiography may inform selection of high-risk smokers for lung cancer screening CT, beyond Centers for Medicare & Medicaid Services (CMS) eligibility criteria. **Methods:** A convolutional neural network (CXR-LC) predicting 12-year incident lung cancer from the chest radiograph image, age, sex, and smoking status (current/former) was developed in 41,856 persons aged 55-74 from the Prostate, Lung, Colorectal & Ovarian trial (PLCO). The final model was tested in held-out smokers from PLCO (n=5,615, 37.9% CMS eligible, 12-year follow-up), and externally in the National Lung Screening Trial (NLST, n=5,493, all CMS eligible, 6-year follow-up). Sensitivity was compared at a fixed screening population size defined by CMS eligibility. Ordinal CXR-LC risk score (low/indeterminate/high/very high) was based on development dataset 12-year probability thresholds (<2%/2-<3.3%/3.3-<8%/≥8%). Results are provided in test datasets only. **Results:** In the PLCO test dataset, CXR-LC was more sensitive than CMS eligibility at a fixed screening population size (74.9% vs. 63.8%, p=0.01) and missed 30.8% fewer lung cancers. CXR-LC risk groups were associated with incident lung cancer in PLCO test dataset smokers (very high vs. low CXR-LC risk: 12.4 vs 1.1 lung cancers/1,000 person-years) with external testing in NLST (all CMS eligible: 12.7 vs 2.3) (Table). This association was robust to adjustment for radiologist findings and the PLCOm2012 risk score. **Conclusions:** CXR-LC identified smokers at high risk of incident lung cancer, beyond CMS eligibility. Research Sponsor: U.S. National Institutes of Health.

Comparing and assessing the reported penetrance of cancer susceptibility genes for breast cancer. *First Author: Kanhua Yin, Massachusetts General Hospital, Boston, MA*

Background: It is critical for oncologists to be aware of unbiased and interpretable cancer risks (i.e., penetrance) in carriers with germline pathogenic variants in cancer susceptibility genes. However, relevant literature is large and varies significantly in study design, patient ascertainment, and types of risk estimates reported. This heterogeneity can cause inconsistent conclusions between studies and create barriers for clinicians to understand and apply them in practice. To further understand the current literature, we assessed penetrance studies associated with non-BRCA breast cancer susceptibility genes based on study design and ascertainment adjustment. **Methods:** We used a validated natural language processing-based abstract classifier to identify all penetrance studies regarding eleven genes: ATM, BARD1, CDH1, CHEK2, NBN, NF1, PALB2, PTEN, RECQL, STK11, and TP53. Relevant studies were then manually annotated as "with ascertainment adjustment" if a study was based on: (1) a general population; (2) a pedigree analysis or a family-based study with appropriate ascertainment adjustment; or (3) a hospital-based study or a panel testing analysis with well-matched cases and controls. **Results:** A total of 49 penetrance studies were identified, with a median of nine studies for each gene (range: 4-16). The case-control study was the dominant study type, accounting for over 80% in five genes, 50% in two genes, and 18% to 43% in the other four genes. The proportion of studies with ascertainment adjustment was generally low (mean: 33%) and varied widely between different genes (7% to 80%). Contradictory breast cancer risks (no increased risk vs. significantly increased risk) were found in eight genes (73%) (Table). The most common ascertainment bias identified was a case-control study with cases (patients) who had a strong family history but using general population controls. **Conclusions:** Ascertainment bias is common in penetrance studies, but few studies adjust for it appropriately. Clinicians should be aware of this issue, and new methods are warranted to select unbiased risk estimates, synthesize them, and provide the accurate general-population penetrance. Research Sponsor: None.

As an example: Reported penetrance of NF1 for breast cancer.

Evaluation of a mainstream model of genetic testing for men with prostate cancer. *First Author: Tahlia Scheinberg, Chris O'Brien Lifehouse, Camperdown, Australia*

Background: In order to identify the ~12% with inherited cancer predisposition, it is recommended that all men with metastatic prostate cancer (mPC) be offered testing. This has implications for treatment choices and cancer prevention in family. Limited geneticists/genetic counsellors globally present a major barrier to testing. We tested a potential solution, mainstreaming, where testing is performed by the patient's oncologist. **Methods:** Men with mPC at three Australian sites were offered germline genetic testing at their medical oncology appointment. Panel testing (*ATM*, *BRCA1*, *BRCA2*, *BRIP1*, *CHEK2*, *EPCAM*, *FANCA*, *HOXB13*, *MLH1*, *MSH2*, *MSH6*, *NBN*, *PALB2*, *PMS2*, *RAD51D* and *TP53*) was performed on saliva/blood (Invitae). Primary outcomes were clinician and patient acceptability (modified Royal Marsden Satisfaction Questionnaires). Secondary outcomes included mutation rates and cost-effectiveness. A sample size of 44 provided 90% power, with a one-sided alpha of 5%, to distinguish a proportion of men happy with mainstreaming of 80% vs. 60% or less. Allowing for 25% drop-out, we aimed to recruit 60 men. **Results:** Of 66 men offered testing from April to November 2019, 63 (95%) accepted. Four pathogenic variants were identified (2 *BRCA2*, 1 *NBN*, 1 *MSH6*). 48 patients and eight clinicians completed questionnaires. Acceptability was high. All (48/48) patients were happy to have been tested, and 45/48 (94%) were happy to have been tested at their oncology appointment. All were happy to receive their results from their oncologist. All clinicians were satisfied mainstreaming and 88% (7/8) felt confident doing so. Mainstreaming was cost-effective, requiring 87% fewer genetic consultations than traditional genetic counselling. **Conclusions:** This study shows that mainstreaming of men with mPC is feasible, resource efficient and acceptable to both clinicians and patients. Widespread implementation as a new standard of care would facilitate timely access to genetic testing for men with mPC. 1522 Poster Session (Board #14), Fri, 8:00 AM-11:00 AM

Discovery of a core-panel of markers for a blood-assay for cancer detection utilizing cfDNA methylation changes. *First Author: Lasika Seneviratne, SCORA/LA Cancer Network, Los Angeles, CA*

Background: Cancer screening is limited to several cancers despite improved outcome A screening test should be acceptable, safe, and relatively inexpensive[1] Tumors shed cfDNA to the blood where abundant tumor-specific methylation changes can be detected [1]https://www.who.int/cancer/detection/variouscancer/en/. **Methods:** This is a prospective, multicenter, observational study under two protocols NCT04264767, NCT04264754. Plasma was collected from 1,255 subjects: 586 treatment-naïve cancer patients and 639 controls, in 21 sites and biobanks. Training set I (211 cases/99 controls) was used to select the 6 final markers for the core panel, training set II (200 controls) was used to lock the algorithm, and set the threshold to a score yielding specificity of 95%. The validation set (342 cases/310 controls) was performed utilizing the pre-specified algorithm and threshold. Plasma was separated from a single EDTA tube within 4 hours of blood draw. EpiCheck's reagents and methylation-sensitive enzymes (Nucleix, Israel) were used for DNA extraction, digestion, and amplification in real-time PCR (ABI 7500 Fast Dx, Applied Biosystems). **Results:** Age was comparable but sex and smoking history were different (more women in cases, more smokers in controls). In the validation cohort twelve cancer types were included, with prominent representation of major cancer types (19% Breast, 14% colorectal and 21% lung) and stages I&II (56%). Specificity and sensitivity were maintained high at 94% and 62%. Highest sensitivity was demonstrated in GI cancers (77% colorectal, 83% esophageal, 100% gastric) and non-solid malignancies (83%). Sensitivity in early stage cancers (stages I, II & IIIA) was 51%, led by Sarcoma (83%) esophageal (76%) and colorectal (61%). **Conclusions:** This 6-marker blood-based methylation assay is a promising initial component in a future cancer screening test, generating significant signal in early cancers and utilizing simple and inexpensive PCR technology. Clinical trial information: NCT04264767, NCT04264754. Research Sponsor: Nucleix.

1523 Poster Session (Board #15), Fri, 8:00 AM-11:00 AM

Comprehensive molecular assessment of mismatch repair deficiency in Lynch-associated ovarian cancers using next-generation sequencing (NGS) panel. *First Author: Rachel Soyoun Kim, University of Toronto, Toronto, ON, Canada*

Background: Abnormalities in mismatch repair (MMR) gene may be the result of pathogenic germline (Lynch syndrome) and somatic mutations as well as epigenetic events. Abnormalities in MMR have been described in non-serous/non-mucinous ovarian cancer (OC) but few studies have examined the causes of these MMR defects (MMRd). To address this, we have completed targeted mutational and methylation sequencing on MMRd OC cases. **Methods:** Women with newly diagnosed non-serous/mucinous OC (N = 215) were prospectively recruited from three cancer centers in Ontario, Canada between 2015-18. Tumors were reflexively assessed for MMR protein expression by immunohistochemistry. Tumor DNA was extracted from macrodissected MMRd cases and MMR-intact (MMRi) controls following pathology review. Matched tumor-normal samples were run on a custom NGS panel to identify germline and somatic mutations, copy number variants, rearrangements and promoter methylation in MMR and associated genes. **Results:** Of the 215 women enrolled in our study, 185 (86%) had OC alone and 30 (14%) had synchronous OC and endometrial cancer. Twenty-eight (13%) cases were MMRd, 11 of which were synchronous. The MMRd cohort had median age of 52.5 years, with mostly stage I (N = 14; 50%), grade 1 or 2 disease (N = 18; 64%) with endometrioid histotype (N = 18; 64%). One patient had recurrence after median follow-up of 33.6 months (13.2-93.6). There was no significant difference in overall/progression-free survival between the MMRd and MMRi patients. Using the NGS panel, Lynch syndrome (LS) was detected in 39% of MMRd cases (11/28; 7 OC and 4 synchronous): 7 *MSH6*, 2 *MLH1*, 1 *PMS2*, and 1 *MSH2*. Clinical germline sequencing was performed on all cases and verified panel findings. An explanation for the observed MMR phenotype was available for 18/20 deficient cases, including 9/10 $MLH1^{-}/PMS2^{-}$ (7 somatic methylation, 1 bi-allelic somatic deletion, 1 germline mutation), 0/1 $PMS2^{-}$, 6/7 $MSH6^{-}$ (6 germline mutations) and 2/2 $MSH2^{-}/MSH6^{-}$ (1 germline mutation, 1 bi-allelic somatic mutation). Concordance between clinical and research panel sequencing results was 90%. None of the germline mutations were missed by the panel. **Conclusions:** Use of our custom NGS panel allows for the streamlined assessment of hereditary and somatic causes of MMR deficiency in OC and may be an attractive screening strategy for LS in this population. Research Sponsor: Canadian Cancer Society Research Institute Prevention Grant.

1524 Poster Session (Board #16), Fri, 8:00 AM-11:00 AM

Genotype and phenotype correlation of common cancer predisposition syndromes in sarcoma cases. *First Author: Milita Zaheed, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia*

Background: Sarcomas are rare heterogenous cancers affecting a predominantly younger population. The most recognised autosomal dominant contributor being pathogenic *TP53* variants associated with Li Fraumeni Syndrome (LFS). When referred, patient eligibility for germline *TP53* testing is assessed using classic or Chompret LFS criteria. Other heritable cancer syndromes which can be associated with sarcoma (breast/ovarian, colorectal) are more commonly considered in clinical practice. In some centres germline testing is offered to only those who meet established clinical criteria. Heritable cancer predisposition has several implications including therapy and clinical risk management. Here we report the concordance between clinical criteria and genotypes in sarcoma families. **Methods:** We included 1,664 sarcoma probands from the International Sarcoma Kindred Study. Eligibility for genetic testing was assessed using internationally accepted clinical criteria for recognised cancer syndromes. Whole genome sequencing was performed on peripheral blood DNA and variants in the ACMG cancer gene list were classified as pathogenic or likely pathogenic using established bioinformatics pipelines. **Results:** The median age of sarcoma diagnosis in 1664 probands (798 males, 866 Females) was 48 years (range 1-93). The median age of first cancer diagnosis was 46.5 years (0-93) with 291 probands having multiple primary cancers. Of 1504 informative pedigrees, 243 (16%) met criteria for testing; 207 (14%) *TP53*; 19 (1%) *BRCA1/2*; 2 (<1%) colorectal cancer (CRC) genes and 15 (1%) familial melanoma. Of 12 *TP53* PVs identified, 9 met *TP53* testing criteria. Of 13 PVs identified in HR genes (7 *BRCA2*, 4 *PALB2* and 2 *BRCA1*) only 1 (*PALB2*) met *BRCA1/2* testing criteria and 2 met Chompret criteria. Both *BRCA1* cases were male with a 1st degree relative with ovarian cancer. In CRC genes (1 *APC*, 2 *MSH2*, 4 *MSH6*, 1 *PMS2*), none met CRC testing criteria but 4 met Chompret criteria. No *CDKN2A* PVs were identified in melanoma families. **Conclusions:** In probands with sarcoma, clinical criteria for eligibility for testing for common non-LFS heritable syndromes perform poorly. This should be considered when making decisions regarding germline testing. Research Sponsor: Rainbows for Kate Foundation, Australian National Health and Medical Research Council.

1525 Poster Session (Board #17), Fri, 8:00 AM-11:00 AM

Characterization of clonal hematopoiesis of indeterminate potential mutations from germline whole exome sequencing data. *First Author: Hsin-Ta Wu, Natera, Inc., San Carlos, CA*

Background: Clonal hematopoiesis of Indeterminate Potential (CHIP) is an age-related phenomenon where somatic mutations accumulate in cells of the blood or bone marrow. It is a source of biological noise that causes false-positives in ctDNA analysis and is present in up to 20% of individuals over the age of 70. The presence of CHIP has been linked to an increased risk of hematologic cancers and cardiovascular disease. The Signatera assay filters CHIP mutations through tumor tissue and germline sequencing thereby reducing false-positive results and focuses on tumor-specific mutations for each patient. **Methods:** Whole exome sequencing data (average depth ~250x) analyzed from patients' buffy coat (n = 159) was used to characterize CHIP mutations. Variant calling was performed using Freebayes variant caller with allele frequency threshold between 1% and 10%. Following which variant annotation and selection was performed based on the top 54 genes that are most implicated in myeloid disorders. The selected variants were further screened based on the reported variants in the literature and/or the Catalog of Somatic Mutations in Cancer (COSMIC). **Results:** The analysis revealed an average of 0.14 (0-2) CHIP mutations per patient with an average variant allele frequency of 3.49% (1%-8.5%). The most common CHIP mutations were observed in *DNMT3A*, (n = 17), *TET2* (n = 7) and *TP53* (n = 7) genes. The percentage of patients with at least 1 mutation found in *DNMT3A, TET2,* and *TP53* were 4.2%, 1.94%, and 1.38%, respectively. Other genes containing CHIP mutation included *CEBPA, ETV6, HRAS, PDGFRA, NRAS, KMT2A, EZH2, GATA2, GNAS* at a frequency below 1%. CHIP mutations were not observed in patients younger than 40 years, but they increased in frequency with every decade of life thereafter. The incidence of CHIP increased from 0.04 for the 40-50 yrs age group to 0.18 for individuals older than 60. Further analysis of associations between incidence of CHIP and cancer type, prior exposure to chemotherapy as well as longitudinal evolution of CHIP mutations during cytotoxic treatment are underway and will be presented. **Conclusions:** CHIP, a common finding in the elderly population is an important factor to consider in ctDNA analysis and most frequently involves *DNMT3A, TET2,* and *TP53* genes. The frequency of CHIP can be impacted by a number of other factors such as cytotoxic chemo- or radiotherapy. Research Sponsor: Natera, Inc.

1526 Poster Session (Board #18), Fri, 8:00 AM-11:00 AM

BRCA testing concordance with national guidelines for patients with breast cancer in community cancer programs. *First Author: Leigh Boehmer, Association of Community Cancer Centers, Rockville, MD*

Background: Current National Comprehensive Cancer Network guidelines for genetic/familial high-risk assessment state that testing for highly penetrant breast/ovarian cancer genes is clinically indicated for women with early onset ($\leq$ 45 years) or metastatic HER-2 negative breast cancer. A recent Association of Community Cancer Centers (ACCC) survey (N = 95) showed that $>$ 80% of respondents reported $\leq$ 50% testing rate of patients with breast cancer who met guidelines. Given this disconnect, ACCC partnered with 15 community cancer programs to assess practice gaps and support interventions to improve access to genetic counseling (GC)/testing. **Methods:** Pre-intervention data from 9/15 partner programs for women diagnosed with stages 0-III breast cancer between 01/01/2017 and 06/30/2019 was collected. De-identified variables included: family history documentation, GC appointment/test results, and timing of results relative to treatment decisions. **Results:** There were 2691 women with stages 0-III breast cancer. Forty-eight percent (1284/2691) had a documented high-risk family history, 57% (729/1284) of whom had a GC appointment. This was a significantly higher rate of GC compared to the 23% (181/778) of women with no family history and 6% (35/629) of women with no documentation of family history ($p < 0.0001$). Patients $\leq$ 45 years old attended a GC appointment 72% (199/278) of the time and 49% (135/278) had genetic test results, with 84% (113/135) receiving results before surgery. For women with test results available before surgery, 37% (119/322) had breast conserving surgery, compared to 60% (144/240) with test results disclosed post-operatively ($p < 0.0001$). **Conclusions:** Genetic testing is underutilized in a community cohort of women with breast cancer. Further analysis is needed to understand the impact genetic test results have on surgical decisions. Opportunities exist to improve current rates of appropriate GC/testing. ACCC will share results of quality improvement projects to illuminate which strategies hold promise in reducing the hereditary breast cancer GC/testing practice gap. Research Sponsor: Pfizer, Inc.

1527 Poster Session (Board #19), Fri, 8:00 AM-11:00 AM

Prevalence and clinical characterization of MMR-D/MSI extra-colonic cancers among germline PMS2 mutation carriers. *First Author: Alicia Latham, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *PMS2*-associated Lynch syndrome (LS) may have a more modest phenotype than that associated with other mismatch repair (MMR) genes (*MLH1, MSH2, MSH6, EPCAM*). Recent studies suggest limited extra-colonic cancers, and modified risk-reducing measures can be provided. Understanding the spectrum of risk is of critical importance as some LS-associated cancers do not have effective screening, requiring risk-reducing surgery (endometrial, ovarian). As MMR-deficiency (MMRD)/ microsatellite instability (MSI) is associated with LS pan-cancer, we sought to characterize *PMS2*-associated malignancies according to MMR/MSI status. **Methods:** Review of cancer patients (pts) consented to an IRB-approved protocol of tumor/germline next-generation sequencing (NGS) identified 43 germline heterozygous *PMS2* mutation carriers. Tumors were evaluated for MSI via MSIsensor and/or corresponding MMR protein expression via immunohistochemical staining (IHC). Clinical variables were correlated with MMR/MSI status, comparing via Chi-square or standard T-test. **Results:** There were $>$ 10 tumor types; 69.8% (30/43) were extra-colonic cancers (endometrial (n = 4), ovarian (n = 6), small bowel (n = 3), urothelial (n = 2), pancreas (n = 3), prostate (n = 3), breast (n = 3), brain (n = 3), biliary (n = 1), spindle cell sarcoma (n = 1), and hepatoblastoma (n = 1)). 46.5% (20/43) of tumors were MMRD/MSI. 61.5% (8/13) of colorectal cancers (CRC) were MMRD/MSI, compared to 40% (12/30) of extra-colonic tumors. All endometrial and small bowel cancers were MMRD/MSI. Of 6 ovarian cancers, 3 were clear-cell, 1 endometrioid, and 2 high-grade serous (HGS). The only MMRD/MSI ovary tumor was HGS. 73.9% (17/23) of pts with MMRP/MSS tumors had recurrent/metastatic disease vs 30% (6/20) of pts with MMRD/MSI tumors (p= 0.004). Mean age at diagnosis did not differ significantly between MMRP/MSS and MMRD/MSI groups (49 vs. 57, respectively, p= 0.146). 11.6% (5/43) of pts had a prior cancer, with only one patient having prior CRC. Pts with extra-colonic tumors were less likely to meet clinical pt and family history LS testing criteria than those with CRC (63.3% (19/30) vs. 7.7% (1/13); $p<$ 0.001). **Conclusions:** While *PMS2*-related LS may have a more modest clinical phenotype, in this single-institution study, 60% (12/20) of patients with MMRD/MSI tumors presented with extra-colonic cancers. We caution counseling pts with *PMS2*-associated LS about reduced extra-colonic risk until more complete information about penetrance, spectrum, and age distribution of cancer is available. 1528 Poster Session (Board #20), Fri, 8:00 AM-11:00 AM

Performance of polygenic risk scores for cancer prediction in an academic biobank. *First Author: Heena Desai, University of Pennsylvania Perelman School of Medicine, Philadelphia*

Background: The discovery of rare genetic variants associated with cancer have a tremendous impact on reducing cancer morbidity and mortality when identified; however, rare variants are found in less than 5% of cancer patients. Genome wide association studies (GWAS) have identified hundreds of common genetic variants significantly associated with a number of cancers, but the clinical utility of individual variants or a polygenic risk score (PRS) derived from multiple variants is still unclear. **Methods:** We tested the ability of polygenic risk score (PRS) models developed from genome-wide significant variants to differentiate cases versus controls in the Penn Medicine Biobank. Cases for 15 different cancers and cancer-free controls were identified using electronic health record billing codes for 11,524 European American and 5,994 African American individuals from the Penn Medicine Biobank. **Results:** The discriminatory ability of the 15 PRS models to distinguish their respective cancer cases versus controls ranged from 0.68-0.79 in European Americans and 0.74-0.93 in African Americans. Seven of the 15 cancer PRS trended towards an association with their cancer at a $p<0.05$ (Table), and PRS for prostate, thyroid and melanoma were significantly associated with their cancers at a bonferroni corrected $p<0.003$ with OR 1.3-1.6 in European Americans. **Conclusions:** Our data demonstrate that common variants with significant associations from GWAS studies can distinguish cancer cases versus controls for some cancers in an unselected biobank population. Given the small effects, future studies are needed to determine how best to incorporate PRS with other risk factors in the precision prediction of cancer risk. Research Sponsor: U.S. National Institutes of Health.

ATM mutation carriers and family history of pancreatic cancer. *First Author: Jeannie Klavanian, Beaumont Hospital, Royal Oak, MI*

Background: Multigene panel testing (MGT) is commonly utilized in patients with a personal or family history of cancer. One of the more common gene mutations identified is in the *ATM* gene, associated with a moderately increased risk of breast and other cancers. There are reports of an association with pancreatic cancer, however the exact risks are unclear. The aim of this study is to describe the family history of pancreatic cancer in a cohort of *ATM* mutation carriers, and to evaluate possible genotype/phenotype correlation. **Methods:** Patients who underwent MGT, between '13 and '19, and tested positive for a pathogenic/likely pathogenic *ATM* mutation were included in this study. Family history, with a focus on pancreatic cancer, and genetic testing results were analyzed. **Results:** A total of 114 patients were identified to carry an *ATM* mutation. Twenty-two (19.3%) individuals had a family history of pancreatic cancer in a close relative, and of those, 13 (11.4%) had an affected first degree relative, and 11 (9.6%) had an affected second degree relative. Among the families with pancreatic cancer, 20 close relatives had a personal history of pancreatic cancer, with the youngest diagnosed at age 40, the oldest diagnosed at age 91, and a mean age of diagnosis of 66.5 years. Thirteen unique variants were identified: 4 splice site, 3 missense, 3 frameshift, 1 nonsense, and 1 silent. Two families had the known high-penetrance *ATM* mutation, c.7271T > C (p.V2424G). **Conclusions:** This study describes the association of pancreatic cancer in individuals found to carry pathogenic *ATM* mutations. A significant proportion (19.3%) of patients had a family history of pancreatic cancer in a close relative, diagnosed as young as age 40. The mean age of diagnosis was slightly younger than the average age in the general population (age 70). As pancreatic cancer screening continues to improve, this information will be an important component to help guide cancer risk assessment and future screening recommendations for *ATM* mutation carriers. Additional larger studies are needed to further characterize pancreatic cancer risks in patients with ATM gene mutations. Research Sponsor: None.

1531 Poster Session (Board #23), Fri, 8:00 AM-11:00 AM

Functional analysis of patient-derived PALB2 missense variants of uncertain significance. *First Author: Shijie Wu, Department of Breast Surgery, the Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Inherited *PALB2* pathogenic variants are associated with an increased lifetime risk for breast cancer development. However, the interpretation of numerous *PALB2* missense variants of uncertain significance (VUS) identified in germline genetic testing remains a challenge. Here, we assessed the impact of breast cancer patient-derived VUS on PALB2 function and identified pathogenic *PALB2* missense variants that may increase cancer risk. **Methods:** A total of seven potentially pathogenic *PALB2* VUS identified in 2,279 breast cancer patients were selected for functional analysis. All these selected VUS were assessed by SIFT, Align-GVGD, and PolyPhen2 *in silico* and were predicted to be deleterious by at least two *in silico* algorithms. The p.L35P [c.104T > C] variant was also included, for which pathogenicity has been recently confirmed. The effects of the VUS on the homologous recombination (HR) activity of PALB2 were tested by U2OS/DR-GFP reporting system. Functional characterization was further validated by protein co-immunoprecipitation and RAD51 recruitment assay. **Results:** *PALB2* variants p.L24F [c.72G > C] and p.L35P [c.104T > C] showed the most significant disruption to the HR activity of PALB2 relative to the wild-type condition, retaining only 52.2% ($p = 0.0013$) and 8.5% ($p < 0.0001$) of HR activity respectively. Moderate but statistically significant HR deficiency was observed for four other variants (p.P405A [c.1213C > G], p.T1012I [c.3035C > T], p.E1018D [c.3054G > C], and p.T1099M [c.3296C > T]). We found no statistical differences for the p.K628N [c.1884G > T] and p.R663C [c.1987C > T] in the HR activity compared to wild-type PALB2. The p.L24F and p.L35P variants compromised the BRCA1-PALB2 interaction and reduced RAD51 foci formation in response to DNA damage. **Conclusions:** We have identified a novel patient-derived pathogenic *PALB2* missense variant, p.L24F [c.72G > C], that compromises PALB2-mediated HR activity. We suggest the integration of the identified pathogenic variants into breast cancer genetic counseling and individualized treatment regimens for better clinical outcomes. 1532 Poster Session (Board #24), Fri, 8:00 AM-11:00 AM

Cancer risk management and family communication of genetic test results among women with inherited breast cancer genes. *First Author: Tuya Pal, Vanderbilt University Med Center, Nashville, TN*

Background: Identification of inherited breast cancer may guide care, with benefits amplified through family testing. **Methods:** Females with a pathogenic/likely pathogenic (P/LP) variant in *BRCA1/2, PALB2, CHEK2,* and/or *ATM* were surveyed about cancer risk management, family communication of genetic test results, and family testing. Comparisons were made across genes. **Results:** The 235 participants with P/LP variants (186 *BRCA1/2*, 28 *PALB2*, 15 *CHEK2*, and 6 *ATM*) had a median age of 54 and 61% had a prior breast cancer diagnosis. For women with P/LP variants in *BRCA1/2*, *PALB2*, and *ATM/CHEK2*, bilateral mastectomy rates were 79%, 61%, and 52%, respectively; and risk-reducing oophorectomy rates were 89%, 30%, and 37%, respectively. All women with *PALB2* and *ATM/CHEK2* P/LP variants with a bilateral mastectomy had a personal or family history of breast cancer; however, only 27% of those with a risk-reducing oophorectomy had a family history of ovarian cancer. Family communication of genetic test results and family testing rates were higher for those with P/LP variants in *BRCA1/2* compared to others. **Conclusions:** Bilateral mastectomy and risk-reducing oophorectomy were relatively common among women with *PALB2* and *ATM/CHEK2* P/LP variants in our study, suggesting overtreatment through risk-reducing surgery. Furthermore, strategies to improve family communication of genetic test results and family testing are needed to amplify testing benefits. 1533 Poster Session (Board #25), Fri, 8:00 AM-11:00 AM

Urgent cancer genetic counseling and testing for young, premenopausal women with breast cancer (BC): Impact on surgical decision-making for contralateral risk-reducing mastectomy. *First Author: Phuong L. Mai, UPMC Magee-Womens Hospital, Pittsburgh, PA*

Background: In women newly diagnosed with unilateral breast cancer (BC), contralateral risk-reducing mastectomy (CRRM) to decrease risk for additional primary BC is an appropriate option for some individuals, such as those with significantly increased risk due to a pathogenic variant (PV) in a breast cancer predisposition gene. Genetic testing at the time of BC diagnosis for young women has become more available and could aid in the decision-making process. We evaluated the trends for CRRM in a cohort of women diagnosed with BC at age ≤45 years who were seen in a multidisciplinary clinic where genetic counseling and testing is offered to each patient. **Methods:** A single institution, prospectively maintained database of patients seen in a BC multidisciplinary clinic between November 2014 and June 2019 was reviewed. Patients were included if they had non-metastatic, unilateral BC diagnosed ≤45 years of age, and underwent genetic testing at the time of BC diagnosis. Associations between surgical treatment (lumpectomy, mastectomy, or mastectomy with CRRM) and age at diagnosis, BC stage, family history, and genetic testing results were evaluated. **Results:** 184 patients were included in the analysis. The prevalence of a PV in a breast cancer predisposition gene was 15.8% (29/184; 1 in *ATM*, 12 in *BRCA1*, 8 in *BRCA2*, 5 in CH*EK2*, 2 in *NBN*, and 1 in *NF1*). 69% of the PV were in *BRCA1* and *BRCA2*. 126 (68.4%) tested negative, and 29 (15.8%) had a variant of uncertain significance (VUS) in various genes. Overall, 63 patients (34.2%) elected to have CRRM. Of the 29 patients with a PV, 24 (82.8%) had CRRM. Women who chose CRRM were younger, more likely to test positive for a PV in a breast cancer predisposition gene, and more likely to have a significant family history of breast and/or ovarian cancer. Among the 155 patients who tested negative or had a VUS, there was no statistically significant association between CRRM and age ($p = 0.58$), test result (negative vs. VUS. $p = 0.12$), or family history ($p = 0.32$). **Conclusions:** For young women with BC seen in a multidisciplinary clinic, a younger age, significant family history, and positive genetic testing result were found to be associated with the decision to undergo CRRM. Among those without a genetic predisposition, having a VUS result was not associated with choosing CRRM. Incorporation of genetic services in the initial evaluation of young patients newly diagnosed with BC could add relevant information in surgical decision making and promote risk-appropriate management. 1534 Poster Session (Board #26), Fri, 8:00 AM-11:00 AM

Five year letrozole versus placebo in *BRCA1/2* germline mutations carriers: Final results of LIBER, a double-blind randomized phase III breast cancer prevention trial. *First Author: Pascal Pujol, Centre Hospitalier Universitaire, Montpellier, Montpellier, France*

Background: Women with germline *BRCA1/2* (gBRCA1/2) mutations have a 70% lifetime risk of breast cancer (BC). Medical prevention by aromatase inhibitors is effective in high-risk patients (pts), including those with familial risk. However, hormone prevention has not been specifically addressed in women (wn) carrying gBRCA1/2 mutations. **Methods:** LIBER is a randomized, double-blind, placebo-controlled phase III trial evaluating 5-year treatment with letrozole 2.5 mg/day (L) versus placebo (P) on decreasing BC incidence in post-menopausal women with gBRCA1/2 mutations (NCT00673335). Eligible wn were aged 40-70 and could have had unilateral BC $>$ 5 years ago. Randomization was stratified on mutation (*BRCA1/BRCA2*), bilateral oophorectomy and history of prior BC. Primary endpoint was 5-year invasive BC-free survival (BC-FS) in wn with or without previous BC. Main secondary endpoints were safety and quality of life (menopause rating scale, SF36). 270 pts were required to observe 37 events to show a gain in 5-year invasive BC-FS from 80% to 92% (HR=0.35) with 1-sided α=0.05 and 90% power. **Results:** 170 wn were randomized from 02/2008 to 02/2013; 86 and 84 were assigned to the P and L arm. Median age was 55 years (range 40-70). Pt characteristics were well balanced; 59% and 41% carried gBRCA1 and gBRCA2 mutations. In P and L arms, 47% and 43% had prior BC, 43% and 42% stopped treatment prematurely, 37 and 23 serious adverse events occurred, and during active treatment, 8 and 10 wn had grade 3/4 toxicity. Median follow-up was 72.7 months. Five-year BC-FS did not significantly differ between the P and L arms (92% vs 91%, HR 0.83; 95%CI: 0.3-2.3, p=0.73) in the overall population, nor in the subgroups of wn with and without previous BC (74% vs 91%; HR 0.43; 95% CI: 0.1-1.3; 90% vs 86%; HR 1.29; 95% CI 0.4-3.9), gBRCA1 versus gBRCA2 or hormone receptor-positive BC. Letrozole had no effect on quality of life. The two groups did not significantly differ in bone density, which decreased over time in the overall population. **Conclusions:** In this prospective preventive trial, BC-FS was not significantly decreased by letrozole versus placebo in women with *BRCA1/2* mutations. However, the study was underpowered (170 of 270 pts expected). Despite no differences in safety and quality of life, drop-out rate was high in both P and L arms. Clinical trial information: NCT00673335. Research Sponsor: institut national du cancer, programme hospitalier de recherche clinique, unicancer, Pharmaceutical/Biotech Company.

1535 Poster Session (Board #27), Fri, 8:00 AM-11:00 AM

Evaluating the association between clonal hematopoiesis and germline pathogenic and likely pathogenic variants in cancer predisposition genes. *First Author: Elizabeth Anne Comen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clonal hematopoiesis (CH) is most commonly associated with mutations in genes with a known or putative role in leukemia and with an increased risk for hematologic malignancies. Nearly 50% of primary breast cancers contain leukocytes with CH mutations and CH mutations can be found in breast cancer (BC) tumor infiltrating leukocytes years prior to the development of secondary leukemia. It is currently not known whether CH is more prevalent among BC patients with both germline pathogenic variants and likely pathogenic variants (collectively referred to as PV) in cancer predisposition genes. Here we evaluated the relationship of CH to PV in 546 BC patients (pts). **Methods:** 546 BC pts underwent targeted capture sequencing of tumor and peripheral blood (PB) samples using MSK-IMPACT. Sequencing results from PB were used for identifying PV affecting up to 89 cancer predisposition genes and somatic mutations in 15 genes commonly associated with CH using previously validated methods. All pts consented via an IRB-approved protocol. **Results:** The majority (82.3%) of pts had non-metastatic disease. 59.7% of the 546 pts received chemotherapy and 42.7% received radiation. Of the 546 pts, 90 patients had germline PV in a cancer predisposition gene for a total of 98 germline PV identified (8 patients had 2 germline PV). Mutations in *DNMT3A* followed by *TET2* were the most common CH mutations identified. *CHEK2* PV were statistically significantly associated with CH in a multivariate analysis after controlling for age, prior chemotherapy and radiation therapy (OR: 3.94, CI: 1.51-10.26, p-value $\leq$0.005). Age by decade was significantly associated with the presence of CH in that model (OR: 1.93, CI: 1.53-2.42, p value $\leq$0.001). Of the 8 patients with *CHEK2* germline PV and CH, the most common mutated CH genes were *DNMT3A* (4 pts), followed by *TET2* (2 pts), although our sample size is too small to test for significant enrichment for any specific CH gene, type of CH mutation, or trinucleotide context. Further, CH was not associated with germline PV in other cancer predisposition genes. **Conclusions:** Our findings provide evidence of an association between *CHEK2* germline PV with CH in BC pts, which will be further tested in an expanded cohort. If this association is confirmed, it might have theoretical and practical implications, including cancer prevention strategies. Research Sponsor: None.

1536 Poster Session (Board #28), Fri, 8:00 AM-11:00 AM

Genome Wide Association Study (GWAS) of cognitive impairment after blood or marrow transplantation (BMT) for hematologic malignancy. *First Author: Noha Sharafeldin, University of Alabama at Birmingham, Birmingham, AL*

Background: Cognitive impairment is prevalent in hematologic malignancy patients treated with BMT (autologous: 18.7%; allogeneic: 35.7%; Sharafeldin JCO; 2018). Given the inter-individual variability in risk of cognitive impairment in this population, we investigated the role of genetic susceptibility using a genome-wide single nucleotide polymorphism (SNP) array platform to identify novel genetic associations. **Methods:** *Discovery:* Cognitive function was assessed objectively in 239 adult BMT recipients at pre-specified timepoints: pre-BMT and at 6 mo, 1y, 2y, and 3y post-BMT. A global deficit score (GDS - a summary score of 14 standardized neuropsychological tests) was computed for each patient; a higher score indicated greater cognitive impairment. SNPs passing standard quality control filters ($>$ 1.4M) were used for analysis. Linear mixed effects models used GDS as the outcome, adjusted for age, sex, BMT type, baseline cognitive reserve, and the first four principal components. We used additive, codominant, and genotype models and an adjusted genome-wide significance threshold of 1.25×10^{-8}. Replication: An independent cohort of 544 BMT survivors (192 cases with self-endorsed cognitive problems and 352 controls without) was used for replication. **Results:** *Discovery:* Median age at BMT was 51.3y; primary diagnoses: 47% leukemia, 32% lymphoma, 21% multiple myeloma; 57% males; 69% non-Hispanic whites: 50% allogeneic BMT, median GDS score = 0.22 (range 0-2). Forty-four SNPs were significantly associated with increased GDS (additive model: 3 SNPs; codominant model: 20 SNPs; genotype model: 21 SNPs). Estimates ranged from increase in GDS score by 0.28 points for each additional copy of risk allele, $p = 1.07 \times 10^{-8}$ to increase in GDS score by 1.82 points for two copies of risk allele, $p = 2.3 \times 10^{-11}$. *Replication:* Median age at BMT was 44y; primary diagnoses: 32% leukemia, 49% lymphoma, 19% multiple myeloma; 54% males; 80% non-Hispanic whites: 34% allogeneic BMT. Three SNPs were successfully replicated: rs116334183 resides within *lncRNA-SEMA6D-2*, which facilitates neuronal migration; rs13286152 86kb downstream of *TLE-1*, which promotes neuronal survival; and rs12486041 0.36Mb downstream from *lncRNA-SPTSSB-1*, which regulates sphingolipid production in neuronal axons and 0.36Mb upstream from *TOMM22P6* linked to neural repair. **Conclusions:** In this first GWAS of cognitive impairment post-BMT, we identify 3 SNPs with plausible links to genes implicated in neuronal integrity. Functional studies are currently underway. Research Sponsor: Leukemia and Lymphoma Society (62771-11, Bhatia).

Heterozygous germline ATM mutations in breast cancer: A single academic center experience. *First Author: Anish S Konde, Oakland University William Beaumont Hospital - Rose Cancer Center, Royal Oak, MI*

Background: Heterozygous germline *ATM* mutation carriers have an increased risk of developing breast, pancreas, and other cancers. The clinical and pathologic characteristics of *ATM*-associated breast cancers have not been well defined. **Methods:** Patients who underwent multigene panel testing (MGPT) between 2013-2019 and identified to harbor *ATM* mutations were included in the study. We evaluated demographics, pathology, and surgical management of our *ATM* mutation carriers with breast cancer. **Results:** At total of 319 individuals were identified to have variants in *ATM*, of which 114 were pathogenic/likely pathogenic. The majority of patients were female (82%) and Caucasian (88%). A total of 56 patients (49%) had a personal cancer diagnosis, the most common of which was breast cancer (n = 39). Nine individuals had more than one primary malignancy. The mean age at breast cancer diagnosis was 52, with a range of 25-82. The majority of patients had invasive ductal carcinoma (74%), grade 2 or 3 (90%), and ER and /or PR positive (87%). Of those with known HER2 status, 24% were positive. Thirty-nine percent of patients were lymph node positive, and 42% had lymphovascular invasion. The most common stage at diagnosis was 2 (53%). Of the 39 mutation carriers with breast cancer, 16 (42%) received radiation therapy, and 16 underwent bilateral mastectomy. Of 114 *ATM* positive patients, there were 55 distinct variants. Sixteen (14%) individuals had a mutation in additional cancer predisposition genes. One variant, c.5015delG, was identified in ten patients in a large, consanguineous Iraqi family with an extensive history of pancreatic and other cancers. Eight individuals were identified to have the known high-penetrance variant, c.7271T $>$ G. **Conclusions:** Our study describes the clinical and pathological characteristics of *ATM* mutations carriers with breast cancer. The majority of patients had intermediate to high grade disease, hormone receptor positive, with a suggestion of a higher rate of HER2 positivity and lymph node involvement. Additional studies are needed to elucidate the unique characteristics of *ATM*-associated breast cancer, which may have implications for personalized management. Research Sponsor: None.

1538 Poster Session (Board #30), Fri, 8:00 AM-11:00 AM

A single-institution and commercial laboratory database analysis of BRIP1-associated cancer risks. *First Author: Kristen Danielle Whitaker, Fox Chase Cancer Center, Philadelphia, PA*

Background: *BRIP1/FANCJ* participates in DNA replication and repair via interactions with *BRCA1* and possibly *MLH1*. Previous studies have reported that pathogenic variants (PV) in *BRIP1* are associated with an ~2-fold increase in risk for ovarian cancer (OC) and triple-negative breast cancer (TNBC). Although multigene panel testing for hereditary cancer (CA) has identified *BRIP1* PV and uncertain variants (VUS) in patients with diverse CAs including breast (BC), colorectal (CRC) and melanoma (Mel), association with these CA types has not been established. **Methods:** We examined *BRIP1* risks in two independent populations: Fox Chase Cancer Center (FCCC) and Myriad Genetics (MGL). At FCCC, pedigrees of *BRIP1* PV (*N*= 10) and VUS families (*N*= 47) were reviewed. The MGL population included patients referred for testing by multigene panel (9/2013-12/2019) (*N*= 586,740). Multivariable logistic regression analysis estimated *BRIP1* CA risks as odds ratios (ORs) and 95% confidence intervals (CIs). Models were adjusted for age, sex, ancestry, personal CA history (PHX), and family CA history. **Results:** In the FCCC cohort, *BRIP1* PV carriers (*N*= 12) reported PHX of early-onset (< 50) BC, CRC, and bladder CA. *BRIP1* VUS were also identified among several patients with striking PHX and negative panel testing: BC < 40 (*N*= 3), bilateral BC (*N*= 4), TNBC (*N*= 2), CRC < 40 (*N*= 3), and a patient with 3 CAs < 40 (CRC, BC, and Mel). All FCCC families with a *BRIP1* PV and select VUS families (*N*= 6) are seen in the Table. In the MGL population, 0.3% (1,678/586,740) carried a *BRIP1* PV. Logistic regression analyses found that female *BRIP1* PV carriers have significantly increased risk for OC (OR 2.40, 95% CI 1.93-2.98) and TNBC (OR 1.93, 95% CI 1.52-2.46). Data were insufficient for testing risk of bladder or prostate CA. Findings did not support associations of *BRIP1* with CRC, melanoma, endometrial, pancreatic or gastric CA. **Conclusions:** *BRIP1* PV and VUS may be identified in patients with diverse CA histories. These results confirm studies showing that *BRIP1* PV are associated with an ~2-fold increased risk of OC and TNBC, but do not support increased risks of CRC, melanoma or endometrial CA in *BRIP1* PV carriers. Research Sponsor: Myriad Genetic Laboratories, Inc.

Effect of detection of epigenomic changes in plasma-derived cell-free DNA on multicancer classification. *First Author: Anna Bergamaschi, Bluestar Genomics, San Diego, CA*

Background: Epigenomic changes in DNA methylation patterns are more precisely delineated by active demethylation events as marked by 5-hydroxymethylation (5hmC) of cytosine residues. 5hmC appears to be dynamically modulated in tumor tissues and can be employed as a cancer biomarker. Strategies which interrogate 5hmC genome-wide patterns in a liquid biopsy context may provide efficient and precise technology for early cancer screening and detection. In this study we identified genome-wide 5hmC changes in plasma based circulating free DNA (cfDNA) from breast, colorectal, lung, pancreatic and prostate cancer patients versus non-cancer individuals. **Methods:** cfDNA was isolated from plasma, enriched for the 5hmC fraction using novel click-chemistry protocol for labelling followed by sequencing and alignment to a reference genome to construct features sets of 5hmC patterns. Regularized classification models were constructed to classify cancer samples apart from non-cancer. **Results:** > 500 non-cancer individuals and > 500 cancer patients across five cancer types (breast, colorectal, lung, pancreas and prostate) were included in this study. About 60% of the cancer samples were early stage disease (I or II). The ability to classify non-cancer versus cancer patients was evaluated by 5-fold cross validation of our trained prediction models. Our models were able to classify all breast cancer with a test auROC of 0.86 while prediction model classification for ER negative samples had an auROC of 0.92. Colorectal performance auROC was 0.9; lung auROC = 0.92, pancreatic auROC = 0.97 and prostate auROC = 0.91. Overall sensitivity range, when allowing 2% false positive, was between 85% and 52%. Further using 5hmC signal in blood we were able to identify several signaling pathways specifically relevant to the biology of the cancers investigated. **Conclusions:** These findings further demonstrate that 5hmC changes in cfDNA enable non-invasive detection of breast, colorectal, lung pancreatic, and prostate cancers. Further, 5hmC signals enabled the identification of a suite of cancer signaling pathways differentially enriched in cancers versus non-cancers. These data suggest that dynamic changes in tumor cell methylation, detectable through 5-hydroxymethylation, are contained in the circulating blood and signal active disease biology. Research Sponsor: None.

1540 Poster Session (Board #32), Fri, 8:00 AM-11:00 AM

First year outcomes of an initiative to increase *BRCA* testing among NCCN guideline-eligible breast cancer patients within a large community OCM practice. *First Author: David Michael Waterhouse, OHC (Oncology Hematology Care)/US Oncology Network, Cincinnati, OH*

Background: Pathogenic variants in *BRCA1/BRCA2* can affect a breast CA pts care: preventative interventions, surgical decisions, medical treatments, screening, and family counseling. National data suggests significant non-adherence to NCCN testing guidelines, with only 1/3 of eligible pts referred for genetic services. In 2018, OHC (Cincinnati) launched an APP-centric genetics program. Specially trained APPs carry out genetic counseling and order NCCN-compliant testing. Early data suggested a significant deficit in physician-driven referrals. From 1/01/18 - 07/31/18, 138 new breast pts were estimated to be NCCN guideline-eligible. Only 28 (20%) pts received genetic services. **Methods:** In 2019, the OHC genetics team implemented a standardized screening process for every new breast CA pt. An EMR template (iKnowMed G2) that included NCCN guidelines was created for initial breast CA consultation and Oncology Care Model (OCM) treatment planning. All pts, not just OCM pts, are subject to OCM treatment planning. This automated screening method ensured all breast CA pts were screened, drastically increasing compliance. Through integration of genetics screening into the templates, pts meeting NCCN criteria for testing are reflexively referred for genetic counseling. With USON/McKesson, integrated data fields were developed in the EMR to automate data collection. **Results:** From 01/01/19 – 12/31/19, 717 new breast CA pts were seen at OHC. 676/717 (94%) were screened. Of those screened, 279 new breast CA pts met NCCN criteria for *BRCA* testing. 140 (50%) eligible new pts had appts with the genetics team. Another 50 (18%) had confirmed testing outside of OHC. 57 (20%) refused appts and/or testing. 32 (11%) did not have appts, representing screen fails. Referrals in non-breast CA pts also increased by 127%; 604 (2019) vs 264 (2018) suggesting a halo effect. Analyses suggest the program to be economically viable, with a financial growth rate of 127%. **Conclusions:** EMR templates embedded with the NCCN guidelines for reflex genetics referral can appropriately increase the utilization of genetic services. Breast genetics screening and resultant appt/testing rates increased significantly 2019 vs 2018. Success in BRCA testing in breast CA will lead to expansion to other cancers and genes. Implementation of structured EMR genetics data fields can automate data collection and measure compliance. Integration of genetics screening into universal OCM treatment planning is feasible, economically viable and scalable. Research Sponsor: Pfizer/ACCC.

1541 Poster Session (Board #33), Fri, 8:00 AM-11:00 AM

Return of results after somatic tumor mutation profiling in advanced cancer: Psychological impacts. *First Author: Phyllis Butow, The Chris O'Brien Lifehouse, Camperdown, Australia*

Background: Somatic tumor mutation profiling (STMP) is entering clinical practice. We aimed to investigate psychological impacts of receiving results. **Methods:** Eligible participants had: advanced solid cancers of any histological type; accessible tissue for STMP; and enrolled in the Molecular Screening and Therapeutics (MoST) Program. 1074 participants (91%) completed a baseline assessment prior to STMP (T0), of whom 570 (47%) received results and completed a post-result assessment (T1) of impact of genetic results (MICRA), anxiety and depression (HADS), cancer-specific anxiety (IES), and satisfaction with decision to have STMP. Linear regression models controlling for age, gender, parental status, cultural diversity, education and ECOG status explored associations between result received and psychological outcomes. **Results:** 360 participants received an actionable result and were recommended personalised treatment: 152 via a MoST sub-study (G1) and 208 via their treating oncologist (G2). 210 received a non-actionable result (G3). At T1, G3 were significantly more distressed and less positive about their result (MICRA subscales) and less satisfied with their decision to have STMP than both G1 and G2; G2 was less positive than G1. IES and HADs were not impacted by type of result. Interactions between gender and age, and result were non-significant for all psychological outcomes. Perceived self-efficacy in coping with results (p=0.015) and knowledge (p=0.04) at T0 was significantly correlated with satisfaction with decision at T1; self efficacy (T0) was also correlated with MICRA total (T1) (p=0.006). **Conclusions:** Pathway to treatment receipt is less important to advanced cancer patients than actionability. Patients' self-efficacy to cope with results prior to testing can identify patients vulnerable to distress post-receipt of STMP results who should be offered psychological counseling. Ensuring good knowledge of STMP at consent may avoid decisional regret. Research Sponsor: National Health and Medical Research Council of Australia grant.

Test of an online tool to facilitate NCCN guideline-compliant access to cancer genetics care. *First Author: Kara J. Milliron, University of Michigan, Ann Arbor, MI*

Background: Minority populations experience inequities of access to cancer genetics. We developed and tested an online family history collection and interpretation tool, InheRET, to determine acceptability, validity and utility.Patients are mostly unable to recall accurate family history in clinic and providers have little time to collect the 3-generation pedigree. Thus, ~90% of high risk patients remain unidentified. We evaluated the impact InheRET has on facilitating National Comprehensive Cancer Network (NCCN) Guideline-compliant referrals for cancer genetic counseling. **Methods:** Patients from 3 clinics were consented online to participate. A user experience survey for patients and providers followed the health history questionnaire. **Results:** 628 patients were consented over a year, 555 (>88%) completed the tool. 439 (79%) completed the post-questionnaire user experience. Review of Inheret's recommendations by a genetic counselor found 100% accuracy. Ease of Use: 84-87% of patients reported tool was easy to use. Understandability: 92-97% of patients reported tool was easy to understand. No significant differences were reported between those with high school (n=28, avg age 50.1 yrs) compared to those with advanced degrees (n=139, avg age 45.4 yrs); patients age 70+ experienced increased difficulties. Among primary care patients (n=135), 43 established patients were newly identified as meeting NCCN referral criteria. Healthcare providers found InheRET useful, did not require extra clinical time, and all wish to continue to use it. The patient provided data were more complete and encompassed more family members than with paper forms. Turnaround-times to receive the patient's information were decreased from 4-6 weeks to ~ 72 hours. A patient scheduling backlog of 400 patients was cleared using InheRET. Previously, 40% of cancer genetics patients were lost to follow up, due to not completing their intake forms. This number was reduced to 6.5%. **Conclusions:** Patients find InheRET to be easy to use and understand and they complete this health history tool more frequently and in greater detail than by paper forms. InheRET provides accurate results, verified by in person interviews, in a timely fashion, saving clinical time, possibly enabling increase in earned clinical revenues (under analysis), and improving patient care overall. Importantly, the 43 primary care patients identified to be at increased risk were already established patients, who had not been previously identified as such by their healthcare providers as being at increased risk. 1543 Poster Session (Board #35), Fri, 8:00 AM-11:00 AM

Potential germline findings identified during somatic tumor testing: Room for improvement. *First Author: Sundas Khan, University of Vermont Medical Center, Burlington, VT*

Background: Genomic testing, useful for treatment planning and identification of patients for clinical trials, may indicate the presence of a germline mutation. We sought to evaluate the incidence of potentially actionable germline mutations detected via genomic testing and determined rates of germline testing among patients with potential germline mutations. **Methods:** This was a retrospective review of patients undergoing genomic testing at The University of Vermont Cancer Center (UVMCC) between 03/02-11/19. Testing was reviewed for mutations in 60 genes associated with hereditary cancer and recognized as clinically actionable by the American College of Medical Genetics. Records were reviewed for clinical follow-up. Positive (pathogenic or likely pathogenic) genomic test results were evaluated with descriptive analyses. Proportions with 95% confidence intervals are presented and comparisons made using a χ^2 test. **Results:** 342 patients underwent genomic testing at UVMCC over the study period, with a median age of 61. Common tumor types include: CNS (19%), NSCLCA (17%), ovarian (8%), and sarcoma (7%). 59% (203/342) had a mutation in $\geq$ 1 gene associated with hereditary cancer. Most common tumor types with potential germline mutations include: NSCLCA (25%), CNS (18%), ovarian (8%), sarcoma (8%), and endometrial (7%). Potential germline mutations were most commonly identified in TP53, CDKN2A, PTEN, and RB1 (each with mutations in >6% of patients). 58 patients in the cohort have undergone germline testing, of which 19% were positive for germline mutations. Of patients with mutations in the highly penetrant BRCA, PALB2, and Lynch genes, 71% were positive for germline mutations. Young age ($<$ 50) did not enrich for germline mutations ($p > 0.05$). Only 18% (36/203) of patients with potential germline results were referred for genetic counseling. **Conclusions:** Genomic testing can reveal hereditary cancer syndromes. While the majority of patients with tumor mutations in genes associated with hereditary cancer will not have germline mutations, genetic testing is the only way to confirm this. 19% of patients who underwent genetic testing in this cohort had a pathogenic germline mutation. This was enriched to 71% when considering genes rarely mutated in tumors (BRCA, PALB2, and Lynch genes). Only 17% of this cohort underwent genetic testing, representing a significant missed opportunity given the implications of these findings for both patients and families. Patients and their providers should be aware of the potential for germline findings when genomic testing is performed. Research Sponsor: None.

1544 Poster Session (Board #36), Fri, 8:00 AM-11:00 AM

Outcome of patients with breast cancer and a germline *BRCA* mutation in a prospective cohort. *First Author: Banu Arun, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There are limited large prospective single institution studies on outcome of breast cancer in patients with germline *BRCA1* and *BRCA2* mutation. The primary aim of this study was to determine the effect of a germline *BRCA1* or *BRCA2* mutation on recurrence-free survival (RFS) and overall survival (OS) in patients with breast cancer. **Methods:** This is a prospective cohort study of patients with invasive breast cancer recruited from the UT MD Anderson Cancer Center Breast Medical Oncology and Clinical Cancer Genetics Center. For the purpose of this analysis, newly diagnosed breast cancer patients who have had germline *BRCA1* and *BRCA2* testing within 12 months were included. Clinical and pathological data, and data regarding outcomes were collected in this prospective cohort. The Kaplan-Meier method and corresponding log-rank test were used to estimate OS and RFS and to compare survival by mutation status. **Results:** Between 1996 and 2015, 3026 patients were recruited. Median age at diagnosis was 45 (19-87) years. A germline *BRCA* mutation was detected in 361 (11.9%) patients (207 with *BRCA1*, 154 with *BRCA2*). After a median follow-up time of 5.3 (0.04-20.7) years, 437 (14.4%) patients recurred and 340 (11.2%) were deceased. At median follow-up time 5 years, 79.3% of *BRCA1*, 91.4% of *BRCA2* and 89.6% of *BRCA* negative patients were disease free; this difference was significant ($p = 0.0001$). Difference in OS between *BRCA1/2*-positive and *BRCA*-negative patients was also significant ($p = 0.0001$), with 81.2% of *BRCA1*, 93.4% of *BRCA2* and 90% of *BRCA* negative patients being alive at 5 years. Amongst 600 patients with triple negative breast cancer (TNBC) patients, DFS and OS were not significantly different between the 3 groups. Of those patients diagnosed under 40 years (n = 937), RFS and OS was significantly different between 3 groups at 5 years (0.001 for RFS and OS); 75% *BRCA1*, 92% *BRCA2* and 86% *BRCA* negative patients were disease free and 77% *BRCA1*, 94% *BRCA2* and 88% *BRCA* negative patients were alive. **Conclusions:** Patients with *BRCA1* or *BRCA2* mutations have different survival outcomes. The prognosis of the first cancer needs to be taken into consideration when deciding for preventive surgeries to prevent second primary breast cancers in these patients. Furthermore, for *BRCA1* mutation carriers more effective therapy strategies need to be evaluated to improve outcome. Research Sponsor: None.

Tumor detection rates in screening carriers with *SDHx*-related hereditary paraganglioma-pheochromocytoma syndrome based on prior tumor history. *First Author: Samantha Greenberg, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Patients with germline pathogenic variants (PVs) in the *SDHx* genes have increased risk for paragangliomas/pheochromocytomas (PGL/PCC), renal cell carcinomas, and gastrointestinal stromal tumors. Expert recommendation suggests individuals with *SDHx* PVs undergo biennial whole-body imaging and annual biochemical testing. This study aimed to evaluate tumor detection rate using standard biochemical and imaging protocols for individuals with *SDHx* PVs, particularly in those with and without *SDHx*-related tumor history, and in those with biochemical testing data. **Methods:** A retrospective longitudinal observational study at the Universities of Michigan, Pennsylvania, and Utah Huntsman Cancer Institute was conducted from the start of each center's screening program through March 1, 2018. Individuals with *SDHx* PVs had clinical imaging with whole body MRI/CT and biochemical testing per expert recommendation. *SDHx*-related tumors identified during clinical screening were measured. **Results:** A total of 263 individuals with *SDHx* PVs completed 491 screens. Individuals with *SDHB* PVs were the most prevalent (n = 188, 71.5%). The average number of screens per subject was 1.87 (range 1-7). A majority (n = 194, 73.7%) of individuals did not have a prior history of PGL/PCC. Overall, *SDHx*-related tumors were detected in 17.1% (n = 45) of the cohort. Of the 46 scans that identified an *SDHx*-related tumor, 85% of them (n = 39) were baseline scans. *SDHx*-related tumors were identified in 18.6% (n = 36/194) of individuals that did not have a prior history of PGL/PCC, whereas they were identified in 13.0% (n = 9/69) of individuals that did have a prior history of PGL/PCC ($p = 0.39$). Biochemical testing was available for 70% (n = 343) of imaging screens, of which 18% (n = 61) had positive biochemistry. Of those with positive biochemistry, 19 tumors were identified on imaging (6%). Sixteen tumors were identified on imaging with negative biochemistry (5%) with a sensitivity of 54% and a specificity of 94%. Utilizing a cut-off of two times the upper limit of normal, 9.91% (n = 34) biochemical tests were positive, and 15 (44.12%) had an *SDHx*-related tumor on corresponding imaging. **Conclusions:** Current *SDHx* screening protocols are effective at identifying *SDHx*-related tumors. Tumors were detected in subjects with a prior history of PGL/PCC and those with no prior history. This suggests lifelong screening is important for all *SDHx* carriers. Imaging is a crucial piece of *SDHx* screening given biochemical testing's sensitivity and specificity. Research Sponsor: None.

Germline alterations other than *BRCA* in triple negative breast cancer (TNBC) patients who underwent neoadjuvant therapy (NAT) on a prospective clinical trial. *First Author: Banu Arun, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Previous studies have related germline *BRCA* mutations to pathologic complete response (pCR) in TNBC cohorts. However, prospective data is lacking on the frequency of non-*BRCA* germline mutations and pCR in TNBC patients who received neoadjuvant therapy (NAT). The aim of this study was to describe germline alterations in comparison with pCR in a prospective cohort of TNBC receiving NAT. **Methods:** Pre-NAT blood was drawn from patients enrolled in a clinical trial of genomically tailored NAT (ARTEMIS: NCT: 02276443, per eligibility patients had to have negative clinical *BRCA* tetsing). Germline DNA was extracted and sequenced on a HiSeq4000 sequencer (Illumina, coverage 60X). Reads were aligned to human reference hg19. Variants were filtered against public databases of normal cohorts: esp6500, 1000 genome, ExAC with a frequency cutoff at 1% in any ethnicity. Two integrative scores were used to evaluate the deleteriousness of the missense variants and the variants predicted to be damaging by both scores were included in the analyses. A 105 pan-cancer susceptibility gene panel was selected based on literature data and commercially available gene panels. NAT included anthracycline and taxane based chemotherapy +/- targeted therapy based on tumor genomic expression. Univariate logistic regression models were used to fit pCR for individual mutations, excluding genes mutated in fewer than three patients. All statistical analyses were performed using R version 3.6.1. with a significance of p=0.05. **Results:** Germline results and pCR were available for 152 patients. Median age was 55 yrs (range: 24-77). 7.9% were stage (st) I, 65.8% st II, 26.3% st III. 55 pts (36%) had pan-cancer associated germline mutations, whereas 33 (21%) had a breast-cancer associated mutation. Greater than 1% mutations were seen in seventeen genes (Table). There was no significant difference in pCR rate after NAT among pts with different germline mutations versus without mutation. **Conclusions:** Breast cancer related germline mutations other than *BRCA* in TNBC are relatively common supporting at least a breast panel (not only *BRCA1/2*) testing. Treatment implications of different germline mutations and their impact on pCR is ongoing on an extended series. Research Sponsor: None.

Ancestry-specific gene expression profiles in TNBC tumors. *First Author: Windy Marie Dean-Colomb, Lousiana State University School of Medicine, New Orleans, LA*

Background: Due to persistent disparities in breast cancer mortality, there has been a renewed focus on investigating tumor biology. Deeper exploration has exposed distinctions in tumor biology based upon self-reported race and ancestry. The disparities associated with Triple Negative Breast Cancer (TNBC) across the modern African Diaspora suggests that there is a genetic ancestry connection between its aggressive tumor biology and clinical outcomes. Understanding this connection could hold the key to improving clinical outcomes in this group. **Methods:** We investigated 75 TNBC primary tumors using Self-Reported Race (SRR) groups: African American (AA, n = 42) and European American (EA, n = 33). Using best practices established by TCGA, we analyzed bulk RNA sequencing to measure changes in genome-wide expression levels. We next quantified global ancestry in a novel manner using RNAseq variants using 1000 Genomes as the reference data. We then identified African and European ancestry-associated genes using a logistic regression (adjusted FDR $p < 0.05$) between quantified ancestry and gene expression levels. **Results:** We identified > 150 genes associated with quantified African ancestry. We also found using quantified ancestry was a more robust method to screen for differentially expressed genes than SRR. Using an updated TNBC subtyping method, we noted higher incidences of Basal-like 2 tumors in AAs. Pathway analyses indicated several canonical cancer pathways; including, TP53, NFKB1 and AKT, have altered functionality in patients of African descent. For example, TP53-associated genes were activated in TNBC tumors of AA versus EA. This upregulation, rather than loss of function, is suggestive of polymorphic and/or ancestry-specific expression regulation, likely driven by population-private genetic variants. Lastly, we used TCGA data to validate a subset of African ancestry-specific genes that were upregulated in AA patients in our cohort. Specifically, PIM3, ZBTB22 and PPP2R4 each retained significant upregulation, in our cohort, but also TNBC tumors from TCGA (p = 0.0018, 0.023 and 0.022, respectively). **Conclusions:** Our study has uncovered ancestry-specific gene expression profiles in TNBC tumors. The distinct distribution of TNBC subtypes and altered functional oncologic pathways are evidence that biological underpinnings in TNBC can be driven by shared genetic ancestry. These findings emphasize the need to investigate patient populations of various ancestral origins in order to fully appreciate the molecular diversity in tumor biology for precision of disease management. Outcomes of Lynch syndrome (LS) patients treated with immune checkpoint inhibitors (ICI). *First Author: Shahla Bari, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: LS is caused by a germline mutation in one of several DNA mismatch repair (MMR) genes: MLH1, MSH2, MSH6 or PMS2 (d-MMR). A minority of LS patients have MMR proficient tumors (p-MMR). ICI therapy has dramatically changed outcome of d-MMR (majority of LS patients. However, data about response to ICI in LS patients, irrespective of their tumor MMR status is scarce. The aim of this study was to evaluate outcomes of ICI therapy in all LS associated Cancer. **Methods:** This was a retrospective analysis of LS associated cancers treated with one of the 6 ICIs at our center. We also looked at age, sex, microsatellite status, response and survival. **Results:** Out of 262 LS patients analyzed, 194 had cancer and 22 received ICIs. Among the patients analyzed, the mean age at diagnosis of 1st cancer was 51 yrs. There were 10 females (47%). 10 patients had colorectal (45%), 3 urothelial (14%), 2 renal cell, 2 cholangiocarcinoma and one each of esophageal, ovarian, uterine, glioblastoma multiforme and pancreatic cancer. One patient died from progressive disease after receiving a single dose and was not included in the analysis. 17 patients (80%) received Pembrolizumab, 11 patients were microsatellite unstable (MSI), 3 were microsatellite stable (MSS) while 7 were unknown. 2 patients achieved complete response (CR) (10%), 1 patient had partial response (PR) (5%), 13 had stable disease (62%) while 5 had progressive disease (23%) leading to a disease control rate (DCR) of 76%. Of the 3 known MSS Lynch syndrome patients, 2 did not respond while the 3rd continues to respond at 9 months of therapy. Of the 5 patients who had PD, 2 were MSS, 2 unknown and 1 MSI. Among the 16 patients who responded, 15 of 16 (94%) had sustained response and have not experienced disease progression or relapse. 3 of these patients have been off therapy (1 due to immune related adverse evet) and have had no relapse. One responder progressed after 18 cycles of therapy. The DCR was 71% at 12 months as well as 48 months of follow up. Median progression survival has not been reached. Similarly, median overall survival has not been reached. **Conclusions:** Our study is the one of the largest reported analysis of LS associated cancer patients treated with ICIs and included LS patients with both MSI and MSS tumors. Though small, our data suggests robust DCR and prolonged responses in Lynch associated MSS tumors treated with ICI. This encouraging response in MSS tumors along with higher response rates in LS associated cancers as compared to non-LS MSI tumors, suggests that there may be additional drivers of response to ICI in LS patients leading to superior responses. Clinicopathologic features of invasive breast cancer (BC) diagnosed in carriers of germline *PALB2*, *CHEK2* and *ATM* pathogenic variants. *First Author: Danika Scott, Stanford University School of Medicine, Stanford, CA*

Background: While germline pathogenic variants (PVs) in *BRCA1/2* account for a large proportion of hereditary breast cancer (BC), PVs in *PALB2*, *CHEK2* and *ATM* are increasingly detected. However, the phenotype and clinical features of invasive BC with these PVs have not been fully described. **Methods:** We identified patients with a PV or likely PV in *PALB2*, *CHEK2* or *ATM* tested clinically at Stanford between 2014 - 2019 who provided informed consent to be included in a prospective cancer genetics registry. Data on baseline demographics, genetic testing history, and clinicopathologic features of diagnosed BC were collected. For patients with a subsequent diagnosis of metastatic BC, we calculated disease-free interval (DFI). **Results:** 130 patients met inclusion criteria for analysis: *ATM* (N=39), *CHEK2* (N=58), *PALB2* (N=33). Nearly all (98.5%) were women, with 2 male BC in *ATM* carriers. Non-Hispanic White ethnicity was most common in *ATM* (64.1%, 95% CI 48.4%-77.3%) and *CHEK2* carriers (69.0%, 95% CI 56.1%-79.4%), but comprised only 39.4% (95% CI 24.7%-56.4%) in *PALB2* carriers. Asian/Pacific Islander (24.2%, 95% CI 12.6%-41.3%) and Hispanic (30.3%, 95% CI 17.3%-47.5%) ethnicities were enriched among *PALB2* mutation carriers. In total, 97.7% learned of their PV status only after a preceding diagnosis of BC and 43.1% were diagnosed with BC at age ≤ 45. Data regarding invasive BC subtypes, incidence of subsequent primary BC, and metastatic recurrence are listed below in the table. Additional data on stage, grade and sites of metastatic spread will be presented. **Conclusions:** We observed clinically important differences in the spectrum of BC subtypes among carriers of *ATM*, *CHEK2* and *PALB2* PVs, in addition to racial/ethnic differences with Asian/Pacific Islander and Hispanic ethnicity enriched among carriers of *PALB2* PVs. Research Sponsor: BRCA Foundation.

1550 Poster Session (Board #42), Fri, 8:00 AM-11:00 AM

A noninvasive multi-analytic approach for lung cancer screening of patients with pulmonary nodules. *First Author: Hong Zheng, Department of Thoracic Surgery, Xinqiao Hospital, Chongqing, China*

Background: Low-dose computed tomography (LDCT) is an effective approach for lung cancer screening of high-risk patients with pulmonary nodules, however with varying false positive rates depending on the somewhat subjective judgement of the practice professional. Artificial intelligence derived from machine learning of comprehensive patient profiles, including multi-omics and clinical data, has the potential to provide more objective assessment of patient's risk in order to aid clinician's decision making. We have developed a multi-analyte algorithm-based assay (MAAA) that incorporates ctDNA mutation, ctDNA methylation, and protein biomarker profiles evaluated through non-invasive blood-based testing, as well as patient's clinical information, to improve the diagnostic efficacy of lung cancer. **Methods:** 98 high-risk patients with pulmonary nodules were enrolled in two independent cohorts (68 for training/testing and 30 for independent validation). The malignancy of the pulmonary nodules were established through pathology of surgical-removed nodules. Prior to surgery, each patient was also subject to cell-free DNA-based sequencing for DNA mutation and DNA methylation profiling, as well as serum protein biomarker profiling. On the training/testing patient cohort, machine-learning-based predictive models were first built for malignancy status prediction based on each type of molecular or clinical features. A final ensemble model was then constructed to incorporate the measurements based on molecular and clinical markers to provide the ultimate recommendation on the malignancy of the pulmonary nodule. The performance of each individual model and the final ensemble model was benchmarked on the training/testing cohort, and also validated on the independent validation cohort. **Results:** On the 30-patient independent validation cohort, individual prediction models based on clinical information, protein marker, ctDNA mutation, and ctDNA methylation profiles achieved predictive AUC of 0.59, 0.48, 0.71, and 0.84, respectively. The final ensemble model achieved predictive AUC of 0.86, which has strongly indicated that an integrative, algorithm-based approach of multi-analytic molecular and clinical profiles greatly outperforms any single-analytic profiling. **Conclusions:** Multi-analyte algorithm-based approach can be utilized to assist in lung cancer screening for patients with pulmonary nodules. It has demostrated a high accuracy through independent validation, and has outperformed any single-analyte testing in our study. Research Sponsor: None.

1551 Poster Session (Board #43), Fri, 8:00 AM-11:00 AM

Green tea extract to prevent colorectal adenomas in men and women: Results of the MIRACLE trial. *First Author: Thomas Jens Ettrich, Ulm University, Department of Internal Medicine I, Ulm, Germany*

Background: Prevention of colorectal adenomas (CA) can reduce colorectal cancers (CRC). Epidemiological and experimental data suggest that the green tea catechin epigallocatechingallate has an antineoplastic effect in the large bowel. MIRACLE is the largest trial so far to examine the effect of three-year daily intake of green tea extract (GTE) on the incidence of metachronous CA in a Caucasian population. **Methods:** Prospective, parallel group, double-blinded, placebo-controlled, randomized multicenter trial (40 German centers, recruitment 11/2011-6/2015). Patients (n = 1001, age 50-80y), polypectomy ≤ 6 months and tolerating GTE well (one-month run-in) were randomized to receive decaffeinated GTE standardized to EGCG (150 mg bid, capsules) or placebo (P) for 3 years. Primary endpoint: Incidence of metachronous CA at the 3-year follow-up colonoscopy. Secondary endpoints: Occurrence, number, localization, size, histological subtype of CA, frequency of CRC, biomarker and safety. Strata: study center, low-dose aspirin (≤100 mg/d). **Results:** Clinical parameters were well balanced. CA incidence at the 3-year follow-up colonoscopy was analyzed in the modified ITT set (modITT; n = 309 patients (GTE), n = 323 (placebo), timely follow up colonoscopy) and the per protocol set (PP, modITT set without major protocol violations). Incidence of CA was 55.7 % (P) and 51.1% (GTE), (modITT, adj. RR 0.905, one sided, p = 0.081), respectively 54.3 % (P) and 48.3% (GTE) (PP, adj. RR 0.883, one sided, p = 0.058). These differences did not reach statistical significance. In the preplanned exploratory analysis regarding gender incidence of CA in females was 47.9% (P) and 47.6% (GTE) in the modITT-set (adj. RR 0.989; 95%-CI: 0.753,1.299; p = 0.935), respectively 45.4% (P) and 46.9% (GTE) in the PP-set (adj. RR 1.014; 95%-CI: 0.748, 1.373; p = 0.930). In contrast, in the male population incidence of CA in the follow-up colonoscopy was 60.4% (P) and 52.9% (GTE) in the modITT-set (adj. RR 0.846; 95% CI 0.717, 0.999); p = 0.048), respectively 59.1% (P) and 49.1% (GTE) in the PP-set (RR 0.803, 95% CI: 0.666, 0.969; p = 0.022). Thus, GTE intake was associated with a significant, 12.4 relative and 7.5% absolute reduction of metachronous CA in the male modITT population. There were no differences with respect to safety between the groups. **Conclusions:** GTE reduced the incidence of metachronous CA. However, a significant effect was only observed in the in the male population whereas there was no effect in the female population. Clinical trial information: NCT 01360320. Research Sponsor: German Cancer Aid Foundation (Stiftung Deutsche Krebshilfe).

1552 Poster Session (Board #44), Fri, 8:00 AM-11:00 AM

Non-invasive detection of urothelial carcinoma (UC) by cost-effective low-coverage whole genome sequencing from urine exfoliated cells DNA. *First Author: Shuxiong Zeng, Changhai Hospital, Navy Medical University, Shanghai, China*

Background: Urothelial carcinoma (UC) is a malignancy with frequent chromosomal aberrations. The FISH assays were more sensitive as compared to cytology tests. Here we investigated cost-effective whole genome sequencing technology, which is able to detect all chromosomal aberrations for UC diagnoses. **Methods:** UC patients and control group are prospectively recruited in trial NCT03998371. First-morning-voided urine were freshly collected before TURBT or cystectomy. Urine Exfoliated Cells DNA was analyzed by illumina HiSeq X10, followed by genotyping by bioinformatics workflow UCAD. **Results:** 195 individuals were prospectively recruited. 121 UC patients and 67 non-tumor diseases were included in this study. 7 other malignancies as confirmed by pathological testing were excluded. Frequent chromosome copy number changes were found in cancer patients as compared non-tumor controls, including chromosome 3 gain, 17 gain, 7 gain and 9p loss used in FISH assays were found. In addition to that, chr9q loss, 8q gain, 5q loss, 17p loss, 11p loss, 1q gain, 8p loss, 10q loss, 6q loss, 4q loss and 11q loss were also frequent in cancer patients (AUC > 0.65). Metacentric chromosomes showed better AUC compared to acrocentric and telocentric chromosomes (P = 1.7e-03). A novel diagnosis model UCAD was built by incorporating all the chromosomal changes. The model reached performance of AUC = 0.933. At the optimal cutoff |Z| > = 3.16, the sensitivity, specificity and accuracy were 84.7%, 97.9% and 89.0% respectively. The prediction positivity was found correlated with urine microscopy visible epithelial cells (P = 0.00069), tumor invasiveness (Ta/Tis vs the other, P = 0.0048) and tumor grade (P = 0.0030), but not microscopy RBC/WBC findings, urine culture findings, smoke and drinking history. The UCAD model outperformed cytology tests by predicting all 16-cytology positive and 12 cytology negative tumors with comparable specificity. The model found 75.0% more tumors. And UCAD identified more upper urinary tract cancer (P = 0.012) and smaller tumors (< 3cm, P = 5.9e-04). The adding of cytology to UCAD did not improve diagnosing sensitivity and specificity. UCAD reproduce the diagnoses among morning - void urine, morning, afternoon urine samples with correlation coefficient $R^2 > 0.98$. All the urine samples showed high concordances with matched tumor samples ($R^2 > 0.85$). **Conclusions:** UCAD could be a high specific, robust UC diagnoses method with improved sensitivity as compared to cytology tests. Clinical trial information: NCT03998371. Research Sponsor: None.

1553 Poster Session (Board #45), Fri, 8:00 AM-11:00 AM

Relationship between *CYP2D6* genotype, tamoxifen metabolites, and adverse events, tumor biomarkers and breast cancer recurrence in a low-dose phase III trial in noninvasive disease. *First Author: Andrea De Censi, Division of Medical Oncology, E.O. Galliera Hospital, Genoa, Italy*

Background: Low dose tamoxifen (T, 5 mg/d) given for 3 years halved recurrence in 500 women with non-invasive disease (DeCensi et al. JCO 2019). Retrospective studies with 20 mg/d have shown an association between low levels of endoxifen (9-16 nM) or Z-4OHtam (3.26 nM) and recurrence, but recent prospective studies have not confirmed these findings. We measured *CYP2D6* genotype and 8 metabolite levels to determine their associations with adverse events, tumor biomarkers (IGF-I, SHBG, C-reactive protein, CRP) and breast cancer recurrence. **Methods:** CYP2D6 genotyping was performed in the T arm (n = 183) as previously described (Johansson H et al. BCRT 2016). T and metabolites were measured at 1 (n = 169) and 3 y (n = 152) as previously described (Helland T et al. BCR 2017). We tested linear relationships between metabolite levels and biomarkers, adjusting for age, BMI, treatment compliance and baseline biomarker levels. Cumulative incidence of recurrence according to endoxifen levels was calculated by the Cox model. **Results:** Endoxifen concentrations were associated to CYP2D6 metabolizer status (p < 0.001). Median (IQR) endoxifen levels were 8.4 (5.2-11.3) and 8.8 (5.8-11.5) at 1 and 3 y, with only 42% and 47% of subjects reaching 9 nM. Median endoxifen levels were related to pill count (5.5, 7.1 and 9.0 nM/L for medication possession rate < 83.3%, 83.4-99.9%, 100%, respectively). There was no difference in metabolite levels and menopausal symptoms. There was an inverse relationship between endoxifen and endometrial thickness at 3 y (p = 0.04), and between endoxifen or tamoxifen levels and IGF-I levels at 3 y (p = 0.001). T levels were positively associated with SHBG levels in postmenopausal women (p-interaction = 0.04). Endoxifen, T and 4OHtam decreased CRP, with a greater effect in premenopausal women (p-interaction = 0.02). An increase in CRP after 3 years was associated with a HR of 4.37 (95% CI, 1.14-16.73, P = 0.03) of recurrence compared to women with no increase of CRP. Median (IQR) endoxifen levels at year 1 were 8.4 (5.3-11.4) in patients who recurred vs 7.5 (5.1-10.2) in those who did not recur (p = 0.6), although this comparison was underpowered. **Conclusions:** T levels themselves may contribute to clinical activity by decreasing IGF-I and increasing SHBG. Elevated CRP is a predictive factor for recurrence which is down-regulated by T and metabolites. Endoxifen is below 9 nM in the majority of subjects treated with 5 mg/day, although this threshold was obtained in studies up to 20 years. Clinical trial information: NCT01357772. Research Sponsor: Italian Ministry of Health, Italian Association for Cancer Research (AIRC).

1554 Poster Session (Board #46), Fri, 8:00 AM-11:00 AM

Mammography adherence among medically underserved women undergoing cancer genetic risk assessment. *First Author: Candice Schwartz, University of Illinois at Chicago College of Medicine, Division of Medical Oncology, Chicago, IL*

Background: Medically underserved women bear a disproportionate burden of breast cancer (BC) mortality. Early detection is vital for reducing BC deaths. Cancer genetic risk assessment (CGRA) provides an opportunity to identify women at highest risk so that risk-adapted screening can be implemented. The effect of CGRA on mammography adherence among underserved women is unknown. **Methods:** We conducted a study to test the feasibility of performing cancer genetic risk assessment (CGRA) as part of standard primary healthcare at two Federally Qualified Health Centers in Chicago, IL. Racial/ethnically diverse women age 25-69 without a personal history of BC underwent CGRA at the time of an annual well-visit and received the result from their PCP. Medical record review provided data on mammography adherence. Demographic data and measures of perceived BC risk, BC cultural beliefs, fatalism, and BC worry were collected with an enrollment survey. McNemar's test compared the rate of adherence to screening mammography before and after implementation of CGRA, defined as completing a screening mammogram within 18 months prior to or following CGRA, resp., among women eligible for screening (age $>$ 40 at study enrollment). Logistic regression models tested for associations between mammography adherence and demographic characteristics/health beliefs. **Results:** Data was available for 90 participants with increased BC risk (IR) who were eligible for screening and 98 eligible, average risk (AR) participants (in total, 61% black and 37% Latina). Overall, adherence improved from 38% at baseline to 49% following CGRA ($p = 0.03$). Adherence increased from 35% to 51% among IR participants ($p = 0.04$), and from 40% to 47% among AR participants ($p = 0.39$). Data on predictors of adherence will be presented. **Conclusions:** Implementing CGRA as a standard component of primary healthcare improved adherence to screening mammography among racial/ethnically diverse underserved women. The effect was seen primarily in those with increased risk. This intervention could be used to improve uptake of mammography in the subgroup of underserved women who benefit the most from screening. 1555 Poster Session (Board #47), Fri, 8:00 AM-11:00 AM

A sensitive and quantitative multimodal blood test for the detection of colorectal adenomas and cancer: Correlation with size and number of polyps. *First Author: Shai Friedland, Stanford University Medical Center Gastroenterology and Hepatology, Stanford, CA*

Background: Colonoscopic polypectomy is the primary reason for declining colorectal cancer incidence and mortality. Epidemiological evidence has ordered the timing and risk of pre-cancerous adenomas, localized and invasive cancer along a 7-10 year continuum. The increased size and number of index polyps are correlated with an increased probability of progression to cancer and informs surveillance colonoscopies. **Methods:** A single-center, IRB-approved, prospective, blinded study was conducted at the VA Palo Alto Health Care System. Results for 354 patients with no prior diagnosis of CRC who were scheduled for colonoscopy are presented. Indications for colonoscopy were 86% asymptomatic and 14% with symptoms or positive-FIT. Patients had blood drawn immediately prior to colonoscopy. The test analyzes three biomarkers: circulating gastrointestinal epithelial cells (CEC), validated somatic mutations, and methylation (SEPTIN9) of cell-free DNA and uses incident risk to calculate a CMx Score, scaled from 0 to 100. Multivariate regression methods were used to assess the degree of association between the pre-defined CMx Scores and polyp sizes and number, adjusting for both DNA mutation and DNA methylation status. **Results:** There is a significant association between CMx Scores and polyp size (F value = 5.80, p-value = 0.017). DNA mutation (F value = 1.29, p-value = 0.263) and methylation status (F value = 0.34, p-value = 0.560) were non-significant. Similarly, there is a significant association between CMx Scores and number of polyps (F value = 23.71, p-value $<$ 0.0001). Again, DNA mutation (F value = 1.57, p-value = 0.210) and methylation status (F value = 1.34, p-value = 0.248) were non-significant. These results suggest that CMx Scores, which incorporate CEC, are providing predictive information of polyp sizes and number above and beyond DNA mutation and methylation status alone. **Conclusions:** A novel non-invasive multimodal blood-based assay that analyzes cell-free DNA for somatic mutations and methylation, CEC and integrates SEER incidence risk is significantly associated with polyp size and number. The opportunity to track progression and potentially inform colonoscopy interval is notable. Research Sponsor: CellMax Life.

Disease Category	Subject	Sensitivity (%)	Mean Index Polyp Size (mm)	Mean Polyp Number	Mean CMx Score
Colorectal Cancer	11	100	38.3	4.0	71.3
Advanced Adenomas	53	75.5	17.6	5.2	49.9
Non-advanced Adenomas	178	48.3	5.1	3.1	35.6
Non-Neoplastic Findings	33	9.1	4.4	1.8	20.0
Negative Colonoscopy	79	**Specificity** (%) 89.9	-	0	18.1

3,3'-Diindolylmethane (DIM): A nutritional intervention and its impact on breast density in healthy BRCA carriers compared to non-treated carriers—A prospective clinical trial. *First Author: Rinat Yerushalmi, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel*

Background: Women who carry the *BRCA* mutation are at high lifetime risk of breast cancer, but there is no consensus regarding an effective and safe chemoprevention strategy. A large body of evidence suggests that 3,3-diindolylmethane (DIM), a dimer of indole-3-carbinol (I3C) found in cruciferous vegetables, can potentially prevent carcinogenesis and tumor development. The primary aim of this prospective study was to investigate the effect of DIM supplementation on breast density, a recognized predictive factor of breast-cancer risk. **Methods:** Participants were 23 healthy female *BRCA* carriers (median age 47 years; 78% postmenopausal) who were treated with oral DIM 100 mgx1/d for one year. The amount of fibroglandular tissue (FGT) and background parenchymal enhancement (BPE) on magnetic resonance imaging (MRI) performed before and after the intervention were scored by two independent expert radiologists using the Breast Imaging and Reporting Data System (BI-RADS). Each woman in the cohort was matched by age (within 3 years) and menopausal status to a woman attending the clinic who was not participating in the study and who underwent breast MRI in parallel year. **Results:** A decrease in the average score for FGT amount from 2.8 ± 0.8 at onset to $2.65 \pm 0.842.8$ after one year ($p = 0.031$), with no significant change in BPE ($p = 0.429$). A group of DIM-untreated age- and menopausal-status-matched clinic patients did not show a significant change in FGT amount ($p = 0.33$) or BPE ($p = 0.814$) in a parallel year. Mean estradiol level decreased from 159 to 102 pmol/L ($p = 0.01$), and mean testosterone level, from 0.42 to 0.31 pmol/L ($p = 0.007$). Side effects were grade 1. **Conclusions:** One year's supplementation with DIM 100 mgX1/d in *BRCA* carriers was associated with a significant decline in FGT amount on MRI. Larger randomized studies are warranted to corroborate these findings. Clinical trial information: NCT02197000. Research Sponsor: Israel Cancer Association.

1557 Poster Session (Board #49), Fri, 8:00 AM-11:00 AM

Development of a novel liquid biopsy test to diagnose and locate gastrointestinal cancers. *First Author: Yuying Wang, BGI Genomics, Shenzhen, China*

Background: Cancers of the gastrointestinal (GI) system, including esophagus, stomach, pancreas, gallbladder, liver, bile duct, colon, and rectum are estimated to account for 38% of all cancer incidences and nearly 46% of cancer-related deaths in China. We conducted a multi-center study to evaluate the feasibility of using genetic and epigenetic abnormalities in plasma cfDNA to diagnose and locate GI cancers. **Methods:** We performed parallel genetic and epigenetic profiling of plasma cfDNA from hepatocellular carcinoma (HCC), colorectal cancer (CRC) and pancreatic cancer (PC) patients as well as age-matched healthy individuals by ultra-deep sequencing targeting cancer driver genes, and by targeted bisulfite sequencing covering genome-wide CpG islands, shelves, and shores. **Results:** Using a pre-specified mutation scoring system, we found that cfDNA mutation profiling achieved a sensitivity of 59.6%, 67.2%, and 46.8% for detecting HCC (n = 322), CRC (n = 244) and PC (n = 141) respectively, with a specificity of 95% in healthy controls (n = 207). For 901 plasma cfDNA samples that underwent methylome profiling, we first applied a machine learning approach to classify each cancer type versus healthy controls in the training cohort (HCC: n = 125; CRC: n = 105; PC: n = 97; healthy individuals: n = 84). Random Forest models with 10-fold cross validation achieved an AUC of 0.96 ± 0.04,0.89 ± 0.06, 0.91 ± 0.07 for HCC, CRC, and PC, respectively. Further analyses were performed on the validation cohort, including 172 HCC patients, 162 CRC patients, 60 PC patients, and an independent cohort of healthy individuals (HCC validation: n = 63; HCC independent validation: n = 109; CRC validation: n = 104; CRC external validation: n = 58; PC validation: n = 60; healthy controls: n = 96). The trained model achieved a sensitivity of 83.1% (specificity = 95.8%), 89.5% (specificity = 95.8%), and 76.7% (specificity = 91.7%) for HCC, CRC, and PC, respectively. Using regional methylation markers from diagnostic models for individual cancer types, we built a tissue-of-origin classification model, which achieved a cross-validation accuracy of 83.3% in the training cohort and an accuracy of 80.1% in the validation cohort in assigning correct cancer types. **Conclusions:** Plasma cfDNA methylome profiling identified effective biomarkers for the detection and tissue-of-origin determination of GI cancers, and outperformed mutation-based detection approach. Therefore, a liquid biopsy test capable of detecting and locating GI cancers is feasible and may serve as a valuable tool for early detection and intervention. Research Sponsor: BGI Genomics.

1558 Poster Session (Board #50), Fri, 8:00 AM-11:00 AM

Evaluation of a mobile cervical cancer screening program in São Luis, Maranhão, Brazil: Impact and challenges. *First Author: Rachel Jorge Dino Cossetti Leal, Hospital do Câncer Aldenora Bello, São Luís, Brazil*

Background: Cervical cancer (CC) still represents a public health priority in Brazil, with estimated incidence of 15,43 cases per 100.000 women. CC is the most frequent cause of cancer and cancer-related mortality in women in the state of Maranhão. The Brazilian national screening program recommends cervical cytology (Pap test) every 3 years in women 25-64 years old. Although of public access, the screening program continues to be non-organized. This was a real-life CC screening intervention through a mobile screening unit (MSU) in communities of São Luis, Maranhão. **Methods:** Prospective, intervention-based, analytic study, from April to August, 2018. Women in the assisted communities were offered Pap tests. Tests were collected and results were retrieved within 4 weeks along with further screening recommendations. Quality control and monitoring of the test were done. A structured questionnaire was applied. **Results:** 960 tests were collected and 545 women answered the questionnaire. Median age: 43 (34 – 52), with 88.2% of women within the target age. Socioeconomic charachteristics: 47.3% completed high school education; 37.8% were housewives, 16.1% were unemployed; 56.3% were married; 59.8% had a monthly family-income up to 1 minimum wage ($ 250,00). Previous Pap tests and difficulties: 94.1% had at least one previous test; 78,2% had a test within the past 3 years; 48.4% referred to dificculties to scheduling, 23.3% time constraints, 11.2% being ashamed, and 10.4% financial restrains. There were 65 (6.9%) abnormal results (LSIL in 3%, HSIL in 0.7%, and in situ adenocarcinoma in 1 case), for whom further investigation was recommended. Follow-up was possible in 31 of these cases. More than 50% were still awaiting for additional screening tests at time of contact (>6 month interval). **Conclusions:** MSU strategy faccilitated the access to Pap tests, their results and recommendations. Although Pap test was easily available, the non-organized process of invitation, follow-up and referal of positive cases for further investigation, as offered by the Brazilian public health services, limit screening efficacy and CC control. Evaluation of circulating miRNAs for earlier cancer detection through machine-learning expression profiling. *First Author: Jason Chia-Hsun Hsieh, Chang Gung Memorial Hospital, Guashan Township, Taoyuan County, Taiwan*

Background: Earlier cancer diagnosis leads to higher patient survival rate and reduces financial burdens for patients and their families. Over the past five years, liquid biopsy has demonstrated tremendous promise in the early detection of tumor presence. In addition to circulating tumor cells and circulating tumor DNAs, extracellular microRNAs (miRNAs) have also been shown to be promising diagnostic biomarkers. Through machine-learning profiling, we sought to determine whether or not we could use individuals' miRNA expression to distinguish between healthy subjects and cancer patients. **Methods:** Blood samples were collected from healthy donors and from patients of various cancer types. Plasma samples were purified within two hours of sample collection, followed by miRNA extraction. After performing reverse transcription of miRNAs into cDNAs, expression analysis of miRNAs was done using a novel multi-gene, amplification-based detection system that simultaneously analyzes over 160 miRNAs. For subsequent data processing, miRNAs without amplification signals across all profiles were first removed, resulting in 135 miRNAs. These 135 resulting miRNAs were then used as features in Support Vector Machine (SVM) to build OncoSweep classifier, a proprietary prediction algorithm for classification of the samples. Ten-fold cross validation was used to evaluate the performance of OncoSweep. **Results:** 344 healthy donor samples and 417 cancer patient samples were collected for the study. The prediction algorithm, OncoSweep, was derived based on the miRNA expression patterns of the healthy and the patient samples. The algorithm scored an overall accuracy for cancer prediction of 86.47%, with a sensitivity of 91.4%, a specificity of 85%, a PPV of 85% and an NPV of 88.5%. **Conclusions:** Utilizing machine-learning method of analyzing circulating miRNA expression profiles, the derived algorithm OncoSweep shows significant promise in cancer prediction. Validation is currently being performed in a larger study. We believe circulating miRNAs, through stringent sample processing and machine-learning methodology, are powerful biomarkers for earlier cancer detection. Research Sponsor: Quark Biosciences, Inc.

1560 Poster Session (Board #52), Fri, 8:00 AM-11:00 AM

Epigenetic control of breast cancer susceptibility. *First Author: Natascia Marino, Indiana University School of Medicine, Indianapolis, IN*

Background: Epigenetic mechanisms such as DNA methylation are important regulators of gene expression and are frequently dysregulated early in breast carcinogenesis. The relationship between DNA methylation aberrations in normal breast tissue and breast cancer risk remains unclear. **Methods:** Disease-free breast tissue cores donated by 71 high-risk (Tyrer-Cuzick lifetime risk ≥20%) and 79 average-risk women were obtained from the Komen Tissue Bank and processed for whole methylome (Diagenode's MethylCap Library and single-end 75-bp sequencing on Illumina Nextseq) and whole transcriptome (Illumina Nextseq) profiling. Reads from RNA-seq data were aligned to the human genome reference, GRCh38.p12 using STAR v.2.5.2b and tested for differential gene expression using DESeq2 ver. 1.24.0. For DNA methylation data, difference of variation in deduplicated read coverage among 250-bp fixed sized bins spanning CpG islands between high- and average-risk libraries was computed as z-ratios to identify differentially methylated regions. Pathway analysis was performed using IPA v06_01. **Results:** We identified 1355 CpGs that were differentially methylated between high- and average-risk breast tissues ($\Delta Z > 0.5$, FDR < 0.05). Hypomethylated CpGs were overrepresented in high-risk tissue and were found predominantly (68%) in non-coding regions. Hypermethylated CpG sites were found equally in the gene body and non-coding regions. Transcriptomic analysis identified 112 differentially expressed genes (fold change≥2, FDR < 0.05), involved in chemokines signaling, metabolism and estrogen biosynthesis. Among those, FAM83A (logfc = 2.3, FDR = 0.004) was previously described as epigenetically dysregulated in multiple cancers and transforms breast epithelial cell *in vitro*. Methylation-expression correlations revealed 11 epigenetically regulated genes including cellular transformation-associated BMPR1B. Two hypomethylated/upregulated long non-coding RNAs were also identified in high-risk breasts. **Conclusions:** This is the first gene expression/DNA methylation analysis of normal breasts from women at either high or average risk of breast cancer. Our discovery of epigenetically regulated genes associated with breast cancer risk provides an opportunity to mechanistically dissect breast cancer susceptibility and risk-associated molecular alterations. Unlike the current focus of identifying germline mutations or single nucleotide polymorphisms responsible for higher risk, our studies reveal an epigenetic mechanism, which is not discernable through simple genomic sequencing. Research Sponsor: Breast Cancer Research Foundation, Catherine Peachy Fund.

Adoption of opportunistic salpingectomy for ovarian cancer prevention: Results from a nationwide sample of privately insured women. *First Author: Pritesh S Karia, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Recent evidence indicates that the Fallopian tube is the site of origin for many high-grade serous ovarian cancers, particularly in *BRCA* carriers. This has led to the emergence of opportunistic salpingectomy (OS) as a novel ovarian cancer prevention strategy. Despite limited data, some national societies now recommend OS for ovarian cancer prevention during benign hysterectomy or in place of tubal ligation for sterilization in average-risk women. We assessed patient characteristics associated with increased likelihood of OS and national trends in OS adoption before and after release of recommendations. **Methods:** Data from MarketScan were used to identify women who underwent hysterectomy, tubal ligation, and OS from 2010-2017. Rates of OS were compared and interrupted time series analysis with segmented Poisson regression was used to examine immediate and persistent changes in OS rates before and after recommendations. Rates were calculated quarterly and models were adjusted for age and seasonality. **Results:** A total of 309,574 tubal ligations, 13,574 OS for sterilization, 293,000 hysterectomies, 22,798 hysterectomies with OS were included. Quarterly rates of OS for sterilization and hysterectomy with OS were 3.13 and 4.82 per 100,000 women, respectively. About 92% of OS for sterilization and 56% of hysterectomy with OS were performed in women < 45 years. The most common indication for hysterectomy with OS was uterine fibroids (46%). About 8% of OS for sterilization and 10% of hysterectomy with OS were performed in women with a family history of breast or ovarian cancer. After adjusting for age and seasonality, there was a 250% immediate increase (RR: 3.50; 95% CI: 2.59-4.72) followed by a 14% (RR: 1.14; 95% CI: 1.10-1.18) persistent increase in the quarterly rate of OS for sterilization after versus before recommendation release. There was a 109% immediate increase (RR: 2.09; 95% CI: 1.15-3.81) in the quarterly rate of hysterectomy with OS after versus before recommendation release. No persistent change in the rate of hysterectomy with OS was observed. Significant declines in hysterectomy and tubal ligation rates were observed and these declines were temporally associated with the release of recommendations. **Conclusions:** OS for ovarian cancer prevention has rapidly diffused into clinical practice with the speed of adoption bolstered by recommendations from national societies. Future studies evaluating the overall efficacy and long-term complications of OS are needed to support its continued widespread use. Research Sponsor: None.

1562 Poster Session (Board #54), Fri, 8:00 AM-11:00 AM

Breast cancer events in women with atypical ductal hyperplasia who do not undergo surgical excision. *First Author: Lyndsey Jo Kilgore, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Atypical ductal hyperplasia (ADH) found on core needle biopsy is associated with an upgrade to carcinoma in 10-30% of women, thus surgical excision remains the standard of care. We sought to review the incidence of breast cancer in women with ADH managed by either observation or surgical excision over a 15 year period. **Methods:** Our prospectively maintained registry was reviewed to identify patients with ADH diagnosed by core needle biopsy between 1/2004 and 10/2018. Observed patients were deemed low risk for upgrade after multidisciplinary review confirmed adequate sampling, limited atypia and concordance between imaging and histology. Surgical patients were excluded if upstaged to carcinoma following excision. Patients with $<$ 1 year follow-up were excluded. Subsequent breast cancer was classified as ipsilateral or contralateral to the previous ADH and was further classified as index site if the new cancer was identified in the same quadrant as prior ADH. Multivariate logistic regression models were used to assess potential predictors of subsequent breast cancer events. **Results:** Four hundred and seventy-eight women with 483 ADH lesions met criteria; 305 were observed and 173 underwent excision. Median follow-up was 5.2 years, range 1.1-15.3. At the time of ADH diagnosis, 91 women had a personal history of breast cancer. Age $<$ 50 was the only statistically significant difference between the groups (24.6% vs. 33.3%, p = 0.04). Race, receipt of chemoprevention, prior breast cancer history and median follow-up were not significant between the groups. Prior history of breast cancer was associated with subsequent breast cancer risk in multivariate analysis (OR 2.25, 95% CI 1.04-4.87, p = 0.04). After excluding patients with a history of breast cancer, multivariate analysis demonstrated no association of age, race, use of chemoprevention or surgical excision with future cancer risk. Among the 387 patients without a prior breast cancer history, 21 patients developed a subsequent cancer; 10 in the surgical group and 11 in the observed group (7.3% vs. 4.4% respectively, p = 0.2). Two cancers were identified at the index site in the surgery group (2/137, 1.5%) and three in those observed (3/250, 1.2%). **Conclusions:** Observation, rather than surgical excision, is safe in selected women that have a core biopsy diagnosis of ADH. Index site failures are rare and are superseded by cancer risk elsewhere in the breast. National screening and diagnosis recommendations should consider recommending observation for this select group of patients with ADH. Research Sponsor: None.

1563 Poster Session (Board #55), Fri, 8:00 AM-11:00 AM

Mammography utilization among women with a negative circulating tumor DNA-based early cancer detection test. *First Author: Claire Jones, Geisinger Health System, Danville, PA*

Background: Blood-based tests may enable minimally invasive detection of multiple cancer types. One such test, CancerSEEK, employs ctDNA and protein biomarkers for this purpose. Test performance has been evaluated in women without a history of cancer in an ongoing prospective study called DETECT-A. The introduction of such blood tests holds promise, and their future utility lies in augmenting, not displacing, standard-of-care (SOC) cancer screening. One important safety concern is that a negative test result could provide false reassurance that discourages adherence to SOC cancer screening. To investigate this possibility, we studied delivery of mammography to DETECT-A participants before and after receipt of a negative CancerSEEK result. **Methods:** DETECT-A screened 10,000 women aged 65-75 using CancerSEEK. Participants completed a survey about cancer screening at enrollment and at one-year post-enrollment. We analyzed only those participants who had received a negative CancerSEEK result, were insured by Geisinger Health Plan (GHP), and had completed both surveys. GHP claims data were used to identify mammograms performed within one year prior-to and post-enrollment. Overall utilization was determined by combining claims and survey data at enrollment and one-year post-enrollment. In addition to comparing SOC screening rates pre- versus post-testing, we evaluated the impact of primary care physician (PCP) type (Geisinger versus any other institution), as screening reminder mechanisms differ between institutions. **Results:** Of the 2,241 participants who met analysis criteria, 73.6% (n = 1,650) had a mammogram in the year before enrollment while a significantly great number (79.3%, n = 1,777) did so during the one-year follow-up ($\chi^2(1) = 59.05$, $p < 0.001$). At enrollment, there were 591 participants who had not had a mammogram completed in the previous year, but 404 (68.4%) of them did have a mammogram during the one-year follow-up. The rate of change in mammography utilization did not differ between those who had a Geisinger versus a non-Geisinger PCP ($\chi^2(2) = 1.83$, p = 0.40). **Conclusions:** Participants in a study using a novel blood test for earlier cancer detection had a significantly higher rate of annual mammography after study enrollment and testing. These results indicate that introduction of a minimally invasive ctDNA and protein biomarker-based cancer screening test may engender greater, not lesser, utilization of SOC cancer screening. Further study is required to understand the root causes of increased utilization in this context. Research Sponsor: Marcus Foundation.

1565 Poster Session (Board #57), Fri, 8:00 AM-11:00 AM

Mediation of black/white disparities in triple negative breast cancer by socioeconomic position, reproductive factors and diabetes in the Nurses' Health Study Cohorts I & II. *First Author: Lydia Marcus, University of Wisconsin Milwaukee, Milwaukee, WI*

Background: The higher rates of triple negative (TN) breast cancer (BC) observed among black compared to white women may be attributable to social and reproductive factors, as well as biological conditions like diabetes mellitus type 2. We examine the extent to which the black/white race disparity in TNBC is transmitted through these factors. **Methods:** Data are from the Nurses' Health Study I and II prospective cohorts and include non-Hispanic (nH) black (n = 97) and nH white (n = 8,876) women aged 25-55 years at enrollment with invasive BC diagnoses. Participant characteristics are self-reported or drawn from medical records. We estimated average controlled direct associations (ACDA) using logistic regression with model-based standardization to evaluate the age/body mass index (BMI)-adjusted prevalence difference for TN versus luminal A/B type BC by race, and performed a series of ACDA (with comparison of rescaled coefficients (RC)) controlling for diabetes, mean family income before diagnosis (cont.), husband's education ($<$ college, college, graduate school), parental ownership of participant's childhood home (yes/no), age at menarche (cont.), age at first birth (cont.), parity (integer), and breastfeeding (BF) (parous/never BF, parous/ever BF). **Results:** Compared to nH whites, nh black women had higher prevalence of TNBC (24.5% v. 45.4%; $p < 0.01$), higher prevalence of diabetes (5.5% v. 11.3%; p = 0.01), lower prevalence of BF (59.2% v. 46.6%; p = 0.02), higher mean BMI (26.1 v. 29.9; $p < 0.01$), and lower mean family income ($17,304 v. 15,750; $p < 0.01$). BMI, age, and menopause were positively associated with prevalence of diabetes. In the age/BMI adjusted model, nH black women were 20%-points more likely than nH whites to have TNBC (95% Confidence Interval (CI): 0.11, 0.29). This disparity was reduced to 18.1% after also adjusting for BF (95% CI: 0.09, 0.28), to 13.7% after additionally adjusting for socioeconomic indicators (95% CI: 0.02, 0.25), and to 13.3% after adjusting for all potential mediators (95% CI: 0.01, 0.26). Based on the method of RC, socioeconomic indicators accounted for the largest fraction of mediated effects and BF accounted for most of main effect attenuation associated with reproductive factors; diabetes accounted for negligible effect. **Conclusions:** Our findings support the hypothesis that observed racial differences in TNBC diagnoses may be at least partially mediated by differences in socioeconomic position and reproductive patterns, namely breastfeeding. Research Sponsor: University of Wisconsin.

1566 Poster Session (Board #58), Fri, 8:00 AM-11:00 AM

Projection of cancer incidence and death to 2040 in the US: Impact of cancer screening and a changing demographic. *First Author: Lola Rahib, Cancer Commons, Los Altos, CA*

Background: Coping with the current and future burden of cancer requires an in-depth understanding of cancer incidence and death trends. As of 2020, breast, lung, prostate, and colorectal cancer are the most incident cancers, while lung, colorectal, pancreas, and breast cancer result in the most deaths. Here we integrate observed cancer statistics and trends with observed and estimated US demographic data to project cancer incidences and deaths to the year 2040. **Methods:** Demographic cancer-specific delay-adjusted incidence and death rates from the Surveillance, Epidemiology, and End Results Program (2014-2016) were combined with US Census Bureau population growth projections (2016) and average annual percentage changes in incidence (2011-2015) and death (2012-2016) rates to project cancer incidences and deaths through the year 2040. We examined the 10 most incident and deadly cancers as of 2020. We utilized Joinpoint analysis to examine changes in incidence and death rates over time relative to changes in screening guidelines. **Results:** We predict the most incident cancers in 2040 in the US will be breast (322,000 diagnoses in 2040) and lung (182,000 diagnoses in 2040) cancer. Continuing decades long observed incident rate trends we predict that melanoma (173,000 diagnoses in 2040) will become the 3rd most common cancer while prostate cancer (63,000 diagnoses in 2040) will become the 5th most common cancer after colorectal cancer (139,000 diagnoses in 2040). Lung cancer (61,000 deaths in 2040) is predicted to continue to be the leading cause of cancer related death, with pancreas (45,000 deaths in 2040) and liver & intrahepatic bile duct (38,000 deaths in 2040) cancer surpassing colorectal cancer (34,000 deaths in 2040) to become the second and third most common causes of cancer related death, respectively. Breast cancer deaths (29,000 in 2040) are predicted to continue to decrease and become the fifth most common cause of cancer death. Joinpoint analysis of incidence and death rates supports a significant past, present, and future impact of cancer screening programs on the number of cancer diagnoses and deaths, particularly for prostate, thyroid, melanoma incidences, and lung cancer deaths. **Conclusions:** We demonstrate marked changes in the predicted landscape of cancer incidence and deaths by 2040. Our analysis reveals an influence of cancer screening programs on the number of cancer diagnoses and deaths in future years. These projections are important to guide future research funding allocations, healthcare planning, and health policy efforts. Research Sponsor: None.

1567 Poster Session (Board #59), Fri, 8:00 AM-11:00 AM

Malignancies associated with DPP4 inhibitors and GLP1 receptor agonists: Data from a large real-world database. *First Author: Jiasheng Wang, Met-MetroHealth Medical Center, Cleveland, OH*

Background: DPP44 inhibitors (DPP4i) and GLP1 receptor agonists (GLP1Ra) control type 2 diabetes (T2DM) by promoting GLP-1 pathway; its activation can lead to dysplasia or tumor inhibition based on tissue types. Moreover, DPP4 can act as a tumor suppressor or activator. Few studies have looked at the risk of DPP4i and GLP1Ra on various types of cancer. **Methods:** We inquired an aggregated electronic health record database, Explorys (IBM, NY). Patients (Pts) diagnosed with T2DM from 1/05 to 6/19 were included and followed for 5 years after starting DPP4i, GLP1Ra, or metformin. Odds ratio (OR) were calculated after 6mo of lag time. **Results:** We identified 344,550, 112,000, and 1,245,930 pts in the DPP4i, GLP1Ra, and metformin group, respectively. The three groups were well balanced except pts in the GLP1Ra group had higher BMI. Within 5 years, 24,260 pts (9.5%) in DPP4i, 5,580 (8.7%) in GLP1Ra, and 57,490 (9.3%) in metformin group developed any types of cancer. When adjusted for sex, age, smoking status, alcohol abuse history, hemoglobin A1C ($\leq$9.0% vs $>$ 9.0%) and BMI ($<$ 30 vs $\geq$30 kg/m^2) around initiation of antidiabetic agents, the aOR was 1.01 (95%CI .94-1.08) for DPP4i and 1.06 (95%CI .93-1.20) for GLP1Ra, comparing with the metformin group. For specific cancer types, DPP4i users were associated with significantly higher risk of bladder, kidney, liver cancer and melanoma; while the risk of breast, lung and prostate cancer were reduced. GLP1Ra users were associated with higher risk of thyroid cancer; while the risk of bladder, colon, lung, and prostate cancer were reduced. **Conclusions:** DPP4i and GLP1Ra were not associated with increased cancer risk overall. However, they were associated with increased or decreased risk of specific cancer types. Research Sponsor: None.

1568 Poster Session (Board #60), Fri, 8:00 AM-11:00 AM

A comparison of patients' and physicians' expectations regarding precision oncology tests. *First Author: Navdeep Dehar, University Of Calgary, Calgary, AB, Canada*

Background: With the increasing number and frequency of biomarker and genetic tests that are offered to patients with cancer, it is important to ensure that they fully understand the implications of these tests. In this survey study, we aimed to compare the attitudes and expectations of patients and cancer physicians about the role of biomarker and genetic testing in clinical decision-making. **Methods:** Two separate, complimentary, self-administered questionnaires for cancer patients and their physicians, respectively, were collected in Calgary, Alberta, Canada. Survey responses from patients were subsequently matched with those of their corresponding oncologists to form patient–oncologist dyads. We determined the concordance rates between responses of patients and those of their oncologists. **Results:** A total of 113 patients and 15 physicians participated in the study from July to September 2019. Patients demonstrated good understanding of general cancer biology (79%) and diagnostic processes (91%) associated with precision oncology. About 70% patients were willing to undergo minor procedures, and participate in research involving biomarker or genetic testing; however, this was over-estimated by their physicians in 82% of cases. Many patients felt that their tumor should be tested to guide treatment (70%) and were not bothered by potential delays in treatment due to testing (23%). These views from patients were largely shared by their oncologists (concordance 64%). While only 28% patients thought that they had enough knowledge to make informed decisions, majority (68%) said that they needed more information. Importantly, knowledge and expectations regarding the applications of biomarker or genetic test results on actual diagnosis and prognosis were grossly discrepant between patients and their oncologists (concordance 26% and 36%, respectively). **Conclusions:** Patients and cancer physicians tend to be aware of the advances in precision oncology and are willing to participate in biomarker and genetic testing and research. However, they do not consistently agree about the roles and applications of these tests, which may result in misplaced expectations. Strategies to improve education and communication are needed to align these expectations and improve the quality of clinical decision-making. Research Sponsor: None.

1569 Poster Session (Board #61), Fri, 8:00 AM-11:00 AM

Protein intake and breast cancer incidence and mortality. *First Author: Kathy Pan, Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center, Torrance, CA*

Background: Associations between dietary protein intake and breast cancer are unclear, in part due to limitations of dietary self-report. Women's Health Initiative (WHI) investigators compared the accuracy of food frequency questionnaire (FFQ) data on energy and protein intake with objective measures of dietary intake using biomarkers (doubly labeled water for energy and urinary nitrogen for protein [n=544]). Subsequently, regression equations incorporating participant characteristics were developed acknowledging differential reporting dietary data errors based on participant characteristics (Neuhouser Am J Epidemiol). FFQ findings were then used to determine biomarker- adjusted animal vs vegetable protein ratios. **Methods:** We examined associations of energy and protein intake with breast cancer incidence and mortality in Women's Health Initiative (WHI) participants 50-79 years of age at entry between1993-1998, with breast cancers verified by medical record review and survival enhanced by serial National Death Index (NDI) searches through 2016. Associations between sources of protein intake (animal versus vegetable) quintiles and breast cancer incidence and mortality were estimated using multivariable Cox proportional hazards regression. **Results:** With 100,024 eligible participants, after 14 years follow-up, women with higher total protein intake had greater body mass index, were more likely White, menopausal hormone therapy users with higher total energy intake and fat intake. With 6,340 incident breast cancers, 764 deaths from breast cancer and 2,059 deaths after breast cancer, higher vegetable protein intake was associated with significantly lower breast cancer incidence (P for linear trend = 0.01) while higher animal protein intake was associated with significantly higher breast cancer incidence (P for linear trend = 0.03). Higher vegetable protein intake was also associated with significantly lower risk of death after breast cancer (P $<$0.001) but not with lower risk of deaths from breast cancer (breast cancer followed by death attributed to breast cancer). Animal protein intake was not associated with deaths from breast cancer or deaths after breast cancer. **Conclusions:** Based on findings from biomarker-calibrated determination of protein intake by source, higher vegetable protein intake was associated with significantly lower risk of breast cancer incidence and of death after breast cancer while higher animal protein intake was associated with significantly higher risk of breast cancer incidence, but not mortality. Research Sponsor: U.S. National Institutes of Health.

1570 Poster Session (Board #62), Fri, 8:00 AM-11:00 AM

Dietary advanced glycation end products (AGEs) and breast cancer mortality in the women's health initiative (WHI). *First Author: Lindsay Leuthen Peterson, Washington University in St. Louis, St. Louis, MO*

Background: Breast cancer (BrCa) is the second leading cause of cancer death and constitutes about 14% of total cancer deaths among US women. Advanced glycation end-products (AGEs) are implicated in chronic diseases including cancer and cardiovascular diseases (CVD). AGEs are naturally found in animal products and processed foods, and preparing food at high temperatures increases AGE formation. Our goal was to assess the association between post-diagnosis dietary N$^{\varepsilon}$-carboxymethyl-lysine (CML)-AGE intake, a common measure of AGE, and mortality from all-causes, BrCa and CVD among participants with invasive BrCa in the Women's Health Initiative (WHI). **Methods:** The WHI enrolled postmenopausal women aged 50 to 79 years from 1993-1998 into randomized controlled trials and a prospective observational study to examine causes of morbidity and mortality. In this analysis, we included 2,073 women diagnosed with invasive BrCa during follow-up who completed a food frequency questionnaire (FFQ) after diagnosis, had energy intakes between $\geq$600 kcal/day and $\leq$5000 kcal/day, and had CML-AGE intake data available. Women were followed from BrCa diagnosis until death or censoring through March 2018. Cox proportional hazards regression models estimated the hazard ratios (HR) and 95% CIs of mortality risk from all-causes, BrCa and CVD by tertiles of dietary CML-AGE intake with adjustment for age, income, race/ethnicity, study arm, time from diagnosis to FFQ completion, education, physical activity, smoking, BMI, ER/PR status, diagnosis stage, postmenopausal hormone use, intake of energy, alcohol, fat, red and processed meats. **Results:** After a median 15.1 years of follow-up, 642 deaths were reported including 198 BrCa-specific and 129 CVD-specific deaths. The average time from BrCa diagnosis to FFQ completion was 1.5 years. Compared to the lowest tertile of CML-AGE intake, there was an increased risk in the highest tertile for all-cause mortality (HR: 1.51, 95% CI: 1.17-1.94), BrCa (HR: 1.86, 95% CI: 1.19-2.91) and CVD (HR: 2.14, 95% CI: 1.19-3.84) mortality. **Conclusions:** Higher dietary AGE intake after BrCa diagnosis in postmenopausal women was associated with increased risk of mortality from all-causes, BrCa and CVD. Exposure to AGEs could be modified through dietary counseling and evaluated in relation to reduced mortality risk after BrCa diagnosis. Research Sponsor: Susan G. Komen, Other Foundation.

1571 Poster Session (Board #63), Fri, 8:00 AM-11:00 AM

Metabolic syndrome, metabolic comorbid conditions, and risk of early-onset colorectal cancer. *First Author: Hanyu Chen, Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO*

Background: The etiology and contributors to the rising incidence of early-onset colorectal cancer (CRC diagnosed under age 50), driven largely by distal and rectal cancer, remain largely unknown. Metabolic syndrome is associated with higher risk of CRC diagnosed at older ages; however, its association with early-onset CRC remains unclear. **Methods:** We conducted a nested case-control study among participants aged 18-50 years with ≥2 years of enrollment and prescription drug coverage in the IBM MarketScan Commercial Databases (2006-2015). Incident CRC cases were identified using ICD-9-CM diagnosis codes. Controls without any cancer were identified using frequency matching on age, sex, geographical region, and duration of insurance enrollment. Metabolic syndrome was defined using either ICD-9-CM diagnosis codes or the presence of at least 3 of the following: obesity, hypertension, hyperlipidemia, and hyperglycemia/type 2 diabetes. In addition to ICD-9-CM codes, hypertension, hyperlipidemia, and hyperglycemia/type 2 diabetes were also defined based on regular use of medications. Multivariable logistic regressions were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs). **Results:** A total of 4,673 early-onset CRC and 40,832 controls were included. Metabolic syndrome was associated with increased risk of early-onset CRC (OR: 1.33, 95% CI 1.16-1.52), after adjusting for a range of potential confounders. The number of metabolic comorbid conditions was positively associated with risk of early-onset CRC in a dose-response fashion. Compared to individuals without any conditions, individuals with 1, 2, ≥3 metabolic conditions had a 13% (OR: 1.13, CI 1.04-1.22), 18% (OR: 1.18, CI 1.07-1.31), and 40% (OR: 1.40, CI 1.22-1.61) higher risk of early-onset CRC (P_{trend}<0.001), respectively. These associations were driven by proximal (OR for ≥2 vs 0 metabolic comorbid conditions: 1.40, CI 1.15-1.69) and distal colon cancer, OR ≥2 vs 0: 1.25, CI 1.03-1.53), but not rectal cancer (OR≥2 vs 0: 1.07, CI 0.92-1.24). **Conclusions:** Metabolic syndrome and metabolic comorbid conditions were associated with increased risk of early-onset CRC, largely driven by proximal and distal colon cancer. Metabolic dysregulations may contribute to the rising incidence of early-onset CRC. Research Sponsor: U.S. National Institutes of Health.

1572 Poster Session (Board #64), Fri, 8:00 AM-11:00 AM

Is there a genomic fingerprint of Radon (Rn)-induced lung cancer (LC)? Comparison of genomic alterations in LC specimens from high and low Rn zones. *First Author: Hina Khan, Rhode Island Hospital-The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Rn-222 is a radioactive gas found in rocks and soil. It emits alpha particles that cause dsDNA breaks and increase potential for carcinogenesis. Rn is the 2nd leading cause of LC in the US after smoking. EPA estimates >15,000 deaths/yr (9% of LC deaths) from Rn. We hypothesize that the impact of Rn exposure may be reflected in LC gene mutation (mut) profiles. **Methods:** Using commercial NGS assays, we retrospectively analyzed genomic DNA alterations in FFPE specimens from 159 LC patients (pts) from the Lifespan Cancer Institute in Rhode Island (2014- 2019), followed by validation in a larger cohort of 5,532 pts using Caris platform. Based on EPA Rn maps, we identified counties with high indoor Rn levels (>4 pci/L; HR), and compared gene mut patterns with those from low Rn zones (<4 pci/L; LR). Based on pt's zip code of residence, we categorized them to HR and LR. In the validation cohort, p values adjusted for multiple comparison (q) of < .05 were considered significant. **Results:** In the pilot cohort, 35 pts (22%) were in HR and 124 (78%) in LR zones. Adenocarcinoma histology was most frequent (73%) and smoking prevalence was high (75%) in both groups. Most prevalent alterations were *TP53, KRAS* and *CDKN2A* muts. In the HR, we noted more frequent recurrent muts in 2 DNA repair genes (DDR): *ATM* (11 vs 1%, p= .00086) and *CHEK2* (6 vs 0%, p= .047) when compared to LR group. When classified into major pathways implicated in lung carcinogenesis, higher frequency of mutations were seen in DDR in HR zones vs. LR (29 vs 13%, p= .038). In the validation cohort, 1,433 (26%) pts were in HR and 4099 (74%) in LR zones. Among the DDR genes, *ATM* muts in HR group tended to be more frequent (4.7 vs 3.4% in LR, p= .03) as well as *PALB2* (0.9 vs 0.4%, p= .02) while no difference seen in *CHEK2*. Other genes with significantly higher prevalence in HR were *TP53, SMARCA4 and NFE2L2* (q< .05); while *KMT2D, KEAP1, CDKN2A, MET, NF2, DNMT3A, CCND1 and FAS* show a trend (p< .05). *EGFR* muts were significantly more frequent in LR zones (8.4 vs 14.6%, q= .001). Similar to the pilot cohort, DDR pathway alterations trend to be higher in HR zones (14 vs 12%, p= .05). Using a high TMB cut-off >10, tumors from HR zones had significantly higher TMB when compared to LR zones (56 vs 48%, q= .0005). **Conclusions:** To our knowledge, this is the first attempt to elucidate the pathobiology of Rn induced LC using gene mut analyses. Our observations suggest that LC associated with higher Rn exposure may have disabled DNA repair pathways and higher TMB. Assuming uniform tobacco smoke exposure, higher Rn was not associated with EGFR mut. Research Sponsor: institutional finances.

1573 Poster Session (Board #65), Fri, 8:00 AM-11:00 AM

The increasing incidence of colorectal cancer in younger patients in the United States: Who, what, when, and where? *First Author: Mary Kathryn Abel, UCSF School of Medicine and Department of Surgery, San Francisco, CA*

Background: Prior studies have shown an increase in the rate of colorectal cancer (CRC) in young individuals in the United States. However, few studies have evaluated the health disparities that exist in this population, particularly using large, national cohorts. We examined differences in age, race, stage, region, and tumor location in younger and older patients with CRC. **Methods:** Data were extracted from the United States Cancer Statistics (USCS) for individuals diagnosed between 2001 and 2014. CRC incidence data among individuals < 50 years old were compared to those > 50 years old. Age-specific and age-adjusted incidences and trend analyses reported as annual percent change (APC) were performed using SEER*Stat and Joinpoint regression. **Results:** Of 1,886,441 individuals, the overall age-adjusted incidence of CRC decreased from 52.59 (per 100,000) in 2001 to 35.22 in 2014, with an APC of -3.24. Although over 35% cases were diagnosed in the Southern United States, the Northeast had the highest age-adjusted incidence at 45.26 per 100,000 patients. Younger patients were diagnosed with distant disease at 25.8% compared to only 18.4% in older patients. Younger patients were also more likely to have sigmoid or rectal cancers compared to older patients (64.3% vs. 45.7%). Of the 170,244 individuals < 50 years, 90,855 (53.4%) were men and 79,389 (46.6%) were women. The age-specific incidence in this younger cohort increased from 5.63 to 6.48 between 2001-2014, with an APC of +1.24 in 2001-2008 compared to +2.55 in 2012-2014. The incidence of CRC in patients aged 0-29, 30-39, and 40-49 years was 0.41 (per 100,000), 6.08, and 21.09, respectively. Black individuals < 50 years had the highest age-specific incidence of CRC (7.16 per 100,000) compared to Asian (6.43), White (6.07), or Hispanic (4.76) individuals. **Conclusions:** Our data suggests that CRC is increasing in young patients, particularly for those between 40-49 years and Black individuals. In our younger cohort, CRC was more commonly found in the sigmoid colon and rectum compared to older patients. Further research is warranted to direct resources towards improved colonoscopy or sigmoidoscopy screening for younger patients at risk. Research Sponsor: None.

1574 Poster Session (Board #66), Fri, 8:00 AM-11:00 AM

Geographic disparity of outcome in patients with cancer over decades: The surveillance, epidemiology, and end results. *First Author: Kenichi Sakurai, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Improvements in prevention, early detection and therapy of cancer have decreased cancer related mortality yet health disparities continue to exist. We investigated the impact of such disparities in cancer survival. **Methods:** In the Surveillance, Epidemiology, and End Results, we identified 784,341 patients with cancer from 1990 to 2016 in Georgia; 68,493 in 1990-1999, 371,353 in 2000-2009, and 322,932 in 2010-2016. We assessed overall survival (OS) of patients with all cancers, chronic myeloid leukemia (CML), and lung cancer given the dramatic improvement in patient outcomes in CML since 2000 compared to the consistently poor outcome in lung cancer. We assessed distance from each county to the one National Cancer Institute-designated cancer center (NCI-CC) in Georgia. **Results:** The 5-year OS of patients with any cancer was 55% with median OS 80 months; the 5-y OS of each county ranged from 33% to 82% (interquartile range[IQR], 51%-65%)(P < 0.001). The improvement of OS was minimal over decades: 5-year OS was 52%, 55%, and 55% in 1990-1999, 2000-2009, and 2010-2016, respectively; the median was 69 months, 80 months, not reached, respectively (P < 0.001). In patients with lung cancer and CML, the 5-year OS was 15% and 52% with the median of 9 months and 67 months, respectively. The geographic difference between counties was relatively small and constant over time in patients with lung cancer, represented by the width in the range and IQR: range 5%-17%, IQR 9%-13%, median 13% in 1990-1999; range 2%-24%, IQR 10%-14%, median 14% in 2000-2009; and range 4%-24%, IQR 12%-17%, median 17% in 2010-2016. However, the geographic difference was more prominent in patients with CML and widened after introduction of modern therapy: range 20%-42%, IQR 26%-34%, median 32% in 1990-1999; range 14%-83%, IQR 38%-64%, median 53% in 2000-2009; and range 14%-80%, IQR 40%-57%, median 57% in 2010-2016. Multivariate Cox regression showed age (hazard ratio[HR],1.040;95% confidence interval[CI],1.039-1.040;P < 0.001), median county income (HR,0.919; 95% CI,0.916-0.921;P < 0.001), African American (HR,1.021;95% CI,1.210-1.227;P < 0.001), and distance to NCI-CC (each 100 kilometers) (HR,1.021;95% CI,1.017-1.025;P < 0.001) as predictive factors. **Conclusions:** The disparity of cancer care exists between geographic locations. The geographic difference of survival seems more prominent when highly effective therapies are available. Research Sponsor: None.

1575 Poster Session (Board #67), Fri, 8:00 AM-11:00 AM

Population genetic screening for hereditary breast and ovarian cancer in at-risk patients: A novel testing and prevention model for community hospitals reveals high mutation rates rurally. *First Author: Charles Hendrix Shelton, Vidant Health, Nags Head, NC*

Background: Genetic testing for at risk non-cancer patients continues to increase (Guo F, et al Cancer 2020). We identified a high risk of familial breast and ovarian cancer in rural eastern North Carolina, and created a systematic approach for genetic screening, counseling and testing. **Methods:** A family history questionnaire was designed to assess for the risk for hereditary breast and ovarian cancer (HBOC) using NCCN guidelines, and used at key intake points within the unaffected population to determine eligibility for genetic testing. First it was offered at the time of all mammograms. Second, we offered it in the primary gynecology care setting to capture younger patients not participating in screening mammography. Patients meeting HBOC criteria were sent a letter and two phone calls to schedule genetic counseling. Analysis via descriptive statistics. **Results:** 3000 rural women screened using our systematic approach to genetic risk assessment. 22.4% (673/3000) of female patients met NCCN criteria for HBOC panel testing. All offered consultation and counseling. With a backlog to see patients due to higher than expected accrual, 217 patients have completed pre-test genetic counseling, 201 completed local 19-gene panel test, and 201 had post-test counseling. Germline mutations (=>1) that predict for genetic susceptibility to cancer(s) occur in 7.8% of our screened and tested population. Currently 1 in 400 patients screened in our unaffected population carry a BRCA mutation, and 1 in 200 carry some pathogenic mutation that increases risk for HBOC. **Conclusions:** This rural model of screening and prevention of at risk patients for HBOC is successful at detecting pathogenic mutations in unaffected patients before they are diagnosed with cancer. Interestingly, the rate of positivity in the unaffected population (meeting criteria) is as high as the known breast cancer population rate of germline mutations (5-10%), validating the use of testing guidelines with our model. Discovering this susceptibility before a cancer diagnosis resulted in appropriate high risk management with prevention and risk reduction strategies. We plan to expand this model to the male screening population in 2021, and streamline genetic assessment and testing for the larger population at risk by engaging more rural primary care clinics over time to increase testing compliance. We also plan to consider broader gene panels as newer mutations become linked to HBOC. Clinical trial information: UMCIRB 19-001052. Research Sponsor: Pfizer and ACCC.

1576 Poster Session (Board #68), Fri, 8:00 AM-11:00 AM

Burden of genetic testing in an academic biobank by pathological and family history-based criteria in prostate cancer (PCa). *First Author: James Ding, University of Pennsylvania, Philadelphia, PA*

Background: Approximately 5% of localized PCa and 12% of metastatic PCa are associated with germline mutations in DNA repair genes. The National Comprehensive Cancer Network (NCCN) issued genetic testing guidelines to identify PCa patients (pts) likely to harbor a germline DNA repair mutation. The overall burden of this guideline-based, resource-intensive genetic testing is unknown. Using supervised phenotype-genotype information extraction algorithms, we determined the projected genetic testing burden at a single institution adhering to NCCN PCa genetic testing guidelines. **Methods:** A PCa cohort of 2127 pts was identified from the Penn Medicine BioBank via ICD 9/10 codes. Phenotypic data were extracted from the Penn Medicine Cancer Registry and electronic health record systems via natural language processing and manual chart review. Pts were classified based on 9 germline genetic testing criteria outlined in the NCCN PCa guidelines (Version 4.2019). **Results:** 895/2127 pts met at least 1 of the 9 NCCN genetic testing criteria, corresponding to a 42.1% overall genetic testing burden. 35.2% qualified for testing via high-risk localized PCa and 6.4% qualified via metastatic disease. Of the pts with localized PCa (n=2014), 15.1% qualified for genetic testing via high Gleason score, 5.1% via high-risk family history, 3.7% via PSA>20ng/mL, 8.7% via Ashkenazi Jewish descent, and 0.8% via intraductal/ductal histology. **Conclusions:** In this single-center PCa cohort, germline genetic testing was NCCN-guideline recommended for a larger proportion of pts than would otherwise be expected based on previously published reports. Future studies are needed to validate the sensitivity and specificity of these criteria for identifying germline mutations. Our study also highlights a need for novel methods to improve the efficiency of genetic testing for a large cohort. Research Sponsor: Penn Medicine Basser Center Grant.

Number of pts in a biobank meeting individual genetic testing criteria.

	Criteria[1]	# of pts meeting criteria	Total pts with data for criteria	% of pts
1	Regional: Any T, N1, M0	28	1178	2.4%
2	Metastatic: Any T, Any N, M1	113	1763	6.4%
3	High risk: T3 or T4	380	1081	35.2%
4	High risk: Gleason score 8-10	361	1929	18.7%
5	High risk: PSA at diagnosis >20ng/mL	109	1589	6.9%
6	Very high risk: Gleason primary 5	40	1928	2.1%
7	Ashkenazi Jewish	187	1773	10.6%
8	≥3 cancers on same side of family	111	2113	5.3%
9	Intraductal/ductal histology	20	2127	0.9%

[1] Not included due to lack of data: Brother, father, or multiple family members with PCa (not clinically localized grade 1) diagnosed <60 years old or who died from PCa

1577 Poster Session (Board #69), Fri, 8:00 AM-11:00 AM

Video vs. in-person genetic counseling for men considering germline prostate cancer testing: A patient-choice study. *First Author: Veda N. Giri, Departments of Medical Oncology, Cancer Biology, and Urology, Cancer Risk Assessment and Clinical Cancer Genetics Program, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: Germline testing (GT) for prostate cancer (PCA) is rapidly increasing with higher demand for genetic counseling (GC). Alternate GC strategies need to be studied to address pretest informed consent. Here we conducted a patient-choice study of pretest video-based genetic education (VBGE) or in-person GC (IPGC) and assessed men's preference and patient-reported outcomes from the first cohort of the Evaluation and Management for Prostate Oncology, Wellness, and Risk (EMPOWER) study. **Methods:** Eligibility for EMPOWER includes any male with PCA or at-risk for PCA based on family history or African American race. Men may choose pretest IPGC or VBGE. All receive results by a genetic professional. Demographics and PCA features were collected at baseline. The following outcomes and scales were assessed: baseline anxiety (GAD-7 scale), change in cancer genetics knowledge from baseline (Giri 2019), decisional conflict for GT (O'Connor 1993), and satisfaction (DeMarco 2004). Understanding of personal GT results was assessed after disclosure (Giri 2019). Descriptive statistics summarized results with counts and percentages for categorical variables and mean and standard deviation for continuous variables. Data were compared with Fisher's exact, Chi-squared, or Wilcoxon two-sample tests, as appropriate. Mean change in cancer genetics knowledge was compared with t-tests. Significance level was set a priori at 0.05. All analyses were performed with SAS 9.4 (Cary, NC). **Results:** At the time of this analysis, 94 men were enrolled. Characteristics of the cohort were: White (88.3%), bachelor's degree (67%), PCA diagnosis (93%), mean age of consent 59 years (IPGC) and 61 years (VBGE), Gleason > = 8 (32%), and > = T3 (31%). The majority preferred VBGE (77%) vs. IPGC (23%). Men who opted for IPGC had lower educational levels (< = high school/GED) (18% IPGC vs 7% VBGE) and reported higher baseline anxiety (45% IPGC vs. 24% VBGE). Cancer genetics knowledge improved significantly with IPGC vs. VBGE (+2.5 vs +0.8; $p < 0.01$). No differences were observed in decisional conflict, satisfaction, or understanding of personal GT results between IPGC vs. VBGE. Both groups had high rates of GT uptake (IPGC 91%, VBGE 93%). Pathogenic mutations were identified in 15% in IPGC group and 10.4% in VBGE group. **Conclusions:** A substantial proportion of men opted for VBGE, and results suggest that VBGE is comparable to IPGC for men considering PCA GT. IPGC may be more suitable for men with lower knowledge of cancer genetics and greater levels or anxiety. Further study is warranted. Implementation of systematic germline genetic testing (GT) for metastatic prostate cancer (mPC) patients at the Puget Sound VA prostate oncology clinic. *First Author: Alexandra Sokolova, University of Washington, Seattle, WA*

Background: There is increasing clinical relevance for GT in patients with mPC to evaluate the 2-fold possibilities of molecularly targeted therapies and implications for relatives. NCCN guidelines recommend GT for subsets of men, including those with mPC. While exciting, there are new logistical challenges around workflows for delivering GT services. We sought to address these challenges through a prospective pilot study designed to systematically deliver GT to all men with mPC receiving care at the Puget Sound VA prostate cancer (PUG-VA PC) Clinic. Our hypothesis was that systematic universal GT for men with mPC would identify similar prevalence rates of germline pathogenic/likely pathogenic variants (P/LPV) among veterans compared to previously reported cohorts. **Methods:** We conducted an IRB-approved, prospective trial testing feasibility of a systematic workflow to identify all veterans with mPC seen at PUG-VA PC Clinic between 11/2016-1/2020 to discuss and offer GT. A research coordinator pre-screened each clinic schedule to identify patients with mPC, notified the oncologist to discuss pretest education and GT with the patient at the appointment. Consenting patients provided a saliva sample same day in clinic for the CLIA-certified Color Genomics 30-gene cancer gene panel. Results were issued to patients and providers, and results were discussed by email and phone with a genetic counselor. Uptake of GT and prevalence of P/LPV was measured and compared to previously reported data from the retrospectively tested UW TAN cohort. χ^2-test was performed. **Results:** 84% (190/227) of approached veterans with mPC consented and 80% (182/227) completed GT. 6.6% (12/182) of men were found to carry P/LPV in DNA repair genes: 3 in *BRCA2,* 2 in *BRCA1*, 4 in *ATM,* and 3 in *CHEK2*. Overall, 6.6% rate of P/LPV in DNA repair genes was comparable to the 8.8% previously reported in the UW TAN cohort ($p = 0.69$). **Conclusions:** Dedicated clinic-based strategies to offer and provide GT and services for veterans with mPC is feasible and results in high GT consent and uptake, especially with direct oncologist involvement. Proportion of consenting to proceed with GT was nearly identical to a referral-based specialty Prostate Cancer Genetics Clinic (Pouv, Sokolova, and Cheng, unpublished). The proportion of P/LPV in the PUG-VA PC population was comparable to a geographically similar retrospective cohort. Updated data, including detailed demographics and GT results, will be reported at final presentation. Research Sponsor: U.S. National Institutes of Health, Prostate Cancer Foundation.

1579 Poster Session (Board #71), Fri, 8:00 AM-11:00 AM

Development and validation of the PREMMplus clinical prediction model for multigene hereditary cancer risk assessment. *First Author: Matthew B. Yurgelun, Dana-Farber Cancer Institute, Boston, MA*

Background: Current clinical prediction models provide syndrome-specific numeric estimates of an individual's likelihood of having a specific hereditary cancer syndrome (e.g., $PREMM_5$ for Lynch syndrome; BRCAPRO for *BRCA1/2*). With the emergence of multigene panel testing (MGPT), there is a need to evaluate individuals' risk of carrying a pathogenic variant in a diverse array of cancer susceptibility genes in parallel. This study's aim was to develop and validate the PREMMplus clinical prediction model for multigene cancer risk assessment. **Methods:** PREMMplus was developed in a cohort of 7296 individuals who had undergone germline MGPT at a single center. Logistic regression models were used to examine candidate predictive variables – including age, sex, ethnicity, and personal/family history of cancer – to provide a numeric estimate of an individual's likelihood of carrying a pathogenic/likely pathogenic germline variant in one of 18 cancer susceptibility genes (11 high- [*APC*, *BRCA1/2*, *CDH1*, *EPCAM*, *MLH1*, *MSH2*, *MSH6*, biallelic *MUTYH*, *PMS2*, and *TP53*] and 7 moderate-penetrance [*ATM*, *CDKN2A*, *CHEK2*, *PALB2*, *PTEN*, *RAD51C*, and *RAD51D*]). Model performance was validated in an independent dataset of 14845 individuals who had undergone MGPT at a commercial laboratory. **Results:** Using clinical characteristics, including personal/family history of 18 cancers plus colorectal adenoma burden, PREMMplus demonstrated an excellent ability to predict pathogenic variants in high penetrance genes at 90% sensitivity. PREMMplus had acceptable performance with the addition of 7 moderate penetrance genes. PREMMplus was well-calibrated and demonstrated comparable performance in the external validation dataset. **Conclusions:** PREMMplus is the first validated risk assessment model to quantify an individual's likelihood of carrying pathogenic variants in a wide diversity of cancer risk genes, and can be used to select individuals who should undergo MGPT. As expected, PREMMplus's discriminatory capacity was reduced with the inclusion of moderate penetrance cancer risk genes. Research Sponsor: U.S. National Institutes of Health.

Cohort	Outcome	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value	# Needed To Test to Detect 1 Carrier	AUC (95% CI)
Development	11 high penetrance genes	90%	34.8%	7.4%	98.4%	13.5	0.74 (0.71-0.77)
Development	18 high/ moderate penetrance genes	90%	23.9%	10.6%	96.0%	9.4	0.67 (0.65-0.69)
Validation	11 high penetrance genes	90%	22.8%	5.5%	97.9%	18.3	0.69 (0.66-0.71)
Validation	18 high/ moderate penetrance genes	90%	17.8%	9.8%	94.8%	10.2	0.62 (0.60-0.64)

1580 Poster Session (Board #72), Fri, 8:00 AM-11:00 AM

Hereditary leiomyomatosis and renal cell cancer syndrome (HLRCC): Genotype and phenotype characteristics in a cohort of 197 patients. *First Author: Ana Beatriz Sanchez-Heras, Cancer Genetic Counseling Unit. Hospital General Universitario de Elche, Elche, Spain*

Background: HLRCC is a hereditary condition with autosomal dominant inheritance due to germline mutations in the fumarate-hydratase gene (*FH*). It is characterized by skin leiomyomas (SLM) in 48-84% of individuals, uterine leiomyomas (ULM) in 30-72%, renal cysts (RCy) and renal cell cancer (RCC) in 15-34%. We aimed to describe the genetics, the clinical features and the potential genotype-phenotype associations in the largest cohort of *FH* mutation carriers from Spain. **Methods:** We performed a multicenter, observational, retrospective study of individuals with genetic or clinical diagnosis of HLRCC. We collected clinical information from medical records. We analyzed genetic variants and looked for genotype-phenotype associations. Statistical analyses were performed by IBM-SPSS Statistics-v.22. **Results:** We included 197 individuals (113 women, 84 men), 74 index cases and 123 relatives. Twenty-seven different variants were detected, 26 pathogenic (12 missense, 5 frameshift, 4 large-deletions, 3 splice-site and 2 nonsense) and 1 variant of unknown significance (missense). Of 182 patients with full skin examination, 64.8% presented SLM (median age 36 years; range 8-85). ULM were diagnosed in 90.3% of 103 women with gynecologic exam (median age 30 years; range 17- 55). Hysterectomy was performed in 62.9% (median age 34 years; range 21-54). Of 153 patients with radiological records, 37.3 % presented RCy. Nineteen patients (10.9%) presented RCC, 11 males and 8 females (median age 37 years; range 10-67). The histological diagnoses were: 14 papillary, of which 10 were type 2; 3 clear cell carcinoma and 2 unclassified carcinoma. Six tumors had stage I, 2 stage II, 3 stage III, 4 stage IV, and 4 not available. The median overall survival among patients at stages 3-4 was 2.9 years [1.3-4.5]. Patients with missense pathogenic variants showed higher risk of developing SLM ($p = 0.043$) and ULM ($p = 0.002$) than those with loss of function variants. **Conclusions:** In our cohort, the frequency of RCC (10.9%) is lower than that published in cohorts of similar sample size. The most frequent histology was the papillary type-2; however, other histological patterns do not exclude HLRCC. Individuals with missense pathogenic variants show higher incidence of SLM and ULM. Research Sponsor: None.

1581 Poster Session (Board #73), Fri, 8:00 AM-11:00 AM

Using sequential next-generation sequencing assays to identify germline cancer predisposition variants. *First Author: Ira Lignugaris Kraft, University of Chicago, Chicago, IL*

Background: Next-generation sequencing (NGS) increasingly guides clinical care in hematological malignancies by identifying DNA mutations that change dynamically over time. Clinical samples contain variable numbers of malignant and non-malignant cells. So, careful interpretation is required to determine if a particular variant is somatic, germline, or clonal hematopoietic in origin. **Methods:** The University of Chicago uses a targeted NGS assay of ~1200 genes, reporting 150 as a clinical test. We aimed to identify individuals with hereditary predisposition by detecting persistent variants on sequential assays regardless of disease state. **Results:** 943 NGS assays from July 2017 – Feb. 2020 on 711 patients [ages 1 mo – 95 yrs, median 65 yrs] were included. 2,320 variants in 33 genes were identified with 144 patients having the same variant identified on more than one assay. Single nucleotide variants (SNVs) with variant allele frequency (VAF) ≥ 0.3 were prioritized. The first candidate gene identified with potential germline SNVs was *CSF3R*. 28 unique SNVs in *CSF3R* were found, 14 were confirmed as germline, 6 somatic, and 8 were unconfirmed due to lack of available tissue. At least 2 confirmed germline *CSF3R* variants were likely deleterious based on functional testing. Sequential SNVs were quantified using the coefficient of variation, characterizing each by change in VAF over time. Using a worst-case-scenario analysis, in which unconfirmed variants were not counted as germline, a computer algorithm was designed to identify potential germline variants (specificity 0.89, PPV 0.75). Via an iterative method, the algorithm compares new assays to a pool of previously reported tests, flagging patients with potential germline mutations so that biopsies may be studied in the lab, records reviewed, and referrals placed to genetic counselors. To date, 61 patients with 89 likely germline variants have been identified. Known hereditary hematological malignancy genes, such as *ATM, ASXL1*, *CHEK2*, *DDX41*, *TSC1*, and *RUNX1,* had the most variants identified. Limitations include the challenge in distinguishing variants that do not change over time, reliance on a targeted NGS panel, and normalizing VAF data prior to analysis. **Conclusions:** These data highlight the utility of NGS of bone marrow and peripheral blood samples to identify patients suspected of having germline DNA variants. In addition to identifying known predisposition syndromes, one may discover new inherited cancer syndromes and help guide clinical practice in real time. Research Sponsor: None.

1582 Poster Session (Board #74), Fri, 8:00 AM-11:00 AM

Value of multigene panel retesting of families with *BRCA1/2* mutation-negative hereditary breast and ovarian cancer (HBOC). *First Author: Ekaterina Meshoulam Nikolaeva, Mutua Terrassa, Terrassa, Spain*

Background: Despite the use of clinical eligibility criteria and mutation predictive models, a great proportion of families are negative for germline mutations in *BRCA1/2* genes. Traditionally, risk assessment of inconclusive results included the recommendation of high-risk surveillance protocol, the update of incident cancer cases in the family and the consideration of additional testing to rule out the possibility of phenocopy. More recently, next generation sequencing multigene panels have become a standard practice in cancer genetics clinics worldwide. We addressed the value of multigene panel retesting of *BRCA1/2* negative HBOC families in our institution. **Methods:** After genetic counseling session and informed consent, a total of 137 individuals (119 probands and 18 extra cancer-affected relatives) from distinct *BRCA1/2* negative families were retested using a panel containing 11 breast and ovarian cancer susceptibility genes (*BRCA1/2, PALB2, ATM, CHEK2, PTEN, TP53, STK11, BRIP1, RAD51C, RAD51D*). **Results:** According to the BOADICEA model, the remaining probability of mutation in *BRCA1/2* or *PALB2 genes* in our cohort was 5.5% (0.1-61). The reasons for considering retesting were the addition of any incident cancer diagnosis in 33 cases (24%), a prior study with a low sensitivity screening technique (dHPLC) in 6 families (5%) and the expansion of the study to other putative breast and ovarian susceptibility genes in 98 families (71%). Overall, 3 pathogenic (2 *BRCA2*, 1 *CHEK2*) and 8 likely pathogenic variants (1 *BRCA2*, 4 *CHEK2* and 3 *ATM*) were found. The prevalence was 8%. The detection rate among 19 families with a $> 10\%$ remaining probability of mutation in *BRCA1/2* and *PALB2* genes was 26%. The 3 clinically significant variants in *BRCA2* were detected in 2 families and 1 updated cancer family history (BOADICEA remaining probability of 59, 61 and 12%, respectively). Cascade testing was subsequently done in 15 relatives resulting 8 in mutation carriers and 9 true negatives. **Conclusions:** Our results support the value of updating cancer incident cases and considering expanded panels in selected families. Research Sponsor: None.

Effect of genetic testing results on patient-reported quality of life among patients undergoing panel testing for newly diagnosed ovarian cancer. *First Author: Sarah S. Lee, New York University School of Medicine, New York, NY*

Background: This study compared patient-reported stress, anxiety, and depression between newly diagnosed ovarian cancer patients with pathogenic genetic testing results versus patients with non-informative results (i.e., variants of uncertain significance (VUS) or negative). **Methods:** Patients underwent genetic testing (GT) via a facilitated referral pathway (Frey et al, Gynecol Oncol 2020) through which they were referred for genetic counseling and GT by their gynecologic oncologist within six weeks of diagnosis from 10/2015 to 5/2019. English-speaking patients completed three quality of life (QoL) instruments: Impact of Events Scale (IOES), State-Trait Anxiety Questionnaire (STAI), Hospital Anxiety and Depression Scale (HADS) immediately pre-and post-GT and 6 months post GT. Two-way mixed ANOVA was performed to analyze effect of GT results on QoL over time with significance $p < 0.05$. **Results:** One hundred ten patients were enrolled in the pathway and 83 (76%) patients underwent GT. Among these, 15 (18%) had potentially actionable pathogenic mutations (*BRCA1*-8, *BRCA2*-4, *MSH2-2*, *MRE11A*-1); 26 (31%) had VUS results; 3 (4%) had both a pathogenic mutation and a VUS result; and 42 (51%) had negative results. Sixty patients (72%) completed QoL assessments pre and post GT, and 37 (44%) patients at 6-9 months post GT. For all patients, GT results did not affect QoL scales across our time points. By mean scores across all-comers, patients demonstrated mild stress at each time point and clinically significant anxiety immediate post-GT. All patients had a statistically significance decrease in HADS depression scores over time from pre-GT to 6 months post-GT (mean score 4.98 vs 2.97, $p = 0.020$). Patients with VUS had lower HADS mean anxiety scores across time (3.62) compared to patients with pathogenic (7.44) or negative mutations (6.83, $p = 0.029$). For patients without mutations, there was a significant decrease in clinically significant anxiety by STAI-state score at 6 months ($p = 0.002$) and a decrease in borderline anxiety by HADS scores at 6 months ($p = 0.005$). This effect was not present for patients with pathogenic mutations or VUS. **Conclusions:** A pathogenic result does not impact QoL scales immediately pre or post GT or at 6 months post GT, though patients with negative mutations were more likely to show a decrease in anxiety over time. Patients should be recommended GT at time of diagnosis of ovarian cancer without concern of increased stress, anxiety, or depression based on GT results. Research Sponsor: NYU Langone Health, Pharmaceutical/Biotech Company.

1585 Poster Session (Board #77), Fri, 8:00 AM-11:00 AM

Genetic testing and referral patterns of non-*BRCA* mutation carriers at increased or uncertain risk of ovarian cancer. *First Author: Sarah S. Lee, New York University School of Medicine, New York, NY*

Background: While the management of *BRCA1/2* is clear, management of non-BRCA mutations with increased risk or uncertain risk of ovarian cancer (OC) is not well established. Previously, we reported that referral to a gynecologic oncologist (GO) resulted in a 30-fold increased uptake of risk reducing surgery (RRS). We aimed to identify trends in genetic testing (GT) and referral to a GO of patients (pts) with such mutations. **Methods:** In this retrospective cohort study at 3 satellite sites within 1 institution from 2014 to 2018, pts were identified by ICD-10 codes Z15.01, Z15.02, Z15.09, Z15.89, C50.919, Q99.8, and C54.1. Pts with mutations with increased risk of OC (*MLH1, MSH2/6, PMS2, EPCAM* (LS genes), *RAD51C/D, BRIP1, STK11)* and uncertain risk of OC (*PALB2, ATM, BARD1, NBN)* were included; *BRCA1/2* and variants of uncertain significance were excluded. Outcomes of interest were patterns of GT and referral to a GO. Chi square and logistic regression were used with $p < 0.05$. **Results:** Of 20,000 pts with above ICD-10 codes, 240 pts had genes of interest. Mutations in increased risk of OC included: LS genes, 131; *BRIP1*, 14; *RAD51D*, 8; *RAD51C*, 5; *STK11*, 1. Mutations associated with uncertain risk of OC were: *ATM,* 43; *PALB2*, 23; *NBN*, 10; *BARD1,* 5. Pts with known mutations prior establishing care at our institution (N = 69) were less likely to be referred to a GO (22% vs 78%, $p = 0.015$). Pts with LS genes were more likely to be referred to a GO (52% vs. 25%, $p < 0.001$), to be tested by a GC (52% vs 25%, $p < 0.001$), and to be tested for family history (FH) of known mutation (69% vs 30%, $p < 0.001$). Provider performing GT included: genetic counselor (GC), 66 (28%); medical oncologist, 44 (18%); general obstetrician-gynecologist, 44 (18%); breast surgeon, 6 (3%), and primary care provider, 5 (2%). Of 66 pts tested by a GC, 46 (70%) were referred to GO, vs 48/105 (45%) pts who underwent GT by non-GC ($p = 0.001$). Reasons for GT among pts were: FH of cancer, 113 (47%); personal history of cancer, 56 (23%); known FH of a mutation, 49 (20%); and unknown indication, 22 (9%). When controlling for age, parity, race, insurance, GT provider, and reasons for GT, mutations with increased risk of OC were associated with referral to a GO (OR 3.55, 95% CI 1.88-6.72), along with pts who were tested by a GC (OR 2.65, 95% CI 1.27-5.51). **Conclusions:** Only ~30% of pts underwent GT by a GC, which was associated with increased referral to a GO. LS genes are better known and were associated with higher uptake of GO referral. Education of OC risks of these newer mutations among providers performing GT may increase referral to a GO and uptake of RRS. Research Sponsor: None.

1586 Poster Session (Board #78), Fri, 8:00 AM-11:00 AM

Comparison of genomic instability test scores used for predicting PARP activity in ovarian cancer. *First Author: Kirsten M Timms, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

Background: Clinical trials have explored the utility of various genomic instability (GI) scores or gene panels to assess deficiencies in the homologous recombination (HR) DNA repair pathway and support PARP inhibitor use in ovarian cancer; however, these methods of assessing homologous recombination deficiency (HRD) may not be equivalent. The myChoice HRD test is the only analytically and clinically validated, FDA-approved HRD test that includes *BRCA1/2* mutation status and three measures of GI. We compared the proportion of patients identified as candidates for PARP inhibitor use by two measures of HRD [percent loss of heterozygosity (%LOH), 11-gene panel] to myChoice HRD. **Methods:** Whole-genome SNP analysis was used to reconstruct ovarian tumor genomic profiles to calculate the myChoice HRD score and %LOH in 2 cohorts (clinical laboratory cohort, N = 3,278; SCOTROC4 trial, N = 248). Mutation screening for a set of 11 genes in the HR pathway (*ATM*, *BARD1*, *BRCA1*, *BRCA2*, *BRIP1*, *CHEK2*, *MRE11A*, *NBN*, *PALB2*, *RAD51C*, *RAD51D*) was performed for a subset of tumors from the SCOTROC trial (n = 187). Samples were considered positive if the myChoice HRD score was above the threshold (threshold scores of 42 and 33 were assessed), %LOH above the threshold (16%), or a pathogenic variant in one of the 11 HR genes. The correlation between positive results from %LOH and the 11-gene panel were compared to myChoice HRD. Percent positive agreement (PPA) was the proportion of positive test results from myChoice HRD that were also positive by %LOH or the 11-gene panel. **Results:** The table shows the correlation and PPA between myChoice HRD, %LOH, and the 11-gene panel. Overall, 19%-61% of patients identified as positive by myChoice HRD would have been missed by %LOH or the 11-gene panel in these two cohorts. **Conclusions:** These data show that HRD tests used in published and ongoing clinical trials are not equivalent, and they should not be considered interchangeable in predicting PARP inhibitor response in clinical practice. Research Sponsor: Myriad Genetic Laboratories, Inc.

	%LOH	11-gene panel
Clinical testing dataset		
Correlation	0.845	-
PPA – myChoice HRD ≥42	67.7%	-
PPA – myChoice HRD ≥33	53.5%	-
SCOTROC4 cohort		
Correlation	0.89	n/a*
PPA – myChoice HRD ≥42	80.88%	53.06%
PPA – myChoice HRD ≥33	60.61%	38.57%

1588 Poster Session (Board #80), Fri, 8:00 AM-11:00 AM

Effects of initiating in-office germline testing in safety net clinic patients with epithelial ovarian cancer. *First Author: Scott Jordan, University of Miami-Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Germline genetic mutations occur in approximately 25% of women with epithelial ovarian cancers. Recent advances in frontline maintenance therapy for patients with hereditary breast and ovarian cancer syndrome make timely germline testing critical. Adherence to genetic testing remains low (approximately 30% nationally), including at our safety net hospital where germline testing by a genetic counselor was performed in only 38% of patients. After initiating in-office genetic testing, our aim was to compare current patients with historical controls to determine whether this intervention shortened the time to testing and results. **Methods:** IRB approval was obtained. Patients seen for a diagnosis of epithelial ovarian cancer between 4/1/2018 and 12/31/2019 were identified. Patients with only one visit or those who received testing elsewhere were excluded. Patient and visit data were abstracted for each visit during the study period. Comparison was made between patients treated before (control cohort) and after in-office testing was initiated (intervention cohort) on 5/21/2019. Categorical variables were compared using Chi Squared and Fisher's Exact test. Mann Whitney U test was used to compare time from first clinic visit to the date of genetic testing and to the reporting of test results in the chart. All tests were two-sided and significance was set at $p = 0.05$. **Results:** 74 patients were identified and 504 clinic visits were analyzed. 57 (77%) patients were White Hispanic, 15 (20.3%) were Black, and 2 (2.7%) were White non-Hispanic. 56 (75.7%) underwent germline testing. Overall median time to testing from the first clinic visit was 21.2 weeks, and median time to reporting of results was 37 weeks. Though there was no significant difference in testing rate between the cohorts, the time to the date of genetic testing in the intervention group was approximately one-third as long as in the control group (9.6 vs 32.1 weeks, $p < 0.001$). Among the 52 patients with reported genetic results, results were recorded in a clinic note at 4.1 weeks from first visit in the intervention group, compared with 28.8 weeks in the control group ($p < 0.001$). In the intervention group, during clinic visits without genetics performed to date, testing was performed at that visit 25% of the time. **Conclusions:** By initiating in-office testing, time to testing and receipt of results were meaningfully shortened. Removing delays to test results will greatly improve the ability of our patients to receive potentially life-saving maintenance therapy following front line treatment. Research Sponsor: None.

1589 Poster Session (Board #81), Fri, 8:00 AM-11:00 AM

Prospective agnostic germline testing in pediatric cancer patients. *First Author: Elise Fiala, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We report our large cohort of pediatric cancer patients undergoing prospective agnostic germline sequencing. Our dataset is a significant addition to the 1,573 children reported to date who have undergone agnostic germline sequencing in previous large sequencing studies, each with ascertainment bias. **Methods:** 676 patients with pediatric solid tumors underwent matched tumor-normal targeted DNA sequencing from July 2015 to February 2020. At least 76 genes associated with cancer predisposition were analyzed in the germline, and variants were classified per American College of Medical Genetics guidelines. Pathogenic and likely pathogenic (P/LP) variants were reported to patients/families, who were offered genetic counseling and cascade testing with screening recommendations and referral to a surveillance clinic as appropriate. **Results:** One or more P/LP variants were found in 17% (115/676) of individuals when including low, moderate and high penetrance mutations in recessive and dominant genes, or 12% (81/676) when including moderate and high penetrance mutations in dominant genes. P/LP variants were detected in 40% (21/53) of patients with retinoblastomas, 8% (13/161) with neuroblastomas/ganglioneuroblastomas, 13% (14/112) with brain/spinal tumors, 8% (20/245) with sarcomas, and 12% (13/105) with other solid tumors. The most frequent mutations were in *RB1* (n = 28) and *TP53* (n = 8) in patients with associated tumors. Of patients with moderate/high penetrance mutations, 30% (24/81) had unexpected tumor types, with potential therapeutic relevance in 58% (14/24) including *BRCA1* n = 2, *BRCA2* n = 3, *RAD51D* n = 1, *ATM* n = 1 *MLH1* n = 1, *MSH2* n = 1, *MSH6* n = 1, *PMS2* n = 3, and *SUFU* n = 1. Two patients received immunotherapy based on their germline finding. **Conclusions:** P/LP germline variants are frequently present in patients with pediatric cancer. We are contributing significantly to the cohort size of agnostic sequencing in pediatric cancers. Our experience is similar to other studies with a ~12% detection rate of moderate and high penetrance mutations. Moderate/high penetrance mutations were concordant with the patient's cancer history in 70% of cases, higher than previously reported, likely due to an enrichment of retinoblastoma. While many mutations are identified in patients with associated tumor types, a large proportion of mutations are unexpected based on the patient's history. Clinical actionability of these findings may include screening, risk reduction, family planning, and increasingly targeted therapies. Research Sponsor: Marie-Josee and Henry R. Kravis Center for Molecular Oncology, the Neihaus Center for Inherited Cancer Genomics, the Crawford fund, and the Corning fund.

1590 Poster Session (Board #82), Fri, 8:00 AM-11:00 AM

Streamlining the genetics pipeline to increase testing for patients at risk for hereditary prostate cancer. *First Author: Barry Tong, UCSF, San Francisco, CA*

Background: Metastatic prostate Cancer (mPCa) is increasingly recognized as a heritable disease and germline genetic testing has increasingly become a part of standard of care. At the University of California at San Francisco (UCSF) Genitourinary (GU) Medical Oncology clinic, approximately 850 new patients with mPCa are seen annually. A feasibility pilot Genetic Testing Station (GTS) was developed to expand access to genetic testing among this high-risk population. GTS is facilitated by Genetic Counselor Assistants (GCA) under the supervision of genetic counselors. **Methods:** This is a feasibility pilot of a GTS model among patients with mPCa. In this model, all patients with mPCa are offered a same day GTS visit with a GCA. At the GTS, the patient receives pre-test education via videos developed by genetic counselors. The patient provides informed consent, a family history, and a saliva sample for Invitae's 87-gene panel. All positive results trigger a genetic counselor visit while non-positive results either receive a letter or a genetic counselor visit (in person or via telehealth). To evaluate the model, testing frequency and laboratory turnaround time (TAT) was assessed before and after the pilot. **Results:** In the first four months of the GTS pilot (10/14/2019 – 02/10/2020), 94 patients were referred and received genetic testing. Eight germline positives were identified (BRCA2, CHEK2, HOXB13 MSH6, RECQL4). The average TAT was 8 days. 9.3% of patients were found to have pathogenic mutations through the prostate GTS which is comparable to previously published rates of germline mutations in metastatic prostate cancer patients. In a 4-month time frame the prior to the intervention (10/01/2018-1/31/2019), 26 genetic testing orders were placed. The average laboratory TAT in this prior process was 17 days. Rates of positive germline mutations in the prior model was 8.6%. **Conclusions:** The GTS is a feasible method to increase access to germline genetic testing among a high-risk population. It may reduce barriers to testing and facilitate real-time discussion of treatment and prevention strategies with patients and family members. As a result, we will continue to operate the GTS. This model provides a framework for scaling access for and cascade testing in other high-risk patient groups. Research Sponsor: None.

1591 Poster Session (Board #83), Fri, 8:00 AM-11:00 AM

Diagnostic yield of germline genetic testing following tumor testing in prostate cancer patients. *First Author: Kingshuk Das, Invitae, San Francisco, CA*

Background: NCCN guidelines recommend germline testing for patients with localized or advanced prostate cancer meeting family history or clinical/pathologic criteria. However, the guidelines for somatic molecular analysis generally consider advanced disease only, primarily to inform therapy. As the analytical and clinical specifications of both testing modalities differ accordingly, we examined the results of germline testing following prior somatic testing. **Methods:** We reviewed somatic and germline variants in an otherwise unselected consecutive series of patients who: (a) had a current or previous diagnosis of prostate cancer; (b) had undergone tumor sequencing; and (c) were referred for germline testing. Indications for germline testing included: potential germline origin of somatic test result, treatment or surgical planning, personal or family history, and patient concern. **Results:** 208 patients met study criteria of whom 81 (39%) harbored a pathogenic germline variant (PGV) in a cancer predisposition gene. Certain genes were more likely to harbor germline variants, and 98% (81) of PGVs were potentially actionable (Table). 9.6% of PGVs were not reported by somatic testing, reflecting analytical limitations of the somatic testing. Of note, 11 patients (14%) had PGVs identified after diagnosis of a subsequent primary malignancy. **Conclusions:** The high PGV rate of 39% was unexpected, given reported rates of 11.8% in patients with metastatic prostate cancer and 6% in high-risk localized disease (NCCN)--even considering potential clinician ascertainment bias. This finding, the potential clinical utility of 98% of PGVs identified, the significant proportion unreported by somatic testing, and the fraction of patients diagnosed with a PGV after a subsequent malignancy all suggest that germline testing is an underutilized tool in the care of prostate cancer patients and their families. Research Sponsor: None.

Cancer risk and overall survival in APC I1307K carriers. *First Author: Stephen B. Gruber, City of Hope National Medical Center, Duarte, CA*

Background: The germline variant *APC* I1307K is one of the most commonly identified pathogenic variants on germline genetic testing panels. The purpose of the Molecular Epidemiology of Colorectal Cancer study was to quantify the risk of colorectal cancer among carriers, characterize the clinical, pathologic, and molecular features of colorectal cancers arising in patients with *APC* I1307K, and to describe the overall and disease-specific survival of carriers with colorectal cancer. Here, the final results of the Molecular Epidemiology of Colorectal Cancer Study are reported with respect to *APC* I1307K. **Methods:** We consented 6,006 incident, pathologically confirmed cases of colorectal adenocarcinoma and 5,023 age, sex, and ethnicity matched controls without colorectal cancer between March 31, 1998 and July 1, 2017 within a geographically defined area of Northern Israel. Comprehensive, in-person epidemiologic interviews were conducted for cases and controls, with uniform histopathologic review, detailed molecular analysis, medical record review and clinical follow-up for up to 21 years. **Results:** The demographic and clinical features of incident colorectal cancer cases matched the population distribution of colorectal cancer in Israel. *APC* I1307K was identified in 429 (7.1%) of cases and 201 (4.0%) of controls. The estimated relative risk of colorectal cancer among carriers was 1.89 (95% confidence interval, 1.59 - 2.24), $p < 0.0001$. The prevalence and odds ratios differed by ethnic group. Homozygous carriers were at especially high risk, with an odds ratio of 3.90 (95% confidence interval 1.11–13.71). *APC* I1307K carriers were significantly less likely to have microsatellite instable tumors ($p = 0.04$). Overall survival of *APC* I1307K carriers was not significantly different than survival of non-carriers, after adjustment for age, stage, sex, ethnicity, and microsatellite instability. **Conclusions:** *APC* I1307K is an actionable germline mutation that confers meaningful lifetime risk of colorectal cancer in heterozygous and homozygous carriers. *APC* I1307K is not an independent prognostic factor for overall survival or disease specific survival and is not associated with the MSI phenotype. Cumulative lifetime risk estimates inform genetic counseling and provide data for policies regarding the timing and frequency of screening and other preventive strategies. Research Sponsor: U.S. National Institutes of Health.

1593 Poster Session (Board #85), Fri, 8:00 AM-11:00 AM

Relative and absolute risk of second primary neoplasms of the central nervous system. *First Author: Elisa Liu, NYU School of Medicine, New York, NY*

Background: Cranial radiation is known to increase the relative risk for developing a second primary neoplasm, but existing analyses do not take into account differential survival or follow-up. The absolute risk, or true incidence, of developing a second primary neoplasm in the central nervous system (CNS) is not well characterized. **Methods:** Patients diagnosed with cancer from between 1976 and 2016 were sampled using the Surveillance, Epidemiology, and End Results (SEER) Program. Relative risks were estimated using standardized incidence ratios (SIRs) and absolute risks were estimated using cumulative incidence (CI) functions with death as a competing risk. Among CNS primaries, comparison groups were matched by age, sex, year of diagnosis, primary histology, and lesion location. **Results:** Over 3.8 million patient records, including 13,167 second primary CNS tumors, were extracted from SEER. The relative risk of developing a second primary CNS neoplasm is elevated in all patients diagnosed with a CNS primary cancer (SIR = 9.6), but higher in those who received radiation (SIR = 13.1) or chemotherapy (SIR = 12.6). The absolute risk of developing a second primary CNS neoplasm at 25-years is highest in CNS and endocrine cancers (CI 1.0% and 0.50%, respectively). Among long-term ($>$ 10-year) survivors of CNS primaries, the 25-year CI of a second primary CNS neoplasm was 4.4%. Cranial radiation increased the incidence of second primary tumors in pediatric patients (25-year CI 4.8% vs 1.2%, p = 0.007), but not adults (25-year CI 5.1% vs 4.9%, p = 0.85). Chemotherapy did not increase CI in either pediatric (25-year CI 7.0% vs 5.4%, p = 0.87) or adult (25-year CI 3.6% vs 5.8%, p = 0.11) populations. Meningiomas (39.3% vs 22.0%, p = 1e-6) and glioblastomas (21.1% vs 14.6%, p = 0.03) represent a greater proportion of the second primary CNS tumors in those who received cranial irradiation. **Conclusions:** The risk of developing a second primary CNS neoplasm is elevated in patients with a prior CNS cancer. Cranial irradiation increased the CI of second primary tumors in pediatric patients but did not affect adult patients. The association between radiation therapy and risk for subsequent cancers may be limited to the pediatric population. Research Sponsor: None.

1594 Poster Session (Board #86), Fri, 8:00 AM-11:00 AM

Results of a prospective phase II national study: Prophylactic radical fimbriectomy (NCT01608074), in women with a documented high risk of breast/ovarian cancer—Final pathological results and outcomes. *First Author: Eric Leblanc, Centre Oscar Lambret, Lille, France*

Background: Risk-reducing salpingo-oophorectomy (RRSO) is the gold standard in surgical prophylaxis of pelvic high-grade serous carcinoma (HGSC) for women at risk of breast/ovarian cancer. Due to significant adverse effects of early oophorectomy, 20-30% of women delay or deny performing this operation. Recent data highlight the fallopian origin of most pelvic HGSC, especially its fimbrial part. Thus, we suggested a new two-step risk-reducing procedure: the radical fimbriectomy (RF) with delayed oophorectomy (DO) (Leblanc et al Gyn Oncol 2011), leading to the current RF/DO Phase 2 study. We present the definitive results on primary and secondary objectives of this trial. **Methods:** *BRCA1/2* carriers or any women with a documented familial risk of breast/ovarian cancer were first counseled to perform a classical laparoscopic RRSO. If they denied, they were offered to enter the RF/DO study. All specimens were submitted to the SEE-FIM pathological protocol. Pathological data along with all intra- and 30-day and beyond post-operative adverse events were prospectively recorded. Follow-up consisted in an annual clinical breast and gynecological examination, with tumor markers and hormonal status assessment. Primary endpoint was the rate of pelvic serous carcinoma. Secondary endpoints were procedure morbidity, rates of tubal abnormalities, breast cancer, secondary oophorectomy. **Results:** From January 2012 to October 2014, 121 RF were performed: 120 by laparoscopy, 1 laparotomy (concurrent myomectomy). An occult neoplasia was found in 3 cases with 1 invasive HGSC. Intraoperative complications were two grade1 bleedings without transfusion with no grade $\geq$3 early post-operative or delayed complication. With a median follow-up of 5.3 years (0.2 -7.6), no patient developed any pelvic HGSC, 21 patients developed a breast cancer (3 de novo, 18 recurrences/contralateral.). 1 cancer-free *BRCA1*-mutated lady delivered safe twins, after an uneventful post-RF pregnancy obtained with assisted reproductive technology (ART). Overall, 29 women underwent DO (by choice: 12 or menopause: 17) resulting in grade 3b complication in 1 case, but no pathological abnormality. **Conclusions:** RF/DO appears as a safe, well tolerated and effective procedure in terms of occult neoplasia detection. A successful pregnancy with ART was possible after radical fimbriectomy. Longer follow-up and larger cohort are necessary to confirm its efficacy in terms of ovarian cancer prophylaxis. Clinical trial information: NCT01608074. Research Sponsor: PHRC 2011.

1595 Poster Session (Board #87), Fri, 8:00 AM-11:00 AM

Outcomes of lung cancer screening among cancer survivors: An NCCN institution experience. *First Author: Bradley Maller, University of South Florida, Morsani College of Medicine, Tampa, FL*

Background: In 2013, the USPTF recommended low-dose CT (LDCT) screening for individuals at high risk of lung cancer based on data from the National Lung Screening Trial. However, the trial excluded participants with cancer diagnosis $<$ 5 years except for non-melanoma skin cancer, making it unclear whether the data will be generalizable to cancer survivors. This population, while at increased risk of secondary lung cancer, may be prone to false positive results due to anatomic defects or recurrent cancers. Our NCCN institution serves a large number of cancer survivors. We evaluated the outcomes of LDCT screening and the adherence to annual screening among cancer survivors, compared with individuals without cancer history (IWC). **Methods:** Prospectively maintained database of LDCT screening participants was analyzed. Eligibility was per NCCN criteria and cancer survivors needing regular chest CT were not offered LDCT. Participants were asked to complete a self-administered questionnaire on risk factors. Positive result was defined as Lung-RADS $\geq$3, corresponding to nodule $\geq$6 mm. Adherence to LDCT screening was defined as having T1 screening, excluding those $<$ 18 months from T0 at time of analysis. Predicted risk of lung cancer was calculated per PLCOm2012 model. **Results:** To date, 454 subjects have undergone LDCT screening. Positive results occurred in 60 subjects (13.2%) at T0; lung cancer was diagnosed in 10 subjects (2.2%); and other cancers were diagnosed in 5 subjects (1.1%). There were 152 cancer survivors, including survivors of breast (52), prostate (26), bladder or kidney (19), lung (14), and head and neck cancer (13). The median time from cancer treatment to LDCT screening was 6 years (range 0-55). Cancer survivors were older than IWC: median age 67.4 vs. 63.5 years ($p<$ 0.001) and more likely to be active smokers: 37.5% vs. 29.5%, ($p=$ 0.09). The median predicted risk of lung cancer at 6 year was 5.5% vs. 3.2%, ($p=$ 0.15). No significant difference in the screening outcomes was found between groups. Among cancer survivors (N = 152), positive screening occurred in 15 (9.9%); lung cancer was diagnosed in 1 (0.7%); and other cancers were diagnosed in 3 subjects (1.9%). Non-adherence to LDCT screening occurred in 31 out of 152 cancer survivors (20.4%), compared with 81 out of 262 (30.9%) IWC, ($p=$ 0.02). **Conclusions:** About one-third of LDCT screenings at this NCCN institution occurred among cancer survivors. We found no evidence of increased false positive results. However, a higher rate of adherence to annual screening was observed among cancer survivors than IWC. Research Sponsor: James Esther King Biomedical Research.

TPS1597 Poster Session (Board #89), Fri, 8:00 AM-11:00 AM

ECOG-ACRIN tomosynthesis mammographic imaging screening trial (EA1151). *First Author: Etta Pisano, Beth Israel Deaconess Medical Center, Boston, MA*

Background: This randomized trial is intended to determine whether tomosynthesis (TM) should replace the current standard for breast cancer (BC) screening, digital mammography (DM). It is hypothesized that the population of women assigned TM screening for 3-5 rounds will have fewer advanced cancers than the population assigned to DM screening. **Methods:** 164,946 women, ages 45 to 74 years who present for screening mammography and consent to participate will be enrolled across 150 sites in the US, Canada and abroad. Women will be randomized to TM or DM. The frequency and number of screening examinations over a five year period will vary based on menopausal status and whether they have specific risk factors, including - hormone use, family history of BC, deleterious genes, prior benign breast biopsy with diagnosis of LCIS or atypia any kind, or dense breasts. Blood and buccal cells will be collected from as many enrolled women as are willing to provide the samples. All breast biopsies during the trial will undergo gene expression analysis for the PAM50 and other progression pathways (PAM50-plus). All subjects enrolled will be followed long term for at least eight years. The primary endpoint is the proportion of participants who have an advanced breast cancer diagnosed at any time within 4.5 years of randomization in to the trial. Secondary endpoints include measures of diagnostic and predictive performance; rates of recall, biopsy, and interval cancers, prevalence of breast cancer subtypes, and tumor subtype based on PAM50-plus analysis. As of January 17th 2020, there are 104 sites open and 21,452 women enrolled in the trial. The DSMC last reviewed the trial in June 2019 and suggested that the trial continue as planned. Clinical trial information: NCT03233191. Research Sponsor: U.S. National Institutes of Health.

2000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Intervention combining nurse navigators (NNs) and a mobile application versus standard of care (SOC) in cancer patients (pts) treated with oral anticancer agents (OAA): Results of CapRI, a single-center, randomized phase III trial. *First Author: Olivier Mir, Gustave Roussy Cancer Institute, Villejuif, France*

Background: Various interventions aiming to improve a safe use of oral anti-cancer agents have previously been reported. These retrospective studies involved nurse-led follow-up and use of health technologies. However, the potential impact of these combined strategies is limited by a lack of rigorous methodology. **Methods:** We performed a randomized phase 3 trial comparing an intervention combining NNs and a mobile application vs. SOC in cancer pts treated with OAA (excluding hormonal therapy) in our tertiary cancer center. Pts initiating OAA (all types of cancer, PS $<$ 3, life expectancy $>$ 6 months), were randomized in a 1:1 basis. The intervention combined a nursing-led follow-up and a mobile application for patients. NNs provided regular phone follow-ups to manage symptoms and assess toxicities, adherence and supportive care needs. Pts had access to a mobile application to record tracking data, contact NNs via secure messaging or a dedicated phone line. The intervention lasted 6 months. The primary endpoint was the Relative Dose Intensity (RDI). Secondary endpoints included adherence, toxicity, response and survival, quality of life, pts experience (PACIC Score), end-of-life support, and economic estimation of the use of healthcare resources. **Results:** From October 2016 to May 2019, 609 pts (median age: 62 years, 20-92; PS2: 11.8%) were included. 39% were receiving oral chemotherapy, and 61% other OAA. The RDI was significantly higher in the CAPRI arm (93.4% $\pm$0.26 vs. 89.4% $\pm$0.19, p = 0.04). The CAPRI intervention also improved PACIC scores (mean: 2.94$\pm$0.83 vs. 2.67$\pm$0.89, p = 0.01), the number of unplanned hospitalizations (15.1% vs. 22.0%, p = 0.04), hospitalization duration (mean: 2.82$\pm$6.96 days vs. 4.44$\pm$9.60, p = 0.02), and treatment-related grade$\geq$3 toxicities (27.6% vs. 36.9%, p = 0.02). **Conclusions:** Compared to SOC, the CAPRI intervention improved RDI, pts experience, hospitalizations and their duration, as well as the rate of treatment-related grade$\geq$3 toxicities. This type of intervention should represent a new standard in pts receiving OAA. Clinical trial information: NCT02828462. Research Sponsor: Fondation Philanthropia Lombard Odier, Other Government Agency, Pharmaceutical/Biotech Company.

2001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Chemotherapy remote care monitoring program (CRCMP): Integration of an SMS text patient-reported outcome (PRO) in the electronic health record (EHR) to identify patients needing pharmacist intervention for chemotherapy-induced nausea and vomiting (CINV). *First Author: Shannon Hough, University of Michigan, Ann Arbor, MI*

Background: CINV is a feared side effect of cancer therapy. Despite advances in management, CINV is a common cause for emergency department (ED) evaluation and other unplanned health care utilization. The University of Michigan Rogel Cancer Center initiated the CRCMP to proactively identify patients (pts) experiencing CINV and intervene prior to the need for urgent evaluation. **Methods:** Pts receiving highly emetogenic chemotherapy are identified by administration of a NK1 antagonist. Once enrolled in the CRCMP, pts receive a daily text message survey for 7 days after treatment. The survey is based on the validated MASCC anti-emesis tool (MAT). Responses are stored within a flowsheet in the EHR. Responses above a set threshold trigger a message to the team pharmacist for intervention. Data presented was reviewed from EHR and claims data. **Results:** In 8 mo, 652 pts received a NK-1 antagonist (2244 total cycles) and 387 pts enrolled in the CRCMP (59%). Each pt enrolled for an average of 1.8 cycles of chemo (range 1-8). Of patients enrolled, 61.4% were female and 86.2% were Caucasian. Chemotherapy intent was curative for 51.7% and palliative for 48.3% of pts. Pts enrolled most commonly received cisplatin-based (29.7%) followed by carboplatin-based (22.5%), and 5-fluoruracil-based (20.9%) therapy. Text message response rate was 94% (N=18,143 responses of 19,256 total messages sent). During 861 cycles of therapy, 7% of responses noted vomiting and 33% of responses noted nausea. Since implementation of CRCMP, total hospitalization, ED, and urgent care use has decreased (p=0.029) compared to historical data. When utilization for nausea-related diagnoses was considered, the reduction was more notable (Table). **Conclusions:** Pts engaged in the CRCMP for CINV, allowing for rapid assessment of PROs by a pharmacist. Health care utilization related to nausea was reduced following implementation of CRCMP. While these changes were numerically small, reduction in unnecessary care utilizing PROs can contribute to high value care for cancer patients. Research Sponsor: None.

2002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Home-based management of cancer patients (CPs) experiencing toxicities while on anticancer treatment: The impact of a nurse-led telephone triage (NTT). *First Author: Lorenzo Calvetti, Department of Oncology, San Bortolo General Hospital, Vicenza, Italy*

Background: Novel organization models are needed to ensure early management of new treatment-related toxicity of anticancer treatments. Aim of this prospective observational study was to evaluate the impact of the introduction of NTT in reducing hospitalization of CPs. **Methods:** CPs on active medical treatment at the Department of Oncology of San Bortolo Hospital (Vicenza, Italy) were given instructions to refer to NTT in case of treatment-related adverse events (TRAEs). The service was opened Mon to Fri from 8am to 8pm. Assessment of TRAEs was performed by trained oncology nurses according to the CTCAE scale and subsequent actions were taken according to the severity of the events. The assessment was made under supervision of a medical oncologist in charge of the service while on duty. Primary endpoint of the study was to compare the rate of hospitalization of CPs on anticancer treatment after the introduction of NTT compared to 2017-2018 period. **Results:** From September 2018 to September 2019 1,075 patients received systemic anticancer treatment (versus 936 patients in the equivalent 2017 – 2018 period). Total consultations at NTT were 429; 581 TRAEs were reported. 117 patients reported more than one TRAE. CTCAE were graded as G1 237 (40.8%), G2 231 (39.8%) or G3-G4 113 (19.4%). The most common grade $\geq$ 3 TRAE was fever (38 events (33.6%) that resulted a febrile neutropenia in 7 cases) followed by cancer pain (15 (13.3%)) and fatigue (9 (8%)). In the observation period, 109 CPs on treatment were hospitalized versus 138 in the 2017-2018 period with a normalized hospitalization rate of 10.1% versus 14.7 % (p = 0.002, chi-square) with a reduction of normalized number of hospitalizations of 44 (estimated cost savings of 380.160 euros). **Conclusions:** Our results provided evidence of successful implementation of the NTT system in reducing rates of hospitalization through emergency room in cancer patients receiving modern medical treatments. Research Sponsor: None.

2003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Changes in cancer mortality rates after the adoption of the Affordable Care Act. *First Author: Anna Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The Affordable Care Act (ACA) was designed to improve health status in the US primarily through improving access to health insurance. As adoption of Medicaid expansion varied at the state level, this study aims to compare cancer mortality rates over time between states who did (EXP) and did not adopt (NonEXP) Medicaid expansion. **Methods:** Age-adjusted mortality rates per 100,000 were gathered from the National Center for Health Statistics from 1999-2017 to establish trends. Only deaths due to cancer in patients less than 65 were included. Absolute change in cancer mortality was calculated from 2011-2013 and then from 2015-2017 with 2014 as washout year. Changes within subpopulations (gender, race, ethnicity) were also assessed. Mortality changes between EXP and NonEXP groups were via "difference in differences" analysis. **Results:** Overall age-adjusted cancer mortality in the US fell from 1999-2017 from 66.9 to 48.8 per 100,000. EXP states had higher population (157 vs 118 million) with less black/African Americans (19.2 vs 21.8 million) and more Hispanics (33.0 vs 21.7 million) than NonEXP states (all examples from 2017). The overall age-adjusted cancer mortality was consistently worse in NonEXP states, cancer mortality fell from 64.7 to 46.0 per 100,000 in EXP states and from 69.0 to 51.9 per 100,000 in NonEXP states from 1999-2017 (both trends p $<$ 0.001, comparison p $<$ 0.001). Comparing the mortality changes in the peri-ACA years (2011-2013 vs 2015-2017) between the 2 cohorts, the difference in differences between EXP and NonEXP states was -1.1 and -0.6 per 100,000 respectively (p = 0.006 EXP, p = 0.14 NonEXP). The estimated overall cancer mortality benefit gained in EXP states after Medicaid expansion ($\Delta\Delta\Delta$) is -0.5 per 100,000 (p = NS). In EXP states, this translates to an estimated 785 less cancer deaths in 2017. Age-adjusted cancer mortality per 100,000 was worse in NonEXP states for black patients (58.5 EXP vs 63.4 NonEXP in 2017) however there was no differential mortality benefit after ACA expansion when comparing between the peri-ACA years. Of the subpopulations assessed, Hispanics in EXP states had the highest differential cancer mortality benefit at -2.1 per 100,000 (p = 0.07). **Conclusions:** This is the first study to show a directly measured cancer survival benefit from the ACA on a national scale using a comprehensive database. Hispanic populations appear to have the highest differential cancer mortality benefit after Medicaid expansion. Further study is needed to elucidate why other populations like black patients did not appear to reap the same mortality decrease. Research Sponsor: None.

2004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Survival impact of multidisciplinary thoracic oncology care in a regional healthcare system. *First Author: Raymond U. Osarogiagbon, Multidisciplinary Thoracic Oncology Program, Memphis, TN*

Background: Much-advocated, the value and impact of multidisciplinary care and planning (MDC) needs greater evidence. We compared non-small cell lung cancer (NSCLC) patient characteristics, treatment patterns and survival in a large community healthcare system spanning 3 US states with some of the highest lung cancer incidence and mortality rates. **Methods:** We identified MDC patients in the Tumor Registry NSCLC data from 2011-2017. Because the MDC program was located in metropolitan Memphis, we separated non-MDC patients by location of care resulting in 3 cohorts: MDC, non-MDC metropolitan care and non-MDC regional care. Using National Comprehensive Cancer Network guidelines, we categorized treatment by stage as 'preferred', 'appropriate' (allowable under certain circumstances). We compared demographic and clinical characteristics across cohorts using chi-squared tests and compared survival using Cox regression with Bonferroni adjustment. We repeated survival analysis with propensity matched cohorts. **Results:** Of 6259 patients, 14% received MDC, 56% metro care and 30% regional care; MDC had the highest rates of African Americans (34% v 28% v 22%), stage I-IIIB (63 v 40 v 50), urban residents (81 v 78 v 20), stage-preferred treatment rates (66 v 57 v 48), stage-appropriate treatment rates (78 v 70 v 63;), and lowest non-treatment rates (6 v 21 v 28). All $p<0.001$. Compared to MDC, the hazard for death was higher in metro (1.4, 95% confidence interval 1.3-1.6) and regional (1.7, 1.5-1.9); hazards were higher in regional care v metro (1.2, 1.1-1.3); all $p<0.001$ after adjustment. Results were similar for MDC comparisons after propensity matching with and without adjusting for preferred treatment. No differences in regional and metro cohorts. **Conclusions:** In this large community-based healthcare system, receipt of MDC for NSCLC was associated with significantly higher rates of guideline-concordant care and survival, providing strong evidence for recommending rigorous implementation of MDC. Research Sponsor: PCORI.

Barriers to prescribing targeted therapies for NSCLC patients with highly actionable gene variants in the VA National Precision Oncology Program. *First Author: Vishal Vashistha, Duke University Health System/Durham VA Health Care System, Durham, NC*

Background: Next-Generation Sequencing (NGS) gene panels are often completed to guide therapeutic decisions for patients with advanced stage non-small cell lung cancer (NSCLC). Patients with highly-actionable gene variants may experience improved therapeutic treatments and reduced toxicities with use of targeted agents. Ensuring appropriate prescription of targeted therapies is therefore of high importance. We sought to identify barriers to targeted agent use within the Veterans Health Affairs' (VHA) National Precision Oncology Program (NPOP). **Methods:** A retrospective evaluation examined the cohort of NSCLC patients who underwent NGS multi-gene panels through NPOP between July 2015 and February 2019. A level of evidence for drug actionability was assigned to each observed oncogenic gene variant using an artificial intelligence offering (IBM Watson for Genomics: WfG). WfG level 1 and 2A evidence was reviewed by NPOP staff to exclude gene variants that did not conform to NPOP level 1 and 2A definitions. Anti-neoplastic drug prescriptions and oncology provider notes were obtained for all included patients from the VHA Corporate Data Warehouse. Review of clinical notes of patients who did not receive targeted agents was performed to categorize the reason(s). **Results:** Of 1764 NSCLC patients who successfully underwent NGS gene panel testing, 156 (8.9%) received therapeutic level 1 (7.3%) or 2A (1.6%) options for targeted agents based on WfG evidence analysis. In total, 117 (6.6%) patients had NPOP level 1 and 2A gene variants, all within *ALK*, *BRAF*, *EGFR*, *ERBB2*, *MET*, and *RET*. Of these, 49 (41.2%) patients were not prescribed available targeted agents. The three most common reasons were: (1) treating provider did not comment on NGS results (30.7%), (2) patient did not carry a diagnosis of advanced stage disease (18.4%), and (3) patient had begun an alternative systemic therapy prior to completion of sequencing (16.3%). No patient was denied access to a level 1 or 2A targeted drug due to utilization-management review. **Conclusions:** A substantial minority of patients with advanced NSCLC bearing highly-actionable gene variants are not prescribed available targeted agents. Further provider- and pathologist-directed educational effort are needed, as well as implementation of health informatics systems to provide near real-time decision support for test ordering and interpretation. Launch prices and price developments of cancer drugs in the United States and Europe. *First Author: Kerstin Noëlle Vokinger, Harvard Medical School, Program on Regulation, Therapeutics, and Law/University of Zurich, Boston, MA*

Background: Cancer drug costs are rising in the US and Europe. While drug manufacturers set prices without restriction in the US, European countries have regulations that allow national authorities to directly negotiate drug prices at launch and over time. We analyzed and compared the launch prices and price developments of cancer drugs in the US, Germany, Switzerland and England. **Methods:** We identified new drugs indicated to treat solid tumors in adults that were FDA-approved between 2009 and 2019 and had also been approved by the EMA and Swissmedic by 31 December 2019. Launch prices and post-launch price changes as of 1 January 2020 were extracted and adjusted to average sales prices for monthly treatment costs in the US and compared to comparable currency-adjusted ex-factory monthly treatment costs in Germany, Switzerland, and England. A cross-sectional analysis was conducted to infer yearly trends in launch prices and post-launch price changes across the countries. **Results:** The study cohort included 42 drugs for solid tumors, of which 40 (95%) drugs were first approved in the US compared to Germany and England, and 41 (98%) to Switzerland. Average launch prices for monthly treatment costs per patient were $15,178 in the US vs $7,049 in Germany, $7,421 in Switzerland and $8,176 in England, i.e., 215% (interquartile range [IQR] 263%-187%), 205% (IQR 202%-185%) and 186% (IQR 166%-189%) higher in the US compared to Germany, Switzerland and England respectively. Post-launch prices of 36 (86%), 40 (95%), and 38 (90%) drugs decreased over time with total savings of monthly treatment costs for all drugs in the study cohort of $86,744, $44,936, and $1744 in Germany, Switzerland, and England respectively. By contrast, prices of 8 (19%) drugs decreased, while 34 (81%) increased post-launch in the US with total additional expenses of $128,192 for monthly treatment costs. **Conclusions:** Launch prices for cancer drugs are far higher in the US than in Germany, Switzerland, or England. These price disparities continue to increase substantially after market entry since cancer drug prices, in general, decrease over time in Europe and increase in the US. Spending on cancer drugs could be reduced in the US if it adopted the principles used to more effectively negotiate drug prices in Europe. Research Sponsor: Swiss Cancer Research Foundation.

2007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

The BRCA founder outreach study: Initial results of a digital health model. *First Author: Kelly Morgan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NCCN now endorses BRCA founder mutation genetic testing (GT) via longitudinal studies in all Ashkenazi Jewish (AJ) individuals. The BRCA Founder OutReach (BFOR) study offers pre-GT online education with posttest engagement of primary care providers (PCPs). **Methods:** The study in 4 US cities enrolls those age > 25 with > 1 AJ grandparent. Participants enroll online with chatbot and video education, have GT at local centers, receive results from their PCP or BFOR staff, and are surveyed 12 weeks post disclosure and annually for 5 years. Univariate analyses and multivariable (MV) logistic regression models were used to evaluate characteristics associated with not completing GT, selecting PCP to disclose GT, and positive GT. **Results:** As of January 2020, 4754 participants consented (77.5% female, median age 51); 37.7% never previously considered GT. Cancer family histories (FHx) were 56.4% low risk (LR), 36.4% high risk (HR), and 7.2% had a familial mutation (FM). To date, 3658 participants (76.9%) completed and 677 (14.2%) did not complete GT; the remainder are pending. Only 34.8% of participants selected PCP to disclose GT, and 42.6% of PCPs agreed. Of the 124 mutation carriers (3.4%) identified, 60.5% had a FM. At the 12-week survey, 65.4% of mutation carriers planned to proceed with recommended screening or scheduled risk reducing surgery; 3.5% of those with negative GT and HR FHx reported further GT. Satisfaction was high (mean 9.58/10, SD 1.12) and unrelated to result ($p>.05$). **Conclusions:** A digital model for founder mutation testing engaged those with LR FHx and no prior experience with GT. Older participants were more likely to complete the study. Males were less likely to enroll but more likely to carry mutations. The majority of those who tested positive had a FM. A minority of results were disclosed by PCPs. Continued follow up is needed to determine long term outcomes. 2008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized trial of web-based genetic education versus usual care in advanced cancer patients undergoing tumor genetic testing: Results from the ECOG-ACRIN NCI Community Oncology Research Program (NCORP; EAQ152) COMET trial. *First Author: Angela R. Bradbury, University of Pennsylvania, Philadelphia, PA*

Background: Enthusiasm for precision oncology may obscure the complex psychosocial and ethical considerations for tumor genetic testing. Low patient genetic knowledge has been documented and heightens the risk for adverse experiences. We developed a web-based intervention to increase genetic knowledge and decrease distress among advanced cancer patients undergoing tumor genetic testing. **Methods:** 594 patients (80% from NCORP Community Sites) were recruited and randomized to web-intervention (n = 293) or usual care (n = 301), prior to receipt of tumor genetic test results. Primary outcomes were genetic knowledge, anxiety, depression, and cancer-specific distress measured at T0 (prior to intervention), T1 (post-intervention), T2 (after receipt of tumor results) and T3 (3 months post receipt of tumor results). Secondary outcomes included satisfaction, regret and disappointment. The effect of web-intervention was evaluated using t-test, multiple linear regression and logistic regression, with an intent-to-treat approach. **Results:** Patients randomized to web-intervention had better knowledge improvement than those randomized to usual care (T1-T0, $p < 0.0001$; T2-T0, $p = 0.003$). No difference was observed in change scores for anxiety, depression or cancer-specific distress. To find the moderators of intervention effect (including sex, age, education, and literacy) two 2-way interactions were noted with statistical significance: higher depression among those in the intervention arm versus the control arm for patients with lower literacy ($p = 0.03$); and lower cancer-specific distress among women in the intervention arm than with usual care but no such effect noted in men ($p = 0.01$). 71% of patients reported receiving tumor test results and this did not differ by arm. Only 20% of patients reported regret and disappointment at T2, which was more likely for those without a mutation of interest (MOI) detected vs those with a MOI detected (OR = 2.08, 95% CI, 1.13 to 3.83, $p = 0.02$). **Conclusions:** Web-based education prior to receipt of tumor genetic test results increases patient understanding of tumor genetic testing. While the intervention did not significantly reduce distress, results suggest that women who received the intervention had lower cancer-specific distress than those with usual care. Future refinements to the web-intervention are needed to address low literacy groups, men and patients with no actionable results. Clinical trial information: NCT02823652. Research Sponsor: U.S. National Institutes of Health.

Prospective validation of a machine learning algorithm to predict short-term mortality among outpatients with cancer. *First Author: Chris Manz, University of Pennsylvania, Philadelphia, PA*

Background: Oncologists accurately identify only 35% of patients with cancer who will die in six months. There is an urgent need for automated, accurate prognostic systems to inform treatment and advance care planning in oncology. We assessed the prospective performance of a previously described ML algorithm (Parikh et al, JAMA Netw Open, 2019) to predict short-term mortality in a cohort of general oncology outpatients. **Methods:** Our prospective cohort consisted of patients aged ≥18 years who had a medical or gynecologic oncology encounter between March 1 and April 30, 2019 in either a tertiary academic practice or one of twelve community practices within a large academic cancer system. We used a retrospectively validated gradient-boosting ML algorithm, based on 559 structured electronic health record (EHR) variables, to predict 180-day mortality prior to each oncology encounter. For patients with multiple encounters, we selected the last encounter to assess performance. We assessed several performance metrics, including area under the receiver operating curve (AUC), area under the precision-recall curve (AUPRC), scaled Brier score (sBrier; a measure of calibration ranging from 0 [random] to 1 [perfect]), and positive predictive value (PPV). **Results:** Of 25,537 unique patients, median age was 64.4 (interquartile range 53.3 – 73.0), 76.8% were White, 56.5% were treated at a community center, and 4.1% died within 180 days. The ML algorithm had an AUC of 0.89 (95% confidence interval [CI] 0.88-0.90), AUPRC 0.34, and sBrier 0.29. At a prespecified threshold of 40%, observed 180-day mortality was 44.5% (95% CI 40.7 – 48.4%) in the high-risk group vs. 3.0% (95% CI 2.8% – 3.3%) in the low-risk group. There was an 85-fold difference in mortality (13.6% vs. 0.16%) in the top vs. bottom risk quartiles. The model was well-calibrated for mortality risks ≤40% and slightly under-calibrated for mortality risks > 40%. Performance varied across cancer types in the tertiary hospital but did not vary by race or practice type (Table). **Conclusions:** In this prospective cohort study among outpatients with cancer, a ML prognostic algorithm based on EHR data had better discrimination and calibration that published cancer-specific models. This is one of the first ML prognostic models to be prospectively validated in oncology. Research Sponsor: University of Pennsylvania Center for Precision Medicine.

Multi-institutional comparative effectiveness of advanced cancer longitudinal imaging response evaluation methods: Current practice versus artificial intelligence-assisted. *First Author: Andrew Dennis Smith, University of Alabama at Birmingham, Birmingham, AL*

Background: Current-practice methods to evaluate advanced cancer longitudinal tumor response include manual measurements on digital medical images and dictation of text-based reports that are prone to errors, inefficient, and associated with low inter-observer agreement. The purpose of this study is to compare the effectiveness of advanced cancer longitudinal imaging response evaluation using current practice versus artificial intelligence (AI)-assisted methods. **Methods:** For this multi-institutional longitudinal retrospective study, body CT images from 120 consecutive patients with multiple serial imaging exams and advanced cancer treated with systemic therapy were independently evaluated by 24 radiologists using current-practice versus AI-assisted methods. For the current practice method, radiologists dictated text-based reports and separately categorized response (CR, PR, SD, and PD). For the AI-assisted method, custom software included AI algorithms for tumor measurement, target and non-target location labelling, and tumor localization at follow up. The AI-assisted software automatically categorized tumor response per RECIST 1.1 calculations and displayed longitudinal data in the form of a graph, table, and key images. All studies were read independently in triplicate for assessment of inter-observer agreement. Comparative effectiveness metrics included: major errors, time of image interpretation, and inter-observer agreement for final response category. **Results:** Major errors were found in 27.5% (99/360) for current-practice versus 0.3% (1/360) for AI-assisted methods ($p < 0.001$), corresponding to a 99% reduction in major errors. Average time of interpretation by radiologists was 18.7 min for current-practice versus 9.8 min for AI-assisted method ($p < 0.001$), with the AI-assisted method being nearly twice as fast. Total inter-observer agreement on final response categorization for radiologists was 52% (62/120) for current-practice versus 75% (90/120) for AI-assisted method ($p < 0.001$), corresponding to a 45% increase in total inter-observer agreement. **Conclusion:** In a large multi-institutional study, AI-assisted advanced cancer longitudinal imaging response evaluation significantly reduced major errors, was nearly twice as fast, and increased inter-observer agreement relative to the current-practice method, thereby establishing a new and improved standard of care. Prospective study of an AI enabled online intervention to increase delivery of guideline compliant cancer care, on the ground. *First Author: C. S. Pramesh, Director, National Cancer Grid, Mumbai, India*

Background: Despite survival benefits of guideline compliant cancer care, under treatment and over treatment are prevalent. Navya is an AI enabled online intervention that matches a patient's medical record with NCCN and NCG guidelines (National Cancer Grid, India) and layers live multidisciplinary expert review to recommend actionable treatment plans. It was developed to standardize care and mitigate morbidity and mortality, by delivering on-t ime, guideline based expert treatment plans. **Methods:** From July 2019 to January 2020, all patients who received a Navya treatment plan based on guidelines and live expert review were included. Intended treatment plans were prospectively collected from the patient. Compliance of intended plans with NCCN (including Resource Stratified Framework) or NCG was measured. Noncompliant intended plans were categorized as overtreatment or undertreatment. After delivery of Navya plan, prospective phone follow up assessed whether noncompliant intended plans were changed to guideline compliant care. **Results:** Of 1707 consecutive patients who received a Navya plan, 1549 intended plans were available. Patients were diverse with respect to geographic, socioeconomic, and primary tumor distribution: West of India: 28%, North: 26%, East: 21%, South: 15%, Central: 7%, International: 3%; 35% of patients with income < $300/month; GI: 23%, Breast: 14%, Head & Neck: 11%, Thoracic: 10%. Of the 1549 intended plans, 441 (28.47% (95% CI ± 0.26%)) were not compliant with NCCN or NCG. Undertreatment was 35%, overtreatment 26%, incomplete staging workup 28% and 11% could not be categorized. Of 441 patients with noncompliant intended plans, 80.19% (± 0.97%) shared the Navya plan with their treating oncologists and 50.40% (± 0.88%) changed their intended plan to receive the Navya treatment plan. Intervention with Navya increased on-the -ground guideline compliance by ~15% (from 71.53% ±0.42% to 85.87% ± 1.73%). **Conclusions:** Guideline compliant care ensures best achievable clinical outcomes with existing therapies. A technological earthshot that significantly increases adoption of guideline based care is the first step towards cancer moonshots. Research Sponsor: None.

Four distinct patient-reported outcome (PRO) trajectories in longitudinal responses collected before, during, and after chemotherapy. *First Author: Douglas W. Blayney, Stanford University, Stanford, CA*

Background: Cancer chemotherapy, whether given with curative or palliative intent, is toxic. Toxicity is routinely captured in clinical trials by investigator observation and increasingly by PRO. The ability to capture PRO in the routine treatment workflow has been standard at Stanford since 2015 (Roy et al ASCO 2020). Analysis of longitudinally captured, real world PRO and prospectively identifying patients (pts) whose quality of life (QOL) is at risk of deteriorating either permanently or temporarily is needed. Routine serial PRO measurement should enhance precision care delivery, precision toxicity detection and management. **Methods:** We identified patients undergoing chemotherapy at Stanford and analyzed PROMIS (PRO Measurement Information System) responses. Pts with PROMIS survey information at three intervals—pre-treatment, during chemotherapy and post chemotherapy—were identified. We evaluated global physical health (GPH) and global mental health (GMH). Pts with a clinically significant decrease (CSD) in GPH or GMH scores were identified. A k-median cluster analysis was used to identify patient trajectory clusters and a machine-learning model was applied to identify risk factors for CSD and predict CSD. **Results:** We identified 670 adult oncology patients undergoing chemotherapy who completed at least one PROMIS survey in each interval. GPH scores were 48.4 $\pm$ 9.1 before, 47.1 $\pm$ 8.5 during, and 48.5 $\pm$ 8.9 after chemotherapy and GMH scores were 50.5 $\pm$ 8.2, 49.1 $\pm$ 8.5, and 50.7 $\pm$ 9.0, respectively. The majority of patients did not have a CSD in GPH or GMH post treatment compared to pretreatment scores. Pretreatment scores were the strongest predictor of a CSD in GPH and GMH. Trajectory clustering identified four distinct trajectories: Temporary Improver, Temporary Deteriorator, Improver, Inexorable Deteriorators. We were not able to predict any cluster based on pre-treatment features. **Conclusions:** Using routinely collected PROMIS surveys in a real-world setting, we are able to predict patients with post-treatment decreases in their physical and mental well-being. We further defined four novel patient trajectories during chemotherapy, which could guide personalized supportive interventions to improve patient's chemotherapy experience. Identification of patients at risk for deterioration and the patterns of deterioration could help guide efficient deployment of toxicity mitigating and supportive care interventions to patients most in need. Research Sponsor: U.S. National Institutes of Health.

Patient-reported care satisfaction and symptom burden in hospitalized patients with cancer. *First Author: Emilia R. Kaslow-Zieve, Massachusetts General Hospital, Boston, MA*

Background: Hospitalized patients with cancer often experience high symptom burden, which may impact their care satisfaction and use of health care services. Yet, studies describing these patients' care satisfaction, symptom burden, and health care utilization are lacking. **Methods:** We prospectively enrolled patients with cancer and unplanned hospitalizations from 9/2014-4/2017. Upon admission, patients self-reported their care satisfaction (FAMCARE items asking about satisfaction regarding speed with which symptoms are treated and coordination of care) and physical (Edmonton Symptom Assessment System [ESAS]) and psychological (Patient Health Questionnaire 4 [PHQ4]) symptom burden. We used regression models to identify patient factors associated with care satisfaction. We also explored associations between patients' care satisfaction, symptom burden, and hospital length of stay (LOS) in models adjusted for age, sex, marital status, comorbidity score, cancer type, cancer documented as curable/incurable, time since cancer diagnosis, and admission to a dedicated oncology service. **Results:** We enrolled 1,576 of 1,749 (90.1%) consecutive patients (mean age = 63.19$\pm$13.39 years, 46.3% female). Most reported being very satisfied/satisfied with the speed with which symptoms are treated (89.0%) and coordination of care (90.1%). Older age (B = 0.01, $P < .02$ for both) and admission to a dedicated oncology service (B = 0.20, $P < .01$ for both) were each independently associated with higher satisfaction with the speed with which symptoms are treated and coordination of care. Higher satisfaction with the speed with which symptoms are treated was associated with lower PHQ4 depression (B = -0.14, P = .01), PHQ4 anxiety (B = -0.11, $P < .01$), ESAS physical (B = -1.30, $P < .01$), and ESAS total (B = -2.44, $P < .01$) symptoms. Higher satisfaction with coordination of care was associated with lower PHQ4 depression (B = -0.14, P = .02), PHQ4 anxiety (B = -0.16, $P < .01$), ESAS physical (B = -1.30, $P < .01$), and ESAS total (B = -2.75, $P < .01$) symptoms. Satisfaction with the speed with which symptoms are treated (B = -0.47, P = .03) and coordination of care (B = -0.50, P = .03) were both associated with shorter hospital LOS. **Conclusions:** Most hospitalized patients with cancer reported high care satisfaction, which was associated with older age and admission to a dedicated oncology service. We found relationships among higher care satisfaction, lower symptom burden, and shorter hospital LOS, underscoring the importance of efforts to enhance symptom management and care coordination in this population. Mapping PRO-CTCAE responses to clinician-graded adverse events, dose reductions, interruptions, and discontinuations in phase I cancer trials. *First Author: Geoffrey Alan Watson, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Typically symptomatic adverse events (sy-AEs) on clinical trials are reported by clinicians using the CTCAE. To complement clinician collected sy-AEs and understand tolerability better, the patient report outcome version of the CTCAE (PRO-CTCAE) has been developed to provide the patient (pt) perspective on severity of AEs (graded scale 0-4) and their interference in daily life (scale 0-4). The aim of this study was to correlate PRO responses with the grade (G) of AEs, dose interruptions/reductions and dose limiting toxicities (DLTs). **Methods:** Pts enrolled on phase 1 clinical trials at Princess Margaret were surveyed electronically on tablet using the full library of items for PRO-CTCAE. The PRO-CTCAE was administered at baseline (prior to therapy), mid-cycle 1, and mid-cycle 2. AEs on study were recorded by physicians using the CTCAE. The electronic medical records were analyzed for an association between reported sy-AEs and PRO score. Summary statistics were used to describe patient and disease characteristics, as well as the outcomes. Spearman's method was used to correlate PRO severity and interference responses. Logistic regression was used to assess which factors were associated with CTCAE G 3-4 vs G 2 AEs. **Results:** We analyzed 158 pts: median age 60yrs, 77 (49%) were male; all were ECOG $\leq$1 and 22, 55 and 81 pts completed 1, 2 and 3 surveys, respectively. Clinician reported G2, 3 and 4 sy-AEs occurred in 81, 47 and 3 pts, respectively and all of these were related to a PRO item except 5% (4/81), 9% (4/47) and 33% (1/3), respectively because either the AE occurred after 3rd time point or patient not able to complete the PRO (encephalitis). Sy-AEs causing dose interruptions, reductions, DLTs and discontinuations occurred in 45 (28%), 12 (7.5%), 5 (3%) and 12 (7.5%) pts, respectively; with a corresponding PRO item in 40 (89%), 12 (100%), 4 (80%) and 11(92%) pts, respectively. For patients who had CTCAE G2, G3/4 AEs, interruptions and discontinuations, their severity and inference levels were positively correlated (coefficient 0.49, $p < 0.001$; 0.45, $p < 0.001$ 0.59, $p < 0.001$, 0.86, $p < 0.001$). Dose interruptions (p = 0.0027) and reductions (p = 0.0061) were significantly associated with G3-4 compared to G2 AEs. **Conclusions:** This is the first time an association between PRO-CTCAE severity and interference; and CTCAE G2, 3, 4 AEs, dose interruptions and discontinuations has been demonstrated. Additional modelling and more patient data are being analyzed to explore the relationship. Research Sponsor: None.

Cancer diagnoses and survival rise as 65-year-olds become Medicare eligible. *First Author: Deven C. Patel, Stanford University, Stanford, CA*

Background: A "Medicare effect" has been described to account for increased health care utilization occurring at the age of 65, when individuals become eligible for government-sponsored health care. The existence of such an effect in cancer care, where it would be most likely to reduce mortality, has been unclear. **Methods:** Patients aged 61-69 diagnosed with lung, breast, colon, or prostate cancer from 2004-2016 were identified using the Surveillance, Epidemiology, and End Results database and dichotomized based on eligibility for Medicare (age 61-64 vs 65-69). Using age-over-age percent change calculations, trends in cancer diagnosis, AJCC staging, and survival were characterized. **Results:** 134,991 patients were identified with lung cancer; 175,558 with breast; 62,721 with colon; and 238,823 with prostate. The age-over-age growth in the number of cancer diagnoses was highest at age 65 when compared to all other ages within the decade, for all four cancers (Table: $p<0.01$, $p<0.001$, $p<0.01$, $p<0.001$ respectively). Comparing age 65 diagnoses to the 61-64 year old cohort, the greatest difference for all four cancers was seen in stage I (lung $p<0.001$; breast $p<0.002$; colon $p<0.001$; prostate $p<0.02$). The older (65-69), Medicare-eligible cohort had higher cancer specific 5-year survival than the 61-64 aged cohort for lung (22.0% vs 21.0%, $p<0.01$) and colon cancer (66.2% vs 63.2%, $p<0.01$). **Conclusions:** The 65 age threshold for Medicare eligibility is associated with more cancer diagnoses, particularly in stage I, resulting in improved cancer-specific survival for some cancers. Near-elderly individuals may be delaying care until the age of 65. A Medicare-for-all system would thus be likely to reduce cancer mortality. Research Sponsor: None.

Association between a national insurer's pay-for-performance program for oncology and changes in prescribing of evidence-based cancer drugs and spending. *First Author: Justin E. Bekelman, University of Pennsylvania, Department of Radiation Oncology, Philadelphia, PA*

Background: Efforts to standardize quality and control cost growth for cancer care have focused heavily on promoting evidence-based cancer drug prescribing. We evaluated the association between a national commercial insurer's ongoing pay-for-performance (P4P) program for oncology and changes in prescribing of evidence-based cancer drugs and spending. **Methods:** Retrospective difference-in-differences quasi-experimental study utilizing administrative claims data from the insurer's commercial health plans in 14 states covering 6.7% of US adults. We included patients 18 years of age or older with breast, colon, or lung cancer who were prescribed cancer drug regimens by 1,867 participating oncology physicians between 2013 and 2017. We leveraged the geographically staggered, time-varying rollout of the P4P program to simulate a stepped-wedge study design. Specifically, we estimated a patient-level model clustered by physician and used physician fixed-effects to examine pre- to post-intervention changes in evidence-based prescribing and spending for patients of participating physicians eligible earlier versus later in the period of P4P program rollout. We evaluated four categories of spending over a 6-month episode period: cancer drug spending; other (non-cancer drug) health care spending; total episode spending; and patient out-of-pocket spending. **Results:** The P4P program was associated with an increase in evidence-based regimen prescribing from 57.1% of patients in the pre-intervention periods to 62.2% in the post-intervention periods for a difference of +5.1 percentage points (pp) (95% CI 3.0 pp to 7.2 pp, $P< 0.001$). The P4P program was also associated with a differential $3,235 (95% CI $1,004 to $5,466, $P= 0.005$) increase in cancer drug spending, a differential $253 (95% CI $101 to $406, $P= 0.001$) increase in patient out-of-pocket spending, but no significant changes in other health care spending or total health care spending over the 6-month episode period. **Conclusions:** A national insurer's oncology P4P program was associated with a 5.1 percentage point increase in prescribing of evidence-based cancer drug regimens. Our findings suggest that P4P programs may be effective in increasing evidence-based cancer drug prescribing at national scale -- enhancing cancer care quality. However, they may also increase out-of-pocket expenses and may not lead to savings in total health care spending during the 6-month episode. Research Sponsor: None.

Out-of-pocket cost of screening with breast MRI for women at high risk for breast cancer. *First Author: I-Wen Pan, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The prevention provision of Affordable Care Act (ACA) mandates private insurance to waive cost sharing for preventive services with grade A or B recommendations from the US Preventive Services Task Force. Although several professional societies have recommended augmenting screening mammography with MRI for women at high risk for breast cancer, the ACA prevention provision does not apply to screening MRI. This study examined the proportion of high-risk women having zero cost sharing associated with breast MRI for screening purposes and estimated out of pocket (OOP) costs as well as sources of variations. **Methods:** We identified women who underwent MRI and mammography for breast cancer screening from Marketscan database, 2009-2017. We quantified OOP costs as the sum of copayment, coinsurance, and deductible and defined zero cost sharing as having no OOP cost. We calculated the proportion of zero cost sharing for mammography and that for MRI and compared the time trend of each before and after ACA (enacted in 2010). We used multivariable logistic regression to examine factors associated with zero cost sharing for MRI use. We estimated OOP costs of MRI and examined cost variations by geographic regions or whether a woman had high deductible plans. **Results:** 25,232 women were included in the analysis. For screening mammography, the rate of zero cost sharing increased from 81% in 2009 to 91% in 2011 (post ACA) then 97% in 2017. For MRI, the rate was 41%, 37%, and 25%, respectively. The odds ratio (OR) of zero cost sharing for MRI screening was significantly lower for women with high deductible plans (OR = 0.65, 95% CI: 0.59-0.72) and for those resided in South (vs. Northeast) region (OR = 0.50, 95% CI: 0.46-0.53), after controlling for age, MSA, family breast cancer history, and year. OOP costs of MRI varied by region and insurance plan (Table); the mean OOP cost for women with high deductible plan were more than twice the mean cost for those in other plan types. **Conclusions:** With the financial protection under the ACA prevention provision applying to only screening mammography, many women at high risk for breast cancer are subject to high OOP costs for MRI screening. Those enrolled in high deductible plans and resided in the South are especially vulnerable financially. Research Sponsor: U.S. National Institutes of Health.

Post-hoc power of clinical trials supporting anticancer drug approval by FDA. *First Author: Michelle Nadler, Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada*

Background: Regulatory approval of drugs is based typically on randomized control trials (RCTs) observing statistically significant superiority of an experimental agent over a prior standard. Statistical significance can result from large effect size and/or over-sampling (as a result of large sample size or long follow-up). Here we explore the source(s) of statistically significant results in trials supporting anti-cancer drug approval by the FDA. **Methods:** We searched Drugs@FDA to identify anti-cancer drug approvals for solid tumors (excluding lymphoma) from 2015-2019. We retrieved corresponding manuscripts and associated appendices and extracted data on study characteristics, statistical plan, primary outcomes and accrual and follow-up times. Post-hoc power was calculated based on observed results and was compared to expected effect size and power in the statistical plan. We explored associations with higher than expected power resulting from over-sampling using binary logistic regression. **Results:** We identified 75 unique drug-approvals reporting 94 endpoints. The most common tumour types were lung, breast, melanoma, and renal cell carcinoma. The most common endpoints were progression free survival and overall survival (OS). In 74 endpoints (79%), observed power was greater than expected power. The magnitude of higher than expected power ranged from 0.1 to $>$ 20%. Of these, 59 (80%) had an effect size greater than predicted in the statistical plan. In 44/74 over-powered endpoints (60%), post-trial power was 100%. When post-hoc power was calculated based on expected effect size rather than observed effect size, 50 endpoints (85%) remained over-powered. Higher than expected power resulting from over-sampling was associated with OS compared to other endpoints (OR 3.03), with targeted agents compared to immunotherapy (OR 1.63) and inversely associated with year of approval (OR 0.57). **Conclusions:** Most cancer drug approvals result from statistically significant studies which are over-powered due to greater than anticipated effect size. Approximately 1 in 5 studies are over-powered likely due to over-sampling. In this setting, benefit observed in RCTs may not translate to the real-world setting. Research Sponsor: None.

Methodology, results, and publication of oncology clinical trials: Insights from all the world's randomized controlled trials (RCTs) 2014-2017. *First Author: Shubham Sharma, Queen's University, Kingston, ON, Canada*

Background: Clinical cancer research is now a global effort. Most published overviews of oncology trials are restricted to a specific disease site or cohort of high-profile journals. Here we describe authorship, trial characteristics, design, and results of all oncology RCTs published globally during 2014-2017. **Methods:** A structured literature search was designed using PUBMED to identify all RCTs evaluating anti-cancer therapies published during 2014-2017. Data were captured regarding authorship, participants, study characteristics, design, and results. Among superiority RCTs that met the primary endpoint (i.e. statistically "positive"), we calculated the ESMO-MCBS to identify trials with substantial clinical benefit (MCBS scores 4/5 or A/B). Outcomes were compared with Chi Square or Fisher's Exact tests. **Results:** The study cohort included 694 RCTs. The most common cancers evaluated were breast (17%, 121/694), lung (15%, 104/694) and colorectal (8%, 58/694). Treatment intent was curative, adjuvant/neoadjuvant, and palliative in 10% (68/694), 25% (176/694), and 65% (448/694) of trials respectively. Median sample size was 443 (IQR 246-718). Seventy percent (488/694) of RCTs were supported by industry; 87% (601/694) of experimental arms tested systemic therapy. Ninety-two percent (636/694) of RCTs were led by investigators in 28 high-income countries; the most common countries leading these trials were US (27%, 174/636), France (10%, 64/636), Germany (10%, 62/636), Japan (9%, 59/636), and UK (9%, 57/636). The most common primary endpoints were PFS (32%, 220/694), OS (31%, 215/694), and DFS (11%, 79/694); Forty-six percent of all trials (318/694) met their primary endpoint. Among superiority trials with "positive" results, 33% met ESMO-MCBS threshold for substantial clinical benefit. The median impact factor (IF) of journals which published the overall study cohort of trials was 21 (IQR 7-27); trials meeting their primary endpoint were published in higher profile journals (median IF 25 vs 18, $p < 0.001$). **Conclusions:** At the global level, oncology clinical trials are dominated by high-income countries and study diseases which do not necessarily reflect the global burden of cancer. The vast majority of trials are funded by industry and only one third of "positive" trials meet ESMO-MCBS threshold for substantial clinical benefit. Research Sponsor: None.

Absence of optimism bias in industry-sponsored cancer trials. *First Author: Sonal S Noticewala, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Randomized controlled trials (RCTs) in oncology power their studies to detect expected effect sizes. Prior studies have shown that there is optimism bias, the *a priori* overestimation of treatment effect size among cooperative-group-supported RCTs. However, it is unknown whether such bias is present among industry-supported trials. **Methods:** All published phase 3 clinical oncology RCTs were identified through ClinicalTrials.gov. Only superiority-design RCTs assessing a therapeutic intervention to improve disease-related outcomes were included. We compared the ratio of observed to expected hazard ratio (OEHRR) between trial subgroups using the Mann-Whitney U-test; comparisons of median OEHRR to a hypothetical median of 1 was performed using the Wilcoxon Signed Rank test. **Results:** We identified 140 phase 3 trials with available hazard ratio (HR) data. Of these, 123 trials (88%) were industry-sponsored, and 38 trials (27%) were cooperative-group-supported. For all trials, the median OEHRR was 1.099 (IQR = 0.855-1.291), demonstrating evidence of optimism bias when compared to a hypothetical median OEHRR of 1 ($p = 0.018$). In the subgroup analysis, compared to non-industry-sponsored trials (median OEHRR 1.253, IQR 1.061-1.334), industry-supported trials (median OEHRR 1.061, IQR 0.829-1.274) had a significantly lower OEHRR ($p = 0.022$) and did not demonstrate optimism bias ($p = 0.15$). Similarly non-cooperative group trials (median OEHRR 1.208, IQR 1.019-1.317) had a significantly lower OEHRR ($p = 0.005$) and did not demonstrate optimism bias ($p = 0.562$) compared to cooperative group trials (median OEHRR 1.208, IQR 1.019-1.317), which did demonstrate optimism bias ($p < 0.001$). **Conclusions:** Cooperative group trials, which represent a minority of trials, suffer from optimism bias. In contrast, industry-funded trials, which account for the majority of trials, do not demonstrate evidence of optimism bias, and have very close concordance between observed and expected effect size. These findings suggest that the powering and design of industry-funded trials better models the outcomes eventually observed. The reasons for this are likely complex and multifactorial, but may include financial constraint considerations, as industry-supported trials may not be as financially-limited as cooperative group studies. Therefore, industry-supported studies may be able to power trials with sufficient participants to reflect the estimated effect size. Research Sponsor: None.

2021 Poster Session (Board #13), Fri, 8:00 AM-11:00 AM

Distress screening through PROMIS at an academic cancer center and network site: Implementation of a hybrid model. *First Author: Mohana Roy, Stanford University and Stanford Cancer Institute, Stanford, CA*

Background: The NCCN guidelines recommend routine distress screening of patients with cancer, but the implementation of such programs is inconsistent. Up to one in three such patients experience distress, however fewer than half of them are identified and referred for supportive services. **Methods:** We implemented a hybrid (electronic and paper) distress screening tool, using a modified version of the PROMIS-Global Health questionnaire. Patients received either an electronic or in-clinic paper questionnaire to assess overall health and distress at the Stanford Cancer Center and its associated integrated network site. Iterative changes were made including integration with the electronic health record (EHR) to trigger questionnaires for appointments every 60 days. A consensus "positive screen" threshold was defined, with data collected on responses and subsequent referrals placed to a supportive care services platform. **Results:** Between June 2015 and December 2017, 53,954 unique questionnaires representing 12,744 distinct patients were collected, with an average completion rate of 58%. Approximately 30% of the questionnaires were completed prior to the visit electronically through a patient portal. The number of patients meeting the positive screen threshold remained ~ 40% throughout this period. Following assessment by the clinical team, there were 3763 referrals to cancer supportive services. Among the six most common referral categories, those with a positive screen were more likely to have a referral placed (OR 6.4, 95% CI 5.8-6.9 p-< 0.0001), with a sensitivity of 80% and a specificity of 61%. However, 89% of responses with a positive screen did not have a referral to supportive care services. **Conclusions:** The hybrid electronic and paper use of a commonly available patient reported outcome tool, as a high throughput distress screening tool, is feasible at a multi-site academic cancer center. Our positive screen rate for referrals was sensitive and consistent, but with a low positive predictive value. This screening also resulted in variable clinical response and overall increased clinical burden. Future directions for our group have included refining the threshold for a positive screen and implementation of a real-time response system, especially to address acute concerns. Research Sponsor: None.

2022 Poster Session (Board #14), Fri, 8:00 AM-11:00 AM

Association of hospital type and patient volume growth with timely cancer treatment. *First Author: Zachary AK Frosch, Division of Hematology & Oncology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Studies have suggested superior outcomes for patients with cancer treated at National Cancer Institute (NCI) and academic hospitals, leading some to advocate for complex cancer care to be delivered at regional referral centers. However, growing demand at such centers may exceed their capacity to provide timely treatment, which could be detrimental to patient outcomes. We evaluated the relationship between hospital type, the average annual growth rate in patient volume (PV), and time to treatment initiation (TTI) trends. **Methods:** We used the National Cancer Database to identify patients undergoing initial treatment for a new diagnosis of cancer (breast, lung, prostate, colorectal, melanoma, bladder, non-Hodgkin lymphoma, renal, uterine or pancreatic) in 2007-2016. The exposure was hospital type (NCI, academic, community or integrated network). The primary outcome was TTI over time. We estimated both the average annual growth rate for PV and adjusted TTI trends by hospital type using linear mixed effects models, including a hospital type-by-time interaction and, when modeling TTI, a patient volume-by-time interaction. **Results:** We identified 4,218,577 patients treated at 1351 hospitals (49% at 897 community, 23% at 177 academic, 14% at 50 NCI and 14% at 227 integrated network hospitals). Over the study period, PV grew by 40% at NCI and 25% at academic hospitals, compared to 8% at community hospitals (p-value for trend both < 0.001). Meanwhile, mean TTI increased by 3.2 days at community, remained stable at academic (+0.3 days) and decreased by 4.3 days at NCI hospitals (p-value for trend both < 0.001 vs community). A higher annual PV growth rate was associated with a statistically but not clinically significant TTI increase (0.05 days for each 100 patient/year increase in the growth rate, $p = 0.001$). **Conclusions:** Patients with newly diagnosed cancer are increasingly receiving treatment at NCI and academic hospitals. While TTI at NCI and academic hospitals is longer than in the community, PV growth has been possible without delaying cancer treatment. Further study is needed to determine whether continued growth at this rate is sustainable. Research Sponsor: None.

Are ED visits in cancer patients preventable? Care patterns before an ED visit. *First Author: Arthur Hong, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Medicare's Oncology Care Model alternative payment program participation requires 24-hr patient access to clinician phone advice. Many participating practices have established oncology urgent care clinics to reduce the frequent ED visits in the early phase after cancer diagnosis. However, little is known about patients' use of pre-ED visit clinical advice via phone. We combined EHR data on phone/secure messaging encounters, outpatient visits, and regional ED visits, to assess how often patients visit the ED without prior clinical advice, and to compare ED visit severity between those with and without preceding clinical advice. **Methods:** We linked adults ages 18+ from Parkland Health and Hospital System (PHHS), the Dallas County public safety net system, and UT Southwestern (UTSW) NACR Gold-certified cancer registry (2012-2018), to their respective EHR, and identifiably linked patients to a regional health information exchange of ED and hospital encounters. Exchange data included hospital name, ED disposition, diagnoses, and ED Severity Of Illness. We tallied ED visits within 6 months (180 days) after cancer diagnosis and EHR clinical contacts for 24 hours prior to ED visit (telephone/secure messaging, outpatient visits). After descriptive statistics, we used mixed-effects multivariate logistic regression clustering at patient level to model ED disposition after a pre-ED clinical contact. **Results:** We matched 8,289 Parkland (54% female, 78% Medicaid/charity assistance) and 10,817 UTSW patients (50% female, 12% Medicaid), who generated 21,009 and 22,696 ED visits, respectively. Two-thirds of all ED visits occurred without preceding clinical contact (70.2% PHHS, 66.7% UTSW); large shares of ED visits were to 67 other regional hospitals (22.2% PHHS, 69.5% UTSW). Telephone encounters and outpatient visits to any specialty were the most common contact before ED visit (UTSW: 28.2 and 12.4%; PHHS: 8.7 and 16.1%), but while nearly all UTSW clinic visits were to oncology, only 30% of PHHS clinic visits were to oncology. Though ED visit severity was slightly higher for ED visits without preceding clinical contact (46% vs. 43% ≥Major severity, $p < 0.01$), patients were discharged home more often if clinical contact preceded ED visits (aOR of hospitalization 0.82, 95% CI: 0.74 – 0.90). **Conclusions:** Two-thirds of ED visits occurred without prior clinical contact, and though these no-contact ED visits had higher severity of illness, they were more often discharged home from the ED. Future work should identify patient-oriented options to optimize the use of clinical care and the ED. 2024 Poster Session (Board #16), Fri, 8:00 AM-11:00 AM

The impact of early integrated supportive care on length of stay at an NCI-designated cancer center. *First Author: Jessica Kaltman, City of Hope National Medical Center, Los Angeles, CA*

Background: With movement towards value-based care, institutions seek ways to reduce costs by decreasing inpatient stays. A multidisciplinary approach to supportive care, especially when provided early, is one way to realize value-based care. We assess the impact of pre-admission versus post-admission involvement of an Integrated Supportive Care Model (ICSM) on inpatient length of stay (LOS) at a NCI-designated cancer center. **Methods:** Data was collected from 2014 to 2016 at City of Hope. The Integrated Supportive Care Model at City of Hope includes: palliative care, psychiatry, psychology, interventional pain, social work, child-life, distress screening, and couples program. "Pre-admission" was defined as seeing at least one service prior to hospital admission; "Post-admission" defined as seeing at least one service during admission. "Short LOS" for hematology patients was categorized as $\leq$ 14 days and for oncology patients as $\leq$ 3 days. Continuous LOS between patients receiving an ISCM intervention pre- and post-admission was compared using Kruskal-Wallis test. Univariate and multivariable logistic regression was done to examine association between involvement of ISCM pre- and post-admission and categorical LOS. P-values < 0.05 were considered statistically significant. **Results:** 1,627 (809 with hematologic malignancy, 818 with oncologic malignancy) patients with only one hospitalization during the study time were included. For hematology patients, involvement with the ISCM pre-admission was associated with shorter LOS ($\leq$ 14 days) compared with involvement post-admission (29.3 vs 11.1%, multivariable OR = 4.08, $P < 0.001$). Median LOS for hematology patients who participated in the ISCM pre-admission was shorter than those who received ISCM services post-admission (21 vs. 22 days, $p = 0.049$). Similarly, for oncology patients, ISCM involvement pre-admission was associated with shorter LOS ($\leq$ 3 days) compared to involvement post-admission (91.4% vs 8.6%, multivariable OR = 3.74, $P < 0.001$). Median LOS for oncology patients who received an ISCM intervention pre-admission was shorter than those who received an ISCM intervention post-admission (2 vs. 6 days, $p < 0.001$). **Conclusions:** In hematologic and oncologic malignancies, use of an ISCM prior to patient's first hospitalization is associated with significantly shorter LOS compared with those who received ISCM services during the hospital stay. This suggests efforts should be made to include an ISCM early in the trajectory of illness, prior to first hospitalization. Research Sponsor: City of Hope.

2025 Poster Session (Board #17), Fri, 8:00 AM-11:00 AM

Integrating breast cancer screening into a cervical cancer screening program in three rural districts in Rwanda. *First Author: Lydia E. Pace, Brigham And Women's Hospital, Boston, MA*

Background: In low-income countries where mammography is not widely available, optimal strategies to facilitate earlier breast cancer detection are not known. We previously conducted a cluster randomized clinical trial of clinician trainings in Burera District in rural Rwanda to facilitate earlier diagnosis among symptomatic women; 1.3% of women evaluated at intervention health centers (HCs) were diagnosed with cancer. Early stage breast cancer incidence was higher in intervention areas. Subsequently, Rwanda Biomedical Centre, Rwanda's national health implementation agency, adapted the program in 3 other districts, offering screening clinical breast exams (CBE) to all women aged 30-50 years receiving cervical cancer screening and any other woman requesting CBE. A navigator facilitated patient tracking. We sought to examine patient volume, service provision and cancer detection rate in the adapted program. **Methods:** We abstracted data from weekly HC reports, facility registries, and the referral hospital's electronic medical record to determine numbers of patients seen, referrals made, biopsies, and cancer diagnoses from July 2018-December 2019. **Results:** CBE was performed at 17,239 visits in Rwamagana, Rubavu and Kirehe Districts (total population 1.34 million) over 18, 17 and 7 months of program implementation respectively. At 722 visits (4.2%), CBE was abnormal. 571 patients were referred to district hospitals (DH); their average age was 35 years. Of those referred, 388 (68.0%) were seen at DH; 32% were not. Of those seen, 142 (36.6%) were referred to a referral facility; 121 of those referred (85.2%) actually went to the referral facility. Eighty-eight were recommended to have biopsies, 83 (94.3%) had biopsies, and 29 (34.9% of those biopsied; 0.17% of HC visits) were diagnosed with breast cancer. **Conclusions:** Integrating CBE screening into organized cervical cancer screening in rural Rwandan HCs led to a large number of patients receiving CBE. As expected, patients were young and the cancer detection rate was much lower than in a trial focused on symptomatic women. Even with navigation efforts, loss-to-follow-up was high. Analyses of stage, outcomes, patient and provider experience and cost are planned to characterize CBE screening's benefits and harms in Rwanda. However, these findings suggest building health system capacity to facilitate referrals and retain patients in care are needed prior to further screening scaleup. In the interim, early diagnosis programs targeting symptomatic women may be more efficient and feasible. Research Sponsor: Breast Cancer Research Foundation.

2027 Poster Session (Board #19), Fri, 8:00 AM-11:00 AM

Pilot program of remote monitoring for high-risk patients on antineoplastic treatment. *First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Early detection and management of symptoms in patients with cancer improves outcomes, however, the optimal approach to symptom monitoring and management is unknown. This pilot program uses a mobile health intervention to capture and make accessible symptom data for high-risk patients to mitigate symptom escalation. **Methods:** Patients initiating antineoplastic treatment at a Memorial Sloan Kettering regional location were eligible. A dedicated staff of RNs and nurse practitioners managed the patients remotely. The technology supporting the program included: 1) a predictive model that identified patients at high risk for a potentially preventable acute care visit; 2) a patient portal enabling daily ecological momentary assessments (EMA); 3) alerts for concerning symptoms; 4) an application that allowed staff to review and trend symptom data; and 5) a secure messaging platform to support communications and televisits between staff and patients. Feasibility and acceptability were evaluated through enrollment (goal $\geq$25% of new treatment starts) and response rates (completion of $>$ 50% of daily symptom assessments); symptom alerts; perceived value based on qualitative interviews with patients and providers; and acute care usage. **Results:** Between October 15, 2018 and July 10, 2019, the pilot enrolled 100 high-risk patients with solid tumors and lymphoma initiating antineoplastic treatment (median age: 66 years, 45% female). This represented 29% of patients starting antineoplastics. Over six months of follow-up, the response rate to the daily assessments was 56% and 93% of patients generated a severe symptom alert (Table). Both patients and providers perceived value in the program and 5,010 symptom-related secure messages were shared between staff and enrolled patients during the follow-up period. There was a preliminary signal in acute care usage with a 17% decrease in ED visits compared to a cohort of high-risk unenrolled patients. **Conclusions:** This pilot program of intensive monitoring of high-risk patients is feasible and holds significant potential to improve patient care and decrease hospital resources. Future work should focus on the optimal cadence of EMAs, the workforce to support remote symptom management, and how best to return symptom data to patients and clinical teams. Research Sponsor: None.

Prevalence of symptoms reported at moderate and severe levels on one or more days % (n = 100).

Symptom	Moderate	Severe
Pain	73%	74%
Anxiety	73%	21%
Depression	70%	14%
Functional status	66%	53%
Diarrhea	62%	12%
Decreased Oral Intake	61%	18%
Nausea	58%	25%
Dyspnea	38%	22%
Emesis	24%	9%

2028 Poster Session (Board #20), Fri, 8:00 AM-11:00 AM

Interest in cessation treatment and survival among smokers in a community-based multidisciplinary thoracic oncology program. *First Author: Meghan Meadows, University of Memphis, School of Public Health, Memphis, TN*

Background: Tobacco cessation is essential to high quality oncology care. Many patients smoke when diagnosed and continue to smoke during treatment, which adversely affects treatment response and survival. Although most patients are motivated to quit, few receive effective cessation therapy. The multidisciplinary clinic (MDC), where patients, their caregivers, and key specialists coordinate care, is an ideal setting to integrate a cessation program. To assess the need for cessation services within a MDC setting, we surveyed incoming patients about their smoking status, interest in quitting, and willingness to participate in a clinic-based cessation program. **Methods:** The study was conducted in the Multidisciplinary Thoracic Oncology Program at Baptist Cancer Center, Memphis TN. We evaluated sociodemographic/clinical characteristics, smoking status, and tobacco dependence of consecutive new patients diagnosed with lung cancer from 2014-2019, who completed a social history questionnaire. Current smokers reported their interest in quitting and their willingness to participate in a cessation program. Chi square tests and logistic regression models were used to compare characteristics of those who would participate vs. those who would not/were unsure. Kaplan-Meier curves and multivariable Cox regression were used to evaluate the association between willingness to participate in a cessation program and overall survival, adjusted for age, sex, race, and total pack-years of smoking. **Results:** Of 641 patients, the average age was 69 years (range: 32-95), 47% were men, 64% white/34% black, and 17% college graduates; 90% had ever smoked, 34% currently smoked, and 24% quit smoking within the past year. Among current smokers, 60% were very interested in quitting and 37% would participate in a clinic-based cessation program. Willingness to participate was associated with greater interest in quitting ($p = 0.0010$) and greater overall survival (log rank $p = 0.01$;HR: 0.48, 95% CI: 0.24-0.95) but was not associated with any sociodemographic, clinical, or smoking-related characteristics. **Conclusions:** Over half (58%) of patients in a community-based MDC program were current smokers/recent quitters. Willingness to participate in a cessation program was associated with improved survival, suggesting patients with favorable prognoses are especially interested in receiving cessation support. There is considerable need for cessation services and relapse-prevention support within a coordinated, MDC lung cancer care setting. 2029 Poster Session (Board #21), Fri, 8:00 AM-11:00 AM

Nickel and dimed: Parking fees at NCI-designated cancer centers. *First Author: Anna Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Nonmedical costs from cancer treatment can be a significant out-of-pocket expense. As treatment may span over months, parking costs can become a significant burden on patients and caregivers. This cross-sectional study aims to report parking fees at National Cancer Institute (NCI)-designated cancer centers and to project parking costs for the treatment duration of certain cancers. **Methods:** Parking fees from NCI treatment centers were obtained via online search or phone call in Fall of 2019. City cost of living, median city household income, and discount availability were documented. Pearson correlation was used between parking costs and city variables. Parking costs were estimated for treatment of node positive breast cancer (12 daily rates plus 20 1-hr rates), definitive head and neck cancer (35 1-hr rates) and acute myeloid leukemia (AML) (42 daily rates). RStudio Version 1.2.5033 was used for analyses. **Results:** Parking costs were obtained for 100% of the 63 NCI centers included. Median city cost of living relative to New York City was 75.0 (out of 100); median city household income was $55,295 (range $28,974-$120,573). Twenty-five (40%) of NCI centers did not have detailed parking cost information online. Average parking costs were $3.55/hr (median $2, range 0-$15) and $7.79/day (median $5, range 0-$40). Twenty centers (32%) offered completely free parking for patients. Free parking was available at 43 (68%) centers for radiation appointments and 34 (54%) centers for chemotherapy appointments. Averaged estimated parking costs including discounts for a course of treatment for breast cancer was $122.03 (range 0-$800); head and neck cancer, $85.56 (range 0-$665); and AML hospitalization, $327.33 (range 0-$1470). City cost of living was positively correlated with daily parking costs ($R = 0.7$, $p < 0.01$) and negatively correlated with both free daily parking ($R = -0.33$, $p = 0.02$) and free parking during radiation ($R = -0.34$, $p = 0.02$) or chemotherapy ($R = -0.37$, $p < 0.01$). The median city household income was correlated with the daily parking costs ($R = 0.30$ $p = 0.02$) but not with free daily parking ($R = -0.19$, $p = 0.16$), free parking for patients on radiation ($R = -0.23$, $p = 0.09$) or on chemotherapy ($R = -0.21$, $p = 0.14$). **Conclusions:** Patients may face significant nonmedical costs through parking fees, even at centers that reflect the highest standard of care. There was high variability in costs with the potential for patients to pay hundreds of dollars in parking in order to receive their care. Efforts to minimize financial toxicity should focus on this potentially under-reported patient concern. Research Sponsor: None.

2030 Poster Session (Board #22), Fri, 8:00 AM-11:00 AM

Implementation of Symptom Care Clinic (SCC) for acute symptoms management at outpatient oncology ambulatory centers. *First Author: Han Xiao, Memorial Sloan Kettering Cancer Center, Basking Ridge, NJ*

Background: With improved overall cancer survival, increasing number of cancer patients are undergoing active treatment. This, in return, add burden in acute symptom management related to disease and treatment. This has resulted in increasing unplanned emergency room (ER) visits and negatively impacted patients experience and health cost. We establish Symptom Care Clinic (SCC) embedded in suburban ambulatory oncology centers to reduce unplanned ER lists and to improve patient experience. **Methods:** Together with all stakeholders, we developed six SCCs at regional ambulatory centers in NY and NJ. Clearly defined work flow and algorithm were developed to ensure appropriate patient referral. On-site radiology and laboratory services are available. The SCCs are staffed with combination of Advanced Practice Provided (APP) and physicians or APP alone supported by on site medical oncologist or remote central Urgent Care Center Attendings. We evaluated clinic volumes, reduction ins unplanned ER visits and patient experience. **Results:** From October 2017 to December 2019, total of 17,542 SCC visits were documented. Total of 17,479 lab and 5,355 radiology tests as well as 3,915 infusions were performed. The top five most common laboratory tests are CBC, blood cultures, CMP, respiratory panel and urine culture. The most common symptoms are fever, nausea/vomiting/dehydration, rash and pain. Among all SCC visits during this period, 83% were discharged home and 17% were transferred to ER or hospitals. During 2019, total 10,736 SCC visits were recored, APP evaluated 73.7% of visits and physicians 16.3% with comaprable recidivism rate, 2.52% and 2.75%, respectively. Conservatively, we estimated that approximately 40% of visits would have been Er visits based on numbers of CBC and other testes performed. Qualitative feedbacks from patients indicated positive experience in convenient access, cohesive care coordination and time saving from traveling to and waiting in ER. **Conclusions:** We successfully implemented an effective acute symptom management system in busy ambulatory oncology centers that is patient centric. Out data showed that SCC reduced unplanned ER visits and that APP/physician model has low recidivism rate. Research Sponsor: None.

2032 Poster Session (Board #24), Fri, 8:00 AM-11:00 AM

Impact of an immuno-oncology (IO) education/monitoring program on patient's self-efficacy and adverse event reporting from immune checkpoint inhibitors (ICIs). *First Author: Parneet Kaur Cheema, William Osler Health System, University of Toronto, Brampton, ON, Canada*

Background: ICIs have unique side effects of immune related adverse events (irAEs). For early detection and management of irAEs, at a large community hospital we implemented a standard IO nursing baseline assessment, education and monitoring program. We studied it's impact on a patient's irAE reporting and self-efficacy (confidence to manage symptoms) of ICIs. **Methods:** Prospective study conducted at William Osler Health System, Brampton, Canada from May 2018-December 2019. Patients aged $> = 18$, English speaking that received an ICI for cancer were included. Patients underwent a standardized baseline nursing assessment and education class. Patients identified at the assessment as high risk (risk of grade 3/4 irAE $>20\%$) had weekly nurse proactive calls. Cancer Behaviour Inventory – Brief Version (CBI-B) (Heitzmann et al, 2011) was used to evaluate patient's self-efficacy. **Results:** Eighty patients were enrolled. Median follow up of 4.1 months. Baseline demographics: median age 69, 70% males, 77% Caucasian, 81% ECOG 0/1, 66% had English as their first language and 19% highest education was elementary, 30% high school, 26% trade diploma and 21% post-secondary. Fourty-one percent had limited cancer health literacy (measured by CHLT6 (Dumenci et al, 2014)). ICIs prescribed were 70% monotherapy anti-PD1/PDL1, 13% combination nivolumab/ipilimumab, 17% anti-PD1/PDL1 + chemotherapy/other therapies. Majority had a diagnosis of non-small cell lung cancer (55%), melanoma (19%) and renal cell carcinoma (9%). A statistically significant improvement in the average CBI-B scores were found pre and post baseline assessment/education ($p < 0.001$) and this improvement was maintained over time at follow-up visits (non-significant change in scores from post education results). Fourty-three percent of patient's experienced $>$ 1 irAE. Most were grade 1/2 at time of detection (65%). Method of detection was mainly by patient self-reporting (62%), followed by proactive calls (27%). Only 3 patients had detection of an irAE with an ER visit. Rate of discontinuation of ICIs due to toxicity was 8.8%. **Conclusions:** In this diverse patient population with almost half of patients having limited cancer health literacy, a standardized IO baseline assessment, education and monitoring program resulted in improved patient self-efficacy with most irAEs detected by self-reporting and proactive calls. Our IO program can be a model for other oncology programs. Research Sponsor: None.

2033 Poster Session (Board #25), Fri, 8:00 AM-11:00 AM

Evaluating barriers to uptake of comprehensive genomic profiling (CGP) in advanced cancer patients (pts). *First Author: Kortnye Maureen Smith, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Despite increasing evidence of benefit supporting CGP in personalizing cancer therapy, its widespread uptake remains limited. Barriers include low patient understanding, unmet patient expectations related to low utility, clinician concerns over cost-effectiveness, perceived value, and discomfort in management of complex genomic results. **Methods:** This prospective cross-institutional demonstration study was designed to evaluate implementation of CGP in the care of adult and paediatric advanced cancer pts, incorporating pt reported outcomes (PROMs), discrete choice experiment (DCE), ongoing process optimization and clinician evaluations. DNA sequencing of FFPE tumor and matched blood was completed with CGP (PMCC Comprehensive Cancer Panel; 391 genes) via central laboratory. A tumor board reported results weekly with emphasis on therapeutic relevance. Oncologists performed consent and results delivery. Pts completed pre-and post-test surveys, including validated and study-specific questions, DCE and if eligible, semi-structured interviews. Qualitative interviews were undertaken with study clinicians and laboratory staff to evaluate processes. **Results:** 86% (315) of 365 enrolled pts had successful CGP; of these 63% (199) had relevant therapeutic, diagnostic or germline results. 50 (16%) had treatment change at 6m, 49 (16%) had germline mutations. 293 (88% of adult pts) completed PROMs. 17 of 19 clinicians/laboratory staff approached consented to an interview. At consent pts cited multifaceted value in testing, showed good understanding of basic concepts, but most (69%) overestimated the likelihood of result-led change. Post-test pts remained consistently satisfied with accessing CGP; valuing research contribution, taking opportunities and information for family. 21% struggled with understanding results but there were low levels of decisional regret following participation (89% had nil/mild regret). Pt-elicited preferences (via DCE) indicated priority for high rates of clinical utility and timeliness. Clinicians sited collaboration and communication as critical to delivery of CGP. **Conclusions:** Pts undergoing CGP are generally satisfied, and derive value on its use beyond potential therapeutic benefit. Our results suggest that to improve test utility and delivery of CGP with value to pts and investing institution, focus must be placed on addressing the additional barriers to its wider implications including efforts to improve process efficiencies, clinician genomic literacy and decision-making support. Effect of a supportive medicine program for cancer patients on patient connectivity to care and health care utilization. *First Author: Brooke Worster, Sidney Kimmel Cancer Center, Philadelphia, PA*

Background: The benefits of supportive medicine (SM) for cancer patients include improved quality of life, increased patient satisfaction, improved symptom management, increased cost savings and improved survival rates. At one NCI-designated cancer center, all patients were screened for distress; those who screened positive or were directly referred by a provider were enrolled into our multi-disciplinary SM program. Here, we document the impact of the supportive medicine program on outcomes of emergency department (ED) visits, hospital readmission, and non-billable touchpoints associated with patient navigation and resource referrals. **Methods:** The program systematically screened for biopsychosocial distress utilizing the National Comprehensive Cancer Center Distress Thermometer (DT) and the Problem Checklist (PC) to identify practical, emotional, spiritual and physical issues. Patients were categorized into three types: screened and enrolled in the SM program, and screened and not enrolled in the SM program, or provider referral into the SM program. Data included patient's age, number of hospital admissions, emergency department visits, and non-billable touchpoints at 90 and 180 days after the distress screening or referral. Descriptive data were analyzed with counts and percentages for categorical variables and summarized with mean and standard deviation for numerical variables. For investigation of the effects of time and patient type on the change in utilization rate, generalized estimation equations for Poisson regression were conducted for each outcome. **Results:** In all, 2,738 patients were included in the analysis. Patients who were referred from a provider tended to be younger ($p < .01$) and more likely to die within 90 days ($p < .001$). At 180 days, ED visits decreased 18% for patients referred to the SM program and 42% for patients screened into the SM program, compared to a 3% decrease in ED visits among those not enrolled in the SM program ($p < .01$). Similarly, hospital admissions decreased 34% for patients referred to and 39% screened into the SM program, compared to a 4% increase for patients not enrolled in the SM program ($p < .01$). Non-billable touchpoints increased among all types of patients. **Conclusions:** An SM program reduces hospital admissions and ED visits, therefore improving outcomes and potentially reducing the cost of care for cancer patients. Future research should link this data to claims data to definitely evaluate the impact of SM programs on cost. Research Sponsor: None.

2037 Poster Session (Board #29), Fri, 8:00 AM-11:00 AM

Disparities in the treatment of brain metastases from breast cancer: Insights from the National Cancer Database. *First Author: Zena Chahine, Allegheny General Hospital, Pittsburgh, PA*

Background: Breast cancer is the most common malignancy in women accounting for over 300,000 cases per year. Unfortunately, brain metastases are found in a sub-group of patients with breast cancer even at presentation. Management of brain metastases typically includes radiotherapy with conventional whole brain radiation therapy (WBRT) or more focused stereotactic radiosurgery (SRS). We queried the National Cancer Database (NCDB) to analyze the incidence of brain metastases at diagnosis in breast cancer patients, as well as trends in radiation use/technique. **Methods:** The NCDB was queried for patients who were diagnosed with breast cancer between 2004-2015 and had brain metastasis at presentation (N = 4,491). We excluded patients without brain radiation and inadequate follow up. Odds ratios were calculated to identify factors associated with treatment. Multivariable cox regression was used to determine predictors of survival. **Results:** Using the eligibility criteria above 1,505 patients were identified in the NCDB. The cohort had a median age of 58 years. A small portion were uninsured (7%) population uninsured and 81% of radiation treatments were delivered in metropolitan areas. Two hundred sixty-one (17.3%) patients received SRS while 1,244 (82.7%) received WBRT. Those patients with private insurance, higher income, metro location, and having care delivered at an academic center were more likely to receive SRS. Conversely, the likelihood of receiving WBRT was significantly higher in those with luminal type cancer, African Americans, the uninsured, and those located in urban areas or treated at a community cancer center. On Cox regression, predictors of worse survival were age > 60 with Hazard Ratio (HR) 1.3 (95% CI 1.17-1.49), a comorbidity score > 2 with HR 1.45 (95% CI 1.1-1.9), and extra cranial metastatic disease with HR 1.33 (95% CI 1.15-1.54). **Conclusions:** This analysis of the NCDB demonstrates socioeconomic and demographic disparities in the treatment of patients with brain metastases from breast cancer. There is a continued need to reduce these disparities and improve access to care for at-risk populations affected by this highly prevalent malignancy. Research Sponsor: None.

2039 Poster Session (Board #31), Fri, 8:00 AM-11:00 AM

Affordable Care Act Medicaid expansion does not reduce guideline concordant cancer care disparities in vulnerable populations. *First Author: Michelle Ju, UT Southwestern, Dallas, TX*

Background: The receipt of timely, guideline concordant cancer amongst racial/ethnic and socioeconomic vulnerable populations remains a significant health policy issue. The Affordable Care Act (ACA) with implementation of Medicaid Expansion sought to reduce cancer disparities by reducing uninsured rates, theoretically improving healthcare access and delivery. We assessed the impact of Medicaid expansion on racial/ethnic disparities in the receipt of timely guideline concordant cancer care. **Methods:** We identified patients between 40-64 years of age with all stages of cancer (lung, colorectal, breast, uterine, and cervical) in the National Cancer Database, 2012-2015. Patients were assigned to Medicaid expansion cohort based on state of residence and whether Medicaid expansion was enacted at date of diagnosis in that state. Guideline concordant care was defined based on NCCN guidelines. We constructed an ecological model with multivariate regression analysis on rate of guideline concordant care receipt with covariates including race/ethnicity, Medicaid expansion, SES, gender, Charlson-Deyo score, and treatment facility type. **Results:** We identified 445,952 patients, 12% Black, 6% Hispanic white, median age 55 years. Patients in the lowest SES quartile following Medicaid expansion had the greatest increase in rates of insured status, although all SES quartiles had increased insured rates compared to non-Medicaid expansion regardless of race/ethnicity. In our ecological model, the rate of receipt of guideline concordant care declined by 0.5% per year between 2012-2015. After adjusting for covariates, Asians were 2.8% less likely to receive guideline concordant care than non-Hispanic whites, Blacks 3.8% less likely, and Hispanics 6.3% less likely ($p < 0.0001$). Racial/ethnic disparities in receipt of guideline concordant cancer care remained after Medicaid expansion with no differential benefit. **Conclusions:** Insurance gains under the ACA Medicaid expansion did not affect the rate of guideline concordant care receipt. Significant racial disparities persist in the likelihood of receiving guideline concordant care, particularly among Hispanics. Further studies are needed to determine additional barriers to cancer care access/delivery and identify key targets aimed at improving equity. Research Sponsor: None.

2040 Poster Session (Board #32), Fri, 8:00 AM-11:00 AM

Dynamic 30-day readmission prediction for cancer patients via clinical embeddings. *First Author: Chi Wah Wong, City of Hope National Medical Center, Duarte, CA*

Background: Existing models typically predict unplanned 30-day readmission for cancer patients at discharge[1]. Performing prediction dynamically during hospital stay may allow earlier intervention for high risk patients. In addition, readmission risk may be associated with the outcome of a variety of labs and diagnoses. Models including all those elements may not be practical due to large number of variables relative to number of samples. Embeddings have the potential to represent medical concepts in low dimensional spaces[2]. In this study, we developed a machine learning model utilizing embedding representations of ICD and LOINC codes to dynamically predict readmission risk. **Methods:** This is a single institutional study examining inpatient 30-day unplanned readmissions from Jan 2013 to Dec 2016 (n = 16361 total, n = 5685 in hematology). The readmission rate was 18% (24% for hematology). We used gradient boosted trees models with 10-fold cross validation and included baseline factors that are typically available shortly after admission: gender, age, service, admission count within 6 months, insurance, emergency admission, admission year, allogeneic or autologous stem cell transplant (hematology only). For dynamic factors, we randomly selected a timepoint (TP, median = 2.4 days) during each visit. We utilized publicly available clinical embeddings[2] to generate 300 dimensional representations for ICD9s and LOINCs in the patients' Electronic Medical Records. We considered diagnoses (ICD9) between 6 months prior to admission and TP, and lab tests (LOINC) ordered between admission time and TP. We used records from Jan 2017 to Dec 2017 for prospective validation (n = 3785 total, n = 1424 in hematology), with 17% readmission rate (22% for hematology). **Results:** Prospective validation Area Under Receiver Operating Characteristic Curve (AUC) using baseline factors were 0.72 (average precision "AP" = 0.33) and 0.65 (AP = 0.32) for overall and hematology populations, respectively. By including dynamic factors, we obtained AUCs of 0.74 (AP = 0.4) and 0.7 (AP = 0.39) for overall and hematology populations, corresponding to 3% and 8% AUC (21% and 22% AP) improvements, respectively. **Conclusions:** We found that dynamic readmission prediction utilizing clinical embeddings improves the prediction performance comparing with using baseline factors only. The model shows potential to improve patient care and reduce costs by predicting and preventing readmissions when the patient is still in the hospital. [1] J Surg Oncol 2018; 117:1113-1118. [2] AMIA Jt Summits Transl Sci Proc. 2016;41-50. Research Sponsor: None.

2041 Poster Session (Board #33), Fri, 8:00 AM-11:00 AM

Prediction of mental health disorder onset and impact on emergency visits following a cancer diagnosis. *First Author: William Chen, UCSF Department of Radiation Oncology, San Francisco, CA*

Background: Cancer patients are at increased risk of mental and emotional distress. The aim of this study is to investigate risk factors and timing of mental health disorder (MHD) onset following a cancer diagnosis, and evaluate its impact on emergency visits. **Methods:** All patients with a new onset diagnosis of malignancy (*ICD*-10 codes C00-C97, with conversion of *ICD*-9 codes) were identified from an institutional de-identified electronic health data warehouse. Demographic data, Charlson comorbidity index excluding cancer, mortality, and time to onset of a new MHD diagnosis (*ICD*-10 codes F00-F99) and emergency visits were extracted and used to calculate rates and Cox-model hazard ratios. A predictive logistic model of MHD was tested on an internal hold-out sample (25%). **Results:** A total of 110,306 patients with 338,208 person-years of follow up were identified with a new diagnosis of cancer from February 1980 to July 2019, of which 95,474 (86.5%) had no prior diagnosis of MHD. Actuarial rates of new MHD among previously MHD-free patients were 8.1% at 6 months, and 14.1% and 20.8% at 2 and 5 years. Median time to onset of MHD was fastest among head and neck cancer (57 days, HR 2.32 [2.1-2.6]), urinary organ cancer (94 days, HR 2.21 [2.0-2.4]), and lung and thoracic cancers (99 days, HR 2.47 [2.2-2.7]), compared to skin neoplasms (987 days, HR 1.0). Median time to onset was less than one year for all malignancies except for skin neoplasms and male genital cancers (840 days). Male sex, older age, Charlson score, divorce or legal separation, self-identification of a gender-neutral partner, African American or American Indian race, Hispanic ethnicity, current or former smoking status, and self-identification as Christian were associated with higher risk of MHD onset, while married status and native Hawaiian or Pacific Islander race were protective. A logistic model predicted new MHD with an AUROC of 0.72. Onset of new MHD was associated with greater rates of emergency visit (HR 1.92 [1.8-2.0], adjusted for cancer type and Charlson score), and patients with new MHD who experienced an emergency visit had a mean of 3.75+/-0.03 (SEM) total emergency visits versus 2.65+/-0.02 ($p < 0.0001$). Finally, onset of new MHD was associated with greater mortality even after adjusting for age, Charlson score and cancer type (HR 1.29, [1.23-1.35]). **Conclusions:** Onset of new mental health diagnosis after a cancer diagnosis was correlated with greater rates of emergency visits and mortality. Cancer patients with risk factors identified here may benefit from increased social and mental health support. Research Sponsor: None.

2042 Poster Session (Board #34), Fri, 8:00 AM-11:00 AM

Predicting the risk of VISIT emergency department (ED) in lung cancer patients using machine learning. *First Author: Pablo Rodriguez-Brazzarola, Grupo de Inteligencia Computacional en Biomedicina, ETSI Ingeniería Informática, Universidad de Málaga, Málaga, Spain*

Background: Lung cancer patients commonly need unplanned visits to ED. Many of these visits could be potentially avoidable if it were possible to identify patients at risk when the previous scheduled visit takes place. At that moment, it would be possible to perform elective actions to manage patients at risk to consult the ED in the near future. **Methods:** Unplanned visits of patients in active cancer therapy (i.e. chemo or immunotherapy) are attended in our own ED facilities. Our Electronic Health Record (EHR) includes specific modules for first visit, scheduled visits and unplanned visits. Lung cancer patients with at least two visits were eligible. The event of interest was patient visit to ED within 21 or 28 days (d) from previous visit. Free text data collected in the three modules were obtained from EHR in order to generate a feature vector composed of the word frequencies for each visit. We evaluate five different machine learning algorithms to predict the event of interest. Area under the ROC curve (AUC), F1 (harmonic mean of precision and recall), True Positive Rate (TPR) and True Negative Rate (TNR) were assessed using 10-fold cross validation. **Results:** 2,682 lung cancer patients treated between March 2009 and October 2019 were included from which 819 patients were attended at ED. There were 2,237 first visits, 47,465 scheduled visits (per patient: range 1-174; median 12) and 2,125 unplanned visits (per patient: range 1-20; median 2). Mean age at diagnosis was 64 years. The majority of patients had late stage disease (34.24 % III, 51.56 % IV). The Adaptive Boosting Model yields the best results for both 21 d or 28 d prediction. **Conclusions:** Using unstructured data from real-world EHR enables the possibility to build an accurate predictive model of unplanned visit to an ED within the 21 or 28 following d after a scheduled visit. Such utility would be very useful in order to prevent ED visits related with cancer symptoms and to improve patients care. Research Sponsor: Pfizer.

Development and validation of natural language processing (NLP) algorithm for detection of distant versus local breast cancer recurrence and metastatic site. *First Author: Yasmin Karimi, Division of Medical Oncology, Stanford School of Medicine, Stanford, CA*

Background: Electronic health records (EHR) are used for retrospective cancer outcomes analysis. Sites and timing of recurrence are not captured in structured EHR data. Novel computerized methods are necessary to use unstructured longitudinal EHR data for large scale studies. **Methods:** We previously developed a neural network-based NLP algorithm to identify no recurrence vs. metastatic recurrence cases by analyzing physician notes, pathology and radiology reports in Stanford's breast cancer database, Oncoshare (Cohort A). To validate this algorithm for local vs. distant recurrence, we identified a distinct Oncoshare cohort (Cohort B). Cases were manually curated for longitudinal development of local or distant recurrence and metastatic sites. A two-sided t-test was used to compare mean probabilities between local and distant recurrence cases. Next, we combined cases in Cohorts A and B to train and validate a novel NLP classifier that identifies metastatic site. The combined cohort was randomly divided into training and validation sets. Sensitivity and specificity were calculated for the NLP algorithm's ability to detect metastatic sites compared to manual curation. **Results:** In Cohort B: 350 metastatic cases were identified. Mean probability for local and distant recurrence was 0.43 and 0.79, respectively and differed significantly for patients with local vs. distant recurrence ($p<0.01$). In Cohorts A and B: 632 metastatic cases were used for determination of sites. Sensitivity and specificity were highest for detection of peritoneal metastasis followed by liver, lung, skin, bone and central nervous system (table). **Conclusions:** This NLP algorithm is a scalable tool that uses unstructured EHR data to capture breast cancer recurrence, distinguishing local from distant recurrence and identifying metastatic site. This method may facilitate analysis of large datasets and correlation of outcomes with metastatic site. Research Sponsor: None.

Improved prognostication for lung cancer patients from computed tomography imaging using deep learning. *First Author: Felipe Torres, University of Toronto, Toronto, ON, Canada*

Background: Clinical TNM staging derived from computed tomography (CT) imaging is a key prognostic factor for lung cancer patients when making decisions about treatment, monitoring, and clinical trial eligibility. However, heterogeneity among patients, including by molecular subtypes, may result in variability of survival outcomes of patients with the same TNM stage that receive the same treatment. Artificial intelligence may offer additional, individualized prognostic information based on both known and unknown features present in CTs to facilitate more precise clinical decision making. We developed a novel deep learning-based technique to predict 2-year survival from pretreatment CTs of pathologically-confirmed lung cancer patients. **Methods:** A fully automated, end-to-end model was designed to localize the three-dimensional (3D) space comprising the lungs and heart, and to learn deep prognostic features using a 3D convolutional neural network (3DCNN). The 3DCNN was trained and validated using 1,841 CTs of 1,184 patients from five public datasets made available in The Cancer Imaging Archive. Spearman's rank correlation (R) and concordance index (C-index) between the model output and survival status of each patient after 2-year follow-up from CT acquisition was assessed, in addition to sensitivity, specificity and accuracy stratified by staging. **Results:** 3DCNN showed an overall prediction accuracy of 75.0% ($R = 0.32$, C-index = 0.67, $p < 0.0001$), with higher performance achieved for stage I patients (Table) . 3DCNN showed better overall correlation with survival for 1,124 patients with available TNM staging, in comparison to TNM staging only ($R = 0.19$, C-index = 0.63, $p < 0.0001$); however, a weighted linear combination of both TNM staging and the 3DCNN yielded a superior correlation ($R = 0.34$, C-index = 0.73, $p < 0.0001$). **Conclusions:** Deep learning applied to pretreatment CT images provides personalized prognostic information that complements clinical staging and may help facilitate more precise prognostication of patients diagnosed with lung cancer. Research Sponsor: None.

2045 Poster Session (Board #37), Fri, 8:00 AM-11:00 AM

Driving quality improvement: How clinical decision support can facilitate compliance with evidence-based pathways. *First Author: Debra A. Patt, McKesson Specialty Health and US Oncology Network, The Woodlands, TX*

Background: Cancer care is changing rapidly with more detailed understanding of disease and more numerous therapeutic choices. As treatment choice is more complex, mechanisms to improve compliance with evidence based treatment can improve the quality of cancer care. **Methods:** A retrospective cohort study was conducted from January 2014-May 2016 evaluating the impact of a clinical decision support system (CDSS) on compliance with evidence based pathways (EBP) across 9 statewide community based oncology practices. These EBP are developed with physician input on efficacy toxicity and value and incorporated in to a CDSS that is used within the Electronic Health Record (EHR) at point of care to alter the choice architecture a clinician sees when prescribing therapy. A multi-level logistic regression model was used to adjust for group effects on physician or practice behavior. SAS 9.4 software was used and GLIMMIX was applied. Individual physician benchmark compliance was evaluated using McNemar's test. **Results:** Regimen compliance with EBP was measured pre- and post-implementation of the CDSS tool across a large network encompassing 9 statewide practices and 633 physicians who prescribed over 30,000 individual patient treatment regimens over a 6 month period. The CDSS that is incorporated within the EHR significantly improved compliance with EBP across the entire cohort of practices, and in individual practices (see Table). Individual oncologists reached a target of 75% compliance more often (58% vs 72%) after implementation of the tool ($p < 0.001$). **Conclusions:** CDSS is a tool that improves compliance with EBP that is effective at improving targets of compliance broadly, at the practice, and at the individual clinician level. Clinical informatics solutions that influence physician behavior can be inclusive of physicians in design, iterative in process, and nudge as opposed to force clinician behavior to drive quality improvement. These clinical informatics solutions grow in importance as the complexity of cancer care continues to increase and we seek to improve upon the quality and value of care delivery. Research Sponsor: Texas Oncology, US Oncology.

Identifying and overcoming clinical trial enrollment barriers: Can an integrated clinical pathways tool help bridge the gap? *First Author: Mishellene McKinney, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Barriers to clinical trial (CT) enrollment continue to be a national challenge, with only about 3% of adult cancer patients treated within a CT. A key recommendation from the 2013 NCI-ASCO Cancer Trial Accrual Symposium was to use information technology to enhance identification of potentially eligible patients for CTs. We assessed if the implementation of a Clinical Oncology Pathways System (COP) with integrated CT information increased enrollment of CT's, and categorized physician-identified reasons for non-enrollment. **Methods:** In 2018, Roswell Park Comprehensive Cancer Center (RP) implemented ClinicalPath pathways (formerly Via Oncology) for medical oncology. The COP software embeds interventional CTs that are open to accrual at RP in the pathway specific to a patient's disease type, stage and biomarkers. The provider is presented with relevant CTs and must select screening for the trial or provide a reason for bypassing the CT from a drop-down list prior to being presented standard care options. CT screening requests from the COP system from 6/1/18-5/31/19 were reviewed. Screening requests and actual enrollment data were matched. The accrual-to-study ratio (ASR), defined as the number of consented accruals divided by the number of CTs open to accrual at RP at any time during the period, was calculated for the study period and the baseline from 6/1/14-6/1/18. The reasons physicians did not elect to screen for CTs were summarized. **Results:** There can be multiple trials presented for each pathway decision.There were 1,606 decision points with at least one embedded trial. Of these, 1,289 decision points matched 2,242 CTs that were not selected for screening. 317 trials were selected for screening. The most common reasons for not screening were patient ineligibility (41%), provider bypassing the CT by selecting treatment "off pathway" (28%), patient not interested (12%), patient already on CT (8%) and "other" (9%). Audits confirmed that the majority of ineligible patients had co-morbidities such as organ dysfunction or brain metastasis that precluded them from the CT. Among the 317 trials selected for CT screening, 108 (34%) patients enrolled in CTs. The ASR increased from the four-year historical average baseline of 4.08 to 4.33 one year post-implementation. **Conclusions:** The use of COP with embedded CT was associated with a modest increase in ASR. Stringent eligibility criteria was the primary barrier to enrollment. Adopting a broader set of clinical trial eligibility criteria could increase enrollment to CT. Research Sponsor: Genentech.

Machine learning algorithms to predict financial toxicity associated with breast cancer treatment. *First Author: Chris Sidey-Gibbons, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Financial burden caused by cancer treatment is associated with material loss, distress, and poorer outcomes. Financial resources exist to support patients but objective identification of individuals in need is difficult. Accurate predictions of an individual's risk of financial toxicity prior to initiation of breast cancer treatment may facilitate informed clinical decision making, reduce financial burden, and improve patient outcomes. **Methods:** We retrospectively surveyed 611 patients who had undergone breast cancer therapy at MD Anderson Cancer Center to assess the financial impact of their care. All patients were over 18 and received either a lumpectomy or a mastectomy. We collected data using the FACT-COST patient-reported outcome measures alongside other financial indicators including income and insurance status. We extracted clinical and perioperative data from the electronic health record. Missing data were imputed using multiple imputation. We used this data to train and validate a neural network, LASSO-regularized linear model, and support vector machines. Data were randomly partitioned into training and validation samples (3:1 ratio). Analyses were informed by international PROBAST recommendations for developing multivariate predictors. We combined algorithms into a voting ensemble and assessed predictive performance using area under the receiver operating characteristics curve (AUROC), accuracy, sensitivity, and specificity. **Results:** In our validation sample, 48 of 203 (23.6%) women reported FACT-COST scores commensurate with significant financial burden. The algorithm predicted significant financial burden relating to cancer treatment with high accuracy (Accuracy = .83, AUROC = .82, sensitivity = .81, specificity = .82). Key clinical predictors of financial burden from linear models were neo-adjuvant therapy ($\beta_{regularized}$ 0.12) and autologous, rather than implant-based, reconstruction ($\beta_{regularized}$ 0.10). **Conclusions:** Machine learning models were able to accurately predict the occurrence of financial toxicity related to breast cancer treatment. These predictions may be used to inform decision making and care planning to avoid financial distress during cancer treatment or to enable targeted financial support for individuals. Further research is warranted to further improve this tool and assess applicability for other types of cancer. Research Sponsor: None.

2048 Poster Session (Board #40), Fri, 8:00 AM-11:00 AM

Semi-automated discovery of real-world patient pathway from U.S. electronic health records: Advanced non-small cell lung cancer (aNSCLC). *First Author: Fei Yang, Roche Diagnostics Information Solutions, Basel, Switzerland*

Background: A good understanding of cancer care continuum presents opportunities to uncover unmet medical needs and improve outcomes and clinical workflow efficiency. However, patient care is poorly understood in real-world clinical practice. This study aimed to discover real-world patient pathways for advanced non-small cell lung cancer (aNSCLC). **Methods:** This study included patients diagnosed with aNSCLC (stage IIIB and above) at their initial diagnoses between 2011-2018 from the Flatiron Health electronic health records (EHR)-derived deidentified database. Overall survival (OS) was calculated using the Kaplan-Meier method. We also explored the application of process mining analytics (Heuristics Miner & Directly-Follows Graphs) to describe and visualize real-world patient pathways, following patients from initial diagnosis, through any National Comprehensive Cancer Network guideline-recommended companion diagnostics (CDx; including EGFR, ALK, ROS1, KRAS, BRAF, or PD-L1) and treatment patterns, until death or end of the study. **Results:** A total of 39,156 eligible patients were included. During a median follow-up of 0.78 years (interquartile range [IQR] 1.27), 28,801 (73.6%) patients died (median OS 11.6 months [95% CI 11.4 -11.8]). We established a semi-automated process discovery pipeline that transforms high-dimensional EHR datasets in table format as input into real-world event logs and produces a series of patient pathway graphs as output. The patient pathway graphs showed 19,878 (50.8%) patients had CDx testing within a median 11 days (IQR 18) and 29,241 (74.7%) patients started first-line therapy within a median 1.2 months (IQR 1.2) after the initial diagnosis. When we stratified analysis by years of initial diagnosis (2011-2014 vs 2015-2018), 38.8% (6808 of 17546) vs. 60.5% (13070 of 21610) patients had their first CDx testing within median 12 days (IQR 21) vs. 10 days (IQR 17) respectively. **Conclusions:** This study suggested an uptake of 56% increase of CDx utilization over the last 8 years in real-world clinical setting and that patient pathways can be analyzed and visualized in a semi-automated fashion. Research Sponsor: ROCHE DIAGNOSTIC INFORMATION SOLUTION.

2049 Poster Session (Board #41), Fri, 8:00 AM-11:00 AM

Concordance study of treatment guidance from an online patient assistance algorithm (OCPAP) and treatment recommendation of a multidisciplinary panel of oncologists in India. *First Author: Amit Kumar Jotwani, Netdox Health Private Limited (Onco.com), Hyderabad, India*

Background: OCPAP (online cancer patient assistance pathway) is an algorithm-based online platform for patients to help them understand their treatment options. It is based on basic inputs like cancer type, stage, patient's performance status and treatment received. It is developed by a team of oncologists from onco.com based on standard guidelines. Till date, more than 30,000 users from 18 countries have used OCPAP platform to get directional treatment recommendations. Onco.com also provides onco tumour board (OTB) services to help patients to get a detailed opinion from a multidisciplinary panel of oncologists. We presented initial data on development of OCPAP™ at the ASCO Breakthrough Summit 2019 (OCPAP Breakthrough Abstract). Here we present a concordance analysis of treatment recommendations from OCPAP platform against opinion of OTB panel. **Methods:** We analysed data from 448 eligible cases (those with 15 types of solid cancers) where an OTB opinion was provided and compared it with OCPAP treatment recommendation. We entered data from 448 anonymised OTB case records in to the OCPAP platform and recorded the output in terms of treatment recommendations. The study was blinded by its very design as we took data of cases from the time when the platform was non-existent. **Results:** We compared and analysed the recommendation provided by OCPAP in terms of surgery, chemotherapy, targeted therapy, radiation, clinical trials, palliative care or best supportive care against the opinion of OTB panel. Overall the concordance rate was found to be 93% for all cases and it was above 90% for all types of cancers included, except for brain tumors where it was 78% mainly due to variation in surgical operability and imaging findings influencing the treatment recommendation. The concordance rate was above 90% for all stages of disease and was highest for metastatic disease where it was 95%. The reasons for discordance were mostly related to availability of more detailed insights about the disease for OTB, like clinical details, performance status, imaging findings, molecular data and oligometastasis. **Conclusions:** The treatment direction recommended by OCPAP was found to be consistent with the one provided by OTB panel for most solid cancers. This indicates that OCPAP is an effective and simple online tool for patients to understand their treatment options, validate their ongoing treatment and be able to actively participate in their treatment decisions. Research Sponsor: None.

2050 Poster Session (Board #42), Fri, 8:00 AM-11:00 AM

Ranking of therapeutic regimens for hormone receptor-positive, HER2-negative, metastatic breast cancer (MBC) using information theoretic network meta-analysis. *First Author: Xuanyi Li, Vanderbilt University, Nashville, TN*

Background: Hormone receptor-positive (HR+), HER2-negative (HER2-) metastatic breast cancer (MBC) is treated with targeted therapy, hormone therapy, chemotherapy, or combinations of these modalities. Evaluating the increasing number of treatment options is challenging, especially since few regimens have been compared head-to-head in randomized clinical trials (RCTs). Potential solutions include expert-driven guidelines (e.g. NCCN guidelines), algorithmic scales (e.g. the ASCO and ESMO Value Frameworks), traditional Bayesian network meta-analysis (NMA), and information theoretic (IT) NMA, a graph theory-based approach that also enables dynamic ranking of regimens over time. **Methods:** We used IT-NMA to rank regimens for HR+/HER2- MBC. The analysis includes RCTs of regimens identified from HemOnc.org and a recent large traditional NMA (Giuliano et al. 2019). Variables used in ranking include primary endpoints, no. of patients enrolled, p-value, hazard ratio for time-based outcomes (e.g. overall survival) or odds ratio for fixed endpoints (e.g. response rate), and year of publication. **Results:** The analysis included 238 RCTs enrolling 92,971 patients published between 1974-2019. There were 277 unique regimens, taking into account variations in dosage, frequency, and no. of cycles. As of 2019, out of 85 ranks, combinations of targeted therapy and hormone therapy (e.g. letrozole & palbociclib) are ranked the highest (Table). Over time, we observe that novel treatments tested in escalation trials tend to rise to the top of the rankings (e.g. paclitaxel & bevacizumab in 2007, driven by ECOG E2100), and monotherapy approaches tend to fall to the bottom. **Conclusions:** In 2019, the combinations of hormone or chemotherapy and targeted therapy are ranked higher than hormone therapy or chemotherapy alone. Our ranking result is similar to previous studies with a notably larger number of comparisons (Giuliano et al. is the largest published study, with 131 regimens/50,029 pts analyzed). Informatic theoretic NMA is a promising method of indirect rankings of treatment that also enables dynamic regimen ranking over time. Research Sponsor: U.S. National Institutes of Health.

Five highest and five lowest ranked regimens.

Rank	Value*	Regimen
1	22.8	Letrozole & Palbociclib
2	16.6	Letrozole & Ribociclib
3	11.1	Paclitaxel & Bevacizumab
4	9.7	Capecitabine, Paclitaxel, Bevacizumab
5	9.6	Anastrozole & Ribociclib
81	-15.6	Weekly paclitaxel
82	-15.8	Fulvestrant 500
83	-16.4	Letrozole
84	-17	Fulvestrant 250
85	-42.1	Tamoxifen 20

2051 Poster Session (Board #43), Fri, 8:00 AM-11:00 AM

An automated EHR-based tool for identification of patients (pts) with metastatic disease to facilitate clinical trial pt ascertainment. *First Author: Jeffrey J. Kirshner, Hematology-Oncology Associates of Central New York, Syracuse, NY*

Background: Efforts to facilitate patient identification for clinical trials in routine practice, such as automating electronic health record (EHR) data reviews, are hindered by the lack of information on metastatic status in structured format. We developed a machine learning tool that infers metastatic status from unstructured EHR data, and we describe its real-world implementation. **Methods:** This machine learning model scans EHR documents, extracting features from text snippets surrounding key words (ie, 'Metastatic' 'Progression' 'Local'). A regularized logistic regression model was trained, and used to classify patients across 5 metastatic status inference categories: highly-likely and likely positive, highly-likely and likely negative, and unknown. The model accuracy was characterized using the Flatiron Health EHR-derived de-identified database of patients with solid tumors, where manually abstracted information served as standard accurate reference. We assessed model accuracy using sensitivity and specificity (patients in the 'unknown' category omitted from numerator), negative and positive predictive values (NPV, PPV; patients 'unknown' included in denominator), and its performance in a real-world dataset. In a separate validation, we evaluated the accuracy gained upon additional user review of the model outputs after integration of this tool into workflows. **Results:** This metastatic status inference model was characterized using a sample of 66,532 patients. The model sensitivity and specificity (95%CI) were 82.% (82, 83) and 95% (95, 96), respectively; PPV was 89% (89, 90) and NPV was 94% (94, 94). In the validation sample (N = 200 originated from 5 distinct care sites), and after user review of model outputs, values increased to 97% (85, 100) for sensitivity, 98% (95, 100) for specificity, 92 (78, 98) for PPV and 99% (97, 100) for NPV. The model assigned 163/200 patients to the highly-likely categories, which were deemed not to require further EHR review by users. The prevalence of errors was 4% without user review, and 2% after user review. **Conclusions:** This machine learning model infers metastatic status from unstructured EHR data with high accuracy. The tool assigns metastatic status with high confidence in more than 75% of cases without requiring additional manual review, allowing more efficient identification of clinical trial candidates and clinical trial matching, thus mitigating a key barrier for clinical trial participation in community clinics. Research Sponsor: Study sponsored by Flatiron Health, which is an independent subsidiary of the Roche group.

2052 Poster Session (Board #44), Fri, 8:00 AM-11:00 AM

Novel artificial intelligence (AI)-based technology to improve oncology clinical trial fulfillment. *First Author: TJ Bowen, Deep Lens, Inc., Columbus, OH*

Background: Less than 5% of US adult cancer pts are enrolled on clinical trials. Challenges in clinical trial fulfillment limit available treatment options, slow enrollment and ultimately delay new therapies from reaching market. Pt screening requires multiple clinical team members to find pts that meet strict inclusion/exclusion criteria. We evaluated the impact of new technology, Deep Lens VIPER, in identifying more qualified pts for clinical studies, and reduction of staff burden. **Methods:** We implemented Deep Lens VIPER at Hoag Hospital (Newport Beach, California), accessing the electronic medical records and pathology systems (EMR/LIS) to effectively identify pts who are candidates for 20 ongoing recruiting clinical studies. VIPER was fed pt data from 5,706 surgical pathology pts over a 4-month period (October 1, 2019 - January 31, 2020). Proprietary AI identification and matching technology was configured to align cancer pts with those 20 clinical studies, each with unique study criteria. Following an initial machine-assisted triage step, a research coordinator was alerted when pts who met protocol criteria were ready for final approval steps. Results were analyzed and a qualitative assessment of usability was also performed. **Results:** VIPER was able to triage all 5,706 surgical pathology cases (100%), identifying 1,045 pts (18.3%) with malignant neoplasms that would qualify for further analysis for clinical trials enrollment. Further triage based on inclusion and exclusion criteria led to the identification of 150 previously unidentified pts for 16 of the 20 studies. The 16 different studies for which potential pts were identified, included 11 tumor types, 12 biomarkers and 3 basket studies. Working with the VIPER system, 1 novice care team member performed initial identification of all 150 previously unidentified pts. The VIPER system increased monthly candidate pt catchment for 16 of the 20 studies under investigation, which is approximately 600 patients annually added for final triage for studies being conducted. **Conclusions:** We demonstrate the use of an AI-based platform to identify pts for clinical trial enrollment who would be missed using traditional recruiting methods. One staff member effectively triaged participants from 20 different studies with unique inclusion/exclusion criteria. These studies were previously managed by 6 different care team members with limited time for recruitment. Scaling this platform to additional institutions and more studies is ongoing to validate these findings. Research Sponsor: Deep Lens, Inc.

2053 Poster Session (Board #45), Fri, 8:00 AM-11:00 AM

Model selection applied to 750 outpatient ICD-9 codes identifies hazards important for all-cause cancer mortality in 2 million veterans with 14 years of follow-up. *First Author: Benjamin McMahon, Los Alamos National Laboratory, Los Alamos, NM*

Background: Cost-benefit analysis before undergoing cancer treatments can involve a broad array of factors, yet existing statistical algorithms are limited to a few of the most commonly observed competing risks. Using 20 years of Veteran medical records from the Veteran's Administration, we identify a broad array of outpatient descriptors providing contributions to computed mortality comparable in size to common cancers. **Methods:** 1,911,632 Veterans born between 1927 and 1968 with medical records extending from October 1, 2000 until either recorded death after October 1, 2005 (47%) or observation during CY 2019 were split equally into age-matched test and training sets. The 20 year-long record was split into three intervals: 5 years during which ICD codes were tallied, 14 years of waiting, and establishment of continuation in care during 2019. The 750 most common outpatient ICD9 codes were recorded as present/absent for each patient and used in a generalized linear model to predict subsequent mortality, subject to LASSO model selection and 10-fold cross validation. Gender was included as a covariate as well as age at time of prediction, up to the 4^{th} power. **Results:** The C-statistic for predicting mortality in 14 years of follow-up was 0.835 on training data and 0.833 on test data when using the 498 codes selected by LASSO. Prevalent codes with the largest model coefficients were (ICD 9 code: model coefficient, # alive/# deceased in test set) congestive heart failure (428.0: 0.66, 9k/48k), chronic airway obstruction (496.: 0.60, 42k/105k), and tobacco use disorder (305.1: 0.54, 107k/123k), while the prevalent codes most protective in comparison to baseline were hyperlipidemia (272.4: -0.21, 211k/225k) and colon cancer screening (V76.51: -0.16, 49k/39k). In comparison, observed cancer ICD 9 coefficients were lung (162.9: 1.03, 1k/7k), colon (153.9: 0.18, 3.1k/7.0k), and prostate (185.: 0.06, 16k/32k). 74 predictors contribute with coefficients greater than colon cancers, such as 'no household member able to render care' (V60.4: 0.28, 1.1k/4.2k). **Conclusions:** A wide variety of structured data contribute at a similar level of importance in prediction of 14-year mortality. While various selection biases, co-linearity of predictors, differences in treatments, and missing data are significant impediments to utilization of predictive models in clinical practice, we have demonstrated an ability to identify and quantify predictors from a large data set with model selection techniques. Research Sponsor: This work was supported by Department of Veterans Affairs, Office of Research and Development, Million Veteran Program MVP000 and MVP017.

2054 Poster Session (Board #46), Fri, 8:00 AM-11:00 AM

Novel evidence synthesis system to support living systematic reviews and living guidelines for cancer immunotherapy. *First Author: Irbaz Bin Riaz, Mayo Clinic, Rochester, MN*

Background: Systematic reviews that summarize the toxicity of Immune checkpoint inhibitors (ICIs) become outdated very soon after publication. Therefore, we reported results of a toxicity meta-analysis at 2019 ASCO meeting and informed the intent to create a living systematic review (LSR). LSRs combine human and machine effort and support rapid evidence synthesis and living clinical practice guidelines. Now, we report our experience maintaining a LSR on toxicity of ICIs. **Methods:** Steps include quarterly literature searches to identify new clinical trials reporting ICI-associated adverse events (AEs), AI-enabled screening of new citations which meet the inclusion criteria, automated cumulative meta-analysis and an online reporting platform. Standard data formats and protocols were designed for inputting text, tables and graphics. Software was written to interpret these data and output the information in the appropriate format, such as a forest plot and summary tables. Finally, a dynamic interface that enables user inputs and displays the associated output was designed. **Results:** The LSR is continuously updated incorporating toxicity data from new clinical trials as it becomes available. We have screened 8000 relevant citations and summarized the odds of Grade 3 or higher AEs and AEs of special interest in patient receiving ICIs. The results are updated on quarterly basis and are available online. The results are updated on quarterly basis and will be available on a website at the time of publication. Prototype with dummy data is available at this link. This interface can also be manipulated via user input to organize and sort data tables and forest plots by type of cancer, name or mechanism (PD-1 or PD-L1) of ICI agent, single agent or combination, type of control arm, line of treatment and several other clinically relevant filters. For example, a user can instantaneously generate a meta-analysis summarizing the risk of colitis or pneumonitis in metastatic lung cancer trials with pembrolizmuab. **Conclusions:** This LSR engine can prospectively synthesize toxicity data from ICI trials in an efficient manner providing accurate and timely information for advanced clinical decision support at point-of-care. Efforts are ongoing to improve efficiency of screening, improve AI-enabled processes for automated screening and data abstraction, and test across multiple clinical questions. Fragility index of trials supporting approval of anti-cancer drugs in common solid tumors. *First Author: Alexandra Desnoyers, Princess Margaret Cancer Centre & University of Toronto, Toronto, ON, Canada*

Background: The Fragility Index (FI) quantifies the reliability of positive trials by estimating the number of events which would change statistically significant results to non-significant results. Here, we calculate the FI of trials supporting approval of drugs for common solid tumors. **Methods:** We searched Drugs@FDA to identify randomized trials (RCT) supporting drug approvals by the US Food and Drug Administration between January 2009 and December 2019 in lung, breast, prostate, gastric and colon cancers. We adapted the FI framework (Walsh et al. J Clin Epidemiol 2014) to allow use of time to event data. First, we reconstructed survival tables from reported data using the Parmar Toolkit (Parmar et al. Stat Med 1998) and then calculated the number of events which would result in a non-significant effect for the primary endpoint of each trial. The FI was then compared quantitatively to the number of patients in each trial who withdrew consent or were lost to follow-up. Multivariable linear regression was used to explore association between RCT characteristics and the FI. **Results:** We identified 69 RCT with a median of 669 patients (range 123-4804) and 358 primary outcome events (range 56-884). The median FI was 26 (range 1-322). The FI was $\leq$10 in 21 trials (30%) and $\leq$20 in 31 trials (45%). Among the 69 RCT, the median number of patients who withdrew consent or were lost to follow up was 27 (range, 6-317). The number of patients who withdrew consent or were lost to follow-up was equal or greater than the FI in 42 trials (61%). There was statistically significant inverse association between FI and trial hazard ratio (p0,001) and a positive association with number of patients who were lost to follow-up or withdrew consent (p0,001). There was no association between trial sample size, year of approval or reported p-value and the FI. **Conclusions:** Statistical significance of trials supporting drug approval in common solid tumors relies often on a small number of events. In most trials the FI was lower than the number of patients lost to follow up or withdrawing consent. Post-approval randomized trials or real-world data analyses should be performed to ensure that effects observed in registration trials are robust. Research Sponsor: None.

Core limitations in clinical trials leading to anticancer drug approvals by the U.S. Food and Drug Administration. *First Author: Talal Hilal, University of Mississippi Medical Center, Jackson, MS*

Background: To date, a comprehensive evaluation of core limitations in clinical trials leading to anti-cancer drug approvals by the US Food and Drug Administration (FDA) has not been undertaken.The aim of this analysis was to assess the percentage of clinical trials with core limitations, defined as lack of randomization, lack of overall survival data, inappropriate use of crossover, and use of sub-optimal control arms that led to FDA approvals from 2014 to 2019. **Methods:** This observational analysis included all approved anti-cancer drug indications by the FDA from July 2014 through July 2019. All indications were investigated and each clinical trial evaluated for design, enrollment period, primary endpoints, and presence of core limitations. The standard of care therapy was determined by evaluating the literature and published guidelines 1-year prior to start of clinical trial enrollment. Crossover was examined and evaluated for optimal use. We then calculated the percentage of approvals based on clinical trials with any or all core limitations. **Results:** A total of 187 anti-cancer approvals were evaluated. The number of anti-cancer drug approvals doubled over time with 68 in first half of study period (June 2014 to December 2016) to 119 in second half of study period (January 2017 to July 2019). Of those, 125 (67%) were based on a clinical trial with at least one core limitation. 64 (34%) approvals were based on a single-arm clinical trial. Of the remaining 123 approvals based on randomized trials, 60 (32%) had a core limitation. Of all randomized trials, 37 (30%) lacked overall survival benefit, 31 (25%) had a sub-optimal control, and 17 (14%) used crossover inappropriately. **Conclusions:** The majority of cancer drugs are approved based on clinical trials with core limitations. Efforts to minimize core limitations at the time of clinical trial design are essential to ensure that new anti-cancer drugs being marketed truly improve patient outcomes over current standards. Gender-based disparities in clinical trials supporting FDA approval of oncology drugs. *First Author: Marjorie Zettler, Cardinal Health, Dublin, OH*

Background: Adequate gender representation in clinical trials of new drugs is critical in order to accurately detect possible differences in response and toxicity (Özdemir et al, JCO 2018). The under-representation of women in oncology clinical trials has been previously described, however data on registrational trials, which are the basis for drug approval and inform the prescribing information, is lacking. We conducted an analysis of the trials supporting Food and Drug Administration approval of oncology drugs over a 5-year period to evaluate the representation of women vs. men. **Methods:** Prescribing information for novel new drugs approved from 2014-2018 was reviewed for the proportions of men and women in the evaluable population of the supporting clinical trials. Sex-specific cancers were excluded. Prevalence estimates for the indications were obtained from the Surveillance, Epidemiology and End Results database and the published literature. A participation to prevalence ratio (PPR) was calculated for each trial by dividing the percentage of women in the trial by the percentage of women in the disease population. A PPR value closer to unity represents even gender distribution and the range 0.8-1.2 is considered to reflect an acceptable representation of women. Data are presented using descriptive statistics. **Results:** A total of 46 oncology drugs were approved based on 56 trials enrolling 13,862 patients (7941 [57%] men; 5,921 [43%] women). Of the 56 trials, 38 (68%) had a PPR within the 0.8-1.2 range, 15 (27%) fell between 0.4-0.7, and 3 (5%) had a PPR of 1.3. The proportion of trials with unbalanced gender representation was comparable for hematological malignancy and solid tumor indications and did not improve over time. Fewer unbalanced trials were Phase III or employed a randomized design. Nine of the 18 (50%) unbalanced trials enrolled <100 subjects, compared to 3 of the 38 (8%) balanced trials. **Conclusions:** A third of registrational trials for oncology drugs lacked balanced gender distribution. Of the trials lacking balance, the vast majority (80%) had under-representation of women. Phase I-II trials and smaller trials had greater gender disparity, a concerning finding in a precision medicine environment where an increasing number of registration trials have double digit accrual. Further research is needed to understand the implications of unbalanced gender accrual in registrational trials, and to develop strategies for preventing disparities. Research Sponsor: Cardinal Health.

2059 Poster Session (Board #51), Fri, 8:00 AM-11:00 AM

Performance status restriction in phase III cancer clinical trials. *First Author: Ramez Kouzy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with good performance status (PS) tend to be favored in randomized clinical trials (RCTs), possibly limiting the generalizability of trial findings. We sought to characterize trial-related factors associated with the use of eligibility criteria that restrict patients by PS, and analyze patient accrual breakdown by PS. **Methods:** We searched ClinicalTrials.gov for phase III RCTs between 2003-2018. Randomized multi-arm trials assessing a therapeutic intervention in cancer patients were included. PS data were extracted from corresponding manuscripts. Trials with PS restriction Eastern Cooperative Oncology Group (ECOG) ≤1 were identified. Factors associated with PS restriction were determined, and trial patient accrual was analyzed. **Results:** Six-hundred trials were included with PS data for 238,213 patients. In total, 527 studies (87.8%) specified an upper PS restriction cutoff as part of their exclusion criteria, and 237 studies (39.5%) had a strict inclusion criterion of patients with ECOG PS ≤1. Enrollment criteria restrictions based on PS (ECOG PS ≤1) were more common among industry-supported trials (P< 0.001) and lung cancer trials (P < 0.001). Nearly half of trials that led to subsequent FDA approval included strict PS restrictions. Binary logistic regression revealed stable use of restrictive PS eligibility criteria between 2007-2018 (P= 0.789). The vast majority of patients enrolled across all trials had an ECOG PS of 0 to 1 (96.3%). Even among trials that allowed patients with ECOG PS ≥2, only 8.1% of enrolled patients had a poor PS (ECOG 2 or higher).Trials of hematologic cancers had the largest proportion of patients with ECOG PS ≥2 (8.7%), while lung, breast, gastrointestinal and genitourinary trials all included less than 5% of patients with poor PS (P< 0.001). Only 4.8% of patients enrolled in trials that led to subsequent FDA approval had a poor PS. **Conclusions:** The use of PS restrictions in oncologic RCTs is pervasive, and exceedingly few patients with poor PS are enrolled. The selective accrual of healthier patients has the potential to severely limit and bias trial results. Future trials should consider a wider cancer population with close toxicity monitoring, to ensure generalizability of results, while maintaining patient safety. Research Sponsor: None.

2060 Poster Session (Board #52), Fri, 8:00 AM-11:00 AM

Trends in FDA cancer registration trial design over time, 1969-2020. *First Author: Jeremy Lyle Warner, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: The FDA has issued hundreds of cancer drug indications, with many new drugs, expanded indications, and biosimilars approved in recent years. While the gold standard for regulatory approval is the randomized controlled trial (RCT), RCT design including selection of control arms can differ considerably. We sought to investigate trends and patterns in RCT trial design used to support FDA approvals in oncology. **Methods:** We reviewed the available FDA package inserts of oncology drugs (N=258) for RCTs cited to support initial and expanded indication approvals as of January 2020; biosimilars were excluded. RCTs were linked to the HemOnc ontology, which contains trial-level metadata including publication year, endpoints, and trial design. Log-linear regression was performed to evaluate trends in approvals over time by endpoint. Study drugs were categorized as cytotoxic therapy, targeted therapy, or immunotherapy. RCTs were categorized by four designs: escalation (adding a drug or increasing the drug dose in an established regimen), in-class comparison (comparing two drugs in the same therapeutic class), out-of-class switch (comparing drugs in distinct therapeutic classes), and de-escalation (removing a drug or reducing the drug dose in an established regimen). **Results:** We identified 556 registration trials, 372 (67%) of which were RCTs. Approvals have been increasing exponentially over time (R^2 0.9, p<0.001), both for RCTs reporting overall survival (OS) endpoints (R^2 0.77, p<0.001), and non-OS endpoints (R^2 0.67, p<0.001). Of the three most common trial designs (Table), in-class comparisons were least likely to report OS (28%; escalations 47%; out-of-class switches 43%, p=0.01 by Chi-squared). Class switches were common in immunotherapy trials compared to targeted or cytotoxic therapy. **Conclusions:** Despite growth in FDA approvals, a minority of registration trials report paradigmatic shifts in therapeutic approach (out-of-class switches), with the relative exception of immunotherapy trials. Escalation is the most common route to FDA approval, even though this design inevitably increases cost and toxicity. This suggests that new oncology drug approvals are not alone a useful metric of practice-changing innovation. Research Sponsor: U.S. National Institutes of Health.

Distribution of RCT design by therapeutic category.*

2061 Poster Session (Board #53), Fri, 8:00 AM-11:00 AM

Use of real-world data to understand barriers to interventional clinical trial enrollment in community oncology clinics (COC). *First Author: Johnetta Blakely, Tennessee Oncology, Nashville, TN*

Background: Increasing enrollment in clinical trials remains a national priority, yet there are limited data from COCs on the degree to which common trial exclusion criteria (EC) and socioeconomic factors play a role in low enrollment rates. **Methods:** We analyzed data from the nationwide Flatiron Health electronic health record (EHR) derived de-identified database. COC were eligible if they had given a clinical trial study drug to ≥2 patients (pts)/year. We included pts with one of eight advanced or metastatic solid tumors who received ≥1 line of systemic anticancer therapy between 1/1/2014 and 11/30/2019. We defined EC as either: creatinine > 1.5 mg/dl or CcI < 45 ml/min, Hb < 9 g/dL, ANC < 1500/ul, plts < 100,000/ul, bilirubin > 1.5 upper limit of normal (uln) or AST/ALT > 2.5 uln within 30 days or ECOG performance status (PS) ≥ 2 within 60 days prior to start of therapy. We calculated the percentage of pts with ≥1 EC relative to the group of candidate pts, stratified by therapy line (1L, 2L, 3L+). We used multivariate logistic regression models to evaluate the effect of EC and socioeconomic factors (age, race, Medicaid) on the likelihood of receiving a clinical study drug for each line of therapy. **Results:** In this sample of 35 COCs, 26,988 pts received ≥1 systemic therapy. Pts with ≥ 1 EC: 28.4% in 1L, 34.2% in 2L, 37.4% in 3L. Percentages of pts with an ECOG PS ≥ 2 were: 15.6% (1L), 18.2% (2L), 19.8% (3L). Pts receiving a clinical study drug: 1.7% of 26,988 in 1L, 2.0% of 12,738 in 2L, 2.9% of 5,333 in 3L+, and 3.1% in any line. Excluding pts with ≥1 EC from the denominator modestly improved overall accrual: 2.0% of 19,729 in 1L, 2.3% of 8,588 in 2L, 3.7% of 3,470 in 3L+. In multivariate logistic regression, ECOG PS ≥ 2 was strongly associated with not receiving a study drug [odds ratio (95% CI); 1L: 0.25 (0.16-0.4); 2L: 0.28 (0.17-0.49); 3L: 0.21 (0.1-0.44)]. The likelihood of receiving a clinical study drug (any line) was lower for pts who are Black [0.63 (0.48-0.82)], Latino [0.49 (0.32-0.75)], and pts older than 70 years [0.63 (0.54-0.72)]. Medicaid pts were not significantly less likely to receive study drug [0.83 (0.64-1.07)]. **Conclusions:** In COC, common trial EC reduce pt availability for trials by > 25%. Poor PS is highly prevalent and influential. These EC and complex trial requirements challenge COC's ability to recruit representative pt populations. Future efforts to increase enrollment in trials must consider common EC along with well known barriers to enrollment of unrepresented groups. Research Sponsor: Flatiron Health, Inc.

2062 Poster Session (Board #54), Fri, 8:00 AM-11:00 AM

A pilot study of a wearable monitoring system as an adjunct to geriatric assessment in older adults with cancer. *First Author: Karlton Wong, UCLA, Santa Monica, CA*

Background: Advances in health technology provide potential tools that can aid in assessing and monitoring the functional status of the growing older adult population diagnosed with cancer. We piloted a novel wearable monitoring platform, Sensing in At-Risk Populations (SARP), which consists of a smartwatch, software application for health monitoring, and a central data processing and analytics engine. **Methods:** This is a prospective single center, single arm study, utilizing the SARP platform to risk stratify older adults with cancer and determine correlation with treatment-related adverse events and healthcare utilization. Pts age ≥60 undergoing active treatment, were offered participation. Pts were instructed to wear the smartwatch for ≥7 days. We used Kruskal-Wallis to correlate wearable data with clinical outcomes: toxicity, ED visits, hospitalizations, and mortality. We also compared SARP data to independently collected ECOG PS, CARG score, ADLs, and IADLs. **Results:** From 8/2016 to 8/2017, 54 older adults were consented, and 26 had wearable data available for analysis. The average age was 72 years, with 18 males and 8 females. 12 pts had ECOG PS of 0, 12 with ECOG of 1, and 2 with ECOG of 2. 4 pts had CARG score of low, 17 intermediate, and 3 high. Energy intensity was significantly correlated with ED visits, with an effect size of 0.95 (p = 0.04). Similarly, energy intensity and hospitalizations had an effect size of 0.87 (p = 0.06). The CARG scores were noted to be significantly correlated with dose delay and dose reduction with an effect size 0.45 (p = 0.05) and 0.4 (p = 0.05), respectively. Spearman correlation analysis demonstrated that walking time, active time, and energy intensity positively correlate with ADLs and IADLs, and inversely correlated with ECOG PS and CARG risk. **Conclusions:** Though this is a limited study due to sample size, the overall trend demonstrated that the SARP platform offers an adjunct tool in assessing and risk stratifying older patients with cancer undergoing active therapy. Additional cohorts are now enrolled with an at-home monitoring system. Research Sponsor: AHRQ R01HS024394.

2063 Poster Session (Board #55), Fri, 8:00 AM-11:00 AM

Home ePRO compliance in prostate cancer clinical studies. *First Author: Sarah Tressel Gary, ERT, Boston, MA*

Background: Patient-reported outcomes (PRO) and electronic PRO (ePRO) play an important role in the development and approval of cancer products. Regulatory agencies are encouraging the inclusion of PRO-based endpoints that are indicative of clinical benefit in terms of patient symptoms and overall quality of life (QOL). Compliance with completion of ePRO assessments is an important component for obtaining accurate and high-quality data when conducting clinical trials. Traditionally, ePRO data in oncology trials has been collected mainly at clinic visits due to concerns over poor compliance at home. However, since symptoms and QOL can vary widely through a treatment course, it is often necessary to collect ePRO data more frequently in between clinic visits. It has been hypothesized that home completion, length of time in a study, and number of assessments may affect compliance. **Methods:** To address this hypothesis, ePRO compliance data was analyzed from two clinical studies in prostate cancer. Both studies used a handheld smartphone that contained an application to collect ePRO data. At the randomization visit, subjects completed ePRO assessments in clinic (2-3 questionnaires). Subsequently, all assessments were completed at home, including a daily diary and 1-4 questionnaires completed every 4-8 weeks for up to 14 months. Compliance was calculated as the number of assessments received divided by the number of assessments expected in a given assessment period. To evaluate assessment burden, each assessment period was categorized as requiring a lower number (daily diary and 1 questionnaire) or higher number (daily diary and 2-4 questionnaires) of assessments. **Results:** A total of 1,040 patients were included in the analysis. Overall compliance at the single clinic visit was 100%, which was expected since it was a required randomization visit. Overall compliance at home over 14 months was 80%. Compliance ranged from 78% to 89% over the duration of the studies, with no effect of time in the study on compliance. Compliance remained high even as patient numbers declined. Compliance when patients were required to complete a lower number of assessments (80%) was similar to compliance when patients were required to complete a higher number of assessments (79%). Compliance by region varied from 72% (Middle East) to 87% (Asia and Eastern Europe). **Conclusions:** The collection of ePRO at home provided high compliance that did not vary with length of time in the study or due to assessment burden. At home ePRO assessments provide an effective and feasible approach for recording symptoms and QOL in prostate cancer patients. Research Sponsor: ERT.

2064 Poster Session (Board #56), Fri, 8:00 AM-11:00 AM

Self-reported overall wellbeing (OWb), physical function (PFn), and PRO-CTCAE symptom scores in post-operative and chemotherapy patients. *First Author: Hannah Hazard, West Virginia University, Morgantown, WV*

Background: A standardized, validated tool for capturing symptoms from cancer patients, PRO-CTCAE, has been used to reduce symptom burden, decrease acute care needs, and preserve quality of life. The association between specific PRO-CTCAE symptom scores and single item measures of OWb and PFn were characterized to understand symptom constellations. **Methods:** A novel Epic-based symptom management program (eSyM) was deployed for GI, GYN, and thoracic cancer patients starting chemotherapy (Memphis Baptist) or having surgery (WVU Medicine). Patients received automated prompts to complete surveys via the patient portal (MyChart) on a fixed schedule, approximately twice/week. Each survey included one OWb item, one PFn item, and at least 6 PRO-CTCAE items (pain, nausea, vomiting, fatigue, anxiety, insomnia). The OWb and PFn items, which were created *de novo*, included 5 ordinal response options with corresponding pictograms (emojis from very happy to very sad for OWb; a figure walking to one prone in bed for PFn). Composite scores were generated: 0 for no symptoms, 1-2 for mild/moderate symptoms, and 3 for severe symptoms. We describe OWb and PFn and analyze associations between these items and PRO-CTCAE symptom scores. **Results:** Between 9/10/19-1/22/20, we collected 908 eSyM responses from 166 chemotherapy patients at Baptist (Age, M = 65), and 480 eSyM responses from 97 postoperative patients at WVU (Age, M = 57). The OWb and PFn scores demonstrated moderate correlation with PRO-CTCAE symptom scores (Baptist r = 0.63; WVU r = 0.75), and moderate correlation with mean symptom scores among surgery patients at WVU (r = 0.74); but lower correlation among chemotherapy patients at Baptist (r = 0.53-0.55). Scores improved over time following surgery, but not after initiation of chemotherapy. Among the 730 eSyM responses with none/mild values for both OWb and PFn (52.9% of all responses), only 4.5% reported any severe symptom; among 651 responses with impairment of OWb and/or PFn, 45.2% reported at least one severe symptom. **Conclusions:** Integration of eSyM into the Epic EHR enabled tracking of OWb, PFn, and PRO-CTCAE items. When asked alongside PRO-CTCAE symptom items, two single item OWb and PFn measures provided distinct information and correlated with symptom burden. These results demonstrate the feasibility of integrating ePRO collection into routine post-operative and medical oncology care and that PRO-CTCAE items provide information that is distinct from that obtained from global metrics of well-being. Clinical trial information: NCT03850912. Research Sponsor: U.S. National Institutes of Health.

Mobile apps: Breaking barriers to early cancer detection in underserved communities. *First Author: Carlos A. Munoz-Zuluaga, Mercy Medical Center, Baltimore, MD*

Background: Despite being potentially curable with early detection and timely treatment, breast (BC) and cervical cancers (CC) remain leading causes of death for Colombian women. Lack of cancer screening education, tedious administrative processes, and geographical limitations hinder early cancer detection. Today, technological tools permeate all levels of society and could gather data for user risk stratification, deliver clear and customized information, and help with care coordination, tracking, and addressing communication, transportation, and financial barriers. We aimed to assess the effectiveness of a free mobile application (mApp) to reach women, understand misconceptions about cancer screening, identify users at risk for BC and CC, and coordinate screening tests in Cali, Colombia. **Methods:** The mApp, Ámate, was developed over 4 months and advertised to women (≥14 years) in waiting rooms of 4 healthcare facilities in Cali, Colombia for 23 months. Ámate used educational, evaluative, and risk factor questions followed by brief explanations to assess the population's knowledge, educate users on BC and CC, and identify users in need of BC and/or CC screenings. Correct answers yielded points redeemable for cellular data. Women who required screening were subsequently navigated to a healthcare provider and enrolled in the national cancer program. **Results:** From August 2017-August 2019, 1,043 women from Cali downloaded Ámate and answered all questions. Misconceptions about BC included beliefs that BC can be prevented (87%), obesity does not increase the risk of BC (49%), deodorant causes BC (17%), and only women with a relative with BC can get BC (16%). For CC, misconceptions included that pap smears should not be performed while sexually active (64%), vaginal pain is an early sign of CC (44%), and only women contract HPV (33%). Overall, 31.5% (329) were identified as at-risk and needed a mammogram and/or pap smear. So far, 30% (98) were successfully navigated and completed their recommended screening test(s). Barriers to enrollment in these programs included patient unwillingness, using fake contact information, limited available appointments, and denied access due to healthcare coverage. **Conclusions:** Ámate is an accessible tool that identifies women at-risk for breast and cervical cancer and detects barriers to early cancer detection. Administrative obstacles exist and must be addressed to improve early cancer detection/screening. Ámate is currently being tested in other areas of Colombia and may be useful in other underserved countries. Research Sponsor: American Cancer Society, Susan G. Komen Foundation.

2066 Poster Session (Board #58), Fri, 8:00 AM-11:00 AM

MSK eConsent: Digitalizing the informed consent process to improve participant engagement and understanding. *First Author: Michael T. Buckley, Memorial Sloan Kettering Cancer Center, NY, NY*

Background: eConsent was developed to digitize the research participant consenting experience with an educational engagement model. The eConsent platform tiers consent document content in an easy-to-navigate format, using videos, images, and access to supplementary information. We hypothesize that enhancing the consenting experience improves participant engagement and comprehension. **Methods:** Here we present two projects: 1) qualitative assessment of patient engagement in the eConsent process using a standardized 5-question survey sent to all patients who used it during 9 months in 2019, and 2) a report of our preliminary findings from exempt protocol, *Assessing Participant Engagement and Protocol Education in the Consent Process* (X19-055) that quantitatively compares paper and electronic consenting and a) assesses patient agency and b) tests comprehension of key consent elements in 2 protocols: *Storage and Research Use of Human Biospecimens* (06-107) and *Genomic Profiling in Cancer Patients* (12-245). **Results:** 1) 940 patients completed the qualitative experience survey (27% response). Most respondents (777; 83%) indicated that electronic consenting was very easy (371) or easy (406) to use. Only 25 (3%) said electronic consenting was somewhat difficult to use, 3 indicated it was difficult (0.3%), and 64 were neutral. Most (896; 95%) recommended electronic consenting to other MSK patients. Those who reported a 1 unit increase in technology discomfort, only reported a .48 unit increase in eConsent discomfort ($P < .001$). 2)Quantitative 10-question electronic tests were sent to each patient's portal account within 72h after consenting via paper or eConsent to protocols 06-107 and 12-245. To date, for 06-107: 18 paper consenters completed the test with a score of 76% vs 23 eConsent users who scored 80%. For 12-245: 43 paper consenters scored 69% vs 13 eConsent users scoring 80%. Scores are a surrogate marker for patient comprehension and show that 12-245 protocol participants' average testing scores are higher when participants are consented with eConsent vs paper ($P < .01$). 06-107 protocol participants' average test scores are trending toward eConsent improving patient understanding ($P = .11$). We will follow this trend as our sample size increases to a total of 500 participants. Patient agency questions received favorable responses from most patients (100%-84%). **Conclusions:** eConsent enhances participant engagement and understanding and does not impose a digital burden on participants. Research Sponsor: None.

2067 Poster Session (Board #59), Fri, 8:00 AM-11:00 AM

A prospective trial of standard versus multimedia counseling in patients undergoing endometrial cancer surgery. *First Author: Katherine Tucker, University of North Carolina, Division of Gynecologic Oncology, Chapel Hill, NC*

Background: A patient's understanding of surgery is often limited, especially in the setting of complex oncologic procedures. A recent review found that interventions such as the use of written materials, videos, and websites, improve patients' knowledge of the procedure and their satisfaction with decision making. We sought to determine if a video-based approach in patients undergoing robotic endometrial cancer staging improves satisfaction with perioperative counseling. Secondary objectives were physician satisfaction, patient comprehension, and visit length. **Methods:** From 2018-2019, patients were randomized to standard physician education or multimedia-based education, which included watching two novel animated videos followed by focused physician counseling. Basic demographic information was collected. Patient satisfaction was assessed using the Client Satisfaction Questionnaire-8 (CSQ-8, a validated satisfaction survey, scored 8-32) and a global satisfaction score (10-point scale). Physician satisfaction was assessed using a global satisfaction score. Comprehension was assessed with a 9 question survey at 3 time points. Descriptive statistics were used to compare groups. **Results:** Of 76 patients randomized, the majority were Caucasian (68%), 50-70 years old (70%), and had at least some college education (75%). Most patients had undergone prior surgery (83%) and one fourth had a prior cancer diagnosis. Demographic variables and surgical history were similar between groups. The video patients reported higher satisfaction on the CSQ-8 (31.57 ± 1.02 vs 30.62 ± 2.09, $p < 0.05$) and global satisfaction score (9.95 ± 0.23 vs 9.74 ± 0.55, $p < 0.05$). There was no difference in comprehension scores between groups at either the initial or postoperative visit. At the time of surgery, comprehension scores were higher in the standard education group compared to the video group ($p < 0.01$). There was no difference in physician satisfaction between groups. Among the video group, there was improvement in physician satisfaction between the first and second half of patients enrolled ($p < 0.05$). There was no difference in visit length. **Conclusions:** While multimedia education improved patient satisfaction in the preoperative setting, this was not clinically significant. Provider satisfaction improved over time with the use of a video aid. Multimedia education may be implemented in perioperative counseling based on provider preference and consideration should be made for further study of satisfaction after the initial implementation period. Clinical trial information: NCT03899441. Research Sponsor: Fowler Fellowship Fund.

2068 Poster Session (Board #60), Fri, 8:00 AM-11:00 AM

The association between drug industry payments and NCCN guideline panel membership. *First Author: Aaron Philip Mitchell, Memorial Sloan Kettering Cancer Center, New York City, NY*

Background: The high frequency of financial relationships between the pharmaceutical industry and influential oncologists who author clinical practice guidelines may influence guideline recommendations. Therefore, we assessed the financial relationships held by NCCN Guidelines panelists before and after joining the panel, compared to those held by a matched set of oncologists. **Methods:** Membership of NCCN Guidelines panels for the 20 most common cancers was obtained from archival guidelines and linked manually to Open Payments records of industry payments. We identified physicians who newly joined an NCCN panel during the August 2013-December 2018 study period, and we included medical oncologists who had at least 1 year of Open Payments data before and after joining. These medical oncologists who joined an NCCN panel (panelists) were matched 1:2 to medical oncologists with the same gender, institutional affiliation, and medical school graduation year, who did not join an NCCN panel (non-panelists). The dollar value of industry payments was then calculated over the 1 year before (pre-join) and after (post-join) the date that each panelist joined. We used generalized linear models to assess differences in industry payments between the panelists and matched non-panelists in the pre-join period. We used difference-in-difference estimation (DiD) to assess whether joining an NCCN panel was associated with increased payments in the post-join period. **Results:** There were 54 panelists and 108 non-panelists (matched from 1447 eligible oncologists at NCCN institutions). Mean per-oncologist payments among panelists were greater than non-panelists in the pre-join period ($11,259 vs $3,427, p = 0.02). From the pre-join to post-join period there was a similar increase in mean per-oncologist payments among panelists and non-panelists ($2,236 vs. $1,569, DiD estimate +$667, p = 0.77). **Conclusions:** Medical oncologists who were selected to an NCCN Guidelines panel had greater financial ties to industry compared to peer oncologists who were not selected. This difference was present prior to joining; oncologists did not experience a greater increase in financial payments from industry in the 1-year period after joining an NCCN panel. These results suggest an opportunity to reduce the potential influence of industry in oncology clinical practice guidelines through the selection of guideline panelists with fewer ties to industry. Actionable policy barriers for receiving standard of care treatment among unresected stage III non-small cell lung cancer (NSCLC) patients in the United States. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: Recent data suggests that a significant number of good performance, unresectable stage III non-small cell lung cancer (NSCLC) patients do not receive standard-of-care treatment, i.e. concurrent chemoradiotherapy (cCRT) followed by durvalumab, despite being eligible. However, little is known about actionable policy barriers to delivery of cCRT to this patient population. **Methods:** The National Cancer Database (2004-2016) was used to identify unresected stage III NSCLC patients aged 18-79 years with Charlson comorbidity score ≤ 1. cCRT was defined as the initiations of chemotherapy (CT) and radiation therapy (RT) that were ≤ 14 days (n = 53,444) apart. The remaining treatment groups included sequential CRT (sCRT; n = 16,666), CT only (n = 15,416), RT only (n = 11,579), and no first course treatment (n = 16,691). Multinomial logistic regressions were used to examine the likelihoods of receiving different treatment modalities, controlling for patient demographics, Charlson comorbidity score, health insurance, facility type, social deprivation index (SDI, a comprehensive socio-economic measure; higher SDI indicates lower socioeconomic status [SES]), driving time to facility, diagnosis year, and region. **Results:** Of the total 113,796 patients assessed (median age 66 years), most were male (55.7%), non-Hispanic white (81.7%), and with SDI score ≥ 50 (51.3%). 29.5% had Charlson comorbidity score = 1 while the rest had 0. In adjusted analyses (predicted margins), 47.0% patients received cCRT (sCRT: 14.6%; CT only: 13.5%; RT only: 10.2%; no treatment: 14.7%). Compared to the privately insured, Medicaid, Medicare, and uninsured patients were more likely to receive RT only (relative risk ratios [95%CI]: 1.93 [1.77-2.11]; 1.51 [1.41-1.61]; 1.80 [1.61-2.01], respectively) and no treatment (1.84 [1.71-1.99]; 1.54 [1.45-1.63]; 2.19 [2.01-2.40], respectively) rather than cCRT (all $p < .001$). Moreover, higher SDI was associated with higher likelihood of receiving RT only (highest vs lowest SDI scores: 1.42 [1.33-1.52]), or no treatment (1.46 [1.38-1.55]) rather than cCRT (all $p < .001$). Longer driving time was associated with higher likelihood of receiving CT only (> 120 mins vs < 30 mins: 1.24 [1.10-1.39]), or no treatment (1.33 [1.18-1.50]) rather than cCRT (all $p < .001$). **Conclusions:** Health policies should focus on patients who are not privately insured and live in neighborhoods with low SES. Moreover, helping their transportation needs may also improve the likelihood of receiving cCRT. Research Sponsor: AstraZeneca.

2070 Poster Session (Board #62), Fri, 8:00 AM-11:00 AM

Opioid prescribing patterns among generalists & oncologists for Medicare Part D beneficiaries from 2013-2017. *First Author: Trevor Joseph Royce, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC*

Background: In response to the opioid crisis, recent policies aiming to reduce opioid prescribing, misuse, & abuse have generated concern that patients with cancer pain may unintentionally experience reduced access to necessary opioid therapy. It is unknown how opioid prescribing patterns have changed between generalists and oncologists during this era. **Methods:** We conducted a longitudinal repeated cross-sectional study estimating adjusted annual national trends in opioid prescribing among generalists & oncologists using the Medicare Part D Prescriber Public Use Files 2013-2017. Poisson models estimated annual adjusted predicted mean rates of opioid prescribing-per-1,000 total prescriptions & long-acting opioid prescribing per-1,000 opioid prescriptions. Poisson models estimated adjusted incidence rate ratios (aIRRs) to quantify annual changes in prescribing rates. **Results:** From 2013-2017 the annual adjusted predicted mean rate of opioid prescriptions per 1,000 total prescriptions decreased from 53.4 to 41.3 among generalists (aIRR = 0.78; $p < 0.01$) and from 133.2 to 105.9 among oncologists (aIRR = 0.83; $p < 0.01$). The rate of long-acting opioid fills per 1,000 opioid prescriptions decreased from 96.0 to 87.0 (aIRR = 0.87; $p < 0.01$) and 235.1 to 222.5 (aIRR = 0.95; $p < 0.01$) for generalists & oncologists, respectively (Table). **Conclusions:** We found large declines in overall opioid prescribing rates among generalists (-22%) and oncologists (-17%) from 2013-2017. Long-acting opioid prescribing rates decreased over 2.5-times more among generalists than oncologists. Opioid policy & advocacy have been effective in reducing the extent of opioid prescribing in the Medicare population but how much of the decrease in prescribing by oncologists is 'appropriate' versus 'inappropriate' deserves further investigation. Research Sponsor: U.S. National Institutes of Health.

Timing of US Food and Drug Administration (FDA) cancer drug approvals relative to publication of clinical trial results. *First Author: Ali Raza Khaki, University of Washington, Seattle, WA*

Background: Publication of clinical trial results in peer reviewed literature is essential to inform clinicians regarding the use of new anti-cancer treatments, which often have a low therapeutic ratio and require careful assessment of risks and benefits. Publication of registration trials should precede FDA approval to facilitate evaluation and implementation of new therapies. The timing of trial publication relative to FDA drug approvals has not been systematically investigated. **Methods:** We collected all FDA drug approvals for a cancer indication between 2000-19. Trials were identified using FDA labels as well as drugs and publications indexed on HemOnc.org. Approvals for generics/biosimilars, non-oncology indications and label revisions without supportive evidence were excluded. Dates of approval, the approval pathway, approval type (new vs expansion), and the first full publication related to the registration were recorded. Trials and approvals were matched using available metadata. We calculated the proportion of drugs approved prior to publication overall and for those receiving accelerated approval (AA). We used logistic regression to compare rates of pre-publication approval by approval pathway and by new vs expanded approval. **Results:** Among a total of 378 drug approvals, 139 (37%) had pre-publication approval. Of these, the median overall time from approval to publication was 140 days (IQR 64-281 days). For those with approval after publication, median time from publication to approval was 157 days (IQR 72-359 days). The number of drugs approved pre-publication rose by 27% between the first and last quarters of the study period, though, the proportion decreased as more anti-cancer drugs have been approved in recent years (Table). More drugs were approved pre-publication through AA than regular approval (46% vs 34%, OR 1.66 [95% CI 1.03-2.70], p=0.04) and as new approvals vs. expanded approvals (45% vs 32%, OR 1.76 [95% CI 1.15-2.70], p=0.01). **Conclusions:** A substantial minority of FDA approvals occur before trial results are published, with the odds being higher for drugs receiving AA and for new approvals. Since clinicians rely upon published results to inform risk/benefit decisions, efforts are needed to ensure trial results are published by the time of FDA approval of new cancer drugs and indications. Research Sponsor: U.S. National Institutes of Health.

Mismatch between mortality burden and number of FDA registration trials in highly lethal cancers. *First Author: Bishal Gyawali, Brigham and Women's Hospital, Boston, MA*

Background: Treatment successes in cancer are achieved through new drugs tested in clinical trials. However, drug discovery has been disparate across cancer types for various reasons. We sought to investigate if the number of trials used to support United States Food and Drug Administration (FDA) drug approvals is proportional to the incidence and mortality burden of highly lethal cancers, i.e. those with an expected relative mortality of >5% per *Cancer Statistics, 2020* (Siegel et al.). **Methods:** All FDA labels for 258 antineoplastic cancer drugs approved as of January 2020 were reviewed for citations of registration trials supporting initial approval and additional indications. Trials were identified by matching described characteristics (e.g., patients enrolled, clinical trial NCT codes) to publications indexed on HemOnc.org. Trials were labeled by cancer type studied and type of trial (randomized vs non-randomized). **Results:** We identified 559 registration trials in total. Results for the six highly lethal cancers are shown in the table. The percent of registration trials was roughly proportional to incidence, but not mortality burden. For example, despite the 22% expected mortality burden of lung cancer, it had a share of only 11% of registration trials whereas breast cancer has an expected 7% mortality burden, with a share of 14% of registration trials. Chronic myeloid leukemia is expected to cause 1,130 deaths in 2020 (0.2%) and has had 20 registration trials (3.6%). The highly lethal cancers had a higher rate of randomized trials supporting approval than other cancers (84% vs 56%, p<0.001 [Chi-square]). **Conclusions:** While the findings may in part be due to disease biology (e.g., pancreatic ductal adenocarcinoma has proven resistant to many novel therapies), our evaluation highlights a potential mismatch between resources and needs. Randomized trials were more often used to support new drug approvals in highly lethal cancers. These findings will be important in regulatory policy. Research Sponsor: U.S. National Institutes of Health.

Reliability and correlations among quality measures for lung, breast, and colorectal cancer. *First Author: Jessica Cleveland, Dana-Farber Cancer Institute, Boston, MA*

Background: Alternative payment models for oncology seek to improve quality and reduce spending. Yet the ability to measure high-quality care across oncology practices remains uncertain. We characterized quality of care for oncology practices using registry and claims-based measures of processes, utilization, end-of-life care, and survival and assessed correlations of practice-level performance across measure type and cancers. **Methods:** Using SEER-Medicare data, we studied individuals with newly diagnosed lung (N = 95,635), breast (N = 78,736), or colorectal (CRC, N = 51,385) cancers in 2010-2015 treated in oncology practices with ≥20 patients (502, 492, and 347 practices, respectively). We measured receipt of guideline-recommended treatment and surveillance (processes), hospitalizations or emergency department visits during 6-month chemotherapy episodes (utilization), care intensity in the last month of life (EOL), and 12-month survival (lung and CRC only). We calculated summary process, utilization, and EOL measures for each patient (number of measures met divided by the number for which the patient was eligible). We used hierarchical linear models with practice-level random effects to estimate summary measures and survival for each practice. We calculated practice-level reliability (a measurement's reproducibility) for each measure based on the between-measure variance, within-measure variance, and sample size. **Results:** Few practices had ≥20 patients eligible for most measures (38%, 37%, and 31% of practices had ≥20 patients for any lung, breast, and CRC measures, respectively). Measure reliability was low. Only 13%, 7%, and 20% of measures for lung, breast, and CRC, respectively, had a median reliability across practices ≥0.7. Among practices with ≥20 patients with summary measures of each type within cancer, correlations across measure types were low (all correlation coefficients (r)≤0.21 except a weak correlation of the CRC process summary measure with 1-year CRC survival, r = 0.38, $p < 0.001$). Summary process measures were minimally or not correlated across cancer type (lung, breast, CRC; all correlation coefficients ≤0.16). **Conclusions:** Claims-based measures of care processes, utilization, EOL care, and survival are limited by small numbers of fee-for-service Medicare patients across practices, even after pooling 6 years of data. Measures have poor reliability and are poorly correlated across measure or cancer type. Additional research is needed to identify reliable quality measures for practice-level alternate payment models. Research Sponsor: Arnold Foundation.

2074 Poster Session (Board #66), Fri, 8:00 AM-11:00 AM

Physician whistle-blower's experiences in hematology-oncology safety litigation against pharmaceutical companies. *First Author: Ashley Caitlin Godwin, University of South Carolina College of Pharmacy, Columbia, SC*

Background: Some clinicians have reported initial series of severe or fatal adverse drug reactions (ADRs) that affected large hematology-oncology patient numbers and for which pharmaceutical manufacturers subsequently paid large settlements or fines for allegedly failing to inform physicians about such ADRs. Based on their large human costs (> 1,000 serious illnesses or deaths) and large financial costs (> $100 million in settlements or fines), we have termed these ADRs as titanic ADRs. At a Senate hearing on one titanic, Vioxx, (a COX-2 inhibitor that was evaluated for colorectal cancer prevention), the clinician reporter was termed a "whistleblower" by a senator although this individual had not filed a formal whistleblower lawsuit. We identified physicians who would fit this characterization of whistleblowers and had published titanic hematology-oncology ADR reports in high impact journals. **Methods:** Hematology-oncology titanic ADRs were identified by collaborators with two NIH-funded drug safety networks (RADAR and SONAR (1998-2019)). Exclusion criteria included having also filed a whistleblower lawsuit. Qualitative research analyses evaluated content of statements made by whistleblowers to national reporters or at congressional hearings. **Results:** 18 physicians who reported titanic hematology/oncology-associated ADRs in peer-reviewed literature and discussed their findings in national news media outlets are included. Titanic ADRs included death, nephrogenic systemic fibrosis, coronary artery disease, and venous thromboembolism related to COX-2 inhibitors, heparin, gadolinium dye, thalidomide, lenalidomide, epoetin, and darbepoetin. Related financial settlements ranged from $100 million to $4.85 billion. Whistleblowers were from the United States, Denmark, and Germany. Primary motivations were public health and medical awareness. Whistleblowers reported having gone through lawsuits and having had executives request that the whistleblowers' university terminate employment. One whistleblower was quoted saying "I believe that the lawsuit is an attempt to silence me." **Conclusions:** Clinician whistleblowers of titanic hematology-oncology ADRs experienced reputational, financial, and personal threats. Motivations for reporting titanic ADRs were mainly public health and medical awareness focused. This differs from our previous study on clinicians publishing on non-titanic ADRs, where the primary motivation was scientific curiosity. Research Sponsor: American Cancer Society.

2075 Poster Session (Board #67), Fri, 8:00 AM-11:00 AM

Resource and reimbursement barriers to comprehensive cancer care (CCC) delivery: An Association of Community Cancer Centers (ACCC) survey research analysis. *First Author: Al Bowen Benson, Northwestern Medicine, Chicago, IL*

Background: CCC delivery is recommended in guidelines, required by accreditation bodies, and essential for high-quality cancer management. Barriers, such as insufficient reimbursement and lack of specialist staff, prevent consistent access to and delivery of CCC, particularly supportive oncology services. Challenges especially persist in community programs, where access to philanthropy and similar funding is limited. ACCC conducted a representative survey of its member programs to elucidate capacity and barriers to CCC delivery in the community/academic setting in order to inform policy and value-based payment reform. **Methods:** Survey development methodology included item generation with expert review, iterative piloting and cognitive interviews to achieve content and internal validity. An online survey was piloted at the ACCC 2018 Annual Meeting and sent to member programs via email link. The final survey included 22 questions on availability and funding for supportive services. Twenty-seven supportive oncology services were assessed for availability, reasons not offered, reimbursement/funding and patient payment. Analyses were conducted with SAS. **Results:** 172 of 704 ACCC member programs responded and completed the majority of survey as of 10/7/19. Despite a high proportion of programs offering supportive oncology services, gaps between cost and reimbursement were present for all (Table). Deficits in reimbursement are compensated by patient out-of-pocket payments, grants and donations. Most centers report needing more staffing in psychology (61%), social work (60%), navigation (59%), nutrition (57%), palliative care (56%), genetic counseling (52%), and financial counseling (53%). Gaps were observed regardless of region or practice type. **Conclusions:** There is a lack of sufficient reimbursement, staffing, and budget to provide CCC across the U.S., regardless of region or practice type. Oncology care models and reimbursement policies must include CCC services to optimize delivery of care. Research Sponsor: Association of Community Cancer Centers.

Annual trends in opioid prescribing for patients (Pts) with metastatic non-small cell lung cancer (mNSCLC): Cancerlinq data analysis, 2010 to 2017. *First Author: Judith A. Paice, Northwestern University, Chicago, IL*

Background: Despite opioid misuse and abuse, opioids remain a mainstay for management of cancer pain. Government, payers, and institutions have implemented policies to reduce opioid use. The impact of these restrictions on oncologist prescriptions (Rx) of opioids and management of cancer pain in pts with cancer is not well known. **Methods:** A retrospective, observational analysis used deidentified EHR data from ASCO's CLQ Discovery database. Study cohort included pts with mNSCLC diagnosis and >1 clinical encounter (including opioid Rx) from CLQ clinician during 2010-2017. Opioids included DEA schedule II and III opioid drugs prescribed for cancer pain, excluding cough suppressants. Annual Rx rates were defined as the number of mNSCLC pts who had ≥ 1 opioid Rx dated 2010-2017 per CLQ total mNSCLC pts who had ≥1 clinical encounter in the year. Annual rates demonstrate trends in opioid prescribing patterns over time. **Results:** 18,106 pts with mNSCLC clinical activity between 2010 and 2017 were identified. Overall, 39.8% of pts had opioid Rx in 2010-2017. Annual Rx rates increased from 2010-2015 and fell 2016-2017 (see table). Hydrocodone was the second most frequently prescribed opioid overall (N=4211 pts), but Rx rates began to decline in 2012. Tramadol and acetaminophen + codeine Rx rates gradually increased throughout the time period. DEA initially scheduled Tramadol as schedule IV in 2014. **Conclusions:** Opioids are commonly prescribed by oncologists for patients with mNSCLC. Rx rates have declined since 2015, likely due to increased government, payer, and institutional restrictions on access. Hydrocodone Rx declined since 2012, perhaps exacerbated by reclassification from schedule III to schedule II by the DEA (October 2014). Rxs for schedule IV and III opioids (known to be of lower potency) increased modestly, likely due to comparatively fewer prescribing restrictions. Additional research is needed to understand whether the decline continues and the impact on management of cancer pain, particularly among metastatic patients. Research Sponsor: ASCO and Concerto HealthAI.

Year of Activity	Number of Pts With Diagnosis N	Pts With Opioid Rx N (%)	Pts with Hydrocodone Rx Among Opioid Rx Pts	Pts with Tramadol and/or Acetaminophen + Codeine Rx Among Opioid Rx Pts
2010	2520	449 (18%)	118 (26%)	15 (3%)
2011	2647	550 (21%)	212 (39%)	22 (4%)
2012	4084	878 (21%)	324 (37%)	53 (6%)

Pivotal trial endpoints and prices of cancer drugs in the US and Europe. *First Author: Kerstin Noëlle Vokinger, Harvard Medical School, Program on Regulation, Therapeutics, and Law/University of Zurich, Boston, MA*

Background: A key clinical outcome for new cancer drugs is improvement in overall survival (OS), defined as time from the date of randomization to the death from any cause. However, many cancer drugs are approved by regulators based on changes to surrogate measures of OS, such as progression-free survival or overall response rate. When surrogate measures are not validated, they can provide misleading information about drug efficacy. We categorized pivotal trial endpoints for recently-approved cancer drugs in the US and Europe as showing improvements in OS vs non-OS surrogates, and evaluated the correlation with drug prices. **Methods:** We identified new drugs FDA-approved between 2009 and 2018 that were indicated to treat solid and hematologic tumors in adults and that had also been approved by the EMA and Swissmedic by December 2019. Launch prices were extracted and adjusted to average sales prices for monthly treatment costs in the US and compared to currency-adjusted ex-factory monthly treatment costs in Germany, Switzerland, and England. Pivotal clinical trial primary endpoints were collected from the drug labeling and FDA medical reviews for the US, and the EMA public assessment reports for Europe, and categorized as OS in any trial vs. not. Pearson's correlation tests assessed the association between launch prices and OS vs non-OS endpoints in each country. **Results:** 54 drugs were approved by the FDA, EMA, and Swissmedic during the study period. In the US, 30 (56%) were approved based on OS by contrast to 35 (65%) in the EMA. The number of cancer drugs approved by the FDA based on OS decreased in the past years. By contrast, the number of approved cancer drugs by the EMA based on OS were stable. There was no association for the US (p = 0.05), Germany (p = 0.13) and England (p = 0.12), while Switzerland revealed an association (p = 0.03) between OS endpoint and price. **Conclusions:** Reductions in use of OS endpoints as the basis for cancer drug approval in the US is concerning. Drug pricing should be better aligned with the benefit that drugs provide to patients, as measured by clinical trial outcomes such as OS. Research Sponsor: Swiss Cancer Research Foundation.

2078 Poster Session (Board #70), Fri, 8:00 AM-11:00 AM

The clinical impact of ASCO "choosing wisely" recommendations on staging imaging for early stage breast cancers: An interrupted time-series analysis utilizing SEER-Medicare data. *First Author: Alan Baltz, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: The "Choosing Wisely" (CW) list, released by the American Society for Clinical Oncology (ASCO), highlights low-value procedures. In 2012, the CW recommendations advised against the use of staging imaging, including Positron Emission Tomography (PET), Computerized Tomography (CT) and radionuclide bone scans, for the staging of early breast cancer at low risk for metastasis. The objective of this study was therefore to assess the impact of the ASCO CW recommendations on staging imaging among early stage breast cancers. **Methods:** Women above the age of 66 with an early stage incident breast cancer diagnoses between 2010 and 2015 were identified within the linked SEER-Medicare data. The primary outcome of interest was the proportion of patients with a claim for staging imaging in the six months following the breast cancer diagnosis. Negative binomial regression, adjusting for pre-recommendation trends, was performed to estimate the changes in the rate of imaging staging within each year following the release of the recommendation. **Results:** A total of 50,004 women were identified during the study period. Prior to the release of the recommendations in 2012, the staging imaging rates among women newly diagnosed with early stage breast cancers were 5% greater in 2010 ($p<.01$) and 4% greater in 2011 ($p<.01$). Following the release of the recommendations, staging imaging rates did not decrease significantly in 2013 (2%;p=0.18). Imaging rates did, however, significantly decrease by 13% in 2014 ($p<0.01$) and by 16% in 2015 ($p<0.01$). **Conclusions:** The CW recommendation was associated with a significant decrease in unadvised staging imaging among incident early stage breast cancer diagnosis in the second and third year following its release. These findings demonstrate an improvement in the proportion of potentially inappropriate staging imaging in early stage breast cancers. The creation and dissemination of resources, such as the CW recommendations, serves as a powerful tool to improve clinical practice, quality of care, and patient safety from secondary malignancies, anxiety, and overdiagnosis. Research Sponsor: UAMS Laura Hutchins Distinguished Chair in Hematology Oncology.

2079 Poster Session (Board #71), Fri, 8:00 AM-11:00 AM

Understanding practice variation with a clinical pathways system: Differences by physician and practice factors, and changes in practice over time. *First Author: Emily Foster, Dana-Farber Cancer Institute, Boston, MA*

Background: Clinical oncology pathways aim to support clinical decision-making and reduce unwarranted practice variation across an enterprise. The Dana-Farber Cancer Institute (DFCI) implemented web-based oncology pathways with DFCI-customized content in each disease center and at each of its satellites. Our pre-specified aim was an on-pathway rate of 70-85%. **Methods:** Treatment decisions were electronically captured as on- or off- pathway. Monthly metrics about usage and on-pathway rate were shared with users on a monthly basis. Physicians were categorized into quintiles based on the calculated on-pathway performance during the first 90 days of each individual's use of the platform. On-pathway rates were then calculated for days 91-360 to study changes in behavior over time. Physician and practice factors were examined to determine any differences by initial on-pathway quintile classification. **Results:** 122 physicians were eligible for inclusion in this analysis (minimum 5 navigations in each study period). On-pathway rates showed significant variability in the initial 90-day period: quintile 1 median 100%, quintiles 2-4 80.2%, and quintile 5 50% (Table). In the follow-up period, median on-pathway rates shifted into the pre-specified goal range for all groups. Physicians in quintiles 1 or 5 of initial on-pathway rate were more likely to have fewer total navigations than were physicians in quintiles 2-4 (p=0.003). While no other physician or practice characteristic differed significantly by on-pathway rate group, physicians in the first or last quintile were more likely to be in an academic setting, have a PhD, or navigate fewer pathways. **Conclusions:** Over time, the deployment of a web-based clinical pathways program resulted in greater uniformity in physician practice, based on on-pathway rate. Familiarity with the pathways platform and its navigation, monthly feedback about usage, and evolution of content over time are some factors that might have played a role. Research Sponsor: None.

Comparison of on-pathway rate between 0-90 days of use and 91-360 days of use, by quintile group.

	0-90 Days of Use			91-360 Days of Use			
Quintile Group	Range	Median (IQR)	Mean±STD	Range	Median (IQR)	Mean±STD	P-value*
Quintile 1 (n = 26)	94.7-100%	100% (100-100%)	99.4±1.7%	54.5-100%	84.0% (77.8-95.8%)	84.1±13.2%	<0.0001
Quintiles 2-4 (n = 72)	66.7-94.1%	80.2% (75.9-87.5%)	80.8± 8.1%	38.5-100%	80.6% (69.7-84.9%)	77.2±13.0%	0.024
Quintile 5 (n = 23)	37.5 – 66.0%	50% (50-58.3%)	52.2± 8.0%	48.3 – 87.5%	71.1% (60-77.8%)	70.2±11.6%	<0.0001

Association of financial conflicts of interest with academic success among junior faculty in hematology and oncology. *First Author: Angela J. Fought, University of Colorado Denver, Denver, CO*

Background: Financial conflict of interest (COI) represents a complex issue in hematology and oncology. Little is known about when COIs develop during a career and if these correlate with early career success. We evaluated self-reported COIs for junior faculty members at 10 academic cancer centers and examined if these financial relationships with industry correlated with measures of academic career success. **Methods:** The study evaluated 229 assistant professors from the top 10 cancer centers based on the 2018 US News Cancer rankings. Faculty characteristics were determined from hospital websites including the number of years since completing fellowship. Data regarding National Institute of Health (NIH) funding were obtained. Industry funds (Sunshine Act funds; SAF) were identified from the Centers for Medicare & Medicaid Services (CMS) Open Payments database from 2013-2017. Self-reported COIs were obtained from the American Society of Clinical Oncology (ASCO) or American Society of Hematology (ASH) disclosures databases, and through review of disclosures from recent publications. Measures of academic success included h-index and number of publications. We assessed the influence of number of COIs and SAF received on measures of academic success. **Results:** Of the 229 included faculty, 45% were female, 39% graduated fellowship in 2015 or later, 35% were double-boarded, 40% had dual degrees and 15% received NIH funding. Approximately 46% of faculty had at least 1 COI. COIs (ASCO/ASH) were positively correlated with COIs self-reported in publications and total SAF (Spearman correlations 0.57 and 0.54, both $P < 0.01$). The development of COIs and the number of SAF increased with years in practice (Spearman correlations 0.37 and 0.28, both $P < 0.01$). COIs and SAF correlated with h-index (Spearman correlation 0.40 and 0.41, both $P < 0.01$). After adjusting for years since fellowship, linear regression demonstrated that log-transformed h-index and number of publications were associated with SAF ($P < 0.01$) and COIs (ASCO/ASH) ($P = 0.01$). **Conclusions:** Financial COIs were present in nearly half of the faculty and increased with more time since completing fellowship. Measures of academic success were positively correlated with COIs (ASCO/ASH) and SAF. These data suggest that cultivating industry relationships may aid faculty in establishing early academic success. Research Sponsor: None.

2081 Poster Session (Board #73), Fri, 8:00 AM-11:00 AM

Adoption of behavioral restrictions as anti-infective measures: A survey among solid tumor patients. *First Author: Eliya Shachar, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: Despite lack of evidence, a wide range of rigorous behavioral and social restrictions are recommended in various guidelines and websites in an attempt to mitigate infections. These include patient guided sites. We aimed to study the practices of patients with solid tumors treated with active therapy. **Methods:** We conducted an anonymous survey among cancer patients treated at a tertiary care center, addressing behavioral approach to infection prevention, by assessing adopted social (seven items), environmental (five items), and dietary (eight items) limitations, as well as compliance to influenza vaccinations. Clinical data included neutropenic fever (NF), and therapy myelosuppressive potential. Multivariable Poisson regression adjusted for sex, age, disease status, therapy to estimate the impact of these restrictions. **Results:** 214 patients with solid tumors responded to the survey, the majority female (59%), with a median age of 63. The most common tumor types included breast (28%), lung (14%), and colon (9.3%). Most (68%) were treated with chemotherapy, 17% with immunotherapy, 11% with biologicals and 3% with chemo-immunotherapy. Only 6% were admitted for NF. Sources of information regarding restrictions included physicians (4%), nurses (32.9%), and internet (9.8%); the majority were self-imposed. 53% maintained environmental limitations (traveling, sun exposure, hair dying), 37% adopted social restrictions (abstained from children, public places), and 21% affirmed dietary constraints (raw vegetables, tap water consumption). Females practiced stricter environmental and dietary restraint ($p < 0.05$), with a numerical trend reflecting stricter female social measures ($p < 0.4$). With no difference in practices among patients treated for a malignant disease and curative intent, and no difference in practice across therapies, in those treated with chemotherapy and immuno-therapy. 37% affirmed difficulty in adherence to these limitations. **Conclusions:** Our findings indicate that despite lack of evidence, cancer patients adopt anti-infective behavioral measures, which have a deleterious impact on quality of life. These practices are being used even among patients at low or no risk of NF. These findings call for implementation of an education program and development of practical instructions enabling patients to resume their normal life Research Sponsor: None.

2082 Poster Session (Board #74), Fri, 8:00 AM-11:00 AM

Telemedicine visits reduce time to biopsy, travel time and costs for interventional radiology patients. *First Author: Suken Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Telemedicine has been utilized to increase access to care for patients in primary care practices and more recently, specialty practices. The purpose of the study was to test the hypothesis that adding a telemedicine clinic practice could decrease the time to biopsy, travel time and cost for interventional radiology (IR) clinic patients. **Methods:** Telemedicine visits were performed by a physician or advanced practice provider (PA or NP) at a single institution, academic medical center to patients at 3 MSK regional locations in NY and NJ. Total patient encounters and data from November 2017 to October 2019 were analyzed. Primary outcome measures were wait time from the IR referral to biopsy procedure visits, patient travel time and travel cost, stratified by in-person vs telemedicine visit. Round-trip travel distance and costs for patients were calculated by determining the offset travel. Cost (economic) benefit was the sum of: Federal cost per mile for travel, toll and parking costs, and doctor visit lost wages. **Results:** There were 172 MSK Regional site telemedicine visits. There was a significant reduction in time from referral to biopsy for telemedicine visits compared to in-person visits (12 vs 17 days, $p < 0.0001$). Additionally, there was a significant reduction in travel time for telemedicine visits vs travel time to Manhattan for an in-person visit ($p < 0.0001$). Telemedicine visit patients had to travel 367 less hours than an in-person visit and saved a total of 11,222 in miles that they did not have to travel. Telemedicine patients accrued $14,652 in economic benefits due to reduced travel costs and lost wages from work. **Conclusions:** Telemedicine significantly reduced the time to biopsy, travel time and cost for Interventional Radiology patients compared to in-person visits. Telemedicine for IR patients increases access to care for patients and allow for more efficient use of physician time and resources. Research Sponsor: None.

2083 Poster Session (Board #75), Fri, 8:00 AM-11:00 AM

Documentation patterns and impact on observed side effects of the CANKADO ehealth application: An exploratory analysis of the PreCycle trial. *First Author: Tom Degenhardt, University of Munich, LMU, Munich, Germany*

Background: PreCycle (NCT03220178), a multicenter, randomized phase IV Intergroup trial evaluates the impact of ePRO assessment on quality of life (QoL) in HR+/HER2- locally advanced or metastatic breast cancer patients (pts) treated by palbociclib (P) and an aromatase inhibitor or P+fulvestrant. Pts willing to use the web/APP-eHealth solution CANKADO are eligible. Patients are randomized (2:1, stratified by therapy line) to the active (CANKADO PRO-React) or inactive inform arm. Primary endpoint is time to deterioration (TTD) of QoL. **Methods:** The trial started in 2017 and is ongoing (81 centers); regular safety reports are routinely provided to the study sponsor. Analysis of distribution of serious adverse events (SAE) was initiated by the trial leadership and performed using the Oct 15, 2019 safety report. Data that could bias primary or secondary endpoints were not analyzed. Bayesian inference (non-informative prior) was used to estimate probabilities; no corrections for potential multiplicities were made. **Results:** At data cut-off, 261/281 randomized patients had received study medication and provided CANKADO documentation. At time of evaluation, a total of 40298 days were documented. CANKADO was used on 59% (+/-10%) of all days over a 2-year period. SAEs were observed in 26/175 (14.9%) of all active-arm patients vs. 18/86 (20.9%) of inform-arm patients (90% probability of reduction in inform patients). Total SAEs were 36 (active) vs. 27 (inform); corresponding SAE incidence per hundred patients was 20.6 vs. 31.4, a relative reduction of about one-third. **Conclusions:** CANKADO is well accepted and used regularly by pts in PreCycle, so far over a 2-year period. The present (unplanned) analysis suggests a potentially substantial, clinically relevant reduction in relative SAE incidence among 1stL pts using PRO-React, with a more modest decrease overall. This analysis is preliminary, representing a snapshot, and cannot provide a definitive explanation for the observed SAE reduction. PreCycle will continue to enroll patients in order to further evaluate the potential benefits of interactive eHealth support. 2084 Poster Session (Board #76), Fri, 8:00 AM-11:00 AM

Administration of immune checkpoint inhibitors using teleoncology model of care in Far North Queensland: A multicenter review of safety outcomes. *First Author: James Fletcher, Liz Plummer Cancer Centre, Cairns and Hinterland Hospital and Health Service, Cairns, QLD, Australia*

Background: The Teleoncology model of care, as developed and implemented across health services in Far North Queensland (Australia), improves access to specialist oncology services, including telehealth supervised administration of Oncology drugs for patients in rural/remote towns. There is limited published data regarding the safety of checkpoint inhibitor immunotherapy when it is administered via Teleoncology. Aim: Evaluate safety of immunotherapy administration via Teleoncology, including immune-related adverse events (irAE), treatment delays, hospital admissions and interhospital transfers, in comparison to a retrospective control population. **Methods:** Retrospective review of all patients treated with immunotherapy via Teleoncology as part of Cairns and Hinterland Hospital and Health Service (CHHHS) and the Townsville Teleoncology Network (TTN) between January 2015 and April 2019. A retrospective cohort treated at Townsville Cancer Centre over the same time period was used as a control group. **Results:** Fifty-one patients received a total of 624 cycles of immunotherapy (all single agent anti-PD-1/L-1) via Teleoncology. The control population included 142 patients who received 1697 cycles of immunotherapy. Baseline characteristics were well matched between groups. Compared to the control population, patients treated via telehealth did not have statistically significant differences in the rate of Grade 3+ irAE (13.7% v 8%), hospital admissions (13.7% v 7.4%) or protocol suspensions due to immune toxicity (16% v 10%). One patient with Grade 3+ irAE required interhospital transfer for investigation and management, which occurred within 24 hours of presentation to hospital. There were no treatment-related mortalities in either group. **Conclusions:** Checkpoint inhibitor immunotherapy can safely be delivered using the Teleoncology model of care in rural and remote centres. The incidence of toxicity for single agent immunotherapy was predictably low and not significantly different between groups, however the numbers in this retrospective study were small. The time to recognition and management of immune mediated toxicity in rural and remote centres is an important factor that was not assessed in this study and will be considered in future work. Research Sponsor: None.

2085 Poster Session (Board #77), Fri, 8:00 AM-11:00 AM

TeleTriage at a high-volume specialty cancer center: Aligning patient volume and need with available resource. *First Author: Stutman E Robin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The Memorial Sloan Kettering (MSK) Urgent Care Center (UCC) functions as the emergency room for MSK. With 23,000+ visits annually, increasing volume and acuity means more days over capacity. Patients experience increased wait times to see clinicians, complete evaluation, and transfer to an inpatient bed. The UCC TeleTriage Program is a remote triage program which aims to align patient volume and need with available resources, improve patient experience, and streamline flow through the UCC. By managing resources more efficiently and expediting initial evaluation, the program promotes timely patient access to care, while maintaining MSK's standard of care. **Methods:** UCC TeleTriage began July 2018 with the Gastrointestinal Medical Oncology service. The Service Nurse refers patients to TeleTriage on weekdays, from 9a.m.- 4:30p.m. The TeleTriage clinician contacts each patient within 30 minutes of referral, takes the history, and determines the initial plan. Patients are directed to a local ER, clinic, or UCC based on level of acuity, real-time GPS, and specific need. For stable patients coming to UCC, TeleTriage focuses on initiating testing prior to registration in UCC. **Results:** TeleTriage patients have (virtual) contact with a UCC clinician within 30 minutes of referral, whereas non-TeleTriage patients wait 110 minutes or more. TeleTriage patients are discharged from UCC up to 42 minutes more rapidly. TeleTriage patients who receive imaging prior to registration in UCC receive a final disposition up to 93 minutes sooner. About 4% of TeleTriage patients are managed at home. In a small number of TeleTriage patients with severe complications of cancer-treatment, significant morbidity was avoided due to early intervention and coordination of care. **Conclusions:** TeleTriage patients have contact with a UCC clinician measurably faster than non-TeleTriage patients. Their evaluation is also started earlier. By managing less acute patients at remote sites or at home, TeleTriage can help patients avoid unnecessary travel, (time) expenditure, and hospital contact. TeleTriage patients who come to UCC, spend less time in UCC than non-TeleTriage patients and they discharge faster. By utilizing cancer care expertise, TeleTriage can significantly impact patient outcomes and utilize resources more effectively. Research Sponsor: Memorial Sloan Kettering Cancer Center.

TPS2086 Poster Session (Board #78), Fri, 8:00 AM-11:00 AM

Implementing a clinical risk prediction tool for patients undergoing active cancer treatment. *First Author: Nathan Handley, Thomas Jefferson University, Philadelphia, PA*

Background: Acute care utilization (ACU), encompassing both emergency department visits and hospitalizations, is common in patients with cancer, with nearly three quarters of patients with advanced disease hospitalized at least once in the year after their diagnosis. Efforts to prospectively identify these patients prior to ACU have led to the development of a variety of scoring systems for specific cancer patient populations, including the elderly and those initiating palliative infusional chemotherapy. Prospectively identifying patients may enable early interventions to reduce ACU. However, few studies have demonstrated effective implementation of such prediction tools in clinical practice. We developed an oncology risk score (ORS) for active oncology patients (defined as patients with an active cancer diagnosis in the last 12 months who had a Medical Oncology encounter in a 180-day period) to prospectively determine risk of ACU. Patients are defined as high risk (18% of patients, accounting for 57% of historical ACU), intermediate risk (25% of patients, accounting for 25% of ACU), or low risk (56% of patients, accounting for 18% of ACU) by the ORS. We are currently deploying a pragmatic implementation initiative to evaluate the impact of targeted nurse navigator (NN) outreach to patients defined as high risk for ACU by the ORS. **Methods:** The ORS is embedded within the health system electronic medical record. The ORS will be queried on a weekly basis. NNs will contact identified patients, prioritizing patients not yet identified by the navigation team by other means. Following chart review, NNs will either meet patients in person (if a visit is already planned within 24 hours) or complete standard navigation outreach and documentation (consisting of phone call and barrier assessment, as well as appropriate nursing intervention) if no visit is planned. NNs will determine follow up cadence based on clinical judgement. Efficacy will be determined using a case-control method. Case patients will be OCM patients defined as high risk by the ORS (historical n = 289); control patients will be non-OCM high risk patients (historical n = 388). The total number of patients in the case and control groups, as well as the proportion of patients in the group utilizing acute care, will be monitored over time. Proportion of high risk patients known to navigation will be tracked. ACU in medium and low risk groups will also be monitored. Targeted outreach to high risk patients using the ORS began on 2/5/2019. Research Sponsor: None.

TPS2087 Poster Session (Board #79), Fri, 8:00 AM-11:00 AM

A multi-stakeholder platform to prospectively link longitudinal real-world clinico-genomic, imaging, and outcomes data for patients with metastatic lung cancer. *First Author: Michael W Lu, Genentech, Inc., South San Francisco, CA*

Background: Making personalized diagnostics and treatments a reality for every cancer patient necessitates comprehensively capturing the patient journey. Real-world data has shown promise for the future of clinical research and advancing precision medicine. However, certain limitations exist such as data quality management as well as bias and confounding factors associated with retrospective analyses. We present a multi-stakeholder platform to prospectively collect and link real-world clinico-genomic, imaging, and outcomes data to longitudinal blood genomic profiling for lung cancer. **Methods:** This study is enrolling approximately 1000 patients with metastatic non-small cell lung cancer or extensive-stage small cell lung cancer who will initiate standard-of-care systemic anti-neoplastic treatment, regardless of line of therapy, at 20 community oncology and academic practices within the Flatiron Health network. Relevant clinical data points from both structured and unstructured fields will be collected through the electronic health records via technology-enabled abstraction, eliminating the need for case report forms. Digital pathology and clinical images at standard-of-care visits will be collected. Blood samples for circulating tumor DNA (ctDNA) profiling using FoundationOne Liquid will be collected at three timepoints: enrollment, first tumor assessment, and end of treatment. Tumor tissue samples may be submitted at baseline for genomic profiling using FoundationOne CDx. Overall survival follow-up will occur until death, withdrawal of consent, loss to follow-up, or end of study. The objectives are to evaluate 1) the feasibility of building a scalable, prospective platform and 2) the associations between ctDNA and real-world clinical outcomes, including overall survival. Enrollment is ongoing. Clinical trial information: NCT04180176. Research Sponsor: Genentech, Inc.

TPS2088 Poster Session (Board #80), Fri, 8:00 AM-11:00 AM

Technology-enabled longitudinal monitoring of patient-reported outcomes (PROs) to individualize care of immune-related adverse events (irAEs) in patients (pts) treated with immune checkpoint inhibitors (ICIs). *First Author: Pavlos Msaouel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ICIs have become the therapeutic standard for many cancers but are associated with unique and diverse irAEs that often occur at home. Appropriately timed and specific interventions are critical to recovery. Thus, there is a need to effectively & efficiently monitor in real time pts treated with ICIs. To improve outcomes, we have activated a clinical trial developed to determine the feasibility and safety of an electronically enabled strategy to remotely monitor symptoms and prompt communication that will guide and inform specific patient-driven "course corrections" in response to potential irAEs. **Methods:** This is an adaptive prospective trial that uses a mobile irAE-specific PRO application we developed to monitor and alert the care team in real time when severe symptoms are reported. In parallel with the mobile symptom collection, serum and urine biomarkers are collected at baseline, first tumor restaging, and upon the development of irAEs. Optional stool microbiome analyses are also performed. To facilitate the generalizability of our inferences, we are using broad inclusion criteria: ECOG performance status $\leq$3; any line of ICI given as standard of care or as part of therapeutic clinical trials; elderly pts are included. Because the relationship between PROs and irAEs is currently undefined, we designed our trial to use adaptive symptom thresholds that will notify the healthcare team of suspicion for irAEs. The mobile application will use these dynamic thresholds to determine whether or not to alert the healthcare team. The positive and negative predictive value of each symptom for identifying subsequent irAEs will be assessed at scheduled interim analysis time points. The care teams' responses to the alerts, and all of the clinical outcomes for the pts over time will be collected as part of the trial. The primary goal of the trial is the assessment of the predictive power of the mobile PRO symptom collection in combination with serum and urine markers to identify grade 2 or higher adverse events that require intervention (e.g., dose modifications, hospitalizations, and therapeutic interventions) within two weeks of symptom onset. Effective remote monitoring of irAEs will leverage our understanding of ICI toxicity and empower pts to be effective partners in their care. The trial has currently enrolled 17 pts towards the enrollment target of 100 pts. Clinical trial information: PA19-0095. Research Sponsor: Project Ronin.

TPS2089 Poster Session (Board #81), Fri, 8:00 AM-11:00 AM

ApricityRx companion digital therapeutic for evidence-based mitigation and phenotype-linked molecular characterization of irAEs in patients receiving immune checkpoint therapy (ICT). *First Author: Matthew T Campbell, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Presentation of immune-related adverse events (irAEs) is heterogeneous and unpredictable in patients receiving immune checkpoint therapy (ICT). ICT has been approved for cancer patients as single agent, combination of dual ICT, ICT plus chemotherapy, and ICT plus targeted therapy. Given the ever increasing complexity in recognizing and managing irAEs, coupled with the lack of skilled resources and clinical experience in real world practice, there is increasing demand for digital solutions that can detect early toxicity and support evidence-based interventions in real world practice. To this end, we have developed ApricityRx, a companion digital therapeutic for end-to-end irAE management. In addition to (i) teaching patients about immune-related toxicities and (ii) empowering them to monitor key symptoms and vital signs, ApricityRx continuously analyzes the combined patient-reported data and longitudinal EMR data to (iii) detect symptom-triggers and lab test-triggers of irAEs, and (iv) activate the clinical team to triage, evaluate and treat in a timely fashion, while (v) providing access to synthesized longitudinal patient information and expert guidance on evidence-based management and care. In a feasibility trial conducted in a community setting, we demonstrated two-thirds of the study participants completed on average 5 eCheck-ins per calendar week (overall average 4 times per week), with 5% of the check-ins resulting in notifications alerting the clinical team to evaluate for the early signs of an irAE. **Methods:** To accelerate translational research in irAEs and to develop predictive biomarkers for risk stratification, we are launching a single-arm, open-label study that utilizes ApricityRx in patients receiving ICT alone or in combination. The objectives of the study will include (i) defining the operative characteristics of ApricityRx as an irAE mitigation strategy; (ii) identifying patients and time points for phenotype-triggered biospecimen collection and molecular characterization. The study aims to enroll initially up to 100 participants per site, with a total target of 1,000. Research Sponsor: Apricity Health.

2500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized phase III study of high-dose methotrexate and whole brain radiotherapy with or without concomitant and adjuvant temozolomide in patients with newly diagnosed primary central nervous system lymphoma: JCOG1114C. *First Author: Kazuhiko Mishima, Saitama Medical University International Medical Center, Hidaka-shi, Saitama, Japan*

Background: Temozolomide (TMZ) is an oral alkylating agent that penetrates the blood-brain barrier with moderate toxicity, and has shown anti-tumor activity in primary central nervous system lymphoma (PCNSL) in single arm studies. Our goal was to determine whether the addition of concomitant and adjuvant TMZ chemotherapy to standard treatment of high-dose methotrexate (HD-MTX) and whole brain radiotherapy (WBRT) for PCNSL improves survival in a randomized controlled trial. **Methods:** We did an open-label, randomized phase III trial at 30 hospitals in Japan enrolling immunocompetent patients (pts) aged 20-70 years with histologically confirmed newly diagnosed PCNSL. Pts enrolled at step 1 registration received HD-MTX (MTX; 3.5 g/m^2 at day 1, 15, 29). Pts who received at least 1 cycle of HD-MTX were randomly assigned (1:1) at step 2 registration to receive WBRT (30 Gy) ± 10 Gy boost (control arm: A) or WBRT ± boost with concomitant TMZ (75 mg/m^2 daily) and adjuvant TMZ (150-200 mg/m^2 daily for 5 days every 28 days) for two years after initiation of HD-MTX or until tumor progression (experimental arm: B). Randomization was adjusted by institution, PS (0-1 / 2-3), age (≤60/≥61 years), presence or absence of intraparenchymal tumor after HD-MTX. The primary endpoint was overall survival (OS). The planned sample size was 130 pts in total, to provide an 80% power to detect a 0.52 hazard ratio (65% vs 80% in 2y-OS) for arm B to A and a one-sided alpha of 5%. **Results:** Between September 29, 2014 and October 15, 2018, 134 pts were enrolled, of whom 122 were randomly assigned and analyzed; 62 to arm A and 60 to arm B. At the planned interim analysis, the 2-y OS was 86.8% (95% CI: 72.5-94.0) in arm A and 71.4% (56.0-82.2) in arm B. The hazard ratio was 2.18 (95% CI: 0.95 to 4.98) with predictive probability for showing the superiority of arm B at the final analysis was calculated to be 1.3%. The study was terminated due to futility. The 2-y progression-free survival was 60.6% (43.6-73.8) in arm A and 49.9% (34.4-63.5) in arm B with a hazard ratio of 1.54 (0.88 to 2.70). The most common grade 3 and 4 toxicities were lymphopenia, observed in 7 (11.5%) pts during WBRT in arm A, 18 (30%) pts during WBRT + concomitant TMZ and 18 (37.5%) pts during adjuvant TMZ in arm B. **Conclusions:** This study failed to demonstrate the benefit of the addition of TMZ to WBRT and adjuvant TMZ in newly diagnosed PCNSL. Possible biomarkers including methylation status of the MGMT promoter in the tumors will be analyzed. Clinical trial information: jRCTs031180207. Research Sponsor: AMED.

2501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Randomized phase II study of rituximab, methotrexate (MTX), procarbazine, vincristine, and cytarabine (R-MPV-A) with and without low-dose whole-brain radiotherapy (LD-WBRT) for newly diagnosed primary CNS lymphoma (PCNSL). *First Author: Antonio Marcilio Padula Omuro, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: MTX-based chemoradiotherapy is effective in PCNSL, but carries a risk of severe neurotoxicity (NT), especially in the elderly. In a phase II single arm study, R-MPV-A chemotherapy was combined with substantially reduced doses of radiotherapy (23.4 Gy), achieving prolonged progression free survival (PFS) and overall survival (OS) with acceptable NT. Because R-MPV-A had never been tested without radiotherapy, we conducted a randomized study to determine if the low doses of radiation played a role in the observed disease control, and to characterize NT as compared to chemotherapy alone. **Methods:** Patients were stratified by MSK RPA class and randomized to receive R-MPV-A with LD-WBRT (chemoRT arm) versus R-MPV-A alone (chemo arm). MTX dose was 3.5g/m2 infused over 2 hours. Filgrastim and pegfilgrastim support was given to all patients. LD-WBRT dose was 23.4 Gy (1.8 Gy X 13). The primary endpoint was intent-to-treat (ITT) PFS. A sample size of 89 would provide 80% power to detect a hazard ratio (HR) of 0.63, with one-sided alpha level of 0.15. **Results:** A total of 91 patients were randomized, of whom 4 were ineligible. Among eligible patients, 43 were enrolled in the chemoRT arm and 44 in the chemo arm. Median age was 66 (chemoRT) and 59 (chemo). Median KPS was 80 for both arms. Response rates following R-MPV were 81% (chemoRT) and 83% (chemo). In the chemoRT arm, 37 patients (86%) received LD-WBRT. After median follow-up of 55 months (m), the median ITT PFS was 25 m in the chemo arm and not reached in the chemoRT arm (HR 0.51; 95% CI [0.27, 0.95]; p = 0.015). The 2-year PFS was 54% (chemo) and 78% (chemoRT). Salvage radiotherapy has been given to 11 patients in the chemo arm. Median OS was not reached in either arm, with data still maturing. In both arms, most common grades 3 or 4 toxicities were anemia (27%), lymphopenia (41%), neutropenia (35%), thrombocytopenia (26%), ALT (23%) and AST (13%). One patient died from sepsis (chemo arm). As per investigators' assessment, the rate of clinically defined moderate to severe NT was 11.4% (chemo) and 14% (chemoRT), p = 0.75. **Conclusions:** The study met the primary endpoint, demonstrating the addition of LD-WBRT to R-MPV-A improves PFS in newly diagnosed PCNSL. As per investigator's assessment, NT rates were not statistically significantly increased, but further neuropsychological testing and neuroimaging analyses are ongoing to characterize cognitive decline and how it compares to other consolidation treatments. Clinical trial information: NCT01399372. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

2502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Alliance A071401: Phase II trial of FAK inhibition in meningiomas with somatic NF2 mutations. *First Author: Priscilla Kaliopi Brastianos, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Patients with progressive or recurrent meningiomas have limited treatment options. Clinical trials of systemic therapies for meningiomas have failed to demonstrate benefit. FAK inhibition has a synthetic lethal relationship with NF2 loss. Given the predominance of NF2 mutations in meningiomas, we evaluated the efficacy of GSK2256098, a FAK inhibitor, as part of the first genomically-driven phase II study in recurrent or progressive grade I-III meningiomas. **Methods:** Eligible patients (pts) whose tumors screened positively for NF2 mutations were treated with GSK2256098 750mg po bid until progressive disease in 2 separate cohorts: grade I or II/III meningiomas. Two co-primary endpoints were used: progression-free survival at 6 months (PFS6) and response rate (RR) by Macdonald criteria; per study design, the trial would be declared positive if either endpoint was met. RR was evaluated across the overall cohort; PFS6 was evaluated within each subgroup. Historical benchmark data was obtained from Kaley et al. Neuro Oncol 2014. In the grade I group, 12 evaluable pts provided >79% power to detect a PFS6 rate >65% (vs. null hypothesis of 25%; alpha=0.014). In the grade II/III group, 24 evaluable pts provided >85% power to detect a PFS6 >41.5% (vs. null 15%; alpha=0.02). The threshold for promising results for PFS6 was: 7+/12(grade I) and 8+/24(grade II/III) pts. For RR, 36 evaluable pts provided >94% power to detect RR >20% (vs. null 2.5%; alpha= 0.012). **Results:** Of 322 pts screened for all mutation cohorts of the study, 36 eligible and evaluable pts with NF2 mutations were enrolled. Across all grades, one pt had a partial response and 24 had stable disease as best response to treatment. In Grade I pts, the observed PFS6 rate was 83% (10/12 pts; 95% CI: 52-98%). In Grade II/III pts, the observed PFS6 rate was 33% (8/24 pts; 95% CI: 16-55%). The study met PFS6 efficacy endpoint both for the Grade I and the Grade II/III cohorts. Treatment was well tolerated. Only 7 patients had a maximum grade-3 adverse event that was at least possibly related to treatment; toxicities across these pts included: proteinuria (2), rash (1), pain (1), ALT (1), AST (1), cholecystitis (1), hypertriglyceridemia (1), apraxia (1), and lymphopenia (1) with no grade 4 or 5 events. **Conclusions:** GSK2256098 had excellent tolerability andresulted in an improved PFS6 rate in pts with recurrent or progressive NF2-mutated meningiomas. Trial endpoint was met. FAK inhibition warrants further evaluation in this patient population. Support: U10CA180821, U10CA180882; https://acknowledgments.alliancefound.org Clinical trial information: NCT02523014. Research Sponsor: U.S. National Institutes of Health.

2503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

The role of tumor markers for relapse detection in central nervous system non-germinomatous germ cell tumors (CNS-NGGCT): A pool analysis of cooperative group clinical trials. *First Author: Adriana Fonseca, The Hospital for Sick Children, Toronto, ON, Canada*

Background: CNS-NGGCT are rare tumors that have been successfully treated with multimodal therapies. With a 5-yr EFS and OS of 72-84% and 82-93% respectively, surveillance and relapse detection is essential. Tumor marker (TM) elevation has proven to be a highly sensitive method of relapse detection in extracranial-NGGCT. We aim to determine the role of TM for relapse surveillance in children and adolescents with CNS-NGGCTs. **Methods:** European and North American data from germ cell tumor trials (SIOP GCT96, SFOP-TGM TC 90/92, COG-ACNS0122 and COG-ACNS1123) were pooled for analysis. Additionally, patients treated in the UK, Germany and France under strict protocol-guidelines were included. Details regarding imaging, pathology and TM elevation at diagnosis and relapse were collected. We report the proportion of relapses detectable by TM elevation. **Results:** Four-hundred and eighty-four patients enrolled in prospective cooperative group CNS-NGGCT trials from 1989 to 2016 were pooled for analysis. One-hundred and thirteen (23%) patients experienced a relapse/progression (SIOP GCT96: n = 57; SFOP TGM TC 90-92 n = 23, COG-ACNS0122 n = 16 & COG-ACNS1123 n = 17) and constitute the population of this report. Median age at diagnosis was 13 (range:1-30) years. The most common primary location was pineal in n = 60 (53%) patients. The site of relapse was available for 100 patients, 48 patients relapsed locally, 36 relapsed with distant disease, combined relapses were seen in 22 patients and 4 patients relapsed with TM elevation alone. TM in serum and/or CSF at diagnosis was available in 93(82%) patients, and in 90(80%) patients at the time of relapse. Eighty-four patients had TM available at both timepoints. At diagnosis 81 (96%) patients had TM elevation and 3 (4%) had negative TM. At relapse, 74(94%) patients with positive TM at diagnosis had TM elevation, while 7(6%) had TM negative. Conversely, 2/3 patients with negative TM at diagnosis, relapsed with elevated TM. **Conclusions:** Herein, we have assembled the largest prospective cohort to date of relapsed intracranial germ cell tumors. TM are highly sensitive detecting relapse/progression in CNS-NGGCT patients with elevated TM at diagnosis. The routine use of TM for relapse surveillance in patients with CNS-NGGCT can decrease the frequency of cross-sectional imaging, therefore, reducing lengthy hospital visits, sedation procedures and decreasing health-care costs. 2504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Vorasidenib (VOR; AG-881), an inhibitor of mutant IDH1 and IDH2, in patients (pts) with recurrent/progressive glioma: Updated results from the phase I non-enhancing glioma population. *First Author: Ingo K. Mellinghoff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Isocitrate dehydrogenase 1 and 2 mutations (m*IDH1/2*) occur in approximately 70% and 4% of low-grade gliomas (LGGs), respectively, promoting oncogenesis via increased production of D-2-hydroxyglutarate. In this ongoing phase 1 trial, VOR, a potent, oral, reversible, brain-penetrant, first-in-class dual inhibitor of mIDH1/2, is being evaluated in advanced m*IDH1/2* solid tumors, including gliomas. Safety and preliminary results were presented previously (Mellinghoff et al., J Clin Oncol 2018). Here, we report updated data for the non-enhancing glioma pt population. **Methods:** Pts with recurrent/progressive m*IDH1/2* glioma received VOR daily (continuous 28-day cycles). Key eligibility criteria included: ≥18 years; histologically or cytologically confirmed glioma with documented m*IDH1/2*; ECOG 0-2; and evaluable disease by RANO-LGG criteria. Dose escalation cohorts enrolled using a Bayesian logistic regression model (BLRM) escalation guided by the overdose control (EWOC). Tumor response was evaluated by MRI every 8 weeks using RANO-LGG criteria by local assessment. **Results:** As of 28 Nov 2019, 22 pts with non-enhancing glioma had received VOR and 8 (36%) remain on treatment. M/F, 8/14; grade 2/3, 17/5; median age, 47 years; m*IDH1/2*, 20/1; 1p19q intact, 9/22; median (range) number of prior systemic therapies, 2 (1–4). Common (≥5 pts) treatment-emergent adverse events (AEs) of any grade and regardless of causality included increased ALT/AST (63.6%/59.1%), headache (45.5%), nausea (40.9%), neutropenia (31.8%), fatigue and hyperglycemia (27.3% each), and seizures and decreased white blood cell count (22.7% each). Transaminase elevations were grade 1 in severity at dose levels < 100mg and were less frequent (5 [38.5%] of 13 pts). Three subjects had related grade ≥3 AEs; 2 discontinued due to AEs. Objective response rate was 13.6% (1 partial response, 2 minor responses), and 17 (77.3%) pts achieved stable disease. 60.5% of pts were progression free and alive at 24 months. **Conclusions:** In this previously treated population with non-enhancing glioma, VOR was associated with a favorable safety profile. The study results also show encouraging preliminary activity within that population, with PFS duration extending to 24 months or longer in 60% of participants. A global randomized phase 3 study of VOR in grade 2 non-enhancing glioma pts who have had surgery only is currently enrolling (NCT04164901). Clinical trial information: NCT02481154. Research Sponsor: Agios Pharmaceuticals, Inc.

2505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase Ib/II study of olutasidenib in patients with relapsed/refractory IDH1 mutant gliomas: Safety and efficacy as single agent and in combination with azacitidine. *First Author: Macarena Ines De La Fuente, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL*

Background: Isocitrate dehydrogenase 1 mutations (mIDH1) are present in >70% of patients with Grade II/III gliomas resulting in production and accumulation of (R)-2-hydroxyglutarate causing DNA hypermethylation and promoting tumorigenesis. Olutasidenib is an oral, potent, brain penetrant (Kpuu=0.4 in intact rodent), and selective inhibitor of mutated IDH1 protein. **Methods:** Patients (pts) with relapsed/refractory (R/R) mIDH1 gliomas received olutasidenib 150 mg BID, orally either as single agent (SA) or in combination (CO) with azacitidine in a dose confirmation phase Ib followed by efficacy evaluation phase II study (NCT: 03684811). **Results:** As of 31-Oct-2019, 29 pts with R/R mIDH1 glioma were treated with olutasidenib as SA (n=24) or CO (n=5). The median age was 45 yrs (range: 23-64) & 62% were male. WHO Glioma Grade (Gr) at study entry was: II (17%), III (52%) & IV (31%). Median number of prior treatments was 2 (1-5); 86% had received prior temozolomide. mIDH1 status was locally determined (IHC, NGS or PCR): R132H (86%), R132L (7%), R132C (3.5%) & unspecified (3.5%). The median duration of olutasidenib treatment for SA & CO was 4.8 (1-11.4) & 1 (0.2-2.3) months, respectively. Fifteen pts discontinued (disease progression [n=12], AE [n=1], withdrew consent [n=1], other [n=1]). For SA, the most common (>25%) TEAEs (all grades, regardless of attribution) were: fatigue (50%), nausea (50%), diarrhea (33%), ALT increase (29%) & headache (29%). For CO, TEAEs that occurred in ≥ 2 pts were: nausea (n=4), fatigue (n=2), neutropenia (n=2), ALT increase (n=2) & AST increase (n=2). There were 2 protocol defined DLTs in the CO cohort, 1 pt with Gr 4 ALT, Gr 3 AST & Gr 3 GGT elevations & 1 pt with Gr 3 ALT elevation. No pts experienced a TEAE of QTcF prolongation. SA best responses are shown in Table; CO pts are too early for response assessment. The median PFS for SA was 8.3 months. Twenty (87%) and 11 (48%) pts were alive and progression-free at 6 & 12 months, respectively. **Conclusions:** SA olutasidenib at 150 mg BID demonstrates acceptable safety and tolerability with preliminary clinical activity in glioma pts. Evaluation of CO is ongoing. Updated safety and clinical activity, as well as evaluations of serum/CSF PK/PD will be provided. Clinical trial information: NCT03684811. Research Sponsor: FORMA Therapeutics, Inc.

2506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Temozolomide-induced hypermutation is associated with high-grade transformation, distant recurrence, and reduced survival after transformation in initially low-grade *IDH*-mutant diffuse gliomas. *First Author: Nancy Ann Oberheim Bush, University of California San Francisco, San Francisco, CA*

Background: Temozolomide, a commonly used alkylating agent to treat gliomas, can induce somatic hypermutation. The prevalence and clinical implications of this phenomenon are not well characterized. **Methods:** We used targeted and whole exome sequencing from a cohort of 82 patients with recurrent *IDH*-mutant low grade gliomas undergoing re-operation to evaluate the prevalence as well as the clinical implications of hypermutation. **Results:** Hypermutation was identified at transformation in 57% of recurrent gliomas exposed to Temozolomide, 94% of which were transformed to higher WHO grades. All patients who developed hypermutation were exposed to Temozolomide. Hypermutation was associated with transformation to higher WHO grade (OR 12.0 95% CI 2.5 – 115.5, p = 0.002) and shorter survival after transformation (HR 2.1, 95% CI 1.1-4.0, p = 0.018) compared with non-hypermutated transformed tumors, controlling for grade, molecular subtype, age, and prior radiotherapy. Patients with transformation to glioblastoma had poor survival regardless of hypermutation (p = 0.78). Hypermutated tumors were associated with development of discontiguous disease at a significantly higher frequency (p = 0.003), including four cases with spinal dissemination. **Conclusions:** TMZ-induced hypermutation is associated with high grade transformation, unique patterns of dissemination and shortened survival after transformation. Next generation sequencing should be considered in this patient population. These data have important implications for the management of newly diagnosed and recurrent *IDH*-mutant low grade gliomas. Research Sponsor: U.S. National Institutes of Health.

2507 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Utilizing phenotypic characteristics of metastatic brain tumors to predict the probability of circulating tumor DNA detection from cerebrospinal fluid. *First Author: Meichen Li, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Brain metastases occur in approximately 20% of tumor patients and is often associated with terminal events and poor prognosis. Cerebrospinal fluid (CSF) can be a promising source for detecting circulating tumor DNA (ctDNA) specific to the central nervous system (CNS) instead of peripheral blood due to the blood-brain barrier. However, CSF's suboptimal ctDNA detection rate might limit its clinical application. Precise screening of suitable patients is needed to maximize clinical benefit. **Methods:** We sequenced 425 cancer-relevant genes in CSF and matched extracranial tissue or blood samples obtained from 67 lung cancer patients with brain metastases. The impact of clinical factors, including age, gender, tumor size, number of lesions, and distance of lesions to the ventricle on CSF ctDNA detection was then evaluated by univariate logistic regression. To predict the probability of successful CSF ctDNA detection, best subsets regression was employed for feature selection and cross validation was used for performance assessment to determine the final model. **Results:** We detected somatic alterations in 39/67 (58%) CSF ctDNA, 57/66 (86%) plasma ctDNA and 45/49 (92%) tissue samples. Mutation detection rate of CSF ctDNA was significantly lower than that from extracranial tissue and plasma ($P < 0.001$). Univariate analysis revealed significant association ($P < 0.05$) of high CSF ctDNA detection rate with the following features: (1) intracranial lesion size (*T*), (2) shortest distance between the largest lesion and the ventricle (D_{top}), and (3) shortest distance between all intracranial lesion and the ventricle (D_{all}). We also revealed a trend of higher detection rate in patients with CNS symptoms (S_{CNS}). Subsequent best subsets analysis and cross validation suggested best prediction power with lesion size and largest lesion-ventriclar distance (area under curve [AUC], 0.76 [95% CI, 0.71 to 0.85]; accuracy, 0.75 [95% CI, 0.70 to 0.81]). Final probability can then be derived from $Logit\ P = 0.11 \times T - 0.16 \times D_{all}$ (AUC, 0.82; sensitivity, 0.91; specificity, 0.74). The detection of CSF ctDNA was significantly improved from 58% to 83% (P = 0.03) based on the model. **Conclusions:** This study established a regression model to predict the probability of CSF ctDNA that can be useful to facilitate clinical decisions and avoid excessive practice when monitoring tumor evolution in the brain. Research Sponsor: None.

2508 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

A prospective validation cohort study of baseline plasma cell-free DNA (cfDNA) as a prognostic biomarker in newly diagnosed glioblastoma (GBM). *First Author: Stephen Joseph Bagley, Abramson Cancer Center, Philadelphia, PA*

Background: Due to significant interpatient heterogeneity, survival outcomes vary widely in patients with GBM. Novel prognostic biomarkers are needed. We aimed to determine the prognostic impact of baseline plasma cfDNA concentration in patients with GBM. **Methods:** We analyzed 84 patients with newly diagnosed GBM and at least 7 months of follow-up time. The first 41 patients comprised a previously published derivation cohort (Bagley, Clin Cancer Res 2020). The subsequent 43 patients served as an independent validation cohort. cfDNA was extracted from plasma collected prior to initial surgical resection and quantified by qPCR for a 115 bp amplicon of the human ALU repeat element. Receiver operating characteristic (ROC) curve analysis was used in the derivation cohort to (1) assess the accuracy of plasma cfDNA concentration for predicting progression-free survival status at 7 months (PFS-7), a landmark based on the median PFS for newly diagnosed GBM (Stupp, N Engl J Med 2005), and (2) derive the optimal cutoff for dichotomizing patients into high- and low-cfDNA groups. In the validation cohort, logistic regression was used to measure the association of plasma cfDNA concentration (high vs. low) with PFS-7, adjusted for age, isocitrate dehydrogenase (*IDH)* 1/2 mutational status, 0-6-methylguanine-methyltransferase (*MGMT*) methylation, extent of resection, and performance status. Multivariate Cox regression was used for overall survival (OS) analysis. **Results:** In the derivation cohort, the optimal cutoff for plasma cfDNA was 25.0 ng/mL (area under the curve [AUC] = 0.663), with inferior PFS and OS in patients with cfDNA above this cutoff (PFS, median 4.9 vs. 9.5 months, log-rank p = 0.001; OS, median 8.5 vs. 15.5 months, log-rank p = 0.03). In the validation cohort, baseline plasma cfDNA concentration over the cutoff was independently associated with a lower likelihood of being alive and progression-free at 7 months (adjusted OR 0.13, 95% CI 0.02 – 0.75, p = 0.02). OS was also worse in in the validation cohort in patients with high plasma cfDNA (adjusted HR 3.0, 95% CI 1.1 – 8.0, p = 0.03). **Conclusions:** In patients with newly diagnosed GBM, high baseline plasma cfDNA concentration is associated with worse survival outcomes independent of other prognostic factors. Further validation in a larger, multicenter study is warranted. Research Sponsor: U.S. National Institutes of Health.

2509 Clinical Science Symposium, Fri, 8:00 AM-9:30 AM

Single cell mapping of human brain tumors reveals tumor-specific education of tissue-invading leukocytes. *First Author: Ekaterina Friebel, Institute of Experimental Immunology, University of Zürich, Zürich, Switzerland*

Background: Brain tumors can be both of intracranial origin (e.g. gliomas) or spread from another location in the body (metastases). Tumor growth in the CNS is commonly favored by a highly immunosuppressive tumor microenvironment (TME). Whether the TME is predominantly shaped by the CNS microenvironment or by the nature of the malignancy is unknown, as is the origin and function of CNS tumor-associated macrophages (TAM). **Methods:** We have mapped the leukocyte landscape of brain tumors using high-dimensional profiling with mass cytometry (CyTOF). We designed two CyTOF panels (one lymphoid and one myeloid focused) measuring 74 parameters at the single-cell level and analyzed samples from 47 individuals with the most common tumor entities being glioblastoma and metastases from melanoma and lung cancer as well as control tissue from epilepsy surgery. **Results:** The heterogeneous composition of tissue-resident and invading immune cells within the TME alone permitted a clear distinction between glioblastoma and metastases. Tissue-invading leukocytes accumulate in metastases, whereas gliomas predominantly contain tissue-resident reactive microglia. In gliomas, isocitrate dehydrogenase 1 (IDH1) mutations are associated with minimal host responses whereas IDH1-wildtype gliomas comprise monocyte-derived macrophages (MDM) similar to metastases. These MDM show a distinctive signature trajectory indicative of tumor-driven education. **Conclusions:** The immune cell composition of the brain tumor TME is tumor entity-specific, rather than dictated by the CNS tissue. Defining the distinct immunological signature of brain tumors can facilitate the rational design of targeted immunotherapy strategies. Research Sponsor: None.

Controlled IL-12 in combination with a PD-1 inhibitor subjects with recurrent glioblastoma. *First Author: E. Antonio Chiocca, Brigham and Women's Hospital, Boston, MA*

Background: Monotherapy with intratumoral Ad-RTS-hIL-12 (Ad), a gene therapeutic conditionally expressing IL-12 under the transcriptional control of oral veledimex ("Controlled IL-12"), was shown in a phase 1 study (NCT02026271) to elicit a new and sustained intra-tumoral infiltration of T cells with co-expression of PD-1. We report updated findings following completion of enrollment (with follow-up ongoing) for a phase 1 substudy (NCT03636477) evaluating safety and tolerability of local, Controlled IL-12 in combination with nivolumab (nivo) in adults with recurrent glioblastoma (rGBM). **Methods:** Multicenter, open label, dose-escalation phase 1 trial to evaluate safety and tolerability of local, Controlled IL-12 with nivo in adult subjects with rGBM. Ad was administered by single intratumoral injection (2×10^{11} viral particles, Day 0 at time of resection) plus V (10 or 20 mg) PO QD x 15 with nivo (1 or 3 mg/kg) IV on Days -7, 15, then Q2W. **Results:** 21 subjects were treated (Cohort 1: V 10 mg, nivo 1 mg/kg, n = 3; Cohort 2: V 10 mg, nivo 3 mg/kg, n = 3; and Cohort 3: V 20 mg, nivo 3 mg/kg, n = 3 + 12 expansion). Safety data were similar to Ad+V monotherapy. Adverse reactions during follow-on nivo dosing were consistent with anti-PD-1 labeling, manageable, and generally reversible with no synergistic toxicities. Focusing on the 20mg V cohort (recommended phase 2 *dose)*, serum IL-12 mean ± SEM (screening, 0.4 ± 0.1 pg/mL; Day 0, 0.6 ± 0.1 pg/mL), increased after Ad+V to 8.7 ± 3.3 pg/mL on Day 3. Similarly, serum IFN-g levels did not increase due to nivo alone (screening, 0 ± 0 pg/mL; Day 0, 0 ± 0 pg/mL), increasing after Ad+V to 6.2 ± 2.3 pg/mL on Day 7. Additionally, nivo alone did not significantly increase circulating T cells ($CD3^+$ $CD8^+$%) (paired differences comparison, Day 0 to screening) 3.1%, p =0.13, whereas Ad+V significantly increased peripheral T cells (Day 28 - Day 0) 3.6%, p =0.02. Pseudoprogression followed by a decrease in size (SPD) has been shown as evidenced by serial MRIs in a subgroup of subjects. Preliminary overall survival findings will be presented. **Conclusions:** Controlled IL-12 with PD-1 inhibition is a rational combination with initial data consistent with immune-mediated effects, a favorable safety profile, and early evidence of anti-tumor effects. An additional phase 2 study combining Controlled IL-12 with cemiplimab-rwlc in adults with rGBM is ongoing. Clinical trial information: NCT03636477. Research Sponsor: Ziopharm Oncology.

2511 Poster Discussion Session; Displayed in Poster Session (Board #2), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Phase I/II study to evaluate the safety and clinical efficacy of atezolizumab (atezo; aPDL1) in combination with temozolomide (TMZ) and radiation in patients with newly diagnosed glioblastoma (GBM). *First Author: Shiao-Pei S. Weathers, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: Immunotherapy strategies such as PD-1/PD-L1 inhibition may work synergistically with radiation, which is known to increase antigen presentation and promote a pro-inflammatory tumor microenvironment. This trial evaluated the safety and clinical efficacy of concurrent atezo with radiation therapy and TMZ followed by adjuvant atezo and TMZ in patients with newly diagnosed GBM, unselected for MGMT status. **Methods:** Eligibility criteria included patients with newly diagnosed GBM age > 18 yrs who had undergone only surgery. The primary endpoint was safety in Phase I (n = 10) and OS in Phase II (n = 50). Secondary endpoints included progression free survival (PFS), overall response rate (ORR), and duration of response. All 60 patients were evaluated for efficacy. Correlative endpoints include profiling of tumor immune cell populations and peripheral blood for evaluation of circulating chemokines/cytokines. **Results:** 60 patients were enrolled. With median follow-up time of 16.7 months (data cutoff = 30 Dec 2019), 24 patients had died and 32 had progressed. Median OS was 17.1 months (95% CI: 13.9, not reached). Median PFS was 9.7 months (95% CI: 7.6-15). Median PFS in MGMT methylated patients (n = 18) was 16.7 months (95% CI: 7.85, not reached) and 7.9 months (95% CI: 6.70-12.4) in MGMT unmethylated patients (n = 33). Treatment-related adverse events with maximum CTCAE grade > 3 occurred in 33 patients; the most common were LFT elevation (n = 5) and lymphopenia (n = 23). To date, 17 of the enrolled 60 patients underwent re-resection post treatment with atezo. The matched paired tumor analysis of pre and post treatment tissue will provide valuable insights into mechanisms of anti-PD-L1 therapy resistance. Tumor immunocorrelative studies are pending. **Conclusions:** Concurrent use of atezo with radiation and TMZ was tolerable and demonstrated modest efficacy. Clinical trial information: NCT03174197. Research Sponsor: Genentech.

Updated safety phase I trial of anti-LAG-3 alone and in combination with anti-PD-1 in patients with recurrent GBM. *First Author: Michael Lim, The Johns Hopkins Hospital, Baltimore, MD*

Background: Preclinical GBM data targeting the checkpoint molecule Lag-3 have shown promising anti-tumor immune response with resultant improved survival when combined with anti-PD-1. Here we report our experience from a multi-arm safety study in patients with recurrent GBM treated with anti-Lag-3 and in combination with anti-PD-1. **Methods:** A phase I, open label, multicenter, multi-arm dose-finding/safety study of anti-LAG-3 (BMS-986016) alone or in combination with anti-PD-1 in patients at first recurrence of GBM was carried out in The Adult Brain Tumor Consortium (ABTC) (1501). The primary objectives were safety and to define MTD (DLT rate $<$ 33%) for both the mono and combination arms. The major secondary objective was efficacy. The key inclusion criteria were: adults with first recurrence of GBM following RT+TMZ, TLC$\geq$1000/ul, KPS$\geq$ 60%, on a stable corticosteroid regimen, measurable disease, and written informed consent. Three pre specified dose levels of anti-Lag-3 at 80mg, 160mg, and 800mg were tested. Anti-PD-1was given at a flat dose of 240 mg in combination with anti-LAG-3 at 80 mg and 160 mg. **Results:** To date, the phase I portion of study completed its accrual and 33 patients were enrolled into the anti-LAG-3 alone or in combination with anti-PD-1 arms. The median age and KPS was 56 and 90 respectively. 39% tumors were MGMT methylated and the median treatment cycle was 3. The highest safe dose for Anti-LAG-3 alone is 800 mg without a DLT. Two DLT were observed in combination arms of Anti-LAG-3 +anti-PD-1 (80 mg/240mg), a grade 3 muscle weakness and a grade 4 edema. Three DLTs were observed in the higher Anti-LAG-3 + anti-PD-1 group (160 mg/240mg): grade 3 hypertension, syncope, and edema. 80% of the DLTs occurred after cycle 2 of the treatment. The estimated overall mOS was 8 months. Seven (44%) patients in the combination arm are still alive and 3 out of the 7 are living beyond 20 months suggesting a subset benefit. **Conclusions:** The phase I part of trial has completed enrollment. The MTD is 800mg for anti-LAG-3 as a monotherapy. For the combination arms, 160 mg of Anti-LAG-3 and 240 mg of anti-PD-1 was the MTD. DLTs were late onset events. Clinical trial information: NCT02658981. Research Sponsor: NCI - ABTC, BMS for correlative studies.

MDNA55 survival in recurrent glioblastoma (rGBM) patients expressing the interleukin-4 receptor (IL4R) as compared to a matched synthetic control. *First Author: John H. Sampson, Duke University Medical Center, Durham, NC*

Background: MDNA55 is an engineered IL-4 fused to pseudomonas exotoxin A being developed for GBM, an aggressive, universally fatal disease. No curative therapy exists and 75% of patients are not eligible for resection at recurrence. MDNA55 targets IL4R overexpressed in GBM, the immunosuppressive tumor microenvironment, and high expression is associated with poor survival outcomes in GBM. A Ph 2b trial of MDNA55 was completed in rGBM using convection-enhanced delivery to bypass the BBB. Here we report results from the Ph 2b trial and comparison against a matched Synthetic Control Arm (SCA). **Methods:** MDNA55-05 is an open-label, single-arm study of intratumoral delivery of $\leq$ 240 μg MDNA55 as a single treatment via $\leq$ 4 catheters in *de novo* GBM without IDH1/2 mutation at 1st or 2nd recurrence not eligible for resection, tumors $\leq$ 4 cm, KPS $\geq$ 70. IL4R expression in GBM tissues was determined by H-Score using a validated IHC assay. 1^o endpoint is median overall survival (mOS); 2^o endpoint includes the impact of IL4R status on mOS. An eligibility-matched SCA was identified retrospectively from patient registries at major neurosurgery centers with access to GBM tumor tissue banks under IRB-approved protocols. **Results:** 44 subjects comprise the MDNA55 per protocol analysis population: median age 56 (35 - 77); median dose 177 mg (range 18 – 240 mg), 50% had KPS $\leq$ 80. No systemic toxicities observed, drug-related AEs were primarily neurological and characteristic of GBM, no deaths attributed to MDNA55. Median OS was 11.6 months (95% CI 7.9 – 15.2). When stratified by IL4R expression, mOS in IL4R High (n = 21) was 15 vs. 8.4 months in IL4R Low (n = 19); p = 0.2175. OS12 is 57% vs. 33%. When compared to the SCA (n = 81), MDNA55 subjects survived significantly longer: mOS 12.4 vs. 7.7 months; p = 0.0077. When comparing IL4R High groups, mOS in MDNA55 (n = 21) was 15.8 vs. 6.2 months in the SCA (n = 17); p = 0.0626. Subgroup analysis in unmethylated MGMT subjects also show better survival with MDNA55 (n = 23) than the SCA (n = 31); mOS 12.3 vs. 7.7 months (p = 0.0268), indicating that MDNA55 may be beneficial in patients resistant to temozolomide. **Conclusions:** MDNA55 subjects represent a difficult to treat population (*de novo* GBM, IDH wild-type, not eligible for surgery at recurrence). Single treatment with MDNA55 prolongs survival by nearly 10 months in a subset of rGBM expressing high levels of IL4R when compared to a matched SCA, providing an unprecedented outcome for this highly lethal disease. Clinical trial information: NCT02858895. Research Sponsor: Medicenna Therapeutics, Cancer Prevention & Research Institute of Texas.

INO-5401 and INO-9012 delivered intramuscularly (IM) with electroporation (EP) in combination with cemiplimab (REGN2810) in newly diagnosed glioblastoma (GBM): Interim results. *First Author: David A. Reardon, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Novel T cell-enabling therapies, in combination with checkpoint inhibition, may improve OS in GBM. INO-5401 (synthetic DNA plasmids encoding for hTERT, WT-1 and PSMA), plus INO-9012 (synthetic DNA plasmid encoding IL-12), with the PD-1 checkpoint inhibitor cemiplimab, is given to patients with newly-diagnosed GBM to evaluate tolerability, efficacy and immunogenicity of the combination. **Methods:** Phase I/II, single arm, 2 cohort study (A: MGMT unmethylated, B: MGMT methylated). The primary endpoint is safety; efficacy and immunogenicity are secondary. Nine mg INO-5401 plus 1 mg INO-9012 (every 3 weeks for 4 doses, then Q9W) is given with EP by CELLECTRA 2000 with cemiplimab (350 mg IV Q3W). RT is given as 40 Gy over 3 weeks. TMZ is given with radiation (all patients), followed by maintenance (Cohort B only). **Results:** Fifty two subjects were enrolled: 32 in Cohort A; 20 in Cohort B. 35% women and 90% white. Median age 60 years (range 19-78 years). Common Grade $\geq$3 AEs reported were: platelet count decreased (11.5%), tumor inflammation (7.7%), seizure (7.7%), ALT increased (7.7%), lymphocyte count decreased (7.7.%). One Grade 5 unrelated event of urosepsis was reported. Of 69 SAEs reported there was only 1 related to the combination therapy, Grade 1 pyrexia. 48% of subjects reported irAEs, most frequently ALT increased (9.6%), AST increased (7.7%), diarrhea (7.7%), pyrexia (7.7%) and tumor inflammation (7.7%). 71% of the reported SAEs and irAEs occurred within the first 12 weeks of treatment. OS at 12 months was 84.4% (95% CI 67.2, 94.7) in Cohort A; Cohort B will be presented at ASCO. ELISpot assessments demonstrated T cell responses to INO-5401. Flow cytometry demonstrated evidence of activated INO-5401-specific CD8+T cells with lytic potential (CD38+Prf+GrzA+) when compared with baseline, post-treatment in the majority of patients assayed. **Conclusions:** INO-5401 + INO-9012 in combination with cemiplimab and RT/TMZ has an acceptable safety profile, is immunogenic and may show a survival advantage in patients with newly-diagnosed GBM. OS18 data will be presented later this year. Clinical trial information: NCT03491683. Research Sponsor: Inovio.

A phase I/II clinical trial of autologous CMV-specific T cells in glioblastoma (GBM) patients to reveal a lack of immune effector function. *First Author: Shiao-Pei S. Weathers, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: Cytomegalovirus (CMV) antigens are present in $>$ 90% of GBMs but not in normal brain making it an attractive immunological target. **Methods:** Highly functional autologous polyclonal CMV pp65 specific T cells were expanded under GMP-compliant conditions from GBM patients and administered after 3 weeks of lymphodepleting dose-dense temozolomide (ddTMZ, 100 mg/m^2). The phase I component used a 3+3 design ascending through four dose levels (5 x 10^6 cells to 1 x 10^8 cells). Treatment was repeated every 6 weeks for a total of 4 cycles. Dose expansion was conducted in recurrent GBM patients undergoing resection and in newly diagnosed GBM patients following concurrent chemoradiation. *In vivo* persistence and effector function of the adoptively transferred CMV-specific T cells was determined by dextramer staining and multiparameter flow cytometry in serially-sampled peripheral blood and in the tumor microenvironment. **Results:** 65 patients were screened, 25 underwent leukapheresis, and 20 completed at least 1 cycle. Median age 48 (27-69), 35% were MGMT methylated, and 10% were IDH mutated. No dose limiting toxicities (DLTs) observed. Complete radiographic response was observed in 1 patient, partial responses in 2, stable disease in 9, and progressive disease in 8. The median PFS time was 1.3 months (95% CI: 0-8.3 months) and the median OS time was 12 months (95% CI: 6 months to not reached). Repeated infusions of CMV-TC were associated with significant increase in circulating CMV+ CD8+ T cells, but cytokine production reflective of effector activity (CD107a, TNFα, IFNγ, IL2) was suppressed in these cells including directly from the GBM microenvironment. **Conclusions:** Adoptive infusion of CMV-specific T cells after lymphodepleting ddTMZ was well-tolerated. However, effector function of the adoptively transferred T cells was attenuated indicating further modulation of the T cell is required to prevent its dysfunction prior to proceeding to large scale clinical studies. Clinical trial information: NCT02661282. Research Sponsor: MD Anderson Glioblastoma Moon Shots Program, Other Foundation.

Inefficiencies in the phase II to phase III transition as a modifiable factor that is impeding successful drug development for glioblastoma. *First Author: Adithya Balasubramanian, Olivia Newton-John Cancer Centre, Austin Health, Melbourne, VIC, Australia*

Background: Improving the outcomes of patients with glioblastoma (GBM) represents one of the most significant challenges in neuro-oncology. We have observed inefficiencies in the availability and use of phase 2 data when planning phase 3 studies, and have undertaken a detailed review of key design parameters of phase 2 and 3 trials in GBM to identify and quantify the impact of this phenomenon. **Methods:** Studies between 2005-2019 inclusive were identified though MEDLINE search using keywords and MeSH terms, and manual bibliography searches. P2Ts were restricted to those referenced by the corresponding P3Ts. Clinical, statistical and sponsor characteristics were extracted by two reviewers (AB&AG). For each P3T, corresponding Phase 2 trial (P2T) data was "optimally matched" (OM) where same drug was used in similar schedule and similar GBM population; "partially matched" (PM) where dissimilar schedule and/or treatment setting; and "lacking" in all other circumstances. The statistical data used in the P2/3 transition were compared by Pearson Correlation, Fisher's Exact or Chi-square testing as appropriate. **Results:** Of 20 P3Ts identified, 6 (30%) lacked any phase 2 data. Of the remaining 14 P3T, 9 had 1 prior P2T, 4 had 2 P2T and 1 had 3 P2T, for a total of 20 P3T-P2T pairs (called dyads). Further, there were 13 OM dyads and 7 PM dyads. OM dyads showed strong concordance for mPFS (r^2= 0.95, $p < 0.01$) and mOS (r^2= 0.84, $p < 0.01$), whilst PM dyads did not ($p > 0.05$). We identified several inefficiencies in translation from P2T to P3T. Firstly, 3 P3T had statistical assumptions of primary endpoint that may have been too optimistic. 2 of these P3Ts aimed for an expected endpoint that was higher than the actual outcomes from a matched P2T. 1 P3T was unable to reach the desired sample size. We note that 4 P3Ts had actual primary endpoint HRs that were < 0.9 but with $P > 0.05$. Finally, we investigated whether there were absolute thresholds for efficacy in P2Ts to inform whether to proceed with P3Ts. For P2Ts in the newly diagnosed setting, all those with mPFS $<$ 14 months and/or mOS $<$ 22 months had subsequent negative P3Ts. For P2Ts in recurrent disease, all those with mPFS $<$ 6 months and mOS $<$ 12 months had negative P3Ts. Applying these thresholds to the studies in our review, 10 of the 12 negative P3Ts (83%) with matched P2Ts need not have been initiated, sparing 4739 patients' from unnecessary trial participation. **Conclusions:** Our data strongly supports the vital role of properly designed P2Ts in informing P3Ts for drug development for primary CNS tumours. 4-miRNA signature combined with *MGMT* methylation status in glioblastoma: A multicentric retrospective biomarker analysis with accompanying prospective cohort study. *First Author: Maximilian Niyazi, University Hospital, LMU Munich, Munich, Germany*

Background: Previously, we identified a prognostic 4-miRNA signature (built from let-7a-5p, let-7b-5p, miR-125a-5p and miR-615-5p) in glioblastoma patients treated according to the EORTC26981/22981-NCIC CE3 protocol. We present results of a novel external validation and will report on a completed prospective study on blood plasma samples of glioblastoma patients prior to chemoradiotherapy (CRT). **Methods:** The external validation cohort (n = 103) contained IDH1/2 wildtype tumors with known *MGMT* promoter methylation from the LMU-Munich (n = 37), the University Hospital Düsseldorf (n = 33) and TCGA (n = 33). Risk groups from the combination of miRNA signature with *MGMT* promoter methylation were analyzed for overall survival (OS) and prognostic performance using C-index. Within the prospective study (n = 52), blood samples were taken prior to RT, on d42 and d84 (22 cases analyzed up to now). Risk scores were obtained from signature miRNA expression levels in resection or biopsy specimen (retrospective, endpoint OS) and blood plasma (prospective, PFS). **Results:** The 4-miRNA signature was independent of sex and *MGMT* promoter methylation ($p > 0.1$) and defined high-risk (n = 47, med. OS: 16.4months) and low-risk (n = 56, med. OS: 26.9months) patients (HR: 2.08, 95%CI: 1.25-3.46, p = 0.004). Patients with methylated (med. OS: 23.7months, n = 54) compared to non-methylated *MGMT* promoter (med. OS: 16.8months, n = 49) had superior OS (p = 0.007, HR: 0.48, 95%-CI: 0.28-0.82). Combining the 4-miRNA signature and *MGMT* promoter methylation resulted in the signature-low-risk/*MGMT*-promoter-methylated (med. OS: 37.4months), signature-low-risk/*MGMT-promoter*-unmethylated (med. OS: 24.7months), signature-high-risk/*MGMT-promoter*-methylated (med. OS: 16.4 months) and signature-high-risk/*MGMT*-unmethylated groups (med. OS: 14.3months, Log-rank p = 0.002) with superior prediction performance. **Conclusions:** We confirmed the 4-miRNA signature as an independent prognosticator in IDH-wildtype glioblastoma while combination with *MGMT* promoter methylation outperformed other established prognostic factors. Our hypothesis is, that blood plasma samples will allow the risk stratification of glioblastoma patients before CRT. Phenotypic alterations driving its prognostic value remain to be determined and will allow for 1) risk stratified trials, 2) pathway analysis and targeting and 3) testing in healthy subjects to elucidate its screening potential. Long-term analysis of the WHO-defined molecular subgroups of high-risk grade II gliomas treated with radiation and temozolomide on NRG Oncology/RTOG 0424. *First Author: Erica Hlavin Bell, The Ohio State University, Columbus, OH*

Background: This study sought to evaluate the prognostic significance of the three WHO-defined molecular glioma subgroups (*IDH*wt, *IDH*mt/non-codel, and *IDH*mt/codel) in NRG Oncology/RTOG 0424, a phase II trial of high-risk low-grade gliomas treated with radiation (RT) and concurrent and adjuvant temozolomide (TMZ) after biopsy/surgical resection. Notably, this is the first clinical study to evaluate the prognostic value of the WHO subgroups in RT + TMZ-treated high-risk grade II (G2) gliomas using prospectively-collected long-term survival data. **Methods:** *IDH1/2* mutation status was determined by next-generation sequencing. 1p/19q co-deletion status was determined by Oncoscan and/or 450K methylation data. Overall survival (OS) and progression-free survival (PFS) by marker status were determined by the Cox proportional hazard model and tested using the log-rank test in a post-hoc analysis. Patient pre-treatment characteristics were included as covariates in multivariate analyses. **Results:** Of all the eligible patients (N=129), 80 (62%) had sufficient quality DNA for both *IDH* and 1p/19q analyses. Of these 80, 54 (67.5%) were *IDH*mt, and 26 (32.5%) were *IDH*wt. Of the 54 *IDH*mt patients, 26 (32.5% of total, 48% of *IDH*mt) were *IDH*mt/codel, and 28 (35% of total, 52% of *IDHmt*) were *IDH*mt/non-codel. Both *IDH*mt subgroups were significantly correlated with longer PFS (*IDH*mt/co-del = 8.1yrs (5.2-not reached (NR)); *IDH*mt/non-codel = 7.5yrs (3.9-11.8); *IDH*wt = 1.0yr (0.6-1.7), $p<0.001$) and OS (*IDH*mt/co-del = 9.4yrs (8.2-NR); *IDH*mt/non-codel = 8.8yrs (5.9-NR); *IDH*wt = 2.3yrs (1.4-3.4), $p<0.001$) relative to the *IDH*wt subgroup. Upon univariate and multivariate analyses, both molecular *IDH*mt subgroup comparisons relative to *IDH*wt remained significant ($p<0.001$) even after incorporation of known clinical variables. **Conclusions:** These analyses suggest that G2 glioma patients harboring *IDH1/2* mutations, regardless of co-deletion status, demonstrated longer survival with RT + TMZ relative to *IDH*wt tumors, although sample size is limited and analyses were post-hoc. These results also support the notion that outcomes for *IDH*wt high-risk G2 gliomas remain dismal (median = 2.3yrs, similar to G3 anaplastic astrocytoma); these patients should be separated from *IDH*mt patients in future G2 glioma trials, and warrant novel treatment strategies. Superior therapy response predictions for patients with glioblastoma (GBM) using Cellworks Singula: MyCare-009-03. *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: Despite using cytogenetic and molecular-risk stratification and precision medicine, the current overall outcome of GBM patients remains relatively poor. Therapy selection is often based on information considering only a single aberration and ignoring other patient-specific omics data which could potentially enable more effective treatment selection. The Cellworks Singula™ report predicts response for physician prescribed therapies (PPT) using the novel Cellworks Omics Biology Model (CBM) to simulate downstream molecular effects of cell signaling, drugs, and radiation on patient-specific *in silico* diseased cells. We test the hypothesis that Singula is a superior predictor of progression-free survival (PFS) and overall survival (OS) compared to PPT. **Methods:** Singula's ability to predict response was evaluated in an independent, randomly selected, retrospective cohort of 109 GBM patients aged 17 to 83 years treated with PPT. Patient omics data was available from TCGA. Singula uses PubMed to generate protein interaction network activated and inactivated disease pathways. We simulated PPT for each patient and calculated the quantitative drug effect on a composite GBM disease inhibition score based on specific phenotypes while blinded to clinical response. Univariate and multivariate proportional hazards (PH) regression analyses were performed to determine if Singula provides predictive information for PFS and OS, respectively, above and beyond age and PPT. **Results:** In univariate analyses, Singula was a significant predictor of both PFS (HR = 4.130, $p < 0.000$) and OS (HR = 2.418, $p < 0.0001$). In multivariate PH regression analyses, Singula (HR = 4.033, $p < 0.0001$) remained an independent predictor of PFS after adjustment for PPT (p = 0.1453) and patient age (p = 0.4273). Singula (HR = 1.852, p = 0.0070) was also a significant independent predictor of OS after adjustment for PPT (p = 0.4127) and patient age (p = 0.0003). Results indicate that Singula is a superior predictor of both PFS and OS compared to PPT. Singula provided alternative therapy selections for 29 of 52 disease progressors detected by Cellworks. **Conclusions:** Singula is a superior predictor of PFS and OS in GBM patients compared to PPT. Singula can identify non-responders to PPT and provide alternative therapy selections. Research Sponsor: None.

The imaging substudy of the randomized ARTE trial: MRI and 18FET PET associations with overall survival benefit from bevacizumab in elderly patients with newly diagnosed IDH wildtype glioblastoma. *First Author: Hans-Georg Wirsching, Department of Neurology, University Hospital, Zürich, Switzerland*

Background: Bevacizumab failed to demonstrate overall survival benefit despite markedly prolonged progression-free survival in glioblastoma patients. Reasons for this divergence may include suboptimal patient selection and delayed diagnosis of progression on MRI scans under bevacizumab. Imaging analyses of retrospective and uncontrolled clinical trial cohorts suggest MRI diffusion mapping as a predictor of benefit from bevacizumab. Moreover, amino acid PET has been proposed by the RANO working group for the differentiation of tumor versus edema or gliosis based on proof-of-principle studies demonstrating earlier detection of progression with PET compared to MRI. **Methods:** ARTE (NCT01443676) was a 2:1 randomized, multi-center, open-label trial of hypofractionated radiotherapy in combination with intravenous bevacizumab every 2 weeks (BEV/RT) versus RT alone in patients with newly diagnosed glioblastoma aged 65 years or older. Patients with histologically and molecularly confirmed IDH wildtype glioblastoma aged 65 years or older were analyzed. MRI was available from 67 and serial ^{18}FET PET from 30 patients in this post hoc analysis. ^{18}FET PET intensity ratios and herein reported MRI parameters including tumor volumetric analyses and ADC were analyzed blinded for outcome and study arm. **Results:** Demographic, clinical and molecular parameters were balanced between treatment arms. Overall survival benefit from bevacizumab was observed for larger contrast-enhancing tumor volumes (hazard ratio [HR] per cm^3 0.94, 95% CI 0.89-0.99, p = 0.032) and higher ADC (HR 0.18, 95% CI 0.05-0.66, p = 0.025) on pre-treatment MRI. Response in the BEV/RT arm by the standard MRI-based RANO criteria was associated with overall survival by trend (HR 0.56, 95% CI 0.30-1.10, time-dependent p = 0.094). In a multivariate model controlling for established risk factors, ^{18}FET tumor-to-brain uptake ratios (TBR) of non-contrast-enhancing tumor portions predicted inferior overall survival specifically in the BEV/RT arm (HR [per 0.1 ^{18}FET TBR] 1.50, 95% CI 1.05-2.13, time-dependent p = 0.025). Controlling for ^{18}FET TBR at first follow-up identified benefit from BEV/RT by trend (HR 0.41, 95% CI 0.16-1.07, p = 0.069). **Conclusions:** Large contrast-enhancing tumor mass and high ADC identify patients with overall survival benefit from bevacizumab. Under bevacizumab, non-contrast enhancing tumor portions can be adequately monitored by amino acid PET. Research Sponsor: Roche.

Estimated clinical efficacy and radiographic response characteristics of PD1 inhibition in newly diagnosed and recurrent glioblastoma in clinical practice: A report from the iRANO Working Group. *First Author: Benjamin M. Ellingson, University of California, Los Angeles, CA*

Background: Despite concerns of immunotherapy-induced inflammatory response during PD1 inhibition, questions remain as to the true incidence of inflammatory response and potential clinical implications. The goals of the project were to use GBM patients pooled from academic centers to estimate radiographic PFS and OS, as well as determine the incidence of immunotherapy-induced inflammatory response. **Methods:** 152 patients with newly diagnosed (N = 57) or recurrent (N = 95) GBM treated with either nivolumab or pembrolizumab from Dana-Farber (N = 88), UCLA (N = 35) or UCSF (N = 29) were included in this study. Radiographic progression was defined by a 25% increase in bidirectional measurements according to RANO. **Results:** Median PFS and OS for newly diagnosed patients was 162 and 520 days, respectively, while median PFS and OS for recurrent patients was 72 and 225 days, respectively. No difference in OS was observed in recurrent patients treated with nivolumab vs. pembrolizumab (P = 0.58), but recurrent patients treated with nivolumab trended toward a longer PFS (P = 0.097). Of the recurrent patients with OS and PFS data available and radiographic progression, 95% of them progressed within 6 mos of starting treatment. Median post-progression survival (PPS) in recurrent patients with PFS $<$ 6 mos was 151 days, while PPS for patients with PFS $>$ 6 mos was 178 days (P = 0.51). In the 77 recurrent patients who progressed within 6 mos, 36.4% had an OS that was $>$ 9 mos, while 63.6% had an OS $<$ 9 mos, suggesting the majority of patients with "early progression" also died early and a minority of patients had what could be considered "immune-related inflammation". Of the 81 recurrent patients with documented progression, only 2.5% showed stabilization within 3 mos of first progression, 30.9% died before the 3-month confirmation scan could be obtained, 24.7% showed continued tumor growth by 3 months, and 48.1% had no follow-up confirmatory imaging exams. Of the 70 patients who progressed within 6 mos and had documented death, 2.9% had disease stabilization, 31.4% died before the 3-month confirmation, and 75.7% had either documented tumor growth or had no follow-up confirmatory imaging exams. **Conclusions:** This study suggests immunotherapy-induced inflammation followed by a favorable PPS is uncommon in GBM. While patients treated with other types of immunotherapy may exhibit different imaging characteristics, these data provide an important basis to refine the iRANO criteria. 2522 Poster Session (Board #13), Fri, 8:00 AM-11:00 AM

Eradication of medulloblastoma by NKG2D-specific CAR T-cells. *First Author: Hongjiu Dai, Nanjing Kaedi Biotech Co. Ltd., Nanjing, China*

Background: Medulloblastoma (MB) is a cancerous malignant brain tumor, that most often occurs in young children. Standard-of-care therapies for treating pediatric MB have long-term side effects, even in children who are cured. Recently people are exploring the potential of chimeric antigen receptor T (CAR-T) cell therapy in brain tumor, yet the clinical outcome is limited. It's reported that NKG2D ligands are wildly expressed in MB cells, which supports NKG2D system might play an important role in MB therapy. Here, we take advantage of NKG2D-specific CAR-T cells (KD-025) for MB treatment. **Methods:** HTB186, HTB185 and HTB187 MB cell lines as well as MB cancer patient samples were evaluated for NKG2D ligands expression. The KD-025 showed antigen-specific stimulation by cytokine secretion and target cell lysis. HTB186 cells, which stably express luciferase protein, were used to establish in vivo subcutaneous and xenograft models in NSG mice. Mice received a single treatment of 10 million KD-025 intravenously. **Results:** NKG2D ligands were detected on HTB186 and HTB187 cells and most of screened BM patient samples. The KD-025 was generated with CD8 hinge region and transmembrane region, 4-1BB costimulatory region and CD3 zeta region. The KD-025 expression was $>$ 50% on the surface of T cells confirmed by flow cytometry. Co-incubation of KD-025 with HTB186 cells specifically upregulates TNF-α, IFN-γ, IL-10 and IL-2 cytokines and strongly lysis tumor cells even at low E:T ratio (70-80% at 8:1). Strikingly, KD-025 markedly eliminated xenograft tumors in vivo and did not exhibit significant treatment-related toxicity in the treated mice. Regarding to T cell persistence, the CAR-T cells are barely detectable 24 days after injection, which is comparable with CD19 CAR in our experiments as well as published data. No obvious pathological changes were found in the tested organs. **Conclusions:** Our work with the KD-025 contributes to the growing body of research committed to discovering a novel therapy for MB. NKG2D ligands are highly expressed on human MB samples. KD-025 potently respond to MB and eliminate tumor in a xenograft mouse model with no obvious safety issues. The results support future clinical trial of KD-025 in patients with MB, where the need for effective treatment is great. Research Sponsor: Nanjing Kaedi Biotech, INC.

2523 Poster Session (Board #14), Fri, 8:00 AM-11:00 AM

MGMT methylation as a prognostic factor in IDH wild type anaplastic gliomas. *First Author: Enrico Franceschi, Department of Medical Oncology, Bellaria Hospital, Azienda USL - IRCCS Institute of Neurological Sciences, Bologna, Italy*

Background: Anaplastic gliomas are classified according to the presence of IDH-mutation. IDH wild type (IDH wt) is associated with poor prognosis and limited effectiveness of treatments.The aim of this study was to find out if MGMT methylation represents a prognostic factor in this setting. **Methods:** Anaplastic gliomas are classified according to the presence of IDH-mutation. IDH wild type (IDH wt) is associated with poor prognosis and limited effectiveness of treatments.The aim of this study was to find out if MGMT methylation represents a prognostic factor in this setting. **Results:** The analysis included 73 pts with grade III, IDH wt (19.3%) gliomas. Median follow-up time was 69.9 months. Median age was 50 (Range: 18-75), M/F ratio was 40(54.8%)/33(45.2%).MGMT promoter was methylated in 34 pts (46.6%) and unmethylated in 39 pts (53.4%). After surgery, 9 pts (12.3%) received RT alone, 57 pts (78.1%) received both RT and CT (sequential, concomitant or both). Median survival was 26.2 months. In multivariate analysis age (HR = 1.064, 95%CI: 1.030-1.099; P $<$ 0.001) and MGMT methylation (HR = 0.422, 95%CI: 0.210-0.848; P = 0.015) were independently associated with risk for death. **Conclusions:** IDH wild type confers a dismal prognosis in patients with grade III gliomas. MGMT methylation, as was demonstrated in glioblastoma, represents a prognostic factor that correlated with lower risk for death. Further studies will investigate potential correlations with treatments. Research Sponsor: None.

Leptomeningeal disease after surgical resection and radiosurgery for brain metastases and neurologic death: A multi-institutional analysis. *First Author: Roshan Sudhir Prabhu, Southeast Radiation Oncology Group, PA, Charlotte, NC*

Background: Postoperative radiosurgery (SRS) has been associated with up to 30% risk of subsequent leptomeningeal disease (LMD). We previously demonstrated that radiographic pattern of LMD (classical "sugarcoating" [cLMD] vs. nodular [nLMD]) in this setting is prognostic. The association between radiographic pattern of LMD, type of salvage treatment (tx), and neurologic death (ND) has not been well described. **Methods:** The records of patients (pts) with brain metastases (BM), of which 1 was resected and treated with adjunctive SRS, and who subsequently developed LMD were combined from 7 tertiary care centers. Pts with classically radiosensitive tumors or prior or planned whole brain radiotherapy (WBRT) were excluded. ND was defined as symptomatic CNS progression around the time of death without life threatening systemic symptoms or progression. Salvage radiotherapy (RT) for LMD was categorized according to use of WBRT vs. focal cranial RT. **Results:** The study cohort consisted of 147 pts, of which 125 had died with known cause, 107 also received LMD salvage tx, and 82 also had cranial MRI follow-up. The ND rate in the 125 pts who died with known cause was 79%; the rate in pts who underwent LMD salvage tx (n = 107) was 76%. Univariate logistic regression demonstrated radiographic pattern of LMD (cLMD vs. nLMD, odds ratio [OR] 2.9, p = 0.04) and 2nd LMD failure after salvage tx (OR 3.9, p = 0.02) as significantly associated with ND. The ND rate was 86% for cLMD vs. 68% for nLMD pattern. WBRT was used in 95% of pts with cLMD vs. 52% of pts with nLMD. In the nLMD cohort (n = 58), there was no difference in ND rate based on type of salvage RT (WBRT: 67% vs. focal cranial RT: 68%, p = 0.92). Second LMD failure (vs. not) was associated with higher ND in the nLMD cohort (77% vs. 52%, p = 0.02). Of the 26 pts with nLMD who experienced 2nd LMD failure, 7 had classical 2nd LMD, of which 100% experienced ND, and 19 had nodular 2nd LMD, of which 68% experienced ND (p = 0.09). **Conclusions:** LMD after surgery and SRS for brain metastases is a clinically significant event with high rates of neurologic death. Classical LMD pattern (vs. nodular) and 2nd LMD failure after salvage tx were significantly associated with higher risk of neurologic death. In the nodular LMD cohort, radiographic pattern of 2nd LMD may be associated with risk of subsequent neurologic death. Pts with nodular LMD treated with salvage focal cranial RT or WBRT had similar risk of neurologic death. Methods to decrease LMD and the subsequent high risk of neurologic death in this setting warrant investigation. Research Sponsor: None.

2525 Poster Session (Board #16), Fri, 8:00 AM-11:00 AM

Genomic profiling of breast cancer brain metastases reveals targetable alterations. *First Author: Sheheryar Kairas Kabraji, Dana Farber Cancer Institute, Boston, MA*

Background: Genomic characterization of breast cancer brain metastases (BCBMs) has thus far been limited. The objective of this study was to describe the landscape of genomic alterations in patients (pts) with BCBMs. **Methods:** Targeted next-generation DNA sequencing of > 300 cancer-related genes (OncoPanel) was prospectively performed on primary and metastatic (met) tumors in 321 pts with a diagnosis of BCBM between August 2016 and April 2019 at Dana-Farber Cancer Institute (table). Enrichment analysis of genomic alterations was performed using a two-sided Fisher exact test and differences in tumor mutation burden (TMB) between groups were assessed using two-sided Mann-Whitney U test. Multiple comparison correction was performed using the Benjamini-Hochberg procedure. **Results:** All subtypes were represented in BCBM (25 HR+/HER2-; 24 HR+/HER2+; 27 HR-/HER2+; 18 TNBC; 5 unknown; n = 99) and extracranial (EC) samples: (96 HR+/HER2-; 32 HR+/HER2+; 22 HR-/HER2+; 41 TNBC; 31 unknown; n = 222). BCBMs were found most commonly to have mutations or copy number alterations in *TP53, ERBB2, PIK3CA, GATA3, PTEN, ESR1, CDH1, BRCA2, ARID1A, BRCA1* (>5% frequency, table). Two pts acquired *ERBB2* amplification (amp) between the matched primary breast sample and brain met. In pair-wise comparisons of BCBMs to unmatched primaries or EC mets, only *ERBB2* amp was significantly enriched (table, † = adjusted p < 0.05). There was no significant difference in TMB between BCBM and EC mets (median 9.12 vs 7.26, p = 0.15). In contrast, TMB was significantly higher in BCBMs compared to unmatched primaries (median 9.12 vs 7.26, p=0.005). **Conclusions:** BCBMs display similar mutations and copy number alterations compared to primary tumors and EC mets in pts with BCBM. These data suggest that BCBMs contain actionable genomic alterations that are most often also reflected in EC disease. Alterations in *ERBB2, PIK3CA/PTEN*, and *BRCA1/2* represent potentially targetable alterations in pts with BCBM. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Other Government Agency, Pharmaceutical/Biotech Company, Fashion Footwear Association of New York.

Immune microenvironment profiling of breast cancer brain metastases using multiplex immunofluorescence. *First Author: Gaia Griguolo, Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy*

Background: Despite clinical implications, the complexity of brain metastases (BM) immune microenvironment in breast cancer (BC) patients is poorly understood. Multiplex immunofluorescence (mIF), a novel imaging technique allowing simultaneous visualization and quantification of several IF labeled proteins while maintaining spatial information, holds promise to comprehensively describe BCBM immune microenvironment, potentially providing valuable information to improve treatment. **Methods:** Clinical data and archival BM samples were collected for 60 BC patients undergoing neurosurgery (2003-2018) at three institutions. BM immune contexture was characterized using a custom mIF panel, including cell subtyping (CD4, CD8, FOXP3, CD68), activation (Granzyme B) and localization (keratin for tumor recognition) markers. Mean immune cell density (cells/mm2) for each sample was determined by digital image analysis and classified in tumor and stroma areas. Associations between immune subpopulations, BC subtype and overall survival from BM diagnosis (OS) were studied. **Results:** Up to date, 30 BCBM samples have been analyzed; 33% HR+/HER2-, 20% HR-/HER2+, 10% HR+/HER2+, 37% HR-/HER2-. At a median follow-up of 46 months, BC subtype was the only clinical variable associated with OS (longest for HER2+ and shortest for HR-/HER2-, log-rank p = 0.002). In the total sample area, no significant difference in immune cell densities was observed according to BC subtype. In the tumor area, HR+/HER2- tumors showed higher densities of CD8+ and CD68+ cells compared to other subtypes (p = 0.036 and p = 0.016, respectively). In stroma, HR-/HER2- tumors presented numerically higher densities of CD4+ and FOXP3+ cells and higher ratio of CD4/CD8 and FOXP3/CD8 ratio (not statistically significant). Higher CD4/CD8 and FOXP3/CD8 ratio in the stroma was significantly associated with worse OS, even after correction by BC subtype (Table). **Conclusions:** In BCBM, immune infiltrate differs according to BC subtype. Preliminary results suggest that a more tolerogenic immune microenvironment is associated with worse OS and might represent a target for optimization of immunotherapy for these patients. Updated results for all 60 patients will be presented. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

	Univariate Cox Model for OS		Multivariable Cox Model for OS (correction by BC subtype)	
	Hazard Ratio (95% CI)	**p**	**Hazard Ratio (95% CI)**	**p**

2527 Poster Session (Board #18), Fri, 8:00 AM-11:00 AM

Clinical outcome of patients experiencing central nervous system progression on first-line pertuzumab and trastuzumab for HER2-positive metastatic breast cancer in a real-life cohort. *First Author: Laetitia Collet, Centre Léon Bérard, Lyon, France*

Background: Isolated central nervous system (CNS) progression on first-line systemic therapy with Trastuzumab (T) and Pertuzumab (P) for HER2-positive metastatic breast cancer (MBC) is a therapeutic challenge. Our aim was to describe the clinical outcome and current treatment strategies for such patients in a large retrospective cohort. **Methods:** Patients (pts) were selected among all MBC pts included in the French *Epidemiological Strategy and Medical Economics* (ESME) database involving 18 specialized cancer centers (NCT03275311). CNS progression-free survival (CNS-PFS), progression-free survival (PFS) and overall survival (OS) from diagnostic of brain metastases (BM) were estimated using the Kaplan-Meier method. **Results:** Between January 2008 and December 2016, 995 pts were treated with first-line T and P for their HER2-positive MBC. They were 55 years old in median, with tumors expressing hormone-receptors in 62%. A total of 132 pts (13%) experienced isolated CNS progression on T and P, with a median time from metastatic diagnosis to CNS progression of 12 months. It was the first CNS progression for 108 pts (82%) while 24 (18%) already had BM at time of metastatic relapse. After CNS progression, T and P were continued for 58% of pts (n = 73). The remaining 47 pts were switched to another HER2-directed therapy (T-DM1 for 57%, T alone or combined with chemotherapy for 36% and lapatinib for 21%). Among those 132 pts, 37% received whole-brain radiotherapy, 18% stereotactic radiation therapy, and 11% surgery. Systemic treatment was combined with CNS-directed therapy for 50% of pts. Median follow-up is 21 months (95%CI: 14.9-25.5) from the diagnosis of CNS metastases. Median OS (mOS) of the 132 pts is 35 months (95%CI: 29.2-53,6), and median PFS 7 months (95%CI: 6.3- 9.2). A total of 77 pts (58.3%) experienced a new CNS progression with a median CNS-PFS of 9 months (95%CI: 7.6-12,0). Patient who stayed on T and P had a significantly better OS in comparison to pts who were switched to another systemic HER2-directed therapy (mOS not evaluable *vs*23 months), whereas PFS and CNS-PFS were similar between groups. **Conclusions:** In this real life setting, isolated CNS progression occurred among 13% of pts with HER2+ MBC on first-line treatment with T and P, after a median time of 12 months. Following current ASCO recommendations, continuation of T and P after CNS-directed therapy, seemed to be adequate. Nevertheless, time to subsequent progression is short and better therapeutic options are needed. Research Sponsor: None.

2528 Poster Session (Board #19), Fri, 8:00 AM-11:00 AM

Radiation-induced changes in the inflammatory microenvironment composition of lung cancer brain metastases. *First Author: Ariane Steindl, Medical University of Vienna, Vienna, Austria*

Background: Radiotherapy was postulated to impact the inflammatory microenvironment composition in patients with lung cancer brain metastases (BM). **Methods:** Formalin fixed and paraffin embedded BM specimens from treatment naïve patients (group 1) and from patients treated with radiation therapy including whole brain radiotherapy and/or stereotactic radiosurgery (group 2) or prophylactic cranial irradiation (group 3) before BM resection were identified from the Vienna Brain Metastasis Registry. T cell subsets (CD3+,CD8+,CD45RO+,FOXP3+,PD-L1+) were investigated using the Ventana Benchmark Ultra system Definiens software. **Results:** Specimens from 41 patients (28/41;68.3% NSCLC, 13/41;31.7% SCLC) were included in the study. A significant difference in CD3+TIL density between group 1 (median: 964.5cells/mm2) and group 2 (median: 283.4cells/mm2; p-value=0.021; Mann-Whitney-U test), as well as group 3 (median: 168.8 cells/mm2; p-value= 0.028; Mann-Whitney-U test) were observed. Furthermore, CD8+ and FOXP3+TIL densities of group 2 (CD8+ median: 172.1cells/mm2; FOXP3+ median: 210.7cells/mm2) were numerically lower compared to group 1 (CD8+ median: 190.1 cells/mm2; FOXP3+ median: 221.2 cells/mm2). Of 10/41 (24.4%) patients further resected BM tissue specimens after initial resection were available. Here, the inflammatory microenvironment of BM treated with radiation therapy between the resections was significantly associated with lower densities of CD3+ (median: 105.1 cells/mm2) and CD8+ (median: 20.3cells/mm2) compared to radiation-naïve patients (CD3+ median: 825.4cells/mm2; CD8+median: 105.5cells/mm2; p=0.037; Mann-Whitney U-test). **Conclusions:** Radiation treatment was associated with lower densities of TIL subsets in our BM cohort. Although results have to be interpreted with caution due to the limited sample size, further studies investigating the sequencing of radiotherapy and immune modulating therapies might be of interest. 2529 Poster Session (Board #20), Fri, 8:00 AM-11:00 AM

Advanced imaging to assess longitudinal vascular changes in brain metastases treated with immune checkpoint inhibition. *First Author: Albert Kim, Massachusetts General Hospital, Boston, MA*

Background: Immune checkpoint inhibitors (ICI) have recently been shown to be effective for brain metastases (BM) for melanoma and lung cancer. This breakthrough has prompted interest in evaluating ICI in BM of other histologies. However, accurately assessing intracranial response in patients undergoing ICI is a challenge, as current measures cannot distinguish pseudoprogression from true tumor progression. To shed light on potential biomarkers of response, we prospectively use perfusion MRI to identify characteristic vascular signatures in a BM-specific trial of ICI. **Methods:** As part of an ongoing phase II study of pembrolizumab for patients with untreated or progressive, previously treated BM from any histology, patients underwent advanced MRI that includes tumor volume measurements and perfusion imaging with dynamic susceptibility contrast MRI. To calculate volumetric radiographic response, all enhancing voxels were summated. A volumetric increase of >40% was categorized as progressive disease (PD), a decrease of >60% as partial response (PR), and stable disease (SD) as between -60% and +40%. **Results:** 53 patients have been enrolled, of whom 44 have received at least baseline advanced MR imaging. Histologies include 21 with breast cancer, 5 with non-small cell lung cancer, 4 with melanoma, and 13 with other cancers. At baseline, the total number of BM was 1-50+ per patient. Based on summing the entire enhancing intracranial disease burden, best volumetric responses for the 33 evaluable patients include 4 PR, 10 SD, and 19 PD. On preliminary analysis, there was a correlation between increased tumor cerebral blood volume/flow with tumor progression. Correlation of additional vascular physiologic parameters (e.g. vessel caliber, tissue oxygenation) and volumetric response to patient outcome and standardized response criteria (iRANO) are ongoing. **Conclusions:** Pembrolizumab likely has anti-tumor efficacy in BM. Our data provides potential evidence that effective ICI is associated with a decrease in perfusion. Ongoing analyses to uncover additional vascular changes – specifically longitudinal metrics reflecting vascular structure and function - within BM to ICI are pending. These findings have potential to illustrate mechanisms of efficacy for ICI and biomarkers of response in this patient population. 2530 Poster Session (Board #21), Fri, 8:00 AM-11:00 AM

A phase II double-blind, randomized clinical trial assessing the tolerability of two different ratios of cannabis in patients with glioblastoma multiforme (GBM). *First Author: Judith Lacey, Supportive Care, Chris O'Brien Lifehouse Cancer Hospital, Camperdown, NSW, Australia*

Background: Cannabis has been used for cancer-related symptoms but few trials have assessed quality of life or tolerability, and trials assessing tumour response or survival remain scarce. Treatment for recurrent glioblastoma (rGBM) remains palliative with poor prognosis. The tolerability of THC-containing cannabis products, and their effect on symptoms and quality of life in people with rGBM patients is poorly defined but is essential before efficacy trials can be conducted. **Methods:** We conducted a randomised double-blinded trial assessing the tolerability of two preparations of cannabis in 88 people with rGBM. The two preparations used different cannabidiol (CBD) to tetrahydrocannibidiol (THC) ratios; 1:1 (5.8mg/ml:5.6mg/ml) and 1:4 (3.8mg/ml:15mg/ml). Daily evening doses were individually monitored and titrated. Outcomes included disease response by FACT-Br, MRI imaging 12 weekly, blood pathology, NCI-CTC and clinical monitoring. Symptom assessments were performed 4 weekly for 12 weeks. **Results:** 921 people volunteered for screening across Australia, with 642 excluded, 92 recruited with 88 enrolled. 61 participants completed 12-week follow-up (attrition 30%). Both cannabis oils were well tolerated. Total FACT-Br was similar for both preparations, however, statistical significance was found for the physical section (p = 0.025) and functional (p = 0.014) identifying the 1:1 ratio as the more appropriate combination. Comparing groups to baseline, participants reported improvement of sleep (p = 0.009), improved energy (p = 0.015), and contentment with QoL (p = 0.006). Total cohort compared to baseline, participants reported improvement of sleep (p = 0.0001), pain (p = 0.046), nausea (p = 0.017), anxiety (p = 0.005) and seizure activity (p = 0.022). There were no major adverse events attributable to the cannabis with main side effects noted as dizziness, drowsiness, tiredness, and dry mouth. No abnormal blood pathology nor variance in NCI-CTCAE scores were observed. **Conclusions:** A single nightly dose of THC-containing cannabis was well tolerated in patients in both groups with rGBM and significantly improved sleep and functional wellbeing and QOL in a sample of patients compared to baseline. From this trial, the 1:1 ratio has been identified as the better tolerated product with suprerior symptom and QoL outcomes compared to the 1:4 product. Clinical trial information: ACTRN12617001287325. Research Sponsor: Bioceuticals Pty Ltd.

2531 Poster Session (Board #22), Fri, 8:00 AM-11:00 AM

Concurrent nivolumab and ipilimumab with brain stereotactic radiosurgery for brain metastases from non-small cell lung cancer: A phase I trial. *First Author: Jing Li, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Nivolumab (nivo) and ipilimumab (ipi) were found in the recent phase III CheckMate 227 trial to have an overall survival benefit over chemotherapy for advanced non-small cell lung cancer (NSCLC). However, patients (pts) with untreated brain metastasis (mets) were excluded from that trial. Because 30% of NSCLC pts develop brain mets, we tested nivo/ipi with concurrent stereotactic radiosurgery (SRS) for NSCLC pts with active brain mets. **Methods:** We report the safety data from the phase I portion of an ongoing phase I/II single-institution trial in which one treatment group was given SRS with nivo (3 mg/kg) every 2 weeks (wks) plus ipi (1 mg/kg) every 6 wks x 4 cycles, followed by maintenance nivo (480 mg) every 4 wks until disease progression, unacceptable toxicity, or withdrawal of consent. Brain SRS was delivered within 7 days of initiation of nivo/ipi. The primary endpoints were safety and 4-month (mo) intracranial progression-free survival (PFS). Dose-limiting toxicity (DLT) was defined as > 15% intracranial toxicity (>G3 hypophysitis / neurologic toxicity) or > 30% extracranial toxicity (>G3 non-dermatologic non-lab toxicity or >G4 dermatologic / lab toxicity), refractory to medical management, assessed at 8 wks after treatment initiation. Target accrual for phase I was 10 evaluable pts, with enrollment suspended after every 5 pts for DLT assessment. **Results:** Since June 15, 2018, 13 pts were enrolled and 10 were evaluable for DLT. The median follow-up time was 6.8 mo (range 1.2–18). As of January 6, 2020, only 1 pt had DLT-defined toxicity and thus the predefined stopping criteria were not met. This pt had G3 seizure right after SRS that resolved within a week, and then had increased but asymptomatic CNS edema 4 wks later. Aside from DLTs, 3 pts (25%) developed treatment-related G3 (elevated liver function tests, fatigue, nausea, adrenal insufficiency, and myocarditis) or G4 events (pneumonitis/acute respiratory distress syndrome in 1 pt with confirmed influenza at 7 mos after treatment initiation). This pt subsequently died of hemophagocytic lymphohistiocytosis (considered possibly related to the study drugs). Median intracranial PFS time was 9.7 mo, and the 4-mo intracranial PFS rate was 75%. Extracranial objective response rate was 33% in the 12 evaluable pts with a median response duration of 9.1 mo. **Conclusions:** Concurrent SRS withnivo/ipi was safe for pts with active NSCLC brain mets. Preliminary analyses of efficacy were encouraging for durable intracranial and extracranial response. Clinical trial information: NCT02696993. Research Sponsor: Bristol-Myers Squibb Global Biopharmaceutical Company.

2532 Poster Session (Board #23), Fri, 8:00 AM-11:00 AM

Response assessment and outcome of combining immunotherapy and radiosurgery for brain metastasis from malignant melanoma. *First Author: Emilie Le Rhun, Lille University Hospital, Lille, France*

Background: The evaluation of response in the context of treatment with stereotactic radiotherapy (SRT) or immune checkpoint inhibitors (ICI) or both, which represent major therapeutic options for patients with melanoma brain metastases, remains challenging due to potential tumor hemorrhage, pseudoprogression, and radionecrosis. **Methods:** We reviewed clinical and neuroimaging data of 62 melanoma patients, including 26 patients with BRAF-mutant tumors, with newly diagnosed brain metastases treated with immune checkpoint inhibitors (ICI) alone (n = 10, group 1), SRT alone or in combination with other systemic therapies (n = 20, group 2) or ICI plus SRT (n = 32, group 3). Response was assessed retrospectively using RECIST 1.1, RANO or iRANO criteria. **Results:** The MRI scans of 52 patients were available for central review. Patients received steroids at BM diagnosis in 10% in group 1, 60% in group 2 and 50% in group 3. Pseudoprogression was documented in 7 patients: 3 patients in group 2 (19%) and 4 patients (12%) in group 3. Radionecrosis was documented in 7 patients: 2 patients in group 2 (12%) and 5 patients (16%) in group 3. Patients treated with ICI alone had the worst outcome. Using RANO criteria by central review instead of local investigator assessment increased the rate of progressive disease (PD) as best response for the evaluation of SRT targets but not for the evaluation of the overall brain. Using complete RANO (including clinical assessment and steroid use) instead of RECIST criteria increased the rate of PD as best response, due to clinical deterioration noted in patients with MRI findings that did not qualify for PD. This pattern was seen in patients from all three groups. In contrast, the complete response (CR) rate was unaffected by the criteria used. More PD were also observed when comparing MRI only iRANO criteria versus complete iRANO criteria including clinical status and steroid use. **Conclusions:** Pseudoprogression is uncommon with ICI alone, suggesting that growing lesions in such patients should trigger an intervention. Pseudoprogression rates were similar after SRT alone or in combination with ICI. Response assessment criteria should be considered carefully when designing clinical studies for patients with brain metastases who receive SRT. Research Sponsor: None.

2533 Poster Session (Board #24), Fri, 8:00 AM-11:00 AM

Application of machine learning algorithms for the diagnosis of primary brain tumors. *First Author: Vasilii Khammad, James Cancer Hospital and Solove Research Institute, Columbus, OH*

Background: Primary lesions of the CNS refer to a heterogeneous group of benign or malignant tumors arising in different parts of the brain and spinal cord. According to the 2016 CNS WHO classification, the accurate diagnosis of primary brain tumors requires a layered approach of histologic, anatomic and molecular features to generate an integrated diagnosis with clinical and prognostic significance. However, in the US and worldwide, scarce resources are available to perform all the required tests routinely, so methods that improve pre-test probabilities and decrease false positive results have significant clinical and financial impact. Aims: 1) validate new diagnostic workflows with implementation of modern machine learning/artificial intelligence approaches; 2) design a reliable and interactive computational platform for primary CNS tumor diagnosis. **Methods:** To achieve these goals we have developed a population model in Rstudio, "La Tabla", based on the articles from open resources of MEDLINE database and the latest version of WHO classification of CNS tumors. The data of "La Tabla" is comprised of more than 100,000 adult and pediatric cases, including rare brain tumor diagnoses, such as Gangliocytoma, Diffuse Midline Glioma and etc. **Results:** Boruta package and weights function in R have been used to distinguish the most important features for diagnosis prediction. To visualize correlation between these features (age, ki67 level, tumor location, presence of myxoid areas, calcifications, necrosis and etc.) and all diagnoses in two-dimensional space, we used a t-SNE algorithm. Models trained with decision tree algorithms (randomForest, XGBoost and C5.0) showed high overall accuracy in predicting diagnoses of "La Tabla" (95%, 94% and 92%) and 300 patients at OSUCCC-James (93%, 74% and 87%) in the absence of IHC and molecular data. Neural networks provided by keras and nnet packages predicted diagnoses using just clinical and histological findings with 94% and 88% accuracy on "La Tabla" and James patient databases respectively. Currently, we are building "Shiny" applications with R to deliver easily operated platform for pathologists and physicians. **Conclusions:** In conclusion, we managed to generate models that are able to diagnose primary brain lesions using basic clinical data (age, gender, tumor location), ki67 levels and distinct features of histological architecture. Most of the models distinguish brain tumors and associated molecular status with high accuracy and will serve as a reliable tool for second opinion in clinical neuro-oncology. Research Sponsor: Fulbright Scholarship.

2534 Poster Session (Board #25), Fri, 8:00 AM-11:00 AM

A phase I clinical trial on intratumoral and intracavitary administration of ipilimumab and nivolumab in patients with recurrent glioblastoma. *First Author: Julia Katharina Schwarze, Department of Medical Oncology, Universitair Ziekenhuis Brussel, Brussels, Belgium*

Background: Intravenous (IV) administration of ipilimumab (IPI) and nivolumab (NIVO) has low activity in recurrent glioblastoma (rGB). Intratumoral (IT) and intracavitary (IC) administration of IPI and NIVO is under evaluation in the *GIITIpNi* phase I clinical trial. **Methods:** Patients (pts) with resectable rGB were recruited to cohorts C1, C2 and C4; pts with non-resectable rGB were recruited in C3 (biopsy only). IT administration (brain tissue lining the resection cavity during surgery) of IPI (10 mg)(C1), or IPI (5 mg) plus NIVO (10 mg)(C2, C3 and C4), was followed by IC administration of NIVO at escalating doses of 1, 5 or 10 mg Q2w in both C3 and C4 (via an Ommaya reservoir). In all cohorts, pts received 10 mg NIVO IV Q2w (6x in C1/C2, and 12x in C3/C4). Corticosteroids were contraindicated. **Results:** Forty-six pts (31 male; median age 56y (38-74); IDH1 R132H mutation in 2 pts in C1/C2; NGS somatic mutation analysis for C3/C4 ongoing) with rGB following resection, RT and temozolomide were enrolled (3, 24, 13 and 6 pts in C1, C2, C3 and C4, respectively). All pts received IT administrations. Pts in C1/C2 received a median of 5 IV NIVO administrations. Study treatment has been completed in all pts in C1/C2, in 9 pts in C3, and in 3 pts in C4; pts received a median of 4 (0-10) and 3 (0-7) postoperative IC/IV administrations in C3 and C4, respectively. Two pts in C2 and 1 pt in C3 had an increased perilesional cerebral edema (G3) with neurological deterioration after surgery/IT-injection, that was reversible with steroids. Most frequent AE were fatigue (32 pts, 64%), fever (20 pts, 44%), and headache (25 pts, 50%). In 4 pts from C3, the Ommaya was removed because of bacterial colonization (asymptomatic). There were no G5 AE. There was no dose/AE correlation with increasing IC NIVO doses in C3/C4. Repetitive CSV analysis during therapy (C3/C4) revealed increased lymphocyte counts in 4 pts; scRNA- and TCR-sequencing is ongoing. Gene expression profiling for C1/C2, and pharmacokinetic analysis of NIVO and IPI in CSV for C3/C4 are ongoing. After a median FU of 62w (16-165) for pts in C1/C2, 16 pts have died; median OS is 71w (95% CI 8-134), 1- and 2y-OS% are respectively 51% (95% CI 31-71), and 34% (95% CI 10-59). OS compares favorably to a historical cohort of Belgian rGB pts (n = 469; Log-Rank p .001). After a median FU of 10w (1-37) for pts in C3/C4, 2 pts have died; median OS has not been reached. One pt in C3 achieved a PR that is ongoing at 12m. **Conclusions:** IT/IC administration of NIVO and IPI is feasible and sufficiently safe to warrant further investigation in pts with rGB. Clinical trial information: NCT03233152. Research Sponsor: None.

2535 Poster Session (Board #26), Fri, 8:00 AM-11:00 AM

Intra-operative radiation therapy as salvage treatment option for recurrent glioblastoma multiforme. *First Author: Nidal Salim, European Medical Center, Moscow, Russian Federation*

Background: Glioblastoma multiforme (GBM) is an extremely aggressive cerebral tumor with poor prognosis. The majority of patients relapse after the initial surgery plus adjuvant radiation and chemotherapy. In case of recurrence there is no established standard therapy. The optimal techniques for salvage re-irradiation are unclear, so that procedure poses a challenge. In contrast to traditional external beam radiotherapy (EBRT) intra-operative radiotherapy (IORT) may improve patient's outcome at the cost of minimal side effects and short treatment duration. **Methods:** A total of 30 patients were treated with recurrent GBM between August 2016 and June 2019. All patients underwent maximal safe resection; patients were divided into IORT and EBRT groups. 15 patients were included in each group with similar clinical characteristics. All patients in IORT group underwent maximal safe microsurgical resection with subsequent intraoperative balloon electronic brachytherapy (IBEB) and no further adjuvant treatment. IBEB was performed using Axxent electronic brachytherapy device (Xoft Electronic Brachytherapy (eBx) System, USA. Patients in EBRT group underwent same surgery followed by external beam radiotherapy. Contrast-enhanced brain MRI with perfusion was performed within 24 hours of surgery +/- brain PET-CT with 18-FDOPA and then every 3 months. Both groups were also assigned to subgroups ($\leq$ 2.5cm3 and $>$ 2.5cm3) based on post-operative contrast-enhancing volume (POCEV). Median overall survival (OS) since diagnosis and local progression-free survival (locPFS) following the second surgery were analyzed. Possible toxicities and prognostic factors were also evaluated. **Results:** Median OS was 27 months in IORT group and 21 months in EBRT group. The locPFS range between 3.5 to 39 months in IORT group and only 2 to 10 months in group with EBRT. Kaplan-Meier OS curves in patients with POCEV $\leq$ 2.5cm3 showed more favorable outcomes for patients in the IORT group ($p < 0.05$). In patients with POCEV $>$ 2.5cm3 the median OS was 17 months in IORT group and 13.5 months in EBRT group. **Conclusions:** IORT of recurrent GBM is feasible and provides encouraging local progression-free and overall survival; no high-grade radiation induced toxicities occur and further studies to establish this method are mandatory. The toxicity profile of additional IBEB was manageable. Maximal safe microsurgical resection is the most important prognostic factor and could determine the effectiveness of post-surgical IBEB. Research Sponsor: European Medical Center.

2536 Poster Session (Board #27), Fri, 8:00 AM-11:00 AM

Accelerator-based BNCT in rescue treatment of patients with recurrent GBM: A multicenter phase II study. *First Author: Shin-Ichi Miyatake, Osaka Medical College, Takatsuki, Japan*

Background: Boron neutron capture therapy (BNCT) is tumor-selective particle radiation and theoretically efficacious especially for tumors with infiltrative nature, such as glioblastoma (GBM). The aim of this study is to assess safety and efficacy of accelerator-based BNCT (AB-BNCT) using cyclotron-based neutron generator, BNCT30, and ^{10}B-boronophenylalanine (borofalan(^{10}B)) agent, SPM-011, in patients with recurrent malignant gliomas, chiefly GBM. **Methods:** The multi-institutional open-label, phase II clinical trial for recurrent 27 cases of malignant gliomas (MG) (24 cases were GBM) was conducted with above mentioned AB-BNCT system, using 500mg/kg of SPM-011 (study code, JG002). The patients were enrolled from February 2016 to June 2018. The inclusion criteria are bevacizumab-naïve MG, recurrent after standard treatment composed of XRT and chemotherapy with TMZ. Neutron-irradiation time were determined not to exceed to 8.5 Gy-Eq for scalp dose which was decided by preceding phase I trial. Primary endpoint was 1-year survival rate and secondary ones were median overall survival (mOS), median progression free survival (mPFS) and so on. The results were compared to previous Japanese domestic bevacizumab trial for recurrent GBM (JO22506) which had the similar inclusion criteria with JG002. **Results:** 1-year survival rate and mOS of recurrent GBM cases in JG002 was 79.2% (95% CI:57.0-90.8) and 18.7 months (95% CI:12.9-23.4) (data cutoff = 20 Jun 2019) respectively, while those of JO22506 was 34.5% (90% CI: 20.0-49.0) and 10.5 months (95% CI:8.2-12.4), respectively. Median PFS of JG002 and JO22506 were 0.9 and 3.3 months, respectively. Most important adverse event in JG002 was brain edema. 21 out of 27 cases were treated with bevacizumab after progress disease. **Conclusions:** AB-BNCT demonstrated acceptable safety and prolonged survival for recurrent MG chiefly GBM. AB-BNCT might produce brain edema somewhat after the treatment, which might be the unavoidable adverse event of re-irradiation for recurrent MG, however that seemed to be controlled with bevacizumab. Clinical trial information: JapicCTI-194742. Research Sponsor: Stella Pharma Corporation.

Parameter	JG002(BNCT) GBM (N = 24)	JO22506 (bevacizumab) GBM (N = 29)
1-year survival rate,% (95% CI)	79.2 (57.0-90.8)	34.5 (90%CI, 20.0-49.0)
Median OS, mo (95% CI)	18.7 (12.9-23.4)	10.5 (8.2-12.4)
Median PFS, mo (95% CI)	0.9 (0.8-1.0)	3.3 (2.8-6.0)

2537 Poster Session (Board #28), Fri, 8:00 AM-11:00 AM

Clinical outcomes of the combination of bevacizumab and ttfields in patients with recurrent glioblastoma: Results of a phase II clinical trial. *First Author: Jaleh Fallah, Cleveland Clinic Foundation, Cleveland, OH*

Background: Clinical trials of bevacizumab monotherapy and TTFields monotherapy have shown activity but limited clinical benefit in patients (pts) with recurrent glioblastoma (GBM), with median progression-free survival (PFS) of 2-4 months and median overall survival (OS) of 6-9 months with either treatment modality. In a single-arm phase II clinical trial, the efficacy of the combination of bevacizumab and TTFields in pts with recurrent GBM was investigated. **Methods:** Pts with histologically confirmed GBM or other grade IV gliomas, who had disease progression after chemoradiation were enrolled in a phase II trial of the combination of bevacizumab and TTFields. Bevacizumab was given at a dose of 10 mg/Kg intravenously every 2 weeks and TTFields was worn by the pts continuously for more than 18 hours per day. Treatment was continued until disease progression or unacceptable toxicity. The primary endpoints were PFS at 6 months and OS at 12 months. Survival outcomes were assessed using the Kaplan-Meier method and compared by log rank test. Treatment-related adverse events were reported according to CTCAE, v4.0 criteria. **Results:** From April 2013 to December 2017, 25 pts were enrolled and 23 were evaluable: 18 (78%) men and 5 (22%) women, median age 60 years (range 17–78). 21 pts were Caucasian, 1 was African American and 1 of unknown race. After a median follow up of 31.6 months (range: 4.1-59.0 months), 21 out of 23 pts died (4 women and 17 men). The median PFS was 4.1 months (95%CI, 3.6-9.5) and the median OS was 10.5 months (95% CI, 8.2-14.9). The PFS rate at 6 and 12 months were 33% and 19%, respectively. The OS rate at 6 and 12 months were 82% and 46%, respectively. Women had better OS and PFS compared to men, however, the difference was not statistically significant which can be due to the small study population (table). Grade 3 and 4 toxicities considered definitely or probably related to the treatment included hypertension (n = 1) and cerebral infarction (n = 1). Other reported grade 3-4 toxicities (n = 7) included cough, dysphagia, muscle weakness, hyperglycemia, psychosis, seizure, lymphopenia, transaminitis, and muscle weakness considered unlikely to be treatment-related. **Conclusions:** The combination of bevacizumab and TTFields in is safe and feasible and has clinical efficacy in pts with recurrent GBM. Clinical trial information: NCT01894061. Research Sponsor: NovoCure Ltd, Other Foundation.

Variable	Female (N = 5)	Male (N = 18)	P-Value
Median PFS (95% CI)	13.0 months (3.6 - not reached)	3.9 months (3.0 - 7.9)	0.06
Median OS (95% CI)	16.0 months (6.2 - not reached)	9.9 months (8.2 – 14.0)	0.09

2538 Poster Session (Board #29), Fri, 8:00 AM-11:00 AM

Phase Ib clinical trial of OKN-007 in recurrent malignant glioma. *First Author: James D. Battiste, Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Despite therapeutic advances, the median overall survival for patients with recurrent, high-grade gliomas remains poor. Thus, there is an urgent need for efficacious new therapies. The nitrone compound, OKN-007 (disodium 4-[(tert-butyl-imino) methyl] benzene-1,3-disulfonate N-oxide) is a promising novel anti-cancer agent. In orthotopic glioblastoma xenografts, OKN-007 reduces cell proliferation and angiogenesis, and increases apoptosis. Here we report on the safety, efficacy, and pharmacokinetics (PK) of OKN-007 in adults with recurrent glioma. **Methods:** NCT01672463 is a phase Ib trial of OKN-007 in adults with recurrent gliomas previously treated with standard therapy. Patients with recurrence, adequate performance status and organ function, receiving clinically appropriate doses of steroids, with a life expectancy greater than 8 weeks were eligible. OKN-007 was administered by IV. The study comprised a 3+3 dose escalation design followed by an expansion cohort at the maximum tolerated dose (MTD). The dose escalation drug levels were 20 (n = 3), 40 (n = 3), and 60 mg/kg (n = 3), treating on a schedule of thrice weekly for 4 weeks, then twice weekly for 4 weeks, then once weekly until progression. Drug PK was determined in the dose escalation cohorts. The expansion cohort was treated with 60 mg/kg thrice weekly for 12 weeks, then twice weekly for 12 weeks, then once weekly until recurrence (n = 6). Kaplan-Meier analysis was used to determine progression-free (PFS) and overall survival (OS). **Results:** Median age was 51 years (range, 25-62). No dose-limiting toxicities were observed and 60 mg/kg was chosen for the expansion dose. Of 123 adverse events (AE), 34 were deemed probably (1.6%) or possibly (26%) treatment-emergent (TEAE). The most commonly-occurring TEAE were fatigue (4.1%) and headache (3.3%). No drug-attributable grade 4 or 5 AE were observed. Grade 3 TEAE included headache, urinary tract infection, and increased prothrombin time (0.8% each). Only two grade 1 AE, hypokalemia and dizziness, were considered probably attributable to OKN-007. In patients receiving 60 mg OKN-007/kg, median PFS was 1.4 months and OS was 21 months (log rank p = 0.08 for comparison across doses). Systemic PK exposure was dose proportional. The average half-life of OKN-007 is 2.8 hours. **Conclusions:** OKN-007 appears safe for patients with recurrent glioma. The MTD was not reached. Our data suggest that, compared to standard therapy, OKN-007 may prolong OS in recurrent glioma. Based on new data, a trial of OKN-007 plus temozolomide is underway in patients with newly diagnosed glioblastoma (NCT03587038). Clinical trial information: NCT01672463. Research Sponsor: Oblato, Inc.

2539 Poster Session (Board #30), Fri, 8:00 AM-11:00 AM

Defining the prognostic role of MGMT methylation value by pyrosequencing assay in glioblastoma patients: A large Italian multicenter study. *First Author: Giuseppe Lombardi, Department of Oncology, Oncology 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: MGMT methylation (MGMTmet) status represents an important prognostic factor for glioblastoma (GBM) patients (PTS). Quantitative pyrosequencing approach has proven to be feasible for MGMTmet testing but its value is still unclear. We performed a large, multicentre, retrospective study to identify the association between MGMTmet values and clinical outcome. **Methods:** from 9 Italian neuro-oncology centres, we collected consecutive GBM PTS with assessment of MGMTmet by pyrosequencing approach evaluating CpG islands from 75 to 84. Other inclusion criteria were: histological diagnosis of GBM, ECOG PS $\leq$2, therapy with RT+TMZ. Kaplan-Meier method was used to estimate the survival curves, time-dependent ROC curve for defining the optimal cut-off value of mean percentage of MGMTmet in terms of 2y-OS, Cox regression for multivariable analysis, and restricted cubic spline to investigate the non-linear association between methylation values and OS. **Results:** 681 PTS were enrolled; median age was 60 ys; ECOG PS was 0 in 292 PTS, 1 in 306 PTS, 2 in 83 PTS; 391 PTS (58%) had a complete resection. 8% of PTS received a second surgery. IDH was mutated in 6%. 2y-OS was 31.6%, median OS was 17.4 ms. Median MGMTmet was 3.5% (IQR 0-22%). ROC curve identified a cutoff of 15% of MGMTmet in terms of 2y-OS (sens 78%, spec 57%, AUC = 0.67). 2y-OS was 19.7% and 53.7% for PTS with MGMTmet $<$ and $\geq$15%, respectively ($p < 0.0001$). At multivariable analysis, MGMTmet $<$ 15% was associated with impaired survival (HR 2.7, 95% CI 2.1-3.4; $p < 0.00001$), adjusting for age, KPS, type of surgery and second surgery. A non-linear association between MGMT methylation and survival was identified (non-linear term: $p < 0.0001$), with lower values of MGMT methylation associated with lower survival; indeed, estimated median OS was lowest (14 months, 2ys-OS: 17.4%) with MGMTmet of 4%, 21ms (2yr-OS: 40.9%) with MGMTmet of 20%, 27ms (2yr-OS: 40.9%) when MGMTmet was 40%, then leveled around 30ms (2yr-OS: 54.5-59.8%) when MGMTmet was $>$ 40%. **Conclusions:** this study represents one of the largest trials analyzing MGMTmet by pyrosequencing approach. Lower values of MGMTmet were associated with impaired survival and the relationship was non-linear. Noteworthy, we identified a strong prognostic value of MGMTmet which could be used as stratification factor in prospective clinical trials Research Sponsor: None.

2540 Poster Session (Board #31), Fri, 8:00 AM-11:00 AM

Phase II trial of bevacizumab and temozolomide for treatment of elderly patients with newly diagnosed glioblastoma. *First Author: Donna Molaie, UCLA Health, Los Angeles, CA*

Background: Glioblastoma (GBM) in elderly patients differ molecularly as compared to younger patients, and may have increased angiogenic activity. Bevacizumab (BV) is an anti-angiogenic monoclonal antibody against vascular endothelial growth factor. We conducted a clinical trial to evaluate the efficacy and safety of BV and temozolomide (TMZ) for elderly patients with a new diagnosis of GBM, while deferring radiotherapy. **Methods:** This is a phase II, single-arm, multicenter, open label trial. Eligible patients have a tissue diagnosis of GBM with no treatment other than surgery, age $\geq$ 70, KPS $\geq$ 60, and adequate organ function. TMZ was initiated within 2 weeks of surgery and BV was initiated within 4 weeks thereafter. TMZ was administered at 150-200 mg/m^2/day for 5 days every 4 weeks and BV at 10mg/kg every 2 weeks. A historical control group of 42 patients with similar criteria who received concurrent TMZ and RT followed by adjuvant TMZ, was derived for comparison from an institutional patient database. The primary endpoint is overall survival (OS) and secondary endpoints are progression-free-survival and safety. **Results:** 50 patients were enrolled from June 2010 to January 2016. Median age is 75 (range 70-87), and median KPS is 80 (range 60-100). 17 patients had a biopsy only, 26 patients have MGMT promoter methylation, and all patients are IDH wildtype. The study and control group are well matched in terms of age and molecular markers, however, the study patients had worse initial KPS and higher baseline tumor volume. At time of analysis, all but 2 patients were deceased. The median OS was 12.6 months for study patients (95% CI, 10.9-15.9 months) and 16.3 months for control patients (95% CI, 12.9-22.4 months). In a multivariate Cox analysis, baseline tumor volume (HR = 2.6, p = 0.0001) and MGMT promoter methylation (HR = 0.49, p = 0.004) were significant prognostic markers. Treatment type did not have a significant impact on OS (HR = 1.5, p = 0.14). Treatment-related serious adverse events included: pulmonary embolism (5), cerebral hemorrhage (3), pneumonia (1), intestinal perforation (1), deep venous thrombosis (6), hypertension (2), atrial fibrillation (1), congestive heart failure (1), cardio-respiratory arrest (1), lymphopenia (2), thrombocytopenia (8), and neutropenia (5). **Conclusions:** The results of this study suggest for patients with newly diagnosed GBM age $\geq$70 and KPS $\geq$60, treatment with BV and TMZ is equivalent to standard chemoradiotherapy, and has tolerable side effects. Complete endpoint analysis will be presented with the poster. Clinical trial information: NCT01149850. Research Sponsor: Genentech, Memorial funds in honor of Jeri Weiss.

2541 Poster Session (Board #32), Fri, 8:00 AM-11:00 AM

A pediatric and young adult phase I dose escalation study of BXQ-350 for solid and central nervous system tumors. *First Author: Mohamed Abdelbaki, Nationwide Children's Hospital, Columbus, OH*

Background: BXQ-350 is a novel agent composed of the multifunctional, lysosomal activator protein Saposin C (SapC) and dioleoyl- phosphatidylserine (DOPS) and has demonstrated antitumor effects in both *in vitro and in vivo* preclinical models. Many tumors, including high-grade glioma and diffuse intrinsic pontine glioma (DIPG), and cells of tumor vasculature have aberrantly exposed phosphatidylserine (PS)-rich domains on the cell surface. BXQ-350 is an anti-tumor agent in development from Bexion Pharmaceuticals, Inc. that selectively targets tumor cell PS, particularly those translocated to the outer leaflet of the plasma membrane in tumor cells. BXQ-350 activates and participates in various cellular processes, including apoptosis and necrosis, and may also exhibit novel mechanisms leading to cell death that require further investigation. **Methods:** Nine refractory solid (2) and central nervous system (7) tumor patients (5F:4M, age 4-23 years of age) were enrolled in a 2-site dose escalation phase I first-in-pediatric trial (NCT03967093) which completed in 2019. All patients received at least one dose of BXQ-350 which was administered as an intravenous infusion. Dosing began at 1.8 mg/kg and escalated to the highest planned dose level of 3.2mg/kg. **Results:** There were no BXQ-350-related serious adverse events, dose limiting toxicities, or withdrawals. The highest planned dose of 3.2 mg/kg was achieved safely but a maximum tolerated dose was not established. One osteosarcoma patient had progressive disease prior to completing cycle one of treatment and was removed from trial. Eight patients (DIPG-3, HGG-1, GBM-1, Pineoblasotoma-1, Ependymoma-1, Osteosarcoma-1) completed at least one cycle, with one DIPG patient completing cycle five. **Conclusions:** BXQ-350 was well tolerated with no significant dose-limiting toxicities at the highest planed dose level. A pediatric phase I trial in newly diagnosed patients is planned for 2nd quarter 2020. Clinical trial information: NCT03967093. Research Sponsor: Bexion Pharmaceuticals.

2542 Poster Session (Board #33), Fri, 8:00 AM-11:00 AM

Post-marketing safety surveillance of tumor treating fields (TTFields) in patients with high-grade glioma in clinical practice. *First Author: Wenyin Shi, Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA*

Background: Tumor Treating Fields (TTFields) are an antineoplastic treatment delivering low intensity, intermediate frequency, alternating electric fields through two pairs of transducer arrays locoregionally applied to tumor bed. TTFields are FDA-approved for glioblastoma (GBM; 200 kHz) and mesothelioma (150 kHz). Safety and effectiveness were demonstrated in the phase III EF-11 and EF-14 trials in recurrent GBM (rGBM) and in newly diagnosed GBM (ndGBM), respectively. The main TTFields-related adverse event (AE) was array-associated manageable skin irritation. We report AEs from TTFields-treated patients in the real-world, clinical practice setting. **Methods:** Unsolicited, global, post-market surveillance data from TTFields-treated patients (October 2011–February 2019) were retrospectively analyzed using MedDRA v21.1, stratified by region (US, EMEA [Europe, Middle East, Africa], or Japan), diagnosis (ndGBM, rGBM, anaplastic astrocytoma and anaplastic oligodendroglioma, or other brain tumors that includes brain metastases from different cancer types), and years of age ($<$18, pediatric; 18 to 64, adults; or $\geq$65, elderly). **Results:** Of 11,029 patients, 53% had ndGBM, 39% had rGBM (at any line of recurrence), 6% had anaplastic astrocytoma/oligodendroglioma, and 1% had other brain tumors. Most were adults (73%) and 26% were elderly ($\geq$65 years of age). The majority of patients were males (66.3%) compared to females (33.7%), with a ratio representative of a typical GBM population. The most reported TTFields-related AE was array-associated local skin reaction, with an incidence of 38% in ndGBM, 29% in rGBM, 38% in anaplastic astrocytoma/oligodendroglioma, 31% in other brain tumors, 37% in pediatric, 34% in adults, and 36% in elderly patients. Most skin AEs were mild to moderate and resolved with no treatment or over the counter topical ointments. Incidence of other TTFields-related AEs in patients with ndGBM and rGBM, respectively, included heat sensation (under-array warmth; 11%, 10%), electric sensation (under-array tingling; 11%, 9%), and headache (7%, 6%). **Conclusions:** This retrospective, global, TTFields safety surveillance analysis revealed no new safety signals, with favorable safety and tolerability comparable to published TTFields/GBM trials. The most common TTFields-related AE was array-associated local skin reaction. The safety profile remained consistent among subgroups (diagnosis, age, or region) and total cohort, indicating feasibility in multiple subpopulations, including elderly patients. 2543 Poster Session (Board #34), Fri, 8:00 AM-11:00 AM

Phase I study of BPM31510 and vitamin K in patients with high grade glioma recurrent after a bevacizumab-containing regimen. *First Author: Seema Nagpal, Stanford University, Stanford, CA*

Background: BPM31510 is an ubidecarenone-lipid conjugate nanodispersion in clinical development for advanced malignancies, including high grade glioma (HGG). BPM31510's anti-cancer effect is mediated by induction of mitochondrial superoxide and activation of cell death in glioblastoma models. Herein, we present preliminary pharmaco-kinetic and dynamic data, and survival from a phase I study of BPM31510 + Vitamin K in HGG with progression after bevacizumab (BEV). **Methods:** This was an open-label phase I study of BPM31510 continuous infusion with Vitamin K (10mg IM qweek) using a mTPI design, starting at 110mg/kg 2X/week, allowing 2 dose escalations & 1 de-escalation. Patients had received ChemoRT and were in recurrence after BEV. **Results:** Of 12 patients treated with BPM31510, 9 completed the 28-day DLT period. 2 patients came off study for progressive disease; 1 patient after asymptomatic hemorrhage into tumor bed (G1). 10 patients had primary GB, 2 had AA. Median age was 54.5yo (27-67) and KPS 70 (60-90). On Day 1 of BPM31510, a dose dependent increase in Cmax was observed; Tmax values were similar for all doses. AUC was linear with dose escalation. For all doses, Day 4 Cmax values were higher compared to Day 1. In contrast there was variable decrease in Tmax (table). Of evaluable patients, 4 patients received the highest dose 171mg/kg, where a single patient experienced DLT: G3 AST & ALT. The most common grade 1/2 AEs were elevated AST, rash, and fatigue, each occurring in 4 patients. The mOS for 9 eligible/evaluable patients was 128 days (95% CI: 48-209) while PFS was 34 days (95% CI of mean 8.9). Two patients are currently alive $>$12 months. **Conclusions:** BPM31510 + vitamin K demonstrated a safe profile to maximum dose of 171mg/kg twice/week with potential therapeutic utility in treatment-refractory HGG patients. Multi-omic molecular profiles characterizing AE and response to be reported from the study will be investigated for next phase of clinical development. Clinical trial information: NCT03020602. Research Sponsor: Berg Health, LLC.

2544 Poster Session (Board #35), Fri, 8:00 AM-11:00 AM

Depatuxizumab mafodotin (Depatux-M) plus temozolomide (TMZ) in recurrent glioblastoma patients: Real-world experience from a multicenter study of Italian Association of Neuro-Oncology (AINO). *First Author: Mario Caccese, Department of Oncology, Oncology 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: Precision medicine is a promising tool in oncology. Depatux-M is a new antibody-drug conjugate, consisting of a specific antibody against activated EGFR and a cytotoxic agent with antimicrotubule activity. The Intellance2/EORTC 1410 phase II trial, showed interesting results for Depatux-M and TMZ combination in EGFR-amplified glioblastoma (GBM) patients (PTS) at first recurrence after RT and TMZ. In our study, we investigated clinical outcome and safety of this combination used in recurrent GBM PTS as "compassionate use". **Methods:** In this prospective observational study, PTS were enrolled from 7 centres of AINO. Major inclusion criteria were: histologically confirmed diagnosis of GBM, 1 or more prior systemic therapies, ECOG PS $\leq$ 2 and EGFR-amplified (analyzed by FISH). According to original schedule, patients received Depatux-M 1.25 mg/kg every two weeks combined with TMZ until disease progression or unacceptable toxicity. Kaplan-Meier method was used to estimate the survival curves, RANO criteria for radiological assessment, CTCAE v5.0 for drug related adverse events. **Results:** From October 2018 to June 2019, we enrolled 36 PTS: median age was 57, ECOG PS 0-1 in 88% of PTS, MGMTmet in 64%, 42% received the treatment as second-line therapy and 27% underwent further chemotherapy at progression. At the time of analysis, 13 PTS (36%) had died and 27 PTS (75%) had progressed. Median OS was 8.7ms (95%CI not available), 6ms OS was 68%; median PFS was 2.3ms (95% CI 1.8 – 2.8), 6ms PFS was 37%. All PTS were evaluable for response: disease control rate was 47%: stable disease was reported in 36% and partial response in 11% of PTS. Drug-related adverse events led to dose reductions of Depatux-M in 17% of PTS, in 28% was delayed and in 8% was permanently discontinued. The most frequent grade 3-4 adverse events were ocular toxicity in 67% and haematological toxicity in 17% of PTS; no death was considered drug-related. **Conclusions:** We report the first "real world" experience of Depatux-M plus TMZ in recurrent GBM. We showed encouraging clinical benefit, despite most patients were treated beyond the second-line of therapy. Overall the results are closed to those reported in previous phase II trial. Although toxicity was higher than expected, it was manageable and only a small group of patients discontinued the treatment due to serious adverse events Research Sponsor: None.

2545 Poster Session (Board #36), Fri, 8:00 AM-11:00 AM

Preliminary assessment of low-intensity transcranial magnetic stimulation (TMS) during the treatment for brain glioblastomas. *First Author: Ivan A. Popov, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation*

Background: The standard treatment of malignant brain gliomas, including surgical and radiation therapies, does not provide recovery and a long-time favorable prognosis. The development of technologies and international guidelines on the introduction of electric (TTF) and electromagnetic (TMS) fields in combination treatment for glioblastomas aims to improve immediate results, as shown in experiments on human glioblastoma cell culture. The TMS protocol requires further refinement in parameters of frequency, intensity, and exposure with an assessment of the immediate results of combined treatment. **Methods:** The study included 60 patients diagnosed with MBG receiving osteoplastic craniotomy with radical (within visible unchanged tissues) tumor removal. Starting from the second day after the surgery, patients of group 1 (n = 30) received 10 sessions of magnetotherapy in the double exposure mode. For the first morning exposure, we used an ultra-low-frequency magnetic field (ULFMF) (0.03 to 9.0 Hz) on the hypothalamus projection area to induce a general antistress reaction. After 2.5-3 hours, local (on the surgical site) TMS exposure with the Neuro-MSD system (Russia) was applied in the pulse algorithm, up to 1 GHz and 5 Hz, 15 mT, 3 min. The induction was reduced exponentially (C = 0.8). The control group 2 (n = 30) did not receive ULFMF or TMS. Magnetic resonance imaging (MRI) was used to determine the volume of tumors (Vt, cm^3) and perifocal edema (Ve, cm^3) calculated according to the Shrek's formula for an ellipsoid ($V = a \times b \times c \times \pi/6$). **Results:** Before surgery, $Vt = 54.7 \pm 5.7 cm^3$ in group 1, in group 2 - $Vt = 60.9 \pm 8.5 cm^3$ (no statistical differences). After surgery and the subsequent course of ULFMF and TMS, residual tumor volumes in group 1 were 2.5 times lower than in controls ($p < 0.05$). The difference between Ve values before and after treatment was on average 80.7 cm^3 in group 1 and 41.8 cm^3 in group 2 ($p < 0.05$). **Conclusions:** The inclusion of sequential ULFMF and TMS exposures into postoperative therapy for gliomas, taking into account various vectors of the influence on the projection of centers of homeostasis regulation and the surgical field, as well as the development of programmed modes of biotropic exposure parameters, improves antitumor and anti-edematous effects. Research Sponsor: None.

2546 Poster Session (Board #37), Fri, 8:00 AM-11:00 AM

MRI changes in patients with newly diagnosed glioblastoma treated as part of a phase II trial with bavituximab, radiation, and temozolomide. *First Author: Ina Ly, Massachusetts General Hospital, Boston, MA*

Background: Glioblastoma and tumor endothelial cells express phosphatidylserine (PS), a highly immunosuppressive membrane phospholipid. Bavituximab – a chimeric monoclonal antibody – binds to β2-glycoprotein 1 (β2-GP1) to form a complex of β2-GP1 with PS, resulting in immune activation against tumor cells and anti-angiogenic effects. Phase I/II trials in other solid cancers demonstrated response rates up to 75% when bavituximab was given with cytotoxic chemotherapy. Preclinical data in glioblastoma models suggested synergistic effects of PS blockade, radiation, and temozolomide. **Methods:** 33 adult patients with *IDH*-wild-type, *MGMT*-methylated or -unmethylated newly diagnosed glioblastoma were enrolled in this phase II trial (NCT03139916) and received 6 weeks of chemoradiation, followed by 6 cycles of adjuvant temozolomide (C1-C6 aTMZ). Bavituximab (3 mg/kg) was given weekly, starting week 1 of chemoradiation, for 18 weeks with the option to continue if tolerated. Physiologic MRIs were performed pre-treatment, pre-C1, pre-C3, and pre-C5 aTMZ. Within the enhancing tumor region, median tumor K^{trans} (reflecting vascular permeability) and relative cerebral blood flow (rCBF) were measured. Median percent changes during treatment were compared to pre-treatment values. **Results:** Median progression-free survival (mPFS) was 8 months. Based on a median overall survival (mOS) of 17.1 months, patients were categorized into above-median survivors (AMS) and below-median survivors (BMS). All patients had pre-treatment scans. 31 had evaluable pre-C1, 25 had pre-C3, and 7 had pre-C5 scans. Compared to BMS, AMS had a greater reuction in enhancing tumor volume and rCBF, and a greater increase in K^{trans} during treatment (table). One patient remains on study; 23 patients have died. Bavituximab was well tolerated. **Conclusions:** mPFS and mOS in patients treated with bavituximab, radiation and temozolomide were comparable to standard chemoradiation and aTMZ. Lower rCBF in AMS may reflect decreased tumor perfusion while higher K^{trans} could imply enhanced drug delivery to the tumor. Bavituximab induces changes in tumor vasculature that may improve survival in a subset of patients. Clinical trial information: NCT03139916. Research Sponsor: Peregrine Oncologie, National Comprehensive Cancer Network.

% change in MRI parameters compared to baseline at pre-C1, pre-C3, and pre-C5 timepoints. AMS: above-median survivors; BMS: below-median survivors.

	Enhancing tumor volume		rCBF		K^{trans}	
MRI	**AMS**	**BMS**	**AMS**	**BMS**	**AMS**	**BMS**
Pre-C1	-46.4	-8.1	-33.4	-6.0	85.8	5.1

2547 Poster Session (Board #38), Fri, 8:00 AM-11:00 AM

Impact of lymphopenia on survival for elderly patients with glioblastoma: A secondary analysis of the CCTG CE.6 (EORTC 26062-22061, TROG03.01) randomized clinical trial. *First Author: Andrew Jehyun Song, Sidney Kimmel Cancer Center, Philadelphia, PA*

Background: Lymphopenia (LMP) may lead to worse outcomes for patients with glioblastoma (GBM). This study is a secondary analysis of the CCTG CE.6 trial evaluating the impact of chemotherapy and radiation on LMP, as well as the association of LMP with overall survival. **Methods:** CCTG clinical trial CE.6 randomized elderly GBM patients ($\geq$ 65 yrs) to short course radiation alone (RT) or short course radiation with temozolomide (RT + TMZ). In this study LMP (mild-mod: grade 1-2; severe: grade 3-4) was defined per CTCAE v3.0 criteria, and measured at baseline, 1 wk and 4 wks post-RT. Pre-selected key factors for the analysis included age, sex, ECOG, extent of resection, MGMT methylation, MMSE, and steroid use. Multinomial logistic regression models were used to identify factors associated with LMP and multivariable Cox regression models were used to study effect of LMP on survival. **Results:** A total of 562 patients were included for analysis (281 RT vs 281 RT+TMZ). At baseline, both arms (RT vs RT+TMZ) had similar rates of mild-mod (21.4% vs 21.4%) and severe (3.2% vs 2.9%) LMP. The 1 wk post-RT LMP rates were also similar (p = 0.25). However, RT+TMZ pts were more likely to develop both mild-mod LMP (18.2% vs 27.9%) and severe LMP (1.8% vs 9.3%) [$p < 0.001$] at 4 wks post-RT. Developing mild-mod and severe LMP post-RT were both associated with baseline LMP ($p < 0.001$) and RT+TMZ ($p < 0.001$). Severe LMP at 4 wks post-RT was also associated with biopsy only ($p < 0.02$). After adjusting for confounding factors, 4 wks post-RT LMP was not significantly associated with PFS or OS regardless of severity. However, baseline LMP (HR 1.3) was significantly associated with worse OS (HR: 1.30, 95% C.I.: 1.05-1.62, p = 0.02), regardless of MGMT status. Other factors significantly associated with worse outcome included: males (HR 1.41), biopsy only (HR 1.59), and lower MMSE (HR 1.03). **Conclusions:** Short course RT alone does not lead to LMP after treatment. Development of LMP post-RT is associated with addition of TMZ and baseline LMP. However, only baseline LMP is associated with worse OS regardless of MGMT status. This may be considered as a prognostic biomarker for elderly GBM patients and warrants further validation. Clinical trial information: NCT00482677. Research Sponsor: None.

2548 Poster Session (Board #39), Fri, 8:00 AM-11:00 AM

Association of peripheral blood CD4+ T-cell depletion under temozolomide with inferior survival of patients with IDH wildtype glioblastoma. *First Author: Michael Weller, Laboratory of Molecular Neuro-Oncology, Department of Neurology, and Neuroscience Center Zürich, University Hospital and University of Zürich, Zürich, Switzerland*

Background: Standard first line chemoirradiation with temozolomide is associated with distinctive peripheral blood immune cell profiles in IDH wildtype glioblastoma. Whether such profiles at recurrence are associated with survival has not been studied in detail. **Methods:** Peripheral blood mononuclear cells of 21 healthy donors and of 91 patients with IDH wildtype glioblastoma were analyzed by flow cytometry at 1st recurrence. Patients received either (i) standard chemoirradiation with temozolomide (TMZ) followed by dose-intensified TMZ at first recurrence within the phase II trial DIRECTOR (N = 52) or (ii) hypofractionated radiotherapy with or without bevacizumab (N = 39) followed by investigators' choice within the phase II trial ARTE. Patients were classified based on unsupervised analyses of PBMC profiles at 1st recurrence. Associations with survival were explored in multivariate Cox models controlling for established prognostic and predictive factors. **Results:** At 1st recurrence, two patient clusters were identified in the DIRECTOR cohort which differed in CD4+ T-cell fractions, but not with respect to CD8+ T-cells, CD4+;CD25+;FoxP3+ regulatory T-cells, B-cells or monocytes. The composition of CD4+, CD8+ or regulatory T-cell fractions was similar in both clusters. All control samples clustered with the $CD4_{high}$ cluster. Patients in both clusters did not differ by established prognostic factors, including age, O6-methylguanine-DNA-methyl-transferase (*MGMT*) gene promoter methylation, tumor volume, Karfnosky performance score or steroid use. Progression-free survival was similar ($CD4_{high}$ *vs* $CD4_{low}$ 2.1 *vs* 2.4 months, p = 0.19), whereas post-recurrence overall survival was longer among the $CD4_{high}$ cluster (12.7 *vs* 8.7 months, p = 0.004). At 2nd recurrence after dose-intensified TMZ re-challenge, monocyte fractions increased, whereas memory CD4+ T-cell fractions decreased. Higher memory CD4+ fractions were associated with longer overall survival at 2nd recurrence (p = 0.004). The reported associations were retained in multivariate Cox models controlling for established prognostic factors. In the ARTE cohort, CD4+ T cell fractions at 1st recurrence did not differ compared to diagnosis (p = 0.91) and there were no associations with bevacizumab (p = 0.28) or survival (p = 0.74), supporting that the effects observed in the DIRECTOR cohort were driven by TMZ. **Conclusions:** We conclude that TMZ-associated memory CD4+ T-cell depletion may have deteriorating effects on the survival of glioblastoma patients. Research Sponsor: MSD.

2549 Poster Session (Board #40), Fri, 8:00 AM-11:00 AM

Molecular features of gliomas with high tumor mutational burden. *First Author: Joanne Xiu, Caris Life Sciences, Phoenix, AZ*

Background: TMB-H in gliomas is caused by molecular alterations or alkylator treatment- induced genomic changes characterized by a large number of G:C>A:T transitions. Our study describes the molecular features of TMB-H gliomas. **Methods:** Gliomas were tested with NextGen sequencing (592 genes), MGMT promoter methylation (MGMT-m) fragment analysis and IHC at Caris Life Sciences. Microsatellite instability (MSI) was test by NGS, FA/IHC. The GC:AT transition rate was calculated as the prevalence of G:A and C:T changes seen in each tumor and > 80% was regarded as high transition(TR-H). TMB values were compared using Wilcoxon Rank Sum. TMB-H was defined as the top quartile of all TMB values (TMB>9). **Results:** TMB in the 3129 gliomas ranged from 0 to 372 mutations/MB (mean: 8.5, median: 6). TMB-H was observed in 31% of glioblastomas, 16% of astrocytomas (astro) (22% of grade III, 7% of grade I/II) and 22% of oligodendrogliomas (oligo) (32% of grade III and 15% of grade I/II). MGMT-m (58% vs. 47%; p=0.0001), pathogenic (p) or likely p (lp) EGFR (14% vs 10%, p=0.004) and PIK3CA mutations (13% vs. 9%, p=0.002), as well as p/lp in 30 other genes were more prevalent in TMB-H cases (p<0.01). In the 613 TMB-H tumors, TR-H was seen in 12% (73) and was strongly associated with increased TMB (median TMB 52 in TR-H vs. 9 in TR-L,) and MSI-H (7.3% vs. 1.1%), both p<0.0001. Tumors with both TR-H and MSI-H had a mTMB of 114 vs. 49 in TR-H /MSS tumors. MSI-H and TR-L tumors had an mTMB of 23 vs. 9 in MSS /TR-L tumors (p<0.0001). All 5 POLE-MT tumors had TMB of >100 (median 264) and TR-L; 4 of the 5 were also MSI-H. PDL1 IHC had no correlation with TMB, MSI or transition rates. In 89 paired samples taken >150 days apart (regardless of intervening treatment), acquisition of TMB-H was seen in 11 pairs: 8 glioblastomas, 2 grade II/III astro and 2 oligo. In the paired tumors that acquired TMB-H status compared to those that did not, a significantly higher prevalence of MGMT-m (82% vs. 37%, p=0.008) and IDH mutation (64% vs. 19%, p=0.004) were seen. 10 of the 11 recurrent tumors with acquisition of TMB-H had TR-H while none in the other 78 pairs. **Conclusions:** TMB varies significantly in gliomas and associates with POLE, TR-H and MSI-H, but not with an increase of PD-L1. POLE-mutated tumors had the highest TMB levels. TR-H, an indicator of alkylator-induced phenotype, is associated with a higher TMB than MSI-H, however, TR-H may synergize with MSI-H to further increase TMB. Tumors with an IDH mutation and MGMT-m are more prevalent in tumors with high TMB gain. Further understanding of molecular and immune profile of the TMB-H may facilitate more individualized treatment planning. Research Sponsor: None.

2550 Poster Session (Board #41), Fri, 8:00 AM-11:00 AM

Escalation portion of phase II study to evaluate the safety, pharmacokinetics, and clinical activity of the PI3K/mTOR inhibitor paxalisib (GDC-0084) in glioblastoma (GBM) with unmethylated O6-methylguanine-methyltransferase (MGMT) promotor status. *First Author: Patrick Y. Wen, Dana-Farber Cancer Institute, Boston, MA*

Background: Paxalisib (previously GDC-0084) is a potent, oral, selective, brain-penetrant, small molecule inhibitor of class I phosphoinositide 3-kinase and mammalian target of rapamycin. The PI3K pathway is upregulated in ~85% of GBM cases and paxalisib has shown efficacy in preclinical models. A phase I study (NCT01547546) investigated paxalisib dosed once daily in 47 patients with recurrent high-grade gliomas and established a maximum tolerated dose (MTD) of 45mg once daily. The current phase II study aims to explore the safety, tolerability, and clinical activity of paxalisib in newly diagnosed GBM and an unmethylated MGMT promotor following surgery and temozolomide chemoradiation per Stupp regimen. **Methods:** Part 1 of this study is an open-label, dose-escalation phase to assess the safety, tolerability and MTD. Dose-escalation started at 60mg and progressed in 15mg increments using a 3+3 design. Part 2 is an expansion cohort recruiting 20 patients randomized to administration in fed or fasted states at the MTD. **Results:** Part 1 is complete and reported here. Nine patients were recruited and an MTD of 60mg was determined. DLTs were hyperglycemia and oral mucositis. AEs were generally reversible and consistent with the PI3K inhibitor class with the most common events were rash, oral mucositis, and fatigue. PK at the MTD was broadly consistent with the data published for the phase 1 study. For eight response-evaluable patients in Part I the median progression-free survival (PFS) was 8.4 months, and 25% of patients remained progression free after 15 months of follow-up. Part 2 is ongoing. **Conclusions:** A higher MTD of 60mg was identified in newly diagnosed GBM with unmethylated MGMT promotor status than the 45mg MTD previously identified in recurrent high-grade glioma. An encouraging PFS signal is described in this poor-prognosis, unmethylated MGMT patient population. Clinical trial information: NCT03522298. Research Sponsor: Kazia Therapeutics Limited.

2551 Poster Session (Board #42), Fri, 8:00 AM-11:00 AM

Tumor treating fields effects on the blood-brain barrier in vitro and in vivo. *First Author: Ellaine Salvador, University of Wuerzburg, Department of Anesthesia and Critical Care, Division Molecular Medicine, Wuerzburg, Germany*

Background: The greatest hurdle, which even potent and effective drugs targeting central nervous system (CNS) tumors and other disorders face, is the blood brain barrier (BBB). The inability to cross the tight regulatory mechanism renders these drugs futile. Of late, administration of tumor treating fields (TTFields) as part of a combined treatment modality for glioblastoma demonstrated increased overall patient survival. Still, the effects of TTFields on the BBB have not yet been investigated. Here, we report the potential of TTFields application to open up the BBB. **Methods:** Murine brain endothelial cells were treated with 100-300 kHz TTFields for 24-96 h. Cells were also allowed to recover from 24-96 h after treatment. Subsequently, changes in cell morphology, integrity, and permeability were observed via staining of intercellular junction proteins (IJP) as well as transendothelial electrical resistance (TEER) and permeability assays. In vivo, rats were treated with 100 kHz TTFields or heat for 72 h after which they were IV injected with Evan´s Blue (EB)/ TRITC-dextran (TD) which was later quantified from the brain. Rat brain cryosections were also stained for IJPs as well as immunoglobulin G (IgG) to assess vessel structure. Finally, serial dynamic contrast-enhanced (DCE) MRI with gadolinium (Gd) contrast agent was performed pre- and post- TTFields. **Results:** Upon TTFields application, IJPs such as claudin-5 were delocalized from the cell membrane to the cytoplasm with maximal effects at 100 kHz. In addition, BBB integrity was significantly reduced and permeability for 4 kDa molecules was significantly increased. Cell morphology recovery was first observed at 48 h post-treatment and completely restored to normal after 96 h, indicating a reversibility of the TTFields effect on the BBB. In addition, EB and TD permeated the rat brain post-TTFields treatment. Brain cryosections displayed IJPs delocalization as well as IgG accumulation in the brain parenchyma. Confirming these observations, increased Gd in the brain was shown by DCE-MRI post-TTFields application. A reversion to normal conditions was detected 96 h after end of treatment, which was demonstrated by no difference in contrast enhancement between control and treated rats. **Conclusions:** TTFields application both in vitro and in vivo points towards its ability to transiently open the BBB. This presents TTFields as a novel aid for drug delivery geared towards treatment of CNS tumors and other related diseases. Hence, it is indicative of the possibility of an enhanced and more effective combinatorial therapeutic strategy. Research Sponsor: Novocure Ltd.

2552 Poster Session (Board #43), Fri, 8:00 AM-11:00 AM

Genome-wide methylation analysis in long-term survivors of glioblastoma (GBM). *First Author: Justin Chau, University of Iowa Hospitals and Clinics, Iowa City, IA*

Background: Identification of tumor characteristics that may be associated with survival in patients with glioblastoma (GBM) has been largely characterized by IDH mutations and MGMT promoter methylation status. However, these genetic changes and other currently available data are not sufficient to explain the longevity experienced by a subset of long-term survivors (LTS) - patients surviving longer than 3 years past diagnosis. **Methods:** The study identified GBM patients established and treated at University of Iowa Holden Comprehensive Cancer Center from 2007-2017 whose disease recurred after initial resection. Patients were categorized LTS if they survived > = 3 years beyond initial definitive resection; short-term survivors (STS) if less than 3 years. Pathologic specimens at initial and repeat resection underwent genome wide methylation analysis using the Infinium EPIC microarray system. Data were analyzed to identify genes that exhibited differentially methylated CpG regions. **Results:** Resection specimens from GBM survivors were compared to those of STS. A total of 29 samples were analyzed and compared (15 LTS and 14 STS samples). Multidimensional scaling plots identified significant differences in genomic constitution between LTS and STS specimens. Granular analysis yielded 89 differentially methylated regions significantly associated with long-term survival (adjusted $p < 0.05$). *PTPRN2* ($p = 0.000376$), *PTPN11* ($p = 1.38E-05$), and *PAX6* ($p = 0.000671$) were found to exhibit numerous differentially methylated CpG sites between MGMT-methylated vs. unmethylated specimens. Further notable, higher levels of differentially methylated CpG shores and open-seas regions on chromosome 12 were associated with long-term survival ($p = 1.89E-08$). **Conclusions:** Our study identified multiple significant epigenetic differences that, functionally or consequentially, may be associated with extended survival in GBM patients. The implication that CpG shores, rather than islands, are associated with long-term survival raises further intriguing questions regarding the depth of epigenetic complexity in this disease. More immediately, the surprising association of multiple protein phosphatases with LTS in our study may hint at the class' previously unspecified, yet integral, role in delaying disease progression and identify new, novel avenues for therapy. Lymphocyte-activation gene 3 (LAG-3) expression in the inflammatory microenvironment of glioma. *First Author: Maximilian Mair, Department of Medicine I, Division of Oncology, Medical University of Vienna, Vienna, Austria*

Background: The blockade of lymphocyte-activation gene 3 (LAG-3), an inhibitory receptor on tumor-infiltrating lymphocytes, is currently under investigation in many extracranial tumor entities. **Methods:** 54 patients with diffuse glioma were included: 35 patients with glioblastoma (GBM, median age at diagnosis: 61 years) as well as 14 with WHO grade II and 5 with WHO grade III glioma (lower-grade glioma, LGG, median age at diagnosis: 45 years). Isocitrate dehydrogenase 1/2 mutations (IDH-mt) were present in 17/54 patients and 37/54 patients had IDH wildtype (IDH-wt) tumors. LAG-3 expression on tumor-infiltrating lymphocytes (TILs) was analyzed by immunohistochemistry (monoclonal anti-LAG-3 antibody, clone 17B4, LSBio Inc.). **Results:** LAG-3^+ TILs could be observed in 5/54 (9.3%) samples, while $CD3^+$ TILs were present in 32/54 (59.3%) and $CD8^+$ TILs in 24/54 (44.4%) samples. Only IDH-wt glioma presented with LAG-3^+ TILs ($p = 0.168$). Samples with LAG-3^+ TILs presented with a numerical trend towards higher presence of $CD3^+$ (5/27 $CD3^+$ vs. 0/22 $CD3^-$, $p = 0.072$) and $CD8^+$ TILs (4/24 $CD8^+$ vs. 1/30 $CD8^-$, $p = 0.159$). 4/7 (57.1%) samples presenting with PD-1^+ TILs also presented with LAG-3^+ TILs ($p = 0.001$). Furthermore, glioma samples with $LAG3^+$ TILs presented with higher expression of PD-L1 (median: 1% vs. 0%; $p = 0.166$). There was no difference in overall survival (OS) according to LAG-3^+ TIL infiltration (median OS in LAG-3^+: 21.7 months vs. LAG-3^-: 41.4 months, $p > 0.05$). **Conclusions:** LAG-3^+ TILs are rarely observed in IDH-wt and absent in IDH-mt glioma. Gliomas with an active inflammatory microenvironment present more frequently with $LAG3^+$ TILs. The diverse composition of the inflammatory microenvironment and particular inflammatory subgroups should be considered in future clinical trials on immune-modulating therapies in glioma. Clinical, radiological, and genomic features of BRAF V600E-mutated adult glioblastoma. *First Author: Mary Jane Lim-Fat, Dana-Farber Cancer Institute, Boston, MA*

Background: Although uncommon, detection of a BRAF V600E mutation in adult patients with glioblastoma has become relevant given the increased availability of NGS and encouraging therapeutic activity of BRAF/MEK inhibitors. The clinical course, radiological characteristics and genetic mutations in this patient population has, however, not been well described. **Methods:** Adult patients treated at Dana-Farber Cancer Institute or Massachusetts General Hospital with glioblastoma diagnosed from 2013-2019 and an identified BRAF V600E mutation on immunohistochemistry staining or institutional NGS platform were included. Patient demographics, treatments and outcomes were collected retrospectively. Molecular diagnostics (Oncopanel or SNaPSHOT) and cytogenetics (array CGH) were reviewed for relevant mutations or copy number variants (CNV). Qualitative MRI data was analyzed using Visually Accessible Rembrandt Images (VASARI) feature set. Response assessment was performed using the RANO criteria. **Results:** Nineteen glioblastoma patients had a BRAF V600E mutation (16 on NGS and 19 on IHC). The median age at diagnosis was 41 (22-69) years; 13/19 were female, 12/19 were Caucasian. Only 1/19 had an IDH mutation; 10 of the 17 with known methylation status had MGMT unmethylated tumors. The most frequent mutations on NGS or CNV on array-CGH were TERT (12/16), CDKN2A (10/16), EGFR (7/16), PIK3R1 (6/16) and CKDN2B (6/16). Most tumors were well circumscribed (12/19) and all were contrast-enhancing on MRI. While no patient had clear leptomeningeal involvement at diagnosis, 11/19 eventually developed subependymal or leptomeningeal dissemination. Six patients were treated with BRAF/MEK inhibition following progression after standard of care therapy, with 3/6 patients showing partial response and 2 showing stable disease as their best response. PFS after BRAF/MEK inhibition ranged from 1.9 to 19 months. Grade 1 skin rash was present in 1 patient, but no other adverse events were reported. Median OS for the patients with confirmed deaths (15/19) was 22.6 (14.5 – 39.0) months. **Conclusions:** Compared to the general glioblastoma population, adult patients with BRAF V600E mutations are younger, more frequently female, and have a higher median OS despite a much higher incidence of leptomeningeal dissemination. Outcome following BRAF/MEK targeted therapy was encouraging. Understanding the natural history and features of these tumors may help better screen patients for BRAF/MEK inhibition and identify novel therapeutic strategies. Research Sponsor: None.

2555 Poster Session (Board #46), Fri, 8:00 AM-11:00 AM

Proteomic profiling to identify therapeutics targets in glioblastoma (GBM). *First Author: Sheeno P. Thyparambil, OncoPlex Diagnostics, Culver City, MD*

Background: Glioblastoma (GBM) is an aggressive primary brain tumor with poor prognosis. Treatment at diagnosis is largely confined to surgery, radiation and temozolomide (TMZ) with median progression-free survival (PFS) of 7 months and median overall survival (mOS) of 15 months. GBM tumors recur in most cases and in patients with recurrent GBM, the mOS is 6.2 months. The lack of effective therapies underscores the importance of exploring other agents. We propose that quantitating therapy-associated protein biomarkers can improve treatment personalization for GBM. **Methods:** 97 FFPE GBM tissues were microdissected and solubilized for mass spectrometry-based proteomic analysis of therapy-associated protein biomarkers in our CLIA certified lab. We quantified protein levels of MGMT, hENT1, RRM1, TOPO1 and EGFR/TUBB3 (antibody target and payload resistance markers, respectively, for anti-EGFR ADCs) simultaneously. The multiplexed assay also quantified additional 24 clinically relevant proteins. **Results:** 43/57 patients were predicted to respond to TMZ based on undetectable levels of MGMT, confirming wide utility of this agent. 42/97(43%) patients were predicted to have gemcitabine sensitivity based on high expression of the response marker (hENT1 > 100 amol/ug) and low expression of the resistance marker (RRM1 < 700 amol/ug). 11/97(11%) patients expressed TOPO1 > 1350 amol/ug (75^{th} percentile of all indications tested by author's laboratory), suggesting likely response to irinotecan and topotecan. EGFR expression ranged from < 100 amol/ug to > 25000 amol/ug, including overexpression (> 1500 amol/ug) in 22%(21/97) of cases. While expression of EGFR(81/97, 84%) suggested likely response to anti-EGFR ADC, concurrent expression of TUBB3(78/81) may indicate resistance to several known payloads, such as taxanes and MMAE. Conjugation with another payload that targets sensitivity marker TOPO1 (68% expression) is a likely option. Proteomic analysis also revealed detectable levels of multiple RTKs (FGFR(4), AXL(20), IGF1R(10), MET overexpression(1), and HER2 overexpression(2)), indicating potential response to RTK inhibitors. Exploratory investigation in tumor vs TME using proteomics and metabolomics is ongoing. **Conclusions:** In this population of GBM patients, proteomic analysis identified protein targets of multiple approved and investigational therapies. Gemcitabine, which crosses the blood-brain barrier, may be considered as a salvage option after TMZ failure. Proteomic quantitation of EGFR and TUBB3 may improve patient selection for EGFR-targeting ADCs. Research Sponsor: OncoPlex Diagnosis (mProbe).

2556 Poster Session (Board #47), Fri, 8:00 AM-11:00 AM

Ibrutinib-based combination therapy exhibited therapeutic benefit in newly diagnosed primary central nervous system lymphoma. *First Author: Feili Chen, Guangdong Provincial People's Hospital, Guangzhou, China*

Background: Ibrutinib has shown single-agent activity in relapse/refractory (R/R) primary central nervous system lymphoma (PCNSL), and the high dose methotrexate (HD-MTX) has been the backbone of treatment of de-novo PCNSLs. Combination therapy of HD-MTX and ibrutinib has recently shown activity in R/R PCNSLs. **Methods:** Eleven newly diagnosed PCNSL patients who underwent combination therapy of HD-MTX and ibrutinib were analyzed for treatment response and safety profile. HD-MTX was given at 3.5 g/m2 every 2 weeks for a total of 8 doses. Ibrutinib was held on days of HD-MTX infusion until HD-MTX clearance. Single-agent daily ibrutinib was administered continuously after completion of induction therapy until disease progression, intolerable toxicity, or death. Patients' clinicopathologic characteristics were retrospectively reviewed and genomic traits were further analyzed. **Results:** Nine out of 11 patients have completed the induction phase of ibrutinib-based combination therapy and received ibrutinib maintenance in addition to two patients whose disease progressed during the therapy. An objective response rate (ORR) of 82% (9/11) was observed, including 7 patients with complete response (CR, 64%) and 2 patients with partial response (PR, 18%). The median progression-free survival (PFS) was 7.4 months while the median overall survival (OS) was not reached. The combination therapy of HD-MTX and ibrutinib was well tolerated and has acceptable safety. In addition, the presence of ctDNA in cerebrospinal fluid (CSF) samples closely correlated with tumor response. Sustained tumor responses were associated with the clearance of ctDNA from the CSF. **Conclusions:** Combination of ibrutinib and HD-MTX has acceptable safety and has demonstrated anti-tumor activity in newly diagnosed de-novo PCNSL patients. The detection of ctDNA in CSF is feasible for monitoring tumor burden in PCNSL patients. Research Sponsor: None.

2557 Poster Session (Board #48), Fri, 8:00 AM-11:00 AM

Clinical, radiologic & prognostic profile of IDH wild type diffuse astrocytic glioma with molecular features of glioblastoma. *First Author: Oluwatosin Akintola, MGH/DFCI/BWH/HMS, Boston*

Background: In 2018, The Consortium to Inform Molecular and Practical Approaches to CNS Tumor Taxonomy (cIMPACT-NOW) recommended that IDH-wildtype diffuse astrocytic glioma Grade II/III with either EGFR amplification, combined whole chromosome 7 gain and whole chromosome 10 loss (+7/−10), or TERT promoter mutation should receive an integrated histological and molecular grade classification: Diffuse astrocytic glioma, IDH-wildtype with molecular features of glioblastoma, WHO grade IV. The natural history, radiologic characteristics and standard management for these patients has not been well described. They are typically excluded from clinical trials for WHO Grade IV gliomas. **Methods:** Adults diagnosed at Massachusetts General Hospital with IDH wildtype diffuse astrocytoma and EGFR amplification or TERT promoter mutation from 2011-2019 were identified. Demographics, functional status, radiologic features, MGMT promoter methylation status, time to progression, and overall survival were collected retrospectively. Qualitative MRI data was analyzed using the VASARI feature set. Response assessment was performed using the RANO criteria. **Results:** 50 patients were identified (table). 37/50 patients received standard Stupp protocol, 2/50 received hypofractionated radiotherapy with temozolomide, 6/50 received radiotherapy alone, and 1 patient received a MEK inhibitor. None were enrolled in clinical trials at diagnosis. mPFS was 10 months in the 47/50 with confirmed progression and mOS in the patients with confirmed deaths (40/50) was 17.5 months (4-47). 9/50 patients are alive with survival ranging 6-52 months. **Conclusions:** Outcomes for patients with molecularly defined GBM were variable. Analysis of the cohort to characterize factors that led to the observed variability is in progress. More studies on molecularly defined glioblastomas are required to better understand their behavior and to provide guidance for their inclusion or exclusion in clinical trials. Targeting glioblastoma with novel immunocytokines. *First Author: Patrick Roth, University Hospital Zürich, Zürich, Switzerland*

Background: There is an urgent need for novel treatment options for patients with glioblastoma, the most frequent malignant primary brain tumor. In contrast to other types of cancer, immunotherapeutic approaches have so far not been successful against glioblastoma. Converting the glioma microenvironment from a "cold" and immunosuppressive status into a more "hot" and immunopermissive phenotype may allow for clinically meaningful anti-tumor immune responses. **Methods:** We explored the activity of novel immunocytokines based on the L19 antibody, specific to a tumor-associated epitope of extracellular fibronectin, for the targeted delivery of three pro-inflammatory cytokines (IL-2, IL-12, TNF) to the microenvironment of gliomas. Following an extensive preclinical assessment in 2 orthotopic immunocompetent mouse glioma models, we used a fully-human L19-hTNF fusion protein to treat human patients with recurrent glioblastoma. **Results:** Intravenous administration of L19-mIL12 or L19-mTNF prolonged survival and cured a proportion of tumor-bearing mice while no effect was seen with L19-IL2. When L19-mIL12 or L19-mTNF were administered to glioma-bearing $RAG^{-/-}$ mice, no therapeutic activity was observed which suggests adaptive immunity as an underlying mechanism. On a mechanistic level, both immunocytokines induced the infiltration of the tumor site with lymphocytes and promoted the expression of pro-inflammatory cytokines in the tumor microenvironment. In addition, L19-mTNF induced tumor necrosis. Based on these preclinical findings, we initiated a phase I/II clinical trial with a fully-human L19-hTNF fusion protein for patients with isocitrate dehydrogenase (IDH1R132H) wildtype WHO Grade III or IV glioma at first relapse (NCT03779230). Treatment was safe and well tolerated in the first three glioblastoma patients. Administration of L19-hTNF resulted in reduced regional blood perfusion in the tumor region and was associated with more necrotic areas within the tumor as well as an increased number of tumor-infiltrating CD4 and CD8 T cells. **Conclusions:** The data obtained with the comprehensive preclinical characterization and subsequent clinical translation form the basis for future studies with immunocytokines as novel treatment option for patients with malignant brain tumors. Clinical trial information: NCT03779230. Research Sponsor: Philogen, Swiss National Sience Foundation.

2559 Poster Session (Board #50), Fri, 8:00 AM-11:00 AM

Evaluation of glioblastoma tumor microenvironment after treatment with pembrolizumab. *First Author: Nazanin Majd, MD Anderson Cancer Center, Houston, TX*

Background: Neoadjuvant pembrolizumab improved outcome of patients with recurrent Glioblastoma (GBM) in two early phase clinical trials. However, several large phase II/III studies in patients with newly diagnosed and recurrent GBM failed to demonstrate a therapeutic benefit of anti-PD-1 therapy. Therefore, identification of biomarkers of response is crucial for appropriate patient selection and further clinical development of anti-PD-1 therapy. We reported the outcome of our window-of-opportunity clinical trial of neoadjuvant pembrolizumab in 15 patients with recurrent GBM, demonstrating rare CD8+ T cells and abundant of CD68+ macrophages in GBM tissue after 3 weeks of anti-PD-1 treatment (NCT02337686). In the current study, we compared tumor infiltrating lymphocyte (TIL) and PD-L1 scores, known biomarkers of response to anti-PD-1 therapy in other cancers, in pre-trial vs. on-trial tumor tissue and associated these markers with survival. **Methods:** We determined TIL score (morphological assessment of the presence or absence of TILs, 0-3) and PD-L1 H score (defined as [1*1+ %]+[2*2+ %]+[3*3+ %], 0-200) and correlated these with survival. The Wilcoxon signed rank test was used to compare levels of PD-L1 H or TIL scores between pre-trial and on-trial specimens. The Cox proportional hazards models were used to assess associations between correlative markers and progression free survival or overall survival (OS). **Results:** The on-trial TIL level (median: 3) was significantly higher than the pre-trial TIL level (median: 1) ($p = 0.031$). However the difference between pre-trial and on-trial PD-L1 levels was not statistically significant ($p > 0.9$). Patients whose on-trial PD-L1 H score was ≥ 3 trended toward a longer OS than those with a PD-L1 H score < 3 (HR [95% CI] = 0.225 [0.043, 1.183]) ($p = 0.0782$). **Conclusions:** Although GBM tissue lacks abundant T cells, treatment with pembrolizumab increases trafficking of T cells to the tumor microenvironment, which is necessary but not sufficient to induce an effector T-cell response. Elevated PD-L1 expression may be a biomarker of response to anti-PD1 therapy in GBM, which needs confirmation in larger studies. Further genomic, transcriptomic, and methylation profiling of the pre-trial and on-trial tissues is ongoing. Clinical trial information: NCT02337686. Research Sponsor: Merck.

2560 Poster Session (Board #51), Fri, 8:00 AM-11:00 AM

A pilot study of levetiracetam as a sensitizer of temozolomide for newly diagnosed glioblastoma: A prospective, open-label, phase II study (KBTS-1601 study). *First Author: Chae-Yong Kim, Seoul Natl Univ Bundang Hosp, Seoul, South Korea*

Background: We evaluated the survival benefit of levetiracetam as a chemosensitizer of temozolomide for patients with newly diagnosed glioblastoma. **Methods:** This was an open-label, multicenter, phase II study (NCT02815410**)**. Eligible patients were aged 18 years or older and had newly diagnosed glioblastoma with an ECOG performance status of 0-2. All patients received radiotherapy with concurrent temozolomide (75 mg/m^2/day) followed by adjuvant temozolomide (150-200 mg/m^2/day for 5 days during six 28-day cycles). The first dose of levetiracetam was given just after the surgery at 250mg orally twice a day and increased up to 500mg twice a day prior to radiation. This prospective study was designed to test whether levetiracetam in conjunction with temozolomide improved survival. The historical control group was based on data from a study by Gwak et al. for Korean patients with newly diagnosed glioblastoma with a median overall survival(OS) of 17.5 months and a median progression-free survival (PFS) of 10.1 months. **Results:** Forty-six patients were enrolled between August 2016 and January 2019. The median follow-up duration was 24.9 months (range, 7.9-35.5). All patients completed standard radiation therapy with temozolomide, and 39 (84.8%) patients completed six cycles of adjuvant temozolomide. Median overall survival (OS) was 30.0 months, and median PFS was 15.0 months. OS at 6, 12, and 24 months was 100%, 91.3%, and 60.7%, respectively. PFS at 6, 12, and 24 months was 93.2%, 65.3%, and 22.6%, respectively. **Conclusions:** Addition of levetiracetam during concurrent and adjuvant temozolomide along with radiotherapy in patients with newly diagnosed glioblastoma may result in improved outcomes compared to historical data and merits further study. Clinical trial information: NCT02815410. Research Sponsor: Korean local company fund.

2561 Poster Session (Board #52), Fri, 8:00 AM-11:00 AM

Amide proton transfer MRI can accurately stratify gliomas according to their IDH mutation and 1p/19q co-deletion status. *First Author: Sotirios Bisdas, University College London, London, United Kingdom*

Background: Amide proton transfer (APT) MRI provides sensitive metrics at the amides and amines offsets from the water resonance and has been shown in small cohorts to differentiate low from high grade gliomas with better diagnostic performance than diffusion- and perfusion-weighted MRI. The purpose of our study was to assess APT-MRI performance to stratify gliomas according to their IDH mutation and 1p/19q status. **Methods:** Forty-five patients with primary gliomas and diffuse astrocytomas (26 WHO grade II, 11 WHO grade III, 8 WHO grade IV) underwent prospectively multiparametric MRI with APT imaging at 3T scanner. The molecular classification identified 9 patients with IDH-wildtype, 1p/19q retained and 36 with IDH-mutant (22 had 1p/19q-retained, 14 had 1p/19q-codeleted). Tumour segmentations were manually created and the masks were superimposed on the calculated magnetisation transfer ratio asymmetry (MTR_{asym}) spectra and proton transfer ratio APT maps. Individual and group analysis was conducted to analyse the statistical differences between quantitative imaging parameters for the IDH mutation and 1p/19q codeletion statuses. **Results:** The MTR_{asym} spectra showed a clear difference between IDH-wildtype and IDH-mutant gliomas, with the IDH-mutant gliomas presenting a stronger contribution in the amines ($p < 0.001$). In IDH-mutant 1p/19q-retained and IDH-mutant 1p/19q-codeleted, the MTR_{asym} spectra showed similarities in shape with higher intensity (approx. 60%) for the IDH-mutant 1p/19q-retained gliomas over the entire spectrum indicating an increased content in amines and amides in IDH-mutant 1p/19q-retained ($p < 0.01$). Notably, the latter entities showed higher amides levels than the IDH-wildtype gliomas ($p < 0.03$). **Conclusions:** APT-MRI shows a remarkable potential to disentangle the protein metabolism in gliomas, to link metabolic patterns to the IDH and 1p/19q status and hence provide robust surrogate biomarkers for non-invasive histomolecular classification with potential use as treatment monitoring tools. Research Sponsor: Biomedical Research Council, National Institutes of Health Research.

2562 Poster Session (Board #53), Fri, 8:00 AM-11:00 AM

Role of high-dose chemotherapy with autologous stem cell transplantation for primary central nervous system lymphoma: A systematic review. *First Author: Shaha Nabeel, Zucker School of Medicine/Northwell Health at Mather, Port Jefferson, NY*

Background: High dose chemotherapy (HDCT) followed by autologous stem cell transplant (ASCT) has shown to overcome intrinsic chemo-resistance and improve disease control in Primary Central Nervous System Lymphoma (PCNSL). Our study reviews the treatment outcome in PCNSL with sequential HDCT and ASCT. **Methods:** 8/34 studies were finalized after systematic search of PubMed, Cochrane, and Clinicaltrials.gov for treatment of PCNSL with HDCT followed by ASCT. **Results:** 251/288 patients were evaluated. Mean age was 55.5 years. 227 underwent HDCT-ASCT. 174 were newly diagnosed (ND) and 77 had relapsed refractory (R/R) PCNSL. ND patients showed superior outcomes in terms of progression free survival and overall survival. Combinations of High dose Rituximab, Busulfan and Cyclophosphamide significantly improved survival outcomes in RR patients. Significant toxicities mainly included pancytopenias and opportunistic. **Conclusions:** Primary CNS lymphoma treated with HDCT followed by ASCT has shown promising outcomes and has set a benchmark for future studies. Research Sponsor: None.

Clinical experience of ONC201 in patients with recurrent H3 K27M-mutant spinal cord glioma. *First Author: Sylvia Christine Kurz, NYU Langone Health, New York, NY*

Background: High-grade gliomas of the spinal cord are a rare and understudied entity, representing $< 5\%$ of all spinal cord tumors. Reported median survival times range from 10-16 months. Up to 53% of tumors harbor the H3 K27M mutation, which is associated with an unfavorable prognosis. Postsurgical treatment often includes radiation $\pm$ temozolomide, although the role of chemotherapy has not been conclusively established. At recurrence, there are no effective therapies and most clinical studies exclude patients with spinal cord tumors. We report our clinical experience with ONC201, a small molecule DRD2 antagonist and caseinolytic protease P agonist, in patients with recurrent H3 K27M-mutant diffuse gliomas of the spinal cord (scDG). **Methods:** Adults and children with recurrent H3 K27M-mutant scDG received ONC201 in two Phase II clinical trials enrolling adult recurrent H3 K27M-mutant glioma patients (NCT02525692; NCT03295396) and in one Phase I clinical trial enrolling pediatric patients (NCT03416530). Adult patients received ONC201 at the RP2D dose of 625 mg weekly and pediatric patients received the RP2D of 625 mg weekly, scaled by body weight. All patients began ONC201 as a single agent until disease progression. Five patients continued ONC201 combined with bevacizumab beyond progression. **Results:** As of January 15, 2020, 12 evaluable patients (adult n = 8, pediatric n = 4) received ONC201. The median age was 20.9 (range: 7-72) years. The median follow-up time for the single agent ONC201 group was 5.4 (range 1.3-9.7) months while that of the combination group is 7.4 (range 6.2-25.1) months. The median number of ONC201 doses was 10 (range: 5-39) for the ONC201 single agent group and 34 (range: 21-100) for the combination group. Five of 7 patients remain alive in the ONC201 single agent group while 3 of 5 patients remain alive in the combination group. Three patients in the ONC201 single agent group and 2 patients in the combination group continue on treatment. There were no drug-related toxicities requiring dose reduction or discontinuation. **Conclusions:** Treatment with ONC201 alone or combined with bevacizumab is well tolerated in patients with recurrent H3 K27M-mutant scDG and a subset of patients experiences prolonged survival that exceeds historical outcomes. Clinical trial information: NCT02525692; NCT03295396; NCT03416530. Research Sponsor: NCI.

2564 Poster Session (Board #55), Fri, 8:00 AM-11:00 AM

Survival of subjects with recurrent glioblastoma receiving intratumoral administration of controlled IL-12 with limited exposure to dexamethasone. *First Author: Rimas Vincas Lukas, Northwestern Memorial Hospital, Chicago, IL*

Background: Interleukin-12 (IL-12) results in anti-tumor responses in preclinical models but requires tightly controlled production to achieve safety and elicit immune system activation to realize efficacy. A phase 1 "main study" (NCT02026271) enrolled subjects with Grade III or IV gliomas who at the time of resection received intratumoral administration of a replication-deficient adenovirus expressing IL-12 under control of a transcriptional switch (Ad-RTS-hIL-12, Ad) regulated by veledimex (V), referred to as "Controlled IL-12". It was anticipated that dexamethasone (dex), a lymphocytotoxic corticosteroid used to control edema, might diminish response to immunotherapies. We report updated findings from a substudy of subjects who were dex-free during the 4 weeks prior to Ad administration. **Methods:** Multicenter, phase 1 substudy (NCT03679754) that assesses safety and tolerability of Controlled IL-12 by local injection (Day 0, time of resection) of Ad (2 x 10^{11} viral particles) + V (20 mg PO QD x15 doses, Days 0-14) in subjects that were bevacizumab naïve and not receiving dex 4 weeks prior to Ad. **Results:** 36 subjects were treated. Of the 36, a majority received low-dose corticosteroids ($\leq$ 20 mg dex total during V) as compared with the main study (75% vs 40%). More subjects in the substudy as compared with the main study had multifocal vs. unifocal disease (39% vs 7%). The safety profile was similar for both. Adverse reactions were mild to moderate and were manageable and reversable upon withholding V. Activation of the switch in both the main study and substudy (V 20 mg; n = 51) resulted in increased mean peak values (Day 0-28) of serum IL-12 (25.8 vs. 20.4 pg/mL) and IFN-g (57.0 vs. 39.5 pg/mL). Initial median overall survival (mOS) (unifocal, $\leq$ 20 mg dex cumulative, n = 20) was 16.2 (8.9, 18.5) mons (mean follow-up 12.3 mons) (Neuro Oncol 2019; 21 [suppl_6]: vi5). mOS including the impact of dex and key subject characteristics from the two studies (n = 51) will be updated and tumor response data will be provided. **Conclusions:** Monotherapy with Controlled IL-12 resulted in sustained increase in serum recombinant IL-12 and downstream endogenous IFN-g. There is evidence of immune-mediated anti-tumor effects which is associated with increased mOS as compared with historical controls. Follow up will investigate the adverse impact of dex, as well as the effect of additional subject characteristics (*e.g.*, unifocal vs. multifocal disease) on mOS. Clinical trial information: NCT03679754. Research Sponsor: Ziopharm Oncology Inc.

2565 Poster Session (Board #56), Fri, 8:00 AM-11:00 AM

Molecular predictors of response to selinexor in recurrent glioblastoma (GBM). *First Author: Christopher James Walker, Karyopharm Therapeutics Inc, Newton, MA*

Background: The nuclear export protein exportin 1 (XPO1) is overexpressed in many cancers, including GBM. Selinexor is an inhibitor of XPO1 that crosses the blood-brain-barrier and targets cancer cells by sequestering tumor suppressor proteins and oncoprotein mRNAs in the cell nucleus, inducing cancer cell apoptosis. Selinexor is FDA approved for treatment of patients (pts) with refractory multiple myeloma and is under evaluation for GBM. **Methods:** We previously reported encouraging results from a phase II clinical trial of selinexor for molecularly unselected pts with recurrent GBM (ASCO 2019). On available pre-treatment archival tumor tissue from 57 cases, we performed DNA exome and RNA transcriptome sequencing to use both gene mutations and expressions for exploring molecular correlates of response in selinexor treated pts, in a hypothesis generating, post-hoc, exploratory analysis. Pts with inadequate drug exposure were excluded ($<$ 21 days or $<$ 3 doses). We compared OS and PFS between mutated and wild-type patients for genes mutated in at least 5 cases. RNAseq data were used to infer differential protein activities between patients with selinexor sensitive disease (defined as best response of partial or complete response, n = 7) vs. resistant disease (defined as progressive disease as best response, n = 23). **Results:** Two mutated genes were associated with longer survival in selinexor treated pts: *DOCK8* (n = 7; progression free survival [PFS], P = 0.013, hazard ratio [HR] = 3.75 [1.32-10.62]; overall survival, P = 0.009, HR = 15.39 [2.00-118.34]) and *PDX1* (n = 5, PFS, P = 0.014, HR = 4.468 [1.361-14.670]). Other commonly mutated genes in glioma, including *IDH1* (n = 9) were observed but not associated with survival. Protein activities inferred from RNA sequencing data were also correlated with response to selinexor. In a machine learning model, ZC3H12A (also called MCPIP-1), a negative regulator of inflammation; RAB43, a member of the RAS family that binds GTP and regulates vesicle trafficking, and SOCS3, a suppressor of cytokine signaling that can antagonize JAK/STAT signaling and repress innate immunity, predicted clinical benefit from selinexor (area under the ROC curve from leave one out cross validation = 0.89, permutation test P $<$ 0.04). **Conclusions:** *DOCK8* and *PDX1* mutations were favorable prognostic factors in selinexor treated pts. Activity of three proteins (ZC3H12A, RAB43, and SOCS3) predicted clinical benefit from selinexor. Further studies with more pts are required to validate our findings. ClinicalTrials.gov: NCT01986348 Research Sponsor: Karyopharm Therapeutics.

2566 Poster Session (Board #57), Fri, 8:00 AM-11:00 AM

Phase I trial of D2C7 immunotoxin (D2C7-IT) administered intratumorally via convection-enhanced delivery (CED) for recurrent malignant glioma (MG). *First Author: Annick Desjardins, Duke University Medical Center, Durham, NC*

Background: D2C7-IT is a recombinant immunotoxin comprised of a dual-specific antibody fragment targeting EGFRwt and EGFRvIII and a genetically engineered form of the *Pseudomonas* exotoxin, PE38-KDEL. We report the results of a phase I trial evaluating D2C7-IT delivered intratumorally by CED. **Methods:** Eligible patients were adults with recurrent supratentorial WHO grade III or IV MG; solitary tumor; $\geq$4 weeks after chemotherapy, bevacizumab or study drug; adequate organ function; and KPS$>$70%. Two patients per dose level (DL) were to enroll in the dose escalation portion (dose range: 40ng/mL to 23,354ng/mL). **Results:** From May 2015 to May 2018, 43 patients enrolled on study. Observed dose limiting toxicities include: grade 4 seizure (n=1) on DL3, grade 3 confusion and pyramidal tract syndrome (n=1) on DL13, and grade 4 cerebral edema (n=1) and grade 3 dysphasia (n=1) on DL17. Grade 3 or higher adverse events possibly related to D2C7-IT include: seizure (grade 4, n=2; grade 3, n=3), cerebral edema (grade 4, n=1), hydrocephalus (grade 3, n=5), headache (grade 3, n=4), hemiparesis (grade 3, n=4), dysphasia (grade 3, n=3), lymphopenia (grade 3, n=4), thromboembolic event (grade 3, n=3); and one each of grade 3 elevated ALT, urinary tract infection, fall, wound complication, generalized muscle weakness, confusion, encephalopathy, and somnolence. As of February 2020, four patients remain alive, with three patients demonstrating persistent radiographic partial response more than 54, 34 and 28 months after a single infusion of D2C7-IT. **Conclusions:** Dose level 13 (6,920ng/mL) was selected as the optimal phase II dose. Accrual in a dose expansion phase II trial is ongoing, and we are initiating a combination trial of D2C7-IT with checkpoint inhibitior. Clinical trial information: NCT02303678. Research Sponsor: U.S. National Institutes of Health.

2568 Poster Session (Board #59), Fri, 8:00 AM-11:00 AM

Intratumoral drug distribution of adavosertib in patients with glioblastoma: Interim results of phase I study. *First Author: Carlos G Romo, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Wee1 is a key regulator of the G2/M checkpoint and is frequently overexpressed in glioblastoma (GB). Adavosertib is a first-in-class oral, small molecule inhibitor of Wee1 that acts primarily as a DNA damage sensitizer. A phase I clinical trial was conducted to evaluate its safety and establish the recommended phase II dosing. Studies were undertaken to evaluate whether potentially therapeutic concentrations of the drug are achieved in recurrent tumor and adjacent non-enhancing brain regions with presumed intact blood-brain barrier (BBB). **Methods:** Twelve patients received five daily doses of adavosertib pre-operatively at either the maximum tolerated dose (MTD) for concurrent radiation or adjuvant temozolomide. Tissue from contrast enhancing (CE) and non-enhancing (NE) brain regions was obtained for analysis during surgical resection. A second stage is being conducted using microdialysis (MD) to facilitate continuous sampling of extracellular fluid (ECF) and measuring free drug concentrations in: normal-appearing brain, contrast enhancing tumor, and a peritumoral T2 hyperintense area. The concentration of total adavosertib in plasma and tissue homogenates and free drug in ECF were determined by validated LC/MS/MS methods. **Results:** Geometric mean concentrations of adavosertib after a 200 mg dose were 644 ng/mL and 119 ng/mL in CE and NE tissue specimens, respectively (6 patients). At the 425 mg dose, the mean concentrations were 3,576 ng/mL in CE tissue and 885 ng/mL in NE tissue (6 patients). MD was performed in 2 patients. Samples from functional MD catheters were collected from NE brain in patient no. 1 and from two NE areas and a FLAIR hyperintense region in patient no. 2, with the following results in the table. **Conclusions:** The total drug concentration in tissue samples was notably lower in regions of the brain with a relatively intact BBB as compared to contrast enhancing tissue. Concentrations of adavosertib measured by MD vary markedly depending on catheter location. Free drug levels in ECF within brain with a functional BBB, although considerably lower than total drug levels in tissue, were 2-10 times below the previously reported IC_{50} for antiproliferative activity against sensitive GB cell lines (127 ng/mL). Whether or not the target of the drug is effectively inhibited at these concentrations remains to be demonstrated. Clinical trial information: NCT01849146. Research Sponsor: U.S. National Institutes of Health.

Superior therapy response predictions for patients with low-grade glioma (LGG) using Cellworks Singula: MyCare-009-04. *First Author: Manmeet Singh Ahluwalia, Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Neurological Institute, Taussig Cancer Institute and Cleveland Clinic, Cleveland, OH*

Background: Despite using cytogenetic and molecular-risk stratification and precision medicine, the current overall outcome of LGG patients remains relatively poor. Therapy selection is often based on information considering only a single aberration and ignoring other patient-specific omics data which could potentially enable more effective treatments. The Cellworks Singula report predicts response for physician prescribed therapies (PPT) using the novel Cellworks Omics Biology Model (CBM) to simulate downstream molecular effects of cell signaling, drugs, and radiation on patient-specific *in silico* diseased cells. We test the hypothesis that Singula is a superior predictor of progression-free survival (PFS) and overall survival (OS) compared to PPT. **Methods:** Singula's ability to predict response was evaluated in an independent, randomly selected, retrospective cohort of 137 LGG patients aged 14 to 73 years treated with PPT. Patient omics data was available from TCGA. Singula uses PubMed to generate protein interaction network activated and inactivated disease pathways. We simulated the PPT for each patient and calculated the quantitative drug effect on a composite LGG disease inhibition score based on specific phenotypes while blinded to clinical response. Univariate and multivariate proportional hazards (PH) regression analyses were performed to determine if Singula provides predictive information for PFS and OS, respectively, above and beyond age and PPT. **Results:** In univariate analyses, Singula was a significant predictor of both PFS (HR = 3.587, $p < 0.0001$) and OS (HR = 3.044, p = 0.0007). In multivariate PH regression analyses, Singula (HR = 3.707, $p < 0.0001$) remained an independent predictor of PFS after adjustment for PPT (p = 0.3821) and patient age (p = 0.0020). Singula (HR = 2.970, p = 0.0013) was also a significant independent predictor of OS after adjustment for PPT (p = 0.0540) and patient age ($p < 0.0001$). Results indicate that Singula is a superior predictor of both PFS and OS compared to PPT. Singula provided alternative standard of care therapy selections for all 34 disease progressors. **Conclusions:** Singula is a superior predictor of PFS and OS in LGG patients compared to PPT. Singula can correctly identify non-responders to PPT and provide alternative therapy selections. Research Sponsor: None.

2570 Poster Session (Board #61), Fri, 8:00 AM-11:00 AM

Postoperative radiation therapy (PORT) impact on clinical outcomes of resected atypical meningioma: A meta-analysis. *First Author: Kevin M. Gallagher, Feist-Weiller Cancer Center at LSUHSC-Shreveport, Overton Brooks VAMC, Shreveport, LA*

Background: Although meningiomas are among the most prevalent types of brain tumors, atypical meningiomas (AM) account for around 4% of all meningiomas. AMs tend to be more aggressive with relatively higher rates of recurrence and mortality. Gross total resection (GTR) has been the standard of care when possible. However, GTR itself is not always enough to prevent recurrence of AMs. The role of PORT remains controversial in AM as the comparative studies to support its use have provided conflicting results. The purpose of this meta-analysis is to evaluate the impact of PORT on clinical outcomes in resected AMs. **Methods:** A review of the medical literature was conducted using online databases. Inclusion criteria consisted of (i) AM diagnosis, (ii) English language, (iii) Simpson graded resections, and (iv) comparative studies reporting recurrence rates (RcR), Progression Free Survival (PFS), and Overall Survival (OS) with hazard ratios (HR) or Kaplan-Meier curves. A meta-analysis was conducted using an inverse variance method with random-effects model. **Results:** Twenty-two comparative studies with a total of 5,129 patients were included and analyzed. When GTR was attained, PORT was associated with improved RcR (HR = 0.72, 95%CI: 0.59-0.86) and PFS (HR = 0.77, 95%CI:0.65-0.90), but not OS (HR = 0.93, 95%CI:0.83-1.04). When subtotal resection (STR) was attained, PORT was associated with improved PFS (HR = 0.35, 95%CI:0.26-0.48) as well as OS (HR = 0.70, 95%CI:0.54-0.89). **Conclusions:** This is the first meta-analysis to show that PORT is associated with PFS benefit in AMs with GTR and STR. Moreover, PORT significantly improved OS of AMs that underwent STR but had no impact on OS when GTR was achieved. In the absence of randomized clinical trials, this meta-analysis represents the most compelling data supporting the use of PORT in this patient population. Research Sponsor: None.

TPS2572 Poster Session (Board #63), Fri, 8:00 AM-11:00 AM

Phase I/II study of T-DM1 alone versus T-DM1 and metronomic temozolomide in secondary prevention of HER2-positive breast cancer brain metastases following stereotactic radiosurgery. *First Author: Alexandra Dos Santos Zimmer, Women's Malignancies Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: We demonstrated that low doses of temozolomide (TMZ) administered in a prophylactic, metronomic fashion significantly prevented development of brain metastases in murine models of breast cancer. Based on these findings, we developed a secondary-prevention clinical trial. **Methods:** Phase I is a standard 3+3 design: T-DM1 3.6mg/kg IV every 21 days plus TMZ 30, 40 or 50 mg/m2 daily, to identify the maximum tolerated dose (MTD) of the combination, and is completing accrual, with 9 patients accrued, currently on the third and last dose level. Phase II will randomize patients to T-DM1 3.6mg/kg versus T-DM1 3.6mg/kg plus TMZ at recommended phase 2 dose (RP2D), to evaluate if addition of TMZ improves the recurrence-free incidence from distant new brain metastases at one year from 50% to 65%. Patients will undergo radiology guided lumbar puncture at baseline and after 6 weeks of treatment (C3D1) for correlative studies, brain MRI, systemic restaging CTs, and questionnaires for evaluation of symptoms and quality of life. Eligibility: HER2+ breast cancer with brain metastases (up to 10 lesions), treated with SRS and/or resection $\leq$12 weeks before enrollment, no leptomeningeal metastases, no previous WBRT, ECOG $\leq$2 and adequate organ and marrow function. Biomarkers, including cell free DNA from CSF, serum and tumor block, exosomal DNA, serum markers for neuroinflammation, and patient reported outcomes, will be analyzed in an exploratory fashion. Target accrual: up to 18 patients in phase I and 98 in phase II. Clinical trial information: NCT03190967. Research Sponsor: U.S. National Institutes of Health.

TPS2573 Poster Session (Board #64), Fri, 8:00 AM-11:00 AM

Alliance A071701: Genomically guided treatment trial in brain metastases. *First Author: Priscilla Kaliopi Brastianos, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Brain metastases, most commonly derived from melanoma, lung and breast cancers, are the most common brain tumor, with approximately 200,000 cases diagnosed annually in the United States. Median survival is on the order of months. For patients with clinically symptomatic brain metastases, approximately half succumb due to intracranial progression. In preclinical work, we demonstrated that brain metastases and primary tumors are often genetically distinct with frequent alterations in the CDK and PI3K pathway (Brastianos, Carter et al. Cancer Discovery 2015). **Methods:** We are currently accruing to a prospective multi-arm phase II study of CDK, PI3K/mTOR, and NTRK/ROS1 inhibitors in patients with brain metastases harboring alterations associated with sensitivity to these inhibitors (abemaciclib, paxalisib and entrectinib), respectively. Patients with new, recurrent or progressive brain metastases are eligible for this trial. Previously obtained tissue from brain metastases and extracranial sites (primary or extracranial metastases) are screened for the presence of these alterations, and if present in both tumor sites, patients will receive the appropriate corresponding targeted treatment. Screening is carried out with the SNaPshot NGS assay, which is a fully validated clinical test designed and developed at the MGH Center for Integrated Diagnostics. The primary endpoint of response rate (RR) in the central nervous system as per RANO criteria will be evaluated separately for each inhibitor, stratified by histology within each arm. There will be 21 evaluable patients assigned to each of the CDK and PI3K inhibitor and tumor type cohorts (breast, lung and other) and 10 patients assigned to the NTRK/ROS1 inhibitor cohort (lung) for a total of 136 evaluable patients. Although current systemic therapy for brain metastases is often ineffective, we hypothesize that targeted therapies will demonstrate efficacy in patients harboring the appropriate mutations. This study represents a novel individualized therapeutic approach in brain metastases, a disease with a critical need for effective therapy. Support: U10CA180821, U10CA180882, https://acknowledgments.alliancefound.org; Genentech, Kazia Therapeutics Limited, Eli Lilly; Clinical trial information: NCT03994796. TPS2574 **Poster Session (Board #65), Fri, 8:00 AM-11:00 AM**

INDIGO: A global, randomized, double-blind, phase III study of vorasidenib (VOR; AG-881) vs placebo in patients (pts) with residual or recurrent grade II glioma with an isocitrate dehydrogenase 1/2 (IDH1/2) mutation. *First Author: Ingo K. Mellinghoff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Low-grade gliomas (LGGs; WHO grade II) are incurable and ultimately progress to high-grade gliomas. The current treatment options consist of surgery followed by observation ("watch and wait") for pts with lower risk for disease progression or post-operative chemo-radiotherapy (high-risk population). There are no approved targeted therapies. *IDH1* and *IDH2* mutations (m*IDH1/2*) occur in approximately 70% and 4% of LGGs, respectively, and promote tumorigenesis via neomorphic production of D-2-hydroxyglutarate (2-HG). VOR, an oral, potent, reversible, brain-penetrant inhibitor of mIDH1/2, was evaluated in 76 pts with glioma in two phase 1 studies (dose escalation and perioperative) and was associated with a favorable safety profile at doses of $<$ 100 mg daily. Preliminary clinical activity was observed in non-enhancing glioma pts in both studies, most recently with an objective response rate (ORR) of 30.8% at 50 mg QD in the perioperative study and $>$ 90% 2-HG suppression at this dose level relative to untreated control samples (Mellinghoff et al., J Clin Oncol 2019). **Methods:** Approximately 366 pts will be randomized 1:1 to VOR (50 mg QD) or matched placebo and stratified by 1p19q status (intact vs codeleted). Key eligibility criteria include: age $\geq$12 years; grade 2 oligodendroglioma or astrocytoma (per WHO 2016 criteria) not in need of immediate treatment and without high-risk features; centrally confirmed m*IDH1/2* status; $\geq$1 prior surgery for glioma within the previous 5 years but no other anticancer therapy; Karnofsky performance status $\geq$80%; and centrally confirmed measurable, non-enhancing disease evaluable by magnetic resonance imaging. Crossover from placebo to the VOR arm is permitted upon centrally confirmed radiographic progression per RANO-LGG criteria. Primary endpoint is progression-free survival assessed by independent review. Secondary endpoints include safety and tolerability, tumor growth rate assessed by volume, time to next intervention, ORR, overall survival, quality of life assessed by the Functional Assessment of Cancer Therapy–Brain questionnaire, and plasma pharmacokinetics. Exploratory endpoints include seizure activity and neuro-cognitive function. Clinical data will be reviewed regularly throughout the study by an independent data monitoring committee. The study is currently enrolling pts in the US, with additional countries planned (NCT04164901). Clinical trial information: NCT04164901. Research Sponsor: Agios Pharmaceuticals, Inc.

TPS2575 **Poster Session (Board #66), Fri, 8:00 AM-11:00 AM**

A phase II/III randomized, blinded study of tozuleristide for fluorescence imaging detection during neurosurgical resection of pediatric primary central nervous system (CNS) tumors: PNOC012 (Pacific Pediatric Neuro-oncology Consortium). *First Author: Sarah Leary, Seattle Children's Hospital, Seattle, WA*

Background: Tozuleristide (also known as BLZ-100 or Tumor Paint) is a fluorescent imaging drug designed to specifically label and accumulate in tumor tissue, thus enabling more precise surgical tumor resection intraoperatively. Tozuleristide achieves tumor targeting through the peptide portion of the molecule, a modified chlorotoxin peptide, and its imaging properties from a coupled near-infrared fluorescent dye, an indocyanine green. Tozuleristide has been studied in 4 Phase 1 studies, including a trial in pediatric brain cancer subjects. No tozuleristide SAEs or dose limiting toxicity were observed in the 97 subjects treated in the Phase 1 program at doses up to 30 mg in adults or 17.3 mg/m^2 in pediatrics (Hansen S et al, WMIC 2018, P196). Eighty percent of pediatric subjects receiving tozuleristide had tumors considered fluorescence positive, including high and low grade glioma, ependymoma, and medulloblastoma. **Methods:** This study randomizes subjects in a 1:10 ratio to standard of care or tozuleristide arms. The primary efficacy objectives and endpoints are based on equivocal regions of tissue encountered in surgery. Prior to fluorescence assessment, the surgeon assesses the suspected nature of the tissue (more likely tumor/less likely tumor). Tissue specimens of equivocal regions are collected for blinded central pathology assessment. Sensitivity and specificity of the surgeon's designation, fluorescence assessment, and ratios of surgeon to fluorescence assessments comprise the primary efficacy analyses. Tozuleristide is given as an IV bolus dose of 15 mg/m^2 to pediatric subjects 1 to 36 hours prior to surgery. Subjects must have a MRI documented lesion consistent with a CNS tumor for which resection is planned. Measures of safety include adverse events, laboratory measures of hematology, liver and kidney function and changes in vital signs and ECGs. Pharmacokinetic blood samples are collected up to 3 hr post dose. Fluorescence imaging is assessed during surgery using an investigational "Canvas System" imaging device attached to a surgical microscope. Collected pathology specimens will also be subjected to further genetic, molecular and pathology studies, including fluorescence assessment of frozen tissue sections. SAEs and patient reported outcomes are collected for 3 months. The SMC for the study last reviewed the data for this study in July 2019 and recommended the trial continue as planned. Clinical trial information: NCT03579602. Research Sponsor: Blaze Bioscience Inc, Other Foundation.

TPS2576 **Poster Session (Board #67), Fri, 8:00 AM-11:00 AM**

A first-in-human phase I single-agent dose-escalation, food effect and dose expansion study of oral ONC206 in recurrent and rare primary central nervous system neoplasms. *First Author: Brett James Theeler, Walter Reed National Military Medical Center, Bethesda, MD*

Background: Blockade of the dopamine receptor D2 (DRD2) has emerged as a therapeutic target in neuro-oncology. ONC201, a first-generation imipridone that antagonizes DRD2, has demonstrated clinical activity in Diffuse Midline Gliomas, H3K27M-mutant (DMGs). Treatment options beyond surgical resection and radiation therapy are limited for most recurrent and rare primary CNS neoplasms. DRD2 blockade holds promise as a therapeutic target in multiple primary CNS cancers. ONC206 is a next generation imipridone and a chemical analog of ONC201 that possesses favorable drug properties such as oral bioavailability, robust stability, and blood-brain barrier penetrance. ONC206 exhibits enhanced allosteric inhibition of DRD2 and nanomolar affinity/potency as a DRD2 antagonist with complete antagonism and specificity for DRD2. ONC206 demonstrated broad spectrum anti-cancer efficacy in vitro across most solid tumor types tested in a panel of $>$ 1000 human cancer cell lines with nervous system tumors emerging as most responsive. In addition to its broad-spectrum activity in vitro, ONC206 efficacy has been demonstrated in xenograft mouse models. **Methods:** This is an open label, dose escalation, and food effect Phase I study of ONC206at the National Cancer Institute, Neuro-Oncology Branch. Adult patients 18 years and older with recurrent, primary CNS neoplasms will initially be accrued to the dose escalation portion of the study and evaluated for toxicity. Eligible diseases include recurrent glioblastoma, WHO Grade 2 and 3 infiltrating glial neoplasms, and rare primary CNS neoplasms in the NCI-CONNECT program: DMGs, ependymomas, medulloblastomas, and other rare CNS tumor types. The primary endpoint is to determine DLT during the first cycle (28 days). Dose escalation will proceed according to a standard 3+3 design. Both once weekly and more frequent dosing of ONC206 will be explored in the dose escalation scheme. After the MTD is established, food effect will be determined in a dedicated cohort using a balanced, single-dose, two-arm, two-period crossover design. Secondary endpoints will include objective response rate by RANO criteria, overall and progression-free survival, and disease control rate. Exploratory analysis of DRD2 and DRD5 expression, DRD2 dimerization, expression of MYC and N-MYC in tumor tissue in relation to clinical outcomes will also be performed. Research Sponsor: Oncoceutics.

TPS2577 **Poster Session (Board #68), Fri, 8:00 AM-11:00 AM**

BMX-HGG: Phase II trial of newly diagnosed high-grade glioma treated with concurrent radiation therapy, temozolomide, and BMX-001. *First Author: Katherine B. Peters, Duke University Medical Center, Durham, NC*

Background: Patients diagnosed with malignant high-grade gliomas (WHO grade III-IV) experience significant morbidity and mortality associated with these cancers. While the mainstay of therapy for patients with newly diagnosed high-grade glioma is surgery followed by concurrent chemotherapy and radiation therapy (RT), the outcomes remain very poor. BMX-001 (MnTnBuOE-2-PyP^{5+}) is a metalloporphyrin with differential action in response to radiation therapy and chemotherapy-induced oxidative stress. Early preclinical studies demonstrated BMX-001's ability to act as a radioprotectant to healthy tissue such as a central nervous white matter and as a radiosensitizer to cancer cells, in particular, human glioblastoma xenografts. We evaluated the safety of BMX-001 in combination with concurrent RT and temozolomide (TMZ) in a phase I study of newly diagnosed high-grade glioma patients, and we found that BMX-001 is safe and well-tolerated in this population. The maximum tolerated dose of BMX-001 during concurrent RT and TMZ was determined to be 28 mg delivered subcutaneously (SC) followed by 16 biweekly SC doses at 14 mg (Peters et al., Neuro-Oncology 2018). **Methods:** For this multi-site, open-label, phase II study (NCT02655601), we will randomize approximately 160 patients 1:1 to concurrent RT and TMZ with BMX-001 versus concurrent RT and TMZ alone. Key eligibility criteria include newly diagnosed histologically confirmed high-grade glioma (WHO III-IV), 18 $\geq$ years, and Karnofsky performance status $\geq$ 70%. The primary endpoint is overall survival. Secondary endpoints include cognitive performance as assessed by standardized cognitive testing, bone marrow protection, safety and tolerability, progression-free survival, overall tumor response rate, and plasma pharmacokinetics. Exploratory endpoints are health-related quality of life (as assessed by Functional Assessment of Cancer Therapy–Brain, Functional Assessment of Cancer Therapy-Cognition, and Functional Assessment of Chronic Illness Therapy-Fatigue), qualitative hair loss, and white matter integrity (as measured by MRI diffusion tensor/susceptibility imaging). Since November 2018, this phase II study has enrolled 64 of 160 high-grade glioma patients at six sites with future sites planned to be implemented. Clinical trial information: NCT02655601. Research Sponsor: BioMimetix.

TPS2578 **Poster Session (Board #69), Fri, 8:00 AM-11:00 AM**

IPAX-1: Phase I/II study of ^{131}I-iodo-phenylalanine combined with external radiation therapy as treatment for patients with glioblastoma multiforme. *First Author: Josef Pichler, Kepler University Hospital, Linz, Austria*

Background: Many tumor types, including glioblastoma multiforme (GBM), overexpress the L-type amino transporter 1 (LAT-1). ^{131}I-iodo-phenylalanine (^{131}I-IPA) is a small-molecule amino acid derivative taken up by LAT-1 with designated orphan status in the United States and European Union for the treatment of GBM. In preclinical research, combining ^{131}I-IPA with external radiation therapy (XRT) yielded additive cytotoxic effects (Israel *et al. Nucl Med Biol* 2011). Tumor accumulation of ^{131}I-IPA was shown in a proof-of-principle study (Baum *et al. Nucl Med Mol Imaging* 2011) and confirmed with single dosing of 2–7 GBq ^{131}I-IPA in combination with XRT in patients with recurrent GBM (Verburg *et al. Nuklearmedizin* 2013). The ^{131}I-IPA + XRT as Treatment for Patients with Glioblastoma Multiforme (IPAX-1) study evaluates the safety, tolerability, dosing schedule, and preliminary efficacy of ^{131}I-IPA in combination with second-line XRT in patients with recurrent GBM. **Methods:** IPAX-1 is a multi-center, open-label, phase 1/2, dose-finding study recruiting patients with previously confirmed histological diagnosis of GBM and evidence of first recurrence. Other key inclusion criteria are history of GBM standard therapy, at least 6 months since end of first-line XRT, pathologically increased amino acid tumor uptake shown by molecular imaging, and current indication for repeat radiation. Participants receive intravenous ^{131}I-IPA either as a single fraction (1f) followed by XRT, or as three equal fractions (3f) at weekly intervals followed by XRT commencing between the first and second ^{131}I-IPA administration. The 1f regimen (n = 5) evaluates single administration of 2 GBq ^{131}I-IPA. The 3f regimen is used to assess dose escalation, starting with 2 GBq (3 $\times$ 0.66 GBq; n = 5) and increasing in 2 GBq increments (n = 3 per activity level). The highest total dose planned is 8 GBq. XRT delivery is in 18 fractions (2 Gy each) on consecutive working days over 4 weeks. The study's primary aim is to assess the safety and tolerability of ^{131}I-IPA + XRT. Secondary objectives include evaluating the maximum tolerated dose of ^{131}I-IPA, feasibility of fractionated administration, radiation absorbed dose to tumor and biodistribution; and exploring the antineoplastic effect of combination therapy. IPAX-1 enrollments began in July 2019; the study will enroll up to 44 patients and is currently recruiting at five sites in Europe and Australia. Clinical trial information: NCT03849105. Research Sponsor: Telix International Pty Ltd.

TPS2579 **Poster Session (Board #70), Fri, 8:00 AM-11:00 AM**

GBM AGILE: A global, phase II/III adaptive platform trial to evaluate multiple regimens in newly diagnosed and recurrent glioblastoma. *First Author: Meredith Becker Buxton, UC San Francisco, San Francisco, CA*

Background: Glioblastoma (GBM) is an aggressive brain tumor with few effective therapies and is invariably fatal. Developing new therapies for patients with GBM requires focused interaction between industry, academia, nonprofits, patient advocacy, and health authorities, and novel approaches to clinical trials. Industry is wary of developing drugs for GBM due to the high failure rate and high cost of drug development. GBM Adaptive Global Innovative Learning Environment (GBM AGILE) Trial was designed by over 130 global key opinion leaders in consultation with health authorities to provide an optimal mechanism for phase II/III development in GBM. The Sponsor of GBM AGILE is the Global Coalition for Adaptive Research (GCAR), a nonprofit organization. GCAR's mission is to speed the discovery and development of treatments for patients with rare and deadly diseases by serving as sponsor of innovative trials. **Methods:** GBM AGILE is an international, seamless phase II/III platform trial designed to evaluate multiple therapies in newly diagnosed and recurrent GBM. Its goals are to identify effective therapies for GBM and match effective therapies with patient subtypes, with data generated to support regulatory filing for new drug applications. Bayesian response adaptive randomization is used within subtypes of the disease to assign participants to investigational arms based on their performance. The primary endpoint is overall survival. The trial is being conducted under a master Investigational New Drug Application/Clinical Trial Agreement and Master Protocol, allowing multiple drugs/drug combinations from different pharmaceutical companies to be evaluated simultaneously and/or over time. The plan is to add experimental therapies as new information is identified and remove therapies as they complete their individual evaluation against a common control. GBM AGILE received IND approval from the FDA in April 2019, enrolling its first patient in June 2019. Site activation is ongoing in the US, with approximately 40 US planned. The trial received CTA approval from Health Canada in January 2020. Expansion to Europe, China, and Australia is also underway. Clinical trial information: NCT03970447. Research Sponsor: Global Coalition for Adaptive Research, Pharmaceutical/Biotech Company.

TPS2580 **Poster Session (Board #71), Fri, 8:00 AM-11:00 AM**

Phase III TRIDENT trial: Radiation and temozolomide +/- tumor treating fields in newly diagnosed glioblastoma. *First Author: Wenyin Shi, Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA*

Background: Tumor treating fields (TTFields) is a non-invasive, regional antimitotic treatment approved as a standard of care for glioblastoma (GBM). In the EF-14 phase III trial, TTFields (200 kHz) plus temozolomide (TMZ) significantly increased the survival of patients with newly diagnosed GBM (ndGBM) without increase in systemic toxicity. TTFields-related AEs were mainly skin AEs. In preclinical models, TTFields increase the therapeutic effects of radiation therapy (RT). A pilot study showed that TTFields concomitant with RT and TMZ is well tolerated. The benefit of concomitant TTFields with RT and TMZ will be tested in this phase III TRIDENT randomized trial. **Methods:** TRIDENT is an international phase III randomized trial comparing standard RT with TMZ vs the triple combination of RT plus TMZ with concomitant TTFields. RT is delivered through the TTFields arrays. Patients in both arms will receive maintenance TTFields with TMZ. TTFields (200 KHz) will be delivered $>$18 hours/day using Optune. Patients will continue TTFields treatment until second recurrence. Patients with pathologically confirmed newly ndGBM, $\geq$ 18 years, KPS $\geq$ 70, either sex, post-surgery or biopsy, who are amenable for RT/TMZ therapy will be enrolled. Patients will be stratified by extent of resection and MGMT promoter methylation status. The primary endpoint is overall survival (OS). Secondary end points include: progression free survival (PFS; RANO), 1- and 2-year survival rates, overall radiological response (ORR; RANO), progression-free survival (PFS2, PFS6, PFS12); severity and frequency of AEs (CTCAE V5.0); pathological changes in resected GBM tumors post treatment; quality of life (EORTC QLQ-C30); and correlation of OS to TTFields compliance. The hypothesis is that concomitant TTFields with radiation and TMZ will significantly improve OS as compared to radiation and TMZ alone. The sample size is 950, with 475 in each arm to detect a HR $<$0.8 with a 5% type I error. Survival will be measured from the time of randomization until date of death. At the time of analysis, patients who are lost to follow-up or still on protocol follow-up will be censored at the last date known to be alive. Research Sponsor: Novocure.

TPS2581 **Poster Session (Board #72), Fri, 8:00 AM-11:00 AM**

Phase II study of pembrolizumab plus SurVaxM for glioblastoma at first recurrence. *First Author: Manmeet Singh Ahluwalia, Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Neurological Institute, Taussig Cancer Institute and Cleveland Clinic, Cleveland, OH*

Background: Glioblastoma is the most common primary malignant brain tumor with median survival of approximately 15-16 months. Following first recurrence, progression free survival at six months ~15%. There is no therapy in recurrent glioblastoma associated with any survival benefit and there is an urgent need for better therapeutic options. Immunotherapy is one promising option for patients with cancer. This is being explored in glioblastoma and a number of forms of active specific vaccination and immune checkpoint based approaches have been devised and are being investigated in glioblastoma. **Methods:** Pembrolizumab is a potent humanized immunoglobulin G4 (IgG4) monoclonal antibody (mAb) with high specificity of binding to the programmed cell death 1 (PD-1) receptor. Survivin is a 16.5 kDa intracellular protein that belongs to the inhibitor of apoptosis protein (IAP) family. SurVaxM is a 15 amino acid antigenic peptide that targets surviving capable of binding several human MHC class I molecules. Primary Objective is to assess clinical activity of Pembrolizumab and SurVaxM in patients with recurrent glioblastoma using progression free survival at 6 months (PFS-6) as determined using RANO criteria. Secondary Objective(s) includes safety and tolerability of combination, response rates, progression free survival and overall survival. Exploratory Objective include measuring cellular and humoral immune responses during concurrent administration of Pembrolizumab and SurVaxM. This is a phase II study of two arms in patients with recurrent glioblastoma. Arm A is patients with first recurrence of glioblastoma who have failed prior chemotherapy and radiation but have not received any immunotherapy. Arm B is an exploratory arm of glioblastoma patients who have failed prior anti-PD1 therapy. This clinical trial will enroll 41 patients with glioblastoma at first recurrence (bevacizumab naïve) in arm 1.This will include a 6-patient toxicity/safety run-in. There will an exploratory cohort of 10 patients who have failed prior PD1 blockade for a total of 51 patients in 2 arms. Key inclusion criteria include diagnosis of glioblastoma, Age $\geq$18 years old, Previous first line treatment with at least radiotherapy with or without temozolomide and Documented first recurrence of GBM and Karnofsky performance status of 70 and normal organ function. Key exclusion criteria include more than one recurrence of GBM, presence of extracranial metastatic or leptomeningeal disease, patients with $>$ 1 cm midline shift on imaging. Patients must not require $>$ 10 mg daily of prednisone equivalent. Clinical trial information: NCT04013672. Research Sponsor: Merck, Pharmaceutical/Biotech Company.

3000 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Pilot study on outcome and antitumor efficacy of an autologous cancer cell vaccine applied in patients with advanced solid tumors. *First Author: Eglys Gonzalez Marcano, UniFontis, Sickte, Germany*

Background: In the last decade cancer immunotherapy has emerged as the most promising anti-tumor approach. The most commonly used immunotherapies are vaccines and checkpoint inhibitors. An autologous cell vaccine is made with the patient's own tumor cells processed in vitro, which may elicit a cytotoxic T-lymphocytic immune response against tumor cells antigens, resulting in tumor cell death. We performed a pilot study to evaluate the clinical relevance and general outcome of an autologous vaccine as a treatment in different types of cancer. **Methods:** A total of 31 patients (n=31) with advanced solid tumors and the lack of standard treatments were treated with an immunotherapy protocol consisting of 6 intradermal doses of the vaccine, given the first two doses at day 1 and 2, and the rest every two weeks. All patients signed an informed consent form. Response evaluation was assessed by PET/CT identified as metric (iRECIST) response and in some cases tumor markers where available. **Results:** Out of 31 patients treated, 2 patients suffered from pancreatic cancer, 2 from sarcoma, 1 from lung cancer, 13 from breast cancer, 2 from ovarian cancer, 1 from prostate cancer, 1 from cholangiocarcinoma, 4 from colorectal cancer, 1 from non-Hodgkin lymphoma, 1 from gastric cancer, 1 from laryngeal and hypopharyngeal cancer, 1 from fallopian tube cancer, 1 from peritoneal cancer. Side effects related to the therapy were rare including light redness in the area of injection and in one case inflammation of the tumor area. 26 patients were evaluated for metric response and 5 for tumor marker response assessment. For tumor marker follow up 9.6 % had a SD of $>$ 3 month and 6.5 % a PD. For metric follow up 12.9 % had a CR, 6.5 % a PR, 25.8 % a SD of $>$ 3 month and 38.7 % a PD. **Conclusions:** This study have confirmed an anti-tumor response in the majority of patients treated, with none to very low side effects and a good quality of life during the treatment. To obtain more detailed and significant data on the efficacy of this therapy, a further controlled clinical phase study should be performed. Research Sponsor: None.

3001 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Oral DNA vaccination targeting VEGFR2 combined with anti-PDL1 avelumab in patients with progressive glioblastoma: Safety run-in results—NCT03750071. *First Author: Wolfgang Wick, National Center for Tumor Diseases (NCT), UKHD and German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: VEGFR2 overexpression in glioblastoma serves as a target for VEGFR2 primed T cells using VXM01 DNA vaccine encoding for VEGFR2. VXM01 is delivered in a bacterial Ty21a carrier suitable for oral administration. A previous phase I/II study in 14 patients with progressive glioblastoma showed that detection of VEGFR2 specific T cells as well as altered intra-tumoral immunity is correlated with prolonged overall survival, one partial response was reported with VXM01 alone. Three patients received nivolumab in addition to VXM01, which resulted in one complete and one partial clinical response. Based on these findings, a trial combining VXM01 and avelumab was designed. **Methods:** A multicentre, open-label phase I/II study (*EudraCT* 2017-003076-31) in progressive glioblastoma includes 30 patients (24 non-resectable, 6 resectable) previously treated with temozolomide/radiotherapy. VXM01 is administered on day 1, 3, 5, 7 followed by boostings q4w. Avelumab 800mg is given intravenously q2w. Treatment continues up to week 48 followed by a 2 year observation period. The safety run-in phase of dose groups treated with VXM01 10^6 or 10^7 CFU plus avelumab was completed with 9 patients. Safety evaluation by the Data Safety Monitoring Board was performed after 3 and 9 patients treated for at least 5 weeks. Endpoints include safety and tolerability, objective response rate (ORR), clinical response using immune-response assessment in Neurooncology criteria (iRANO), and immunological assays like ELISpot, FACS, TCR-sequencing and tumor stainings. **Results:** No treatment-related toxicities were observed. Three partial responses with tumor reductions of 58, 81 and 95% to baseline were reported in 9 patients according to iRANO. Two of these patients are progression-free $>$ 6 months. Significant VEGFR2 specific T cell responses were measured in several patients, and pre-existing intra-tumoral T cells are positively associated with the effectiveness of the immunotherapy combination. **Conclusions:** VXM01 in combination with avelumab was safe and produces detectable peripheral VEGFR-2 specific immune responses. Three patients had an objective response. Clinical trial information: NCT03750071. Research Sponsor: Vaximm Gmbh.

3002 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase I combination study of vigil and atezolizumab in recurrent/refractory advanced-stage ovarian cancer: Efficacy assessment in BRCA1/2-wt patients. *First Author: Rodney Paul Rocconi, University of South Alabama, Mobile, AL*

Background: Recent studies have shown poor clinical outcomes and limited survival advantage to checkpoint inhibitors (CIs) in advanced stage ovarian cancer (OvC). Vigil is a personalized precision vaccine constructed from autologous tumor tissue transfected with a DNA plasmid encoding GM-CSF and bi-shRNA-furin thereby creating TGFβ expression control and enhancing immune activation. Phase 1 and 2 trials in OvC demonstrate safety, functional immune activation and clinical response benefit. Combining Vigil with CIs may broaden responsiveness of immunotherapy in OvC. **Methods:** This is a randomized, 3-part safety Phase 1 study of Vigil in combination with Atezolizumab in recurrent OvC patients. Part 2 is a randomized, intra-patient crossover study of Vigil first (VF) or Atezolizumab first (AF) for two cycles followed by sequence of the combination of the two agents. Vigil (1×10^6 or 1×10^7 cells/ml) or Atezolizumab (1200mg) were administered 1x every 21 days each cycle until progression or untoward adverse event. We now report the preliminary results of part 2 of the study. **Results:** Twenty-one patients were randomized (1:1) to VF (n = 11) or AF (n = 10), groups were similar in demographics. Grade 3/4 toxic events occurred in 17% of AF patients compared to 3% in VF patients. Median OS of VF patients (n = 11) was not reached vs. AF (n = 10) 10.8 months suggested modest advantage to VF (HR 0.33, one-sided p 0.097). However, the subset analysis of BRCA1/2 wild type (wt) demonstrated more significant overall survival benefit in VF (n = 7) median OS not reached vs. AF (n = 7) 5.2 months (HR 0.12, one-sided p 0.015). **Conclusions:** The combination of Vigil immunotherapy and checkpoint inhibitor atezolizumab in recurrent OvC demonstrated safety and suggest a lower toxicity profile and a significant OS advantage in recurrent *BRCA1/2*-wt OvC patients treated with Vigil first followed by the combination of Vigil and Atezolizumab. Clinical trial information: NCT03073525. Research Sponsor: None.

Group	N (VF/AF)	1-year OS rate (VF/AF)	Median OS (months) (VF/AF)	HR	p-value
ITT	21 (11/10)	90.9% vs 49.2%	NR vs 10.8	0.33 (95% CI: 0.064,1.7)	0.097
BRCA1/2-wt	14 (7/7)	100% vs 22.9%	NR vs 5.2	0.12 (95% CI: 0.018, 0.81)	0.015

3003 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Safety and tolerability of MEDI0562 in combination with durvalumab or tremelimumab in patients with advanced solid tumors. *First Author: Jonathan Wade Goldman, David Geffen School of Medicine, UCLA, Santa Monica, CA*

Background: We report safety and tolerability of MEDI0562, a humanized $IgG1_\kappa$ OX40 monoclonal antibody (mAb), in combination with durvalumab (durva; anti-PD-L1 mAb) or tremelimumab (treme; anti-CTLA-4 mAb) in patients (pts) with previously treated advanced solid tumors. **Methods:** In this phase 1, open-label study (NCT02705482), adult pts received escalating doses of MEDI0562 (2.25, 7.5 or 22.5 mg/kg) every 2 wks (Q2W) in combination with durva (1500 mg/kg) or treme (75 or 225 mg/kg) Q4W, until confirmed disease progression or unacceptable toxicity. Tumor assessments were performed Q8W with immune-related Response Evaluation Criteria in Solid Tumors. **Results:** In total, 27 and 31 pts received MEDI0562 + durva or treme, across 5 dose combination cohorts (3 + 3 design), with a maximum tolerated dose of 7.5 mg MEDI0652 + 1500 mg durva and maximum administered dose of 10 mg MEDI0562 + 225 mg treme. Median duration of exposure was 12.0 (range 2.0–80.9) and 8.0 (range 2.0–42.0) wks, respectively. Two (22.5 mg MEDI10562 + durva) and 3 (2.25 mg MEDI0652 + 225 mg treme, 22.5 mg MEDI0562 + 75 and 225 mg treme) dose limiting toxicities were observed. For MEDI0562 + durva and MEDI0562 + treme groups respectively, treatment-emergent adverse events (TEAEs) were reported in 96.3% and 100% of pts; most common TEAEs were fatigue (55.6%) and pruritus (45.2%), Gr 3/4 TEAEs occurred in 74.1% and 67.7%; and MEDI0562-related AEs were reported in 20 (74.1%) and 24 (77.4%) pts. Six TEAEs in each group led to MEDI0562 discontinuation (22.2% and 19.4%, respectively), 2 led to death (renal failure [7.5 mg MEDI0562 + durva], multiple organ dysfunction syndrome [22.5 mg MEDI0562 + 225 mg treme]). Three response evaluable pts had PR (11.5% [7.5 and 22.5 mg MEDI0562 + durva, n = 26]). Median overall survival was 17.4 and 11.9 mos for MEDI0562 + durva and MEDI0562 + treme, with stable disease seen in 9 pts from each group, 34.6% vs 29.0%, respectively. Serum exposure of MEDI0562 increased dose proportionally. Post treatment serum antidrug antibody (ADA) was detected in 20 pts from MEDI0562 + durva and MEDI0562 + treme (74.1% and 71.4%, respectively). The impact of ADA on MEDI0562 pharmacokinetics was seen at all doses. Mean percentage of Ki67+CD4+ and Ki67+CD8+ memory T cells increased, while mean percentage of OX40+CD4+ memory T cells decreased following the first dose of MEDI0562 + durva or treme. **Conclusions:** The safety profile of MEDI0562 in combination with durva or treme was similar between groups. Clinical activity was observed with MEDI0562 + durva in pts with advanced solid tumors. Clinical trial information: NCT02705482. Research Sponsor: AstraZeneca.

3004 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

A phase I, first-in-human, open-label, dose-escalation study of MGD013, a bispecific DART molecule binding PD-1 and LAG-3, in patients with unresectable or metastatic neoplasms. *First Author: Jason J. Luke, University of Pittsburgh, Hillman Cancer Center, Pittsburgh, PA*

Background: MGD013 is an investigational, first-in-class, Fc-bearing bispecific tetravalent DART molecule designed to bind PD-1 and LAG-3 and sustain/restore the function of exhausted T cells. MGD013 demonstrates ligand blocking properties consistent with anti-PD-1 and anti-LAG-3 benchmark molecules, and improves T cell responses beyond that observed with benchmark or component antibodies alone or in combination. **Methods:** This study characterizes the safety, tolerability, dose-limiting toxicities, maximum tolerated dose (MTD), PK/PD, and antitumor activity of MGD013 in patients (pts) with advanced solid and hematologic malignancies. Sequential single-pt cohorts were treated with escalating flat doses of MGD013 (1-1200 mg IV every 2 weeks), followed by a 3+3 design. Tumor-specific expansion cohorts are being treated at the recommended Phase 2 dose of 600 mg. **Results:** At data-cutoff, 50 pts (46% checkpoint-experienced) were treated in Dose Escalation, and 157 pts (32% checkpoint-experienced) in Cohort Expansion. No MTD was defined. Treatment-related adverse events (TRAEs) occurred in 146/207 (70.5%) pts, most commonly fatigue (19%) and nausea (11%). The rate of Grade $\geq$ 3 TRAEs was 23.2%. Immune-related AEs were consistent with events observed with anti-PD-1 antibodies. Mean half-life was 11 days; peripheral blood flow cytometry analyses confirmed full and sustained on-target binding during treatment at doses $\geq$ 120 mg. Among 41 response-evaluable [RE] dose escalation pts, 3 confirmed partial responses [cPRs] (triple negative breast cancer [TNBC], mesothelioma, gastric cancer) per RECIST 1.1 were observed, while 21 pts had stable disease [SD]. Among select expansion cohorts, PRs have been observed in epithelial ovarian cancer (n=2; both cPRs, and 7 with SD among 15 RE pts) and TNBC (n=2; 1 cPR, 1 unconfirmed PR [uPR], and 5 with SD among 14 RE pts). In a cohort of pts with HER2+ tumors treated with MGD013 in combination with margetuximab (investigational anti-HER-2 antibody), 3 PRs have been observed (breast [n=2], colorectal [n=1]; 1 cPR, 2 uPRs) and 2 pts with SD among 6 RE pts. Objective responses have been observed in several pts after prior anti-PD-1 therapy. Investigations into potential correlative biomarkers including LAG-3 and PD-1 are ongoing. **Conclusions:** MGD013, a novel molecule designed to coordinately block PD-1 and LAG-3, has demonstrated an acceptable safety profile and encouraging early evidence of anti-tumor activity. Clinical trial information: NCT03219268. Research Sponsor: MacroGenics, Inc.

3005 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

PROCLAIM-CX-072: Analysis of patients with advanced solid tumors receiving long-term treatment with CX-072, a PD-L1 probody therapeutic, as a single agent or in combination with ipilimumab. *First Author: Fiona Thistlethwaite, The Christie NHS Foundation Trust and University of Manchester, Manchester, United Kingdom*

Background: Monotherapy with immune checkpoint inhibitors (ICIs) has demonstrated efficacy in many cancers. Combining ICIs PD-L1 + CTLA-4 enhanced efficacy but worsened toxicity vs monotherapy; therefore, CTLA-4 dose modifications are often needed, despite a dose-response effect having been shown for efficacy. CX-072 is an investigational PD-L1 PROBODY therapeutic that is preferentially activated in the tumor microenvironment (TME); localized activation may reduce immune-related AEs (irAEs). PROCLAIM-CX-072-001 identified 10 mg/kg Q2W (Mono10) as the recommended monotherapy dose. Here we provide data for Mono10 and for dose escalation of CX-072 in combination with IPI (Combo), with a focus on long-term ($\geq$6 mo) therapy. **Methods:** Mono10 was evaluated in multiple tumor types. Combo doses evaluated were CX-072 0.3–10 mg/kg and IPI 3–10 mg/kg Q3W. Patients (pts) with $\geq$6 mo treatment duration ($\geq$6M-TD) were compared to those with $<$ 6 mo of treatment ($<$ 6M-TD) as of November 30, 2019. **Results:** Disease control rates (DCR = CR+PR+SD) were 41% for Mono10 (n = 47 of 114; 10 PRs) and 37% for Combo (n = 10 of 27; 1CR + 4 PRs (1CR and 3PRs at 3 mg/kg IPI [IPI3]). Additional results are shown in the table. No treatment-related adverse events (TRAEs) led to death. The most common reason for discontinuation (dc) in all groups was disease progression. **Conclusions:** CX-072 monotherapy demonstrated durable responses consistent with activation of the PROBODY therapeutic in the TME. The safety profile supports the tolerability of CX-072 as monotherapy and when combined with IPI3. CX-072 + IPI3 demonstrated activity in heavily pretreated pts with various tumors. The safety profile of the combination of CX-072 with IPI3 compares favorably to historical data (grade $\geq$3 TRAEs 55% and leading to dc in 36%; Larkin J, et al. *N Engl J Med.* 2015;373:23-34). CX-072 + IPI3 is being explored in a phase 2 study in 2L melanoma Clinical trial information: NCT03993379. Research Sponsor: CytomX Therapeutics, Inc.

	Mono10 < 6M-TD (n = 86)	Mono10 ≥6M-TD (n = 28)	Combo < 6M-TD (n = 21)	Combo ≥6M-TD (n = 6)

3006 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Durvalumab and tremelimumab in combination with FOLFOX in patients with RAS-mutated, microsatellite-stable, previously untreated metastatic colorectal cancer (MCRC): Results of the first intermediate analysis of the phase Ib/II MEDETREME trial. *First Author: François Ghiringhelli, Department of Medical Oncology, Center GF Leclerc, Dijon, France, Dijon, France*

Background: Single agent PD-1/L1 inhibition are not effective in metastatic colorectal cancer (MCRC) with microsatellite stable tumors. However, signal of efficacy was shown using combo therapy of anti-PD-L1 and anti CTLA-4 in multitreated patients. FOLFOX regimen could induced immunogenic cell death and elimination of myeloid derived suppressor cells (MDSCs) thus leading to a potential positive effect on antitumor immune response. **Methods:** This is a single arm exploratory investigator-initiated trial planned to include 57 pts to receive mFOLFOX6 (6cycles) in combination with durvalumab (150mg/q2W) and tremelimumab (75mg/q4W). After 6 cycles of chemotherapy, patients are treated with durvalumab untils progression. Primary endpoint is 6 months' progression-free survival rate. Secondary endpoints are response rate, tolerability and translational research evaluating tissue and blood immune parameter. Upon Simon's design an efficacy intermediate analysis was planned after the 16th patient has passed 6 months. **Results:** As of 1st of January 2020 the 55/57 pts were enrolled and treated with the MEDETREME regimen at 8 French sites. The intermediate efficacy analysis was conducted on the 1st of January after a median of 13.4 months of treatment. The following adverse events were noted: asthenia (81.25%), neuropathy (87.5%), diarrhea (56.25%) and neutropenia (62.5%). Notable grade 3/4 (CTC AE 4.03) include asthenia (18.75%) diarrhea (12.5%) neutropenia (50%) and elevated blood pressure (25%). Most of adverse events were related to chemotherapy. It has been noted one cytolysis grade 3, one thyroid dysfunction grade 3 and one hypophysitis grade 3 related to immunotherapy. Median PFS was not reached. Progression free survival at 6 months was observed in 10/16 pts (62,5%) given 5 CR, 5 PR and 4 SD. Updated translational data will be presented at the meeting. **Conclusions:** The interim safety analysis has supported safety and efficacy of the MEDITREME regimen in first- line MCRC. Finally, results will be presented after maturation of follow up. Clinical trial information: NCT03202758. Research Sponsor: Astra-Zeneca.

3007 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Association of LRP1B pathogenic genomic alterations with favorable outcomes with immune checkpoint inhibitors across multiple tumor types. *First Author: Landon Carter Brown, Duke Cancer Institute, Durham, NC*

Background: Low-density lipoprotein receptor-related protein 1b (LRP1b) is a putative tumor suppressor and one of the most frequently altered genes in cancer. Our prior single-center work suggested that *LRP1B* alterations may enrich for responses to immune checkpoint inhibitors (ICI) in solid tumors including prostate cancer; however, validation of these findings is needed. **Methods:** We conducted a multicenter, retrospective analysis of patients with *LRP1B* alterations (on tissue-based next-generation sequencing panels) treated with ICI at Duke, Johns Hopkins (JHU), and University of Michigan (UM). The primary objective was to assess the association between objective response rate (ORR) to ICI and pathogenic *LRP1B* alterations, defined as deletions or truncating alterations, when compared with *LRP1B* variants of undetermined significance (VUS), defined as missense mutations not predicted to be pathogenic in COSMIC. Missense changes with a COSCMIC FATHMM score of $>$ 0.8 were categorized separately as likely pathogenic. Summary statistics, ORR, progression free survival (PFS), and overall survival (OS) were calculated. **Results:** 101 patients (44 Duke, 35 JHU, 22 UM) with *LRP1B* alterations were treated with ICI. Median age was 61 (range 32-82). The most common tumor types by alteration (pathogenic or likely pathogenic/VUS%) were lung (33/47%), GI (17/13%), prostate (11/7%), sarcoma (2/9%), melanoma (11/0%), and others (26/24%). 93% of patients received single-agent PD-(L)1 inhibition. The ORR for patients with either pathogenic/likely pathogenic alterations, or VUS alterations was 57% and 18%, respectively. After excluding MSI-high or TMB-high ($>$ 10 mut/Mb) tumors, ORR was 14/25 (56%) and 6/36 (17%), respectively. Pathogenic or likely pathogenic *LRP1B* alterations were associated with longer PFS (HR 0.39, 95% CI 0.24-0.63) and OS (HR 0.58, 95% CI 0.36-0.95). **Conclusions:** This multicenter study shows impressive and durable objective response rates to ICI for patients harboring pathogenic *LRP1B* alterations when compared to those with *LRP1B* VUS, independent of TMB/MSI status. Further mechanistic insights and prospective validation studies are warranted. Research Sponsor: None.

	Pathogenic or likely pathogenic (n = 46)	VUS (n = 55)
CR n, (%)	1 (2%)	2 (4%)
PR n, (%)	25 (54%)	8 (15%)
SD n, (%)	11 (24%)	16 (29%)
PD n, (%)	8 (17%)	24 (44%)
NE n, (%)	1 (2%)	5 (9%)
Median PFS (95% CI)	14.1 mo (6.4-26.3)	3.4 mo (2.8-4.8)
Median OS (95% CI)	23.0 mo (11.0-27.3)	8.9 mo (8.0-18.0)
TMB-high n, (%)	23 (50%)	19 (35%)
MSI-high/MSI available n, (%)	5/45 (11%)	1/43 (2%)

3008 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Correlation of pathogenic POLE mutations with clinical benefit to immune checkpoint inhibitor therapy. *First Author: Benjamin Garmezy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mutations in DNA polymerase epsilon (*POLE*) may induce DNA replication errors, increasing neoantigen load and potentially enhancing clinical benefit to immune checkpoint inhibitors (ICI). We present a clinicopathologic analysis of patients (pts) with advanced cancers harboring *POLE* mutations and their response to ICI therapy at MD Anderson Cancer Center. **Methods:** We used targeted exome sequencing via CLIA-certified next generation sequencing assays to identify pts with *POLE*-aberrant tumors and their co-occurring mutations. The pathogenicity of each *POLE* mutation was annotated utilizing InterVar and ClinVar databases. Chi-square analysis was performed. **Results:** Tumors from 12,947 pts were analyzed and 448 (3.5%) pts had a mutation or copy number variation in *POLE* (3.5%), comparable to the TCGA PanCancer Atlas (4.0%). Clinical data were available for 293 pts; the most common cancers were colorectal (14.7%), non-small cell lung (13.7%), cholangiocarcinoma (13.3%) and melanoma (10.2%). There were 267 unique co-mutations, including *KRAS* (23.0%), *ARID1A* (21.5%), *BRCA2* (18.7%), *ATM* (18.4%), *CDKN2A* (17.5%), *BRAF* (15.3%), *EGFR* (15.3%), *ATRX* (12.6%), *CREBBP* (11.7%), *APC* (11.3%), *ATR* (11.0%), *BRCA1* (11.0%) and *CDK12* (10.4%). *POLE* variants were annotated in all pts: pathogenic/likely pathogenic (n = 34, 11.6%), benign/likely benign (61, 20.8%), and variant of unknown significance (198, 67.6%). 104 (35.8%) of 293 pts with *POLE* mutations received PD-1/L1 inhibitors as monotherapy or in combination. 93 (88.4%) of 104 pts were evaluable for response: Radiological CR 4.3% (n = 4), PR 26.9% (n = 25), SD 22.6% (n = 21), PD 46.2% (n = 43), for a clinical benefit rate (CR + PR + SD) of 53.8%. Pathogenic status of *POLE* mutation was associated with clinical benefit to PD-1/L1 inhibitors ($p = 0.04$). TMB ($p = 0.44$), PD-L1 ($p = 0.11$), and MSI ($p = 0.66$) status were not associated with pathogenic status. MSI-H status was not over-represented in pts with ICI clinical benefit ($p = 0.36$). **Conclusions:** Pathogenic *POLE* mutations were associated with clinical benefit to ICI therapy. Further studies are warranted to validate *POLE* mutations as a predictive biomarker. Multiple co-occurring DNA damage response mutations were found, which may contribute to ICI clinical benefit. Research Sponsor: None.

3010 Poster Discussion Session; Displayed in Poster Session (Board #74), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Combined PD-1 inhibition (Pembrolizumab) and CCR5 inhibition (Maraviroc) for the treatment of refractory microsatellite stable (MSS) metastatic colorectal cancer (mCRC): First results of the PICCASSO phase I trial. *First Author: Georg Martin Haag, Department of Medical Oncology, National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany*

Background: Checkpoint inhibition using PD-1/PD-L1 inhibitors does not show clinically relevant activity in MSS/pMMR (Mismatch Repair Proficient) colorectal cancer. Previous work showed that inhibition of CCR5 (C-C chemokine receptor type 5) leads to a macrophage re-polarization towards M1 macrophages within the tumor microenvironment which directly affects immune cell infiltrates. The current phase I trial explores a combined modification of the innate immune system (by CCR 5 blockade) and the adaptive immune system (by PD-1 inhibition) in the treatment of MSS CRC. **Methods:** 20 patients with metastatic MSS/pMMR colorectal cancer with failure of fluoropyrimidines, oxaliplatin, irinotecan, VEGF antibodies and EGFR antibodies (in ras WT patients) received pembrolizumab 200 mg q21d and maraviroc 300 mg bid cont. for 8 cycles, followed by pembrolizumab monotherapy for a maximum of 24 additional cycles. Imaging was performed every nine weeks (RECIST and irRECIST criteria). Primary endpoint was the feasibility rate (rate of patients receiving the protocol treatment during the core treatment without special event: treatment-related Grade $\geq$ 3 immune-related abnormalities, treatment-related Grade $\geq$ 4 AEs or any toxicity-related premature withdrawal of treatment). Secondary endpoints included safety/toxicity, ORR, PFS and OS. **Results:** 20 patients were enrolled. The median number of applied cycles was 3.5 for pembrolizumab and 3.5 for maraviroc. Two patients completed the core treatment period with pembrolizumab and started maintenance treatment. The feasibility rate was 94.7% (90% CI 77.4 to 99.7%), with one patient experiencing a special event. Except this grade 4 event (hyperglycemia) no $\geq$ 3 treatment-related toxicities were observed. According to irRECIST criteria one patient showed a partial response and one a stable disease as best response, resulting in an irDCR of 10.5%. Median PFS according to irRECIST was 2 months (CI 95%, 2 to 3), median OS 9 months (CI 95%, 6 to 20). **Conclusions:** Therapy with pembrolizumab and maraviroc was feasible and showed a beneficial toxicity pattern. Clinical activity in MSS CRC patients was limited, however prolonged disease stabilizations were observed in single patients and overall survival was higher than expected in this heavily pretreated population. Clinical trial information: NCT03274804. Research Sponsor: Merck Sharp & Dohme.

Interim subgroup analysis for response by PD-L1 status of CLASSICAL-Lung, a phase Ib/II study of pepinemab (VX15/2503) in combination with avelumab in advanced NSCLC. *First Author: Michael Rahman Shafique, Department of Thoracic Oncology, Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Antibody blockade of semaphorin 4D (SEMA4D, CD100) promotes tumoral dendritic cell and CD8+ T cell infiltration and reduces function and recruitment of immunosuppressive myeloid cells. Importantly, these mechanisms to overcome immune exclusion and suppression have been shown to complement immune checkpoint therapies in preclinical models. Pepinemab is an IgG4 humanized monoclonal antibody targeting semaphorin 4D. The CLASSICAL-Lung clinical trial tests the combination of pepinemab with avelumab to couple T cell activation via checkpoint inhibition with beneficial modifications of the immune microenvironment via pepinemab. **Methods:** This phase 1b/2, single arm, first-in-human study is designed to evaluate the safety, tolerability and efficacy of pepinemab with avelumab in 62 patients (pts) with advanced (stage IIIB/IV) non-small cell lung cancer (NSCLC), including immunotherapy-naïve (ION) pts and pts whose tumors progressed following immunotherapy (IOF). **Results:** Among 21 evaluable ION pts, 5 experienced partial response (PR), 3 pts had clinical benefit $\geq$ 1 year, and the disease control rate (DCR) is 81%. Pts enrolled in this study were observed to have lower PD-L1 expression relative to prior single agent studies (likely due to approval of pembrolizumab for first line therapy). We, therefore, performed subgroup analysis for response by PD-L1 status. The objective tumor response (ORR) in the PD-L1 negative and low population ($<$ 80% TPS by Dako 73-10 assay) appears to be approximately 2-2.5 fold greater with combination therapy than with historical single agent immune checkpoint controls. Notably, 97% of pts who experienced PR or SD were reported to have tumors with negative or low PD-L1 expression. Among 29 evaluable IOF pts, the combination resulted in 59% DCR, including 2 PR and 7 patients with durable clinical benefit of $\geq$ 23 weeks. Biomarker analysis of pre- and on-treatment biopsies confirmed increased $CD8^+$ T cell density correlating with response. Surprisingly, analysis of myeloid-derived suppressor cells (MDSCs) revealed a relative paucity of these cells in pretreatment NSCLC biopsies as compared to other cancer indications such as HNSCC. **Conclusions:** This trial is nearing completion with only 5 of 62 subjects remaining on study. Preliminary data suggest the combination is well tolerated and shows signs of increased antitumor activity, particularly in PD-L1 negative or low tumors. Updated clinical response data and immunophenotypic analyses will be presented. Clinical trial information: NCT03268057. Research Sponsor: Vaccinex, (Rochester, NY), and from Merck KGaA as part of the alliance between Merck KGaA, (Darmstadt, Germany) and Pfizer, Inc, (New York, NY, USA).

Long-term follow-up of anti-CD19 CAR T-cell therapy for B-cell lymphoma and chronic lymphocytic leukemia. *First Author: Kathryn Cappell, National Institute of Health, Bethesda, MD*

Background: T cells expressing anti-CD19 chimeric antigen receptors (CARs) can cause complete remissions of relapsed lymphoma. We conducted the first clinical trial of anti-CD19 CAR T cells to show responses against lymphoma. This CAR was later developed as axicabtagene ciloleucel. Here, we aimed to assess the long-term durability of remissions and the long-term adverse effects after anti-CD19 CAR T-cell therapy. **Methods:** Between 2009 and 2015, we treated 43 patients with anti-CD19 CAR T cells preceded by conditioning chemotherapy of cyclophosphamide plus fludarabine (NCT00924326). Three patients were re-treated for a total of 46 CAR T-cell treatments. Twenty-eight patients had aggressive lymphoma (diffuse large B-cell lymphoma or primary mediastinal B cell lymphoma), eight patients had low-grade lymphoma (five with follicular lymphoma and 1 each with splenic marginal zone lymphoma, mantle cell lymphoma, and unspecified low-grade non-Hodgkin lymphoma), and seven patients had chronic lymphocytic leukemia (CLL). Patients were treated in three cohorts that differed in the CAR T-cell production process and conditioning chemotherapy dose. **Results:** Of the 43 treated patients, 63% had chemotherapy-refractory lymphoma. Patients had received a median of 4 previous lines of therapy. The median CAR^+ T cell dose per kilogram was 2X10^6. The overall remission rate was 76% with 54% complete remissions (CR) and 22% partial remissions (PR). Patients with CR had higher median peak blood CAR levels (86 CAR^+ cells/μL) than those who did not have CR (16 CAR^+ cells/μL, $P = 0.0041$). Long-term adverse effects were rare except for B-cell depletion and hypogammaglobulinemia, which both improved over time. **Conclusions:** This is the longest follow-up study of patients who received anti-CD19 CAR T cells. Anti-CD19 CAR T cells cause highly durable remissions of relapsed B-cell lymphoma and CLL, and long-term adverse effects of anti-CD19 CAR T cells were rare and usually mild. Clinical trial information: NCT00924326. Research Sponsor: U.S. National Institutes of Health.

	All Patients	Aggressive lymphoma (n = 28)	Low-grade lymphoma (n = 10)	CLL (n = 8)
Median CAR^+ T cell dose per kg	2 X 10^6	2 X 10^6	3 X 10^6	3.5 X 10^6
Chemotherapy refractory (%)	63%	89%	20%	25%
Median prior lines of therapy (Range)	4 (1 to 12)	4 (2 to 12)	4 (1 to 7)	4 (1 to 7)
Overall Response (%)	76%	68%	90%	88%
Complete Response (%)	54%	50%	60%	63%
Median duration of complete response in months (Range)	58 (6 to 113)	50 (6 to 83)	60 (19 to 113)	70 (18 to 99)
Median event-free survival 45 evaluable treatments	60 (1-114)	15 (1 to 85)	66 (1-114)	41 (5-101)

3013 Poster Discussion Session; Displayed in Poster Session (Board #77), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Safety and efficacy results of GC027: The first-in-human, universal CAR-T cell therapy for adult relapsed/refractory T-cell acute lymphoblastic leukemia (r/r T-ALL). *First Author: Xinxin Wang, Gracell Biotechnologies Co., Ltd., Shanghai, China*

Background: Patients with r/r T-ALL usually have high relapse and mortality rates. Due to shared common surface antigen and potential contamination by malignant cells, development of autologous CAR-T therapies for r/r T-ALL has been lagged, regardless of the costly and lengthy process of autologous CAR-T production. Through targeting CD7, a common T cell antigen highly expressed in >95% T-ALL samples, universal CAR-T product GC027 has been developed using lentivirus and CRISPR/Cas9 system with demonstrated anti-leukemia ability in a murine xenograft model. **Methods:** Preliminary safety, anti-leukemic activity and expansion kinetics of GC027 are being evaluated in a single-arm, open-label, multi-center, prospective study for treating adult patients with r/r T-ALL. To date, a total of 5 patients (age 19-38 yrs, median 24 yrs) were enrolled with marrow tumor load 4-80.2% (median prior lines 5). All 5 pts have received a 6-day enhanced preconditioning chemotherapy followed by a single infusion of GC027. No patient was bridged to HSCT. Adverse events, disease response, and expansion kinetics were evaluated in this study. **Results:** As of Feb. 6, 2020, 5 pts had received a single dose of GC027, including 1 at $0.6x10^7$/kg, 3 at $1x10^7$/kg, 1 at $1.5x10^7$/kg. 3 pts achieved MRD negative complete responses (MRD- CR) at D28 evaluation and remained MRD- at follow-up re-evaluations (161, D118, 61, respectively) without bridging to HSCT. 1 pt just achieved D28 MRD- CR at time of submission. 1 pt achieved MRD+ CR at D14, but his disease progressed at D29 and deceased due to relapse. In all 4 pts with MRD- CR, peak expansions of GC027 in peripheral blood were observed between week 1-2, analyzed by flow cytometry and Q-PCR. Grade 3 cytokine release syndrome (CRS) occurred in 4 pts and Grade 4 CRS occurred in 1 pt (ASBMT Consensus Grading). CRS symptoms were manageable and resolved after treatment and supportive care. None developed neurotoxicity or GvHD. One had prolonged cytopenia due to fungal infection and required antifungal therapy. **Conclusions:** With a single infusion of GC027, 80% of the patients had robust CAR-T cell expansion and achieved persistent MRD- CR without using any biologics as part of the preconditioning therapy or bridging to HSCT. The first-in-human, universal CAR-T therapy for r/r T-ALL, GC027 has demonstrated superior clinical efficacy and induced deep response in patients with acceptable safety profile. The trial enrollment is ongoing and updated data will be presented at the meeting. Clinical trial information: ChiCTR1900025311. Research Sponsor: Gracell Biotechnologies Co., Ltd.

Feasibility and preliminary safety and efficacy of first-in-human intraperitoneal delivery of MCY-M11, anti-human-mesothelin CAR mRNA transfected into peripheral blood mononuclear cells, for ovarian cancer and malignant peritoneal mesothelioma. *First Author: Christina M. Annunziata, Women's Malignancies Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: MCY-M11 is a mesothelin-targeting chimeric antigen receptor (CAR) therapy made by a non-viral, mRNA-based platform, for rapid (< 1 day) CAR manufacturing. We are conducting a phase I dose escalation trial in ovarian cancer and malignant peritoneal mesothelioma (MPM) (NCT03608618). **Methods:** MCY-M11 are fresh, non-expanded, autologous peripheral blood mononuclear cells (PBMCs) transfected by flow electroporation with mRNA encoding a human anti-mesothelin CAR. Following a 3+3 design, patients are treated in dose level (DL) escalating cohorts (DL1 1.0×10^7, DL2 5.0×10^7, DL3 1.0×10^8, DL4 5.0×10^8 cells/dose), in one cycle of weekly x 3 doses, intraperitoneal (ip) without preconditioning chemotherapy. **Results:** By January 2020, CP-M11-101 study successfully completed DL1 and DL2 without safety concerns. Based on 11 patients treated in DL1, DL2 and DL3, ip infusion of MCY-M11 is safe and well tolerated. No infusion-related adverse events and no dose limiting toxicities (DLTs) have occurred. No neurotoxicity has been observed. Most reported treatment-related adverse events have been Grades 1-2 per NCI CTCAE. One patient in DL3 presented with G2 pericarditis, fever and transient neutropenia clinically assessed as related SAEs, that resolved without further complications. These events were assessed as on-target off-tumor effects and possibly G1 cytokine release syndrome (CRS). Two unrelated SAEs (G2 confusion in a patient in DL2; G3 enterocutaneous fistula in a patient in DL3) were reported. These 2 patients have been replaced as they did not complete the evaluation period (3 weekly infusions and the DLT 43 day follow up). There have been no treatment-related discontinuations or deaths. Three patients in DL2 showed stable disease (SD) by RECIST 1.1 at the end of the DLT period. Of them, 1 completed the study and did not participate in additional follow up, 1 remained in SD 6 months, and 1 remained in SD 2 months. In DL3, 1 patient remains in SD at 2 months, and evaluation is pending for the other 2 patients. Enrollment is ongoing. **Conclusions:** Feasibility of 1-day manufacturing of MCY-M11 for ip delivery is demonstrated. Treatment has been safe. Initial SD observed in DL2 and DL3 with one-cycle infusions is encouraging and supports exploration of additional strategies such as the addition of preconditioning chemotherapy and multiple cycles to increase efficacy. Clinical trial information: NCT03608618. Research Sponsor: MaxCyte Inc.

Early safety from a phase I, multicenter, open-label clinical trial of talimogene laherparepvec (T-VEC) injected (inj) into liver tumors in combination with pembrolizumab (pem). *First Author: J. Randolph Hecht, David Geffen School of Medicine, University of California, Los Angeles, CA*

Background: T-VEC is a genetically modified, oncolytic HSV-1 designed to selectively replicate within tumors and produce GM-CSF to enhance systemic antitumor immunity. The safety and efficacy of T-VEC in treatment of advanced melanoma has been demonstrated as monotherapy and in combination with checkpoint inhibitors (Andtbacka *JCO* 2015, Chesney *JCO* 2017, Ribas *Cell* 2017). T-VEC has also demonstrated tolerable safety for intrahepatic inj (Hecht *JCO* 2018). This phase 1b, multicenter, open-label, dose escalation study (NCT02509507) evaluates the safety of intrahepatic inj of T-VEC in combination with intravenous (IV) pem in patients (pts) with hepatocellular carcinoma (HCC) or liver metastases (mets). **Methods:** The primary objective is to assess the maximum tolerated concentration (MTC) of T-VEC inj into liver tumors based on the incidence of dose-limiting toxicities (DLTs). DLT rate was evaluated with the mTPI up-and-down design. Eligible pts were ≥ 18 years, had progressive HCC or breast cancer, colorectal cancer, gastroesophageal cancer, melanoma, non-small cell lung cancer, or renal cell cancer liver mets, with measurable liver tumors suitable for inj. This dose escalation study comprised 2 groups: A (non-HCC) and B (HCC). T-VEC was given initially at 10^6 plaque-forming units (PFU)/mL followed by up to 4 mL of 10^7 PFU/mL (cohort 5) or 10^8 PFU/mL (cohort 6) every 21 (±3) days (Q21D). Inj volume was based on lesion size. Pem (200 mg) was given IV Q21D. **Results:** Here we report on three cohorts: A5 (10^7 PFU/mL T-VEC + pem), A6 (10^8 PFU/mL T-VEC + pem), and B5 (10^7 PFU/mL T-VEC + pem). Twenty-nine pts were treated: 7 in A5, 17 in A6, 5 in B5. Median age was 61 years (range: 30, 76). Median number of inj was 4 and median treatment duration was 88 days. One DLT of cholestatic hepatitis was observed out of 6 DLT evaluable pts in cohort A5. No DLTs were observed in cohort A6 and B5. MTC was 10^8 PFU/mL in non-HCC patients; exploration of MTC in the HCC population is ongoing. Treatment-emergent adverse events (TEAEs) were consistent across cohorts. The most common treatment-emergent treatment-related adverse events (TETRAE) were pyrexia (79.3%), chills (37.9%), and nausea (37.9%). Eight pts (27.6%) had grade 3/4 TEAEs: 2pts (6.9%) related to the combination therapy and the rest not related to treatment. No fatal AEs were observed. **Conclusions:** T-VEC intrahepatic inj in combination with IV pem at standard doses has thus far been demonstrated as feasible and tolerable to continue further investigation. Clinical trial information: NCT02509507. Research Sponsor: Amgen Inc.

3016 Poster Discussion Session; Displayed in Poster Session (Board #80), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Pharmacodynamic, safety, and efficacy results of a phase I/II trial of intratumoral INT230-6 alone (IT-01) or in combination with pembrolizumab (PEM) (Keynote A10) in patients with advanced solid tumors. *First Author: Jacob Stephen Thomas, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: INT230-6 is comprised of cisplatin (CIS), vinblastine (VIN) and an amphiphilic penetration enhancer which facilitates dispersion throughout tumors and diffusion into cancer cells when given IT. Preclinical experiments show strong synergy with a PD1 antibody. **Methods:** Solid tumors pts that progressed on standard treatment were enrolled. INT230-6 dose was set by tumor volume, injected Q2weeks x 5. Escalation occurred by increasing number of tumors injected, loading per tumor, and total dose. In another arm, PEM (200mg IV Q3weeks) was combined with INT230-6. Patients were monitored for safety weekly while on INT230-6. Blood and tumors were assessed for PK and PD. **Results:** 46 pts (17 unique cancer types) were enrolled in the monotherapy arm and 4 pts in the PEM combo arm with a median of 3 prior treatments. Doses from 0.3 ml up to-160 ml of INT230-6 (80 mg CIS and 16mg of VIN) were injected. PK results indicate 95% of the drugs are retained in the tumor when compared to historical IV dosing. No dose limiting toxicity was reported. Two pts experienced drug-related SAE's of tumor pain. The most frequent treatment-related AEs were: pain at injected site (48%), fatigue (40%) and nausea (33%). Most AE's were grade 1 and 2, 17% were grade 3, and none ≥ grade 4. Several injected and non-injected tumors had > 30% decreases in diameter. Assessments revealed substantial reductions in tumor volume (> 50%). Stable pts had a median increase of 50% in circulating CD4 and CD8 T-cells, while PD subjects showed decreases in circulating T-cells ($p < 0.05$). Dose-response suggests that monotherapy subjects receiving > 50% of tumors injected at dose/tumor volume ratio of > 1:4 (target dosing), predicts for prolonged SD with 88%(7/8) having SD ≥ 4mo, correlating with reduced tumor viability on IHC, and increase in tumor-infiltrating lymphocytes (TIL's). **Conclusions:** Proof of concept was demonstrated that INT230-6 delivers high drug doses into the tumor without systemic exposure and typical cytotoxic AEs. Systemic and local immune activation was observed. INT230-6 was safe and well tolerated in > 175 deep tumor injections with tumor burden reduction in injected and non-injected tumors (an abscopal effect). Patients who received target dosing often had prolonged disease control post treatment. Updated safety, response and biomarker data from the monotherapy and PEM combo arm will be presented. Clinical trial information: 03058289. Research Sponsor: Intensity Therapeutics.

3017 Poster Discussion Session; Displayed in Poster Session (Board #81), Fri, 8:00 AM-11:00 AM, Discussed in Poster Discussion Session, Fri, 8:00 AM-11:00 AM

Phase I/II study to evaluate systemic durvalumab + intraperitoneal (IP) ONCOS-102 in patients with peritoneal disease who have epithelial ovarian (OC) or metastatic colorectal cancer (CRC): Interim phase I clinical and translational results. *First Author: Dmitriy Zamarin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Metastasis to the peritoneal cavity is associated with end-stage disease in many cancers, including OC and CRC, both of which exhibit poor responses to checkpoint inhibitors. Locoregional treatment with oncolytic viruses may be used to improve the efficacy of checkpoint inhibitors at both treated and distant tumor sites. This study evaluates the combination of IP-administered ONCOS-102, an oncolytic adenovirus encoding for granulocyte macrophage colony stimulating factor (GMCSF), with systemic durvalumab, an anti PD-L1 antibody, in patients with peritoneal disease who have histologically confirmed OC or metastatic CRC and have failed prior standard therapies. **Methods:** This ongoing Phase 1/2, open-label study (NCT02963831) evaluates safety and antitumor/biologic activity of durvalumab (1500 mg IV, every 4 weeks x 12) + ONCOS-102 (IP, weekly x 6); cyclophosphamide is given pre first ONCOS-102 dose. Phase 1 uses a 3+3 design to evaluate the ONCOS-102 dose (1 or 3 x 10^{11} VP) to be given with durvalumab. Phase 2 evaluates the activity of the combination using Simon's 2-stage MINIMAX design. Safety, response rate by RECIST 1.1, and immunological effects in tumors were evaluated for Phase 1; the current abstract reports on the phase 1 results. **Results:** Enrollment opened 7 Sep 2017; data cutoff, 1 Nov 2019. There were 17 patients treated in Phase 1: 8 CRC, 9 ovarian; 94% female; median age, 56 [37-77] years; ECOG PS0, 47%; ECOG PS1, 53%. There were no DLTs. Grade 3 treatment-related AEs included hypokalemia (n = 2); anemia, myocarditis, increased GGT, and influenza like illness (n = 1 each). There were 4 deaths due to PD. One patient had durable confirmed partial response and remains on treatment $>$ 1 year; 4 patients had stable disease as best overall response. Two patients remained on treatment at data cutoff. Analysis of pre- and on-treatment tumor biopsies revealed changes in the tumor-infiltrating immune cells and PD-L1 expression, including an increase in tumor-infiltrating CD8 T cells in 5 of 11 evaluable patients. **Conclusions:** Combination of durvalumab and IP ONCOS-102 was safe, and no DLTs were observed. Preliminary analyses demonstrate evidence of biologic and clinical activity. Phase 2 enrollment is ongoing. Clinical trial information: NCT02963831. Research Sponsor: Ludwig Institute for Cancer Research, Cancer Research Institute, Pharmaceutical/Biotech Company.

Impact of radiotherapy on risk of adverse events in patients receiving immunotherapy: A U.S. Food and Drug Administration pooled analysis. *First Author: Mitchell Steven Anscher, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Immune checkpoint inhibitors (ICIs) are widely used in the treatment of multiple advanced malignancies. Radiotherapy (RT) has been used in combination with ICIs to activate tumor-specific T cell responses, and RT also promotes non-specific acute and chronic inflammatory responses both locally and systemically. More than 50% of patients receive RT at some point during their course of cancer therapy, and relatively little information is available pertaining to the impact of RT, if any, on the risk of adverse events (AEs) in patients receiving ICIs. **Methods:** Pooled data from prospective trials of ICIs submitted to the FDA in initial or supplemental BLAs or NDAs through 12/2019 were included (N=66). Trials from applications that were withdrawn or not approved were not included. Patients were subdivided by whether or not radiotherapy was administered at any time during the course of their cancer treatment. AEs common to both ICI treatment and RT were identified to focus on the following reactions: neutropenia, thrombocytopenia, colitis, hepatitis, pneumonitis, and myocarditis. Descriptive statistics were used to examine AEs associated with the use of radiation and ICIs. **Results:** A total of 25,836 patients were identified, of which 9087 (35%) received RT and 16,749 (65%) did not. Radiation was associated with similar rates of AEs overall with numerically higher hematologic toxicities and pneumonitis and numerically lower colitis, hepatitis and myocarditis (Table). Patients receiving RT were more likely to experience Grade 3-5 hematologic toxicities compared to those not receiving RT. **Conclusions:** To our knowledge, this is the largest report of AE risk associated with the use of radiation and ICIs. Our results show that the incidence of hematologic toxicity and pneumonitis in patients receiving RT may be slightly higher. Analysis to determine comparability of baseline demographic characteristics, comprehensive AE profile, and timing of RT is underway. Research Sponsor: None.

Description of toxicity in patients treated with ICI with or without RT.

	Incidence -risk All Grades (%)		Grades 3-4 (%)		Grade 5 (%)	
Toxicity	**RT (n=9,087)**	**No RT (n=16,749)**	**RT**	**No RT**	**RT**	**No RT**
Neutropenia	8.4	5.8	6.0	3.9	0	0
Thrombocytopenia	6.9	3.8	3.6	1.4	0	0.01

The preliminary efficacy and safety data of KN046 in patients failed on prior immune checkpoint inhibitors therapy. *First Author: Hongyun Zhao, Department of Medical Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, China*

Background: KN046 is a bispecific antibody that blocks PD-L1 and CTLA-4 by interaction with PD1 and CD80/CD86. KN046-CHN-001 (NCT03529526) is a, dose escalation and expansion phase Ia/Ib clinical trial in China. Here we reported safety, tolerability and preliminary efficacy in patients failed on prior immune checkpoint inhibiters (ICIs) treatment. **Methods:** Patients progressed on ICIs (including but not limited to antibodies targeting PD-1, PD-L1, OX40, et al) with pathologically confirmed solid tumor, ECOG 0-1, measurable lesion per RECIST v1.1, no immune-related adverse events (IRAEs) led to ICIs discontinuation, were enrolled and received intravenous KN046 treatment across four dose levels including 3.0 mg/kg (n = 3) and 5.0 mg/kg (n = 20) Q2W; and 5.0 mg/kg (n = 4), 300.0 mg flat dose (n = 2) Q3W. Safety and tolerability were assessed per NCI-CTCAE v5.0. Treatment-emergent AEs (TEAEs) and IRAEs were decided by investigators. Efficacy was evaluated by investigators per RECIST 1.1 every 6 weeks. **Results:** Twenty-nine who progressed on prior ICIs therapy were enrolled (25anti-PD-1 antibody; 3 anti-OX40 antibody; and 1 anti-CD137 antibody) and were included in the current analysis. Among 29 patients, 19 were nasopharyngeal cancer (NPC) and 9 were non-small cell lung cancer (NSCLC). The median duration of the exposure of KN046 was 12 weeks (range 2 to 40). Eleven patients remained on the treatment and 18 discontinued due to disease progression (n = 13), AE (n = 1), death (n = 1) and others (n = 3). Twenty-six (89.7%) patients experienced TRAEs of all grades and 2 (6.9%) experienced grade$\geq$3 TRAEs (1 grade 3 anemia and 1 grade 3 infusion-related reaction). The most common ($\geq$10%) TRAEs were pruritus (8, 27.6%), rash (8, 27.6%), asthenia (6, 20.7%), fatigue (6, 20.7%), pyrexia (5, 17.2%), infusion related reaction (4, 13.8%), alanine aminotransferase elevation (3, 10.3%) and white blood cell count elevation (3, 10.3%). Eleven (37.9%) patients experienced irAEs (with no grade$\geq$3). Objective responses were occurred in 3 (12.0%, 25 evaluable) patients, disease control rate was 52.0% (10 stable disease). Median progression free survival was 2.69 (95%CI 1.31,5.52) months. Median overall survival was not reached. PFS rates for 3 and 6 Months were 41.0% (95%CI 18.5, 62.5) and 21.9% (95%CI 4.6, 47.3). OS rates for 6 and 9 months were88% (95%CI 57.2, 97.1) and 58.7% (95%CI 8.3, 89.2), respectively. **Conclusions:** Overall, KN046 showed a favorable safety profile and promising clinical benefit in advanced solid tumor patients who failed on prior ICIs therapy. Clinical trial information: NCT03529526. Research Sponsor: Alphamab (Australia) Co Pty Ltd.

3021 Poster Session (Board #85), Fri, 8:00 AM-11:00 AM

Envafolimab (KN035) in advanced tumors with mismatch-repair deficiency. *First Author: Lin Shen, Peking University Cancer Hospital & Institute, Beijing, China*

Background: KN035 is a novel fusion protein of humanized anti-PD-L1 single domain antibody and human IgG1 Fc formulated for subcutaneous injection. This open-label phase II study evaluated the safety and antitumor activity of KN035 in patients with advanced microsatellite instability-high/mismatch repair-deficient (MSI-H/dMMR) cancer. **Methods:** The study included patients aged $\geq$18 years with previously treated MSI-H/dMMR colorectal cancer (CRC) or other advanced solid tumors. MSI-H/dMMR status was assessed centrally for CRC and gastric cancer (GC) and locally for other tumors. KN035 was administered at 150 mg once weekly until progression, unacceptable toxicity, or withdrawal. Tumor assessments were every 8 weeks. The primary endpoint was the objective response rate per RECIST v1.1 by independent radiology review. The primary efficacy population (PEP) included patients with CRC who failed fluoropyrimidine (F), oxaliplatin (O), and irinotecan (I) plus those with advanced GC who had failed at least one prior systemic treatment. This was a planned interim analysis performed after the first 50 patients in the PEP had at least two on-study tumor assessments (PEP_i). **Results:** As of December 17, 2019, 103 patients with MSI-H/dMMR advanced cancers were enrolled at 25 centers in China. The PEP_i included 39 patients with CRC and 11 with GC, with a median follow-up of 7.5 months. The overall population included 65 patients with CRC (24 had prior therapy with F and O or I), 18 with GC, and 20 with other tumors, with a median follow-up of 6.7 months. The confirmed objective response rate was 30% (95% CI: 17.9%, 44.6%) in the PEP_i, 54.2% (95% CI: 32.8%, 74.4%) in the CRC patients who had prior therapy with F and O or I, and 34.0% (95% CI: 24.9%, 44.0%) in the overall population. Of patients who had an objective response at the interim analysis, 80% of those in the PEPi, 84.6% of CRC patients who had prior therapy with F and O or I, and 85.7% of those in the overall population were still responding at the time of data cutoff. Median progression-free survival was 6.6 months in both the PEP_i and the overall population. Median overall survival was not reached in either population. Fourteen (13.6%) patients had grade 3–4 treatment-related adverse events. No grade 5 treatment-related adverse events, pneumonitis, or colitis were reported. Local injection-site reactions, all grade 1 or 2, were reported in nine patients. **Conclusions:** Envafolimab demonstrated durable antitumor activity with a manageable safety profile in patients with previously treated advanced MSI-H/dMMR cancer. Clinical trial information: NCT03667170. Research Sponsor: 3D Medicines (Sichuan) Co. Ltd.

3022 Poster Session (Board #86), Fri, 8:00 AM-11:00 AM

Tumor microenvironment associated with increased pretreatment density of activated PD-1+ LAG-3+/− TIM-3− CD8+ T cells facilitates clinical response to axicabtagene ciloleucel (axi-cel) in patients (pts) with large B-cell lymphoma. *First Author: Jerome Galon, HalioDx, Marseille, France*

Background: Axi-cel is a US and EU-approved autologous anti-CD19 chimeric antigen receptor (CAR) T cell therapy for pts with relapsed/refractory large B cell lymphoma after ≥ 2 prior therapies. In ZUMA-1 (NCT02348216), the objective response rate was 83% (58% complete response rate; Locke et al. *Lancet Oncol*. 2019). T cell-related biology (Immunosign 21; Immunoscore) measured pretreatment in the tumor microenvironment (TME) was associated with response to axi-cel (Rossi et al. AACR 2018. #LB-016; Rossi et al. AACR 2019. #CT153). This expanded analysis characterized the pretreatment TME immune contexture and examined associations between immune cell subsets and response. **Methods:** In ZUMA-1, pts received axi-cel at a target dose of 2.0×10^6 CAR T cells/kg. Archival pretreatment tumor biopsy samples were analyzed by multiplex immunohistochemistry (Brightplex). Two panels were developed and applied to assess T cell (CD3, CD8, FoxP3, PD-1, LAG-3, TIM-3) and myeloid cell (CD11b, CD14, CD15, LOX1, S100A9, CD68) subsets (n = 14 total). The association between T cell and myeloid cell subset density, prespecified immune scores (Immunosign 21; Immunoscore), and objective response was evaluated. T test values were based on Brightplex analysis. **Results:** Pretreatment tumor biopsy samples from 18 pts were analyzed (14 objective responders and 4 nonresponders). The pretreatment TME comprised all major myeloid and T cell subsets, with diverse distribution across samples analyzed. The median TME density of monocytes (CD11b+ CD15− CD14+; 1215 cells/mm^2) and macrophages (CD68+; 530 cells/mm^2) was greater than that of the total CD8+ T cell subset (312 cells/mm^2). The pretreatment Immunosign 21 and Immunoscore scores associated positively with the density of all major T cell subsets and some myeloid subsets. The density of activated CD8+ T cells (PD-1+ LAG-3+/− TIM-3−) was most significantly associated with clinical response versus other T cell subsets. The density of nonactivated CD8+ T cells (PD-1− LAG-3− TIM-3−) and exhausted CD8+ T cells (PD-1+ LAG-3+ TIM-3+) were not significantly associated with response. Additional characterization of the immune contexture and correlative analysis of cell subsets will be presented. **Conclusions:** These results suggest that a TME associated with increased density of activated PD-1+ LAG-3+/− TIM-3− CD8+ T cells, measurable pretreatment, facilitates clinical response in pts post–axi-cel. 3023 Poster Session (Board #87), Fri, 8:00 AM-11:00 AM

Product characteristics and pharmacological profile of KTE-X19 in patients (pts) with relapsed/refractory (R/R) mantle cell lymphoma (MCL) in the phase II registrational ZUMA-2 trial. *First Author: Michael Wang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ZUMA-2 is a Phase 2 study evaluating KTE-X19, an autologous anti-CD19 CAR T cell therapy, in pts with R/R MCL (1 – 5 prior therapies, including a BTK inhibitor). In the primary efficacy analysis of ZUMA-2 (N = 60), the objective response rate was 93% (67% complete responses) and was generally comparable among high risk pts (Wang et al. ASH 2019 #754). CAR T cell levels in blood were associated with objective response (including minimal residual disease [MRD] negativity) and toxicity. Here, we describe a comparative analysis of KTE-X19 pharmacology profile in higher vs lower risk pts in ZUMA-2. **Methods:** Product attributes, CAR T cell and serum cytokine levels in blood, and their associations with clinical outcomes, were analyzed using previously described methods (Locke et al. *Mol Ther* 2017). MRD (10^{-5} sensitivity) was assessed by next-generation sequencing. Pharmacology data are reported for all 68 pts treated with KTE-X19 (2×10^6 cells/kg). **Results:** Manufactured KTE-X19 products showed a slight bias to CD8 and effector memory/effector phenotype. Median CD4/CD8 ratio was 0.7 (range, 0.04 – 3.7); T cell phenotypes included naive (median, 24.5%; range, 0.3 – 80.7), central memory (median, 12.8%; range, 2.3 – 51.6), effector memory (median, 24.5% (range, 0.8 – 70.3) and effector (median, 28.7%; range, 2.8 – 65.2). MRD negative (n = 24/29) vs positive pts (n = 5/29) at 1 mo post KTE-X19 had increased median cytokine levels, including IL-15, IL-2, IFN-γ, IL-10, and IL-6, peaking in serum within 7 days post treatment. Pts who were MRD negative by 1 mo post treatment also had increased median peak levels of Granzyme B and soluble PD-L1. Six pts developed Grade 4 neurologic events (NE), including 1 cerebral edema case; 3 had concurrent Grade 4 cytokine release syndrome. These pts had higher peak cytokine levels vs pts without Grade 4 NE, with lack of reversion to baseline by Day 28 of serum IL-6 and sVCAM-1. Peak CAR T cell in blood and serum cytokine levels were generally comparable in higher vs lower risk pts defined as *TP53* mutated (n = 6/36) vs unmutated (n = 30/36), or high vs low Ki-67 proliferation index (PI; ≥ 30% [n = 40/49] and < 30% [n = 9/49]), consistent with the comparable clinical efficacy of KTE-X19 in these subgroups. **Conclusions:** PD profile of KTE-X19 associated with efficacy (MRD status at 1 mo) and treatment-related NE. In contrast to approved therapies, KTE-X19 showed comparable pharmacology and clinical outcomes in pts with higher vs lower risk MCL defined by *TP53* mutation or Ki-67 PI. Clinical trial information: NCT02601313. Research Sponsor: Kite, a Gilead Company.

3024 Poster Session (Board #88), Fri, 8:00 AM-11:00 AM

Assessing readmission after axicabtagene ciloleucel immunotherapy. *First Author: Paula Perkins, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Axicabtagene ciloleucel (axi-cel) is an FDA approved CD19 targeted CAR-T for patients (pts) with diffuse-large-B cell lymphoma (DLBCL) after 2 lines of treatment. Pts are monitored inpatient for minimum 7 days after CAR-T infusion but remain at risk of complications after discharge that can lead to readmission. We report our institutional experience on the rate and etiology of readmissions after initial discharge. **Methods:** In this retrospective study, readmission was defined as an inpatient stay greater than 48 hours while under the auspice of the Immunotherapy service. Cytokine release syndrome (CRS) and neurotoxicity (NT) were graded based on the Lee and CTC v.4 criteria, respectively. Logistic regression models were used to study the association between clinical factors and readmission. **Results:** 44 pts received axi-cel. Median age was 62 (25-79). 33 pts (75%) had primary refractory disease and 14 (30%) had prior transplant. Pts had median 3 lines (2 -9) of treatment before axi-cel. Median time from most recent treatment to leukapheresis was 10 weeks (0.5-109). 22 pts (48%) received bridging therapy between leukapheresis and lymphodepletion (LD). Median duration of initial planned admission was 7.5 days (6-16). Incidence of CRS was 88% (all grades) and 12% (grade 3/4). Median time to start of CRS was 3 days (0-13). Incidence of NT was 61% (all grades) and 16% (grade 3/4) and median time to NT was 6 days (3-14). 6 pts (14%) were readmitted after initial hospitalization (1 had 2 readmissions). Median day of readmission was 13 (9-25). Median duration of subsequent hospitalization was 5 days (2-31). Reasons for readmission were: infection (2), CRS (2), GI bleed (1), progressive disease (PD) (1) and NT (1). 4 of 6 pts had no CRS or NT before readmission. 2 of the 4 were readmitted on days 9 and 13 for NT. The other 2 pts were readmitted for infection and GI bleed. 1 pt had grade 2 CRS and grade 2 NT during first admission and was readmitted on day 25 for PD. Last pt had grade 2 CRS and grade 3 NT during first admission with discharge day 13, readmission day 14 through day 17 with recurrent NT and second readmission day 30 for infection. 3 of 6 pts had ICU admissions during second admissions. There was no association between pre- and post- CAR-T variables and risk of readmission in multivariable models. **Conclusions:** Readmissions after discharge from initial planned hospitalization for axi-cel are not uncommon. This data supports our current policy of close monitoring until at least a month after CAR-T therapy and supports the requirement of a full-time caregiver until discharge from the Immunotherapy service. Research Sponsor: None.

3026 Poster Session (Board #90), Fri, 8:00 AM-11:00 AM

First-in-human clinical trial of the autologous CD7-CART for relapsed/refractory ACUTE lymphoblastic leukemia/lymphoma. *First Author: Mingzhi Zhang, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China*

Background: CD7 represents a potential target for T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/T-LBL). We developed CD7 nanobody derived chimeric antigen receptor T-cells (CD7-CART), and established a non-gene editing strategy by anchoring CD7 in the ER and/or Golgi to overcome the CART fratricide. **Methods:** This single-arm, open-label, phase I study is to investigate CD7-CART cell manufacturing feasibility without contamination of malignant T cells, and the safety and efficacy of the CART on patients with CD7 positive relapsed/refractory T-ALL/T-LBL. 3 subjects, identified as both CD4 and CD8 negative T-ALL or T-LBL were enrolled. CART cells were manufactured by using CD4+/CD8+ sorted T cells from leukapheresis. All patients (Pts) were pretreated with Flu/Cy prior to CART infusion. 1x10^6/kg CART cells were given to case 2 and 3, while 1.5x10^6/kg to case 1. **Results:** Case 1 was diagnosed as refractory ALL with myeloid differentiation, who had received intensive chemotherapy and allogeneic hematopoietic stem cell microtransplantation. Case 2 was diagnosed as ALL (T/B mixed type) but relapsed with CNS involvement, and received radiotherapy in addition to intensive chemotherapy. Prior to CART infusion, case 2 had no abnormal B cells but 17.69% of abnormal early T cellsfrom BM. Case 3 had stage VI of T-LBL, which recurred after multi-cycle chemotherapy of BFM-90 regimen and autologous SCT. After CART treatment, no neurotoxicity was observed in all pts. Case 1 had grade 3 CRSwhile case 2 and 3 had grade 1, although increased IL-6 was detected in all pts. Significant CART expansion and persistence were observed in case 2 and 3, and MRD negative CR was confirmed on day 28 in both pts. The number of generalized lymphadenopathy, lymph node size, and the degree of metabolism were all significantly reduced in case 3. Case 1 had only moderate CART expansion, but abnormal early T cells from BM decreased from 70.03% to 19.57% on day 30. After CART infusion, the number of peripheral abnormal T cells became either undetectable in case 2 and 3, or significantly decreased in case 1. Interestingly, CART had unsustained effect on normal T cells in all pts. As of Feb-10-2020, case 1 has 5 months of OS, including 3 months of PFS. Case 2 and 3 has reached 2 and 1 months of PFS and is still in remission. **Conclusions:** CD7-CART cells can be manufactured without contamination of malignant T cells. CD7-CART therapy is well-tolerated and has great therapeutic potential for relapsed/refractory CD7 positive T cell malignancies. Clinical trial information: NCT04004637. Research Sponsor: National Key R&D Program of China (2016YFC1303403).

3027 Poster Session (Board #91), Fri, 8:00 AM-11:00 AM

Successful tumor-infiltrating lymphocyte (TIL) growth from uveal melanoma (UM) using a three-signal (3.0) method. *First Author: Meredith Pelster, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Metastatic UM is a rare cancer with poor response rates to systemic therapy. Adoptive transfer of patient-specific TIL may represent the best strategy for treatment. TIL are harvested from primary or metastatic tumors and initially expanded in culture with high dose IL-2 prior to undergoing rapid expansion protocol and therapeutic administration. Here, we report improved rates of initial expansion using a previously described TIL 3.0 method which utilizes dual agonistic antibodies to TCR and 4-1BB (Urelumab) for stimulation, respectively, with high dose IL-2, compared to the traditional method. **Methods:** Between 2006 and 2019, patients were consented for TIL harvest from either primary or metastatic UM tumors. Demographics, clinical features, and outcomes of the TIL initial expansion were collected. Success rates, number of cells expanded, and days in culture for the two methods were analyzed using partially overlapping samples t-tests and z-tests. **Results:** There were 85 harvests and expansions from 76 patients using the traditional method and 32 expansions from 30 patients using TIL 3.0. Initial TIL expansion was successful in 97% of TIL 3.0 harvests compared to 35% for the traditional method ($p < 0.001$). More TIL were expanded with TIL 3.0 compared to the traditional method (291.3 million cells vs. 88.6 million cells, $p < 0.001$), and fewer days were required in culture (18.5 vs. 29.0, $p < 0.001$). Both primary UM harvests and metastatic harvests were more successful with TIL 3.0 (90% vs. 12% for primary, $p < 0.001$, and 100% vs. 42% for metastatic, $p < 0.001$). **Conclusions:** Expansion of UM tumors via the TIL 3.0 method led to successful growth in 97% of harvests. Therapeutic administration to patients with TIL 3.0 is under active investigation. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

3028 Poster Session (Board #92), Fri, 8:00 AM-11:00 AM

Association of lymphocyte to monocyte ratio with clinical response and survival in patients with relapsed, aggressive non-Hodgkin lymphoma treated with axicabtagene ciloleucel CAR-T. *First Author: Abdullah S. Al Saleh, Mayo Clinic, Rochester, MN*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy induces complete remission (CR) in 30-40% of patients with non-Hodgkin lymphoma (NHL). However, for patients who do not achieve CR as their first response, predictors for achieving CR as best response can guide management between careful observation or early intervention. Increased absolute lymphocyte count to absolute monocyte count ratio (ALC/AMC) predicts better response rates and survival in NHL patients receiving chemotherapy and/or autologous stem cell transplant. We evaluated the prognostic impact of ALC/AMC in CAR-T therapy for NHL. **Methods:** This was a retrospective review of patients who received CAR-T for NHL from June 2016-August 2019. ALC/AMC was assessed at the start of lymphodepletion (LD) chemotherapy. The receiver operator curve (ROC) was used to determine the best cutoff for ALC/AMC in predicting CR at 3 months. Event-free survival (EFS) was defined from time of CAR-T infusion to relapse or death, whichever occurred first. Overall survival (OS) was defined from time of infusion to death of any cause. **Results:** Forty-seven patients received axicabtagene ciloleucel, with a median follow-up of 14 months. By ROC, ALC/AMC > 0.8 before LD chemotherapy was predictive of achieving CR at 3 months. Baseline characteristics were similar between the high (n = 30) and low (n = 17) ALC/AMC groups. Patients with an ALC/AMC > 0.8 at the time of LD chemotherapy were more likely to achieve CR at 3 months (46% vs. 12%, p = 0.01), 6 months (52% vs. 0%, $p < 0.0005$), and 12 months (42% vs. 0%, p = 0.01). Correspondingly, the EFS and OS were significantly shorter in patients with ALC/AMC$\leq$0.8 vs. those > 0.8 (median EFS: 2 vs. 13 months, $P < 0.0001$) and (median OS: 15 months vs. not reached, P = 0.03), respectively. Association between ALC/AMC ratio and EFS and OS remained consistent in multivariate Cox models after adjusting for other prognostic variables, including abnormal lactate dehydrogenase and increased ferritin level at infusion day. **Conclusions:** ALC/AMC > 0.8 before lymphodepletion chemotherapy is a strong predictor for complete remission as well as improved event-free and overall survival for axicabtagene ciloleucel in NHL. Research Sponsor: None.

3029 Poster Session (Board #93), Fri, 8:00 AM-11:00 AM

A prospective phase I trial of dendritic cell-based cryoimmunotherapy in metastatic castration-resistant prostate cancer. *First Author: Liv Cecilie Vestrheim Thomsen, Centre for Cancer Biomarkers, University of Bergen, Bergen, Norway*

Background: Dendritic cell (DC)-based cryoimmunotherapy (CryoIT) was used to treat metastatic castration-resistant prostate cancer in a Phase I clinical trial. Primary objective was safety of treatment. Secondarily, clinical, radiological and immunological treatment responses were investigated. **Methods:** In 18 patients cryoablation by a freeze-thaw process under general anesthesia was performed, followed by intratumoral autologous immature DC injection. In the last 9 patients checkpoint inhibition of either CTLA-4 or PD-1 was added. Subjects had minimum 46 weeks follow-up. Adverse events (AEs) and blood analyses were registered at all visits. Disease progression was determined by three imaging modalities according to (i)RECISTv1.1 and progression-free survival (PFS) by Kaplan-Meier method. Circulating tumor cells (CTC/7.5 mL, CellSearch) and ultradeep T-cell receptor (TCR) b-chain sequences (TCRSafe) were enumerated. Patients were separated by CTC into none (n=10), 1-4 (n=4) and $\geq$ 5 (n=4). Health related quality of life (HRQoL) measured by EORTC-QLQ C30 questionnaire were answered at inclusion, and 10, 22 and 46 weeks post CryoIT. Scores were calculated according to the EORTC manual. **Results:** Subjects progressing within 22 weeks had higher PSA (p=0.03). AE profile of the total cohort (n=18) was comparable with interim reports (n=13); of 20 possible DC-related AEs one was severe (urinary retention) and 19 mild-to-moderate, and spread independent of treatment regime. Maximum tolerated dose of DC was not reached. By 46 weeks, imaging showed 6 patients partial response or stable disease. Median PFS was 150 days in total cohort. Pretreatment CTC counts $\geq$5 indicated higher progression rates and recurring CTC. Ultradeep TCR-sequencing showed more prevalent and higher expressed (>5-fold) new TCR clonotypes at 2-6 weeks in men without progression. Participants reported high and stable HRQoL scores throughout the study. However, presence of CTC was associated with worse HRQoL scores at week 10 (p=0.031) and 22 (p=0.005). **Conclusions:** DC treatment seems safe and well tolerated, also combined with checkpoint inhibitors. Effect is indicated in subjects with moderate pre-treatment PSA levels. Immune responses are suggested by higher number of novel TCR clonotypes in men with non-progressive disease. Clinical trial information: NCT02423928. Research Sponsor: Alden Cancer Therapy II, Centre for Cancer Biomarkers CCBIO, University of Bergen, Bergen, Norway.

3030 Poster Session (Board #94), Fri, 8:00 AM-11:00 AM

Ongoing, first-in-human, phase I dose escalation study of the investigational CD47-blocker TTI-622 in patients with advanced relapsed or refractory lymphoma. *First Author: Krish Patel, Swedish Cancer Institute, Seattle, WA*

Background: CD47 is an immune checkpoint that binds signal regulatory protein alpha (SIRPα) and delivers a "do not eat" signal to suppress macrophage phagocytosis. Cancer cells frequently overexpress CD47 to escape immune surveillance. TTI-622 is a fusion protein consisting of the CD47-binding domain of human SIRPα linked to the Fc region of human IgG4. TTI-622 acts as a decoy receptor, preventing CD47 from delivering its inhibitory signal and enabling macrophage activation and anti-cancer activity via pro-phagocytic signals present on cancer cells. Unlike many CD47-blocking antibodies, TTI-622 does not bind to human erythrocytes and thus may not cause anemia in patients. **Methods:** In phase 1A, patients with advanced relapsed or refractory lymphoma received IV TTI-622 once per week with dose increased based on traditional 3+3 escalation. Dosing was on a mg/kg basis with the third and subsequent weekly doses approximately 2-fold higher than the first 2 doses (e.g., 0.05, 0.05, and 0.1 mg/kg for weeks 1, 2 and 3). Blood samples were obtained for PK analysis and assessment of CD47 receptor occupancy (RO) on peripheral T cells. **Results:** At data cut-off, 19 patients (11 M, 8 F) of median age 62 years (range, 24-86) with the following lymphomas: DLBCL 10; HL 6; and TCL, MCL and FL, 1 each, with a median of 3 prior therapies (range, 1-8) were enrolled. No DLTs have been observed in 5 dose levels (0.05 to 4.0 mg/kg). Grade $\geq$3 related neutropenia occurred in 2 patients; other related AEs occurring in 2 patients each included abdominal pain, fatigue, and nausea; no patients experienced a related SAE. Acute, post-dose platelet decreases occurred transiently and generally were Grade 1- 2; no related Grade $\geq$3 thrombocytopenia or anemia AEs have been observed. Preliminary PK data indicate a dose-proportional increase in exposure and a T1/2 of approximately 4-5 days following repeat infusions (Week 6). Preliminary biomarker data reveal approximately 60% RO at the end of the first infusion of 2 mg/kg and more sustained 24-hour RO at 1 and 2 mg/kg vs $\leq$ 0.8 mg/kg. To date, 1 patient with stage 4 non-GCB DLBCL (5 prior therapies) initially achieved PR by Wk 8 and CR by Wk 36, with response ongoing. **Conclusions:** TTI-622 is well tolerated at doses up to 4 mg/kg per week. Preliminary data indicate dose-dependent increases in PK exposure and target engagement with 1 DLBCL patient having achieved a durable, ongoing CR. Dose escalation is ongoing and additional safety, PK, biomarker and response data will be available at the time of meeting presentation. Clinical trial information: NCT03530683. Research Sponsor: Trillium Therapeutics Inc.

3031 Poster Session (Board #95), Fri, 8:00 AM-11:00 AM

Modulation of inhibitory signals in CAR T cells leads to improved activity against glioblastoma. *First Author: Khaled Sanber, Center for Cell and Gene Therapy, Department of Medicine, Baylor College of Medicine, Houston, TX*

Background: Early clinical trials have demonstrated the safety of chimeric antigen receptor (CAR) T cells targeting glioblastoma (GBM), however, their efficacy remains limited by multiple obstacles including the immunosuppressive tumor microenvironment. Adoptively transferred CAR T cells remain susceptible to inhibition via the engagement of co-inhibitory receptors on their surface such as PD1, BTLA, CTLA4 and LAG3. The subsequent recruitment of Src homology region 2 containing protein tyrosine phosphatase 2 (SHP2) by these receptors to the immune synapse may represent a common mechanism of T cell inhibition, as SHP2 can de-phosphorylate key signaling molecules that mediate T cell activation (including CD28 and CD3ζ). We hypothesized that SHP2 deletion will simultaneously offset the effects of multiple co-inhibitory receptors, thereby improving the anti-tumor activity of CAR T cells. **Methods:** Electroporation of sgRNA/Cas9 ribonucleoprotein complexes into human T cells was used to knockout (KO) SHP2. Retroviral vector transduction was used to express a clinically-utilized second generation CAR (with a CD28 endodomain) targeting HER2. The phenotype of wild-type (WT) and $SHP2^{KO}$ CAR T cells was evaluated with mass cytometry and flow cytometry. Their anti-tumor function was tested *in vitro* using the xCELLigence assay (an impedance-based cytotoxicity assay), and *in vivo,* in an orthotopic xenograft mouse model of GBM. **Results:** Efficient and reproducible depletion of the SHP2 protein in human T cells was verified using western blotting. The Inference of CRISPR Efficiency (ICE) Assay confirmed efficient editing of the PTPN11 gene encoding SHP2. An anti-HER2 CAR was efficiently expressed in the $SHP2^{KO}$ T cells. SHP2 deletion did not significantly affect CAR T cell expansion, proliferation or baseline phenotype. However, following co-culture with HER2+ LN229-GBM cells, the CD8+ central memory (CCR7+ CD45RA-) and effector memory (CCR7- CD45RA-) subsets were enriched to a greater extent in the $SHP2^{KO}$ CAR T cells. The pattern of cytokine co-expression varied between donors in a single-cell analysis comparing $SHP2^{KO}$ to WT CAR T cells after encountering LN229 cells. Functionally, $SHP2^{KO}$ CAR T cells derived from the majority of healthy donor and patient peripheral blood eliminated LN229 cells more rapidly *in vitro.* In an orthotopic mouse model of GBM, $SHP2^{KO}$ CAR T cells showed better early control of established LN229 xenografts and improved survival in comparison to WT CAR T cells. **Conclusions:** SHP2 deletion in CD28ζ.CAR T cells improves their anti-tumor activity. Research Sponsor: Stand Up to Cancer, Other Foundation.

3032 Poster Session (Board #96), Fri, 8:00 AM-11:00 AM

CYAD-101: An innovative non-gene edited allogeneic CAR-T for solid tumor cancer therapy. *First Author: Hans Prenen, University Hospital Antwerp, Edegem, Belgium*

Background: In contrast to autologous CAR-T cell therapies, allogeneic donor-derived CAR-T cells can be banked and used in a timely fashion overcoming the critical time delay of just in time autologous cell manufacture. CYAD-101 is an allogeneic CAR-T that uses a non-gene edited peptide-based technology (TIM) to control graft versus host disease (GvHD) combined with a NKG2D-based CAR. Pre-clinical studies confirmed that CYAD-101 maintained CAR-directed anti-tumor activity in the absence of the induction of GvHD. Clinical grade CYAD-101 cells were produced for the phase 1 alloSHRINK trial (NCT03692429). **Methods:** A bank of clinical grade CYAD-101 cells was generated through two production runs using a single donor apheresis. Together, the bank generated > 53 billion CYAD-101 cells suitable for the entire dose escalation segment and short expansion phase of the trial (15 patients in total). Both runs showed high consistency with the CYAD-101 product generated composed mainly of $CD4^+$ T cells (>85%) with a transduction level of > 92%, low relative expression of CD69/CD25 and largely absent expression levels of PD-1/LAG-3. The CYAD-101 cells were predominantly (>80%) $CD45RA^-$/ $CD62L^-$/ $CD27^-$ suggestive of an effector memory T cell population. **Results:** Upon co-culture with target K562 cells, CYAD-101 readily produced IFN-γ that was blocked by a NKG2D blocking antibody confirming specificity of the CAR. CYAD-101 cells showed in vitro cytotoxicity against tumor cells and produced an array of Th1 (IFN-γ, IL-2 and TGF-β) and Th2 (IL-4, IL-5) cytokines. Importantly, minimal IFN-γ was produced upon TCR stimulation while stimulation with a non-TCR mitogen (PMA + ionomycin) lead to high levels of IFN-γ. Together, these data show that clinical grade CYAD-101 cells were able to functionally respond through the CAR but showed minimal TCR-driven activation. Fifteen refractory metastatic CRC patients who had previously failed at least one line of oxaliplatin—containing therapy were treated with three doses of CYAD-101 cells given on Day 3 of three successive FOLFOX chemotherapy cycles. Updated clinical results continue to demonstrate an encouraging clinical activity (2 patients with partial response and 9 with stable disease) and the absence of GvHD in the context of CYAD-101 cell engraftment. **Conclusions:** These early clinical results demonstrate the safety and tolerability of a non-gene edited predominantly $CD4^+$ CAR-T therapeutic approach. The initial observations of clinical activity in metastatic CRC patients warrants the continued development of this therapy. Clinical trial information: NCT03692429. Research Sponsor: Celyad SA.

3034 Poster Session (Board #98), Fri, 8:00 AM-11:00 AM

Safety and efficacy of optimized tandem CD19/CD20 CAR-engineered T cells in patients with relapsed/refractory non-Hodgkin lymphoma. *First Author: Yajing Zhang, Chinese PLA General Hospital, Beijing, China*

Background: Chimeric antigen receptor T (CAR T) cells targeting CD19 have been used to achieve breakthroughs in the treatment of hematological malignancies, however, a high recurrence rate is the main obstacle to durable remission following CAR T cell therapy. **Methods:** As an open-label and single-arm phase I/IIa trial (ClinicalTrials.gov number, NCT03097770), we screened 99 patients with r/r B-NHL—including DLBCL, PMBCL, CLL/SLL, MCL, TFL and FL—according to the 2008 WHO Classification of Tumors of Hematopoietic and Lymphoid Tissue, and a total of 87 patients received an infusion of one dose tandem CD19/CD20 CAR-engineered T cells on day 0 in the range of 0.5×10^6-10×10^6 cells per kilogram of body weight after conditioning chemotherapy. The primary objective was to evaluate the safety and tolerability of CAR T cells. Efficacy, progression-free survival (PFS) and overall survival (OS) were evaluated as secondary objectives. Our clinical trials is registered with ClinicalTrials.gov, NCT03097770. Safety was assessed by CTCAE Version 5.0, and clinical response by PET-CT referred to standard international criteria. The trial remains open, and recruitment to extension cohorts with alternative endpoints is underway. **Results:** Between May 11, 2017, and Jan 31, 2020, 99 patients were enrolled and 87 received tandem CD19/CD20 CAR-engineered T cells across phases I/IIa. As of the cutoff date, 74 assessable patients were followed up for a median of 13.5 months (IQR 33.2 - 3.3), 62 (84%) had an objective response, and 55 (74%) had a complete response. The median progression-free survival and overall survival were all not reached. Cytokine release syndrome (CRS) occurred in 62 patients (71%), with 61% grade 1 or 2 and 10% grade 3 or more. CAR-T-cell-related encephalopathy syndrome (CRES) of grade 3 occurred in 2 patients (2%) . Three treatment-related deaths (2 in pulmonary infection and 1 in deposition of CART cells in pulmonary alveoli). **Conclusions:** In this study, optimized tandem CD19/CD20 CAR-engineered T cells induced a potent and durable anti-tumour response with controllable CRS and CRES. Clinical trial information: NCT03097770. Research Sponsor: National Natural Science Foundation of China.

3035 Poster Session (Board #99), Fri, 8:00 AM-11:00 AM

Efficacy of SCRI-CAR19x22 T cell product in B-ALL and persistence of anti-CD22 activity. *First Author: Rebecca Alice Gardner, Seattle Children's Hospital, Seattle, WA*

Background: Loss of CD19 expression is a major cause of limited durable B-ALL remission following CD19 CAR T cells, which might be overcome by utilization of dual CD19xCD22 CAR T cell targeting. **Methods:** A Phase I trial (NCT03330691) of SCRI-CAR19x22 was developed using dual transduction of lentiviral vectors encoding for either a CD19- or CD22-specific CAR T cell construct, both with 4-1BB co-stimulation. Manufacturing was performed in a closed G-Rex system with IL-7, IL-15 and IL-21. After lymphodepletion, CAR T cells were infused at 1 or 3 X 10^6 CAR T cells/kg dose levels. Leukemic response and CAR T cell persistence were evaluated by flow cytometry. **Results:** Products were successfully manufactured in all 28 enrolled subjects with 7.92 average days in culture (range of 7-11 days) and consisted of an average CD8:CD4 ratio of 3.09 (range 0.19 to 8.9). The cellular product CAR composition was 29% CD19, 31% CD22 and 39% CD19 and CD22 targeting. 13 subjects had prior exposure to CD19 or CD22 targeting therapies with diverse expression of CD19 and CD22 on the leukemic blasts. No dose limiting toxicities occurred in the 27 infused subjects. The recommended phase 2 dose is 3 x 10^6 CAR+ cells/kg. CRS was present in 80% of subjects, with 85% of CRS being grade 2 or less, and a peak grade of 3 (n = 3). Mild neurotoxicity occurred in 38%, with a single grade 3 event. 84.6% obtained a CR, of which 95% were MRD negative. Of the 4 subjects who did not achieved a CR, 2 had a pre-existing CD19 negative population and one had previously received CAR T cells and rejected SCRI-CAR19x22. There have been 4 relapses with varying CD19 and CD22 expression as follows: 1 CD19-CD22-, 1 CD19+CD22+, and 2 CD19-CD22+. The in vivo engraftment of CAR T cells peaked most frequently between day +7 and +14 and was predominated by the CD19 CAR+ T cells. **Conclusions:** We demonstrate manufacturing feasibility and safety of SCRI-CAR19x22. While initial efficacy is demonstrated, CD22 activity is poor due to limited expansion of the CD22 CAR-containing components and subjects with pre-existing CD19 negative leukemia fared poorly. Development of a revised CD22 CAR that exhibits a reduction tonic signaling is underway, with plans to explore the new construct in the context of a dual-targeting CD19xCD22 CAR T cell product. Clinical trial information: NCT03330691. Research Sponsor: Philanthropy.

3036 Poster Session (Board #100), Fri, 8:00 AM-11:00 AM

In vitro and in vivo characterization of MDNA11: A long-acting "beta-only" IL-2 superkine in syngeneic mice tumor models and nonhuman primates. *First Author: Moutih Rafei, Université de Montréal, Montréal, QC, Canada*

Background: Use of IL-2 (Proleukin) remains limited due to its short half-life, toxicity, and its ability to preferentially activate Tregs resulting in unwanted immune suppression. Approaches to reduce binding to CD25 (IL2α), such as pegylation techniques, also results in reduced affinity to CD122 (IL2β). To bypass these limitations, we engineered MDNA11, an IL-2 Superkine containing core mutations to diminish binding to CD25 while increasing affinity to CD122. To increase half-life, MDNA11 was fused to an albumin scaffold, which is known to allow accumulation at the tumor site. **Methods:** MDNA11 was evaluated using *in vitro* and *in vivo* studies that included: IL-2 signaling in human PBMCs, Biacore binding analyses, PK studies in mice, and efficacy studies in syngeneic tumor models with or without immune checkpoint inhibitors (ICIs). In addition, dose-range finding studies in cynomolgus monkeys (NHP) were performed to characterize the safety and PK/PD profiles of MDNA11. **Results:** MDNA11 displayed enhanced STAT5 signaling in human NK and naïve CD8 T-cells with diminished Treg activity. In mice, the terminal half-life of MDNA11 was 24-fold longer than IL-2. As a result, MDNA11 triggered effective tumor growth control, as monotherapy or in combination with ICI, in multiple tumor models in spite of q1wk dosing for two weeks. MDNA11 administration to mice with pre-established CT26 colon cancer resulted in tumor-free animals and induced strong memory response and protection against subsequent re-challenges. MDNA11 also inhibited the growth of B16F10 melanomas, which translated into a durable increase in tumor infiltrating CD8 T-cells. When tested in NHP, MDNA11 led to increased circulating CD8 T-cells lasting for almost 14 days with limited effects on Tregs and eosinophils (the latter being a source of IL-5 causing vascular leak syndrome). High doses resulted in mild side effects that were transient and reversible even following repeated dosing. **Conclusions:** The long-acting MDNA11 Superkine has superior potency over IL-2 at activating naïve CD8 T-cells and NK cells, while exhibiting diminished Treg activation. This molecule potently inhibited tumor growth and induced durable regression and long-term memory response. Studies in NHP showed prolonged proliferation of immune effector cells lasting almost two weeks post-MDNA11 administration. The sum of these data underscores the potency of MDNA11 to trigger the host's immune response to control or eradicate established tumors. Research Sponsor: Medicenna Therapeutics.

3037 Poster Session (Board #101), Fri, 8:00 AM-11:00 AM

A randomized phase I/IIa study to evaluate the safety and efficacy of SNK01 (non-genetically modified autologous natural killer cells with enhanced cytotoxicity) plus pembrolizumab in patients with stage IV non-small cell lung cancer. *First Author: Eo Jin Kim, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Despite the increased promise of checkpoint inhibitors in the treatment of lung cancer, the overall response rate is approximately 30% with up to 30% moderate to severe side effects. Natural killer (NK) cells have recently been implicated in antitumor response to immune checkpoint inhibitors. SNK01 is a novel non-genetically modified autologous natural killer cell therapy with enhanced cytotoxicity which has been found to have tumoricidal effects against several lung cancer cell lines. **Methods:** 18 patients with Stage IV NSCLC (PD-L1+, EGFR-, ALK-) who all failed prior frontline platinum-based therapy were randomized 2:1 to Pembrolizumab every three weeks +/- 6 weekly infusions of SNK01 at either 2×10^9 or 4×10^9 cells per infusion. Primary endpoint is safety and secondary endpoints are objective response rate (ORR), progression-free survival (PFS), overall survival (OS), time to progression (TPP), and quality of life (QoL). **Results:** 14 patients have been enrolled up to date and 9 have completed treatment. Median age is 69 (52-73). Two patients discontinued treatment prior to receiving their first dose of SNK01 due to Grade 3 toxicity to Pembrolizumab. Three patients have completed therapy with Pembrolizumab alone and all had progressive disease. Three patients have completed Pembrolizumab with 2×10^9 SNK01 and three patients have completed Pembrolizumab with 4×10^9 SNK01. Of patients receiving full combination therapy, there have been no adverse events or any reported toxicity while overall QoL has been improved. The week 9 overall response rate in the combination group is 66% using iRECIST (3/6 cPR, 1/6 PR). All remaining planned patients are currently being enrolled and a full update will be presented. **Conclusions:** These preliminary results demonstrate that combination therapy with Pembrolizumab and SNK01 is very safe and even appears to reduce checkpoint associated toxicity while increasing overall tumor response compared to Pembrolizumab monotherapy alone in Stage IV NSCLC patients who have failed prior platinum-based treatment. Research Sponsor: NKMAX.

3038 Poster Session (Board #102), Fri, 8:00 AM-11:00 AM

Phase I study of CRISPR-engineered CAR-T cells with PD-1 inactivation in treating mesothelin-positive solid tumors. *First Author: Zhenguang Wang, Molecular & Immunological Department, Bio-therapeutic Department, Chinese PLA General Hospital, Beijing, China*

Background: Our previous phase I study with MPTK-CAR-T (mesothelin-directed 28ζ CAR-T cells with PD-1 and TCR disruption by CRISPR-Cas9 system) demonstrated feasibility and safety of CRISPR-mediated PD-1 inactivation in CAR-T cells, and suggested the natural TCR is beneficial for the proliferation of CAR-T cells in solid tumors. Based on these observations, we initiated a pilot dose escalation study to investigate mesothelin-directed CAR-T cells with only PD-1 disruption by CRISPR (termed as GC008t) in patients with mesothelin-positive advanced solid tumors (NCT03747965). **Methods:** On the data cut-off date (Jan 20, 2020), nine patients (6 pancreatic cancers, 2 ovarian cancers, 1 colorectal cancer) were treated (5 received ≥12 numbers of therapy), three in cohort 1 ($0.1\text{-}0.2 \times 10^7$/kg), four in cohort 2 ($0.5\text{-}1.0 \times 10^7$/kg), two in cohort 3 ($2.5\text{-}5 \times 10^7$/kg). Eight of the 9 patients received lymphodepletion regimen of cyclophosphamide and nab-paclitaxel with or without gemcitabine. Four of the 9 patients received repeat infusions of GC008t per protocol. **Results:** Comparable proliferation capacity was observed *in vitro* between the MPTK-CAR-T and the GC008t products. The mean PD-1 surface expression in cell products was 0.5% (range, 0.2%-0.9%). GC008t infusions were well tolerated with no observed on-target/off-tumor toxicity, autoimmune activity. Only two patients in cohort 3 developed grade 1 CRS with fever and rash. Circulating GC008t expanded with a peak at day 7-14 and became undetectable by qPCR beyond 1 month. The mean peak levels of circulating CAR-T cells between GC008t and MPTK-CAR-T at similar dose level were not statistically significant. Failure of GC008t engraftment after repeat infusion was observed in 2 out of 4 patients. The best response of the 7 evaluable patients was stable disease in 4 and partial response in 2 patients (dosed $\geq 1 \times 10^7$/kg) with PFS of 80 and 160 days. **Conclusions:** Phase I trial of GC008t further establishes that genetic inactivation of PD-1 in CAR-T cells by CRISPR is feasible and safe. The expansion and persistence of CAR-T cells with PD-1 disruption is not improved significantly even in the setting of natural TCR and lymphodepletion. Future endeavors are needed to improve the clinical efficacy of CAR-T therapy in the treatment of solid tumor. Clinical trial information: NCT03747965. Research Sponsor: National Natural Science Foundation of China;National Key Research and Development Program of China;Strategic Priority Research Program of the Chinese Academy of Sciences.

3039 Poster Session (Board #103), Fri, 8:00 AM-11:00 AM

Safety and efficacy of chimeric antigen receptor T cells modified to target mesothelin and express PD-1 antibodies in patients with relapsed/refractory solid cancers in a phase I trial. *First Author: Juemin Fang, Shanghai Tenth People's Hospital, Tongji University, Shanghai, China*

Background: The limitations of chimeric antigen receptor T cells (CAR-T) in solid tumors are immunosuppressive tumor microenvironment and difficult infiltration to tumor. In order to reduce on-target off-tumor toxicities and circumvent the immune-suppressive tumor microenvironment(TME), we modified autologous CAR-T to be specific for mesothelin (MSLN) on cancer cells and secrete PD-1 antibodies (aPD1-MSLN-CAR T cells). Here, we report the safety and efficacy of aPD1-MSLN-CAR T cells in 10 patients with relapsed/refractory solid cancers in this single-arm, open-label, first-in-human phase I pilot study (ClinicalTrial.gov: NCT03615313). **Methods:** aPD1-MSLN-CAR T cells were prepared from peripheral blood mononuclear cells and engineered using PiggyBac Transposon System to target MSLN and secrete PD-1 antibodies. 10 patients with mesothelin positive relapsed/refractory solid cancers after failure to standard therapies were treated with aPD1-MSLN-CAR T cells for two or more cycles until disease progression or intolerable toxicity. The dose escalation of CAR T cells was designed to be 5×10^6/kg, 5×10^7/kg, and 1×10^8/kg, respectively. Adverse events were evaluated according to CTCAE-V4.03 and clinical response was assessed by RECIST 1.1. CAR expression was analyzed using quantitative real-time polymerase chain reaction. PD-1 antibodies were detected by ELISA. Serum IL-2, IL-4, IL-6, IL-10, IFN-γ and TNF-α were measured using flow cytometry. **Results:** The most common adverse events were mild fatigue and fever. Abdominal pain was also observed in 1 patient. Grade 1 and 2 cytokine release syndromes were observed without neurologic symptoms in 10 patients. After aPD1-MSLN-mRNA-CAR T cells treatment, 2 patients (20%) achieved partial response (PR), 4 (40%) remained stable (SD), and the rest 4 (40%) patients developed disease progression (PD). The median PFS was 97 days [95% CI (13, 180)] estimated by Kaplan-Meier method. **Conclusions:** These findings lend support that the combination of modified CAR T cells targeting MSLN with PD1 inhibition for solid tumors is safe. Modified CAR-T cells expressing PD-1 antibodies maybe an option to improve CAR-T efficacy as a result of refined TME. Clinical trial information: NCT03615313. 3040 Poster Session (Board #104), Fri, 8:00 AM-11:00 AM

Final results of controlled IL-12 monotherapy in adults with grade III or IV gliomas. *First Author: E. Antonio Chiocca, Brigham and Women's Hospital, Boston, MA*

Background: Interleukin-12 (IL-12), a master regulator of the immune system, results in anti-tumor responses in preclinical models, but safe use requires tightly controlled production. This phase 1 trial (NCT02026271) is the first to evaluate the safety and tolerability of Ad-RTS-hIL-12 (Ad) under transcriptional control with veledimex (V) in adults with grade III or IV gliomas. **Methods:** Multicenter, phase 1, open-label, 3 + 3 dose escalation study of Ad (a single intratumoral injection, 2×10^{11} viral particles, Day 0) with oral V dosing (Days 0 to 14) of 10, 20, 30, and 40 mg in subjects with rGBM. **Results:** 38 subjects were treated (resection group: V 10 mg (n = 6); 20 mg (n = 15); 30 mg (n = 4); 40 mg (n = 6); and, stereotactic group: V 20 mg, n = 7). The adverse event profile of Ad+ V, was predictable and controllable, with the main adverse reactions (ARs) being mild to moderate. All ARs were manageable and reversible upon withholding V. We observed increased peak (mean ± SEM) serum recombinant IL-12 and downstream endogenous IFN-g: V 10mg 21.4 ± 11.7 pg/mL and 14.6 ± 7.1 pg/mL; V 20 mg 25.8 ± 7.1 pg/mL and 57.0 ± 26.5 pg/mL; V 30 mg 65.7 ± 45.5 pg/mL and 60.7 ± 50.0 pg/mL; V 40mg 108.8 ± 41.0 pg/mL and 167.5 ± 70.9 pg/mL, V 20mg (stereotactic) 25.1 ± 7.2 pg/mL and 69.8 ± 48.5 pg/mL, respectively. In the V 20 mg cohort, there was an increase in tumor-associated T cells ($CD3^+CD8^+$%) from pre-Ad (mean ± SEM) 0.6 ± 0.4 to biopsy (~5 mons) 6.3 ± 5.0 and production of IFN-g 97.2 ± 85.3 pg/g (n = 2). Median overall survival (mOS) in the V 20 mg cohort (resection, n = 15) was 12.7 mons (mean follow-up, 13.1 mons). Subjects with unifocal disease (n = 6) who received low-dose (≤ 20mg total) dexamethasone during active dosing (Days 0-14) had an mOS of 17.8 mons. Tumor response data will be presented. **Conclusions:** Results of Controlled IL-12 in rGBM are promising, with V-dependent and proportional increases in IL-12 and IFN-g resulting in immune activation, with a favorable safety profile and encouraging survival. The 20 mg V dose is the recommended phase 2 *dose*. Controlled IL-12 is being evaluated in a monotherapy substudy (n = 36, V 20 mg) and two combination studies with immune checkpoint inhibitors for rGBM. Clinical trial information: NCT02026271. Selective targeting of HER2-overexpressing solid tumors with a next-generation CAR-T cell therapy. *First Author: Jenny Mu, Arcellx, Inc., Gaithersburg, MD*

Background: Conventional chimeric antigen receptor T cell (CAR-T) therapies have achieved limited clinical success in the treatment of solid tumors, in part due to the challenges of identifying tumor antigen(s) that are uniquely expressed on tumor cells. The dearth of such targets requires that current CAR-T therapies be re-engineered to preferentially target tumor cells thereby mitigating potential on-target off-tumor toxicity to normal cells. Herein we describe a novel cell therapy platform comprising Antigen Receptor Complex T (ARC-T) cells that are readily activated, silenced, and reprogrammed *in vivo* by administration of a novel tumor-targeting soluble protein antigen-receptor X-linker (sparX). The formation of the ARC-T, sparX, and tumor complex is required for the ARC-T to kill the tumor. Because ARC-T activity is entirely dependent on the dose of sparX administered, therapeutic doses of sparX may be defined that preferentially target cells over-expressing a target antigen and thus limit coincident kill of normal cells expressing lower levels of target antigen. **Methods:** We have created a library of sparX that bind different cell surface antigens, including HER2. The HER2 sparX was tested as both monovalent and bivalent constructs *in vitro* by assessing ARC-T cell activation, cytokine release and target cell cytotoxicity. *In vivo* efficacy models utilized NSG mice and incorporated tumor volume measurements and histopathologic assessments to evaluate tumor clearance. **Results:** *In vitro* studies demonstrate that co-culture of ARC-T cells, sparX-HER2 and HER2-expressing target cells drives T cell activation, expansion, cytokine secretion and cytotoxicity of target cells in a dose-dependent manner. Furthermore, by affinity tuning the HER2 binding domain and bivalent formatting of sparX-HER2, we achieved selective killing of HER2-overexpressing breast cancer cells with minimal effect on cells expressing HER2 levels representative of normal tissues. *In vivo* proof-of-principal studies with ARC-T/sparX-HER2 similarly demonstrate complete eradication of HER2-overexpressing solid tumor cells. **Conclusions:** These results demonstrate that a single intravenous dose of ARC-T cells can traffic to a solid tumor site and induce tumor eradication upon systemic administration and co-localization of tumor-targeting sparX in a mouse model. Bivalent formatting of sparX-HER2 further enabled ARC-T sensitivity to target antigen density to avoid the on-target off-tumor toxicity that has hindered conventional monovalent CAR-T treatments. Correlating immune toxicity, blood cell counts, and overall survival in cancer patients receiving immune therapy. *First Author: Rong Lu, UT Southwestern Medical Center, Dallas, TX*

Background: Baseline circulating white blood cell differential counts have been proposed as possible markers of response to Immune therapy (ICI) and immune toxicity (irAE), but have not been validated for clinical practice. **Methods:** 214 patients with various cancers receiving ICI had clinical lab results and overall/organ specific irAE analyzed. Absolute lymphocyte (ALC), eosinophil (AEC) and neutrophil (ANC) counts <7 days of starting and 3-12 weeks after ICI were correlated with survival and development of irAE. The association between overall irAE and cell count changes was evaluated using multivariate logistic regression, adjusting for patients' age, gender, race, and including all 3 types of cell count changes in one model. The association between overall survival and cell counts changes was tested using multivariate Cox proportional hazard model, adjusting for age, gender, race, and overall irAE (yes/no). **Results:** The combination of MEDIAN rise or fall in ALC, ANC and AEC after ICI combined with development of irAE was associated with altered overall survival (OS). Higher statistically significant (p=<0.05) OS was seen in patients with AEC↑/irAE+(n=94; median OS 14.9 months), ANC↓/irAE+(60; 17.9 mo), ALC↑/irAE+(65; 11.5 mo), ALC↓/irAE+(92; 12.2 mo). Lower OS was seen with ANC↑/irAE-(21; 5.4 mo), ALC↑/irAE-(9; 5.8 mo), ALC↓/irAE-(24; 6.1 mo). All these relationships were unchanged if patients were grouped into ANY rise during the 3-12 weeks rather than median. After multivariable adjustment for age/sex/race there was statistically significant association between higher baseline ALC and development of any irAE (p=0.05) and grade ≥2 irAE (p=0.02). No association was seen between overall toxicities and ANC or AEC. Organ-specific irAE's with statistically significant associations included pneumonitis:↓AEC (p=0.05), hepatitis:↓ANC (p=0.05), hypothyroidism:↓ANC (p=0.02), colitis:↑ALC (p=0.02). Skin rash, hypophysitis and adrenalitis were not associated with any cell count changes. **Conclusions:** In patients with cancer receiving immune therapy, the predictive value of serial monitoring in ALC, AEC and ANC is greatly enhanced by the addition of irAE detection. irAEs appear to be a greater predictor of survival than changes in blood counts. In contrast to prior reports we found ANC/ALC/AEC in isolation were less reliable in predicting improved survival. Lack of standardized methods of assessing irAE's confound identifying strong associations with clinical lab-derived cell counts. Research Sponsor: None.

3044 Poster Session (Board #108), Fri, 8:00 AM-11:00 AM

Association of reinvigoration of circulating anti-telomerase CD4 Th1 response in cancer patients with anti-PD-1 response. *First Author: Emeline Orillard, University Hospital Jean Minjoz, Besançon, France*

Background: Increasing evidence highlights the crucial roles played by CD4+ Th1 cells in cancer immunity and immunotherapy (Spitzer et al., Cell 2017, Borst et al., Nat rev Immunol 2018). Here, we investigate the relevance of circulating CD4 Th1 response against shared tumor-associated antigens (TAA) in cancer patients treated by anti-PD-1 immunotherapy. **Methods:** A total of 46 advanced cancer patients (pts) including 32 pts with non-small cell lung cancer (NSCLC), 14 pts with melanoma, were enrolled (ITHER trial NCT02840058). Patients were treated with anti-PD-1 therapy as standard of care (26 pts with nivolumab and 20 pts with pembrolizumab). Peripheral blood mononuclear cells were collected before and after treatment at 1 and 3 months. The presence of circulating TAA-specific Th1 response was measured by IFNy ELISPOT assay using a mixture of 15mer peptides derived from telomerase (TERT) (Laheurte et al., Oncoimmunology 2016 and Br J C 2019). **Results:** At the baseline, the anti-TERT Th1 response was observed in 37% of pts. After anti-PD-1 therapy, *de novo* induction and/or amplification of pre-existing anti-TERT Th1 response was found in 26 % of pts (12/46). Whereas, a decrease of this response was documented in 15% of pts (7/46).The presence of anti-TERT Th1 response in peripheral blood during anti-PD-1 treatment was associated with a prolonged progression free-survival (PFS) as compared to the immune non responder pts (14.4 vs 2.6 months respectively, p = 0.006, HR 0.39 [0.2;0.76]). Similar observation was made for the overall survival (OS) (22.3 vs 12.3 months respectively, p = 0.04 HR 0.45 [0.21;0.96]). Notably, *de novo* reinvigoration of peripheral anti-TERT Th1 response after anti-PD-1 therapy was associated with a better clinical outcome as compared to the group of pts with decreased immune response after treatment (Median OS not reached vs 5.8 months). In contrast, no association with anti-PD-1 response was observed neither with circulating anti-NY-ESO-1 or with anti-viral Th1 response, concurrently measured in these patients. **Conclusions:** The reinvigoration of circulating CD4 Th1 against telomerase in patients treated by anti-PD-1 is associated with a better clinical outcome. These results underline the potential interest of monitoring circulating antitumor CD4 Th1 response for immune checkpoint inhibitors management. Research Sponsor: None.

3045 Poster Session (Board #109), Fri, 8:00 AM-11:00 AM

Novel biomarker panel based on cellular and soluble checkpoint proteins for PD-1/PD-L1 blockade treatment efficacy. *First Author: Hiroki Nagai, Valley Hospital, Paramus, NJ*

Background: Although anti-PD-1/PD-L1 therapy has become one of the standard treatments for advanced cancers, its low treatment efficacy (10-30%) has remained a major issue. We sought to perform a detailed immune profiling of cells and soluble proteins in order to characterize key regulators and signaling molecules and identify therapeutic targets and biomarkers that may improve treatment efficacy and diagnosis. **Methods:** This observational study enrolled 49 advanced cancer patients treated with PD-1/PD-L1 blockade monotherapy. Treatment response was assessed by RECIST 1.1. PBMC and plasma samples were collected at baseline and every 6 weeks following initial treatment. Immune profiling of PBMC was done by multi-parametric flow cytometer, and t-SNE analysis was used to identify key immune subtypes. Soluble proteins were evaluated by LUMINEX assays. Cut-off values were determined by ROC curve analysis. **Results:** Three unique subtypes of immune cells were identified. The population of $CD11c^{+}HLA\text{-}DR^{low}CD80^{+}CD86^{-}$ $CD274^{+}$ cells (regDC) at baseline was significantly higher in patients with progressive disease (PD, n=28) than in patients showing clinical benefit (non-PD, n=21; p=0.030). The higher regDC population also correlated with higher levels of IL-8, IL-10, CXCL1, CXCL5, and CXCL11 in plasma. The population of $CD4^{+}CD25^{+}CD62L^{+}$ T cells (Treg) was also higher in PD patients ($p<0.001$). A unique subtype of $CD4^{+}CD28^{-}$ T cell, however, was higher in non-PD patients ($p<0.001$). For the soluble proteins, the levels of sLAG-3 and sGITR in plasma correlated with better clinical outcome in low regDC patients (p=0.004 and 0.044, respectively). The combined biomarker panel (cellular and protein markers) yields high sensitivity (90.5 %) and specificity (82.1 %) for predicting treatment efficacy. Disease control rate (DCR) and median progression free survival (PFS) are shown in the Table. **Conclusions:** To our knowledge, this pilot study is the first to detect three immune cell subtypes, regDC, Treg and $CD4^{+}CD28^{-}$ cells, associated with clinical outcome in the treatment of PD-1/PD-L1 blockade. Profiling of immune cell subtypes and soluble immune checkpoint proteins can serve to identify therapeutic targets and biomarkers for treatment efficacy. We will report the data with further enrollment. Research Sponsor: None.

	DCR (%)	p value	PFS (days)	p value

3046 Poster Session (Board #110), Fri, 8:00 AM-11:00 AM

Plasma next-generation sequencing (NGS) in advanced non-small cell lung cancer (aNSCLC) patients (pts) treated with immune checkpoint inhibitors (ICIs): Impact of *STK11* and *TP53* mutations on outcome. *First Author: Alberto Pavan, Medical Oncology 2, Istituto Oncologico Veneto IOV-IRCCS, Padua, Italy*

Background: ICIs revolutionized aNSCLC treatment. The next challenge lays on the search for predictive markers. Detection of multiple tumor-related genetic alterations through NGS in cell free DNA is a promising tool, provided the limited availability of tumor tissue in most cases. **Methods:** Between January 2017 and October 2019, aNSCLC pts consecutively referring to our Institution were prospectively screened with plasma NGS while included in two clinical trials: VISION (NCT02864992) and MAGIC trial, an observational study. In VISION trial NGS was performed in plasma (Guardant360 test) and tissue (Oncomine Focus Assay). In MAGIC Myriapod NGS-IL 56G Assay was used. Aim of the study was to evaluate the impact of *STK11*, *KRAS* and *TP53* mutations (muts) on outcome of ICI-treated pts, with overall survival (OS) as primary endpoint. A control group of pts not receiving ICIs was also analyzed. **Results:** A total of 235 NSCLC pts were enrolled and received ICIs. 93 pts were analyzed in plasma at the time of beginning ICIs: median OS was 18.9 m (95% CI: 13.7-24.1) and median immune-related progression free disease (irPFS) 3.8 m (95% CI: 2.5-5.1). 49 (52.7%), 22 (23.7%) and 8 (8.6%) pts carried *TP53*, *KRAS* and *STK11* pathogenic alterations, respectively. *STK11* mutated pts showed a trend for worse OS compared with wildtype counterpart (14.9 m, 95% CI: 6.5-23.3, *versus* 20.3, 95% CI: 13.4-27.2, p = 0.192) *KRAS* muts had no impact on outcome. Pts with *TP53* or *STK11/KRAS* co-mut (n = 3) had worse OS (12.3 m, 95% CI: 9.2-15.4; HR = 3, 95% CI: 1.6-5.8, p = 0.001 and 5.9 m, 95% CI: 1.4-7.6; HR = 2.9, 95% CI: 1.4-6.3, p = 0.007) and worse irPFS (2.8 m, 95% CI: 1.7-3.9, HR = 1.8 95% CI: 1.1-3.1, p = 0.03 and 1.2 m, 95% CI: 0.9-1.5, HR = 2.2 95% CI: 1.2-4.1, p = 0.01). Number of muts negatively impacts pts' OS (HR = 1.2, 95% CI: 1.1-1.3, p = 0.02) and was higher among *TP53* mutated pts ($p <$ 0.001, Mann-Whitney test). In multivariate analysis, *TP53* and *STK11/KRAS* retained significance. A control group of pts not receiving ICIs was analyzed (n = 101): median OS was 16.8 m (95% CI: 13-20.6). Nor *STK11* (n = 10), nor *STK11/KRAS* (n = 6) had impact on OS (HR = 1.8, 95% CI: 0.7-4.7, p = 0.267 and 1.4, 95% CI: 0.7-3.0, p = 0.293) while the presence of *TP53* muts (n = 41) was associated with shorter OS (11.4 m, 95% CI: 7.3-15.5; HR = 2.2, 95% CI: 1.2-4.2, p = 0.009). **Conclusions:** NGS performed in plasma might be used to detect predictive markers. *TP53* muts in plasma at baseline had prognostic value, while *STK11/KRAS* muts were associated with worse outcome to ICIs. Research Sponsor: None.

3047 Poster Session (Board #111), Fri, 8:00 AM-11:00 AM

Changes in lymphocyte/monocyte ratio, prognostic marker to predict overall survival in patients with advanced cancer treated with immune checkpoint inhibitor. *First Author: Sandip H. Patel, The Ohio State University Comprehensive Cancer Center, Department of Internal Medicine, Division of Medical Oncology, Columbus, OH*

Background: Immunosuppressive factors within the tumor microenvironment (TME) pose a barrier to response to treatment with immune checkpoint inhibitors (ICI). Monocytes alter the TME to promote cancer progression through local immune suppression and angiogenesis. Peripheral blood lymphocyte-to-monocyte ratio (LMR) may reflect the interaction between host immunity, represented by lymphocytes, and the tumor microenvironment, represented by monocytes. A low LMR in the peripheral blood may serve as a surrogate biomarker and has been associated with poor prognosis in various cancers; however, its role has not been well defined in the era of treatment with ICI. **Methods:** We retrospectively evaluated 1034 patients with advanced cancer treated with ICI from 2011 to 2017. We calculated LMR as ratio of absolute lymphocyte/monocyte counts at baseline and median of 21 days after first cycle of ICI (on-treatment LMR) and considered low if < 2. Overall survival (OS) was calculated from the initiation of ICI to date of death or censored at last follow-up. Median OS with 95% confidence intervals (CI) was estimated using the Kaplan-Meier method. Log rank test was used for group comparison. **Results:** 536 pts (52%) with LMR $<$ 2 at baseline had shorted median OS compared to 498 (48%) with LMR$\geq$2 (median OS 8.4 months vs 17.8 months, $p < 0.001$). Of 1034 pts with baseline LMR, 837 had follow up LMR evaluable. In patients with baseline and on-treatment LMR, those with baseline LMR < 2, who had on treatment LMR $\geq$2, had OS of 16.8 months (95% CI 10.3-23.5) compared to median OS 8.0 months (95% CI 6-9.4) for patients with on treatment LMR < 2 after first cycle of ICI, $p < 0.001$. Patients with baseline LMR$\geq$2, who had on treatment LMR $\geq$ 2, had median OS of 23 months (95% CI 19.7-28.9), but median OS was 9.4 months (95% CI 7.1-11.1) for patients with on-treatment LMR < 2 after first cycle of ICI, $p < 0.001$. **Conclusions:** We observed a statistically significant association between not only baseline LMR but also change in LMR from baseline after first cycle of ICI and overall survival in cancer patients treated with ICI. The role of LMR at baseline and on-treatment LMR should be evaluated in further studies incorporating known additional prognostic factors for ICI therapy. Research Sponsor: None.

LMR ratio (Baseline)	LMR ratio (After first cycle of Immunotherapy)	Number of Patients (%)	Median Overall Survival (Month) and 95% CI	p value
< 2		536 (52%)	8.7 (7.4-9.9)	< 0.001
	< 2	341	8 (6-9.4)	<
	≥2	90	16.8 (10.3-23.5)	0.001
≥2		498 (48%)	17.8 (15.7-21.6)	
	< 2	108	9.4 (7.1-11.1)	<
	≥2	298	23 (19.7-28.9)	0.001

3048 Poster Session (Board #112), Fri, 8:00 AM-11:00 AM

Neutrophil-lymphocyte score: A novel prognostic scoring system that utilized the dynamic change of neutrophil, lymphocyte, and albumin and its comparison to other indices. *First Author: Songzhu Zhao, Center for Biostatistics, The Ohio State University, Columbus, OH*

Background: Indications for immune checkpoint inhibitor (ICI) in cancer care are expanding rapidly. There is increasing need for accurate decision tool to better guide treatment. We have constructed a new prognostic scoring system, neutrophil-lymphocyte score (NRS), based on the nonlinear dynamic change of neutrophil to lymphocyte ratio (NLR) in relation to survival over the first cycle of ICI treatment. We compared this novel system to existing indices such as NLR, lymphocyte to monocyte ratio (LMR), platelet to lymphocyte ratio (PLR), Advanced Lung Cancer Inflammation Index (ALI), and Systemic Immune-inflammation Index (SII). **Methods:** This is a retrospective analysis of 837 patients at Ohio State University from 2011-18. Neutrophil (ANC), lymphocyte (ALC), platelet (plt), monocyte (AMC), albumin (alb), and body mass index (BMI) were collected at baseline. Repeat labs were collected at cycle 2. NLR = ANC/ALC, ALI = BMI x alb / NLR, LMR = ALC/AMC, SII = platelet x NLR, PLR = plt/ALC. NLR Ratio = baseline NLR / repeat NLR. Based on the association between NLR and the overall survival, we assigned 1 point (p) for baseline NLR < 0.7, 6p for 0.7 to < 2, 5p for 2 to < 3, 4 p for 3 to < 4, 3 for 4 to 5, 2p for 5 to < 9, and 1p for $\geq$9. We also assigned 1p for NLR ratio < 0.6, 2p for 0.6 to < 0.8, 3p for 0.8 to < 1.2, 5p for 1.25 to < 1.4, 3p for 1.4 to < 1.6, and 2p for $\geq$1.6. NLS = sum of these 2 scores . NLS_A = NLS*alb. Time-dependent receiver operator characteristic (ROC) curves with integrated time-dependent area under the curve (TD AUC) values were used to evaluate the predictive accuracy of each index for survival. **Results:** For baseline and repeat values, all indices were statistically significant ($P < 0.001$) in predicting survival. Baseline integrated TD AUC were: ALI 0.704, NLR 0.692, SII 0.663, LMR 0.645, and PLR 0.612. All of the repeat indices at cycle 2 had higher prognostic value than their baseline counterparts. Integrated TD AUC for indices at cycle 2 were: ALI 0.740 (with baseline BMI), NLR 0.729, SII 0.694, LMR 0.671, and PLR 0.652. NLS_A was a composite score based on the dynamic change of NLR from cycle 1 to 2 and the treatment alb with integrated TD-AUC at 0.754. **Conclusions:** Indices constructed from ANC, ALC, AMC, Plt, alb, and BMI can be obtained inexpensively and provide great prognostic value for pts on ICI. We have constructed a novel scoring system (NLS_A) and demonstrated its improvement over the current prognostic indices. Studies with a larger cohort are needed to further improve and validate this system. Dr. Owen is a Paul Calabresi Scholar suppo.

3049 Poster Session (Board #113), Fri, 8:00 AM-11:00 AM

Clinical value of noninvasive biomarkers reflecting a collagen-rich stroma in metastatic melanoma patients treated with anti-PD1 therapy. *First Author: Christina Jensen, Biomarkers & Research, Nordic Bioscience, Herlev, Denmark*

Background: Poor response to anti-PD1/PD-L1 remains a clinical challenge in a subgroup of patients with metastatic melanoma. Recent evidence strongly suggests that these poor responses are associated with TGF-β signaling and CD8+ T-cell excluded tumors characterized by a collagen-rich peritumoral stroma that blocks the interaction between T cells and tumor cells. In the pursuit of identifying non-invasive biomarkers associated with a T-cell excluded phenotype and predict resistance/response to immune checkpoint inhibitor therapy, we evaluated the association between blood-based biomarkers measuring type III collagen formation and cross-linking and survival outcomes in metastatic melanoma patients treated with anti-PD1 therapy. **Methods:** 107 patients with metastatic melanoma who started anti-PD1 monotherapy between May 2016 – March 2019 entered in a prospective real-life study (nivolumab n = 62, pembrolizumab n = 45). Type III collagen formation (PRO-C3) and type III collagen formation and cross-linking (PC3X) were measured with ELISAs in pre-treatment serum. Biomarker levels were associated to Disease Control Rate (according to RECIST v.1.1) by Mann-Whitney test and correlated to survival outcomes by Kaplan-Meier and Cox regression analyses. **Results:** PRO-C3 was significantly elevated in patients with progressive disease compared to the combined group of patients with complete response, partial response and stable disease (p = 0.046). High PRO-C3 and PC3X ($> 75^{th}$ percentile) prior to treatment were significantly associated with poor overall survival (PRO-C3: HR = 2.4, p = 0.008; PC3X: HR = 2.2, p = 0.019) and progression free survival (PRO-C3: HR = 1.91, p = 0.016; PC3X: HR = 1.94, p = 0.013). The median overall survival was 417 and 511 days in biomarker high patients compared to 1269 and 1269 days in biomarker low patients, for PRO-C3 and PC3X, respectively. **Conclusions:** Biomarkers quantified in a pre-treatment liquid biopsy reflecting excessive collagen formation and cross-linking were associated with poor response and survival outcomes in metastatic melanoma patients treated with anti-PD1 therapy. This supports an association between collagen formation and resistance to anti-PD1 therapy. Furthermore, if validated, these non-invasive collagen biomarkers may have potential for guiding patient stratification for immune checkpoint inhibitor therapy and combination therapies. Clinical trial information: NTR7015. Research Sponsor: The Danish Research Foundation, Erasmus Medical Center.

3050 Poster Session (Board #114), Fri, 8:00 AM-11:00 AM

TCR clonality and Treg frequency as predictors of outcome in stage III NSCLC treated with durvalumab. *First Author: Sally CM Lau, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: Novel blood-based biomarkers evaluating T-cell receptor (TCR) clonality as well as the frequency/activation of immune populations hold significant potential for predicting response and elucidating the biology of anti-tumor immunity in stage 3 NSCLC treated with durvalumab. In this study, we sought to characterize clinical and immunologic predictors of durable response to therapy with a specific focus on TCR clonality and peripheral immune populations. **Methods:** Stage 3 NSCLC patients undergoing chemoradiation (CRT) and durvalumab were prospectively recruited and underwent baseline and serial blood collections. TCR repertoire analysis was performed on cfDNA using hybrid-capture TCR sequencing and TCR diversity estimated using Shannon's entropy index. Viably preserved peripheral blood mononuclear cells (PBMC) were analyzed by high-dimensional flow cytometry using validated panels to evaluate T/B/NK-cell, Treg and myeloid populations. Correlations between cell populations were examined using linear and cox regression. **Results:** 134 stage 3 NSCLC patients who received durvalumab had a median PFS was 15.4 months, with worse PFS in patients with PD-L1 1-49% (HR 2.4, p = 0.03) and PD-L1 $<$ 1% (HR 2.6, p = 0.03). Smoking and *EGFR/ALK* mutations were not predictors of PFS. Immune profiling was performed in a pilot of 19 patients. Baseline TCR diversity did not associate with clinical factors or outcome. However, lack of clonal expansion after CRT indicated by a higher Shannon's index was significantly associated with increased frequency of Tregs after durvalumab ($p < 0.05$). In turn, this elevation in Tregs was associated with significantly reduced PFS in *EGFR/ALK* wt patients (p = 0.03) and a trend towards reduced PFS in the overall cohort (HR 5.2, p = 0.1). **Conclusions:** Clonal expansion of T cells after CRT may influence the likelihood of an anti-tumor immune response following PD-L1 blockade in stage 3 NSCLC. Similarly, expansion of peripheral Treg populations is associated with increased likelihood of disease recurrence. Further characterization of TCR clonality, minimal residual disease and T cell subpopulations using serially collected blood is ongoing. Research Sponsor: This study is performed under the auspice of the LIBERATE study, which is an institutional liquid biopsy program at the University Health Network supported by the BMO Financial Group Chair in Precision Cancer Genomics (Chair held by Dr. Lillian Siu), Ontario Institute of Cancer Research, Tumor Genomics Laboratory Grant.

3051 Poster Session (Board #115), Fri, 8:00 AM-11:00 AM

Sequential monitoring of circulating stromal cells from blood is predictive of progression in NSCLC patients undergoing anti-PD-L1 therapy after definitive chemoradiation therapy. *First Author: Daniel Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Cancer Associated Macrophage-Like cells (CAMLs) are a recently described circulating stromal cell common in the peripheral blood of patients with solid tumors. In non-small cell lung carcinoma (NSCLC), patients with CAMLs ≥50μm after completion of chemoradiation therapy (CRT) have been shown to have worse progression free survival (PFS). However, with the recent addition of anti-PD-L1 therapies in conjunction with CRT as standard of care, it has never yet to be evaluated whether CAMLs remain predictive for monitoring progression in NSCLC patients post anti-PD-L1 therapy. **Methods:** A 2 year single blind prospective study was undertaken to test the relationship of ≥50μm CAMLs to PFS based on imaging in lung patients before and after induction of CRT and PD-L1. We recruited 104 patients with pathologically confirmed unresectable NSCLC Stage II (n = 14), Stage III (n = 83), Stage IV (n = 3), and locally recurrent disease (n = 4). Baseline (BL) blood samples were taken prior to start of therapy. A second time point blood sample (T1) was taken at the end of radiotherapy (~40 days). A third time blood sample (T2) was taken after induction of anti-PD-L1 therapy (e.g. Imfinizi, Keytruda, etc.). Blood was filtered by CellSieve filtration and CAMLs were quantified. Analysis by CAML size of $<$ 49 μm or ≥50 μm was used to evaluate PFS hazard ratios (HRs) by censored univariate & multivariate analysis. **Results:** CAMLs were found in 87% of samples averaging 2.9 CAMLs/7.5mL sample. At BL, CAMLs ≥50 μm had similar PFS to patients with $<$ 50 μm CAMLs (HR = 1.1 95%CI 0.6-1.95 p = 0.8661). However, after CRT (T1), patients with CAML size ≥50 μm had worse PFS (HR = 3.2, 95%CI 1.8-5.8 p = 0.0002). After induction of anti-PD-L1 therapy (T2), patients with ≥50 μm CAMLs also had worse PFS (HR = 2.8 95%CI 1.5-5.4 p = 0.0037). CAML size at BL was not accurate at predicting progression within 24 months; however ≥50 μm CAMLs after CRT or after 1 cycle of anti-PDL1 therapy was 71% accurate at predicting progression of disease. **Conclusions:** Our data suggests that in NSCLC, ≥50 μm CAMLs after completion of CRT or appearing after induction of anti-PD-L1 therapy appears to predict progressive disease. If validated, additional studies are needed to determine if CAMLs can serve as a significantly prognostic blood based marker for predicting survival in NSCLC patients early in the treatment regime. Research Sponsor: U.S. National Institutes of Health.

3052 Poster Session (Board #116), Fri, 8:00 AM-11:00 AM

Tumor methylation patterns to measure tumor fraction in cell-free DNA. *First Author: Colin Melton, GRAIL, Inc, Menlo Park, CA*

Background: Cell-free DNA (cfDNA) tumor fraction (TF), the proportion of tumor molecules in a cfDNA sample, is a direct measurement of signal for cfDNA cancer applications. The Circulating Cell-free Genome Atlas study (CCGA; NCT02889978) is a prospective, multi-center, observational, case-control study designed to support development of a methylation-based, multi-cancer detection test in which a classifier is trained to distinguish cancer from non-cancer. Here we leveraged CCGA data to examine the relationship between cfDNA containing tumor DNA methylation patterns, TF, and cancer classification performance. **Methods:** The CCGA classifier was trained on whole-genome bisulfite sequencing (WGBS) and targeted methylation (TM) sequencing data to detect cancer versus non-cancer. 822 samples had biopsy WGBS performed; of those, 231 also had cfDNA targeted methylation (TM) and cfDNA whole-genome sequencing (WGS). Biopsy WGBS identified somatic single nucleotide variants (SNV) and methylation variants (MV; defined as methylation patterns in sequenced DNA fragments observed commonly in biopsy but rarely [$<$ 1/10,000] in the cfDNA of non-cancer controls [n = 898]). Observed tumor fragment counts (SNV in WGS; MV in TM), were modeled as a Poisson process with rate dependent on TF. TF and classifier limits of detection (LOD) were each assessed using Bayesian logistic regression. **Results:** Across biopsy samples, a median of 2,635 MV was distributed across the genome, with a median of 86.8% shared with ≥1 participant, and a median of 69.3% targeted by the TM assay. TF LOD from MV was 0.00050 (95% credible interval [CI]: 0.00041 - 0.00061); MV and SNV estimates were concordant (Spearman's Rho: 0.820). MV TF estimates explained classifier performance (Spearman's Rho: 0.856) and allowed determination of the classifier LOD (0.00082 [95% CI: 0.00057 - 0.00115]). **Conclusions:** These data demonstrate the existence of methylation patterns in tumor-derived cfDNA fragments that are rarely found in individuals without cancer; their abundance directly measured TF, and was a major factor influencing classification performance. Finally, the low classifier LOD (~0.1%) motivates further clinical development of a methylation-based assay for cancer detection. Clinical trial information: NCT02889978. Research Sponsor: GRAIL.

3053 Poster Session (Board #117), Fri, 8:00 AM-11:00 AM

Rechallenging with immune checkpoint inhibition after a treatment-limiting immune-related adverse event. *First Author: Richard Lee O'Neal, University of Kentucky, Markey Cancer Center, Greenville, KY*

Background: Immune checkpoint inhibition (ICI) with cytotoxic T-lymphocyte antigen 4 (CTLA-4), programmed death 1 (PD-1), or programmed death ligand-1 (PD-L1) blockade can be associated with the development of immune related adverse events (irAE), many of which can be treatment-limiting. Due to an absence of randomized controlled trials, the current approach in regards to ICI discontinuation versus rechallenging remains controversial. **Methods:** We assessed all patients who had received ICI at a single academic institution from 5/2015 to 1/2019, identifying those who had delays in their treatment. Retrospective chart review was performed to determine type of ICI, type and grade of irAE, treatment of irAE, and recurrence and grades of irAE if ICI was resumed, as well as to assess overall survival (OS). **Results:** 562 patients received ICI (lung cancer [232, 41%], melanoma [66, 12%], kidney cancer [43, 8%], bladder cancer [27, 5%], and other cancers [194, 34.5%]) from 5/2015 – 1/2019. Of these, 121 (22%) had a treatment-limiting irAE (most commonly dermatitis [24%], colitis [17%], pneumonitis [14%], and hepatitis [12%]). Of the patients who had ICI held, 80/121 (66%) were eventually rechallenged, while 41/121 (34%) discontinued permanently. When rechallenged with ICI, 47/80 (59%) had no further treatment-limiting irAEs, 16/80 (20%) had a recurrence of the same irAE, and 17/80 (21%) developed a different irAE. Of those who were rechallenged, only 17/80 (21%) ultimately had to discontinue because of a second irAE. At a median follow up time of 12.1 months, median OS was not reached in those patients who experienced a treatment limiting irAE and was 8.1 months in those who did not (hazard ratio [HR] for death, 0.33; 95% CI 0.23 – 0.48; $p < 0.001$). At 12 months from initiation of ICI, 77.0% of patients who had a treatment-limiting irAE were alive, compared to 39.6% of those who did not have an event. Restarting ICI after a treatment-limiting irAE was not associated with a change in OS (HR 0.66 [95% CI 0.27 – 1.66], p = 0.38). **Conclusions:** Patients who discontinued ICI secondary to irAEs had relatively low rates of recurrent toxicity when rechallenged with treatment. These patients were just as likely to develop a new toxicity as a recurrence of the original irAE, and relatively few had to discontinue permanently. Development of a treatment-limiting irAE was associated with improved OS compared to those who did not. This study suggests that rechallenging with ICI may be safe in selected patients, though this did not have an impact on OS. Research Sponsor: None.

3054 Poster Session (Board #118), Fri, 8:00 AM-11:00 AM

An open-label, phase I trial of BI 754091 alone and in combination with BI 754111 in Asian patients (pts) with advanced solid tumors. *First Author: Yoon-Koo Kang, Asan Medical Center, Seoul, South Korea*

Background: Dual blockade of immune checkpoint molecules, PD-1 and LAG-3, may enhance the anti-tumor response versus PD-1 blockade alone. This Phase I trial investigated BI 754091, an anti-PD-1 antibody, as monotherapy and in combination with BI 754111, an anti-LAG-3 antibody, in Asian pts with advanced solid tumors. **Methods:** This trial comprised 3 parts. Parts 1 and 2 (dose escalation) were in pts with unresectable/metastatic solid tumors. In Part 1, pts received BI 754091 240 mg intravenously (iv), every 3 weeks (q3w); in Part 2, pts received BI 754091 240 mg in combination with BI 754111 (400 mg, 600 mg or 800 mg iv, q3w). Dose escalation was guided by a Bayesian logistic regression model, with overdose control. The primary endpoint in Parts 1 and 2 was maximum tolerated dose (MTD) of BI 754091 alone or in combination with BI 754111, based on dose-limiting toxicities (DLTs) in Cycle 1. In Part 3, BI 754091 240 mg plus BI 754111 600 mg q3w was assessed in 4 expansion cohorts. Cohorts A–C included pts with: A) gastric/esophagogastric junction cancer; B) esophageal cancer; C) hepatocellular cancer; all had received ≥1 line of prior systemic therapy and no prior anti-PD-(L)1 therapy. Cohort D included pts who had received prior anti-PD-(L)1 therapy for the tumor types in Cohorts A–C. The primary endpoint in Part 3 was objective response (confirmed complete response or partial response [PR] per RECIST 1.1). **Results:** In Part 1, 6 pts received BI 754091 240 mg. In Part 2, 9 pts received BI 754091 240 mg plus BI 754111 (400 mg/600 mg/800 mg; n = 3 per cohort). No DLTs were reported in Parts 1 and 2. In Part 3, 121 pts were treated (97 [80%] male, median age 61 years [range 23–80]); Cohorts A/B/C/D included 33/33/20/35 pts. All-grade adverse events (AEs) and treatment-related AEs (TRAEs) were experienced by 96 (79%) and 47 (39%) pts, respectively. The most commonly reported AEs (all/≥G3) were pyrexia (21%/0%), decreased appetite (17%/2%), anemia (11%/6%), and nausea (9%/0%). 36 (30%) pts reported immune-related AEs, most commonly hypothyroidism, in 7 (6%) pts. Confirmed PR was observed in 6 pts (5%; Cohort A/B, n = 4/2) and 35 (29%) pts had stable disease (Cohort A/B/C/D, n = 9/11/10/5). **Conclusions:** MTD was not reached for BI 754091 monotherapy or for BI 754091 in combination with BI 754111. The recommended dose for the combination was determined as BI 754091 240 mg plus BI 754111 600 mg q3w. Treatment was well tolerated and consistent with that observed in the global trial. Preliminary anti-tumor activity was seen. Clinical trial information: NCT03433898. Research Sponsor: Boehringer Ingelheim.

3055 Poster Session (Board #119), Fri, 8:00 AM-11:00 AM

Evolving development of PD-1 therapy: Cetrelimab (JNJ-63723283) from monotherapy to combination with erdafitinib. *First Author: Victor Moreno, START Madrid-FJD, Fundación Jiménez Díaz University Hospital, Madrid, Spain*

Background: Cetrelimab (CET) is an investigational checkpoint inhibitor (CI). In part 1 of a first-in-human (FIH) trial (LUC1001; NCT02908906), pts with advanced solid tumors with ≥1 prior treatment received CET 80–800 mg Q2W or 480 mg Q4W. Response rates and safety profiles were similar to other CIs. Based on preclinical and clinical data, a phase 1/2 study (NORSE; NCT03473743) of CET + erdafitinib (ERD) in metastatic urothelial carcinoma (mUC) + FGFR alterations (alt) was initiated and is ongoing. **Methods:** In LUC1001 Part 2, pts with nonsmall cell lung cancer (NSCLC), melanoma (MEL), or MSI-H/dMMR colorectal cancer (CRC) received CET IV 240 q2w. Overall response rates (ORR = % complete response + partial response [PR] confirmed) were assessed as per RECIST v1.1. Adverse events (AEs) were assessed for all patients receiving CET IV 240 q2w in parts 1 and 2. **Results:** As of July 1, 2019, 122 pts with NSCLC (n=30); MEL (n=50); or CRC (n= 42) had been treated in Part 2. Median age ranged from 58 to 64 yrs (overall range, 23–86 yrs). Duration of treatment was 8.1 mos (range, 0.0-24.7) for NSCLC; 5.5 mos (range, 0.0-25.0) for MEL; and for 3.0 mos (0.0-16.1) for CRC. ORR was 37% in NSCLC; 53% in PD-L1+ NSCLC (≥50% by IHC), 28% in MEL; 32% in non-uveal MEL, 14% in CRC and 24% in centrally confirmed MSI-high CRC. In all CET IV 240 q2w treated pts in the FIH study (N= 162), treatment-related grade ≥3 and serious AEs were reported in 15% and 12% of pts, respectively. All grade and grade ≥3 immune-related (ir) AEs were reported in 41% and 8% of pts, respectively Most common ir AE: hypothyroidism (8%), asthenia (6%), diarrhea (4%), rash (4%), hyperthyroidism (4%), dyspnea (3%), pruritis (3%) and pneumonitis (3%). There was 1 treatment-related death due to myasthenia gravis. In the phase 1 combination study (NORSE), pts with mUC + FGFR alt (n=17) received fixed-dose CET IV 240 q2w + ERD 6mg, 8 mg or 8mg + up titration (UpT) to 9 mg to establish the RP2D for the combination as CET + ERD 8mg + UpT. In the RP2D group (n=10), 60% had treatment-related grade ≥3 AEs. ORR (all confirmed PR) was 50% in the all treated response-evaluable group (n=16). **Conclusions:** CET is a CI with efficacy and safety profiles in advanced solid tumors similar to approved CIs. In NORSE phase 1, CET+ERD demonstrated antitumor activity in mUC with an acceptable safety profile. NORSE phase 2 is evaluating this combination as first-line therapy in pts with mUC with FGFR alt. 3056 Poster Session (Board #120), Fri, 8:00 AM-11:00 AM

A phase I study of ALX148, a CD47 blocker, in combination with standard anticancer antibodies and chemotherapy regimens in patients with advanced malignancy. *First Author: Laura Quan Man Chow, University of Washington, Seattle, WA*

Background: CD47 is a myeloid checkpoint upregulated by tumor cells to evade the host immune response. ALX148 (A) is a fusion protein comprised of a high affinity CD47 blocker linked to an inactive immunoglobulin Fc region. ALX148 enhances innate and adaptive immune responses against cancer and has previously been shown to be well tolerated in combination with the checkpoint inhibitor (CPI), pembrolizumab (P), and trastuzumab (T) in a range of solid tumors (ASCO 2019 #2514). ALX148 safety and activity in combination with T or P and standard chemotherapy regimens are reported in patients (pts) including head and neck squamous cell cancer (HNSCC) and HER2 positive gastric/gastroesophageal cancer (GC). **Methods:** Pts with advanced malignancy were administered AP or AT. Patients with ≥2L HNSCC progressed on platinum therapy received AP, while those with untreated advanced disease received AP+5FU (FU)+platinum. Pts with ≥2L GC progressed on T+FU+platinum received AT +/- ramucirumab (ram)+paclitaxel (pac). Safety, response, pharmacokinetic and pharmacodynamic (PD) markers were assessed. Data are reported as of 21, Jan. 2020. **Results:** Patients received AP (n=52); AP+FU+platinum (n=1); AT (n=30); or AT+ram+pac (n=3) as of data cutoff. Eighty-two pts experienced any adverse event (AE). Fifty-seven pts administered AP or AT regimens reported mostly low grade ALX148 treatment related (TR) AEs, the most common being fatigue (18%), AST increase (11%), platelets decreased (10%), ALT increase (8.5%), anemia (8.5%), and pruritus (8.5%). Pts receiving AP+FU+platinum or AT+ram+pac reported no TRAEs as of data cutoff. Anticancer activity was observed in response-evaluable pts. AP: HNSCC CPI-naïve (n=10) 40% ORR, mPFS 4.6 [95% CI:0.5; 7.5], mOS not reached with 14.4m median follow-up; AP: HNSCC CPI-experienced (n=10) 0% ORR, mPFS 2.0 [95% CI:0.9;3.6], mOS 7.4 [95% CI:3.1;NC]; and AT: GC (n=20) 20% ORR, mPFS 2.2 [95% CI:1.9;5.4], mOS 8.1 [95% CI:3.4;12.8]. Full peripheral CD47 target occupancy and increased infiltrating immune cells in tumor biopsies were seen. Exploratory analysis of biomarkers associated with response is ongoing. **Conclusions:** Initial data suggests ALX148 demonstrates excellent tolerability in combination with anti cancer antibodies and standard chemotherapy. Clinical activity in pts with advanced CPI naïve HNSCC (including PD-L1 negative) and GC compares favorably with historic controls. Final data from AP and AT cohorts and initial data from chemotherapy combination cohorts will be presented. Clinical trial information: NCT03013218. Research Sponsor: ALX Oncology Inc.

3058 Poster Session (Board #122), Fri, 8:00 AM-11:00 AM

Anti-CTLA-4 probody BMS-986249 alone or in combination with nivolumab in patients with advanced cancers: Initial phase I results. *First Author: Martin Gutierrez, Hackensack University Medical Center, Hackensack, NJ*

Background: Blockade of the CTLA-4 pathway with ipilimumab (IPI) ± nivolumab (NIVO; anti–PD-1) is an effective treatment for a variety of cancers. To optimize the risk-benefit profile of CTLA-4–directed therapy, a Probody therapeutic technology platform (Pb-Tx, CytomX Therapeutics) was used to generate BMS-986249, a peptide-masked version of IPI that is unmasked by tumor-associated proteases. Pb-Tx may localize CTLA-4 activity to the tumor, minimize systemic toxicity, and allow for higher doses of anti–CTLA-4 ± anti-PD-1. In preclinical studies, BMS-986249, given at similar doses, showed comparable intratumoral and reduced peripheral pharmacodynamic activity relative to IPI (Engelhardt, AACR 2020). Here, we present the initial results of the first-in-human phase 1/2 study of BMS-986249 ± NIVO in pts with advanced (adv) cancers (NCT03369223). **Methods:** During dose escalation, pts received BMS-986249 at or above the approved doses of the parent molecule using a Q4W or Q8W dosing schedule as monotherapy (240–2400 mg Q4W or 1600 mg Q8W; ≈ 3–30 mg/kg vs approved 3 mg/kg Q3W IPI) or in combination (240–1200 mg Q4W or 800 mg Q8W) + NIVO 480 mg Q4W. Safety and pharmacokinetics (PK) were evaluated. Efficacy is being assessed in the dose-expansion phase. **Results:** As of December 7, 2019, 82 anti–CTLA-4 naive pts with various adv cancers received BMS-986249 ± NIVO (mono, n = 39; combo, n = 43). Median age 60 (25–78) y; 95% pts had prior systemic therapy. TRAEs occurred in 59% of pts (Gr 3/4, 23%) with mono and 74% of pts (Gr 3/4, 30%) with combo. Diarrhea was the most common any-Gr TRAE (mono, 23%; combo, 21%) and Gr 3/4 TRAE (mono, 15%; combo, 7%). Rates of Gr 3/4 TRAEs increased with higher doses of BMS-986249 but were substantially reduced with Q8W schedule (eg, 800 mg Q4W, 18%; 1600 mg Q4W, 60%; 1600 mg Q8W, 9%). Most TRAEs resolved, no Gr 5 TRAEs occurred. The peptide-masked intact probody accounted for most (73%) of the systemic BMS-986249-related species; elimination of the probody indicated involvement of both catabolism and cleavage processes. **Conclusions:** BMS-986249 ± NIVO displayed a clinically manageable safety profile, allowing assessment of comparably higher BMS-986249 dose intensity (240-1200 mg; ≈ 3-15 mg/kg) + NIVO (480 mg Q4W, full dose) than that tested with IPI + NIVO. The types of TRAEs were consistent with CTLA-4 blockade, and the overall data align with the proposed Pb-Tx mechanism of action. The preclinical and clinical data support the ongoing randomized BMS-986249 + NIVO expansion in pts with adv melanoma, in addition to other adv tumors. Clinical trial information: NCT03369223. Research Sponsor: Bristol-Myers Squibb.

3059 Poster Session (Board #123), Fri, 8:00 AM-11:00 AM

Phase Ib clinical study of CBP501, cisplatin, and nivolumab administered every three weeks in patients with advanced refractory tumors: Efficacy in dose-escalation and expansion cohorts. *First Author: Marc Ryan Matrana, Ochsner Cancer Institute, New Orleans, LA*

Background: CBP501 is a 12-amino acid G2 checkpoint abrogator and calmodulin-modulating peptide that increases platinum influx into tumor cells and induces tumor immunogenic cell death. CBP501 also suppresses platinum-induced release of cytokines by macrophages, lowers cancer stem cell populations, and reduces migration, invasion, and epithelial-mesenchymal transition of tumor cells. We report safety and efficacy outcomes from dose-escalation and expansion cohorts of a Phase Ib study of CBP501 combined with cisplatin and nivolumab (NCT03113188). **Methods:** An open-label Phase I trial was conducted using a 3+3 design: CBP501 and cisplatin were dosed simultaneously by 1h infusion Q3W at 4 different combined dose levels (CBP501: 16 or 25 mg/m^2; cisplatin: 60 or 75 mg/m^2) in the dose-escalation cohort. Nivolumab (240 mg) was dosed on the same day as a 1h infusion following CBP501/cisplatin. CBP501 and cisplatin were fixed at 25 and 60 mg/m^2, respectively, in the expansion cohort. Eligible patients had pathologically confirmed, locally advanced or metastatic solid tumors, age ≥18 years, ECOG PS 0-1, life expectancy > 3 months. The dose-expansion cohort had pretreated metastatic exocrine pancreatic cancer or microsatellite stable colorectal cancer (CRC). Scans were performed every 6 weeks while on study, then every 3 months. **Results:** The most common related adverse events (AEs) were infusion-related reaction (rash, itching, hives; n = 32/37 [Gr 1, n = 4; Gr 2, n = 28]; 86%) and anemia (n = 19/37 [Gr 1/2, n = 10; Gr 3, n = 9]; 51%). There were no additional safety signals other than those known for each agent. At January 9, 2020 (interim analysis), efficacy was evaluable in 17/19 patients in the dose-escalation cohort. Unconfirmed partial response was seen in 18% (3/17; 1 pancreatic, 1 colorectal, 1 cholangiocarcinoma), with > 3 months stable disease (SD) in 41% (7/17), disease control in 41% (7/17), and > 8 months overall survival (OS) in 53% (9/17). In the expansion cohort, efficacy was evaluable in 8/13 patients with pancreatic cancer: > 4 months SD was 50% (4/8), median progression-free survival 4.2 months, and median OS 5.9 months (6/8 ≥3rd line). The CRC cohort median OS for all CRC patients (n = 10) including the dose-escalation cohort (n = 5) was 17.5 months (10/10 ≥3rd line). **Conclusions:** The triple-drug combination is reasonably tolerable with preliminary signs of efficacy in refractory solid tumors, including those in which cisplatin and nivolumab have limited single-agent activity. Clinical trial information: NCT03113188. Research Sponsor: CanBas Co., Ltd.

3060 Poster Session (Board #124), Fri, 8:00 AM-11:00 AM

Characteristics and outcomes of real-world (RW) patients (pts) with microsatellite instability-high (MSI-H) solid tumors treated with pembrolizumab monotherapy (P) after FDA approval. *First Author: Tamara Snow, Flatiron Health, New York, NY*

Background: The first tumor-agnostic, biomarker-based FDA approval in oncology was P in May 2017 for pts with MSI-H or mismatch repair (MMR) deficient tumors. 1 yr overall survival (OS) was >70% for colorectal cancer (CRC) and >60% for non-CRC in P-treated MSI-H clinical trial pts (Le 2019; Marabelle 2019). As tumor-agnostic therapies are a new paradigm, it is important to assess their use and effectiveness in routine clinical practice. We examined characteristics and outcomes of RW pts with MSI-H solid tumors who received P after May 2017. **Methods:** Pts with MSI-H solid tumors who received P after May 2017 were selected from the Flatiron Health-Foundation Medicine (FH-FMI) clinico-genomic database, a nationwide de-identified EHR-derived database linked to comprehensive genomic profiling (CGP) data. Pts with 2+ visits in the FH network from 01/2011-09/2019 with CGP prior to P use were included. Clinical characteristics were assessed at first P use. Time to treatment discontinuation (TTD) and OS from first P use were estimated with Kaplan-Meier analyses of all pts and the largest tumor types. **Results:** 33,395 pts had a solid tumor tested for MSI by CGP, of which 557 (1.7%) were MSI-H (median age 68 yrs; 34% male). 129 MSI-H pts across 33 tumor types received first P after May 2017. CRC (N=36) and Endometrial cancer (N=39) were most common. 52 pts (40%) had a concurrent MMR alteration (MLH1, MSH2, MSH6 or PMS2); median TMB was 32.2 mut/mb (IQR 20.9-47.5). Median number of therapies prior to P was 1; median time from CGP to first P use was 3 mos. Table shows OS and TTD. **Conclusions:** In this RW study, P use was observed across 33 MSI-H tumor types. Median OS exceeded 1 yr across all pts and in CRC, Endometrial, and Other cohorts. 1 yr OS rate was consistent with P trial outcomes. Further study should evaluate whether effectiveness differs across diseases, MSI testing method, or other genomic attributes to improve treatment selection. Research Sponsor: Flatiron health Inc.

OS and TTD in P-treated, pantumor MSI-H pts.

	N	Median TTD, mos [95% CI]	Median OS, mos [95% CI]	N at risk at 12-mos	12-mos OS, % [95% CI]

3061 Poster Session (Board #125), Fri, 8:00 AM-11:00 AM

A first-in-human phase I study in patients with advanced and/or refractory solid malignancies to evaluate the safety of ATOR-1015, a CTLA-4 x OX40 bispecific antibody. *First Author: Jeffrey Yachnin, Karolinska Institutet, Stockholm, Sweden*

Background: ATOR-1015 is a human CTLA-4 x OX40 targeting IgG1 bispecific antibody developed to be a next generation CTLA-4 antibody with enhanced immune activation and tumor-directed activity for improved efficacy and reduced toxicity. **Methods:** The primary objective of the study is to determine the maximum tolerated dose (MTD) and/or the recommended phase 2 dose (RP2D) in patients with advanced solid malignancies. Safety and tolerability of ATOR-1015 are assessed by adverse events (AEs), vital signs, ECG, laboratory evaluations and physical examinations. Secondary objectives include pharmacokinetics (PK), immunogenicity and clinical efficacy. Clinical efficacy is assessed using Response Evaluation Criteria in Solid Tumors for immune-based therapeutics (iRECIST). The study is designed with single patient cohorts for doses below 100 mg followed by a modified 3+3 design (NCT03782467). Intra-patient dose escalation is allowed. ATOR-1015 is administered intravenously every other week as a single agent until confirmed progressive disease, unacceptable toxicity or withdrawal of consent. **Results:** From March 2019 to February 2020, 15 patients have been exposed to ATOR-1015. The median age of the patients is 52 years (range 40-72). The following cancer types have been included: colorectal cancer (n=8), uveal melanoma (n=2), pancreatic cancer (n=2), ovarian cancer (n=2), and cholangiocarcinoma (n=1). Patients received a median of 6 prior lines of therapy (range 3-16). Dose levels from 0.043 mg to 200 mg have been evaluated and declared safe. Dose escalation is ongoing, and 400 mg is under evaluation. The median time on study was 8 weeks (range 2.1-34.3). Four patients are on study and eleven patients have discontinued treatment. Reasons for discontinuation include clinical deterioration (n=7), death due to disease progression (n=2), confirmed disease progression (n=1) and investigator´s decision (n=1). Six of the 15 patients experienced drug-related AEs which were grade 2 or less. Infusion-related reactions (IRR) were reported in four patients. One of those four also had abdominal pain and mediastinal burning sensation. The IRR symptoms were predominantly rash. One patient had vitiligo, and one had rash. No dose-limiting toxicities have occurred. Preliminary PK data show dose-proportional kinetics up to 200 mg. **Conclusions:** The dosing of ATOR-1015 has been safe and well-tolerated up to 200 mg. Dose escalation continues and the current dose level under evaluation is 400 mg. Clinical trial information: NCT03782467. Research Sponsor: Alligator Bioscience AB.

3062 Poster Session (Board #126), Fri, 8:00 AM-11:00 AM

Phase Ia dose escalation of IBI318, a first-in-class bispecific anti-PD-1/PD-L1, in patients with advanced tumors. *First Author: Rui-hua Xu, Sun Yat-sen University Cancer Centre, Guangzhou, China*

Background: With the proven success of PD-1 and PD-L1 monoclonal antibodies, exploiting antibody based immune checkpoint strategies has potential to reduce disease burden and improve patient survival outcome. IBI318, as a first-in-class anti-PD-1/PD-L1 bispecific antibody, could provide more potent anti-tumor activity and more durable response. Here we report preliminary results from an ongoing phase 1a/1b study of IBI318 in advanced tumors. **Methods:** In the dose escalation of Phase 1a, patients with advanced and/or refractory solid tumors or hematological malignancies were enrolled to receive IBI318. Dose escalation was from 0.3 mg to 600 mg (8 cohorts) via an accelerated titration followed by a modified toxicity probability interval-2 design with a 28-day dose-limiting toxicity (DLT) observation period. Patients without DLT will receive IBI318 every two week (Q2W). Tumor assessments were performed every 6 weeks. **Results:** As of Jan 10, 2020, 15 pts who had failed at least one line of treatment had been enrolled (1 pt each in 0.3 mg, 1 mg, 3 mg and 10 mg; 3 pts in 30 mg; 3 pts in 100 mg, 3 pts in 300 mg and 2 pts in 600 mg) for dose escalation and received at least 1 dose of treatment. Median duration of treatment was 6.1 (range: 2.1-24.7) weeks. IBI318 had been well tolerated with no DLT from 0.3mg to 300mg group. 11 of 15 pts had treatment related AEs (TRAEs) and the most common (≥10%) TRAEs were pyrexia (20.0%, G1/2) and infusion-related reaction (20.0%, G1/2). 1 patient in 300 mg had an immune-related AE (G2 arthritis). No ≥G3 TRAE had been observed. 12 pts had at least one on-study tumor assessment. 3 of 9 pts receiving dose level ≥10mg had achieved partial response (1 confirmed, 1 pending confirmation and the other PD after the first PR scan). A total of 10 pts discontinued treatment due to disease progression (8) and AE (2, G4 lung infection and G4 upper gastrointestinal hemorrhage, both were not related to treatment). **Conclusions:** IBI318 has shown an acceptable safety profile. Preliminary efficacy results are promising in advanced cancer patients. The study is currently ongoing at dose level of 600 mg Q2W. Clinical trial information: NCT03875157. Research Sponsor: Innovent Biologics, Inc.

3063 Poster Session (Board #127), Fri, 8:00 AM-11:00 AM

Safety of BI 754111, an anti-LAG-3 monoclonal antibody (mAb), in combination with BI 754091, an anti-PD-1 mAb, in patients with advanced solid tumors. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: LAG-3, an immune checkpoint receptor involved in T-cell regulation, is frequently co-expressed with PD-1. LAG-3 and PD-1 signaling contributes to immune cell exhaustion and reduces the immune response to tumor cells. Dual inhibition of PD-1 and LAG-3 may reactivate the T-cell response better than blockade of either individual pathway. Here, we report combined safety data from 4 trials investigating BI 754111, an anti-LAG-3 mAb, in combination with BI 754091, an anti-PD-1 mAb, in patients with advanced solid tumors. **Methods:** Data from 2 phase I dose-escalation/expansion trials, 1 phase I imaging trial, and 1 phase II trial were included. Eligible patients had advanced and/or metastatic solid tumors with measurable disease and an Eastern Cooperative Oncology Group performance status ≤1. Patients received BI 754111 (intravenously [iv], 4–800 mg) in combination with BI 754091 (iv, 240 mg fixed dose) every 3 weeks (q3w). Patients remained on treatment until progressive disease or unacceptable toxicity. In each trial, safety was assessed by incidence and severity of adverse events (AEs), and graded according to Common Terminology Criteria for AEs, version 5. **Results:** Overall, 321 patients were treated with BI 754111 in combination with BI 754091 (200 [62%] male; median age, 63 years [range 18–88]). Median treatment exposure was 85 days (range 9–625). Of these patients, 282 (87.9%) had any AE (G≥3 in 99 [30.8%]). 285 patients received the 600 mg recommended phase II dose of BI 754111 plus BI 754091 240 mg q3w. Median treatment exposure in these patients was 74 days (range, 8–590). The table shows the 3 most common AEs and 4 most common immune-related AEs, and their frequency. 21 (7.4%) patients had AEs leading to study drug discontinuation, most commonly infusion-related reactions (IRRs) in 6 (2.1%) patients. Serious AEs (all-cause) occurred in 77 patients (27.0%), most commonly pleural effusion in 6 (2.1%) and deep vein thrombosis in 4 (1.4%) patients. 2 patients (0.7%) experienced an AE resulting in death (cardiac tamponade and acute kidney injury, both related to underlying diseases). **Conclusions:** The combination of BI 754111 and BI 754091 had a manageable safety profile, similar to other checkpoint inhibitors. Clinical trial information: NCT03156114, NCT03433898, NCT03697304, NCT03780725. Research Sponsor: Boehringer Ingelheim.

3064 Poster Session (Board #128), Fri, 8:00 AM-11:00 AM

Results of a first-in-human phase I study of SRF231, a fully human, high-affinity anti-CD47 antibody. *First Author: Amita Patnaik, START, San Antonio, TX*

Background: CD47 is a transmembrane protein that acts as a "Don't Eat Me" signal to evade immune recognition. It is overexpressed in multiple cancer subtypes and is associated with poor prognosis. SRF231 is an investigational, fully human, high-affinity CD47-targeting antibody that delivers an activating signal to myeloid cells and displays favorable preclinical characteristics regarding its receptor occupancy/tumor exposure/efficacy relationship. **Methods:** In a Phase 1 study, SRF231-101 (NCT03512340), patients with advanced solid and hematologic malignancies who had failed standard therapy were enrolled in dose escalation cohorts (accelerated single-patient followed by standard 3+3) to establish the preliminary safety of SRF231 as a monotherapy and identify a dose and schedule suitable for expansion. In addition to collection of safety data, clinical outcomes were evaluated based on Response Evaluation Criteria in Solid Tumors (RECIST v1.1) and SRF231 pharmacokinetic (PK) and pharmacodynamic (receptor occupancy) analyses were performed. **Results:** As of January 11, 2020, a total of 46 patients were enrolled, 25 in every-3-week intravenous (IV) dosing schedules and 21 in weekly IV dosing schedules. Weekly dosing schedules also explored the use of a 1.0 mg/kg initiation dose. Other than one patient with recurrent follicular lymphoma, all patients had recurrent/refractory solid tumors. The most common treatment emergent adverse events across dosing schedules were low-grade fatigue (43%), headache (35%), and pyrexia (30%). On every-3-week dosing schedules, 2 dose-limiting toxicities (DLTs) were observed: Grade 3 febrile neutropenia and Grade 3 hemolysis, both at a 12.0 mg/kg dose level. On weekly dosing schedules, 3 DLTs were observed: Grade 4 thrombocytopenia (6.0 mg/kg), Grade 4 amylase and lipase increased (4.0 mg/kg with initiation dose), and Grade 3 fatigue (4.0 mg/kg). The maximum tolerated dose was 9.0 mg/kg on an every-3-week and 4.0 mg/kg on a weekly schedule. Receptor occupancy was maintained at > 90% throughout the dosing period with a 4.0 mg/kg weekly dose schedule. Out of 37 patients who were response evaluable by RECIST, there were no complete or partial responders, although prolonged stable disease has been observed. **Conclusions:** Preliminary data from a Phase 1 study of SRF231, an anti-CD47 antibody, demonstrate that SRF231 may be administered safely and doses of 4.0 mg/kg weekly maintain > 90% receptor occupancy throughout the dosing period. Updated safety data, clinical outcomes, and PK/pharmacodynamic data will be presented. Clinical trial information: NCT03512340. Research Sponsor: Surface Oncology, Inc. Cambridge, MA, USA.

3065 Poster Session (Board #129), Fri, 8:00 AM-11:00 AM

A phase Ib study of TQ-B2450 plus anlotinib in patients with advanced solid tumor. *First Author: Ying Cheng, Jilin Cancer Hospital, Changchun, China*

Background: Anlotinib, an antiangiogenic multi-target tyrosine kinase inhibitor, significantly improved clinical outcomes in solid tumors. TQ-B2450 is an engineered anti-programmed death-ligand 1 antibody. This onging phase 1b study aimed to assess the safety and effect of TQ-B2450 plus anlotinib in advanced solid tumors. **Methods:** This phase 1b study, which included a dose-escalating phase and an expansion phase, enrolled patients with advanced solid tumor who failed in or had no standard treatment between June 2019 and January 2020.Eligible patients were firstly assigned into sequential dose-escalating cohorts including 10mg and 12mg anlotinib plus TQ-B2450 following the conventional 3+3 design. If the starting dose of 10mg anlotinib led to ≥2 dose-limiting toxicities (DLTs), 8mg anlotinib would be administered. After the dose-escalating phase, eligible patients were enrolled into the expansion cohort. The primary outcomes were safety and objective response rate. **Results:** In the dose-escalating phase, three eligible patients received 10mg anlotinib plus TQ-B2450 had no DLTs in the first cycle, neither did three patients with 12mg anlotinib plus TQ-B2450. Then the expansion phase started, sixteen patients received 12mg anlotinib plus TQ-B2450. Finally, a total of 22 patients were included (6 small cell lung cancers [SCLC], 8 non-small cell lung cancers [NSCLC], 2 colorectal cancers, 2 breast cancers, 2 ovarian cancers, 1 thymic carcinoma and 1 cervical cancer). Ten ≥3 grade adverse events were observed (Table). Seventeen patients underwent at least once effect evaluation. One SCLC patient with 10mg anlotinib plus TQ-B2450 had confirmed partial responses (PR). Four patients with 12mg anlotinib plus TQ-B2450 had unconfirmed PR (2 SCLC and 2 NSCLC). And 9 patients had stable disease, 3 patients had progression disease. **Conclusions:** 12mg anlotinib plus TQ-B2450 showed an acceptable safety profile and promising response in advanced solid tumors. Clinical trial information: NCT03897283. Research Sponsor: None.

Assessing the effect of immunosuppressive agents for immune-related adverse event management on tumor response. *First Author: Pankti Reid, University of Chicago, Chicago, IL*

Background: High grade immune-related adverse events (irAEs) to cancer immune checkpoint inhibitors (ICI) require considerable immunosuppression (IS) with high-dose steroids and steroid-sparing IS (SSIS) for steroid-dependent cases. T lymphocyte-specific IS has generally been avoided or used with significant caution due to the fear that these agents may negatively impact ICI efficacy. We sought to determine whether T cell-specific IS agents, such as calcineurin inhibitors (CNIs), have an adverse effect on tumor control when compared to other immunomodulatory drugs (IMDs). **Methods:** We retrospectively analyzed clinical annotations of adult patients treated with ICIs for malignancy from 1/1/2000-12/31/2019, highlighting patients who were managed with SSIS, specifically those most commonly used for autoimmune disease therapy. Topical IS use was excluded. Patients were categorized as tumor responders or non-responders, and irAEs were graded according to National Cancer Institute's Common Terminology Criteria for Adverse Events (CTCAE). Progression-free survival (PFS) was assessed via Kaplan-Meier curve. **Results:** 1331 unique individuals were prescribed ≥1 ICIs, with 526 prescribed systemic steroids (39.5%) and 90 (6.8%) patients prescribed SSIS agents, 25 patients with >1 SSIS: mycophenolate (39), methotrexate (26), leflunomide (5), azathioprine (3), rituximab (24), tocilizumab (3), infliximab (8), etanercept (1), adalimumab (1), golimumab (1) and CNIs (18): cyclosporine, tacrolimus. IMDs hydroxychloroquine (6) and sulfasalazine (5) were also prescribed. The objective response rate was 50.0% in the CNI group compared to 45.5% in the IMD cohort and 45.4% in the irAE group (CTCAE grade matched) with steroids alone without any SSIS. Median PFS were compared between CNI cohort (5.4 months, range 1.3-34 months) to IMD (1.1 months, range 0.4-6.4, p=0.02) and steroid alone (2.4 months, range 0.69-17.7, p=0.48). Multiple regression analysis identified irAE presence as an independent correlates to tumor response (p=0.02). **Conclusions:** T cell-specific IS should not be excluded from irAE treatment algorithm as we observed that PFS was comparable to immunomodulators and similar efficacy was observed compared to steroids alone. Rapid identification and management of irAEs can help mitigate morbidity but there are virtually no reliable clinical trials to guide irAE management with SSIS. These findings support the need for larger, prospective evaluation of immunosuppression use for high grade irAE therapy. Research Sponsor: None.

Fecal microbiota transplantation (FMT) for immune checkpoint inhibitor induced–colitis (IMC) refractory to immunosuppressive therapy. *First Author: Yinghong Wang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ICIs are efficacious treatment for several advanced malignancies. IMC can limit their use, and can be refractory to medical treatment (immunosuppression) with significant morbidity. Gut microbiome alteration affects IMC development. We sought FMT as a novel therapy for IMC refractory to immunosuppressive therapy. **Methods:** 15 patients who received FMT for IMC after failure of immunosuppressive therapy were included (6/2017-1/2020). FMT was performed via colonoscopy with healthy donor's stool. **Results:** Median age was 55 years with 67% males. 5 patients received PD(L)-1, one CTLA-4 and 9 on combination. Majority had genitourinary cancers followed by melanoma. Median time from ICI to IMC was 75 days. 14 patients had grade 3-4 diarrhea and 9 had grade 3-4 colitis. Endoscopy showed mucosal inflammation in 12 patients and normal mucosa in 3 patients. IMC was refractory to 2-3 doses of infliximab or vedolizumab after corticosteroids prior to FMT. Median time from IMC onset to FMT was 75 days. 13 patients received one . 11 patients achieved clinical response within 10 days of FMT (7-14). Symptom remission was maintained for a median follow-up of 13 months. 6 patients resumed non ICI cancer treatments after FMT. 4 patients had persistent symptoms; 2 continued on vedolizumab, 1 had total colectomy, and 1 transferred to hospice. 4-8 weeks after FMT, endoscopic remission was achieved in 64% of the 11 patients who responded to FMT. No adverse events were reported. **Conclusions:** FMT treatment was successful in 73% of patients with for IMC refractory to immunosuppressive therapy. Controlled clinical trials are warranted to confirm our conclusion. Research Sponsor: None.

Characteristics of FMT (n = 15).

Characteristic	Data (N=15)
Median days from IMC onset to FMT (IQR)	75 (58-127)
Median time from FMT to symptom improvement– days (IQR)	10 (7-14)
Resumed cancer treatment after FMT—no (%)	6 (40)
Symptom improvement after FMT—no (%)	11 (73)
Endoscopic remission achieved—no (%)	7 (64)
Histology remission achieved—no (%)	5 (45)

3068 Poster Session (Board #132), Fri, 8:00 AM-11:00 AM

Circulating tumor DNA dynamics as prognostic and predictive biomarkers of response to pembrolizumab in patients with virally-related tumors (VRT) treated within the INSPIRE study. *First Author: Marc Oliva Bernal, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: We previously showed a correlation between circulating tumor DNA (ctDNA) dynamics and response to pembrolizumab in a cohort of mixed tumors treated in the INSPIRE study (Yang et al, ESMO 2019). We investigated the prognostic and predictive value of ctDNA dynamics in patients (pts) with VRT. **Methods:** Pts with VRT (HPV+ squamous cell carcinoma (SCC), EBER+ nasopharyngeal carcinoma (NPC) and MCPyV+ Merkel carcinoma (MC)) and a control cohort of non-VRT (HPV- head and neck SCC) treated with single-agent pembrolizumab were selected for the analysis. ctDNA was assayed at baseline and start of cycle 3 using a pt-specific amplicon-based NGS assay (Signatera). Samples were considered ctDNA positive if ≥2 of 16 pt-specific targets met the qualifying confidence score threshold. Whole exome sequencing (WES) performed in baseline tumor tissue; presence of HPV, EBV and MCPyV in tumor determined through bioinformatic analysis of WES data (VirusFinder, *PMID23717618*). Changes in tumor size (mm) and response data using RECIST 1.1 were collected. Progression-free survival (PFS) and overall survival (OS) were estimated by Kaplan-Meier method. **Results:** Twenty pts with VRT (HPV+ head and neck = 8, cervical = 2 and anal = 2 SCC; EBER+NPC = 2; MC = 6) and 11 pts with non-VRT were included. Median follow-up: 11 months (0,5-11). Treatment response: VRT 6 responders (CR + PR + SD > 18weeks) and 14 non-responders (SD < 18 weeks + PD); non-VRT 3 responders and 8 non-responders. Median OS and PFS for all pts were 10.61 and 3.2 months, respectively. No differences in PFS (p = 0.60) nor OS (p = 0.66) were observed among responders between VRT and non-VRT. Among non-responders, VRT had significantly higher OS but not PFS when compared to non-VRT (HR 0.30, p = 0.01 and HR 0.82 p = 0.62, respectively). VRT had quantitatively higher ctDNA at baseline vs non-VRT (Mean 7.9 vs 0.4 ng, p < 0.001). ΔctDNA (Change in ctDNA between baseline and cycle 3) strongly correlated with changes in tumor measurements and response by RECIST 1.1 (Spearman Rho = 0.75) and was associated with survival regardless of viral status (Table). **Conclusions:** ΔctDNA strongly correlated with changes in tumor response and survival in both VRT and non-VRT. Higher baseline ctDNA was found in VRT. Correlation with circulating viral DNA and radiomics analyses is on-going. Research Sponsor: None.

Variable	HR[1] for PFS	p-value	HR[1] for OS	p-value
VRT vs non-VRT	1.1	0.8	0.6	0.3
ΔctDNA continuous	1.6[2]	**0.01**	1.5[2]	**0.03**
ΔctDNA up vs. down	4.1	**0.003**	4.1	**0.007**

1. Hazard Ratio. 2. Per unit increase in ΔctDNA

3069 Poster Session (Board #133), Fri, 8:00 AM-11:00 AM

Using autoantibody signatures to predict immunotherapy discontinuation in melanoma patients. *First Author: Iman Osman, The Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York, NY*

Background: Immune checkpoint inhibitors (ICIs), e.g., ipilimumab (IPI) and/or nivolumab (NIVO), produce durable survival benefit in a substantial proportion of melanoma patients but can also induce severe immune-related adverse events (irAEs) requiring treatment discontinuation. There is no biomarker to predict irAEs in ICI-treated melanoma patients. Given the similar clinical manifestation between irAEs and autoimmune disorders, we hypothesized that a subset of patients possess a subclinical baseline predisposition to developing irAEs that is characterized by specific autoantibodies (autoAbs). **Methods:** Pre-treatment melanoma patient sera from the CheckMate-238 Phase III trial of adjuvant IPI vs. NIVO were used for autoAb profiling with HuProt proteomic arrays (CDI Labs). The outcome of interest is to predict toxicity events that caused treatment discontinuation. For each treatment arm, we allocated patients to training and testing datasets in a 3:1 ratio. We calculated the area under the curve (AUC) of the receiver operating characteristic curve to select a probability threshold, which was applied to the testing dataset to assess accuracy, sensitivity, and specificity. Functional enrichment among autoAb protein targets was assessed using Metascape. **Results:** There were 707 irAEs among 597 patients (IPI = 423, NIVO = 174), of which 355 required treatment discontinuation (IPI = 287, NIVO = 68). In the training sets, we identified a 170 autoAbs signature consisting of 102 autoAbs for IPI treatment and 68 autoAbs for NIVO treatment. In the independent testing set, the signatures showed AUC of 0.85 (0.78, 0.92), 82% sensitivity, 78% specificity, and overall accuracy of 81% to predict IPI discontinuation, and AUC of 0.87 (0.74, 0.99), 75% sensitivity, 97% specificity, and overall accuracy of 88% to predict NIVO discontinuation. Enrichment of nuclear lumen-associated protein targets was identified among autoAb signatures that predict IPI or NIVO discontinuation. **Conclusions:** The identified signature within a large Phase III trial cohort highlights the potential utility of pre-treatment autoAbs for prediction of patients at high risk of developing irAEs in the adjuvant setting necessitating treatment termination. We are currently validating and refining toxicity-associated autoAb signatures with the goal of developing a Clinical Laboratory Improvement Amendments (CLIA)-certified assay to enable clinicians to optimize immunotherapy delivery and patient selection. 3070 Poster Session (Board #134), Fri, 8:00 AM-11:00 AM

Spatial analysis of tumor immune microenvironment (TIME) in patients treated with Bintrafusp alfa. *First Author: Houssein Abdul Sater, National Cancer Institute, Genitourinary Malignancies Branch, Bethesda, MD*

Background: Bintrafusp alfa is a first-in-class bifunctional fusion protein composed of the extracellular domain of TGF-βRII receptor (TGF-β "trap") fused to a human IgG1 mAb blocking PD-L1. In preclinical models, bintrafusp alfa treatment promoted CD8+ T cell and NK cell activation, and both immune cell (IC) populations were required for optimal bintrafusp alfa mediated tumor control. However, the effect of bintrafusp alfa on TIME in humans has not been reported. **Methods:** In this unplanned interim analysis of a biomarker expansion cohort (NCT 02517398), patients (pts) with advanced non-small cell lung cancer (NSCLC) underwent paired biopsies (bx) before and on treatment with bintrafusp alfa (~ 50 days apart). The objective was to evaluate frequency and localization of tumor infiltrated ICs by IHC. Out of 12 pts, 7 had matched (Pre vs Post) tumor-containing specimens sufficient for multiplex immunofluorescence (MxIF) analysis of TIME. Four pts were excluded as Post bx histology for 3/12 [2 PR (partial response), 1 SD (stable disease)] was negative for tumor (necrosis or fibrosis) and 1/12 did not have a Post bx performed. **Results:** TIME study shows CD8 T cell infiltrates were increased in Post compared to Pre bx (median 161 vs 62/mm^2; interquartile range [IQR] 65–396/mm^2 vs 31–135/mm^2; p = 0·04). While M2 macrophages were also increased (median 800 vs 367/mm^2; IQR 776–1131/mm^2 vs 171–831/mm^2; p = 0·04), the ratio of M1/M2 was reversed in pts with SD (↑) compared to pts with PD (↓). Other ICs such as CD4, T-regs, NK cells and M1 macrophages were not changed. On average compared to baseline, M2 macrophages were > 2 fold closer to every other IC in pts with PD, but > 2 fold further from any IC in pts with SD. Tregs were relatively closer to other IC in PD pts. Linear Discriminant Analysis was also performed and results indicate that differential IC densities (mainly M1 macrophages and CD4 T cells) do perform as classifiers between long (> 5 months) and short (< 5 months) term responses. **Conclusions:** This study suggests that bintrafusp alfa not only can enhance intratumoral effector IC infiltrates (CD8) but also has a modulating effect on the spatial distribution of both M1/M2 macrophages within the NSCLC TIME. The differential proximity of M2 macrophages to other IC infiltrates and changes in M1/M2 ratios in association with response suggests that an M1/M2 macrophage balance is directly involved in response and/or resistance to bintrafusp alfa. Given the limited number of patients in this cohort, we intend to study effects of bintrafusp alfa in a larger cohort of patients. Clinical trial information: 02517398. Research Sponsor: None.

3071 Poster Session (Board #135), Fri, 8:00 AM-11:00 AM

Preliminary dose escalation results from a phase I/II, first-in-human study of MGC018 (anti-B7-H3 antibody-drug conjugate) in patients with advanced solid tumors. *First Author: John D. Powderly, Carolina BioOncology Institute, Huntersville, NC*

Background: Antibody-drug conjugates (ADCs) are cancer agents that have a cytotoxic payload linked to a monoclonal antibody (mAb) that target cancer cells. ADCs offer increased cytotoxic activity while reducing normal tissue exposure. B7-H3 is expressed on multiple solid tumors with limited normal tissue expression. MGC018 is an investigational ADC with a duocarmycin payload linked to an anti-B7-H3 mAb. It is hypothesized that MGC018 has activity against B7-H3 expressing tumors with an acceptable safety profile. **Methods:** This study evaluates safety, dose-limiting toxicities (DLT), and maximum tolerated dose (MTD) of MGC018 in a dose escalation 3+3+3 design. In addition, pharmacokinetics, immunogenicity, and tumor response using RECIST v1.1 are evaluated. Cohort expansion will enroll at the MTD to assess safety and tumor response. **Results:** The study is enrolling Cohort 3 (6 total cohorts planned) in dose escalation. 20 patients (pts) were enrolled as of Feb 03, 2020. At least 1 treatment related adverse event (TRAE) occurred in 16 pts (80.0%). The most common TRAEs were neutropenia/decreased neutrophil count (35%); fatigue, lymphopenia/decreased lymphocyte count (30.0%); palmar plantar erythrodysaesthesia (PPE), skin hyperpigmentation (25.0%); pruritis, nausea, chills, infusion related reaction (20.0%); and vomiting, pyrexia, maculopapular rash (15.0%). Eleven pts (55.0%) experienced TRAEs ≥ Grade 3; events were decreased lymphocyte count/lymphopenia (n = 6), decreased neutrophil count/neutropenia (n = 3), PPE (n = 2), and maculopapular rash (n = 2). Three related serious adverse events occurred in 3 unique pts: pneumonitis in a pt with concurrent bacterial pneumonia, non-infectious gastroenteritis, and stasis dermatitis in a pt with chronic venous insufficiency. One DLT has occurred (Grade 4 neutropenia). No febrile neutropenia was observed. Target lesion decrease was noted in 1 pt each with small cell lung cancer (-6.3%), non-small cell lung cancer (-23.8%), and metastatic castrate-resistant prostate cancer (mCRPC) (-29.4%) with PSA change from 82.8 ng/ml to 57.1 ng/ml. One mCRPC pt with bone only disease had substantial improvement on bone scan and PSA decrease from 60 ng/ml to 4.7 ng/ml. **Conclusions:** Results to date demonstrate a manageable safety profile with early evidence of clinical activity. Continued dose escalation and clinical investigation of MGC018 is ongoing. Clinical trial information: NCT03729596. Research Sponsor: MacroGenics, Inc.

3073 Poster Session (Board #137), Fri, 8:00 AM-11:00 AM

A signal-seeking trial of olaparib and durvalumab in homologous repair-deficient tumors: A sub-study of the cancer molecular screening and therapeutics (MoST) program. *First Author: Anthony M. Joshua, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Data on the utility of a PARP inhibitor in combination with a checkpoint inhibitor remain limited, particularly in the histology agnostic setting with homologous recombination deficiency (HRD). This study evaluated the clinical activity of the combination of olaparib and durvalumab with the primary study endpoint of progression-free survival (PFS) at 6 months (PFS6m). **Methods:** This was a phase II, single-arm, signal-seeking study of the MoST program. Patients were recruited into two cohorts based on HRD genes, agnostic to histology: (1) BRCA 1/2 deficient tumours, excluding breast, prostate, ovarian cancers, and (2) other HRD related genes. Molecular testing was performed using in-house and commercial panels on archival tumour tissue centrally adjudicated by a molecular tumour board. All patients were treated with olaparib 300mg bid for 1 month, followed by combination with durvalumab 1500mg q4 weekly for 13 cycles. Olaparib treatment was then continued until disease progression. **Results:** Between Nov 2017-Feb 2019, 48 patients were enrolled (16 to BRCA 1/2 cohort 1 and 32 to HRD related genes cohort 2). Most common tumour sites were bone/soft tissue (15%, N=7), pancreas (13%, N=6) and stomach (8%, N=4). Overall best response in cohort 1 was PR (25%, N=4) and SD 4 (25%, N=4), and cohort 2 was PR (6%, N=2) and SD (56%, N=18). Median PFS was 3.65m (Cohort 1) and 3.56m (Cohort 2) respectively. PFS6m was 35% (Cohort 1) and 38% (Cohort 2) respectively. PDL1 status was not predictive of olaparib and durvalumab benefit. The most common grade 3/4 adverse events were anemia (11%%, N=4), abdominal pain (9%, N=3), increased lipase (9%,N=3), increased amylase (9%, N=3), dyspnea (6%, N=2), Hyperglycemia dyspnea (6%, N=2), Pancreatitis dyspnea (6%, N=2) and hematuria (6%, N=2). **Conclusions:** Olaparib and durvalumab show promising activity in a histology agnostic setting, particularly in BRCA deficient tumours. Further research is needed to identify biomarkers that correlate with treatment benefit. Results from longer clinical follow-up and additional biomarker analyses will be presented. Clinical trial information: ACTRN12617001000392. Research Sponsor: Department of Health, Australia.

3074 Poster Session (Board #138), Fri, 8:00 AM-11:00 AM

Statin treatment improves response to anti-PD1 agents in patients with malignant pleural mesothelioma and non-small cell lung cancer. *First Author: Luca Cantini, Clinical Oncology, Polytechnic University of Marche, AOU Ospedali Riuniti, Ancona, Italy*

Background: After progression to standard chemotherapy, only a small proportion of malignant pleural mesothelioma (MPM) and non-small cell lung cancer (NSCLC) patients (pts) benefit from anti-programmed cell death (PD-1) treatment. Combination strategies might improve response. In pre-clinical models, statins showed vaccine adjuvant activities and synergized with anti-PD1 agents. In this multi-center study, we evaluated the impact of baseline statin treatment in MPM and NSCLC pts. **Methods:** We separately examined MPM and NSCLC pts treated with anti-PD1 monotherapy after progression to standard chemotherapy at two European academic institutions. As control cohort, MPM pts treated with first-line chemotherapy were also examined. Pts receiving statins at start of treatment were compared with those who did not. Objective response rate (ORR), progression-free survival (PFS) and overall survival (OS) were analyzed. **Results:** A total of 287 patients were examined. Twenty-seven out of 80 (34%) MPM and 36 out of 130 (20%) NSCLC pts received statins at start of anti-PD1 treatment. The most common statins were simvastatin, atorvastatin and rosuvastatin. In MPM pts, statin use was associated with improved ORR (22% versus 5%, $P = 0.05$), longer PFS (median 6.7 versus 2.4 months, hazard ratio (HR) 0.42, 95% confidence interval (CI) 0.23–0.77, $P < 0.01$), and longer OS (median not reached versus 6.0 months, HR 0.43, 95% CI 0.21–0.85, $P = 0.01$). In NSCLC pts, statin use was associated with improved ORR (40% versus 22%, $P = 0.04$), longer PFS (median 7.8 versus 3.6 months, HR 0.59, 95% CI 0.37–0.97.2, $P = 0.03$) but similar OS (median 13.1 versus 10.1 months, HR 0.79, 95% CI 0.49–1.28, $P = 0.30$). At multivariate analyses, after adjusting for ECOG performance status (PS) and histological subtype, the impact of statins remained significant for ORR, PFS and OS in MPM and for PFS in NSCLC. Conversely, no association between statin use and outcomes was found in 77 MPM pts treated with first-line chemotherapy. **Conclusions:** This study shows that statin use at start of anti-PD1 treatment improves response to anti-PD1 agents in MPM and NSCLC pts who progressed to standard chemotherapy in routine clinical practice. This association could not be found in MPM pts treated with first-line chemotherapy, thus suggesting a synergy between statins and anti-PD1 agents. Prospective studies are needed to confirm whether the combination of statin and anti-PD1 therapy could improve outcome in pts with poorly immunogenic thoracic malignancies. Research Sponsor: None.

3075 Poster Session (Board #139), Fri, 8:00 AM-11:00 AM

Interrogation of neoantigen-specific CD8 T cells in peripheral blood following PD-L1 blockade in patients with metastatic urothelial carcinoma (mUC). *First Author: Jeppe Sejerø Holm, Technical University of Denmark, Kgs. Lyngby, Denmark*

Background: Proliferation of CD8 T cells can be detected in the blood of cancer patients (pts) following a single dose of immune checkpoint blockade (ICB) and tends to be more robust in responding pts. Furthermore, tumor mutational burden (TMB) is seen to predict outcome to ICB across cancers. Mutation-derived neoepitopes presented on the tumor cell surface is believed to be recognized by T cells and are thus critical for tumor clearance. However, the capacity to mount a neoantigen T cell response and the kinetics in relation to ICB remain poorly understood. **Methods:** 24 pts with mUC were treated with atezolizumab (anti-PD-L1) 1200mg q3w on IMVigor 210 at MSKCC and included in here. Pt-specific neoepitopes were predicted based on whole-exome and RNA sequencing of pre-treatment archival tumors using the MuPeXI platform. Using DNA-barcode labelled pMHC multimers, we investigated CD8 T cell recognition of mutation-derived neoepitopes by screening pt PBMC samples pre- and post-treatment with atezolizumab (n = 85 PBMC samples). The kinetics of neoepitope-specific CD8 T cells were assessed for association with durable clinical benefit (DCB; defined as progression free survival $>$ 6 mo). **Results:** Neoepitope peptide libraries of between 200-587 peptides were generated per pt (mean = 260 peptides per pt). 31 out of a combined 56 possible pt HLA types across the cohort were utilized for T cell analyses (mean four HLAs per pt). MHC multimer-based screening of pt PBMCs revealed detection of neoepitope-specific CD8 T cells in 22 of 24 pts pre-treatment (range one to 14 neoepitope responses) and 21 of 22 pts post-treatment (up to 273 weeks after trial start; one to 19 neoepitope responses). There were large inter- and intra-patient variations of neoepitope-specific CD8 T cell responses during treatment with the largest increases occurring at the 3-wk, post-treatment initiation timepoint. We observed that pts with DCB tend to raise a broader neoantigen T cell response than patients without DCB. 38% of pts without DCB and 67% of pts with DCB exhibited an increase in neoepitope-specific CD8 T cell responses within 3 wks of treatment initiation. **Conclusions:** Using high-throughput screening, pt-specific neoepitope reactive CD8 T cells could be detected pre- and post-treatment in pts with mUC treated with atezolizumab. Phenotypic characterization of neoepitope reactive CD8 T cells is ongoing. These data may help elucidate the dynamics and characteristics of the T cells of highest relevance to the ICB-induced, anti-tumor immune response. Research Sponsor: Ludwig Grant, Other Foundation.

3076 Poster Session (Board #140), Fri, 8:00 AM-11:00 AM

Checkpoint inhibitor treatment-related cutaneous adverse events in skin of color patients at Memorial Sloan Kettering Cancer Center. *First Author: Amaris Geisler, CUNY School of Medicine, New York, NY*

Background: The advent of immune checkpoint inhibitors (CPIs) for the management of advanced malignancies has led to unintended consequences of nonspecific immune activation. Cutaneous immune related adverse events (irCAEs) are the most common and first to manifest, on average within 3.6 weeks of treatment initiation. irCAEs may require CPI treatment dose reduction or discontinuation and negatively impact patient quality of life. There is substantial variability in the reporting of these toxicities and inadequate reporting in skin of color patients (SOC), who are often underrepresented in oncology clinical trials. The purpose of this study is to characterize irCAEs in SOC cancer patients. **Methods:** A single center retrospective analysis of electronic medical records from 2009-2020 was conducted. SOC was defined as African American, Hispanic, Native American/Pacific Islander, or Asian. irCAEs were graded using the Common Terminology Criteria for Adverse Events (CTCAE) v5.0. **Results:** Of 1459 SOC patients that presented to our institution and received CPIs during the study period, 175 (12%) presented to dermatology for irCAEs [African American (56, 32%); Asian (98, 56%); Hispanic (20,11%); Native American (1, 0.5%)]. Patients' toxicities were stratified by CPI mechanism: anti-PD-1/L1 (139, 79%), combination of anti-PD-1/L1 plus anti-CTLA-4 (29, 17%), and anti-CTLA-4 therapy (7, 4%). Of 376 irCAEs, pruritus (62, 16%), xerosis (42, 11%), maculopapular rash (40, 11%), and cutaneous hyperpigmentation (36, 10%) were most frequently diagnosed. There were 86 (23%) grade 1, 93 (25%) grade 2, and 18 (5%) grade 3 events. Average time from CPI-treatment initiation to irCAE onset was 6.5 months (SD 7.9). Fifteen (9%) patients required CPI dose reduction or discontinuation due to skin toxicity. Topical corticosteroids (133, 76%) were the most frequently used treatment for all irCAEs. **Conclusions:** Our findings suggest that irCAEs occur frequently in SOC cancer patients. Furthermore, a 6.5-month delay in time to diagnosis highlights a need for increased surveillance of these cutaneous toxicities in darkly pigmented skin. Generally, SOC patients present unique diagnostic and management challenges due to differences in skin biology and propensity toward hyperpigmentation; however, in SOC *cancer* patients, the mechanisms of oncologic immunotherapy must be considered in developing successful treatment strategies and management of dermatologic health in this population. Research Sponsor: None.

3077 Poster Session (Board #141), Fri, 8:00 AM-11:00 AM

Novel blood-based biomarker predicting severe toxicity in melanoma anti-CTLA-4 immunotherapy treatment. *First Author: Vylyny Chat, New York University School of Medicine, New York, NY*

Background: Immune checkpoint inhibition (ICI) has improved clinical outcomes of metastatic melanoma (MM). However, 65-80% of treated patients experience immune-related adverse events (irAEs), urging for the availability of personalized and easy-access clinical biomarkers. We have previously shown that germline genetics related to host immunity affects ICI response and MM survival. In this study, we investigated if germline immune-related expression quantitative trait loci (ieQTLs) may predict ICI-induced irAEs in MM. **Methods:** Through a comprehensive interrogation of a healthy twin-cohort expression dataset (MuTHER), we identified 40 ieQTLs most significantly associated with the expression of 382 immune-related genes. These germline variants were genotyped using the MassARRAY system in anti-CTLA-4-treated MM patients, collected as part of a multi-institutional collaboration. Using multivariable logistic regression models, we tested the association of 40 ieQTLs with irAEs in a discovery cohort of 97 MM patients followed by a validation in additional cohort of 97 anti-CTLA-4 treated patients. **Results:** We found rs7036417 significantly associated with severe anti-CTLA-4 irAEs in the discovery (OR = 6.18; 95%CI = 1.61-23.74; p = 0.007) and validation (OR = 6.73, 95%CI = 1.42-31.86; p = 0.02) cohorts. Pooled analysis showed that carriers of two rs7036417 alternate alleles (TT) have a 6-fold increased risk of developing severe irAEs (OR = 6.11; 95% = 2.26-16.56;p = 0.0003). This association was not observed with ICI response or survival. The alternate allele of rs7036417 is associated with higher expression of *SYK* (spleen-associated tyrosine kinase), suggesting that elevated SYK contributes to developing severe irAEs. **Conclusions:** We report that rs7036417, an ieQTL in *SYK*, associates with an increased risk of severe irAEs, independent of ICI efficacy. *SYK* plays an important role in B-cell/T-cell expansion and increased pSYK has been reported in patients with rheumatoid arthritis or systemic lupus erythematosus. Based on our data, the over-expression of SYK likely explains the biological mechanisms of the association between rs7036417 and anti-CTLA4 irAEs. These findings propose a novel blood-based baseline biomarker stratifying the patients at increased risk of severe irAEs, with a clinical effect substantially surpassing those observed for currently available predictors. Our ongoing studies are currently investigating SYK eQTL as a novel target in toxicity-reducing therapies. Research Sponsor: U.S. National Institutes of Health.

3078 Poster Session (Board #142), Fri, 8:00 AM-11:00 AM

Success and failure of additional immunosuppressants in steroid-refractory pneumonitis related to immune checkpoint blockade. *First Author: Jason Beattie, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Severe immune related adverse events (irAEs) with immune checkpoint blockade are uncommon but can be fatal. Steroids are the most common initial treatment for most non-endocrine irAEs, but some patients are or become refractory to steroids. When steroids are not effective, there is limited data to guide management strategies, particularly in the context of pneumonitis. **Methods:** All patients at MSK treated with immune checkpoint blockade from 2013-2020 were queried for receipt of an immunosuppressant (e.g. TNF antagonists, mycophenolate mofetil, cyclophosphamide) beyond steroids. Patient records were then manually reviewed to identify patients who received such therapy for management of immunotherapy-related pneumonitis. **Results:** Among 5363 patients treated with immune checkpoint blockade, 364 (6.8%) received an additional immunosuppressant for an irAE, including 28 (0.5% of all patients treated) patients treated for pneumonitis. Most of these pneumonitis events (19/28, 68%) were grade 3 or higher. Agents used included mycophenolate mofetil (7/28; 25%), TNF antagonists (23/28; 82%), and cyclophosphamide (1/28; 3.5%); more than one medication was used in 3 patients (11%). The indications were primary non-response to steroids (n = 16, 57%) and recrudescence after initial response to steroids (n = 12, 43%). At 90 days from initiation of the additional immunosuppressant, 13/28 (46%) patients were alive with improvement or resolution of pneumonitis while 15/28 (54%) had died. Survival with resolution/improvement was more common in patients treated for recrudescence vs primary non-response (67% vs 25%, p = 0.05). **Conclusions:** Outcomes with additional immunosuppressants in the setting of steroid-refractory immune-related pneumonitis are poor, but resolution can occur in some cases. A deeper understanding of the mechanistic underpinnings of irAEs is needed to more effectively tailor immunosuppressant therapies, particularly in severe pneumonitis events. Research Sponsor: None.

3079 Poster Session (Board #143), Fri, 8:00 AM-11:00 AM

Preliminary results of sintilimab plus different dose of IBI305 (anti-VEGF monoclonal antibody) in patients with advanced hepatocellular carcinoma: A phase Ib study. *First Author: Wen Zhang, Department of Medical oncology, Cancer Hospital, CAMS, Beijing, China*

Background: The study aimed to evaluate the safety and efficacy of sintilimab, a PD-1 blockade, plus IBI305, a biosimilar candidate of bevacizumab, in patients (pts) with advanced hepatocellular carcinoma (HCC). **Methods:** Adults with histocytologically confirmed advanced or metastatic HCC were enrolled in this two-part study. Part 1 was dose escalation trial, with initial dose of sintilimab 200 mg plus IBI305 7.5 mg/kg, q3w (low-dose group). If tolerable, IBI305 was escalated to 15 mg/kg (high-dose group). In part 2 for extension, at least 20 pts were enrolled to each tolerable dose group. **Results:** As data cutoff (Jan. 7, 2020), 50 pts were enrolled, 29 in low-dose group and 21 in high-dose group. 41 patients were systemic treatment naïve. The median treatment cycle was 4 (range: 1-19) in low-dose group and 11 (range: 1-16) in high-dose group. Most TRAEs were G1-2 with the most common being hypertension (28.0%) and pyrexia (26.0%). Totally, the grade 3 or more TRAEs were occurred in 6 (12.0%) pts, including hypertension occurred in 2 (4%) pts. The objective response rate (ORR) per RECIST v1.1 was 24.1% (95%CI: 10.3 - 43.5) in low-dose group, and 33.3% (95% CI:13.3 - 59.0) in high-dose group. As with the cutoff date, the median PFS has not been reached and the 6-month PFS rates were 60.5% (95%CI 36.1, 78.0) and 75.8% (95% CI: 47.3, 90.2), respectively. **Conclusions:** The combination of sintilimab and IBI305 showed promising efficacy and favourable safety profile in advanced HCC in both low-dose and high-dose groups. The preliminary result of this study warrant further exploration of dose selection for anti-VEGF/VEGFR agent when combined with PD-1/PD-L1 antibody. Clinical trial information: NCT04072679. Research Sponsor: Innovent Biologics, Inc.

Antitumor activity in both groups.

3080 Poster Session (Board #144), Fri, 8:00 AM-11:00 AM

Influence of antibiotic therapy (ATB) on oncological outcomes of metastatic non-small cell lung cancer (mNSCLC) patients treated with chemo-immunotherapy (CIT). *First Author: James Clark, Department of Surgery & Cancer, Imperial College London,, London, United Kingdom*

Background: ATB exposure is proven to worsen response and survival in immunotherapy recipients. However, its influence on outcomes from CIT is currently undefined. **Methods:** We conducted a retrospective, multi-centre observational study including 77 mNSCLC patients who received pembrolizumab, pemetrexed and carboplatin CIT as first-line therapy for mNSCLC, between December 1, 2018 and January 1, 2020 in 3 academic referral centres in Europe and in the United States. We documented ATB exposure in the 30 days prior to CIT commencement (pATB) or concurrently (cATB) until CIT cessation. Outcome measures included overall (OS) and progression-free survival (PFS) calculated from commencement of CIT, and overall response rates (ORR) defined by Response Evaluation Criteria in Solid Tumors (v1.1). **Results:** We enrolled 77 patients, 41 of whom were female (n = 53%) with adenocarcinoma (n = 73, 95%), performance status (PS) 0-1 (n = 69, 90%) PD-L1 Tumour Proportion Score < 50 (n = 57, 74%). Median OS was 16.4 months (95%CI 8.4-24.4), median PFS was 6.7 months (95%CI 5.7-7.6). ORR was 48% including 1 complete (1%) and 36 partial responses (47%). Eleven patients (14%) received pATB, with penicillin/cephalosporins (p/c, n = 7, 63%) for <7 days (n = 10, 90%). Thirty-five patients (45%) received cATB with p/c (n = 11, 40%) for <7 days (n = 28, 80%). Most common indication for ATB was peri-procedure prophylaxis in pATB (n = 7, 63%) and suspected febrile neutropenia in cATB (n = 14, 40%). pATB ($p = 0.004$) but not cATB ($p = 0.85$) predicted for worse OS (19.6 vs 6.5 months, Hazard Ratio [HR] 2.9 95%CI 1.3-6.3). Neither pATB nor cATB predicted for PFS or ORR ($p > 0.05$). Multivariable analyses confirmed pATB (HR 2.3 95%CI 1.1-5.5, p = 0.05) to predict for OS independent of PD-L1 status, PS and cATB. pATB+/- groups were balanced with regards to age, gender, PS nor PD-L1 status ($p > 0.05$). **Conclusions:** Whilst cATB does not compromise outcome from CIT, this study reproduces the detrimental effects observed for pATB exposure in immunotherapy recipients. Mechanistic verification of the immune-biologic foundations underlying this association is urgently warranted. Research Sponsor: None.

3081 Poster Session (Board #145), Fri, 8:00 AM-11:00 AM

Targeting HER2 in combination with anti-PD-1 and chemotherapy confers a significant tumor shrinkage of gastric cancer: A multi-institutional phase Ib/II trial of first-line triplet regimen (pembrolizumab, trastuzumab, chemotherapy) for HER2-positive advanced gastric cancer (AGC). *First Author: Sun Young Rha, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Combining anti-PD-1 agent and trastuzumab has shown synergy in HER2 positive preclinical cancer models. We first report the result of a multi-institutional phase Ib/II trial of triple combination (pembrolizumab, trastuzumab, and chempotherapy) as first line therapy for HER2 positive AGC. (PANTHERA trial; NCT02901301). **Methods:** Pembrolizumab 200mg IV D1, Trastuzumab 6mg/kg (after 8mg/kg load) D1, Capecitabine 1000mg/m^2 bid D1-14, and Cisplatin 80mg/m^2 D1 every 3 weeks was selected as recommended phase II dose. The primary endpoint for phase II was ORR per RECIST v1.1. Secondary endpoints included PFS, OS, DoR, safety, and molecular analysis by targeted NGS. **Results:** Total of 43 patients were treated with median follow up of 16.1 months, and 11 pts remained on the treatment (treatment duration range: 1.4 to 24 months). There was significant tumor shrinkage of 95.3% with 54.6% median depth of response, with 76.7% ORR (CR 16.3%, PR 60.5%, conversion surgery 4.6%), and 97.7% DCR. Median PFS was 8.6 months (95% CI 7.2-22.0) and median OS was 18.4 months (95% CI 17.9-NA). Subsequent chemotherapy was given to 83.3% of 30 progressed pts. There were no MSI-H/dMMR or EBV-positive pts. PD-L1 status (57.1% of pts $\geq$ CPS 1 and 14.3% of pts $\geq$ CPS 10 among 35 pts), metastatic organ or baseline tumor burden was not related to the survival. Treatment-related AE ($\geq$G3) occurred in 32 pts (74.4%) including 17 pts (39.5%) with neutropenia G3-4. Immune-related AEs ($\geq$G3) occurred in 4 pts (10%). Ninety-six tumor tissues from 32 pts (paired tumor tissues from 25 pts) were analyzed with targeted NGS. TMB (median 12.7 mut/MB with range of 9.45-16.71) was not related to the PD-L1 expression or survival. **Conclusions:** First-line triplet regimen (Pembrolizumab, Trastuzumab, and Chemotherapy) confers a significant tumor shrinkage for HER2 positive AGC, regardless of PD-L1 status. Phase III Keynote-811 study (NCT03615326) is ongoing based on the protocol of this study. Clinical trial information: NCT02901301. Research Sponsor: MSD, Pharmaceutical/Biotech Company.

Response and survival of PANTHERA Trial (cut-off date: 12-31-2019).

Tumor Shrinkage rate	ORR	DCR	PFS	OS	DoR	6-months PFS
95.3%	76.7%	97.7%	8.6 months (95% CI 7.2-22.0)	18.4 months (95% CI 17.9-NA)	10.8 months (95% CI 7.2-NA)	76.7% (95% CI 65.1-90.5)

3082 Poster Session (Board #146), Fri, 8:00 AM-11:00 AM

Association of a STK11/KEAP1-mutation gene expression signature in lung adenocarcinoma with immune desertion in squamous cell carcinomas and mediation by NFE2L2 deregulation. *First Author: Damian Tobias Rieke, Department of Hematology and Oncology - Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: KEAP1 and STK11 mutations are associated with resistance to immune checkpoint inhibition (ICI) in non-small cell lung cancer (NSCLC). Mechanisms are currently unknown. **Methods:** We examined mutation, methylation, copy number and gene expression data from the cancer genome atlas (TCGA) lung adenocarcinoma (LUAD), lung squamous cell carcinoma (LSCC), head and neck squamous cell carcinoma (HNSCC) and cervical carcinoma (CESC) data sets as well as public single cell gene expression data from a HNSCC cohort. Pathway annotations were performed using gene set enrichment analysis. A previously published cohort of NSCLC patients treated with ICI was analyzed for the predictive value of NFE2L2 mutations on PFS. **Results:** Annotation of STK11 and KEAP1 mutant LUAD revealed identical gene set enrichment for mitochondrial metabolism and downregulation of the STING-pathway, immune checkpoints, and interferon signaling. A STK11/KEAP1-mutation derived gene expression signature was established in LUAD and found to be driven by NFE2L2-regulated genes. This gene expression signature was independently predictive of immune desertion in LSCC, CESC and HNSCC and associated with STING-pathway downregulation in single cell sequencing analyses in HNSCC. KEAP1 and STK11 mutations were less frequent in LSCC, CESC and HNSCC but NFE2L2 mutations were identified in 15, 6 and 5%, respectively. NFE2L2 mutant SCC exhibited upregulation of the 15-gene- signature as well as immune desertion. In NSCLC, NFE2L2 mutations were associated with significantly worse PFS with ICI. **Conclusions:** Alterations of KEAP1, STK11, NFE2L2 and other related genes are linked to NFE2L2 target gene upregulation and immune desertion in LUAD, CESC, LSCC and HNSCC alike. The NFE2L2 pathway should be investigated clinically as a putative negative predictive biomarker for ICI and a potential therapeutic target. Research Sponsor: None.

3083 Poster Session (Board #147), Fri, 8:00 AM-11:00 AM

Prevalence of human leukocyte antigen-B27 supertype in the context of positively charged neoepitopes and association with PD-L1 as an immune escape mechanism. *First Author: Charlene Marie Fares, Department of Medicine, Division of Hematology/Oncology, UCLA, Los Angeles, CA*

Background: Recent evidence suggests efficacy of immune checkpoint blockade may be influenced by human leukocyte antigen (HLA)-B. HLA-B27 supertype has an electronegative binding pocket which favorably binds and displays neoepitopes harboring positively charged amino acids (AAs). Based on immune surveillance, we postulate that B27 tumors that have favorable neoepitopes should face negative selective pressure, and B27 tumors with favorable neoepitopes that develop could be more likely to upregulate immune escape mechanisms. Here we evaluate the relationship between prevalence of B27 and positively charged neoepitopes and assess association between positively charged neoepitopes and expression of PD-L1. **Methods:** TCGA datasets from head and neck squamous cell (HNSC), lung squamous cell (LUSC), and melanoma (SKCM) patients were evaluated. HLA alleles were determined with OptiType and supertype was based on 2008 criteria. Nonsynonymous mutations were annotated with Ensembl VEP and VAtools. pVAC-Seq using NetMHCpan algorithm predicted neoepitopes 9 AAs in length. Favorable B27 neoepitopes were defined as those having new positively charged AA substitutions (H/K/R) from negative or uncharged wildtype AAs. RNA-seq data for the PD-L1 gene were normalized on transcripts per million and log2 transformed. Linear regression tests were performed between PD-L1 gene expression values and fraction of nonsynonymous mutations resulting in neoepitopes with new positively charged AAs in patients with B27. **Results:** Data from 497 HNSC, 494 LUSC, and 468 SKCM patients were analyzed. B27 was observed in 20.1%, 23.2%, and 26.5% of HNSC, LUSC, and SKCM patients, respectively, with a significant difference seen between HNSC and SKCM by chi-square test (χ^2 = 5.14, p = .023). Of new charged AAs resulting from nonsynonymous mutations, 76.3% in HNSC, 74.0% in LUSC, and 72.0% in SKCM were positively charged ($p < .05$ between all histologies, paired t-tests). In B27 patients, association between PD-L1 gene expression and fraction of neoepitopes with new positively charged AAs was seen in HNSC (r = 0.25 p = .036) and SKCM (r = 0.30 p = .007), but not LUSC (r = -0.12 p = .296). **Conclusions:** With increasing fraction of positively charged neoepitopes, a decrease in prevalence of B27 was observed, suggesting improved binding and immune elimination of tumors with favorable neoepitopes. In B27 tumors that develop despite having favorable neoepitopes, upregulation of PD-L1 could be a putative mechanism to evade immune detection. Research Sponsor: None.

3084 Poster Session (Board #148), Fri, 8:00 AM-11:00 AM

Rapid expansion of M-MDSCs and association with high levels of plasma TSLP and primary resistance to PD-1 inhibitors in metastatic NSCLC. *First Author: Sally CM Lau, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: Elevated frequency of peripheral myeloid cell populations has consistently been associated with poor response to immune checkpoint inhibitors (ICI) in metastatic non-small cell lung cancer (mNSCLC). The mechanisms underlying this relationship remains poorly understood. Thymic stromal lymphopoietin (TSLP), a cytokine involved in T-cell maturation, has been implicated in a complex feedback loop leading to tumor growth and expansion of myeloid populations. We hypothesized that TSLP levels directly correlate with the presence and expansion of myeloid derived suppressor cell (MDSC) populations and sought to explore their association with response to PD-1 inhibitors in mNSCLC. **Methods:** mNSCLC patients treated with ICIs underwent baseline and serial blood collection. Peripheral blood mononuclear cells (PBMC) were analyzed by high-dimensional flow cytometry using validated panels to evaluate T/B/NK-cell, Treg and myeloid populations. Plasma cytokines including TSLP were analyzed using ELISA and Luminex assays. Cox and logistic regressions were utilized to correlate biomarkers with progression-free survival (PFS), overall survival (OS) and radiographic response. **Results:** 30 mNSCLC patients treated with single-agent ICI were included in the analysis. TSLP level was significantly associated with expansion of monocytic(M)-MDSCs in response to ICI treatment (p=0.02). M-MDSC frequency after a median of 20 days of ICI treatment was significantly associated with progressive disease (PD), reduced PFS and OS (all $p<0.05$) whereas no correlation was seen with baseline M-MDSC frequency. Patients with a doubling of M-MDSCs (n=11) after treatment had a primary PD rate of 64% vs 24% (OR 7.0, p=0.04) and significantly worse median PFS (2.5 vs 7.8 months, HR 2.6 p=0.04). **Conclusions:** Early expansion of circulating M-MDSCs after treatment with PD-1 inhibitors is associated with elevated baseline TSLP levels and primary disease progression following ICI therapy in mNSCLC. These findings suggest that elevated TSLP and early expansion of myeloid populations may represent an important mechanism of primary resistance to PD-1 inhibitors in mNSCLC. Research Sponsor: None.

3085 Poster Session (Board #149), Fri, 8:00 AM-11:00 AM

A phase I/II study of GB1275, a first-in-class oral CD11b modulator, alone, and combined with pembrolizumab in specified advanced solid tumors or with chemotherapy in metastatic pancreatic cancer (KEYNOTE-A36). *First Author: Drew W. Rasco, START, San Antonio, TX*

Background: GB1275 is a first-in-class CD11b modulator that reduced myeloid-derived suppressor cells (MDSCs) and tumor associated macrophages (TAMs) at the tumor site, repolarized M2 immunosuppressive TAMs to an M1 phenotype, and increased tumor infiltration of activated CD8+ T cells in preclinical models. When combined with an anti-PD-1 antibody or chemotherapy, these immunomodulatory effects translated into potent anti-tumor effects and prolonged survival in orthotopic PDAC models [Panni RZ, et al. Sci Transl Med. 2019 Jul 3;11(499)]. This ongoing first-in-human study consists of dose escalation of GB1275 monotherapy (Regimen A), GB1275 + pembrolizumab (Regimen B), and GB1275 + nab-paclitaxel + gemcitabine (Regimen C), followed by Phase 2 expansion in newly diagnosed metastatic pancreatic, MSS colorectal, and PD-L1-positive gastric/GEJ cancers. Here we report interim results of the dose escalation portion of the trial. **Methods:** The dose escalation phase is based on a standard oncology phase 1, 3+3 design. Cohorts of 3 to 6 patients (pts) with histologically confirmed locally advanced/metastatic pancreatic, esophageal, gastric, MSS colorectal, prostate, or breast cancer were sequentially assigned to ascending dose levels of GB1275 taken orally twice daily (BID) in 1 of 3 regimens: Regimen A was initiated first; Regimen B commenced after completion of the first two cohorts of Regimen A, and Regimen C will be initiated when Regimen A is completed. Dose escalation was based on assessment of safety including dose-limiting toxicity (DLT). Serial blood and tumor samples were collected for pharmacokinetic (PK) and biomarker analyses. **Results:** As of January 21, 2020, 13 pts were treated, with 3 each in Regimen A (GB1275 100mg, 200 mg and 400 mg BID) dose levels and 4 in Regimen B with GB1275 100 mg BID + pembrolizumab. No DLTs have been reported. GB1275 treatment-related adverse events were reported in 5 pts; all were Grade 1 in severity. Preliminary PK analyses showed a mean elimination half-life of ~7 hours. Reduction in peripheral MDSCs was observed in the majority of pts with serial samples. Biomarker analysis in serial tumor tissue is ongoing. **Conclusions:** Preliminary data show minimal treatment-related toxicities with the studied regimens. PK data support BID dosing. Dose escalation is ongoing. Updated data will be presented. Clinical trial information: NCT04060342. Research Sponsor: Gossamer Bio, Inc.

3086 Poster Session (Board #150), Fri, 8:00 AM-11:00 AM

The spatial localization of CD163+ tumor-associated macrophages predicts prognosis and response to therapy in inflammatory breast cancer. *First Author: Christophe Van Berckelaer, Translational Cancer Research Unit, GZA Hospitals & CORE, University of Antwerp, Antwerp, Belgium*

Background: The mechanisms contributing to the aggressive biology of inflammatory breast cancer (IBC) are under investigation. A specific immune response seems to be an important driver, but the functional role of infiltrating immune cells in IBC remains unclear. Tumor-associated macrophages (TAMs) are associated with worse outcome, while CD8+ cytotoxic T cells demonstrate anti-tumor properties in breast cancer. In this study, we assessed spatial associations between CD163+ TAMs, CD8+ cells and cancer cells in IBC, using deep-learning and ecological statistics. **Methods:** We collected clinicopathological variables, evaluated PDL1-positivity (SP142, Ventana) and scored TILs according to the TIL working group guidelines on H&E slides for 144 IBC patients. Immunostainings for CD8 and CD163 (Hematoxylin-DAB) were done according to validated protocols. All slides were digitized, underwent virtual multiplexing and were evaluated in Visiopharm to quantify the number of DAB+ immune cells. Each immune cell was located using XY coordinates and spatial interactions were examined using a Morisita Horn Index (MHI). Tumor cell coordinates were collected using a deep-learning algorithm applied to the CD8-stained slide. This algorithm was trained in 18 images with more than 150.000 iterations (Deeplabv3+). **Results:** Complete pathological response (pCR) after neo-adjuvant chemotherapy was achieved by 30.6% (n= 30/98) of the patients with initially localized disease. Besides PDL1-postivity (*P*= .03), infiltration with CD8+ T cells (*P*= .02) and TAMs (*P*= .01) also predicted pCR. However, a likelihood ratio test showed no difference between a model using CD8+ cells, TAMs or TILs. Interestingly, the colocalization of CD163+ and CD8+ cells (MHI >0.83) was associated with pCR (*P*= .01) and remained significant in a multivariate model (OR: 3.18; 95% CI: 1.04 – 10.6; P= .05) including TIL score, PDL1-positivity and hormone receptor (HR) status. Furthermore, a shorter disease-free survival (DFS) was associated with HR-status, no pCR and the colocalization of TAMs near tumor cells (HR: 3.3; 95% CI: 1.6 – 7.1; P= .002) in a multivariate model. The density of TAMs was not associated with outcome. **Conclusions:** The impact of TAMs on clinical outcome appears to depend on the spatial arrangement. The number of TAMs solely was not associated with outcome, but patients with more TAMs in proximity of the tumor cells had a worse DFS. Surprisingly, the clustering of TAMs near CD8+ cells was associated with pCR independent of the number of TAMs or TILs. Research Sponsor: Research Foundation - Flanders (FWO).

3087 Poster Session (Board #151), Fri, 8:00 AM-11:00 AM

Discovery of a novel shared tumor antigen in human lung cancer. *First Author: Diane Tseng, Stanford University, Palo Alto, CA*

Background: While there has been much attention on mutation-associated neoantigens in tumors, there is less known about non-mutated tumor antigens that are shared across individuals. Understanding tumor-infiltrating T cell recognition of shared tumor antigens is important for understanding cancer immune recognition and escape, and may reveal novel targets for therapy. **Methods:** We have established a novel approach for discovering shared tumor antigens in human lung cancer. This approach involves identifying candidate T cell receptor (TCR) alpha/beta pairs that are predicted to exhibit specificity for shared tumor antigens in the context of a given human leukocyte antigen (HLA). We then screen the T cell receptor for binding to yeast display libraries of peptide-HLA. The Mark Davis lab at Stanford has previously developed an algorithm that groups T cell receptors into antigen specificity groups based on shared motifs within the TCR complementarity-determining region 3 (CDR3) sequences. Leveraging a dataset of over 700K CDR3 sequences from 178 HLA-typed non-small cell lung cancer (NSCLC) patients, we have found up to 4,300 antigen specificity groups after applying stringent cutoffs. We sequenced TCR alpha/beta pairs from 15 patients with lung adenocarcinoma (n = 4,705). **Results:** We identified an antigen specificity group enriched in tumor compared to adjacent uninvolved lungs. Antigen screening of the T cell receptor belonging to this specificity group using an A02 yeast display libraries led to the identification of a dominant peptide after four rounds of enrichment. We functionally validated that the peptide derived from the protein TMEM161A stimulated Jurkat cells expressing the TCR alpha/beta receptor of interest. We show that full-length TMEM161A protein is processed and presented into a peptide that stimulates primary T cells expressing the TCR alpha/beta receptor. We observe that a peptide from Epstein-Barr virus (EBV) protein LMP2 also stimulated the same TCR alpha/beta receptor. We have show that TMEM161A RNA and protein are overexpressed in human lung cancer compared to adjacent uninvolved lungs. **Conclusions:** We have demonstrated a novel approach toward antigen discovery and identified a shared tumor antigen TMEM161A in human lung cancer. Research Sponsor: Lung Cancer Research Foundation, Conquer Cancer Foundation of the American Society of Clinical Oncology, Ellie Guardino Cancer Foundation Award from the Stanford Cancer Institute.

3088 Poster Session (Board #152), Fri, 8:00 AM-11:00 AM

Effect of Kaiso on immune signaling of breast cancer exosomes. *First Author: Windy Marie Dean-Colomb, Lousiana State University School of Medicine, New Orleans, LA*

Background: Exosomes are communication vesicles that act as mediators of intracellular transfer of genetic information, an important role in intercommunication between tumor cells and immune cells. However, the mechanism underlining this cell-cell communication is not well understanding, particularly in African American breast cancer patients. Recently, our lab has demonstrated that Kaiso, a novel bi-modal transcription factor is highly expressed in African American breast cancer and notably, high Kaiso expression correlates with breast cancer aggressiveness and the disparity in survival outcomes of breast cancer patients of African American compared to European American patients. However, the differential expression and biological consequences of Kaiso in immune signaling of breast cancer exosomes has not been studied yet. Herein we demonstrate the biological role of Kaiso in immune signaling in breast cancer exosomes. **Methods:** In this study we utilized Nanostring immune profiling technology along with multiple *in vitro* and *in vivo* assays were used to study the role of Kaiso in breast cancer immune escape. **Results:** Nanostring pan cancer immune profiling demonstrated that European American breast cancer exosomes exhibited higher expression of TILs markers, T cell activation markers and $CD8^+$T Cells markers compared to African American ($p < 0.05$, FDR), while we observed an increase in the expression of the anti-phagocytic molecule CD47 in breast cancer patient exosomes of African American compared to European American patients. In addition to that CD47 and SIRP-α (Signal Regulatory Protein) are highly expressed in Kaiso-scrambled MDA-MB-231 cells (sh-Scr) and exosomes, whereas THBS1, which is a regulator of CD47 expression and is regarded as angiogenesis inhibitor is significantly increased in sh-Kaiso MDA-231 cells and exosomes. Additionally, we observed that Kaiso directly binds methylated sequences in the promoter region of CD47 and THBS1 by ChIP assay. Furthermore, in vivo sh-Kaiso cells injected into athymic mice exhibited delayed tumor formation after four weeks with smaller tumor size as compared to sh-SCR cells ($p < 0.05$), and we observed higher expression of THBS1 with lower expression of CD47 and SIRP-α molecules by IHC and exosomes isolated from *in vivo* tumors ($p < 0.05$), indicating that Kaiso is associated with macrophage mediated immune escape. **Conclusions:** These findings demonstrate the important role of kaiso in immune signaling through exosomes which may be related with more aggressive cancer phenotype in breast cancer, especially in African Americans. Research Sponsor: DOD.

3089 Poster Session (Board #153), Fri, 8:00 AM-11:00 AM

Immune profiling and clinical outcomes in patients treated with ramucirumab and pembrolizumab in phase I study JVDF. *First Author: Roy S. Herbst, Yale University, New Haven, CT*

Background: In Study JVDF (NCT02443324), we combined ramucirumab (VEGFR2 antagonist) and pembrolizumab (PD-1 antagonist) to simultaneously target the tumor microenvironment and immune checkpoints in patients with advanced non-small cell lung cancer (NSCLC), gastric or gastroesophageal junction adenocarcinoma (G/GEJ), urothelial carcinoma (UC) or biliary tract cancer (BTC). We reported that this combination was associated with increased antitumor activity in patients with PD-L1 positive tumors by immunohistochemistry (IHC) compared with PD-L1 negative tumors.1) Here we explore the association between baseline gene expression profiles and clinical outcomes. **Methods:** JVDF was a nonrandomized phase 1a/b trial that treated patients with intravenous ramucirumab at 8 mg/kg on days 1 and 8 (G/GEJ, BTC) or 10 mg/kg on day 1 (G/GEJ, NSCLC, UC) plus pembrolizumab (200 mg day 1) every 3 weeks.[1] Baseline tumor samples from 53 patients across 7 study cohorts were analyzed with the NanoString PanCancer Immune Profiling Panel for RNA expression and the DAKO PD-L1 IHC 22C3 pharmDx assay for PD-L1 protein expression. Clinical outcomes included progression-free survival (PFS), overall survival (OS), and objective response rate (ORR). **Results:** Across cohorts, PD-L1 gene expression was correlated with increased IFNγ gene expression and immune-related gene signatures (T effector, T cell-inflamed (TIS)), and trended with PD-L1 protein expression. Expression of immune checkpoint-related genes and myeloid-derived suppressor cell /regulatory T cell markers was increased in the NSCLC TPS$\geq$50% PD-L1 IHC subgroup (N=8), while no clear pattern of expression was observed in other cohorts. Higher T effector and TIS scores appeared associated with better survival and response in NSCLC cohorts (mean TIS: 1.21$\pm$0.80 in responders (N=7) vs -0.13$\pm$0.57 in non-responders (N=7); p=0.004), and a trend was observed in G/GEJ cohorts (mean TIS: -0.18$\pm$0.30 (N=5) vs -0.39$\pm$0.21 (N=13); p=0.207). Of note, partial responses and stable disease were also observed in NSCLC and G/GEJ patients with a low baseline inflammatory signature score. Additional analyses are ongoing and will be presented. **Conclusions:** Baseline PD-L1 gene and protein expression tends to correlate with immune-related gene expression, and an inflamed tumor microenvironment may be associated with better clinical outcomes with ramucirumab and pembrolizumab. However, interpretation is limited by lack of control arm and sample size.1) Herbst et al. Lancet Oncol. 2019 Aug; 20 (8): 1109-1123. Clinical trial information: NCT02443324. Research Sponsor: Eli Lilly and Company.

3090 Poster Session (Board #154), Fri, 8:00 AM-11:00 AM

Relationship of infusion duration to safety, efficacy, and pharmacodynamics (PD): Second part of a phase I-II study using VSV-IFNβ-NIS (VV1) oncolytic virus in patients with refractory solid tumors. *First Author: Jaime R. Merchan, University of Miami, Miami, FL*

Background: VV1 (Voyager V1) is derived from VSV, an RNA virus with low human seroprevalence, engineered to replicate selectively in and kill human cancer cells. In Part 1 of this study, we demonstrated the safety of intratumoral VV1 and dose-response, using serum IFNβ as a biomarker; we observed viral replication in tumor and concomitant lymphocyte/neutrophil trafficking (SITC 2018). 2 other studies suggested greater efficacy and higher IFNβ levels with IV administration. Longer infusion durations were reported to mitigate infusion reactions (IRRs) for another oncolytic. **Methods:** We studied 3 different infusion durations of VV1 monotherapy at the recommended phase 2 IV dose (1.7×10^{10} $TCID_{50}$) in patients with advanced solid tumors. Endpoints included safety, preliminary anti-tumor activity, viral titers, IFNβ PD and shedding. Patients received IV VV1 once on D1 and were monitored for DLT over 21 days with efficacy assessments every 6 weeks. IRRs were classified using Lee 2014 criteria for CRS as either constitutional symptoms only (G1) or involving hypotension (G2). **Results:** 18 patients were treated at 30, 60 and 180-minute durations (n = 7, 5 and 6, respectively). No DLTs, deaths or G3-4 related IRR AEs were observed. Most pts were female (67%), white (100%), with ECOG PS 0 (61%) and median 4 lines of prior systemic therapy (range 1-14) for colorectal (CRC; 56%), squamous cell carcinoma (11%), pheochromocytoma (11%), sarcoma (11%) or other (11%) cancers. The table shows results (number of patients) by infusion duration. **Conclusions:** There was no difference in safety between the 3 infusion durations, while efficacy and PD markers suggested better anti-tumor effect with 30-minute infusion. VV1 is safe for caregivers, with no viral shedding. Part 3 of this study will now treat CRC patients with VV1 in combination with a checkpoint inhibitor (avelumab). A 5-arm phase 2 basket study in combination with cemiplimab is proceeding with 30-minute infusions. Clinical trial information: NCT02923466. Research Sponsor: Vyriad.

Duration (mins)	N	IRR G1	IRR G2	Total IRRs	RECIST PR/SD	IFNβ > 150 pg/mL	Shedding
30	7	4	3	7	5	4	0
60	5	4	1	5	3	0	0
180	6	2	3	5	1	0	0

3091 Poster Session (Board #155), Fri, 8:00 AM-11:00 AM

Impact of relacorilant, a selective glucocorticoid receptor antagonist, on the immunosuppressive effects of endogenous cortisol. *First Author: Andrew Greenstein, Corcept Therapeutics, Menlo Park, CA*

Background: Cortisol, an endogenous glucocorticoid receptor (GR) agonist, controls a broad transcriptional program that affects T-cell activation, pro-inflammatory cytokine secretion, and immune cell trafficking. By selectively antagonizing GR, relacorilant may reverse the immunosuppressive effects of cortisol in solid tumor cancers. **Methods:** Immune cells and GR expression were assessed by IHC and calculated based on The Cancer Genome Atlas (TCGA) data. Human PBMCs were stimulated with αCD3+IL-12 +/- cortisol or cortisol + relacorilant. EG7 tumor-bearing mice were treated with anti-PD1 (RMP1-14) ip Q5D +/- relacorilant QD. Whole blood mRNA was measured via Nanostring, hematology was performed using standard complete blood count assays, and cytokines were assessed by immunoassays in study NCT02762981. **Results:** GR expression was observed in human tumor and immune cells. Its abundance was positively correlated with tumor infiltration of T_H2, Treg, and PDL1$^+$ cells ($P<$ .001) and negatively correlated with T_H1 cells ($P<$ .001). In PBMCs, cortisol inhibited, and relacorilant restored, CD8$^+$ T-cell activation ($P<$ .001) and pro-inflammatory cytokine secretion (TNFα $P=$ .006, IFNγ $P<$ .05). In the EG7 syngeneic model, relacorilant increased αPD1 efficacy ($P=$ .007) and decreased circulating IL-10 ($P<$ .002). In patients with advanced solid tumors, relacorilant + nab-paclitaxel systemically suppressed the expression of canonical GR-controlled genes (*ptgs2* $P<$ .001) and genes encoding candidate-immunomodulatory drug targets (*cxcl8*, *ptger4*, *ido1;* $P<$ .001). In a small subset of patients (n = 11), sustained clinical response was associated with increased T-cell count ($P=$ .06) and IFNγ ($P=$ .03), as well as decreased Tregs ($P=$ .06) and IL-10 ($P=$ .03). **Conclusions:** Evidence of T-cell activation by relacorilant was observed in PBMCs, syngeneic mouse tumors, and patients with sustained response in a Phase 1 study. This supports the hypothesis that relacorilant can reverse immune suppression by endogenous cortisol in solid tumor cancers. Clinical studies with immune checkpoint inhibitors and relacorilant are planned. Research Sponsor: Corcept Therapeutics.

3092 Poster Session (Board #156), Fri, 8:00 AM-11:00 AM

A phase I study of mRNA-2752, a lipid nanoparticle encapsulating mRNAs encoding human OX40L, IL-23, and IL-36γ, for intratumoral (iTu) injection alone and in combination with durvalumab. *First Author: Manish R. Patel, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL*

Background: mRNA-2752 is a novel mRNA-based therapeutic agent encoding OX40L T cell co-stimulator, IL-23 and IL-36γ pro-inflammatory cytokines. Here we present findings from a first-in-human study of iTu mRNA-2752 in solid tumor patients as monotherapy or in combination with durvalumab (durva). At the time of presentation, data will encompass the monotherapy escalation MTD/RDE along with the supporting translational work, and the available data in combination. **Methods:** iTu mRNA-2752 was administered every 2 weeks for up to 7 doses as monotherapy or in combination with durva in patients with advanced solid malignancy or lymphoma. Biomarker analyses include measurement of IL-23, IL-36γ and pro-inflammatory cytokine proteins in pre- and post-treatment tumor biopsies and plasma. PD-L1 immunohistochemistry was used to further characterize baseline status and changes to the TME with treatment. **Results:** As of 20 December 2019, 23 solid tumor patients have been treated either with mRNA-2752 alone (n = 14) or in combination (n = 9) and has been well tolerated with no dose limiting toxicities or related grade 3/4 toxicities. Of the 17 patients evaluated per RECIST and iRECIST, 1 had a PR (iRECIST), 6 had SD, and 10 had PD. The patient with a PR (52% tumor reduction) received 0.5 mg mRNA-2752 with durva, and had aPD-1/L1 naïve squamous-cell bladder carcinoma. Tumor shrinkage was observed in an additional 5 patients in injected and/or uninjected lesions in both monotherapy and combination. Preliminary biomarker data showed increased IL-23 and IL-36γ protein expression after 6-24 hours, and increased levels of downstream cytokines IL-22 and IL-6, respectively. Pro-inflammatory cytokines (e.g. IFN-γ, TNF-α) were also significantly increased at 1 day and 1-week post-treatment. Significant increases in PD-L1 expression predominantly in tumor-associated immune cells were observed after first dose and persisted up to 29 days after treatment. **Conclusions:** iTu mRNA-2752 given as monotherapy and in combination with durva is tolerable at all dose levels studied, and administration can be associated with tumor shrinkage. Analyses of tumor and plasma biomarkers suggest a sustained immunomodulatory effect of treatment that includes elevated IFN-γ, TNF-α, and PD-L1 levels. These data support the ongoing testing of the mRNA-2752/durva combination in the dose escalation part of the study. Clinical trial information: NCT03739931. Research Sponsor: Moderna Tx. Inc.

3093 Poster Session (Board #157), Fri, 8:00 AM-11:00 AM

Clinical activity of MCLA-128 (zenocutuzumab), trastuzumab, and vinorelbine in HER2 amplified metastatic breast cancer (MBC) patients (pts) who had progressed on anti-HER2 ADCs. *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN*

Background: MCLA-128 (zenocutuzumab), a HER3 pathway inhibitor, is a humanized bispecific full-length IgG1 antibody targeting both HER2 and HER3 with enhanced ADCC activity. The unique Dock & Block mechanism inhibits HER3 from interacting with its ligands and targets HER2 at a different epitope than trastuzumab, blocking HER2/HER3 dimerization and downstream PI3K/AKT/mTOR signaling. In MBC, HER3 overexpression and/or HER3 ligand upregulation are important drivers leading to trastuzumab resistance, indicating a role for MCLA-128. Preclinical activity was seen in HER2+ breast models when MCLA-128 was combined with trastuzumab. Furthermore, single agent MCLA-128 showed consistent antitumor activity in heavily pretreated HER2+ MBC pts. A phase 2, open-label study explored the MCLA-128/trastuzumab plus vinorelbine triplet in an MBC population. **Methods:** This open-label trial planned for up to 40 evaluable women with HER2+/amplified MBC progressing on up to 5 anti-HER2 lines including trastuzumab, pertuzumab and an anti-HER2 ADC. Pts received MCLA-128 (750 mg, 2h IV), trastuzumab (8 mg/kg loading, then 6 mg/kg) and vinorelbine (25 mg/m^2, D1 and 8), q3w. A safety run-in of MCLA-128 + trastuzumab ± chemotherapy was performed. Disease control rate (DCR; RECIST 1.1, per investigator), best overall response (BOR), overall response rate (ORR), safety, and PK are evaluated. Data cutoff was 14Nov2019. **Results:** 28 pts with a median 3 lines (range 2-5) of anti-HER2 therapy (metastatic setting) and 3 (range 1-6) metastatic sites, received a median of 5 (range 1-17) MCLA-128 cycles. Among 26 pts evaluable for efficacy, 20 patients had CR/PR/SD as BOR; DCR was 77% (90%CI: 60-89) with 1 confirmed CR and 4 PRs (2 unconfirmed). Common related AEs (all grades; G3-4) were neutropenia/neutrophil count decrease (61%; 46%), diarrhea (61%; 4%), asthenia/fatigue (46%; 0), nausea (29%; 0). No clinically significant LVEF decline was seen. At the end of cycle 1, mean trough levels of MCLA-128 was 19.1 μg/mL, and mean terminal half-life was 112 h (n = 8-11). Data on the primary endpoint, clinical benefit rate at 24 weeks, and biomarkers will be provided. **Conclusions:** The triplet MCLA-128-based combination is active in heavily pretreated pts with HER2+/amplified MBC. The regimen is safe and well tolerated with a manageable AE profile mostly related to the chemotherapy component. Clinical trial information: NCT03321981. Research Sponsor: Merus NV.

3094 Poster Session (Board #158), Fri, 8:00 AM-11:00 AM

A phase I, open-label, multicenter, single-dose escalation and multi-dose study of a monoclonal antibody targeting CEACAM1 in subjects with selected advanced or recurrent malignancies. *First Author: Roni Shapira, Chaim Sheba Medical Center, Tel Hashomer, Israel*

Background: The carcinomembryonic antigen cell adhesion molecule 1 (CEACAM1, CD66a) is a member of the CEA gene family. CEACAM1 interacts homophilically and heterophilically with CEACAM5, and is involved in various anti-proliferative activities. CEACAM1 is expressed on a variety of epithelial and hematological cells, including multiple types of cancer and activated lymphocytes. High CEACAM1 expression in some tumor types is known to be associated with poor disease prognosis. Recently it was demonstrated CEACAM1 is co-expressed on exhausted lymphocytes with other immune checkpoints such as TIM-3 and may regulate downstream activity. CM24 is a novel humanized α-CEACAM1-specific antibody with nM affinity to the N terminal domain of CEACAM1, which blocks intercellular CEACAM1 interactions. **Methods:** The primary objective was to test the safety and tolerability of CM24 in adult patients with advanced or recurrent cancer. Secondary objectives included assessment of CM24 PK and PD profiles, anti-tumor response and the recommended Phase 2 dose. Patient received IV infusion of CM24 at 7 dose levels ranging between 0.01 and 10 mg/kg in a cycle of 4 doses administered q2wks followed by a 6-week observation only period and additional 6 cycles. **Results:** 27 patients (median pretreatment of 4 prior regimens; range 2-8, 11 colorectal, 7 melanoma, 4 ovarian, 3 gastric, 2 NSCLC; 13 males, 14 females, mean age of 60 years), were included. Treatment with CM-24 was overall well-tolerated without DLTs up to 10 mg/kg. The most frequent AE was grade 1-3 increased alanine aminotransferase (7 subjects) and the most severe AE was grade 3/4 increase in gamma-glutamyltransferase (4 subjects). Drug-related AEs were observed in 63% of the subjects with grade 3-5 occurred in 3.7%. Eight subjects (29.6%) had stable disease as the best overall response. Median overall survival was 4 (3.4, 8.0) and 6.2 (2.7, 10.2) months for the 3 and 10 mg/kg doses, suggesting dose response. Cmax, AUC and t1/2 increased with increasing dose with the longest t1/2 of 11.2 days obtained at 10mg/kg. The average target occupancy of CM24 at 3mg/kg and 10mg/kg were 75% and 93%, respectively. **Conclusions:** PK and target-mediated drug disposition analysis suggest that doses higher than 10mg/kg are needed for target saturation at a q2 week regimen while a q3 week regimen is less optimal. A phase 1/2 clinical trial testing CM24 in combination with anti-PD-1 therapy in patients with NSCLC including assessment of CEACAM1 expression is warranted. Clinical trial information: NCT02346955. Research Sponsor: Merck Sharp & Dohme Corp.

3095 Poster Session (Board #159), Fri, 8:00 AM-11:00 AM

Gut microbiome to predict efficacy and immune-related toxicities in patients with advanced non-small cell lung cancer treated with anti-PD-1/PD-L1 antibody-based immunotherapy. *First Author: Taiki Hakozaki, Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan*

Background: The gut microbiome (GM) plays an important role in shaping systemic immune responses. Preclinical and clinical data suggest that GM influences anti-PD-1/PD-L1 or -CTLA-4 Antibody (Ab)-mediated anti-cancer responses. Furthermore, there is strong evidence that antibiotics (ATB) worsen clinical outcomes based on multiple retrospective and one prospective studies using immune checkpoint inhibitor (ICI). However, whether GM profiling, at baseline or post-ATB, could represent a biomarker of response in advanced non-small cell lung cancer (NSCLC) during ICI therapy remains unknown. **Methods:** We prospectively collected baseline (pre-ICI) fecal samples and clinical data Japanese patients (pts) with NSCLC treated with anti-PD-1/PD-L1 Abs in first or second-line therapy. We performed a 16S rRNA V3-V4 sequencing of gene amplicons of fecal microbes. Amplicon sequence variants were generated with dada2 R package. Diversity analysis was performed with phyloseq R. Differential abundance analysis was performed with both LEfSe and DESeq2 methods. Clinical endpoints were progression-free survival (PFS), overall survival (OS), objective response rate (ORR), and immune-related adverse events (irAE). **Results:** 70 fecal samples were analyzed. Median OS and PFS in all patients were 16.1 and 5.2 months, respectively. 16 pts (23%) were exposed to ATB 1 month prior to ICI initiation. Pts on ATB had lower α-diversity at baseline and underrepresentation of *Clostridiales* and *Ruminococcaceae UCG 13*. When analyzing ATB-free pts, lower α-diversity was observed in non-responders. In addition, *Ruminococcaceae UCG 13* was enriched in patients with OS $>$ 12 months, favorable ORR, and PFS $>$ 6 months. *Clostridiales* order was also enriched in patients with OS $>$ 12 months. Compositional GM differences were also observed between the patients who experienced clinically significant ($\geq$grade 2) irAE; *Lactobacillaceae* and *Raoultella* were enriched in pts who had no significant irAE. **Conclusions:** We demonstrated the negative influence of ATB on GM composition and identified differential bacteria repertoire in pts experiencing favorable clinical outcomes or low grade irAE. Our data pave the way to the development of diagnosis tools aimed at identifying gut dysbiosis to predict resistance or irAE during ICI for NSCLC. Research Sponsor: This work was supported by JSPS KAKENHI Grant Number JP19K16820.

3096 Poster Session (Board #160), Fri, 8:00 AM-11:00 AM

A phase I dose-escalation and expansion study of intratumoral CV8102 as single-agent or in combination with anti-PD-1 antibodies in patients with advanced solid tumors. *First Author: Thomas Eigentler, Department of Dermatology, University Hospital Tübingen, Tübingen, Germany*

Background: CV8102 is a non-coding, non-capped RNA that activates the innate (via TLR7/8, RIG-I) and adaptive immunity dose-dependently. CV8102 injected intratumorally (i.t.), as a single agent or combined with systemic anti-PD-1 antibody (Ab) led to tumor growth inhibition in animal models and showed synergism with PD-1 blockade. **Methods:** An open-label, cohort-based, dose escalation and expansion study in patients with advanced cutaneous melanoma (cMEL), cutaneous squamous cell carcinoma (cSCC), head and neck squamous cell carcinoma (hnSCC) or adenoid cystic carcinoma (ACC) is ongoing investigating i.t. CV8102 as single agent and in combination with anti-PD-1 antibodies. [NCT03291002]. **Results:** As of December 2019, 23 patients in the cohort A (single agent) and 13 patients in cohort C (combination with anti-PD-1 Ab) were exposed to at least one dose of CV8102 at dose levels of 25-600 μg (single agent) and 25-450 μg (combination). No dose limiting toxicities (DLTs) were observed within the first two weeks of study drug treatment. Most frequent TEAEs were G1/2 fatigue, fever, chills and headache. 4 (17%) patients (pts) in cohort A and 3 (23%) pts in cohort C experienced related G3 TEAEs that were manageable with supportive treatment (liver enzyme increases (3), abscess at injection site (1), hypertension (1), asymptomatic elevation of pancreatic enzymes (2)). In cohort A, 2 cMEL patients experienced an objective response according to RECIST 1.1 (1 CR in a PD-1 naïve pt and 1 PR in a PD-1 refractory pt) and 2 further pts (cMEL, hnSCC) showed SD with shrinkage of tumor lesions. **Conclusions:** CV8102 i.t. was well tolerated without dose limiting toxicities to date and showed evidence of single agent activity. Updated results on safety, efficacy and serum biomarkers will be presented. Clinical trial information: NCT03291002. Research Sponsor: CureVac AG.

3097 Poster Session (Board #161), Fri, 8:00 AM-11:00 AM

Immune activation in first-in-human anti-macrophage antibody (anti-Clever-1 mAb; FP-1305) phase I/II MATINS trial: Part I dose-escalation, safety, and efficacy results. *First Author: Petri Bono, Terveystalo Finland and University of Helsinki, Helsinki, Finland*

Background: The scavenger receptor CLEVER-1 mediates the clearance of "unwanted" self-components and is highly expressed on tumor associated macrophages (TAMs). CLEVER-1 expression is associated with immunotherapy resistance and poor survival in several cancers. Pre-clinical studies demonstrate that CLEVER-1 inhibition increases TAM pro-inflammatory cytokine secretion and antigen presentation reactivating CD8 T cell responses with robust anti-tumor activity. Targeting CLEVER-1 could therefore overcome the immunosuppressive tumor microenvironment and has led to the development of FP-1305, a humanized anti-CLEVER-1 IgG4-antibody. **Methods:** The MATINS (Macrophage Antibody To INhibit immune Suppression) trial is a multicenter first-in-human phase I/II study (NCT03733990) to assess the tolerability, safety and preliminary efficacy of FP-1305 in patients (pts) with advanced cancers including immunotherapy-refractory melanoma, cholangiocarcinoma, hepatocellular carcinoma, ovarian cancer, colorectal (CRC), and pancreatic ductal adenocarcinoma. Part 1 consisted of a dose escalation phase; 30 pts (median age 65, range 30-81) were enrolled to examine 5 dose levels (0.1, 0.3, 1.0, 3.0, 10 mg/kg), to determine the optimal dose of FP-1305 for Parts 2 and 3. Two-stage time-to-event continual reassessment method (TITE-CRM) was utilized for the dose escalation in Part 1. Pts received 1-8 cycles (median 3) of FP-1305 Q3w. FP-1305 was well tolerated without dose-limiting toxicities. A consistent increase in blood NK cells, CD8/CD4 T cell ratio, B cells and a decrease in regulatory T cells was demonstrated. FP-1305 dosing led to the activation ($CD25^+$) and Th1 skewing ($CXCR3^+$) of T cell populations including increase in effector CD8 T-cells with downregulation of several inhibitory immune checkpoint molecules (PD-1, PD-L1, CTLA-4, and LAG3). Increased circulating IFNγ levels were detected, with the highest levels in a heavily pretreated metastatic, microsatellite stable (MSS) colorectal cancer patient leading to a partial tumor response (-52%). FP-1305 is the first macrophage checkpoint inhibitor candidate promoting immune switch with promising tolerability and clinical anti-tumor activity. FP-1305 represents a novel treatment option to provoke immune response especially in non-inflamed tumors. Full safety, pharmacokinetic and efficacy results of MATINS trial (Part 1) will be presented for the first time in a final late breaking abstract. Clinical trial information: 2018-002732-24. Research Sponsor: Faron Pharmaceuticals.

3098 Poster Session (Board #162), Fri, 8:00 AM-11:00 AM

First-in-class microbial ecosystem therapeutics 4 (MET4) in metastatic solid cancer patients treated with immunotherapy: MET4-IO. *First Author: Daniel Vilarim Araujo, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Therapeutic augmentation of the intestinal microbiome to improve immunotherapy outcomes is an active area of investigation. Microbial Ecosystem Therapeutics (METs) are consortia of human-derived bacteria designed to be reproducible, scalable and safe alternatives to fecal transplant. MET4 is a first-in-class consortium of taxa associated with immune checkpoint inhibitor (ICI)-responsiveness. Here we describe preliminary results of MET4-IO, an interventional trial assessing the safety and ecological effects of MET4 in ICI recipients. **Methods:** MET4-IO is a randomized investigator-initiated trial, evaluating MET4 in solid cancer patients treated with ICI. MET4-IO involves 3 cohorts of 65 total patients: Group A, a safety cohort of 5 patients already on ICI; Group B, patients starting ICI, randomized 3:1 to receive MET4 or not; Group C, patients on ICI who experience radiological progression but not clinical deterioration, randomized 1:1 to receive MET4 or not. Stool and blood samples are collected at baseline and 4-5 additional time-points. For this interim analysis, 16S rRNA gene sequencing was performed on fecal specimens. Shannon diversity, relative abundance (RA), number and fold-change of MET4 taxa $>$ RA 0.01 were assessed and compared to controls. **Results:** As of January 26, 2020, 21 patients were enrolled (A = 5,B = 12,C = 4), and 15 (71%) received MET4. The mean age was 65.9 years, 40% were females, 52% had head and neck cancer and 19% melanoma. Sixteen patients (76%) were treated with an anti-PD1 agent as monotherapy and 5 with a combination of anti-PD1 and anti-CTLA4 antibodies. G3-4 toxicities (CTCAEv5.0) attributed to ICI were observed in 13% vs. 17% of MET4 exposed and control patients, respectively. Three patients (20%) experienced toxicities attributed to MET4, all grade 1 except G2 dyspepsia in 1 patient. A greater number of MET4-associated taxa were detectable in MET4 recipients than controls ($p < 0.01$), with a trend towards higher cumulative RA ($p = 0.10$). No significant change in Shannon diversity after MET4 was observed, however controls were more likely to lose diversity overtime than MET4 recipients ($p = 0.05$). Colonization with MET4 varied by recipient and by taxon. *Bifidobacterium*, *Collinsella* and *Enterococcus* were significantly more common and abundant in MET4 recipients than controls. **Conclusions:** In this cohort, MET4 treatment was safe and associated with higher MET4-associated taxa in recipients than controls. Further analyses including peripheral blood immunophenotyping are ongoing. Clinical trial information: NCT03686202. Research Sponsor: University Health Network, Pharmaceutical/Biotech Company.

3099 Poster Session (Board #163), Fri, 8:00 AM-11:00 AM

Open-label, phase I study evaluating feasibility and safety of subcutaneous IMP321 (LAG-3Ig fusion protein, eftilagimod alpha) combined with avelumab in advanced stage solid tumor entities: Results from stratum D of the INSIGHT platform trial. *First Author: Thorsten Oliver Goetze, University Cancer Center Frankfurt, Institut für Klinisch-Onkologische Forschung and IKF Klinische Krebsforschung GmbH am Krankenhaus Nordwest, Frankfurt, Germany*

Background: Stratum D of the INSIGHT study investigates the feasibility and safety of s.c. application of IMP321 (eftilagimod alpha) combined with the PD-L1 inhibitor avelumab in advanced stage solid tumors. The MHC class II agonist IMP321 activates antigen-presenting cells followed by CD8 T-cell activation. The addition of avelumab aims at enhancing activity by combining IMP321's activating effects on immune cells with the release of immune inhibitory effects caused by interruption of the PD-1/PD-L1 axis. **Methods:** This investigator-initiated phase I trial consists of four strata: intratumoral (A) or intraperitoneal IMP321 (B); s.c. IMP321 with SOC (C) or with PD-L1 inhibition (D). This abstract focuses on Stratum D. Patients (pts) receive 800mg avelumab i.v. q2w along with s.c. IMP321 injections (6mg IMP321 in cohort 1 and 30mg IMP321 in cohort 2). 12 pts are planned in stratum D: 6 pts in cohort 1 and 6 pts in cohort 2. Primary endpoint is safety. **Results:** So far, 8 pts have been enrolled (6 in cohort 1 and 2 in cohort 2). In 6 pts (cohort 1) treated for different tumor indications (gastric, gallbladder, colon cancer, pleural mesothelioma), no dose limiting toxicities occurred. 3 serious adverse events (SAEs) (1 acute kidney injury grade 5 in 1 pt, 2 preileus grade 3 in 1 pt) were reported, none of them was related to any of the study drugs. In total, 34 adverse events (AEs; grade 1-2, 21; grade 3, 12; no grade 4; grade 5, 1) have been documented in 5 pts. Most common grade 1-2 AEs were pain, nausea, and injection site reaction in 50%, 33%, and 17% of the pts. Most common grade 3 AEs were nausea/vomiting, preileus/ileus, and ascites in 33%, 33%, and 17% of the pts. One AE grade 5 (acute kidney injury) was reported. 4 AEs grade 1-2 were possibly or definitely related to IMP321 (injection site reaction 2x; fever; lipohypertrophy), 6 AEs grade 1-2 were possibly or definitely related to avelumab (nausea 2x; chills; fever; dyspnea; lipohypertrophy). All AEs grade 3-5 were unrelated to any of the study drugs. Of the 8 pts enrolled so far, 4 had disease progression (acc. to RECIST 1.1), 1 partial response, 1 stable disease with some extent of tumor shrinkage, and 2 have not had tumor assessment yet. **Conclusions:** Combination treatment with avelumab 800mg and IMP321 6mg is safe and well tolerated. Cohort 2 will be presented at the meeting. Clinical trial information: NCT03252938. Research Sponsor: Immutep.

3100 Poster Session (Board #164), Fri, 8:00 AM-11:00 AM

Initial results from a phase II study (TACTI-002) in metastatic non-small cell lung or head and neck carcinoma patients receiving eftilagimod alpha (soluble LAG-3 protein) and pembrolizumab. *First Author: Enriqueta Felip, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Eftilagimod alpha (efti) is a soluble LAG-3 protein that binds to a subset of MHC class II molecules to mediate antigen presenting cell (APC) activation and then CD8 T-cell activation. The stimulation of the dendritic cell network and subsequent T cell recruitment with efti may lead to stronger anti-tumor responses than observed with pembrolizumab alone. We hereby report initial results of a phase II trial (NCT03625323). **Methods:** A predefined number of patients (pts) are recruited into this 3-cohort trial irrespective of PD-L1 expression; part A: 1st line, PD-X naïve NSCLC; part B: 2nd line, PD-X refractory NSCLC and part C: 2nd line PD-X naive HNSCC. The study has a Simon's 2-stage design, with objective response rate (ORR) as primary endpoint. Secondary endpoints include disease control rate, progression free and overall survival, PK, PD and immunogenicity. Additional pts (N2) will be recruited for each part if pre-specified thresholds for ORR are met. Up to 109 pts will be enrolled. Efti is administered as 30 mg subcutaneous injection every 2 wks for 8 cycles and then every 3 wks for 9 cycles with pembrolizumab (200 mg intravenous infusion every 3 wks for up to 2 yrs). The study was approved by ethic committees and institutional review boards. **Results:** Between 04 Mar 19 and 31 Jan 2020, 48 pts were enrolled and evaluated for safety and exposure. The median age was 66 yrs (range 48-84) and 73 % were male. The ECOG was 0 in 50 % and 1 in 50 % of pts, respectively. Pts received a median of 5 (7) and in total 311 (413) pembrolizumab (efti) administrations, respectively. Three pts (6.3 %) discontinued study treatment due to AEs. The most common ($>$ 10%) adverse events (AEs) being cough (31 %), asthenia (23 %), decreased appetite (19 %), fatigue (19 %), dyspnea (17 %), diarrhea (15 %) and constipation 13 %). From part A all pts (n = 17) were evaluated. Eight pts (47 %) had a partial response (iPR) and six (35 %) had stable disease according to iRECIST representing an ORR (DCR) of 47 % (82 %). irPRs were observed in all different PD-L1 groups ($<$ 1%; $\geq$ 1 % $\leq$49 %; $\geq$ 50 %). Ten (10; 59 %) pts are still on therapy (8+ months). In part C stage 1 15/18 pts are evaluable and six (40 %) had an iPR to date. **Conclusions:** Efti in combination with pembrolizumab is safe and shows encouraging antitumor activity in all comer PD-L1 1st line NSCLC and 2nd line HNSCC. Stage 2 has opened for both parts. Clinical trial information: NCT03625323. Research Sponsor: Immutep S.A.S.

3101 Poster Session (Board #165), Fri, 8:00 AM-11:00 AM

A phase I study to evaluate the T-cell engager AMV564 alone and in combination with pembrolizumab in subjects with advanced solid tumors. *First Author: Alexander Starodub, Riverside Peninsula Cancer Institute, Newport News, VA*

Background: Overcoming the immune-suppressive tumor environment induced by myeloid-derived suppressor cells (MDSC) is a major challenge in immune therapy. CD33 signaling in immature myeloid cells promotes expansion of MDSC and production of immune-suppressive factors. AMV564 is a bivalent, bispecific T-cell engager that binds CD3 and CD33. Preferential binding of AMV564 to areas of high CD33 density enables selective targeting of MDSC. Ex vivo data (Cheng 2017; *Blood*;130:51) and an ongoing clinical trial in acute myeloid leukemia (NCT03144245) demonstrate the ability of AMV564 to deplete MDSC while sparing monocytes and neutrophils. **Methods:** In this 3+3 dose escalation study, patients with advanced solid tumors receive AMV564 once daily via subcutaneous (SC) injection for 2 out of 3 wks per cycle, alone or in combination with pembrolizumab (200 mg every 3 wks). Key objectives are to evaluate AMV564 safety, identify a maximum tolerated or recommended phase 2 dose, and evaluate PK, immunophenotype of myeloid and T cell compartments, and preliminary efficacy. **Results:** Eleven patients have been enrolled: 8 monotherapy (3 at 15 mcg/d, 5 at 50 mcg/d) and 3 combination (5 mcg/d). Tumor types include ovarian (n = 2), small bowel, gastroesophageal junction, endometrial, rectal, penile, urothelial, squamous cell carcinoma (skin), appendiceal, and non-small cell lung. AMV564 was associated with grade (G) 1-2 injection site reactions and G1-2 fevers, which were manageable with acetaminophen and diphenhydramine, as well as G2 weight gain and G3 anemia. No dose-liming toxicity has been observed in any cohort. Three monotherapy patients (15 mcg/d) were evaluable for efficacy with $\geq$1 on-treatment scan; 2 had SD and 1 PD per RECIST 1.1 criteria. T cell activation, as shown by redistribution from the periphery (margination), was apparent in the first week of dosing for most patients. Compensatory myelopoiesis led to initial expansion of MDSC which were then depleted by AMV564. Increased cytotoxic T cell activation and T-helper (Th) 1 response was evidenced by increased T-bet positive CD4 and CD8 cells and controlled or decreased regulatory T cells. In some patients, effector memory CD8 cell populations (Tem and Temra) were expanded. **Conclusions:** AMV564 is safe and tolerable when administered SC at doses of 15 mcg/d alone and 5 mcg/d in combination with pembrolizumab. AMV564 depleted MDSC populations and altered T cell profiles consistent with activation of cytotoxic T cells and a Th1 response. Clinical trial information: NCT04128423. Research Sponsor: Amphivena Therapeutics.

3102 Poster Session (Board #166), Fri, 8:00 AM-11:00 AM

An increase in serum choline levels to predict progression-free survival (PFS) in patients (pts) with advanced cancers receiving pembrolizumab. *First Author: Geoffrey Alan Watson, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Recent work from our laboratory demonstrated that T cell-derived acetylcholine induces vasodilation and increases T cell migration to infected tissues in response to viral infection (Cox et al. Science 2019). Choline acetyltransferase catalyzes the production of acetylcholine from choline and acetyl-CoA, however acetylcholine is challenging to quantify due to its extremely short half-life while choline is stable. This study is the first reported attempt to correlate serum choline levels in patients (pts) with advanced solid tumors receiving pembrolizumab with treatment outcomes. **Methods:** Blood samples were collected pre-treatment in 106 pts treated with pembrolizumab 200 mg IV Q3W in the investigator-initiated INSPIRE study (NCT02644369). Of these, 81 pts had on-treatment blood samples collected at week 7 (pre-cycle 3). Serum choline was analyzed with an HPLC-tandem mass spectrometry assay. PD-L1 staining was performed in baseline tumor tissues using 22C3 antibody and scored using modified proportion score. Tumor mutational burden (TMB) was calculated based on number of nonsynonymous mutations detected using whole exome sequencing. Multivariable Cox models were used to assess the impact of choline on PFS and OS, while adjusting for cohort, PD-L1 expression and TMB. **Results:** This pan-cancer group of 106 pts (median age 55, 62% females) comprised of 5 cohorts: squamous cell carcinoma of the head and neck = 19 pts, triple negative breast cancer = 22, high grade serous ovarian cancer = 21, melanoma = 19, mixed solid tumors = 32. With a median follow-up of 11 months, the median PFS = 1.9 months and median OS = 13.9 months for the entire cohort. In univariable analysis adjusted by cohort, baseline serum choline levels in 106 pts did not correlate with PFS or OS. However, an increase in serum choline level at week 7 compared to pre-treatment (D choline) in 81 pts was significantly associated with a better PFS (aHR 0.49, 95% CI 0.28-0.85, p = 0.01), and a trend towards a better OS (aHR 0.57, 95% CI 0.32-1.03, p = 0.064). In multivariable analysis, D choline remains significantly associated with an improved PFS (p = 0.0087) after adjustment for cohort, PD-L1 and TMB. **Conclusions:** This is the first exploratory report of serum choline levels in pan-cancer pts receiving pembrolizumab. The association between improved PFS and D choline suggests a possible role for the cholingeric system in the regulation of antitumor immunity. Further nonclinical and clinical studies are required to validate this finding. Research Sponsor: Merck.

3103 Poster Session (Board #167), Fri, 8:00 AM-11:00 AM

Single vector multiplexed shRNA provides a non-gene edited strategy to concurrently knockdown the expression of multiple genes in CAR T cells. *First Author: David Edward Gilham, Celyad, Mont-Saint-Guibert, Belgium*

Background: Engineered T cells expressing chimeric antigen receptors (CAR) are now delivering clinically relevant results in patients with advanced hematological malignancies. One critical area for future development is to modulate gene expression thereby endowing the engineered T cell with specific desired features that enhance anti-tumor activity. **Methods:** Short-hairpin RNA (shRNA) were cloned individually or multiplexed within micro-RNA scaffolds that enabled the co-expression of the individual shRNA with a CAR and a selectable marker all driven by a PolII promoter within a single retroviral vector. Primary human T cells transduced with the CAR-shRNA vectors were selected, expanded in vitro, subjected to negative selection to eliminate any remaining TCR^+ cells and examined for target gene expression and functional activity. **Results:** A 500bp DNA fragment incorporating a shRNA-specific for CD3ζ cloned into a retroviral vectoreffectively knocked down expression of CD3ζ in transduced BCMA-specific CAR T cells. The consequent reduction of cell surface TCR expression resulted in minimal cytokine production upon TCR stimulation in vitro providing a potential allogeneic CAR T approach. These CAR T cells showed no demonstrable evidence of GvHD induction when infused in NSG mice yet maintained BCMA-specific CAR activity in KMS-11 and RPMI-8226 established myeloma models. Initial studies further confirmed that two shRNA could be expressed from a single retroviral vector to modulate the expression of multiple genes. Further engineering of the microRNA framework reduced the size of the transgene load to 394bp while enabling the expression of up to 4 shRNA within a single vector. shRNA specific for CD3ζ, beta-2-microglobulin, CD52 and diacylglycerol kinase alpha were engineered into the framework downstream of a CD19-CAR. Transduced Jurkat cells showed concurrent knockdown of the respective gene products at the mRNA and protein levels. **Conclusions:** A first-in-human clinical trial evaluating the first-generation single shRNA-vector in the context of a BCMA-targeting CAR as a non-gene edited approach to allogeneic CAR T cell therapy will be initiated in 2020. The proof of principle study here shows that multiple shRNAs are active within a single viral vector thereby avoiding the need for bespoke individual clinical reagents to target multiple genes. The multiplexed shRNA vector system is now in further development to explore whether this strategy can enhance the therapeutic potential of CAR T cells. Research Sponsor: Celyad SA.

3104 Poster Session (Board #168), Fri, 8:00 AM-11:00 AM

Combination therapy with DPX-Survivac, intermittent low-dose cyclophosphamide (CPA) and pembrolizumab for the treatment of advanced and metastatic solid tumors: Early safety and efficacy results from a phase II basket study. *First Author: Henry Jacob Conter, William Osler Health System, Brampton, ON, Canada*

Background: DPX-Survivac is a targeted T cell therapy against tumors expressing survivin. The robust and durable survivin specific T cells induced by DPX-Survivac have been shown to infiltrate tumors and are associated with clinical response in blood and solid tumors. In nonclinical studies, treatment with DPX-Survivac increases PD-L1 and PD-1 expression providing the rationale for combination with anti-PD1/L1. This study investigates if enhanced clinical benefits can be achieved in a subset of solid tumor indications with different response rates to pembrolizumab single agent therapy. **Methods:** Subjects with survivin-expressing advanced, recurrent HCC, NSCLC, bladder and MSI-H tumors are enrolled to single arm, non-randomized cohorts that each utilizes a Simon 2-stage design. The primary objectives are to determine the ORR by RECIST 1.1 and safety profile of treatment with DPX-Survivac/CPA and pembrolizumab. Secondary objectives are DoR, DCR, PFS, and OS as measured by iRECIST. Exploratory analyses will look at T cell kinetics and infiltration of the tumor along with extensive biomarker analyses to further support the mechanism of action of DPX-Survivac when combined with pembrolizumab. **Results:** Thirty subjects across HCC (N = 5), NSCLC (12), bladder (6) and MSI-H (7) tumors that express survivin were enrolled for this analysis. The median number of prior lines of therapies was 2 [0 to 10]; 16/30 previously received and progressed on or after CPI therapy. As of the data cutoff, 10 subjects had at least 1 on-treatment scan. Six of 10 subjects (60%) demonstrated target lesion regressions with 3 achieving PR by RECIST (2 bladder, 1 MSI-H [endometrial]) and 3 achieving SD (2 with prior CPI), all are ongoing. Twenty-one of 30 subjects remain on treatment. Nine subjects have discontinued treatment: 5 subjects due to early progression, 2 due to unrelated AEs, and 2 withdrew consent. Treatment has been well tolerated with no immune-related AEs and 2 related SAEs reported. The majority of AE have been grade 1-2 injection site reactions. DPX-Survivac treatment induced a robust survivin-specific T cell response and tumor immune infiltration which are being evaluated for potential correlation with clinical response. **Conclusions:** DPX-Survivac/CPA with pembrolizumab is well tolerated and shows early signs of clinical efficacy and disease control in advanced and metastatic solid tumors. Clinical trial information: NCT03836352. Research Sponsor: IMV Inc.

3105 Poster Session (Board #169), Fri, 8:00 AM-11:00 AM

A phase I, dose-escalation study of ADG106, a fully human anti-CD137 agonistic antibody, in subjects with advanced solid tumors or relapsed/refractory non-Hodgkin lymphoma. *First Author: Li Zhang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: ADG106 is a fully human agonistic anti-CD137 monoclonal IgG4 antibody, targeting a unique epitope of CD137 with novel mechanism of actions for CD137 agonism, CD137 ligand antagonism and potent cross-linking *via* FcgRIIb. This phase 1 study was conducted to assess its safety, tolerability, pharmacokinetic (PK) profile, immunogenicity and preliminary efficacy. **Methods:** Eligible patients with age 18 to 75, ECOG ≤1, measurable lesion received intravenous infusion of ADG106 every 3 weeks for a maximum of 24 months. Accelerated titration was applied in 0.1mg/kg dose level and traditional Fibonacci 3+3 method was applied in 0.5, 1.5, 3.0, 5.0 and 10.0 mg/kg dose levels. A dose-expansion cohort will be started for dose levels that have been proved tolerable and with evidence of clinical or biological activity. **Results:** Data cutoff at Jan 17 2020, 15 patients [5 adenoid cystic carcinoma (ACC), 5 non-small cell lung cancer (NSCLC), 3 nasopharyngeal carcinoma, 1 malignant pleural mesothelioma and 1 follicular lymphoma] were enrolled and received treatment: 0.1mg/kg (n = 1), 0.5mg/kg (n = 3), 1.5mg/kg (n = 5), 3mg/kg (n = 3), and 5mg/kg (n = 3). Of these 15 patients, 6 with ongoing treatment, 9 discontinued (8 progression disease, 1 lack of clinical benefit). Medium treatment duration was 2 cycles (range 2-8). No dose limiting toxicities were observed. Seven (47%) patients experienced treatment-related AEs (TRAEs): rash (13%), pruritus (13%), nausea (7%), pyrexia (7%), hemoptysis (7%), mouth ulceration (7%), vomiting (7%), chest discomfort (7%), LDH increased (7%). All TRAEs were grade 1, no grade ≥3 occurred. One serious adverse event (anemia, not related) was observed. Pharmacokinetic analysis of ADG106 showed a half-life ranging from 5~10 days, with dose-dependent increase of systemic exposure. Treatment induced anti-drug antibodies were developed in 3 (20%) patients. No objective response was observed among the 14 evaluated patients. Disease control rate was 57% (8 stable disease), tumor shrinkage was observed in 3 (21%) patients (2 ACC, 1 NSCLC). **Conclusions:** ADG106 is safe and tolerable at doses up to 5 mg/kg in solid tumors and non-Hodgkin lymphoma. The dose expansion cohorts have started at selected doses. Clinical trial information: NCT03802955. Research Sponsor: None.

3106 Poster Session (Board #170), Fri, 8:00 AM-11:00 AM

Deep learning-based predictive imaging biomarker model for EGFR mutation status in non-small cell lung cancer from CT imaging. *First Author: Abhishek Mahajan, Tata Memorial Centre, Mumbai, India*

Background: Deep learning based radiogenomic (DLR) models present a promising performance in assisting lung cancer care. The purpose of this study was 1) To develop and validate DLR signatures to predict the EGFR mutation, 2) To assess the incremental value of these DLR signatures in comparison to the traditional clinical and semantic features. **Methods:** 223 patients were selected from two phase III randomized trials in patients with advanced non-squamous NSCLC with *EGFR*-sensitizing mutation and EGFR wild type who were planned to receive palliative therapy (trial 1: gefitinib or gefitinib plus pemetrexed and carboplatin and trial 2: pemetrexed maintenance and erlotinib maintenance). Our method is an end-to-end pipeline that requires only the manually selected tumour region in a CT image without precise tumour boundary segmentation or human-defined features. Two deep convolutional neural networks with 3D U-Net architectures are trained to segment lung masses and nodules from 3D regions of the CT image. The primary end point was EGFR prediction using Radiomics and DLR pipeline. We also compared the performance of combination of models in predicting the mutational status. **Results:** A total of 223 patients (mean age, 54.18 years; age range, 28–80 years) were included in this study. There were 121 (54.3%) patients with EGFR mutation and 102 (45.7%) patients who were EGFR wild type. On multivariate logistic regression analysis, Clinical variable and CT semantic features that were found to be significantly associated EGFR mutation were tumor stage, smoking status, pure solid texture, presence of non-tumor lobe nodule, and average enhancement. For predicting EGFR mutation, ROC curve plotted with clinical variables model, CT semantic variables model, Radiomics model, DLR model showed an AUC value of 0.70, 0.73, 0.94, 0.72 respectively. Clinical variables and semantic features were added to the radiomics predictive model and deep learning predictive model independently, showed further improvement in the accuracy for either model from AUC 0.94+/-0.02 to 0.96+/-0.02 and from AUC 0.72+/-0.02 to 0.82+/-0.04 respectively. **Conclusions:** The radiomics and DLR model by machine-learned information, extracted from CT images without precise manual segmentation, could predict EGFR mutation with very high accuracy. This AI based model can be used as non-invasive and easy-to-use surrogate imaging biomarker for EGFR mutation status prediction. Clinical trial information: CTRI/2018/10/022102. Research Sponsor: DBT-BIRAC research grant.

3107 Poster Session (Board #171), Fri, 8:00 AM-11:00 AM

GEN-009, a neoantigen vaccine containing ATLAS selected neoantigens, to generate broad sustained immunity against immunogenic tumor mutations and avoid inhibitory peptides. *First Author: Roger B. Cohen, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Tumor-specific neoantigens provide personalized targets for immunotherapy. Vaccines against epitopes predicted by *in silico* approaches very rarely induce $CD4^+$ and $CD8^+$ *ex vivo* T cell responses regardless of formulation. ATLAS selects neoantigens for vaccine inclusion using *ex vivo* screening of all patient-specific mutations to identify pre-existing $CD4^+$ or $CD8^+$ T cell responses and to exclude Inhibigens, which are inhibitory peptides that suppress immunity and accelerate tumor progression. The Inhibigen burden correlates with patient outcomes in observational studies and rapid tumor progression in mouse models. **Methods:** GEN-009-101 is a phase 1/2a study testing safety, immunogenicity and clinical activity in immune responsive tumors. After next-generation tumor sequencing and ATLAS testing of autologous leukocytes, up to 20 stimulatory synthetic long peptides adjuvanted with poly-ICLC comprise each personalized vaccine. Eight vaccinated patients have been followed for sustained immunological responses and clinical outcomes. **Results:** The 40 doses given across patients have induced only mild local discomfort and no DLT. Vaccination has generated immune responses against 99% of administered peptides, with both $CD8^+$ and $CD4^+$ responses in *ex vivo* fluorospot assays. To date, no patients have developed recurrent disease. Broad immunity develops as early as Day 29 and is sustained for over 12 months. Immune response against individual peptides is correlated with peptide concentration (OR = 1.26, $p \leq 0.0001$) but not with other classifiers such as GRAVY index (Grand Average of Hydropathy), tumor type, injection site or sex. The Inhibigen burden prior to treatment again correlates with disease progression. **Conclusions:** GEN-009 identifies tumor specific immune targets from the individual patient's tumor mutagens. Initial clinical data show that ATLAS antigen selection may be critical to the induction of broad, rapid and sustained immunity against tumor specific neoantigens. Clinical vaccination with PD-1 blockade is in process. Clinical trial information: NCT03633110. Research Sponsor: None.

3108 Poster Session (Board #172), Fri, 8:00 AM-11:00 AM

Evidence of intratumoral localization, activation, and immunomodulatory effect of CX-072, a probody therapeutic targeting PD-L1, in a phase I/II trial. *First Author: Susan Lyman, CytomX Therapeutics, Inc., South San Francisco, CA*

Background: PROBODY therapeutics (Pb-Tx) are masked antibodies designed to be selectively activated in the tumor microenvironment by tumor-associated proteases and to remain largely inactive in normal tissue. CX-072, a Pb-Tx directed against PD-L1, is designed to reduce the potential for immune-associated adverse events in normal tissues while maintaining anti-tumor activity. CX-072 is being investigated in PROCLAIM-CX-072 (NCT03013491), a first-in-human phase 1/2 trial. CX-072 is administered as monotherapy or in combination with ipilimumab to patients with metastatic or recurrent solid tumors or lymphomas for which approved PD-1/-L1–based therapy is not available. We present the updated results of a tissue-based biomarker program designed to assess activation, localization, and mechanism of action of CX-072 in patient tumors. **Methods:** Tumor biopsies were collected during the screening phase, and also 3–5 days after the first or third dose of 0.3–30 mg/kg CX-072. Tumor-associated protease activity was measured by tissue zymography. Intratumoral CX-072 activation was measured using capillary immunoelectrophoresis, and PD-L1 levels were measured by an ultrasensitive ELISA. Intratumoral CD8 expression was analyzed using immunohistochemistry. Intact and total CX-072 in plasma were measured by LC-MS/MS. **Results:** Twenty-six of 30 (87%) evaluable predose biopsies had detectable levels of relevant protease activity. Intratumoral activation of CX-072 was quantifiable in 3 of 8 (38%) biopsies from patients treated with CX-072 at 3 mg/kg and in 12 of 12 (100%) biopsies from patients treated with $\geq$10 mg/kg. In contrast, CX-072 remained predominantly in the intact form in circulation. The molar ratio of activated intratumoral CX-072 to total intratumoral PD-L1 ranged from ~14x to > 100x in patients dosed at 10 mg/kg, and the calculated tumor receptor occupancy for these patients was $\geq$99%, congruent with quantitative systems pharmacology model predictions. An increase in $CD8^+$ T cells and elevation of cytotoxic T-cell markers was observed in the tumors of 11 of 18 (61%) CX-072 monotherapy patients, consistent with inhibition of the PD-L1 pathway. **Conclusions:** These results demonstrate that the Pb-Tx CX-072 behaves as designed in patients. Clinical trial information: NCT03013491. Research Sponsor: CytomX Therapeutics, Inc.

3109 Poster Session (Board #173), Fri, 8:00 AM-11:00 AM

MR1 in combination with tumor mutational burden and PD-1/PD-L1 expression as a potentially novel clinical predictor for T cell exhaustion and immune checkpoint inhibitor response. *First Author: Mark Farha, University of Michigan Medical School, Ann Arbor, MI*

Background: Immune checkpoint inhibitors (ICIs) restore T cell function by reversing T cell exhaustion. Variable response to ICIs warrants the development of precise predictive biomarkers, which is challenging due to difficulty in capturing the interplay of factors involved with tumor cell immune recognition. High intratumoral expression of MR1, the MHC-I related protein basally expressed on cancer cells, may drive T cell exhaustion through presentation of cancer-specific antigens. Here, we construct a database to study the relationship between MR1, tumor mutational burden (TMB), the PD-1/PD-L1 axis and T cell exhaustion across 8,975 sequenced tumors and 27 cancer types. **Methods:** RNA Seq by expectation maximization (RSEM) values from the TCGA were collected and normalized along with expression data for markers of interest (Table). TMB was defined as the number of non-synonymous somatic mutations per sample. For each cancer, 5 cohorts were created based on ascending mean expression levels of MR1, PD-1, PD-L1, and increasing TMB. For each cancer, an "immunogenicity score" for these factors was computed, and its relationship with T cell exhaustion signatures was assessed via linear regression. Data is presented as adjusted R^2 and p-value. **Results:** While PD-1 and T cell exhaustion marker expression were correlated across cancers, the "immunogenicity score" (IS) correlated with exhaustion markers specifically in cancers with FDA-approved ICIs. Excluding MR1 from the score weakened the correlation with EOMES and TBET expression (Table). Each component of the score analyzed independently failed to show a statistically significant correlation for both EOMES and TBET expression. **Conclusions:** In this cross-cancer analysis, we support the hypothesis that presentation of metabolic intermediates in cancer cells via MR1 may drive T cell exhaustion. Also, the novel "immunogenicity score", which incorporates MR1 into standard biomarkers for response to ICIs may convey the global picture of cancer cell recognition by the immune system and warrants further investigation as a tool for predicting clinical response. SBT6050, a HER2-directed TLR8 therapeutic, as a systemically administered, tumor-targeted human myeloid cell agonist. *First Author: Heather Metz, Silverback Therapeutics, Seattle, WA*

Background: Solid tumors are replete with myeloid cells which, when activated, drive potent anti-tumor responses. Clinical development of systemically administered myeloid cell agonists, however, has been hindered by acute toxicities due to peripheral activation of the targeted cell types. Intratumoral administration, the route of delivery typically used for innate immune/myeloid cell agonists, is limited by tumor accessibility and a dependence on abscopal responses. A systemically delivered myeloid cell agonist with tumor-localized activity has the potential to overcome challenges encountered with other innate immune/myeloid cell agonists in clinical development. **Methods:** SBT6050 is a novel therapeutic comprised of a potent toll-like receptor (TLR) 8 agonist payload conjugated to a HER2-directed monoclonal antibody. Delivery of the payload into the endosome of human myeloid cells, where TLR8 resides, requires the co-engagement of HER2 on tumor cells and Fc gamma receptor on human myeloid cells. Thus, SBT6050 is designed for systemic delivery and tumor-targeted activation of human myeloid cells. **Results:** Studies with human immune cells show that SBT6050 potently induces, in a HER2-dependent manner, multiple anti-tumor immune activities due to its direct activation of myeloid cells and the subsequent induction of T and NK cell cytolytic activity. SBT6050 is designed to activate human myeloid cells only in the presence of HER2-positive tumor cells with moderate (2+ by IHC) or high (3+ by IHC) expression levels. Tumor-localized activity has been demonstrated in mouse models using a SBT6050 mouse surrogate. Systemic delivery results in robust single agent efficacy in multiple mouse tumor models, even those engineered to lack T cells, without accompanying peripheral cytokine production. Trastuzumab and SBT6050 bind to distinct epitopes on HER2 and enhanced activity is observed when the two agents are combined. **Conclusions:** SBT6050 is a systemically administered, tumor-targeted myeloid cell agonist that demonstrates single agent efficacy in multiple mouse tumor models without peripheral cytokine production. A first-in-human study with SBT6050 is expected to begin this year for patients with HER2-expressing solid tumors. Research Sponsor: Silverback Therapeutics.

3111 Poster Session (Board #175), Fri, 8:00 AM-11:00 AM

A pilot study of Bruton's tyrosine kinase inhibitor ibrutinib alone and in combination with PD-1 inhibitor nivolumab in patients with metastatic solid tumors. *First Author: Brooke Benner, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Myeloid-derived suppressor cells (MDSC) are expanded in cancer and promote immune suppression. We have shown that ibrutinib inhibits migration and immunosuppressive function of MDSC. Moreover, the combination of ibrutinib and a PD-L1 inhibitor has been found to have synergistic anti-tumor effects in a multiple solid tumor mouse models. Therefore, we conducted a pilot study testing the combination of ibrutinib and nivolumab in patients with metastatic solid tumors. **Methods:** Sixteen patients with advanced solid tumors were recruited to this trial. Ibrutinib was dosed as an oral single agent, starting 7 days prior to cycle 1 of nivolumab and given until cycle 1, day 8 of nivolumab. Nivolumab was administered intravenously on days 1 and 15 on 28-day cycles. Patients had blood samples collected prior to initiation of ibrutinib, day 1 of cycle 1, day 8 of cycle 1, day 1 of cycle 2, and at the time of disease progression. From these specimens, we measured circulating MDSC levels, other circulating immune subsets, T cell proliferation, and cytokines/chemokines levels. Circulating MDSC levels were measured by mass spectrometry. T cell function was evaluated by CFSE to monitor proliferating cells by dye dilution and cytokine/chemokine levels were measured with a U-PLEX assay. Data were analyzed using two-tailed, paired Student's *t*-tests to assess statistical significance. **Results:** An increase in circulating MDSC (22% to 28%; SD 9.158) levels was observed following 7 days of single-agent ibrutinib compared to baseline. However, in combination therapy, MDSC levels decreased (19%; SD 13.17) prior to cycle 2. Despite increasing levels of circulating MDSC, T cell function improved throughout the study. Furthermore, plasma levels of chemokines associated with MDSC recruitment and migration significantly decreased with ibrutinib treatment (IL-12, CCL2, CCL3, and CCL4). Of the 16 patients, four achieved a partial response and four achieved stable disease. Median progression free survival was 3.5 months and median overall survival was 11.5 months. **Conclusions:** The combination of ibrutinib and nivolumab was well tolerated, demonstrated early signs of immune modulation, and showed preliminary signs of promising clinical activity in patients with metastatic solid tumors. Clinical trial information: NCT03525925. Research Sponsor: Pelotonia IRP.

3112 Poster Session (Board #176), Fri, 8:00 AM-11:00 AM

A phase II, open-label study of tomivosertib (eFT508) added on to continued checkpoint inhibitor therapy in patients (pts) with insufficient response to single-agent treatment. *First Author: Anthony B. El-Khoueiry, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Despite the broad activity of checkpoint inhibitors across tumor types, primary or secondary resistance after initial response represents a major challenge. Tomivosertib (T), a potent and highly selective inhibitor of the immunosuppressive kinases MNK-1 and 2, blocks expression of checkpoint proteins PD-1, PD-L1, and LAG-3 as well as immunosuppressive cytokines IL-6 and IL-8. In preclinical models, T was shown to trigger an anti-tumor immune response and enhance the activity of checkpoint inhibitors in a T-cell dependent manner. In prior clinical studies, T had an acceptable safety profile as a single agent and in combination with anti-PD-L1 agent avelumab. **Methods:** Patients experiencing insufficient response (progression or stable disease for 12 weeks or more) to any FDA-approved checkpoint inhibitor in any approved indication were eligible. T at 200 mg oral (PO) BID was added to the existing checkpoint inhibitor until disease progression or unacceptable toxicity was noted. **Results:** 39 pts (23 male, 16 female) were enrolled across seven cancer types. Median age was 68 (range 42-85). Median prior therapies were 2 (range 1-6). The most common cancers were lung (N = 17), urothelial (N = 6), renal (N = 5) and head and neck (N = 5). 36 pts continued on anti PD-1 antibody (Pembrolizumab and Nivolumab, 18 each) and 3 on anti PD-L-1 antibody (Durvalumab 2, Atezolizumab 1) . The most common grade 3/4 treatment related adverse events occurring in more than 1 pt were alanine aminotransferase increase (2), blood creatine phosphokinase increase (2) and maculo-papular rash (2). 7 patients discontinued treatment (18%) due to adverse events attributable to either drug. Three partial responses (PR) per RECIST 1.1 were observed in pts with previous progression on checkpoint inhibitor therapy, one each in NSCLC (1/17), gastric (1/1) and renal cancer (1/5). 7 NSCLC pts (41%) were progression free for $\geq$ 24 weeks. All NSCLC patients entered the study with progression by RECIST 1.1 on single agent checkpoint inhibitor prior to adding T. **Conclusions:** The addition of T to existing checkpoint therapy was well tolerated and manifested clinical activity including objective responses in pts with progression on existing checkpoint inhibitor. A Progression Free Survival rate at 24 weeks of 41% was noted in NSCLC patients. Additional studies evaluating the addition of T to checkpoint inhibitor therapy after progression on anti PD-1 or PD-L-1 therapy are planned. Clinical trial information: NCT03616834. Research Sponsor: eFFECTOR Therapeutics.

3113 Poster Session (Board #177), Fri, 8:00 AM-11:00 AM

Characterization of NRG1 gene fusion events in solid tumors. *First Author: Sushma Jonna, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: *NRG1* fusions are actionable genomic alterations detected across tumor types. The *NRG1* gene encode for neuregulin, which serves as a ligand for ERBB3 and ERBB4 receptors and activates downstream signaling through the MAPK and PI3K pathways. Here, we update the detection of *NRG1* gene fusions across tumor types and further describe fusion characteristics. **Methods:** Samples submitted for clinical molecular profiling that included RNA-sequencing (Archer Dx or Caris MI transcriptome) were retrospectively analyzed for *NRG1* fusion events. All *NRG1* fusions with $\geq$ 3 junction reads were identified for manual review and for characterization of fusion class, intact functional domains, domain prediction, breakpoints, frame retention and co-occurring alterations by NGS. **Results:** A total of 82 *NRG1* fusion events (0.2% of 44,570) were identified. Among the fusions identified, the distribution across tumor types was as follows: non-small cell lung cancer (NSCLC, 54%), breast cancer (11%), ovarian cancer (7%), pancreatic cancer (7%), cholangiocarcinoma (6%), colorectal cancer (5%), and other (10%). Forty-two unique fusion partners were identified, the most common being *CD74* (23%), *ATP1B1* (9%), *SLC3A2* (7%), *RBPMS* (6%) and *SDC4* (4%). Almost half (47%) of all fusion events are expected to include the transmembrane domain contributed by the *NRG1* fusion partner. Lung and pancreatobilliary cancers had the highest rates of transmembrane domain retention from their fusion partners (63.6% and 54.5%, respectively). In all other tumor groups, most fusion partners lacked transmembrane domains. In 15% of cases, the chimeric transcripts are predicted to lead to increased expression of NRG1. The most commonly reported breakpoints in *NRG1* occur in exon 6 and exon 2. While fusions with the *NRG1* breakpoint at exon 2 retain the immunoglobulin (Ig) domain and all downstream portions (including EGF-like domain), those at exon 6 do not contain the Ig portion and result in shorter chimeric proteins. The breakpoints in all *CD74:NRG1* fusions, the most common fusions in NSCLC, occur at exon 5 or 6 and cause truncation of domains upstream of the EGF-like domain. In *ATP1B1:NRG1* fusions, the most common fusions in pancreatobilliary cancers, the breakpoints are at exon 1 or 2 and retain the Ig domain. **Conclusions:** *NRG1* fusion products are diverse across tumor types, but the significance of these variations is not clear. The biological and clinical implications of retaining certain domains of *NRG1* (such as the Ig domain) and of fusion partners warrants further investigation. Research Sponsor: None.

3114 Poster Session (Board #178), Fri, 8:00 AM-11:00 AM

An in vivo model to evaluate donor-dependent cytokine release in response to single-agent or combination immune-oncology therapies. *First Author: Kyle Draheim, The Jackson Laboratory, Sacramento, CA*

Background: Although immune-oncology therapies such as checkpoint inhibitor, bi-specific antibody and CAR-T cell therapies are successfully used for cancer therapy, they can have very severe adverse effects such as cytokine release syndrome (CRS). The animal models and in vitro human PBMC assays presently in use do not reliably predict CRS in patients. Currently, the only widely accepted predictors of CRS are cancer burden and therapeutic dose. Despite this, most pre-clinical assays that evaluate CRS do not incorporate cancer cells and the safety of drug combinations has not been widely explored. A predictive assay that identifies patient/cancer/therapy combinations at risk for developing CRS upfront in addition to treatment efficacy would improve the safety of immune-oncology drug development. **Methods:** We have developed sensitive in vivo humanized mouse models for quantitating CRS that are rapid, reproducible and able to show variation among PBMC donors. The NSG mouse and its derivatives are engrafted with cancer cells and human PBMCs. Mice are then dosed with checkpoint inhibitors or bi-specific antibodies as a single therapy or in combination. Cytokine release is evaluated 2-6 hours post dosing. This assay can be modified to also evaluate efficacy by using luciferase labeled cancer cells and monitoring tumor burden using the Xenogen IVIS imaging system. **Results:** For all therapy groups, each cytokine tested (including human IFN-γ, IL-2, IL-6, IL-10 and TNF) was upregulated 2-6 hours after drug treatment, but different PBMC donors had various cytokines release levels. Cytokine release levels correlated with a dose response, PBMC engraftment levels and tumor burden. We can demonstrate additive and synergistic cytokine release in the combination treated groups and compare efficacy versus single agents. Our in vivo method was able to determine CRS missed in the in vitro testing method. **Conclusions:** We have developed a rapid, sensitive and reproducible novel in vivo PBMC humanized mouse model that can differentiate human PBMC donors based on individual safety response to single agent and combination therapeutics of immune checkpoint inhibitors and bispecific T-cell-engaging antibodies. Additionally, this assay can utilize luciferase labelled cell lines to measure treatment efficacy. Using this assay, we can potentially evaluate both cytokine release and efficacy of current immune-oncology therapies as single agents and in combination. This assay has immediate utility in current and future drug development. Research Sponsor: None.

3115 Poster Session (Board #179), Fri, 8:00 AM-11:00 AM

Association between immune and tumor gene signatures with response or resistance to tislelizumab monotherapy or in combination with chemotherapy in gastroesophageal adenocarcinoma. *First Author: Jianming Xu, Department of Gastrointestinal Oncology, The Fifth Medical Center, General Hospital of People's Liberation Army, Beijing, China*

Background: Tislelizumab, an anti-PD-1 monoclonal antibody, has demonstrated clinical benefit as a single agent and in combination with chemotherapy for patients (pts) with gastroesophageal adenocarcinoma (GEA), including gastric, gastroesophageal junction (G/GEJ), and esophageal adenocarcinoma (EAC). Immune- and tumor-transcriptomic features of response and resistance to tislelizumab were assessed from data collected in two monotherapy studies (NCT02407990, CTR20160872) and one tislelizumab plus chemotherapy study (NCT03469557). **Methods:** Gene expression profiling (GEP), using the 1392-gene HTG EdgeSeq panel, was performed on baseline tumor samples from 103 pts with GEA receiving monotherapy and 13 receiving combination therapy. Signature scores were calculated using the Gene Set Variation Analysis package with publicly available gene signatures (GS). Differential gene signature (DEG) analysis was performed between responders and nonresponders (NRs) using Wilcoxon rank-sum test; GS associated with survival were evaluated using Cox proportional hazards model. **Results:** Of the 76 pts with available GEP data, 64 (n=51 G/GEJ; n=13 EAC) had evaluable responses. Across these pts with GEA, tislelizumab demonstrated antitumor activity (Table). In pts treated with monotherapy, DEG showed IFNγ GS (*IFNG*, *CXCL9*, *CXCL10*, *HLA-DRA*, *IDO1*, *STAT1*) scores were positively correlated with response (P=0.03) as well as progression-free (HR=0.5, 95% CI: 0.27–0.93) and overall survival (HR=0.44, 95% CI: 0.21–0.89). Monotherapy NRs could be clustered into distinct GEP subgroups. Compared with responders, two NR subgroups had lower IFNγ GS (P=0.002, 0.047) along with either higher epithelial-mesenchymal transition (EMT; P=0.027), and angiogenesis (P=0.002) or cell cycle (CC; P=0.097) GS expression. A third NR subgroup showed higher CC GS scores compared with responders (P=0.015), despite high IFNγ GS levels. Unlike tislelizumab monotherapy, responders to combination therapy showed higher CC GS expression versus NRs (P=0.089). **Conclusions:** While higher IFNγ GS was associated with clinical benefit with monotherapy, elevated EMT/angiogenesis and CC GS levels may indicate resistance. The effects of these signatures in pts treated with combination therapy may vary. Both immune- and tumor-intrinsic factors may be considered for validation in a phase 3 study (NCT03777657). Research Sponsor: BeiGene, Ltd.

3116 Poster Session (Board #180), Fri, 8:00 AM-11:00 AM

Investigating the tumor immune infiltrate for populations that predict immune-related adverse events (irAEs) in patients receiving PD-1 inhibitors. *First Author: Steven Michael Blum, Massachusetts General Hospital and Dana-Farber Cancer Institute, Boston, MA*

Background: The mechanistic relationship between clinical benefit and immune-related adverse events (irAEs) in response to immune checkpoint inhibitors (ICIs) remains unclear, with several clinical studies reporting that irAEs are biomarkers of responses. Single-cell RNA sequencing (scRNAseq) analysis of tumors from patients with advanced melanoma before and after treatment with ICIs have identified immune cells that correlate with response to ICIs. We sought to evaluate if these populations were also associated with irAEs. **Methods:** A published scRNAseq data set generated with the Smart-Seq2 protocol (Sade-Feldman M, et al. Cell 2018.) was re-analyzed, stratified by two definitions of irAEs: (1) toxicity requiring systemic immunosuppression (prednisone $>$ 10mg/day) or (2) systemic immunosuppression and/or endocrinopathy. Unbiased single-cell analysis was performed, followed by sub-clustering of T cell populations. The percentage of cells in each cluster was determined on a per sample basis. **Results:** 13,184 immune cells from 39 samples collected from 25 patients were re-analyzed. 27 samples were from patients who did not respond to ICIs, while 12 samples came from responding patients. 21 samples came from patients who required immunosuppression, 5 samples from patients with isolated thyroiditis, and 13 samples from patients who met neither irAE criteria. Unsupervised scRNAseq analyses focused on ICI efficacy re-capitulated published associations between response and populations that included B-cells ($p < 0.01$) and TCF7 expressing T-cells ($p < 0.01$). While these cell populations were not associated with either definition of toxicity, we observed a non-Treg CD4 expressing T cell population (0.8-10.5% cells/sample) that positively correlated with either definition of toxicity ($p < 0.05$) but not efficacy. **Conclusions:** In a patient cohort with advanced melanoma, tumor-infiltrating immune cell populations associated with response to ICI therapy were not associated with irAEs. This suggests that biomarkers of ICI response may not function as biomarkers of irAEs, and ongoing analysis will seek to validate this result. Understanding the differences between ICI response and irAEs may identify new therapeutic targets for maximizing efficacy while mitigating toxicity. 3117 Poster Session (Board #181), Fri, 8:00 AM-11:00 AM

Validation of an immunomodulatory gene signature algorithm to predict response to neoadjuvant immunochemotherapy in patients with primary triple-negative breast cancer. *First Author: Toshiaki Iwase, Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A 101-gene algorithm established as a molecular subtyping method for triple-negative breast cancer (TNBC) includes assignment of an immunomodulatory (IM) subtype based on genes active in immune cell processes. Recently, we isolated the IM concept to an independent 27-gene algorithm and its predictive ability for immunotherapy response was demonstrated in lung cancer. The objective of this study was to validate the predictive accuracy of the IM subtype as determined by the 27-gene algorithm for pathological complete response (pCR) compared with PD-L1 immunohistochemistry (IHC) staining in TNBC. **Methods:** We obtained RNA sequencing data from pretreatment core needle biopsies in 55 patients with stage I-III primary TNBC who received neoadjuvant immunotherapy (durvalumab with weekly nab-paclitaxel followed by ddAC) in phase I/II trial (NCT02489448). The 27-gene algorithm was used to determine IM positivity using a cutoff point previously validated from 71 lung cancer biopsy patients treated with immunotherapy. Results from the algorithm and PD-L1 IHC (antibody, SP263) were compared with pCR. Predictive accuracy of both methods was determined by diagnostic indicators. In cases positive for the IM subtype and pCR, we analyzed the immune microenvironment by deconvoluting the immune infiltration using a computational algorithm. **Results:** Of the 55 patients, 25 (45%) had pCR. Compared with previous subtyping methods, the 27-gene algorithm showed stronger predictive value (odds ratio, 4.125; 95% CI, 1.36-13.47; $P < 0.015$). For PD-L1 IHC, the odds ratio was 2.63 (95% CI, 0.82-9.21; $P = 0.11$). The positive predictive value, negative predictive value, positive likelihood ratio, and negative likelihood ratio for PD-L1 IHC were 0.55, 0.68, 1.43, and 0.54, respectively. For the 27-gene algorithm, these metrics were 0.65, 0.69, 2.09, and 0.51, indicating its superior accuracy for predicting pCR. The computational algorithm showed that the IM subtype and pCR were negatively associated with a macrophage-enriched microenvironment. CD4+ T cells and dendritic cells were significantly increased among the baseline immune cell population in IM-positive patients. **Conclusions:** We conclude that 27-gene algorithm is a clinically applicable and a possible predictive marker for response to neoadjuvant immunochemotherapy for patients with primary TNBC. Our immune microenvironment results suggest that antigen-presenting immune cells have a crucial role in immunochemotherapy response. Research Sponsor: Astra Zeneca.

3118 Poster Session (Board #182), Fri, 8:00 AM-11:00 AM

Significance of meflin-positive cancer-associated fibroblasts in predicting response to immune checkpoint inhibitors in non-small cell lung cancer. *First Author: Yuki Miyai, Department of Clinical Oncology and Chemotherapy, Nagoya University Hospital, Nagoya, Japan*

Background: Tumor immunity is regulated by complex interactions between cancer and immune cells, which also involves other components of the tumor microenvironment (TME). Recently, cancer-associated fibroblasts (CAFs), a major constituent of the TME, have emerged as important regulators of tumor immunity. Specifically, for example, α-smooth muscle actin or leucine-rich repeat containing 15-positive CAFs have been shown to be crucial for the suppression of tumor immunity. However, a comprehensive picture of how other CAF subset(s) are involved in tumor immunity is still lacking. Here, we show the involvement of a CAF subset highly expressing Meflin, which was recently identified as a marker of cancer-restraining CAFs in pancreatic cancer (Mizutani et al., Cancer Res, 2019), in the response of non-small cell lung cancer (NSCLC) patients to immune checkpoint inhibitors (ICIs). **Methods:** A sample cohort of 122 subjects with NSCLC who had received ICI monotherapy with nivolumab, pembrolizumab, or atezolizumab was identified at the Department of Respiratory Medicine at Nagoya University Hospital. We selected 92 eligible patients, collected formalin-fixed paraffin-embedded tumor tissues, and prepared 4–μm-thick slides for the analysis of Meflin expression by RNA-in situ hybridization assay, followed by the evaluation of treatment response of 88 patients using the iRECIST criteria. We assessed the number of Meflin-positive CAFs and divided the patients into Meflin-High (20% and more CAFs express Meflin) and -Low groups. The cut-off value was obtained by the ROC analysis. Primarily, objective response rate (ORR) was compared between Meflin-High and –Low groups. Overall survival (OS), and progression free survival (PFS) were also assessed. **Results:** Patients who started to receive ICIs till the end of March 2019 were enrolled and followed-up until the end of 2019. Analysis of the tumor tissues revealed that 24 (40.7%) of 59 Meflin-High patients responded to the ICI monotherapy. In contrast, none (0%) of 29 Meflin-Low patients showed any significant response (p-value: 0.0000174). Meflin-High groups showed statistically significant prolongations in both OS and PFS with the hazard ratios of 0.3114 [0.1591-0.6094] and 0.3997 [0.2290-0.6976], respectively. **Conclusions:** This retrospective observation indicated that the high infiltration of Meflin-positive CAFs may shape tumor-suppressive immune response and increase the sensitivity to ICIs, which differs from those of other CAF subsets. 3119 Poster Session (Board #183), Fri, 8:00 AM-11:00 AM

Deep learning-based immune phenotype analysis reveals distinct resistance pattern of immune checkpoint inhibitor in non-small cell lung cancer. *First Author: Chan-Young Ock, Lunit Inc., Seoul, South Korea*

Background: Resistance pattern and biological mechanism of immune checkpoint inhibitor (ICI) has been poorly understood. Sine suggested resistance mechanisms would be either innate resistance caused by lack of immune recruitment or acquired immune evasion after durable response of ICI treatment, we hypothesized that resistance pattern of tumor microenvironment would be distinct according to duration of ICI response in non-small cell lung carcinoma (NSCLC). In the current study, we applied deep-learning-based classification of three immune phenotypes (3IP): *inflamed*, *excluded*, and *desert*, to objectively assess the immunologic status of tumor microenvironment. **Methods:** Deep-learning algorithm of H&E Whole-Slide Images (WSI), called Lunit-SCOPE, was trained with 1,824 H&E WSI of NSCLC from Samsung Medical Center (SMC). WSI was divided into patches and each patch (~10 high-power fields) was classified as *inflamed*, *excluded* and *desert*, based on both quantity and localization of immune cells. Among NSCLC patients treated with ICI in SMC, 87 paired treatment-naïve (Pre, patch N = 15,415) and post-progression (Post, patch N = 18,197) tumor tissues were analyzed for Lunit-SCOPE. **Results:** In 87-paired samples, proportions of excluded and desert phenotypes were increased in post-progression tumor tissues (excluded; Pre 26.8% versus Post 32.5%, desert; Pre 19.5% versus Post 25.3%). Focused on 29 patients classified as inflamed in treatment-naïve, proportion of immune phenotypes of post-progression were clearly different according to duration of response, divided by median progression-free survival (PFS) of 3.7 m. Patients with rapid progression without ICI response (PFS $<$ 3.7 m) turned into desert type (46.2%), whereas durable responder (PFS $\geq$ 3.7 m) either still remained on inflamed phenotype (42.9%) or turned into excluded phenotype (21.4%). Patients who remained on inflamed phenotype had favorable overall survival after progression on ICI, compared to turned into desert type (median survival not reached versus 6.6 m, P= 0.0296). **Conclusions:** Resistance patterns of ICI are distinct according to duration of response in patients with inflamed phenotype. Rapid progressor turns off immune into desert phenotype whereas most durable responder keeps immune recruitment into tumor microenvironment, which needs tailored strategy to overcome ICI resistance. 3120 Poster Session (Board #184), Fri, 8:00 AM-11:00 AM

Deep-learning analysis of H&E images to define three immune phenotypes to reveal loss-of-target in excluded immune cells as a novel resistance mechanism of immune checkpoint inhibitor in non-small cell lung cancer. *First Author: Sehhoon Park, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Discovery of predictive biomarker to enrich the responder of immune checkpoint inhibitor (ICI) in PD-L1-low ($<$ 50%) non-small cell lung cancer (NSCLC) is still challenging. Recent study showed that loss of heterozygosity (LOH) of *HLA* led to immune evasion. In the current study, we hypothesized that 3 immune phenotype (3IP): *inflamed*, *excluded* and *desert* would be reliably classified by deep-learning algorithm of H&E image, called Lunit-SCOPE, which would dictate the responder in PD-L1-low NSCLC patients and discover a unique resistance pathway in *excluded* phenotype. **Methods:** Lunit-SCOPE was trained with 1,824 H&E Whole-Slide Image (WSI) of NSCLC from Samsung Medical Center (SMC). WSI was divided into patches (~10 high-power fields) which was classified for 3IP, based on both quantity and localization of immune cells. The 3IP was trained and optimized by considering clinical outcome of 119 NSCLC patients with PD-(L)1 inhibitor (training cohort, patches = 25,897), and validated in 62 patients enrolled in LC-biomarker study (NCT03578185, validation cohort, patches = 8,929). Tumor Proportion Score (TPS) of PD-L1 22C3 immunohistochemistry was assessed by pathologists. Tumor Mutational Burden (TMB) was calculated as number of nonsynonymous alterations throughout whole-exome and *HLA* LOH was called by LOHHLA algorithm. **Results:** Interactive analysis to classify 3IP in training cohort showed that 8,726 (33.7%), 10,965 (42.3%), and 6,206 (24.0%) patches were classified as *inflamed*, *excluded*, and *desert*, respectively. In validation cohort, median progression-free survival (mPFS) of *inflamed* phenotype was 10.1 m, significantly prolonged compared to either *excluded* phenotype (3.0 m, P= 0.0053) or *desert* phenotype (1.4 m, P= 0.0011). *Inflamed* phenotype independently dictated favorable ICI outcome in PD-L1-low (TPS $<$ 50%, mPFS of *inflamed*: 14.3 m vs *excluded/desert*: 1.4 m, P= 0.0233) as well as in PD-L1-high (TPS$\geq$50%, 10.1 m vs 4.2 m, P= 0.0361), respectively. *Excluded* phenotype had higher TMB compared to *inflamed* phenotype had (median 177 vs 107), and *HLA* LOH was also enriched in *excluded* phenotype (31.0%) compared to *inflamed* (17.6%) and *desert* (16.7%) phenotypes. **Conclusions:** Lunit-SCOPE based 3IP classification can predict ICI outcome especially in PD-L1-low ($<$ 50%) patients. *Excluded* phenotype showed poor ICI outcome even with high TMB, partially explained by *HLA* LOH resulting in loss-of-target, as a novel resistance mechanism of ICI. Research Sponsor: Lunit Inc.

3121 Poster Session (Board #185), Fri, 8:00 AM-11:00 AM

Gene signature of antigen processing and presentation machinery (APM) as highly predictive of response to checkpoint blockade in lung cancer and melanoma. *First Author: Jeffrey C. Thompson, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Treatment of non-small cell lung cancer (NSCLC) with immune checkpoint blockade (ICB) has resulted in striking clinical responses, but only in a subset of patients (pts), underscoring the need to identify genomic and molecular determinants of immune evasion. Limited data exist on the potential role of alterations in HLA Class I antigen processing and presentation machinery (APM) in mediating response to ICB. **Methods:** We conducted a retrospective cohort study analyzing transcriptional profiles from pre-treatment tumor samples of chemotherapy-refractory advanced NSCLC pts treated with ICB. RNA was analyzed using the AmpliSeq transcriptomic platform. An APM signature was generated utilizing 8 genes associated with antigen processing (*B2M, CALR, NLRC5, PSMB9, PSME1, PSME3, RFX5, HSP90AB1*) and was examined for its association with response to therapy and progression-free and overall survival (PFS, OS). The APM signature was then evaluated in two independent melanoma cohorts treated with ICB. **Results:** We analyzed pre-treatment tumor samples from 51 advanced NSCLC pts treated with ICB, median age 64 (range 31-92), smokers (n = 43), adenocarcinoma (n = 31). There were 23 responders and 28 non-responders. The APM signature was significantly higher in responders compared to non-responders (average z-score 2.69 vs. -2.49, p = 0.0001). An APM score above the median value for the entire cohort was significantly associated with improved PFS (HR 0.24, 95% CI, 0.12-0.47, log-rank = 0.001) and OS (HR 0.34, 95% CI, 0.18-0.67, log-rank = 0.005). The APM score was significantly correlated with the well-validated T-cell-inflamed resistance gene expression profile (GEP) score (R^2 = 0.32, p $<$ 0.0001). However, the APM score demonstrated improved ability to predict response to ICB relative to the GEP score with AUCs of 0.83 and 0.69, respectively. In an independent cohort of 14 high-risk resectable stage III/IV melanoma pts treated with neoadjuvant anti-PD1 therapy, upregulation of genes involved in antigen processing was associated with improved disease free survival (HR: 0.08, 95% CI, 0.01-0.50, p = 0.0065). In an additional independent melanoma cohort of 28 metastatic pts treated with ICB, a higher APM score was associated with improved overall survival (HR 0.31, 95% CI, 0.09-0.89, log-rank = 0.044). **Conclusions:** Our data demonstrate that defects in antigen presentation may be an important feature in predicting outcomes to ICB in both lung cancer and melanoma. 3122 Poster Session (Board #186), Fri, 8:00 AM-11:00 AM

A machine learning-based approach for the inference of immunotherapy biomarker status in lung adenocarcinoma from hematoxylin and eosin (H&E) histopathology images. *First Author: Cory Batenchuk, Verily Life Sciences, South San Francisco, CA*

Background: The current standard work-up for both diagnosis and predictive biomarker testing in metastatic non-small cell lung cancer (NSCLC), can exhaust an entire tumor specimen. Notably, gene mutation panels or tumor mutation burden (TMB) testing currently requires 10 tissue slides and ranges from 10 days to 3 weeks from sample acquisition to test result. As more companion diagnostic (CDx)-restricted drugs are developed for NSCLC, rapid, tissue-sparing tests are sorely needed. We investigated whether TMB, T-effector (TEFF) gene signatures and PD-L1 status can be inferred from H&E images alone using a machine learning approach. **Methods:** Algorithm development included two steps: First, a neural network was trained to segment hand-annotated, pathologist-confirmed biological features from H&E images, such as tumor architecture and cell types. Second, these feature maps were fed into a classification model to predict the biomarker status. Ground truth biomarker status of the H&E-associated tumor samples came from whole exome sequencing (WES) for TMB, RNAseq for the TEFF gene signatures or reverse-phase protein array for PD-L1. Digital H&E images of NSCLC adenocarcinoma for model development were obtained from the cancer genome atlas (TCGA) and commercial sources. **Results:** This approach achieves $>$ 75% accuracy in predicting TMB, TEFF and PD-L1 status, offers a way to interpret the model, and provides biological insights into the tumor-host microenvironment. **Conclusions:** These findings suggest that biomarker inference from H&E images is feasible, and may be sufficiently accurate to supplement or replace current tissue-based tests in a clinical setting. Our approach utilizes biological features for inference, and is thus robust, interpretable, and readily verifiable by pathologists. Finally, biomarker status inference from a single H&E image may enable testing in patients whose tumor tissue has been exhausted, spare further tissue use, and return test results within hours to enable rapid treatment decision-making to maximize patient benefit. Research Sponsor: Verily Life Sciences.

3123 Poster Session (Board #187), Fri, 8:00 AM-11:00 AM

Extrachromosomal DNA (ecDNA) carrying amplified oncogenes as a biomarker for insensitivity to pembrolizumab treatment in gastric cancer patients. *First Author: Jason H. Christiansen, Boundless Bio, Inc., La Jolla, CA*

Background: In the KEYNOTE-059 study, the anti-PD-1 checkpoint inhibitor pembrolizumab was shown to have a modest overall response of 11.6%. Common predictors of response including, high microsatellite instability (MSI-H), PD-L1 expression, tumor mutational burden (TMB) and tumor inflammation signature (TIS), were not individually sufficient for patient selection. Recent pancancer studies have highlighted a unique population of cancer patients whose tumors appear to be driven by oncogene amplifications on extrachromosomal DNA (ecDNA). These ecDNA-driven tumors are aggressive and characterized by high levels of genomic instability. We sought to understand if tumors that possess ecDNA may represent a subset of the patient group that is non-responsive to anti-PD-1 therapy. **Methods:** We determined the ecDNA status of gastric cancer patients (N = 108) using whole genome sequencing (WGS) from the TCGA Pan-cancer dataset These patients had been previously subtyped for EBV status, genomic stability (GS), microsatellite instability (MSI), and chromosomal instability (CIN). Patients that were ecDNA+ were re-classified into a set regardless of gastric subtype. Additionally, TMB, TIS, and PD-L1 expression levels were collected. **Results:** 32% of gastric cancer patients were positive for ecDNA signatures and mutually exclusive from the 23% of MSI-H patients. We found that ecDNA positive tumors had statistically significantly lower TIS than all other groups (p-value < 0.05) except CIN tumors (p-value = 0.09). The ecDNA positive tumors also had lower PD-L1 expression than all but GS tumors. Only MSI-H showed statistically significantly higher TMB scores compared to every other group (p-value < 0.001), no difference in TMB scores were observed between every other pair of groups. **Conclusions:** Patients whose tumors are ecDNA positive represent a unique population that display signatures for non-response to checkpoint inhibitor therapy, including MSS, low TIS, and PD-L1 expression. Thus, the determination of tumor ecDNA status may have utility as an additional patient selection strategy for checkpoint inhibitor therapy. As ecDNA are not limited to gastric cancers, this study highlights the importance of the development of a clinical diagnostic test for ecDNA status and the need for further research on ecDNA biology, its impact on immunotherapy response, and potential ecDNA-directed therapeutics Research Sponsor: Boundless Bio, Inc.

3124 Poster Session (Board #188), Fri, 8:00 AM-11:00 AM

The prevalence of HLA LOH across 10 cancer types in Chinese patients. *First Author: Jian'An Huang, The First Affiliated Hospital of Soochow University, Suzhou, China*

Background: Recognition of tumor neoantigen is the key to generating immune response. The expression and integrity of human leukocyte antigen (HLA) are the prerequisites for neoantigen presentation, and loss of heterozygosity in HLA (HLA LOH) may facilitate immune evasion. However, the incidence of HLA LOH in Chinese cancer patients is unknown. **Methods:** In this study, 45 samples sequenced with both 1021-gene panel and whole-exome sequencing(WES) were used to evaluate the consistency of HLA LOH in the two testing strategies. The prevalence of HLA LOH analysis was performed in 1546 advanced patients across 10 diverse cancer types and 114 early-stage lung cancer patients who had undergone tumor profiling using 1021-gene panel. Exon 2, exon 3 and bilateral introns of *HLA-A/B/C* genes were well covered in 1021-gene panel. HLA LOH were analysis using LOHHLA algorithm (McGranahan, et al. 2017). **Results:** In the HLA LOH analysis of 45 samples, the consistency of 1021-gene panel and WES was 95.6% (43/45). Among the 1660 samples, 1.3% (21) were detected as HLA homozygous at all of the three site. HLA LOH was found in 45.1% (697/1546) of all the advanced patients, range from 24.1% to 59.7%. In colorectal cancer, the HLA LOH ratio of MSS samples was significantly higher than that of MSI-H samples (46.2%, 61/132 vs 16.7%, 3/18 p =0.0214). For NSCLC, the proportion of HLALOH in early-stage (I-IIIa) lung adenocarcinoma and lung squamous cell carcinoma was 25.7% (18/70) and 65.9% (29/44), respectively, consistent with the report. However, advanced (IIIa-IV) lung adenocarcinoma and lung squamous cell carcinoma were 49.4%(168/340) and 58.7%(179/305), respectively. The reason for the difference between early-stage lung adenocarcinoma and advanced lung adenocarcinoma needs further study. In 43.8% of cases (326/744), LOH occurred simultaneously in HLA-A, B and C,suggesting that the Class I locus was often lost together. **Conclusions:** We can use multi-gene panel for HLA LOH analysis, provided that the relevant regions are well captured. The prevalenceof HLA LOHpresent differences among cancer types.Understanding these distributions may provide more information for immunotherapy research. Research Sponsor: None.

HLA statusacross 10 cancer types in advanced patients.

Cancer types	Percent with HLA LOH
Breast cancer	42.1% (53/126)
Cervical cancer	59.7% (43/72)
Colorectal cancer	43.8% (70/160)
Endometrial cancer	23.8% (10/42)
Gastric and esophageal cancers	39.6% (57/144)
Kidney cancer	32.1% (25/78)
Liver cancer	24.1% (19/79)
Non-small-cell lung cancers	53.7% (347/645)
Ovarian cancer	38.2% (52136)
Pancreatic cancer	32.8% (21/64)

3125 Poster Session (Board #189), Fri, 8:00 AM-11:00 AM

CIMAC-CIDC tissue imaging harmonization. *First Author: Guray Akturk, Icahn School of Medicine at Mount Sinai, New York City, NY*

Background: The Cancer Immune Monitoring and Analysis Centers Cancer Immunology Data Commons (CIMAC-CIDC) network is a NCI Cancer Moonshots initiative to provide state-of-the-art technology and expertise for immunotherapy clinical trials. Multiplex tissue immunostaining is an integral assay provided that examines density and spatial distribution of immune cells and markers in tissues, for their prognostic or predictive value. Two approaches were evaluated for sensitivity, specificity, and reproducibility and subsequently harmonized: chromogenic-based Multiplex Immunohistochemical Consecutive Staining on Single Slide (MICSSS) and Multiplex Immunofluorescence (mIF) based tyramide signal amplification system. **Methods:** Harmonization was performed across CIMACs (Mount Sinai, Dana Farber Cancer Institute, MD Anderson Cancer Center) in multiple steps to prove that comparable data can be generated independent of site and platform. Goals: 1) harmonize image analysis platforms alone using tissues pre-stained with single chromogenic IHC for CD3 (membrane), Ki67 (nuclear), and CD68 (cytoplasmic), 2) compare image acquisition platforms, 3) streamline Antibody (Ab) clones and assess PD-L1 detection in relation to CLIA- assays, 4) harmonize staining protocols, image acquisition, and analysis platforms on 2 test head and neck tumor samples using MICSSS and mIF, 5) validate harmonization results with a tissue microarray on 27 tissues representing multiple tumors. For last steps, each CIMAC used their platforms for PD-L1, PD-1, CD3, CD8, and pan-cytokeratin (PanCK) staining on one of three consecutive slides from serial sections and compared densities of each marker. **Results:** Variables as PD-1 Ab clone, positive control reference tissues, sigma value for nuclear segmentation, and use of machine-learning based cell classifier were found to be key to produce accurate, reliable, comparable data. After visual quality control assessment and comparisons of each Region Of Interest (ROI), an overall inter-site Spearman correlation coefficient of ≥ 0.85 was achieved per marker within each tissue and across tissue types (expect pan-Cytokeratin, ≥ 0.7), with average coefficient of variation ≤ 0.1. **Conclusions:** These results show for the first time that two platforms can deliver harmonized data, despite differences in protocols, platforms, reagents, and analysis tools. Data resulting from retrospective and prospective CIMAC-CIDC analyses may be used with confidence for statistical associations with clinical parameters and outcome. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

3127 Poster Session (Board #191), Fri, 8:00 AM-11:00 AM

VCAN accumulation and proteolysis as predictors of T lymphocyte-excluded and permissive tumor microenvironments. *First Author: Philip Emmerich, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: Immune checkpoint inhibitors (ICIs) represent a major advance for treating solid tumors. However, only a minority of patients (pts) benefit from these therapies and markers that predict response have been elusive. Versican (VCAN) is an immunosuppressive proteoglycan in the tumor microenvironment (TME), which releases an immunostimulatory N-terminal fragment versikine (Vkine) when cleaved by ADAMTS proteases. We have demonstrated in colorectal cancers (CRC) that a low VCAN/high Vkine (VCAN proteolytic predominant [VPP]) phenotype correlates with increased tumor-infiltrating $CD8^+$ T lymphocytes (TILs). Here we examine the accumulation of VCAN as a marker of immune exclusion and its proteolysis as a marker of an immune-permissive TME. **Methods:** Immunohistochemistry for VCAN, Vkine and CD8+ was performed on samples from 1662 pts across breast (BC), CRC, endometrial cancer, pancreatic adenocarcinoma (PDAC), esophageal cancers and neuroendocrine tumors (NETs), across stages of disease (I-IV) and with diverse prior treatments. Stromal intensities of VCAN and Vkine staining quantified in collaboration with blinded surgical pathologists using a 0-3+ scale. 0/1+ were considered "low" for both VCAN and Vkine, whereas 2/3+ were considered "high". The number of $CD8^+$ TILs were counted using 400x magnification, the equivalent of a high power field (hpf). **Results:** Across the entire cohort VCAN phenotypes were diverse (VCAN high/Vkine low, 21%; VCAN high/Vkine high, 23%; VCAN low/Vkine low, 29%; VCAN low/Vkine high (VPP), 27%). Consistent with VCAN accumulation as a marker of T cell exclusion, VCAN low cancers had increased TILs compared to VCAN high (4.8 vs 18.3 TILs/hpf, $p < 0.001$). Low VCAN was identified in 85% esophageal, 79% NET (including small cell lung cancer [SCLC]) 72% endometrial, 47% MSI-H CRCs, 28% triple-negative BC and only 22% MSS CRC, 18% PDAC, 17% ER+ BCs. The VPP subgroup had the highest TILs per hpf across tumors. VPP was identified in 47% of esophageal, 45% endometrial, 41% NETs (including SCLC), 24% MSI-H CRCs, and only 9% MSS CRC, 7% ER+ BCs, 3% triple-negative BCs, and 0% of PDAC (n = 131 PDAC pts). **Conclusions:** VCAN accumulation correlates with T lymphocyte exclusion, while VCAN proteolysis predicts an immune permissive phenotype. VCAN accumulation and proteolysis are now incorporated into ICI clinical trials as a potential marker of response. Future studies will clarify the role of these biomarkers in predicting benefits of immuno-oncology treatment strategies. Research Sponsor: Funk Out Cancer, Bowlin for Colons.

3128 Poster Session (Board #192), Fri, 8:00 AM-11:00 AM

The HLA Ligand Atlas: A novel immuno-oncology resource for T-cell antigen discovery. *First Author: Ana Marcu, University of Tübingen, Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies", Tübingen, Germany*

Background: The human leukocyte antigen (HLA) complex regulates the adaptive immune response by showcasing the intracellular and extracellular protein content to the immune system, which is the basis for T cell-dependent tumor rejection. Therefore, a comprehensive map of the entirety of both HLA class I- and class II-presented peptides from various benign tissues is a highly sought after resource, as it enables the definition of tumor-association on the immunologically pivotal level of the HLA ligandome. **Methods:** Human tissue samples were snap frozen *post mortem* during autopsy. The study was approved by the local IRB. HLA ligands were immunopurified and characterized using an Orbitrap Fusion Lumos mass spectrometer coupled to an Ultimate 3000 RSLC Nano UHPLC System. Data acquisition was performed as technical triplicates in data-dependent mode, and data were analyzed using the containerized, computational pipeline MHCquant. **Results:** In this work, we describe the HLA Ligand Atlas, a comprehensive collection of matched HLA class I and class II ligandomes from 29 non-malignant tissues and 13 human subjects (208 samples in total), covering 38 HLA class I, and 17 HLA*DRB alleles and comprising 48,381 HLA class I and 16,146 HLA class II peptides. Nearly 50% of HLA ligands have not been previously described. The HLA Ligand Atlas is publicly available as a raw data resource, but also in the form of a user-friendly web interface that allows users to quickly formulate complex queries against the data set. Both downloadable data and the query interface are available at www.hla-ligand-atlas.org. **Conclusions:** This data set provides a valuable tool for research in diverse fields such as systems biology, general immunology, autoimmune disease and organ transplantation. Most importantly, the HLA Ligand Atlas provides essential information for translational applications in immuno-oncology. The knowledge of HLA ligands from benign tissues strongly supports the informed design of proteogenomic HLA-dependent target discovery approaches. 3130 Poster Session (Board #194), Fri, 8:00 AM-11:00 AM

Machine learning-based identification of predictive features of the tumor micro-environment and vasculature in NSCLC patients using the IMpower150 study. *First Author: Amaro Taylor-Weiner, PathAI, Boston, MA*

Background: IMpower150 is a phase 3 study measuring the effect of carboplatin and paclitaxel (CP) combined with atezolizumab (A) and/or bevacizumab (B) in patients with advanced nonsquamous NSCLC, testing the hypothesis that anti-PD-L1 therapy may be enhanced by the blockade of VEGF. Here, we apply a machine-learning based approach to quantify the tumor micro-environment (TME) and vasculature and identify associations with clinical outcome in IMpower150. **Methods:** Digitized H&E images were registered onto the PathAI research platform (n=1027). Over 200K annotations from 90 pathologists were used to train convolutional neural networks (CNNs) that classify human-interpretable features (HIFs) of cells and tissue structures from images. Blood vessel compression (BVC) indices were calculated using the long versus short axes for each predicted blood vessel. HIFs were clustered to reduce redundancy, and selected features were associated with progression free survival (PFS) within each arm (ABCP, ACP, and BCP) using Cox proportional hazard models. **Results:** We used the trained CNNs to generate 4,534 features summarizing each patient's histopathology and TME. After association with survival and correction for multiple comparisons we identified clusters that were significantly associated with survival in at least one arm. Among patients receiving treatments that target PD-L1 (ABCP and ACP), high lymphocyte to fibroblast ratio (LFR) was associated with improved PFS (HR=0.64 (0.51, 0.81), $p < 0.001$) and showed no significant association with PFS among patients treated with BCP alone (HR=1.13 (0.85, 1.51), p=0.4). Among BCP treated patients, a higher average BVC within the tumor tissue was associated with improved PFS (HR=0.67 (0.50,0.90), p=0.01) and worse PFS among patients treated with ACP (HR=1.50 (1.10,2.06), p=0.009). **Conclusions:** We developed a deep learning-based assay for quantifying pathology features of the TME and vasculature from H&E images. Application of this system to Impower150 identified an association between high LFR and improved PFS among patients receiving PD-L1 targeting therapy, and between low BVC and improved PFS among patients receiving BCP. These findings support the importance of the TME and vasculature in determining response to PD-L1 and VEGF-targeting therapies. Research Sponsor: Genentech.

3131 Poster Session (Board #195), Fri, 8:00 AM-11:00 AM

Effect of chemokine signaling signatures on resolving discrepancy between TMB and checkpoint expression. *First Author: Christopher Szeto, ImmunityBio, Inc, Santa Cruz, CA*

Background: Tumor mutation burden (TMB) and *PD1/L1* expression are independent biomarkers for immune checkpoint blockade therapy, as seen in the Checkmate227 trial. Here we explore whether chemokine activity, an intermediate step between neoantigen presentation and immune-infiltration, can resolve this lack of association between existing biomarkers. We further use this novel biomarker to corroborate recent findings from Crowther et al. for a role of MHC class 1-related gene (*MR1)* downregulation in immune evasion. **Methods:** 1,395 clinical samples from the NantHealth database with matched tumor:normal whole exomes and deep whole-transcriptomic sequencing (> 200M reads) were available for analysis. The most common indications in the cohort were Breast (18%), Colon (9.8%), Lung (7.8%), Soft-tissue/Sarcomas (7.7%), and Pancreatic (6.1%). TMB was calculated by counting non-synonymous exonic mutations as per Rizvi, 2015. Immune-infiltration and chemokine signaling were inferred from RNAseq expression of published immune-cell-specific genesets (Bindea, 2013) and chemokine ligands (Nagarsheth, 2017) respectively. Significant associations between TMB, chemokine activity, immune-infiltration, and checkpoint expression were analyzed by ranksums test and corrected for multiple-hypothesis testing using Benjamini-Hochberg adjustment. **Results:** As expected, TMB and *PD1/L1* mRNA expression were not correlated in this cohort (r = 0.08 and r = 0.07 respectively). 36.3% of patients classified as highly immune-infiltrated by unsupervised clustering of immune-cell scores, and this subgroup significantly overexpressed all 11 targetable checkpoint genes analyzed including *PD1*, *PDL1, CTLA4, IDO1,* and *VISTA* (adj. p 9.7e-68 to 4e-168). There was no association between immune-infiltrated samples and TMB (t = 0.9, p = 0.35). Twice as many patients classified as chemokine-active (70.0%) and there was significant agreement between immune-infiltrated and chemokine-active patients (OR = 34.8, p = 6.5e-81). Interestingly, there was a weak but significant association between high chemokine-activity and increased TMB (t = 3.3, p = 0.001). Within patients that were chemokine-active but lacked immune-infiltration, *MR1* expression was significantly depleted (t = -10.7, p = 1e-26). **Conclusions:** Chemokine signatures can help resolve discordance between TMB and checkpoint expression. Analysis of discordance between chemokine-active but immune-depleted tumors may aid in identifying targets for converting from cold to hot tumor microenvironments. 3134 Poster Session (Board #198), Fri, 8:00 AM-11:00 AM

Personalized neoantigen/cancer testis antigen nanovaccine (PVAC) in combination with PD-1 monoclonal antibody and/or antiangiogenic treatment in patients with metastatic solid tumors. *First Author: Jia Wei, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: T-cell targeting of mutation-derived epitopes (neoantigens) has been demonstrated to drive anti-tumor responses. Nanotechnology has been reported to enhance immune responses of vaccines. Moreover, immunizing patients against such neoantigens, in combination with checkpoint inhibitor (CPI) and/or antiangiogenic drugs may elicit greater anti-tumor responses. **Methods:** Patient-specific mutation-containing neoantigens were selected on the basis of tumour-specific mutations whole-exome sequencing (WES) and RNA sequencing. Cancer testis antigens were obtained according to immunohistochemical staining and HLA-binding affinity prediction. Personalized neoantigen/cancer testis antigen nanovaccine (PVAC) is an amphiphiles nanovaccine loaded with personalized vaccine encoding multiple neoantigens designed to induce neoantigen specific T cells responses. Patients will receive PVAC in combination with PD-1 monoclonal antibody and/or antiangiogenic drugs. Primary end points include safety and tolerability. **Results:** 13 microsatellite stability (MSS) patients, which had relapsed from standard treatments, are enrolled in this study. 5 patients (1 gastric cancer, 1 liver cancer, 1 cervical carcinoma, 1 soft tissue sarcoma, 1 renal carcinoma) received PVAC in combination with PD-1 mAb, and another 8 patients (3 gastric cancer, 2 colon cancer, 1 NSCLC, 1 renal carcinoma) received PVAC in combination with PD-1 mAb and antiangiogenic therapy. No DLTs were reported. Five patients developed grade 1 and one patients developed grade 2 subcutaneous indurations in the injection sites, which collected with nanovaccine. One patient had grade 2 rash caused by anti-angiogenic drug. No drug related SAEs have been observed. There are 1 CR, 6 PR, 4 SD and 2 PD. Neoantigen specific T cell responses have been detected by IFN-γ ELISpot from PBMCs. **Conclusions:** PVAC is safe and well tolerated. Clinical responses have been observed in combination with PD-1 mAb and antiangiogenic drugs and neoantigen-specific T cell response have been observed after vaccination. Clinical trial information: ChiCTR1900022986. Research Sponsor: the National Natural Science Foundation of China.

3135 Poster Session (Board #199), Fri, 8:00 AM-11:00 AM

ESR1 mutations provide novel targets for breast cancer immunotherapy. *First Author: Jonathan Goldberg, Dana–Farber Cancer Institute, Boston, MA*

Background: Estrogen receptor (ER)-positive breast cancer is not considered immunogenic. Standard treatment is endocrine therapy to include aromatase inhibitors (AI). However, constitutively activating mutations in estrogen receptor alpha (*ESR1*) emerge with treatment making tumors resistant to AI therapy. While these mutations represent a pathway of resistance, they also represent potential neoepitopes that can be targeted with immunotherapy. Here we characterize the role of *ESR1* mutations as novel targets for breast cancer immunotherapy. **Methods:** Immunogenic epitopes derived from mutated *ESR1* (i.e. D538G, Y537S and E380Q) were identified in silico using the Immune Epitope Database and by determining overlapping peptides. In vitro T2 binding assays were used to measure the affinities of these peptides to HLA class-I, specifically HLA-A*0201. Dissociation assays were employed to characterize the stability of the peptide-HLA complex. Peptide-HLA-A*0201 tetramer staining was used to determine the expansion potential of peptide-specific cytotoxic T lymphocytes (CTL) from peripheral blood of healthy females. Cytotoxicity assays were used to determine the ability of peptide-specific CTLs to lyse cells presenting mutated ESR1-derived peptides. **Results:** We identified 22 nonameric and decameric peptides derived from the most common ESR1 mutations; 10/22 demonstrated high affinity (i.e. IC50 $<$ 500nM) binding to HLA-A*0201. The 3 highest predicted peptides demonstrated low IC50 values (13 nM, 19.5 nM and 56.6 nM), indicating very tight binding to HLA-*0201. *In vitro* assays confirmed high affinity binding for 10 of the 22 *in silico*-predicted peptides with an average fold change of 1.52 compared to non-pulsed T2 cells, and a median dissociation half-life of 6.45 hours. Tetramer staining of peptide specific CTLs from normal donor peripheral blood mononuclear cells showed relatively high expansion frequencies, with the highest three frequencies noted for D538G (1.04%), Y537S (0.49%) and V392I (0.27%). Using 4-hour *in vitro* cytotoxicity assays, in comparison with non-pulsed T2 cells, there was significantly higher lysis of peptide pulsed T2 cells that were cocultured with matching peptide-specific CTL: D538G (67.1 % vs 36.9%, $P < 0.001$), Y537S (59.5% vs 37.5%, $P < 0.01$), and E380Q (36.3% vs 7.8%, $P < 0.001$). **Conclusions:** These data confirm the immunogenicity of epitopes derived from the most common ESR1 mutations. Further investigation of these peptides as part of novel immunotherapies, to include vaccine strategies is warranted. Research Sponsor: Parker Institute for Cancer Immunotherapy.

3136 Poster Session (Board #200), Fri, 8:00 AM-11:00 AM

A shared tumor-antigen RNA-lipoplex vaccine with/without anti-PD1 in patients with checkpoint-inhibition experienced melanoma. *First Author: Carmen Loquai, Department of Dermatology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany*

Background: Cancer vaccines are considered unsuitable for patients with advanced tumours and have not been clinically successful. **Methods:** Lipo-MERIT is an ongoing phase 1/2 trial (NCT02410733) with melanoma FixVac, a liposomal RNA vaccine targeting four non-mutant shared tumour-associated antigens (TAAs) (MAGE-A3, NY-ESO-1, tyrosinase, TPTE). Patients with stage IIIB-C and IV melanoma are eligible. The trial comprises 7 dose escalation and 3 dose expansion cohorts, the latter with FixVac alone or combined with anti-PD1. Eight doses of FixVac are administered i.v. weekly/bi-weekly followed by optional continued monthly treatment. This abstract summarizes the findings of an exploratory interim analysis (cut-off JUL2019) of 89 patients. **Results:** 42 of 89 patients had measurable disease at baseline and were eligible for assessment of best objective overall response. All but one patient were stage IV and had undergone previous lines of treatment, 41 patients were checkpoint-inhibitor (CPI)-experienced, and 35 had been exposed to both anti-CTLA4 and anti-PD1 therapy. In the vaccine monotherapy group (n = 25) three patients experienced a partial response (PR) and 7 patients had stable disease (SD). An additional patient showed a complete metabolic remission of metastatic lesions based on [^{18}F]-FDG PET/CT imaging. In the group of patients treated with melanoma FixVac and PD1 blockade, 6 of 17 patients developed a PR. Patients with PR showed induction of poly-epitopic and strong CD4$^+$ and CD8$^+$ T cell immunity against the vaccine antigens. The number of antigen-specific cytotoxic T cells in some responders reached up to low 2-digit percentages of circulating CD8$^+$ T cells and was maintained at high levels by continued vaccination. Overall, 75% of the 50 patients tested by *ex vivo* IFNg ELISpot analysis and all 20 patients tested by IFNg ELISpot after *in vitro* stimulation showed vaccine-induced immune responses against at least one vaccine antigen. Typically, antigen-specific T cells ramped up within the first 4-8 weeks to single-digit and low double-digit percent fractions of circulating CD8$^+$ T cells. Immune responses were of effector memory phenotype and their strength and frequency did not depend on disease status at baseline (measurable *versus* non-measurable disease), on vaccine dose or on treatment (FixVac alone *versus* in combination with anti-PD1). **Conclusions:** FixVac alone and in combination with anti-PD1 mediates durable objective responses in pre-treated, CPI experienced patients with advanced progressing melanoma. Clinical trial information: NCT02410733. Research Sponsor: BioNTech RNA Pharmaceuticals GmbH.

3137 Poster Session (Board #201), Fri, 8:00 AM-11:00 AM

Personalized viral-based prime/boost immunotherapy targeting patient-specific or shared neoantigens: Immunogenicity, safety, and efficacy results from two ongoing phase I studies. *First Author: Charles G. Drake, Herbert Irving Comprehensive Cancer Center, New York, NY*

Background: Neoantigens are key targets of a tumor-specific immune response and CD8 T cells targeting neoantigens drive clinical benefit in patients (pts) treated with checkpoint inhibitors. **Methods:** Two Phase I studies are being conducted to assess the safety, immunogenicity, and early clinical activity of a viral-based neoantigen-targeting prime/boost immunotherapy aimed at maximizing the CD8 T cell response. Both studies use a chimpanzee adenovirus prime followed by increasing doses of repeat boosts with a self-amplifying mRNA in combination with IV nivolumab +/- SC ipilimumab. In the first study, GO-004, patient-specific neoantigens are predicted using Gritstone's EDGE model and incorporated into both prime/boost vectors. In GO-005, shared neoantigens derived from common driver mutations (including several from *KRAS*) are encoded in off-the-shelf prime/boost vectors. **Results:** To date, 12 pts have been treated: 6 pts with GEA, NSCLC, or MSS-CRC (GO-004) and 6 pts with NSCLC, MSS-CRC, or PDA (GO-005) with all pts receiving IV nivolumab and 5 pts also receiving SC ipilimumab. Nine pts continue to receive study treatment. No DLTs have been observed. Treatment-related AEs are reversible and include Grade 1/2 fever (7/12), injection site reactions (4/12), fatigue (3/12), diarrhea (2/12), hypotension (2/12), pruritus (2/12), skin reactions (2/12), anorexia (1/12), dyspnea (1/12), hyponatremia (1/12), infusion-related reactions (1/12), myalgia (1/12), and asymptomatic Grade 3 CK elevation (1/12). At the time of analysis, 8 of 12 pts with $\geq$ 1 radiographic assessment have a best response of stable disease (SD) (3) and progressive disease (PD) (4), and one pt with no evaluable disease at baseline continues on study $>$ 8 months. In GO-005, 1 pt with SD has a 20% reduction in tumor dimensions that correlates with a decrease in ctDNA. In 4 pts in GO-004 analyzed to date, all pts showed substantial neoantigen-specific CD8 T cell responses to multiple neoantigens after priming which increase further in 2 of 3 pts analyzed after subsequent boosts. In GO-005, 1 of 3 pts showed a robust KRAS G12C-specific CD8 T cell response. Induced T cells express IFNg and granzyme B, consistent with an effector response. **Conclusions:** Taken together, these early data support the tolerability of a viral-based prime/boost immunotherapy, demonstrate marked immunogenicity, and are consistent with potential clinical activity. Additional pts and data at higher dose levels will be presented. Clinical trial information: NCT03639714, NCT03953235. Research Sponsor: Gritstone Oncology, Inc.

3138 Poster Session (Board #202), Fri, 8:00 AM-11:00 AM

Multi-antigen active specific immunotherapy induced long-term remission and prevent colorectal cancer relapse. *First Author: Juan Pablo Marquez-Manriquez, CICS USA, Seattle, WA*

Background: Clinical effective multi-antigen active immunotherapy for colorectal cancer (CRC) is still limited and most studies have failed. We consider this is because the targets in some of the studies are not oncogenic drivers. This is especially important for patients that progressed to standard of care treatment. Also, most of the studies with Immune checkpoint inhibitors (ICH) have failed in CRC but potentially may impact and provide better outcomes if used as combination therapies. We treated CRC patients with progressive disease in a pilot study n = 15 and found clinical responses that correlate with the CD8, delayed-type hypersensitivity (DTH) and Th1 parameters. After patients achieved remission we used the same peptides to prevent relapse with clinical and statistics significance. **Methods:** N = 15 CRC patients were enrolled in this pilot trial after approval for the ethic IRB committee from CICS Mexico. Patients were treated with an intradermal vaccine every week for four weeks, every two weeks four times in axillary and inguinal lymph nodes (LN) areas, and finally subcutaneously every month six times in the sites with tumor activity. Previously to the treatment we perform Granzyme B ELISPOT, ELISA, DTH and CT scan as initial controls. We delivered intradermal four peptides from sixteen peptides predicted from four proteins such as Fascin-1, Ape-1, VCP and RCAS1. **Results:** 86% of the patients had an objective clinical responses and 14% stable disease. All the patients had a correlation with the immunological assays as following. 58% of patients had an increased in the CD8 cells demonstrated by Granzyme B; DTH reactions were gradually increasing and by the first month of treatment the DTH were positive for Fascin-1 (78%), Ape-1 (85%), VCP (95%) and RCAS1 (83%) peptides. The more immunogenic peptides by ELISA were Fascin-1 A ($P = 0.001$), Fascin-1 D ($P = 0.005$), Ape-1 C ($p = 0.001$), VCP A ($P = 0.003$), RCAS1 A ($p = 0.001$) and RCAS1 B ($P = 0.01$). **Conclusions:** The treatment was effective with CR and SD responses. Once we validate this data we are planning a clinical study combining the treatment with low dose of ICH. Currently all the patients with CR are now under relapse prevention. We are still treating the patients with SD until disease progression. Importantly we believe that this data may impact the PFS and OS in CRC patients who have Karnoksky $>$ to 80% despite progressive disease to standard of care. Research Sponsor: Sonora Cancer Research Center Foundation from Ciudad Obregon, Sonora, Mexico.

3139 Poster Session (Board #203), Fri, 8:00 AM-11:00 AM

Safety and tolerability of intratumorally administered OH2, an oncolytic herpes simplex virus 2, in patients with advanced solid tumors: A phase I dose escalation clinical study. *First Author: Jing Huang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: There have been limited reports concerning treatment outcomes of oncolytic viruses in solid tumors other than melanoma. OH2 is a genetically engineered oncolytic herpes simplex virus type 2 designed to selectively amplify in tumor cells and express GM-CSF to enhance tumor-specific immune responses. **Methods:** We conducted an open-label, single-center, phase 1 study. Eligible pts were 18-75 years of age; had histologically confirmed advanced solid tumor; had progressed after standard systemic treatments. Pts were required to have tumor(s) deemed safe to inject, with a longest diameter of at least 0.5cm. Other eligibility criteria included measurable lesion as per RECIST v1.1; ECOGPS score of 0-1 and adequate organ functions. A 3+3 dose-escalation strategy was used in the study and 3 dose levels (10^6, 10^7 and 10^8 CCID50/mL) of OH2 were assessed. OH2 was administered intratumorally every 3 weeks for the first cycle and every 2 weeks.Treatment may continue afterwards in ptswith potential clinical benefit at the discretion of the investigators. The primary objective was the safety and tolerability of OH2 injection as defined by the dose limiting toxicities (DLTs) within the first 3 weeks of therapy, and the maximum tolerated dose (MTD). Secondary objectives included efficacy and immunogenicity of OH2. **Results:** 11 pts were enrolled between April 17, 2019 and November 4, 2019. The median follow-up duration was 8.36 months (95%CI: 5.64-11.08). OH2 was well-tolerated as no DLTs were reported and no MTD reached. Before the end of the DLT assessment period,1 pt withdrew consent, and 1 pt died of arrhythmia unrelated to OH2, with negative OH2 DNA copies in serum, urine and saliva samples. Most treatment-related adverse events (TRAEs) observed were of grade 1-2, except that 1 pt in the 10^8 CCID50/mL group developed grade 3 fever. The most common TRAEs were fever (n =5) and blood bilirubin level increase (n = 4). There were no grade 4 or 5 TRAEs. One pt(rectal cancer) had PR and 2 (appendix cancer and ovarian cancer) had SD as per RECIST v1.1. One patient (esophageal cancer) achieved iPR as per iRECIST criteria. The duration of follow-up for the 2 responders were 9.70 months and 8.36 months, respectively, and both had ongoing responses. Notably, regression of a non-injected lesion was observed in 1 patient. **Conclusions:** OH2 had a favorable safety profile with no DLTs and MTD. The dose expansion study in selected tumor types is currently underway. Clinical trial information: NCT03866525. Research Sponsor: Wuhan Binhui Biotechnology Co., Ltd.

3140 Poster Session (Board #204), Fri, 8:00 AM-11:00 AM

Inhaled corticosteroid use and risk of pneumonitis in patients treated with immune checkpoint inhibitors. *First Author: Mingjia Li, The Ohio State University Wexner Medical Center, Division of Hospital Medicine, Columbus, OH*

Background: The identification of risk factors for immune-related adverse events (irAEs) is an important area of research. Among irAEs, pneumonitis carries one of the highest morbidities. There is a lack of strong predictors for pneumonitis in patients (pts) treated with ICI. We sought to identify predictors for the development of pneumonitis, and whether the use of inhaled corticosteroids (ICS) at time of ICI could be protective. **Methods:** Pts with advanced cancer treated with ICI from 2011 and 2018 were included in this retrospective study. Pneumonitis attribution to ICI was determined by treating physician at time of diagnosis. Time to pneumonitis was defined as days from the start of ICI to pneumonitis diagnosis. Pts who never had pneumonitis were censored at the time of last follow up or death. Predictors of pneumonitis were assessed by univariate Cox proportional hazard models at a significance threshold of alpha = 0.05. **Results:** A total of 837 pts were identified, and 30 (3.6%) pts developed any grade pneumonitis (12 grade 2, 14 grade 3, 1 grade 4, 3 grade 5) after receiving ICI (Table). Pts with age ≥65 years (y) had increased risk of developing pneumonitis over pts with age < 65y (HR 2.1, 95 CI: 1.02-4.4, p=0.041). 82 (9.7%) of the total cohort were on inhaled corticosteroid (ICS) at time of ICI, and 9 (11%) developed pneumonitis. Rather than being protective, pts on ICS had higher risk of pneumonitis (HR 4.2, 95 CI: 1.9-9.2, p=0.001). Pts with lung cancer had an increased risk for pneumonitis compared to pts with other cancers (HR 3.2, 95 CI: 1.5-6.4, p =0.003). Other risk factors included performance status, smoking history, line of therapy, or prior treatment including radiation were not statistically significant. **Conclusions:** Rather than a protective effect of ICS, our analysis found a higher risk of pneumonitis in pts treated with ICS. We confirmed an increased risk of pneumonitis for lung cancer pts compared to pts with other cancers, and higher risk of pneumonitis in pts age >65y. We hypothesize that the increased inflammatory status in chronic lung inflammation may predispose pts to pneumonitis that was not ameliorated by ICS. Future study is needed in prospective cohorts to further clarify the underlying inflammatory mechanism. Research Sponsor: Research support provided by the REDCap project and The Ohio State University Center for Clinical and Translational Science grant support (National Center for Advancing Translational Sciences, Grant UL1TR002733). Dr. Owen is a Paul Calabresi Scholar suppo.

Response criteria for intratumoral immunotherapy in solid tumors: itRECIST. *First Author: Gregory V. Goldmacher, Merck & Co., Inc., Kenilworth, NJ*

Background: The approval of intratumoral (IT) immunotherapy for metastatic melanoma and the active development of numerous novel IT drugs have created a need for standardized evaluation of response to this unique treatment strategy. The Response Evaluation Criteria in Solid Tumors (RECIST) is not suitable for assessing responses separately for injected and noninjected tumors. Building on RECIST concepts, we propose an IT immunotherapy RECIST (itRECIST) to capture data and assess local and systemic responses in a standardized fashion for clinical trials involving IT immunotherapies. **Methods:** itRECIST will address the unique needs of IT immunotherapy trials but, where possible, aligns with RECIST 1.1 and iRECIST. It does not dictate which lesions to inject but provides guidelines for collecting data and assessing response as treatment evolves. **Results:** itRECIST enables overall response assessment, separate response assessments in injected and noninjected lesions, and continued assessment following modifications of therapy at initial progression. At baseline, lesions are classified into 4 categories: target injected, target noninjected, nontarget injected, and nontarget noninjected. After baseline, lesions can be reclassified from noninjected to injected if the investigator decides to change the lesions to inject, but target and nontarget designations never change. Overall response at each assessment is based on target lesion response (injected and noninjected), nontarget lesion response, and absence/appearance of new lesions. Noninjected lesion response is determined by comparing tumor burden with baseline and nadir values. Injected lesion assessment is based on visit-to-visit changes in the lesions injected during treatment and on a combined assessment once the patient is off treatment. A new response category is defined to capture progression that would be "confirmed" per iRECIST even though injected lesions are responding and therapy continues. Multiple examples have been created to aid in training and adoption. **Conclusions:** itRECIST is an important step toward a standardized method of response assessment for this promising and evolving therapeutic modality. The proposed guidelines can be adopted into trial protocols and routine clinical practice without the need for complex additional assessments by treating physicians. Until there is evidence to support wider use, itRECIST is intended only to support standardized collection of data and to facilitate exploratory analysis. Authors G.V.G. and A.D.K. contributed equally to this work. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

3142 Poster Session (Board #206), Fri, 8:00 AM-11:00 AM

Analysis of mutation detection of POLD1/pole in pan-cancer. *First Author: Gao Yang, Xiangya Hospital, Central South University, Changsha, China*

Background: Previous studies proved that mutation of *POLD1* and *POLE* elevates base-substitution mutations and lead to the elevation of tumor mutation burden (TMB). Other signature needs to explore to identify driver mutations in these two genes. **Methods:** Using gene-panel target-capture next generation sequencing, we analyzed the TMB and *POLD1/POLE* mutation in 17383 tumor tissue or plasma ctDNA samples from different patients. **Results:** Tumor mutation burdens were calculated of all the 17383 samples. According to the present research and our panel, we use 10 and 100 Mut/Mb to define hypermutation and ultra-hypermutation. Samples with hypermutation possessed 18.8% (n = 3268) and ultra-hypermutation possessed 0.3% (n = 58). In unselected, hypermutation and ultra-hypermutation group, *POLD1* or/and *POLE* mutations were identified in 3.5% (n = 625), 56.1% (n = 32) and 87.9%(n = 372) samples. There were 0.5% (n = 81), 17.0% (n = 73) and 87.7%(n = 51) identified more than one mutation. These results showed that *POLD1* or/and *POLE* mutations were enriched in samples with high TMB. We screened every known *POLE* and *POLD1* driver mutations. There were 22 ultra-hypermutation samples identified these mutations, including A456P(3), P286R(10), V411L(6), M444K(1), S459F(1) in *POLE* and R1016H(1) in *POLD1*. Interestingly, all of them were identified in microsatellite stable (MSS) samples , which suggest that driver mutation may enriched in MSS samples. These already known driver mutation was not detect in 24 high-level microsatellite instability (MSI-H) and ultra-hypermutation samples. We further analyzed 10 *POLD1/POLE* mutations in other 5 MSS and ultra-hypermutation samples. *POLE* L424V was a pathogenic germline mutation but not defined as a driver mutation clearly before. *POLE* P286C had not been biochemically characterized but had different residue with P286R in the same position. Others had not been biochemically characterized (R232H, A234T, V945M, S1064I, Y467H in *POLD1*, D462N and R749Q, E1956D in *POLE*). These mutations were potential driver mutations and further research need to be support. **Conclusions:** We found that not only *POLD1* or/and *POLE* mutations were enriched in samples with high TMB, but also driver mutations were enriched in microsatellite stable tumors. Further researches need to continue to identify more driver mutations of *POLD1* and *POLE*. Research Sponsor: None.

3143 Poster Session (Board #207), Fri, 8:00 AM-11:00 AM

Percutaneous hepatic injection of rose bengal disodium (PV-10) in metastatic uveal melanoma. *First Author: Sapna Pradyuman Patel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PV-10 is a small molecule autolytic immunotherapy in clinical development for treatment of solid tumors. When administered by intralesional (IL) injection, PV-10 can produce immunogenic cell death that may induce a T cell-mediated immune response against treatment refractory and immunologically cold tumors. Given this mechanism of action and clinical data that metastatic uveal melanoma (MUM) generates low response rates to immune checkpoint blockade (CB), we investigated treatment of MUM with percutaneously-delivered PV-10. **Methods:** This open-label Phase 1 basket study (NCT00986661) is evaluating the safety, tolerability, and preliminary efficacy of intralesional PV-10 in patients (pts) with solid tumors of the liver. PV-10 is injected into one or more designated hepatic tumor(s) with a maximum sum of diameters ≤4.9 cm. Response assessments using 2D EASL criteria are performed at Day 28, then every 3 months. Pts with additional injectable tumors are eligible to receive further PV-10 after Day 28. Pts can receive standard of care CB immunotherapy during treatment with PV-10. **Results:** As of February 1, 2020, the initial cohort of 15 pts with MUM to the liver was fully enrolled. Pts had received at least 1 IL injection of PV-10, with an average of 2 hepatic lesions injected per pt (range 1-4). Of these, 4 pts were refractory to prior CB. Three pts received PV-10 alone, 3 received PV-10 + anti-PD-1 and 9 received PV-10 + anti-PD-1 + anti-CTLA-4. Adverse events (AEs) were consistent with established patterns for PV-10 and CB: AEs attributed to PV-10 were transient and included 3 cases of Grade 3/4 transaminitis that resolved within 72 hrs, injection site pain, photosensitivity, and pink discoloration of skin, urine or feces; AEs attributed to CB included nausea, decreased WBC, and fatigue. Response assessments on 24 injected tumors were: 2 complete response (8%), 7 partial response (29%) and 11 stable disease (46%), per 2D EASL. Among the 4 CB-refractory pts, median overall survival (OS) was 9.2 months (range 5.3 - 11.4 months, with 2 pts alive at 5.3 months each), while among the 11 CB-naïve pts OS was undefined (range 0.5 - 21.9+ months, with 1 death at 7.9 months). Pts receiving PV-10 alone (1 CB-refractory, 2 naïve) achieved a median OS of 7.9 months with one CB-naïve pt alive with partial overall response at 21.9 months. **Conclusions:** Response indicative of regression or stabilization in a majority (83%) of injected lesions is encouraging in a disease of major unmet need. Enrollment and follow-up for safety, duration of response and survival are ongoing. Clinical trial information: NCT00986661. Research Sponsor: Provectus Biopharmaceuticals.

3144 Poster Session (Board #208), Fri, 8:00 AM-11:00 AM

Immune-mediated adverse events following concomitant radiotherapy and immunotherapy in patients with melanoma and Merkel cell carcinoma: A preliminary report from an evolving retrospective registry. *First Author: Nikolaos Andreatos, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Radiotherapy (RT) potentiates immune-mediated responses against tumor antigens, an effect that is enhanced by checkpoint inhibitors (CPIs) and may hold therapeutic promise. However, the mechanisms underlying this abscopal effect can theoretically increase the rate of immune-mediated adverse events (irAEs). We estimated the incidence of irAEs in a single-institution cohort treated with concomitant RT and immunotherapy. **Methods:** We retrospectively screened 731 patients that received RT and CPIs at our institution. Patients diagnosed with melanoma or Merkel cell carcinoma (MCC) who underwent RT concurrently or within 30 days of CPI administration were eligible. A radiation period (RP) comprised the interval between the first and last treatment days (≤90 days); a patient could contribute multiple RPs. Data on new irAEs diagnosed within 3 months after RT and relevant demographic and clinicopathologic variables were collected; univariate analysis was performed with the chi-squared test. **Results:** 35 patients (23 male, 12 female) contributed 43 RPs; mean age was 65.5 years (range: 39-90). Five had MCC, and 30 had melanoma (24 cutaneous, 1 uveal and 5 urogenital melanomas). PD-1 inhibitors were most commonly employed (22 RPs), followed by ipilimumab-nivolumab (14 RPs), ipilimumab (4 RPs), and avelumab (3 RPs). CPIs were administered concurrently with RT in 32 RPs and sequentially in 11 RPs. Fourteen RPs comprised intracranial radiation. Importantly, 45.7% of patients (16/35) experienced irAEs, which manifested within a month of RT in 25.7% (9/35). Four patients experienced grade ≥3 irAEs leading to hospitalization; one died of respiratory failure after developing pneumonitis. On univariate analysis, no significant association between tumor type, CPI regimen, concurrent RT, intracranial vs. extracranial RT, and irAE incidence was noted. A trend for increased irAEs within the ipilimumab-nivolumab group was observed ($p = 0.27$). **Conclusions:** Almost half of patients developed new irAEs following RT, with 25% (4/16) of cases warranting hospitalization; these incidence rates appear to exceed rates from historical data and raise concerns about the additive toxicity of CPIs and RT. Comparison to non-RT cohorts and survival analyses are ongoing. Research Sponsor: None.

TPS3145 Poster Session (Board #209), Fri, 8:00 AM-11:00 AM

ZW25, an anti-HER2 bispecific antibody, plus chemotherapy with/without tislelizumab as first-line treatment for patients with advanced HER2-positive breast cancer or gastric/gastroesophageal junction adenocarcinoma: A phase 1B/2 trial-in-progress. *First Author: Do-Youn Oh, Seoul National University Hospital, Seoul, South Korea*

Background: ZW25 is a novel HER2-targeted antibody that binds two distinct extracellular domains of HER2, allowing for multiple mechanisms of action, including activation of ADCC and inhibition of ligand-dependent and -independent cellular growth. ZW25 is well tolerated and showed single-agent antitumor activity in patients (pts) with advanced HER2-positive cancers. Previous reports suggested that tislelizumab, an investigational anti-PD-1 antibody engineered to minimize binding of FcgR on macrophages in order to abrogate antibody-dependent phagocytosis, was generally well tolerated and had antitumor activity alone and in combination with chemotherapy in pts with advanced solid tumors. Combining HER2-targeted agents with chemotherapy has resulted in improved survival; the highly immunogenic nature of HER2 tumors has led to the development of therapies combining anti-HER2 therapies with immune checkpoint blockade. **Methods:** This open-label, two cohort phase 1B/2 study is designed to evaluate ZW25 plus chemotherapy ± tislelizumab as first-line therapy in pts (n≈50) with HER2-positive metastatic breast cancer (mBC; cohort 1) or advanced gastric/gastroesophageal junction adenocarcinoma (GC/GEJC; cohort 2). In cohort 1, pts with HER2-positive (IHC3+ or ISH amplified) mBC must be treatment-naïve for metastatic disease and will receive intravenous (IV) ZW25 30 mg/kg plus docetaxel 75 mg/m^2 IV once every 3 weeks (Q3W). In cohort 2, treatment-naïve pts with HER2-positive (IHC3+ or IHC2+ with ISH amplification) advanced GC/GEJC will receive ZW25 30 mg/kg plus tislelizumab 200 mg IV and chemotherapy (CAPOX regimen: capecitabine 1000 mg/m^2 twice daily and oxaliplatin 130 mg/m^2 IV) Q3W. A safety lead-in phase is designed for the first six pts in cohort 2, followed by dose expansion after a safety monitoring committee review. Primary endpoints are the safety/tolerability profile and objective response rate; secondary endpoints include duration of response, time to response, progression-free survival, disease control rate, and overall survival. Clinical trial information: Registered, NCT number pending will provide as soon as available. Research Sponsor: BeiGene, Ltd.

TPS3146 Poster Session (Board #210), Fri, 8:00 AM-11:00 AM

Bgb-A425, an investigational anti-TIM-3 monoclonal antibody, in combination with tislelizumab, an anti-PD-1 monoclonal antibody, in patients with advanced solid tumors: A phase I/II trial in progress. *First Author: Jayesh Desai, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: While immune surveillance plays a critical role in preventing tumor proliferation and metastasis, tumors develop resistance mechanisms to suppress and/or escape the immune system. T-cell immunoglobulin and mucin-domain containing-3 (TIM-3) and programmed cell death protein-1 (PD-1) function as immune checkpoint receptors on tumor-infiltrating lymphocytes. Overlap in expression and function suggests TIM-3 and PD-1 cooperate to maximize effector T-cell exhaustion, leading to a decreased antitumor immune response. Although blockade of TIM-3 alone is unlikely to result in an efficacious antitumor immune response, combined TIM-3/PD-1 blockade may enhance the antitumor properties of anti-PD-1 therapies alone. BGB-A425 is an investigational IgG1-variant monoclonal antibody against TIM-3. Tislelizumab, an anti-PD-1 antibody, was engineered to minimize binding to FcγR on macrophages in order to abrogate antibody-dependent phagocytosis, a mechanism of T-cell clearance and potential resistance to anti-PD-1 therapy. This phase 1/2 study will assess the safety/tolerability, pharmacokinetic (PK) profile, and antitumor activity of BGB-A425 in combination with tislelizumab in patients with advanced solid tumors. **Methods:** This is an open-label phase 1/2 study (NCT03744468) of BGB-A425 in combination with tislelizumab in patients with histologically/cytologically confirmed advanced, metastatic, unresectable solid tumors. Phase 1 will determine the recommended phase 2 dose (RP2D) for combination treatment; phase 2 will assess the antitumor effects of the combination in select tumor types. In phase 1, up to 42 patients will be enrolled into sequential cohorts of increasing doses of intravenous (IV) BGB-A425 in combination with tislelizumab 200 mg IV, based on a 3+3 study design. During Cycle 1, patients will receive BGB-A425 alone on Day 1 followed by tislelizumab alone on Day 8. If no dose-limiting toxicities are observed, patients will receive both BGB-A425 and tislelizumab sequentially on Day 29 and every 21 days thereafter. Once the RP2D is determined, the combination therapy will be evaluated in up to 120 patients with select tumor types in phase 2. Safety/tolerability profile and RP2D determination (phase 1) and objective response rate per RECIST v1.1 (phase 2) are primary objectives; secondary objectives include antitumor activity, PK profile, and immunogenicity of combination therapy. Clinical trial information: NCT03744468. Research Sponsor: BeiGene, Ltd.

TPS3147 Poster Session (Board #211), Fri, 8:00 AM-11:00 AM

A phase I study of CD40 agonist ABBV-927 plus OX40 agonist ABBV-368 with or without the PD-1 inhibitor budigalimab in patients with advanced solid tumors. *First Author: John D. Powderly, Carolina BioOncology Institute, Huntersville, NC*

Background: CD40 is a key costimulatory molecule for both the innate and adaptive immune systems that is essential for T-cell activation and proliferation. OX40 is a costimulatory molecule that is involved in enhancing nascent immune responses and concomitantly acts to suppress regulatory T-cell activity. ABBV-927 and ABBV-368 are potent agonistic antibodies against CD40 and OX40, respectively. This open-label, Phase 1 study will evaluate the doublet combination of ABBV-927 and ABBV-368 and the triplet combination of ABBV-927, ABBV-368, and the programmed cell death protein-1 (PD-1) inhibitor budigalimab in patients with advanced solid tumors. **Methods:** For this study (NCT03893955), patients must be ≥18 y with an Eastern Cooperative Oncology Group performance status of 0-1. Patients must have an advanced solid tumor that has progressed on standard therapies. Disease-specific cohorts will include patients with non-small cell lung cancer (NSCLC) and triple-negative breast cancer (TNBC). Patients with NSCLC must have previously received a PD-1/PD-ligand 1 inhibitor and a platinum-based therapy and no more than one prior immunotherapy. Patients with TNBC must not have received immunotherapy. Patients with uncontrolled central nervous system metastases will be excluded. The recommended Phase 2 dose (RP2D) will first be identified with ABBV-927 + ABBV-368 in patients with solid tumors (Arm A) and will be expanded in disease-specific cohorts including TNBC. The RP2D of ABBV-927 + ABBV-368 + budigalimab will be identified in patients with NSCLC (Arm B). The primary endpoints are determination of the RP2D of ABBV-927 + ABBV-368, the RP2D of ABBV-927 + ABBV-368 + budigalimab, and overall response rate; duration of response, progression-free survival, safety, and pharmacokinetics are secondary endpoints. Screening began on 21 May 2019, and enrollment is ongoing. Clinical trial information: NCT03893955. Research Sponsor: Abbvie, Inc.

TPS3148 Poster Session (Board #212), Fri, 8:00 AM-11:00 AM

A phase II open-label multicenter study to assess the efficacy and safety of AFM13 in patients with relapsed or refractory CD30-positive peripheral T-cell lymphoma or transformed mycosis fungoides: The REDIRECT study design and rationale. *First Author: Cassandra Choe-Juliak, Affimed Inc, NY, NY*

Background: AFM13 is a tetravalent, bispecific (anti-CD30/anti-CD16A) recombinant antibody being developed for the treatment of CD30-positive T-cell malignancies and Hodgkin lymphoma. AFM13 selectively kills CD30-positive tumor cells by engaging and activating natural killer cells and macrophages. AFM13 was well tolerated at doses of 0.01 to 7 mg/kg and showed clinical activity in patients with relapsed/refractory (R/R) Hodgkin lymphoma in a Phase 1 study. In an ongoing biomarker Phase 1b/2a study in patients with R/R CD30-positive lymphomas with cutaneous involvement, 4 of 8 patients responded (at different doses) including one CR. Based on these findings, this Phase 2 study (REDIRECT) has been initiated. **Methods:** This is a Phase 2, open-label, multicenter global study investigating the efficacy and safety of AFM13 in patients with R/R CD30-positive peripheral T cell lymphoma (PTCL) or transformed mycosis fungoides (TMF). AFM13 is administered at 200 mg weekly via an intravenous infusion until disease progression, unacceptable toxicity, investigator discretion or withdrawal of consent. Cohorts A and B include PTCL patients with ≥10%, and ≥1% to <10% CD30 expression by IHC, respectively. Cohort C includes patients with TMF who express ≥1% CD30. Eligible PTCL patients must have received at least 1 prior line of systemic therapy and, if diagnosed with systemic anaplastic large cell lymphoma, must have failed or be intolerant to brentuximab vedotin. Eligible patients with TMF must have received at least 1 prior line of systemic therapy and have exhausted systemic therapies with regular approval for their disease. This global trial started enrollment in Oct 2019. The primary endpoint is objective response rate as confirmed by an Independent Review Committee for all cohorts. The study will also assess investigator-measured efficacy parameters, safety, PK, immunogenicity and QOL. Disease assessment will be done at screening and every 8 weeks for the first 3 assessments, then every 12 weeks thereafter, regardless of any treatment/cycle delays that may occur. ClinicalTrials.gov identifier: NCT04101331. References: Reusch U et al. *mAbs.* 2014;6(3):728-739. Rothe A et al. *Blood.* 2015;125(26):4024-4031. Clinical trial information: NCT04101331. Research Sponsor: Affimed GmbH.

TPS3149 Poster Session (Board #213), Fri, 8:00 AM-11:00 AM

KITE-439: A phase I study of HPV16 E7 T cell receptor-engineered T cells in patients with relapsed/refractory HPV16-positive cancers. *First Author: Kedar Kirtane, Moffitt Cancer Center, Tampa, FL*

Background: Human papillomavirus 16 (HPV16) is the most prominent subtype across invasive head and neck cancers, as well as cervical cancer and other anogenital cancers (Saraiya M, et al. *J Natl Cancer Inst.* 2015). The HPV16 E7 (E7) viral antigen is important for the survival of HPV-positive tumor cells but is absent from normal human tissue, making it an attractive target for anti-cancer therapy. Preclinical efficacy has been observed with MHC class I-restricted T cell receptor (TCR)-engineered T cells targeting E7 on HPV16-positive tumor cells (Jin BY, et al. *JCI Insight.* 2018). This Phase 1, first-in-human, open-label, multicenter study (NCT03912831) will evaluate the safety and efficacy of KITE-439, an autologous TCR-engineered T cell therapy targeting E7, in HLA-A*02:01–positive patients with relapsed/refractory HPV16-positive cancers. **Methods:** A single-patient dose-escalation schema will be used in Phase 1A of the study, enrolling up to 30 patients. Phase 1A will evaluate safety and inform the recommended dose of KITE-439 for Phase 1B. Approximately 45 patients with squamous cell cancer of the head and neck, cervical cancer, and other HPV16-positive tumors will be included in Phase 1B. Patients in Phase 1A and Phase 1B may receive optional bridging therapy followed by cyclophosphamide and fludarabine conditioning chemotherapy. Patients will then receive an infusion of KITE-439 at 1×10^6 up to 1×10^8 TCR-transduced T cells/kg along with daily subcutaneous IL-2 therapy for a maximum of 14 doses post-infusion. The primary endpoint for Phase 1A is the incidence of adverse events defined as dose-limiting toxicities. The primary endpoint for Phase 1B is investigator-assessed objective response rate per modified RECIST v1.1 criteria (Eisenhauer EA, et al. *Eur J Cancer.* 2009). Secondary endpoints for Phase 1B include duration of response, progression-free survival, overall survival, and safety. Patients ≥ 18 years must be HLA-A*02:01–positive and have relapsed/refractory HPV16-positive cancer, an ECOG PS of ≤ 1, and adequate bone marrow and organ function. Key exclusion criteria include a history of stroke, myocardial infarction, or symptomatic deep vein thrombosis/pulmonary embolism, known infection with human immunodeficiency virus, detectable hepatitis C, or detectable hepatitis B. This study is currently open and accruing patients. Clinical trial information: NCT03912831. Research Sponsor: Kite, a Gilead Company.

TPS3150 Poster Session (Board #214), Fri, 8:00 AM-11:00 AM

Phase I trial of drug resistant immunotherapy: A first-in-class combination of MGMT-modified γδ t cells and temozolomide chemotherapy in newly diagnosed glioblastoma multiforme. *First Author: Lawrence S. Lamb, Incysus Therapeutics, New York, NY*

Background: Temozolomide (TMZ) transiently upregulates GBM-specific stress-induced NKG2D ligands that are targeted by innate immune effector cells. Leveraging this effect is problematic, however, due to the lymphodepleting effects of TMZ.Genetic modification of *ex vivo* expanded and activated with an MGMT-expressing lentivector allows simultaneous chemotherapy and γδ T cell therapy that targets the tumor when NKG2DL are maximally expressed. We have termed this Drug Resistant Immunotherapy (DRI). Patient-derived xenograft mouse models of both primary and recurrent GBM treated with DRI have shown a significant survival advantage that were otherwise impervious to either cell therapy or TMZ. These preclinical findings and associated safety data provide the rationale to initiate a Phase I trial of DRI in primary GBM. **Methods:** This first in human study will evaluate the safety and optimal dosing frequency of the DRI with TMZ (NCT04165941).Eligibility criteria include the following: GBM eligible for resection, ≥18y, adequate organ and marrow function, and KPS≥70. Six to 12patients with newly diagnosed GBM are being enrolled in a 3 + 3 design into 1 of 2 fixed dose levels (DL) of DRI. Following tumor resection and immediately prior to induction chemo/radiotherapy, an apheresis product is collected and γδ T cells expanded in Zoledronic Acid (Novartis) and rhIL-12 (Miltenyi) and transduced with a P140K-MGMT lentivector (Miltenyi Lentigen, Gaithersburg, MD), harvested, and cryopreserved. At initiation of maintenance phase TMZ therapy, patients receive 150mg/m^2 intravenous TMZ concurrently with intracranial injection of 1 x 10^7 γδ T cells (DL1) delivered through a Rickham reservoir previously inserted into the tumor cavity at resection. The patient then receives 4 daily doses of oral TMZ followed by 24d rest. Treatment cycles escalate from 1 to 3 (DL2) DRI doses following a safety observation period and absence of dose limiting toxicity. Maintenance TMZ treatment will continue for 6 cycles. Safety evaluations consist of routine laboratory analyses, clinical measurements (physical exams, vital signs), neurological function and evidence DRI γδ T cell related toxicity. Peripheral blood will be obtained for comprehensive immuno-phenotyping and T cell function analysis. Clinical benefit of DRI will be characterized by evaluating responses (CR, PR, SD and PD) and determining progression-free, median, and overall survival. As of February 2020, enrollment into DL 1 is ongoing. Clinical trial information: NCT04165941. Research Sponsor: Incysus Therapeutics, Inc.

TPS3151 Poster Session (Board #215), Fri, 8:00 AM-11:00 AM

A phase Ia/Ib, open-label first-in-human study of the safety, tolerability, and feasibility of gene-edited autologous NeoTCR-T cells (NeoTCR-P1) administered to patients with locally advanced or metastatic solid tumors. *First Author: Bartosz Chmielowski, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Neoepitopes (neoE) derived from private tumor-exclusive mutations represent compelling targets for personalized TCR-T cell therapy. An ultra-sensitive and high-throughput process was developed to capture tumor mutation-targeted CD8 T cells from patient blood. NeoTCRs cloned from the captured CD8 T cells, when engineered into fresh CD8 and CD4 T cells, effected killing of patients' autologous tumor cells in vitro. These observations have been leveraged for the development of a fully personalized adoptive T cell therapy (NeoTCR-P1). A Phase 1 clinical trial testing NeoTCR-P1 in subjects with solid tumors is ongoing (NCT03970382). **Methods:** During the initial trial phase, escalating doses of NeoTCR-P1 T cells administered without and with IL-2 in the regimen, and following conditioning chemotherapy, will be evaluated in subjects with advanced or metastatic solid tumors (melanoma, urothelial cancer, colorectal cancer, ovarian cancer, HR^+ breast cancer, and prostate cancer). The objective of the Phase 1a study is to establish a recommended Phase 2 dose. Primary endpoints include the incidence and nature of DLTs and overall process feasibility. The proliferation, persistence, and trafficking of NeoTCR-T cells will be characterized. In the expansion trial phase, preliminary anti-tumor activity of NeoTCR-P1 will be assessed in selected tumors. The combination of NeoTCR-P1 dosing plus nivolumab will be tested in a Phase 1b study. Conclusion: This is the first clinical study of an autologous, fully personalized adoptive T cell therapy directed against private tumor-exclusive mutations, generated without using recombinant viral vectors. Clinical trial information: NCT03970382. Research Sponsor: PACT Pharma.

TPS3152 Poster Session (Board #216), Fri, 8:00 AM-11:00 AM

Quilt-3.064: An open-label phase I study of PD-L1 t-haNK in subjects with locally advanced or metastatic solid cancers. *First Author: Tara Elisabeth Seery, Chan Soon Shiong Institute for Medicine, El Segundo, CA*

Background: Tumor cells can escape immunosurveillance through upregulation of PD-L1, which inhibits the proliferation and antitumor activity of T cells. T cells genetically altered to express chimeric antigen receptors (CARs) that recognize tumor-associated antigens have mediated potent responses in patients with hematologic cancers, but have shown limited efficacy in solid tumor cancers and can be associated with severe toxicity, ie, cytokine release syndrome (CRS). Like T cells, NK cells can be genetically modified to express CARs that can specifically recognize and lyse cancer cells. Unlike T cells, NK cell cytotoxicity does not require prior sensitization and is not HLA-restricted, making NK cells an attractive choice for clinical immunotherapy. In addition to their innate cytotoxicity, NK cells mediate antibody-dependent cellular cytotoxicity (ADCC) via expression of CD16. PD-L1 t-haNK is an off-the-shelf, human, allogeneic, NK cell line engineered to express a CAR targeting PD-L1. It can be easily and continuously expanded in culture and preclinical in vitro and in vivo studies have demonstrated effective PD-L1 CAR–mediated antitumor activity against $PD\text{-}L1^+$ MDSCs. PD-L1 t-haNK has also been engineered to express the high-affinity variant of the Fcγ receptor (FcγRIIIa/CD16a 158V), and thus has enhanced CD16-targeted ADCC capabilities, particularly when combined with a monoclonal antibody. As such, a dual-targeted NK approach may be more effective at potentiating antitumor activity and reversing suppression in multiple cancers that express PD-L1 in the tumor microenvironment. **Methods:** This is a dose-escalation study of PD-L1 t-haNK in subjects with locally advanced or metastatic solid cancers, regardless of PD-L1 expression. Dose escalation will involve a standard 3 + 3 design. The primary objectives are to determine safety, maximum tolerated dose (MTD), and designate a recommended phase 2 dose. Secondary objectives include estimates of preliminary efficacy by objective response rate, progression-free survival, and overall survival. Subjects in Cohort 1 will receive $\sim 2 \times 10^9$ PD-L1 t-haNK cells twice per week and assessed for dose-limiting toxicities (DLTs). If no DLTs occur, the dose may increase to $\sim 4 \times 10^9$ cells twice per week in Cohort 2. Dose expansion will occur when the MTD has been determined. PD-L1 t-haNK is administered by IV infusion in an outpatient setting. Enrollment in Cohort 1 has been completed ($N = 6$, > 100 doses total) without DLTs or CRS. Enrollment into Cohort 2 began December 2019. Clinical trial information: NCT04050709. Research Sponsor: NantKwest.

TPS3154 Poster Session (Board #218), Fri, 8:00 AM-11:00 AM

Alliance A151804: Establishment of a national biorepository to advance studies of immune-related adverse events. *First Author: David E. Kozono, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune-related Adverse Events (irAEs) are rare but serious sequelae of treatment with immuno-oncology (IO) therapeutics. These therapeutics, including monoclonal antibodies targeting programmed cell death protein 1 (PD-1), programmed death-ligand 1 (PD-L1) and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4), have had transformative effects on outcomes for patients (pts) with advanced cancers. Although most pts tolerate the therapies well, a few experience irAEs ranging in severity up to life-threatening. These irAEs involve diverse organs including the heart, kidney, liver and lung, and gastrointestinal, musculoskeletal, central and peripheral nervous systems. Because of the relatively low incidence and wide variety of irAEs due to various immunotherapies for multiple tumor types, establishment of an efficient centralized repository for acquisition and organized distribution of well-annotated biospecimens is vital for translational studies that improve understanding of the molecular pathogenesis and treatment of these significant toxicities. **Methods:** This multi-institutional study is open at sites across the National Clinical Trial Network to pts who received $\geq$ 1 IO therapeutics (e.g., CTLA-4, PD-1 or PD-L1 inhibitor) and experienced 1) $\geq$ 1 serious (grade 3–5) adverse events that are likely immune-related, 2) rare infection or 3) tumor hyperprogression. IrAEs of interest include myocarditis, colitis, hepatitis, nephritis, myositis, pneumonitis, meningitis/encephalitis, dermatitis, endocrinopathies and neuropathy. Pts may be on an NCTN or non-NCTN IO trial or be receiving standard-of-care therapy. Registration must occur $\leq$ 72 hours after confirmation of the irAE event. Clinical data are collected at registration, 1 month after registration and for up to 1 year. Biospecimens (tumor blocks, biopsies of inflammatory tissues used to establish irAE diagnosis, and serial blood samples for isolation of plasma, serum and peripheral blood mononuclear cells) are collected at 1-2 timepoints. Stool samples are collected from pts experiencing colitis. Imaging data are collected for pts with hyperprogression or pneumonitis. Goal accrual is 240 pts. Biospecimens and data will be made available to investigators following future submission and approval of proposals. Support: U10CA180821, U10CA180882, U24CA196171; U10CA180820 (ECOG-ACRIN); U10CA180888 (SWOG); U10CA180868 (NRG); https://acknowledgments.alliancefound.org; Clinical trial information: NCT04242095. Research Sponsor: U.S. National Institutes of Health.

TPS3155 Poster Session (Board #219), Fri, 8:00 AM-11:00 AM

A phase I study of AK112, a bispecific antibody that targets PD-1 and VEGF co-expressing T cells, in patients with advanced solid tumors. *First Author: Jermaine Coward, Icon Cancer Care, Brisbane, Australia*

Background: AK112 is a humanized IgG1 bispecific anti-PD-1/VEGF antibody. VEGF blockade potentiates PD-1 inhibition by, *inter alia*, opposing the immunosuppressive effects of VEGF-A, which include suppression of dendritic cell activity and enhancement of checkpoint molecule expression on CD8+ T cells and proliferation of regulatory T cells. Combination therapies involving PD-(L)1 and VEGF inhibitors have been approved for the treatment of selected patients with metastatic non-small cell lung carcinoma, advanced renal cell carcinoma and advanced endometrial carcinoma. A supplemental Biologics License Application has been submitted for an anti-PD-L1 + anti-VEGF combination for the first-line treatment of unresectable hepatocellular carcinoma. Given the strong correlation between VEGF and PD-1 expression in the tumor microenvironment, the simultaneous blockade of these 2 targets by AK112 as a single agent might achieve higher target binding specificities and synergistically produce enhanced antitumor activity compared to co-administration of anti-PD-(L)1 and anti-VEGF therapies. **Methods:** This is a Phase 1a/1b, first-in-human, multicenter, open-label study in patients with advanced or metastatic solid tumor that is refractory/relapsed to standard therapies. The primary objective is to assess safety, tolerability and DLTs; and to determine the Maximum Tolerated Dose (MTD) or Maximum Administered Dose of AK112. Antitumor activity, PK and immunogenicity of AK112 will be studied as secondary objectives. As exploratory endpoints, tumor tissue samples may be evaluated for PD-L1 expression, mRNA expression profile and biomarkers (e.g. CD8+, FoxP3, Granzyme B, apelin and EPHB4). PD-1 receptor occupancy on circulating T-cells and serum VEGF level may also be measured as indications of target engagement. The dose-escalation phase will evaluate 5 dose levels of AK112 (up to 20 mg/kg Q2W IV) using a 3+3+3 study design. Additional subjects (up to 18 subjects) may be enrolled at any dose level not exceeding the MTD for additional PK, PD and safety evaluations to determine the optimal dose level for the dose-expansion phase. Cohorts 1 and 2 have been completed and enrollment to Cohort 3 began in January 2020. The dose-expansion phase will be performed in patients with selected advanced solid tumors who had no prior exposure to drugs targeting T-cell co-stimulation or immune checkpoint pathways. Clinical trial information: NCT04047290. Research Sponsor: Akeso BioPharma, Inc.

TPS3156 **Poster Session (Board #220), Fri, 8:00 AM-11:00 AM**

A phase II study of olaparib in combination with pembrolizumab in patients with previously treated advanced solid tumors with homologous recombination repair mutation (HRRm) and/or homologous recombination repair deficiency (HRD): KEYLYNK-007. *First Author: Timothy A Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The anti-PD-1 antibody pembrolizumab (pembro) has improved clinical outcomes in multiple previously treated advanced solid tumors. The poly (ADP-ribose) polymerase (PARP) inhibitor olaparib (ola) has shown antitumor activity as monotherapy in previously treated advanced cancers with *BRCA1*/*BRCA2* mutations (BRCAm), other HRRm, and ovarian cancer with HRD phenotype. Antitumor activity of PD-(L)1 plus PARP inhibition was reportedly higher than expected with either agent alone in patients (pts) with recurrent ovarian cancer regardless of BRCAm or HRD status and in pts with BRCAm breast cancer. KEYLYNK-007 (NCT04123366) evaluates antitumor activity and safety of ola plus pembro in pts with advanced solid tumors with HRRm and/or HRD. **Methods:** This phase 2, nonrandomized, multicenter, open-label study plans to enroll ~300 pts aged ≥18 y with histologically/cytologically confirmed, previously treated, advanced solid tumors with HRRm and/or HRD per Lynparza HRR-HRD assay (Foundation Medicine, Inc., Cambridge, MA, USA) and ECOG PS 0-1. Pts will be grouped by biomarker status: (1) BRCAm; (2) HRRm without BRCAm; (3) HRD positive without HRRm (loss of heterozygosity score ≥16 per Lynparza HRR-HRD assay). Pts will receive ola 300 mg BID + pembro 200 mg IV Q3W (35 cycles) until PD, unacceptable AEs, intercurrent illness, investigator decision, withdrawal, or pregnancy. Tumor imaging assessment by blinded independent central review (BICR) per RECIST v1.1 or Prostate Cancer Working Group (PCWG)-modified RECIST v1.1 for prostate cancer will occur Q9W for 12 mo, then Q12W until PD, start of new anticancer treatment, withdrawal, pregnancy, or death. AEs will be monitored throughout the study and for 30 days after final dose (90 days for serious AEs) and graded by NCI CTCAE v5. The primary endpoint is ORR (RECIST v1.1 or PCWG-modified RECIST v1.1 by BICR). Secondary endpoints include DOR, PFS (RECIST v1.1 or PCWG-modified RECIST v1.1 by BICR), OS, and safety. ORR will be analyzed by the Clopper-Pearson method; and DOR, PFS, and OS by the Kaplan-Meier method. Clinical trial information: NCT04123366. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS3157 **Poster Session (Board #221), Fri, 8:00 AM-11:00 AM**

AGEN1181, a clinical stage Fc-engineered anti-CTLA-4 antibody with improved therapeutic potential for the treatment of patients with advanced malignancies. *First Author: Steven O'Day, John Wayne Cancer Institute, Santa Monica, CA*

Background: AGEN1181 is a novel Fc-optimized anti-CTLA4 antibody, currently being evaluated in an ongoing multi-center, open-label, phase 1 study in all advanced solid tumors as mono-therapy and combination with anti-PD-1 antibody, AGEN2034 (NCT03860272). AGEN1181 is Fc-engineered to harness a novel mechanism for enhanced FcγR-dependent functionality relative to first-generation CTLA-4 antibodies. In pre-clinical models, AGEN1181 enhances T cell priming, depletion of intratumoral regulatory T cells (Treg) and improved memory formation compared to first-generation anti-CTLA-4 antibodies. Most notably, AGEN1181 demonstrates improved binding to FcγRIIIA and superior T cell responsiveness in populations that only express the low affinity FcγRIIIA receptor relative to first-generation IgG1 CTLA-4 antibodies. The combination of AGEN1181 and AGEN2034 further enhances T cell activation and effector function. **Methods:** This phase 1 study is an open-label, multi-center dose-escalation designed to evaluate the safety, tolerability, dose limiting toxicity (DLT) PK, and pharmacodynamic profiles of patients with refractory advanced solid tumors who did not receive an anti-CTLA4 previously. The study is being conducted in 3 arms; with patients assigned using a standard 3+3 dose escalation design in the mono-therapy arms with AGEN1181 and an accelerated design in the combination with AGEN2034 arm. AGEN1181 is administered as IV infusion as mono-therapy on Day 1 of every 3 weeks (0.1,0.3,1,2,4 mg/kg), every 6-weeks (1,2,4 mg/kg) in parallel cohorts and every 6-weeks (0.1,0.3,1,2,4 mg/kg) in combination with AGEN2034 (3mg/kg Q2Weeks) until disease progression or unacceptable toxicity (maximum 2 years). All 3 Arms are open and enrolling patients. The study is expected to enroll approximately 80 evaluable patients with solid tumors. Dose reductions are not allowed in the event of AGEN1181-related toxicities. Currently 3 cohorts have been completed, first cohort in the combination arm and the fourth cohort in the monotherapy arm are enrolling. Preclinical and clinical assessment of AGEN1181 supports continued development as a potential therapy for refractory or relapsed advanced solid tumors. Clinical trial information: NCT03860272. Research Sponsor: Agenusbio.

TPS3158 **Poster Session (Board #222), Fri, 8:00 AM-11:00 AM**

A phase Ib study of nivolumab in patients with autoimmune disorders and advanced malignancies (AIM-NIVO). *First Author: Ecaterina Elena Ileana Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint inhibitors (ICI) such as anti-PD-1/PD-L1 antibodies have become a pivotal approach to cancer therapy. Nivolumab is an anti-PD1 antibody approved for an increasing number of solid tumors and hematological malignancies. However, patients (pts) with history of autoimmune disorders are excluded from the majority of clinical trials testing ICI. Consequently, the risks of flares and worsening of pre-existing autoimmune disorders in pts with tumor types who otherwise stand to benefit from ICI therapy are largely unknown, posing a challenge for oncologists. We are conducting a phase Ib study to test the hypothesis that nivolumab can be safely administered to pts with varying severity of Dermatomyositis, Systemic Sclerosis, Rheumatoid Arthritis, Systemic Lupus Erythematosus, Inflammatory Bowel Disease, Multiple Sclerosis, Sjögren's Syndrome and Other Autoimmune Disorders (AIM-Nivo). **Methods:** AIM-Nivo is an open-label, multi-center ongoing phase Ib study with nivolumab 480mg IV every 28 days in pts with autoimmune diseases and advanced malignancies (NCT03816345). The study has autoimmune disease-specific cohorts overseen by a multidisciplinary group of experts. The primary objective is to assess the overall safety and toxicity profile of nivolumab in pts with autoimmune disorders and advanced malignancies. Secondary objectives are to evaluate the antitumor efficacy, the impact of nivolumab on the autoimmune disease severity indices, and to explore potential biomarkers of response, resistance or toxicity. Key overall inclusion criteria include age ≥18 years, histologically confirmed advanced malignancies in which ICI are approved or have shown clinical activity. Key overall exclusion criteria include prior therapy with anti-PD-1/PD-L1 antibodies. Specific eligibility criteria are defined for each disease-specific cohort. For each autoimmune disorder, severity level of the disease as defined by disease-specific severity indices will be assessed, and up to a total of 12 pts will be included in each disease cohort at each severity level. Primary endpoints are dose-limiting toxicities, adverse events (AEs) and serious AEs. Continuous monitoring of toxicity will be conducted. Key secondary endpoints are best objective response, progression free and overall survival and cohort specific tumor tissue, blood and non-tumor tissue-based biomarkers. The AIM-Nivo trial opened in May 2019 and is enrolling pts through the National Cancer Institute Experimental Therapeutics Clinical Trials Network (ETCTN). Clinical trial information: NCT03816345. Research Sponsor: U.S. National Institutes of Health.

TPS3159 **Poster Session (Board #223), Fri, 8:00 AM-11:00 AM**

First-in-human phase I/II clinical trial of ONC-392: Preserving CTLA-4 immune tolerance checkpoint for safer and more effective cancer immunotherapy. *First Author: Christian Diego Rolfo, University of Maryland Marlene & Stewart Greenebaum Comprehensive Cancer Center, Baltimore, MD*

Background: A major paradigm in cancer immunotherapy is to use checkpoint inhibitors to break regulatory mechanisms that guard the host against autoimmune diseases. CTLA-4-targeting immunotherapy was the first example to establish this paradigm. However, the clinically tested anti-CTLA-4 antibodies exhibit suboptimal efficacy but high toxicity. Our recent studies have demonstrated that immunotherapy-related adverse events (irAE) and the cancer immunotherapeutic effect (CITE) represent distinct and therapeutically separable activities of anti-CTLA-4 antibodies. The irAEs are attributable to inactivation of the CTLA-4 checkpoint, while the CITE is effective through selective depletion of regulatory T cells (Treg) in the tumor microenvironment. We hypothesize that a safer and more effective CTLA-4-targeting immunotherapy should preserve the CTLA-4 checkpoint while enhancing the efficacy and selectivity of Treg-depletion in tumor microenvironment. In preparation to test this ground-breaking hypothesis clinically, we have generated a next generation of anti-CTLA-4 antibody that preserves the CTLA-4 immune checkpoint by avoiding lysosomal degradation of CTLA-4. The new antibody, ONC-392, has dramatically lower irAEs in a humanized mouse model and significantly more potent activity in depleting tumor-infiltrating Tregs, resulting in more effective CITE. **Methods:** This is an open label Phase IA/IB clinical study to test the safety, pharmacokinetics (PK), and efficacy of ONC-392 as a single agent and in combination with Pembrolizumab in advanced solid tumors and non-small cell lung cancer patients. The study consists of two linked parts: Part A is a dose-finding rapid titration study, with ONC-392 as a single agent in patients with advanced disease of various histology. The aim of this trial is to define the recommended Phase II dose for ONC-392 monotherapy (RP2D-M), Part B is a Phase IA/IB trial of ONC-392 in combination with a standard dose of 200 mg Pembrolizumab in patients with NSCLC. The trial consists of a dose-finding, dose escalation or de-escalation, Phase IA component aimed at defining the recommended phase II dose for ONC-392 in combination with a standard dose of Pembrolizumab (RP2D-C), then progressing into two parallel, single arm, Phase IB expansion cohorts to test for safety and initial efficacy in two groups of patients with NSCLC: Stage IV NSCLC anti-PD(L)1 immunotherapy naïve with PD-L1-positive (PD-L1 TPS ≥ 1%); Stage IV NSCLC refractory/resistant to anti-PD(L)1 immunotherapy. Clinical trial information: NCT04140526. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS3160 Poster Session (Board #224), Fri, 8:00 AM-11:00 AM

A phase Ib, open-label, dose-escalation trial of naptumomab estafenatox (Nap) in combination with durvalumab (MEDI4736) in subjects with selected advanced or metastatic solid tumors. *First Author: Ravit Geva, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: Immunotherapy with the anti-PD-(L)1 checkpoint inhibitors (CPIs) has been largely ineffective in so-called non-immunogenic "cold tumors". Facilitating T cell infiltration is necessary to invoke an immune response which may be augmented or complemented by the activity of CPIs like durvalumab. Selective T cell Redirection Proteins (STRs) are fusion proteins that consist of genetically engineered Superantigen (Sag) linked to Fragment antigen binding (Fab) moieties directed to tumor-associated antigens. Nap is a first in class STR compound, recognizing the tumor-associated oncofetal antigen 5T4, whereas the SAg moiety selectively engages the T cell receptor β variable (TRBV) 7-9. Nap has been shown to induce specific T cells expansion, activation and infiltration into the tumor in pre-clinical and clinical studies. Pre-clinical data demonstrated that the combination of STR with CPI may lead to long term durable responses not possible in most patients receiving single agent CPI therapy and suggests that combining CPIs with STR may be a promising therapeutic strategy for patients with solid tumors. **Methods:** Patients will be treated with the combination of Nap and durvalumab using a flat dose of durvalumab (1120 mg) and the 3+3 design for Nap dose escalation (2, 5, 10, 15 and 20 mcg/kg). The MTD of Nap for the combination treatment will be established based on DLTs occurring during the first treatment cycle. The dose escalation part will be followed by MTD expansion cohort in which 10–15 patients will be treated with MTD of Nap and 1120 mg durvalumab (Clinical trial registry number NCT03983954). Major eligibility criteria include patients with pretreated advanced or metastatic, 5T4 expressing solid tumors, including patients previously progressed on CPI therapy. As of January 2020, enrollment to dose levels 2, 5 and 10 mcg/kg has been completed without DLT, enrollment to dose level 15 mcg/kg will start on February 2020. Clinical trial information: NCT03983954. Research Sponsor: NeoTX Therapeutics Ltd., Pharmaceutical/Biotech Company

TPS3161 Poster Session (Board #225), Fri, 8:00 AM-11:00 AM

Phase II trial of Voyager-V1 (vesicular stomatitis virus expressing human IFNβ and NIS, VV1), in combination with cemiplimab (C) in patients with NSCLC, melanoma, HCC or endometrial carcinoma. *First Author: Mario Sznol, Yale School of Medicine and Smilow Cancer Center, Yale-New Haven Hospital, New Haven, CT*

Background: VV1 is an oncolytic vesicular stomatitis virus engineered to express human IFNβ to enhance cellular anti-tumor immune responses and tumor selectivity, and the human sodium iodide symporter (NIS) for virus tracking by SPECT imaging. Cancer cells are often hyporesponsive to IFNβ, enabling the efficient spread of VV1 and resulting in increased oncolysis. Differently from other oncolytic viruses, VV1 is suitable for both intra-tumoral (IT) and/or intra-venous (IV) administration. Despite considerable anti-tumor activity with checkpoint inhibitors (CPI) among some malignancies, long term survival and overall cures remain elusive. Prior Ph 1 studies have shown significant anti-tumor activity among several malignancies when VV1 was administered either as monotherapy or in combination with a CPI, despite progression on prior CPI monotherapy. Furthermore, pre- and post-treatment biopsy evaluations after VV1 treatment have demonstrated T cell infiltration and inflammation in both IT injected and non-injected lesions. Among IV treated patients (pts), IFNβ was detectable in the serum correlating with viral replication, making it an effective biomarker. C is a high-affinity potent human IgG4 anti-PD-1 monoclonal antibody. Though approved for use in cutaneous squamous cell carcinoma, C has shown anti-tumor activity, similar to other CPI, in several other indications. Therefore, VV1 and C could be an attractive combination for the immunotherapy for several solid tumors. This study represents the first clinical evaluation of VV1 in combination with C in pts with advanced solid tumors. **Methods:** The Ph 2 Simon 2 stage five-arm study of IV administration VV1 in combination with IV C will enroll pts with advanced NSCLC, HCC, melanoma & endometrial cancer. Enrolled pts with NSCLC & melanoma will be recent CPI-progressors, whereas enrolled HCC & endometrial cancer will be CPI-naïve. The study's objectives include assessment of preliminary anti-tumor activity, safety, & immuno-regulatory activity of the combination. Pts will receive IV VV1 once on D1 and IV C once every 3 weeks until confirmed disease progression or intolerable toxicity. Pts enrolled in one melanoma cohort will also receive IT VV1 administered to palpable lesions. Response will be assessed every 9 weeks per RECIST v1.1. The null hypothesis of each cohort's ORR will be tested versus a one-sided alternative yielding a Type I error rate of 5% and power of 80%. Cohorts will be expanded based on signal of activity. Clinical trial information: NCT. Research Sponsor: Vyriad Inc.

TPS3162 Poster Session (Board #226), Fri, 8:00 AM-11:00 AM

A phase Ia/Ib dose-escalation study of intravenously administered SB 11285 alone and in combination with nivolumab in patients with advanced solid tumors. *First Author: Filip Janku, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX*

Background: Activation of the Stimulator of Interferon Genes (STING) pathway in immune cells in the tumor microenvironment (TME) and tumor cells results in the induction of innate and adaptive immunity and subsequent activation of cytotoxic T cells and NK cells for durable anti-tumor responses. SB 11285 is a novel agonist of the STING pathway leading to the activation of tumor-resident APCs and priming of tumor antigen specific CD8+ T cells. In our preclinical studies using multiple tumor-derived cell lines, SB 11285 has been observed to cause the induction of cytokines, such as INF-b, INF- a, TNFa and others consistent with engagement of the STING target, as well as tumor cell death by STING-mediated apoptosis. SB 11285 reduced tumor volumes in multiple rodent tumor models when administered intravenously, intraperitoneally or intratumorally as monotherapy or in combination with checkpoint inhibitors such as anti-CTLA-4 or anti-PD-1 antibody. Systemic administration could additionally facilitate trafficking of newly activated CD8+T cells from periphery into the tumor site. **Methods:** This open-label, multicenter phase 1a/1b clinical trial (NCT04096638) aims to enroll approximately 110 patients in the dose escalation (Part 1) and expansion cohorts (Part 2). Part 1 of the trial is a dose escalation study with IV SB 11285 monotherapy followed by combination with the checkpoint inhibitor nivolumab. Part 1 Dose Escalation of the study will evaluate ascending doses of intravenously administered SB 11285 with respect to dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), recommended phase 2 dose (RP2D) and the pharmacokinetic (PK)/pharmacodynamic profile as monotherapy and in combination with nivolumab. SB 11285, with a starting dose of 0.3μg/kg, will be administered as monotherapy weekly on Days 1, 8, 15, and 22 of repeated 28-day cycles in escalating doses and in combination with nivolumab administered on Q4W schedule. Part 2 Expansion Cohorts of the study will explore initial signs of efficacy in pre-specified tumor types (such as Melanoma, Head and Neck squamous cell carcinoma) using the recommended phase 2 dose (RP2D) of SB 11285 in combination with nivolumab. In addition, the biological effects of SB 11285 will be evaluated by changes in immune cell types and activation state, serum cytokines, and gene expression patterns indicative of activation of the immune compartment. The trial is being conducted at multiple sites in the U.S . Clinical trial information: NCT04096638. Research Sponsor: Spring Bank Pharmaceuticals, Inc.

TPS3163 Poster Session (Board #227), Fri, 8:00 AM-11:00 AM

Phase I/II dose-escalation and expansion study of FLX475 alone and in combination with pembrolizumab in advanced cancer. *First Author: John D. Powderly, Carolina BioOncology Institute, Huntersville, NC*

Background: Regulatory T cells (T_{reg}) can dampen anti-tumor immune responses in the tumor microenvironment (TME). The predominant chemokine receptor on human T_{reg} is CCR4, the receptor for the chemokines CCL17 and CCL22, which are produced by tumor cells, tumor-associated macrophages and dendritic cells, as well as by effector T cells (T_{eff}) in the setting of an inflammatory anti-tumor response. Preclinical studies with orally-available CCR4 antagonists have demonstrated potent inhibition of T_{reg} migration into tumors, an increase in the intratumoral T_{eff}/T_{reg} ratio, and anti-tumor efficacy as a single agent and in combination with checkpoint inhibitors. In a first-in-human trial conducted in healthy volunteers, the oral CCR4 antagonist FLX475 was demonstrated to be well tolerated with outstanding PK properties. A robust PD assay measuring receptor occupancy on circulating T_{reg} demonstrated the ability to safely achieve exposure levels predicted to maximally inhibit T_{reg} recruitment into tumors via CCR4 signaling. These human PK, PD, and safety data have enabled a streamlined design of a Phase 1/2 study of FLX475 in cancer patients both as monotherapy and in combination with checkpoint inhibitor. **Methods:** This clinical trial is a Phase 1/2, open-label, dose-escalation and cohort expansion study to determine the safety and preliminary anti-tumor activity of FLX475 as monotherapy and in combination with pembrolizumab. The study is being conducted in 2 parts, a dose-escalation phase (Part 1) and a cohort expansion phase (Part 2). In Part 1 (Phase 1) of the study, at least 3 to 6 eligible subjects are being enrolled in sequential cohorts treated with successively higher doses of FLX475 as monotherapy (Part 1a) or in combination with pembrolizumab (Part 1b). In Part 2 (Phase 2) of the study, expansion cohorts of both checkpoint-naïve and checkpoint-experienced patients with tumor types predicted to be enriched for T_{reg} and/or CCR4 ligand expression (i.e. "charged tumors") -- including both EBV^+ and HPV^+ tumors and NSCLC, HNSCC, and TNBC -- will be enrolled using a Simon 2-stage design. As of February 4, 2020, Phase 1 dose escalation has been completed and a recommended Phase 2 dose chosen for both FLX475 monotherapy and combination therapy with pembrolizumab. Enrollment into Phase 2 expansion cohorts has been initiated. Clinical trial information: NCT03674567. Research Sponsor: RAPT Therapeutics.

TPS3164 Poster Session (Board #228), Fri, 8:00 AM-11:00 AM

AST-008: A novel approach to TLR9 agonism with PD-1 blockade for anti-PD-1 refractory Merkel cell carcinoma (MCC) and cutaneous squamous cell carcinoma (CSCC). *First Author: Mohammed M. Milhem, Holden Comprehensive Cancer Center, University of Iowa, Iowa City, IA*

Background: AST-008 is a potent spherical nucleic acid configuration of a toll-like receptor (TLR) 9 agonist oligonucleotide being developed for the treatment of MCC and CSCC in patients (pts) progressing on immune checkpoint inhibitor (CPI) monotherapy. Previously presented data suggests AST-008 elicits a Th1-type cytokine response and immune cell activation. This parallel-arm phase II design will permit assessment of efficacy in two advanced skin cancers with high unmet medical need. **Methods:** The study has an open label, multicenter phase Ib/II dose escalation/expansion design. The phase 1b dose escalation used a 3+3 design with increasing doses of intratumoral (IT) AST-008 plus standard flat dose pembrolizumab. The phase II dose expansion is using the recommended regimen (RP2D) of IT AST-008 plus flat dose pembrolizumab or cemiplimab to treat two cohorts of pts with advanced/metastatic MCC or CSCC, respectively. The key objective of the phase II expansion is to provide an estimate of preliminary efficacy of IT AST-008 with pembrolizumab or cemiplimab in pts whose disease progressed on a single-agent CPI therapy. Endpoints also include safety, pharmacokinetic and pharmacodynamic assessments. Pts must have at least two evaluable lesions by RECIST v1.1. One or more lesions may be injected with AST-008, but one lesion (the "witness" lesion) must remain un-injected throughout the study to differentially assess effects of AST-008 on the injected and witness lesions. The RP2D of AST-008 was derived from the dose escalation phase together with pembrolizumab. That RP2D is being used not only in the MCC cohort where AST-008 is combined with pembrolizumab, but also in the CSCC cohort where AST-008 is combined with cemiplimab. To ensure safety of the AST-008/cemiplimab combination, the first 6 pts in the CSCC cohort will be monitored for dose limiting toxicities through the first 5 weeks of dosing, and then the data review committee will assess safety before approving additional patient enrollment to that cohort. Each expansion cohort will enroll up to 29 pts with a Simon two-stage optimal design. In the first stage, 10 pts will be accrued. If there are 0 responses in these 10 pts, enrollment in that arm will be stopped. Otherwise, 19 additional pts will be accrued for a total of 29. The null hypothesis will be rejected if 4 or more responses are observed in 29 pts. This design yields a type I error rate of 0.05 and power of 80% when the true response rate is 20%. The planned phase II enrollment is 58 pts across about 15 US-based sites. Clinical trial information: NCT03684785. Research Sponsor: Exicure Inc.

TPS3165 Poster Session (Board #229), Fri, 8:00 AM-11:00 AM

A phase I/II first-in-human study of a novel anti-MAGE-A4 TCR/anti-CD3 bispecific (IMC-C103C) as monotherapy and in combination with atezolizumab in HLA-A*02:01-positive patients with MAGE-A4-positive advanced solid tumors (IMC-C103C-101). *First Author: George R. Blumenschein, Jr., Department of Thoracic and Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ImmTAC bispecifics are unique T cell receptor (TCR)/anti-CD3 bispecific molecules that are designed to redirect polyclonal T cells against intracellular antigens, in contrast to antibody-based therapies, which are limited to extracellular antigens. ImmTAC molecules recognize a specific peptide presented on defined Class I HLA molecules via an affinity enhanced, engineered, soluble TCR. Through the addition of an anti-CD3 scFv effector domain fused to the TCR targeting domain, ImmTAC molecules redirect T cell activity against cancer cells, regardless of the specificity of the T cell. IMC-C103C is an ImmTAC being investigated against MAGE-A4, which is among the most commonly expressed cancer testis antigens in solid malignancies, but with minimal to absent expression on normal tissues and/or hematopoietic cells. The most advanced ImmTAC in development, tebentafusp (IMCgp100), directed against melanocyte-associated lineage antigen gp100, has shown monotherapy activity in uveal melanoma and PD-1 refractory advanced cutaneous and uveal melanoma. Tebentafusp is being further evaluated in combination with durvalumab and tremelimumab. **Methods:** IMC-C103C-101 is a multi-center, open-label, Phase 1/2 first-in-human study of IMC-C103C as monotherapy and combination with atezolizumab in HLA-A*02:01-positive patients with MAGE-A4-positive advanced cancers. The study includes IMC-C103C monotherapy (Q1W) dose escalation, followed by expansion into indication specific arms to test for efficacy in defined patient cohorts. Concurrently, combinations with atezolizumab are planned. Primary objectives of dose escalation are to identify the MTD/RP2D, and characterize safety/tolerability. Secondary objectives include an assessment of efficacy (best overall response by RECIST v1.1), PK, PD, and ADA. IMC-C103C monotherapy dose escalation is in progress. Clinical trial information: NCT03973333. Research Sponsor: Immunocore Ltd, Pharmaceutical/Biotech Company.

TPS3166 Poster Session (Board #230), Fri, 8:00 AM-11:00 AM

Trial in progress: A phase I/II, open-label, dose-escalation, safety and tolerability study of NC318 in subjects with advanced or metastatic solid tumors. *First Author: Martin Gutierrez, Hackensack University Medical Center, Hackensack, NJ*

Background: Siglec-15 (S15) is a member of the Siglec family (Sialic acid-binding Immunoglobulin Lectins), a distinct subgroup of immunoglobulin (Ig) superfamily proteins involved in discriminating self from non-self-immune regulation (Macauley MS et al. 2014). Nonclinical models demonstrate S15 mediates suppression of T cell proliferation and negatively regulates T cell function. NC318 is a first-in-class monoclonal antibody that blocks S15-mediated immune suppression and prevents tumor growth by normalizing T cell function and restoring anti-tumor immunity in the tumor microenvironment (Wang J et al. 2019). The clinical hypothesis of this study is that NC318 targeting of S15 can improve anti-tumor immune response and provide benefit in multiple oncology indications. **Methods:** This is a multi-center, first in human, phase 1/2, open-label, non-randomized study to determine the safety and tolerability, define maximum tolerated dose and/or pharmacologically active dose, assess preliminary efficacy, and explore predictive and pharmacodynamic biomarkers of NC318 in subjects with advanced or metastatic solid tumors. Key eligibility criteria included measurable disease based on RECIST v1.1 and consent for collection of biopsies at screening and on treatment (optional for phase 1). Phase 1 used a 3+3 dose escalation design to determine the recommended phase 2 dose (RP2D) and schedule of NC318 while identifying drug related toxicities (DLTs). Phase 2 enrollment is limited to non-small cell lung, ovarian, head and neck, and triple negative breast cancer subjects with PD-L1 tumor proportion scores $<$50% (additional tumor types are being evaluated for inclusion). Ongoing exploratory analyses include the assessment of predictive biomarkers associated with treatment benefit, and pharmacodynamic markers associated with study drug activity (e.g. evaluation of tumor biopsies and peripheral markers of inflammation). Phase 1 enrollment began October 2018 and completed in August 2019. The RP2D was defined and the phase 2 opened to enrollment October 2019. Clinical trial information: NCT03665285. Research Sponsor: NextCure, Inc.

TPS3167 Poster Session (Board #231), Fri, 8:00 AM-11:00 AM

Phase II basket trial of olaparib and durvalumab in patients (pts) with isocitrate dehydrogenase (IDH) mutated solid tumors. *First Author: Eric Xueyu Chen, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Somatic IDH mutations are common in low grade gliomas, and rare in other solid tumors with the exception of intrahepatic cholangiocarcinoma (ICA) and certain subtypes of chondrosarcoma. IDH mutations confer a gain-of-function neomorphic activity, such that mutant IDH enzymes preferentially convert αKG to 2-hydroxyglutarate (2HG), resulting in abnormal accumulation of 2HG. 2HG competitively inhibits αKG-dependent dioxygenases, many of which are involved in DNA repair. Preclinical studies show that IDH mutated cancer cells have defective homologous recombination repair and are exquisitely sensitive to poly (adenosine 5'-diphophate-ribose) polymerase (PARP) inhibition. **Methods:** This is a single arm phase II basket study (NCT03991832). Pts with IDH mutated solid tumors are divided into three cohorts; A: low-grade glioma; B: cholangiocarinoma; C: all other solid tumors. Pts are treated with olaparib 300 mg twice daily continuously and durvalumab 1500 mg every 4 weeks until progression, intolerable toxicity or consent withdrawal. Radiological assessment is performed after every 2 cycles of study treatments. Major eligibility criteria include IDH mutation by immunohistochemistry or sequencing, up to 2 lines of systemic therapy for advanced disease, performance status 0 – 2 and adequate organ function. Pts are excluded if they received prior PARP inhibitors and anti-PD-1/PD-L1 antibody. The Simon's optimal 2-stage design is applied for Cohorts A and B. 10 pts will be enrolled in each of Cohort A and B initially. If 2 or more partial responses (PR) are seen in these 10 pts, additional 19 pts will be enrolled for a total of 29 pts in that cohort. The combination is considered to be of clinical interest for further development if $\geq$ 6 PRs are seen in each cohort. Cohort C will enroll 20 pts. Archival tumor tissues and serial blood samples will be collected on study. 2HG levels will be measured and correlated with responses. The study was activated in December 2019. 3 pts have been enrolled into Cohort B. Clinical trial information: NCT03991832. Research Sponsor: None.

TPS3168 Poster Session (Board #232), Fri, 8:00 AM-11:00 AM

First-in-human phase Ib study of ATRC-101, an engineered version of a patient-derived antibody targeting a tumor-restricted ribonucleoprotein complex. *First Author: Jonathan Eliot Benjamin, Atreca, Inc., South San Francisco, CA*

Background: ATRC-101 is a fully human, engineered IgG1 version of an antibody discovered through a a target-agnostic screen to identify patient-derived antibodies that bind selectively to public tumor antigens. The parental antibody was identified from B cells in the active immune response of a patient receiving checkpoint therapy for Stage IV non-small cell lung cancer (NSCLC). A fluorescently conjugated version of ATRC-101 binds selectively to human tumor specimens including a majority of NSCLC, acral melanoma, breast, colorectal, and ovarian cancer samples. No reactivity of toxicological significance is found across a wide range of normal human tissues. ATRC-101 displays dose-dependent, single-agent activity in syngeneic mouse tumor models, including the EMT6 breast cancer model, which displays a T cell-excluded microenvironment often observed in human tumors, and in which checkpoint inhibitors targeting the PD-1 axis exhibit limited activity. Dosing with ATRC-101 in the EMT6 model causes marked changes in the tumor microenvironment, including a shift from the M2 to the M1 macrophage phenotype and infiltration of T cells. ATRC-101 does not appear to act via NK cell-driven ADCC; instead, activity *in vivo* is dependent both on Fc region interactions with Fc receptors, likely on myeloid rather than lymphoid cells, and on the presence of CD8+ T cells. ATRC-101 binds to a target that is a ribonucleoprotein (RNP) complex containing polyadenylate-binding protein 1 (PABP-1) bound to poly(A)RNA. Whereas both PABP-1 and poly(A)RNA are ubiquitously expressed at high levels in normal tissues and have been localized intracellularly, the ATRC-101 target is detected extracellularly on tumor cells grown *in vivo*. The basis for the tumor-selectivity of ATRC-101 as well as the extracellular localization of the target is under investigation. Ascending doses of ATRC-101 were well tolerated in multiple non-clinical safety studies. **Methods:** ATRC-101-A01 is an open-label, 3+3, Phase 1b safety study in patients with acral melanoma, NSCLC, breast, ovarian, and colorectal cancers. Participants are accruing in the first dose cohort. ATRC-101 is administered every 21 days up to 24 months or until disease progression. The primary objective of the trial is to determine the safety and tolerability of ATRC-101. Secondary objectives are to characterize the pharmacokinetic profiles of ATRC-101 and to assess antitumor activity as determined by RECIST 1.1 and lymphocytic infiltration in the tumor microenvironment. Clinical trial information: NCT04244552. Research Sponsor: Atreca, Inc.

TPS3170 Poster Session (Board #234), Fri, 8:00 AM-11:00 AM

Phase I/II open label nonrandomized safety and efficacy study of the viral vectored ChAdOx1-MVA 5T4 immunotherapy in combination with PD-1 checkpoint blockade in intermediate-risk localized or locally advanced prostate cancer and advanced metastatic prostate cancer. *First Author: Mark Tuthill, The Jenner Institute, University of Oxford, Oxford, United Kingdom*

Background: Antigen-specific immunotherapy (Sipuleucel-T) is licenced for the treatment for castrate resistant prostate cancer, but has modest clinical efficacy and is complex to administer to patients. New therapeutic antigen-specific approaches are required to generate and sustain therapeutic immune responses against tumour specific antigens in men with early and advanced prostate cancer. We have previously reported immunogenicity and efficacy data of a novel viral vectored vaccines-based immunotherapy based on two replication-deficient viruses, chimpanzee adenovirus (ChAdOx1) and MVA, targeting an oncofetal self-antigen 5T4, administered as a single agent and in combination with anti-PD-1 in mouse tumour models. We tested this immunotherapy alone in a first-in-human trial, VANCE (NCT02390063), in intermediate risk prostate cancer patients. Based on encouraging safety and exceptional T cell immunogenicity of the VANCE study, the phase I/II trial, ADVANCE (NCT03815942) is being undertaken to test the immunotherapy safety and efficacy in combination with PD-1 blockade in intermediate risk disease and metastatic prostate cancer. **Methods:** Study design: ADVANCE, an open label non-randomised phase I/II study, will recruit 12 patients with intermediate-risk prostate cancer patients (Gleason score $\leq$ 7, local tumour stage $\leq$T3c, PSA$\leq$ 20 ng/ml) scheduled to undergo radical prostatectomy (Cohort 1) and 24 mCRPC patients with disease progression on anti-androgen therapy with either enzalutamide or abiraterone (Cohort 2). Cohort 1 will receive one cycle of ChAdOx1-MVA 5T4 immunotherapy and a single nivolumab infusion. Cohort 2 will receive 2 cycles of ChAdOx1-MVA 5T4 vaccination and three nivolumab infusions. Primary endpoint: Cohort 1 - PSA change from baseline to surgery, Cohort 2 – composite response rate measured as either $\geq$50% reduction of circulating tumour DNA or $\geq$50% serum PSA decrease from baseline at 24-week assessment and the maximal response rate. Secondary and exploratory endpoints include 5T4-specific immune response in the periphery, progression-free and overall survival and reduction of circulating tumour cells. 23 of planned 24 patients have been enrolled in Cohort 2. Enrolment to the Cohort 1 is ongoing. The data analysis is expected to be completed by Q4 2020 for Cohort 2. Clinical trial information: NCT03815942. Research Sponsor: Grant agreement No. 602705.

TPS3171 Poster Session (Board #235), Fri, 8:00 AM-11:00 AM

A phase I/II study of HB-201, an arenavirus-based cancer immunotherapy, alone, or in combination with anti-PD-1 in patients with HPV16+ cancers. *First Author: Bharat Burman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human Papillomavirus 16 (HPV16) is linked to several cancer types; treatment options are limited for patients with HPV16+ recurrent or metastatic cancers. The generation and maintenance of the HPV16+ malignant state requires the stable expression of HPV16-specific E7 and E6 oncogenes, which can also serve as immunogenic tumor-associated antigens. HB-201 is a replication-competent live-attenuated vector based on the arenavirus LCMV encoding a non-oncogenic E7 and E6 fusion protein. In preclinical models, both intravenously (IV) and intratumorally (IT) administered HB-201 demonstrate potent immunogenicity by induction of HPV16-specific cytotoxic T cells and associated efficacy. **Methods:** This is a first in human, Phase I/II study of HB-201 monotherapy or in combination with PD-1 immune checkpoint inhibitor (anti-PD-1) in HPV16+ confirmed recurrent/metastatic cancers. Phase I consists of 2 treatment groups, each conducted with a 3+3 dose escalation design. Group 1 is enrolling patients with HPV16+ head and neck squamous cell carcinoma who will receive HB-201 IV only. Group 2 is enrolling HPV16+ cancer patients with a safely accessible tumor site who will receive HB-201 IT for the first dose, followed by HB-201 IV for subsequent doses (IT-IV). HB-201 will be administered every 21 days. The Phase II component will be conducted with the recommended Phase II doses (RP2Ds) defined in Phase I and will consist of 3 groups: Group A (HB-201 IV only), Group B (HB-201 IV plus anti-PD-1), and Group C (HB-201 IT-IV). Key eligibility criteria include age $>$ 18, ECOG performance status 0-1, confirmed HPV16+ recurrent or metastatic cancer, disease progression from at least 1 systemic standard of care therapy, and measurable disease per RECIST v1.1. The Phase I primary objective is to determine RP2Ds for IV and IT HB-201. The Phase II primary objective is to assess antitumor activity. Secondary endpoints for both phases include safety, tolerability, overall survival, progression-free survival, and duration of response. Exploratory objectives include characterization of immunogenicity of HB-201 and biomarkers associated with immune or antitumor response. Enrollment to Groups 1 and 2 began in December 2019. Clinical trial information: NCT04180215. Research Sponsor: Hookipa Pharma.

TPS3172 Poster Session (Board #236), Fri, 8:00 AM-11:00 AM

Safety and efficacy of neoadjuvant intravesical oncolytic MV-NIS in patients undergoing radical cystectomy (RC) for urothelial carcinoma but ineligible for neoadjuvant cisplatin-based chemotherapy. *First Author: Bradley C. Leibovich, Mayo Clinic, Rochester, MN*

Background: Bladder cancer is a leading cause of cancer death in the United States. Over 90% of bladder cancer cases are urothelial carcinomas (UC) that may present as a non-muscle-invasive (NMIBC) or muscle-invasive disease (MIBC). Standard of care for NMIBC includes transurethral resection of bladder tumor (TURBT), intravesical chemotherapy and immunotherapy with Bacillus Calmette-Guerin (BCG). Patients (pts) with high-grade BCG-refractory NMIBC or MIBC undergo RC, which involves complete bladder removal and pelvic lymphadenectomy. RC severely impacts quality of life with significant morbidity. Oncolytic viruses are showing promise in UC, and MV-NIS has proven efficacy in other tumor types. MV-NIS is an investigational oncolytic measles virus with an excellent safety profile, irrespective of route of administration ($n > 100$). MV-NIS-related adverse events are limited to infusion reactions and transient CBC changes, and little local toxicity is anticipated with intravesical therapy. Clinical efficacy of this oncolytic may be related to absence of measles immunity. Based on this, the clinical strategy for MV-NIS is focused on targeting immune-privileged sites via intra-tumoral or intravesical routes, alone or in combination with checkpoint inhibitors. We hypothesize that intravesical therapy with oncolytic MV-NIS can improve clinical outcomes for (a) BCG refractory NMIBC pts to avoid or delay the need for RC; and (b) MIBC pts undergoing RC. **Methods:** This study is enrolling pts undergoing RC who are ineligible to receive neoadjuvant chemotherapy. The trial has 2 stages to (a) determine the safety and tolerability of intravesical MV-NIS, and (b) assess preliminary efficacy. Part (a) includes 4-24 pts in a timing cohort with doses administered at increasing durations (1-4 weeks) prior to RC to establish safety of a single MV-NIS dose. Part (b) includes an expansion cohort ($n = 12$) to evaluate the safety and efficacy of 2 intravesical doses of MV-NIS at 2-week intervals prior to RC. Safety is assessed using NCI-CTCAE V5 and Clavien-Dindo grading of operative complications. The efficacy endpoint is pathologic stage at time of RC (pT0 rate), which can be compared to pre-study TURBT stage. Additional exploratory studies include PK and PD analyses in urine, blood and tumor. Enrollment is ongoing at 2 Mayo Clinic sites (Rochester, MN and Jacksonville, FL) and the study has now progressed from the timing cohort into the expansion cohort. Clinical trial information: NCT03171493. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS3173 Poster Session (Board #237), Fri, 8:00 AM-11:00 AM

Phase I study of NBTXR3 activated by radiotherapy in patients with advanced cancers treated with an anti-PD-1 therapy. *First Author: Colette Shen, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Despite the past decade of transformative advances in immuno-oncology, the response rate to checkpoint inhibitors (ICIs) remains low (~15%). There is significant interest in developing strategies to overcome resistance to these treatments, thus increasing response rate. Emerging evidence suggests that radiation therapy (RT) could potentially augment the antitumor response to ICIs through synergic effect. However, RT dose and ultimate efficacy are limited by toxicity related to exposure of healthy tissues. NBTXR3 is a first-in-class radioenhancer administered by direct intratumoral injection, designed at the nanoscale to increase RT dose deposition within tumor cells and RT-dependent tumor cell killing, without increasing surrounding normal tissue toxicity. Preclinical and early clinical data suggest NBTXR3 activated by RT can trigger an anti-tumor immune response, producing both local and systemic (abscopal) effects. We hypothesize that NBTXR3 activated by RT, in combination with anti-PD-1 therapy (R3/RT/PD-1), will act synergistically to maximize the local RT effect and produce a systemic response sufficient to increase the proportion of ICI responders or convert ICI non-responders to responders. **Methods:** This trial [NCT03589339] is a multicenter, open-label, phase I study to evaluate safety and tolerability of R3/RT/PD-1 in three cohorts: (1) Locoregional recurrent or recurrent and metastatic head and neck squamous cell carcinoma (HNSCC) amenable to re-irradiation of the HN field, (2) Lung metastases, or (3) Liver metastases, both from any primary cancer eligible for anti-PD-1 treatment. Approximately two-thirds of patients in each cohort will be anti-PD-1 non-responders. NBTXR3 injected volume is based on a percentage of gross tumor volume (GTV). The primary objective is to determine the R3/RT/PD-1 recommended phase 2 dose in each cohort. Secondary objectives are to evaluate anti-tumor response (objective response rate; ORR), safety and feasibility of NBTXR3 injection, and NBTXR3 body kinetic profile. Exploratory objectives will assess biomarkers of R3/RT/PD-1 response, including PD-L1 status by IHC, as well as mRNA and cytokine immune marker profiling. To date, three patients have been treated, one in cohort 1, two in cohort 2. Clinical trial information: NCT03589339. Research Sponsor: Nanobiotix, SA.

3500 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

First-in-human phase I study of ARV-110, an androgen receptor (AR) PROTAC degrader in patients (pts) with metastatic castrate-resistant prostate cancer (mCRPC) following enzalutamide (ENZ) and/or abiraterone (ABI). *First Author: Daniel Peter Petrylak, Smilow Cancer Center, Yale University, New Haven, CT*

Background: Proteolysis Targeting Chimera (PROTAC) protein degraders induce selective degradation of targeted proteins by engaging the ubiquitin proteasome system. ARV-110 is an orally bioavailable PROTAC that specifically degrades AR ≥ 95% and achieves anti-tumor activity in ENZ-naïve and -resistant prostate cancer xenograft models. **Methods:** To define the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of ARV-110, pts with ≥ 2 prior therapies for mCRPC, including ENZ and/or ABI, received ARV-110 orally once daily. Dose escalation is per 3+3 design. Endpoints include dose limiting toxicities (DLTs), adverse events (AEs), pharmacokinetics (PK), biomarkers (e.g., AR mutation analysis), RECIST and PSA response. **Results:** By January 2020, 18 pts were dosed: 35 mg (N = 3), 70 mg (N = 4), 140 mg (N = 8), 280 mg (N = 3). 12 pts received both ENZ and ABI; 14 received prior chemotherapy. 1 of 18 pts experienced a DLT (280 mg) of Grade (Gr) 4 elevated AST/ALT followed by acute renal failure while taking rosuvastatin (ROS). A 2nd pt had Gr 3 AST/ALT with ROS that resolved off ROS, permitting ARV-110 retreatment. ROS plasma concentrations demonstrated significant increases concurrent with AST/ALT elevations in both pts. Subsequently, ROS was prohibited without further ≥Gr 2 AST/ALT AEs. No other related Gr 3/4 AEs were reported. ARV-110 PK was generally dose proportional and at 140 mg reached levels associated with preclinical anti-tumor activity. 15 pts were evaluable for PSA response (excludes 1 pt stopped after 1 dose for early progression and 2 pts initiated 2 weeks before cutoff, all at 140 mg). Of these, 8 pts initiated dosing at ≥140 mg. 2 pts achieved confirmed PSA declines of >50%, both at 140 mg. Prior therapy in both pts included ENZ and ABI, chemotherapy, bicalutamide and radium-223 plus other regimens. 1 pt had 2 AR mutations known to confer ENZ resistance. The 2nd pt also achieved an unconfirmed RECIST partial response (confirmatory scan pending). Both responses were ongoing at data cutoff (8+ and 21+ weeks of treatment). **Conclusions:** To date, ARV-110 has an acceptable safety profile. Concurrent ROS is now prohibited. MTD has not yet been established; determination of RP2D continues. ARV-110 demonstrates antitumor activity in mCRPC after ENZ/ABI with 2 ongoing confirmed PSA responses, one of which was associated with tumor reduction. Updated data for this first PROTAC in clinical testing will be presented. Clinical trial information: NCT03888612. Research Sponsor: Arvinas.

3501 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase I/II study of avadomide (CC-122) in combination with R-CHOP for newly diagnosed DLBCL. *First Author: Neha Mehta-Shah, Washington University School of Medicine, St. Louis, MO*

Background: In certain subsets of patients (pts) with diffuse large B-cell lymphoma (DLBCL), the failure rate of standard R-CHOP treatment is high. Pts with high-risk disease (International Prognostic score [IPI] 3-5) have a particularly poor prognosis, with 3-y survival rates of ~62% with R-CHOP alone. The cereblon E3 ligase modulator avadomide (CC-122) showed activity in pts with relapsed or refractory DLBCL. We report results of avadomide plus R-CHOP in previously untreated pts with high-risk DLBCL. **Methods:** CC-122-DLBCL-002 (NCT03283202) is a phase 1/2 study of avadomide plus R-CHOP-21 in pts newly diagnosed with DLBCL not otherwise specified with IPI scores 3-5 who were aged ≥18 y. Pts received standard R-CHOP and escalating doses (1-3 mg) of oral avadomide for up to six 21-d cycles (Table). All pts received pegfilgrastim support. Primary objectives were to assess safety, tolerability, and complete response (CR) rate. Secondary objectives include evaluation of additional efficacy parameters (objective response rate [ORR], progression-free survival [PFS], and overall survival) and biomarkers. **Results:** As of July 30, 2019, 35 pts were enrolled in the phase 1 part of the study. Median age was 66 y (range, 20-75), 23 pts (66%) were aged > 60 y, 18 (51%) had an IPI score of 3, and 17 (49%) had an IPI score of 4-5. Thirty-two pts (91%) completed 6 cycles of treatment. Median relative total dose intensity of avadomide was 99% and the average relative dose intensity of R-CHOP was 95%. Six pts had dose-limiting toxicities: 1 pt had neutropenia and bacterial hepatic infection; 1 had pneumonia; 1 had febrile neutropenia (FN); 1 had FN and hypotension; 1 had FN due to skin infections; and 1 had sepsis. The recommended phase 2 dose was 3 mg 2/3 wk. Grade 3/4 adverse events in ≥10% of pts were neutropenia (54%), anemia (20%), leukopenia (20%), lymphopenia (14%), hypophosphatemia (14%), and FN (11%). Among 34 efficacy-evaluable pts, the ORR was 88% (n = 30/34), including a CR rate of 79% (n = 27/34) at the end of treatment. With a median follow-up of 10 mo, the 1-y PFS rate was 80% (95% CI, 58-92). Correlative analyses will be presented at the meeting. **Conclusions:** Avadomide plus R-CHOP was well-tolerated with no significant additive toxicities. The promising efficacy in this high-risk pt population warrants further evaluation of immunomodulatory drugs combined with immunochemotherapy for pts with previously untreated DLBCL. Clinical trial information: NCT03283202.Research Sponsor: Celgene, a wholly owned subsidiary of Bristol-Myers Squibb.

Dose Level	Avadomide Dose	Schedule
1	1 mg	D1-5 & D8-12 (5/7 d; 2/3 wk)
2	2 mg	D1-5 & D8-12 (5/7 d; 2/3 wk)
3	3 mg	D1-5 & D8-12 (5/7 d; 2/3 wk)
4	3 mg	D1-5, D8-12, & D15-19 (5/7 d; 3/3 wk)

3502 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

CX-2029, a PROBODY drug conjugate targeting CD71 (transferrin receptor): Results from a first-in-human study (PROCLAIM-CX-2029) in patients (Pts) with advanced cancer. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: CX-2029 is a PROBODY drug conjugate (PDC) of MMAE, a potent microtubule inhibitor, directed against CD71 (transferrin receptor 1). In addition to being an abundant tumor antigen, CD71 is highly expressed on normal cells, precluding targeting by a traditional antibody drug conjugate (ADC). PDCs are masked ADCs, unmasked predominantly by tumor-associated proteases, thereby restricting target engagement to tumors. Both a CD71 PDC and ADC displayed broad activity in multiple xenograft tumor models; in toxicology studies, the PDC was tolerable at doses consistent with efficacy in non-clinical tumor models while the ADC was not. **Methods:** In a phase 1/2 first-in-human study of PDC CX-2029 in advanced solid tumors (NCT03543813), pts with ECOG 0–1 and ≥1 prior systemic therapy were enrolled into escalating dose cohorts of the PDC CX-2029 given IV every 21 days. Endpoints included evaluation of MTD, safety, antitumor activity, and potential biomarkers; plasma and tissue samples were collected for PK/PD analyses. Preliminary results are reported. **Results:** As of 30 November 2019, 34 pts were enrolled (median age 59 y; 59% male; 71% ECOG 1; median [range] of 3 [1–16] prior therapies). Pts received a median of 3 (1–12) CX-2029 doses. Starting dose for escalation was 0.1 mg/kg. Following a single CX-2029 dose, median molar ratio of masked CX-2029 to total CX-2029 for AUC_{tau} was 0.938 (0.864–0.942); the ratio of free MMAE to total CX-2029 was <0.03. Infusion-related reactions were the most common treatment-related AE (TRAE) of any grade (88%; primarily low grade and with first infusion), followed by anemia (56%), fatigue and nausea (24% each), neutropenia (21%), and leukopenia (12%). Grade 3+ TRAEs in ≥10% pts were anemia (35%) and neutropenia (18%). In 32 response-evaluable pts, 1 pt had a confirmed partial response (squamous NSCLC); 9 had stable disease including 1 pt with ocular melanoma treated for 36 weeks. **Conclusions:** The observed safety profile for CX-2029 effectively reduces on-target toxicity for this previously undruggable target, supporting the PROBODY platform. Evidence of anti-tumor activity was observed. Dose escalation continues. Clinical trial information: NCT03543813. Research Sponsor: CytomX Therapeutics, Inc.

3503 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Results from a phase I, open-label study of ceralasertib (AZD6738), a novel DNA damage repair agent, in combination with weekly paclitaxel in refractory cancer (NCT02630199). *First Author: Jeeyun Lee, Samsung Medical Center, Seoul, South Korea*

Background: Ataxia Telangiectasia and Rad3 Related (ATR) is an apical kinase with a critical role in the DNA-damage response. During normal DNA replication, ATR is recruited at stalled replication forks which can progress to double strand breaks if left unrepaired. AZD6738 is an oral inhibitor of the serine/threonine protein kinase ATR, a member of the phosphoinositide 3-kinase related kinase (PIKK) family. **Methods:** Eligible patients (pts) with advanced solid tumours were administered AZD6738 in combination with fixed dose paclitaxel 80 mg/m2 D1, D8, D15 in 28-day cycles. The dose of AZD6738 was escalated to reach a maximum tolerated dose (MTD) in a rolling 6 design. The trial evaluated safety, MTD, pharmacokinetics (PK) and pharmacodynamics (PD). Translational studies on plasma samples included cytokine analysis, panel sequencing of ctDNA, as well as IHC and immunofluorescence of immune cell markers. **Results:** 58 pts (34 melanoma, 15 gastric cancer (GC), 4 sarcoma, 3 colon cancer, 1 neuroendocrine and 1 hepatocellular cancer) were enrolled in 7 dose cohorts ranging 40mg OD to 240 mg BID. One dose-limiting toxicity (DLT) of neutropenic fever occurred in each cohort of n = 6 evaluable pts at AZD6738 160 mg BD and 240 mg BD days 1-14. Per protocol, the maximum tolerated dose of AZD6738 is 240 mg BID days 1-14. The most common toxicities (all causality, all grade) were: anorexia/nausea (n = 15, 26%), leukopenia (n = 11, 19%) and anemia (n = 11, 19%). 51 pts are evaluable for efficacy; we observed 1 complete response (1.9 %, melanoma), 12 confirmed partial responses (23.5%; 2 gastric, 10 melanoma all of which were post-immunotherapy), 18 stable disease (35.3%) and 20 disease progression (39.2%). The overall confirmed response rate from the dose escalation is 25.5%. Genomic analysis of baseline plasma (27 pts) revealed enrichment of NF1 somatic mutations and activating NRAS mutations amongst melanoma pts (6/18 and 4/18, respectively). Cyclical changes in interleukin-12 levels were observed in three pts with disease control which could reflect an immunological component to the mechanism of response. We will present a comprehensive case report of a patient with dramatic and durable response. **Conclusions:** We conclude that AZD6738 can be safely combined with weekly paclitaxel and propose a recommended phase II dose and schedule. The combination of AZD6738 and paclitaxel demonstrated promising anti-tumor activity with durable responses, especially in melanoma pts after failing anti-PD1 therapy. Clinical trial information: NCT02630199. Research Sponsor: None.

3504 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase I monotherapy dose escalation of RGX-202, a first-in-class oral inhibitor of the SLC6a8/CKB pathway, in patients with advanced gastrointestinal (GI) solid tumors. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: About 65% of advanced colorectal cancer (CRC) patients (pts) have creatine kinase B (CKB) expressing tumors. CKB expressing (CKB+) GI cancer cells import creatine via the creatine transporter SLC6a8 and utilize it to generate intracellular ATP. RGX-202, a small molecule inhibitor of SLC6a8, reduces intracellular creatine and ATP levels, leading to apoptosis. RGX-202 treatment triggers complete tumor regressions in multiple CKB+ preclinical models, including KRAS mutant CRC. **Methods:** RGX-202-001 is a phase I escalation/expansion study of RGX-202 +/- FOLFIRI in pts with advanced GI tumors. The primary safety objective during dose escalation is to identify the maximum tolerated dose (MTD), or the maximum tested dose at which multiple dose-limiting toxicities (DLTs) are not observed. The primary efficacy objective is to estimate the antitumor activity of RGX-202 by RECIST. **Results:** As of January 31, 2020, 17 pts have been treated in 4 single agent dose escalation cohorts: 600 mg BID (3 pts), 1200 mg BID (4 pts), 2400mg BID (5 pts) and 3600mg BID (5pts) given continuously. No DLTs were observed and an MTD was not reached. Treatment-related adverse events (TRAEs) occurring in $>$ 2 pts are shown in the Table. There were no Grade 4 TRAEs. At the highest dose, 2 of 3 CRC pts had prolonged disease control: a patient with a KRAS G13D mutant cancer had SD for 14 weeks; and a patient with KRAS G12V mutant (MSS) cancer had a confirmed PR ongoing at 30 weeks. Exposure to RGX-202 was greater than dose-proportional and the average $AUC_{0\text{-}24}$ ranged from ~15,700 ng-hr/mL in cohort 1 to 241,097 ng-hr/mL in in Cohort 4. Serum and urine creatine levels, pharmacodynamic markers of SLC6a8 inhibition, correlated with systemic exposure to RGX-202. **Conclusions:** Among 17 patients treated with single agent therapy, no DLTs occurred; notably, exposures predicted to be sufficient to inhibit human tumor growth from preclinical models were achieved along with concomitant pharmacodynamic effects. These data, along with a durable PR observed in the highest dose cohort, support further development of RGX-202. Consequently, dose escalation in combination with FOLFIRI in patients with advanced GI cancers is underway with plans for expansion in CKB+ CRC pts. Clinical trial information: NCT03597581.Research Sponsor: Rgenix.

3505 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Tolerability and preliminary efficacy of BXQ-350 for refractory solid tumors and high-grade gliomas: First-in-human, first-in-class phase I trial. *First Author: Olivier Rixe, GRU Cancer Center, Augusta, GA*

Background: BXQ-350 is a first-in-class agent comprised of Saposin C (SapC) and dioleoyl phosphatidylserine (DOPS). SapC, a multifunctional lysosomal-activator glycoprotein that preferentially interacts with tumor cell phospholipids, has demonstrated anti-tumor effects in both *in vitro* and *in vivo* preclinical models. The tolerability and preliminary efficacy of BXQ-350 in the first-in-human study are summarized here. **Methods:** Eighty-six refractory solid tumor (ST) or high-grade glioma (HGG) patients age $\geq$18 (36F: 50M, age 24-81) were enrolled in a 3-part first-in-human trial (NCT02859857) from 2016-2019 and received at least one dose of BXQ-350. Doses were administered via intravenous infusion during 28-day cycles until disease progression occurred. The previously reported part 1 dose escalation portion of the study (9 HGG, 9 ST patients) established the highest planned dose of 2.4mg/kg as safe but did not identify a maximum tolerated dose. The part 2 expansion cohort treated 37 patients (18 HGG and 19 ST) and an additional part 3 cohort treated 31 ST gastrointestinal (GI) patients, both at the 2.4 mg/kg dose level. Preliminary antitumor activity was evaluated (RECISTv1.1 or RANO). **Results:** There were no BXQ-350-related serious adverse events, dose limiting toxicities or withdrawals with the exception of 1 allergic type reaction. Three patients (Glioblastoma, Ependymoma, Appendiceal) demonstrated a partial response per RECIST/RANO. Two HGG patients with progressive radiologic enhancement were seen to have treatment effect at surgery, and hence considered to have stable disease. Seven patients (2 HGG, 3 GI, 2 other ST) remain on study and have received treatment for 9+ to 41+ months, with 5 patients treated for $>$ 1 year. A continuing treatment protocol is planned in order to allow these patients to remain on BXQ-350 treatment. **Conclusions:** BXQ-350 was well tolerated with no significant dose-limiting toxicities at the highest planed dose level. Preliminary results indicate this novel agent demonstrated possible anti-tumor activity in refractory solid tumors and HGG. Clinical trial information: NCT03967093). Research Sponsor: Bexion Pharmaceuticals.

3506 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase II study of copanlisib in patients with tumors with *PIK3CA* mutations (*PTEN* loss allowed): NCI MATCH EAY131-Z1F. *First Author: Senthil Damodaran, Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The NCI-MATCH (EAY131) is a platform trial that enrolls patients (pts) with solid tumors, lymphomas, or multiple myeloma to targeted therapies based on matching genomic alterations of interest (NCT02465060). Arm Z1F evaluated copanlisib, a highly selective, pan-Class 1 PI3K inhibitor with predominant activity against both the δ and α isoforms in pts with *PIK3CA* mutations. **Methods:** Pts received copanlisib (60 mg IV) on days 1, 8, and 15 in 28-day cycles until progression/toxicity. Tumor assessment was every 2 cycles. The primary endpoint was objective response rate (ORR); secondary endpoints were PFS, 6-month PFS, and predictive biomarkers. Pts with *KRAS* mutations, HER2+ve breast cancers, lymphomas were excluded. **Results:** 35 pts were enrolled (from 8/2/18 to 12/27/18), of which, 28 pts were available for analysis (7 patients, not eligible or did not start therapy). Multiple histologies were enrolled with gynecologic (n = 7), gastrointestinal (n = 6), and genitourinary (n = 5) the most common tumors. Median age 61 (range 42-78). 75% of pts had $\geq$ 3 lines of prior therapy. 54% of *PIK3CA* mutations were located in the helical domain, 32% in kinase domain and 14% in other domains. Twenty-six pts had co-occurring gene alterations (median 3; range 1-9), with 9 patients having 4 or more gene alterations. The ORR was 11% (3/28, 90% CI: 3%-25%). Partial responses were seen in uterine cancer, clear cell carcinoma of anterior abdominal wall, and liposarcoma. 6 pts had $>$ 6 months of stable disease and clinical benefit rate was 32% (9/28). Two pts are still on treatment. The most common reason for protocol discontinuation was disease progression (n = 18, 69%). Thirty pts were included for toxicity analysis. Ten pts (33%) had grade 1 or 2 toxicities, 16 pts (53%) had grade 3 toxicities, and one patient (3%) had grade 4 toxicity (CTCAE v5.0). Most common toxicities include hyperglycemia (n = 19), fatigue (n = 11), hypertension (n = 10), diarrhea (n = 10), and nausea (n = 9). Total of 5 deaths were reported, none related to treatment. **Conclusions:** Copanlisib showed meaningful clinical activity across various tumors with *PIK3CA* mutation in the late-line refractory setting. Further study either alone or in combinations in select tumors is warranted. G3/4 toxicities observed were consistent with reported toxicities for PI3K pathway inhibition. Clinical trial information: NCT02465060. Research Sponsor: U.S. National Institutes of Health.

3507 Oral Abstract Session, Fri, 8:00 AM-11:00 AM

Phase I study of 9-ing-41, a small molecule selective glycogen synthase kinase-3 beta (GSK-3β) inhibitor, as a single agent and combined with chemotherapy, in patients with refractory tumors. *First Author: Benedito A. Carneiro, Brown University, Lifespan Cancer Institute, Providence, RI*

Background: Overexpression of GSK-3β, a serine/threonine kinase, is associated with advanced stage malignancies, aggressive tumor growth, and chemotherapy resistance. 9-ING-41 is a GSK-3β inhibitor with significant broad spectrum preclinical antitumor activity, including chemotherapy-resistant models. This first-in-human study (NCT03678883) is evaluating the safety, pharmacokinetics (PK), and efficacy of 9-ING-41 monotherapy and in combination with chemotherapy in patients (pts) with refractory malignancies. **Methods:** 9-ING-41 is given intravenously (IV) twice-weekly as a single-agent (21-day cycle) or combined with gemcitabine, gemcitabine/nab-paclitaxel, carboplatin, carboplatin/paclitaxel, doxorubicin, lomustine or irinotecan in patients previously treated with the same chemotherapy. **Results:** As of Jan 2020, 101 pts were enrolled. Tumor types: 25 pancreatic (PDAC), 14 colorectal (CRC), 10 non-small cell lung cancer (NSCLC), 8 GBM and other gliomas, 7 melanoma, 5 appendiceal, 4 breast (BC), 30 others. Seven single agent dose levels (DL) completed (1, 2, 3.3, 5, 7, 9.3, 12.4 mg/kg) without any 9-ING-41-attributable SAEs. 9-ING-41 attributable AEs include: transient visual change (color perception; n = 29), starting at DL 3 (3.3mg/kg), all G1/2; infusion reactions (n = 14), all G1/2, starting at DL 5 (7mg/kg). 9-ING-41's mean terminal half-life is 12-20 hrs. C_{max} and $AUC_{0\text{-}72}$, are dose proportional with no accumulation. One BRAFV600K-mutated melanoma with $>$ 20 brain metastases, post checkpoint/BRAF/MEK failure has an ongoing CR starting at cycle 2 and sustained after 9 months on treatment. 32 (31%) pts had SD as best response (6 PDAC, 6 CRC, 3 appendiceal, 2 BC, 2 salivary gland, 2 melanoma, 1 Merkel cell, 2 GBM/glioma, 1 RCC, 1 HCC, 1 NSCLC, 1 esophageal, 1 parotid gland, 1 nasopharyngeal, 1 peritoneal, 1 T cell-ALL). 8 pts remained on study treatment $>$ 5 months (1 melanoma, 3 PDAC, 1 appendiceal, 1 GBM, 1 peritoneal, 1 salivary gland) with median treatment duration of 198 days (range 163-261). 32 pts continue to receive 9-ING-41. **Conclusions:** 9-ING-41 has dose-proportional PK, is well tolerated with significant antitumor activity as monotherapy and in combination with chemotherapy in pts with refractory tumors. 1 ongoing CR was observed in a refractory BRAF-mutated melanoma. A biologically active dose has been reached, although MTD has not been determined. Enrollment is ongoing. Clinical trial information: NCT03678883. Research Sponsor: Actuate Therapeutics.

Phase Ib study of a novel bivalent IAP antagonist APG-1387 in combination of pembrolizumab for patients with advanced solid tumors. *First Author: Drew W. Rasco, South Texas Accelerated Research Therapeutics, San Antonio, TX*

Background: APG-1387 is an IAP (inhibitor of apoptosis proteins) antagonist that has strong antitumor activity in multiple xenograft cancer models and acts as a host immune modulator, supporting its exploration for use in combination with checkpoint inhibitors for cancer therapy. **Methods:** This "3+3" dose escalation and dose expansion study evaluated APG-1387 combined with pembrolizumab in patients with refractory or intolerant advanced solid tumors (NCT03386526). APG-1387 was administered IV once weekly with pembrolizumab 200 mg on day 1 of a 21-day cycle. Study aims were to assess safety/tolerability, recommended phase 2 dose (RP2D), pharmacokinetics (PK), pharmacodynamics (PD), and efficacy. **Results:** As of December 25, 2019, total 28 patients had been treated in 3 dose cohorts of APG-1387: 20 mg (n = 4), 30 mg (n = 3), and 45 mg (n = 21, 18 in dose expansion). The median line of prior systemic cancer therapies was 3.0 (1-12). No dose-limiting toxicity was observed. The most common treatment-related adverse events (TRAEs; ≥10%) were fatigue (28.6%), arthralgia (14.3%), headache (14.3%), and tumor pain (10.7%). One patient in the 45-mg cohort had grade 2 Bell's Palsy. G3^{+} TRAEs were autoimmune colitis, hypoxia, increased lipase, mucosal inflammation, pneumonitis, and tumor pain in 1 patient each (3.6%). Treatment-related SAEs were 1 G3 autoimmune colitis, 1 G2 myocarditis, and 1 G3 pneumonitis. The maximum tolerated dose (MTD)/RP2D for APG-1387 was 45 mg. Among 25 efficacy-evaluable patients, 1 with ER^{+}, HER2^{-} breast cancer receiving APG-1387 30 mg after failing 5 lines of therapy (PD-1 treatment-naïve, microsatellite stable) achieved confirmed PR (-79.2%) for 6 cycles but discontinued due to pneumonitis; another patient with PD-L1^{-} non–small-cell lung cancer treated at 45 mg had confirmed PR (-65.0%) for 6 cycles (ongoing). Other 11 patients had SD for 2-11 cycles. The disease control rate was 52%. Preliminary PK data showed a dose-proportional increase in APG-1387 exposure from 20 mg to 45 mg. Preliminary PD data showed that APG-1387 induced rapid degradation of cellular IAP1 and X-linked IAP in peripheral blood mononuclear cell samples; Increased serum release of interleukins (IL-12, IL-10) and monocyte chemotactic protein 4 was dose and time dependent. **Conclusions:** APG-1387 combined with pembrolizumab is well tolerated. Encouraging antitumor effects were observed in patients with several tumor types. The ongoing study will further evaluate the efficacy of this combination. Clinical trial information: NCT03386526. Research Sponsor: Ascentage Pharma Group Inc., Rockville, MD.

First-in-human study of palcitoclax (APG-1252), a novel dual Bcl-2/Bcl-xL inhibitor, demonstrated advantages in platelet safety while maintaining anticancer effect in U.S. patients with metastatic solid tumors. *First Author: Nehal J. Lakhani, START-Midwest, Grand Rapids, MI*

Background: Targeting Bcl-2/Bcl-xL proteins is considered as an important approach for anticancer drug development. Palcitoclax (APG-1252) was being developed to reduce on-target platelet toxicity without diminishing antitumor potency. **Methods:** The phase 1 study was to evaluate the safety/tolerability, pharmacokinetics (PK), and preliminary efficacy (assessed per RECIST 1.1) of palcitoclax in US patients with metastatic small-cell lung cancer (SCLC) or other solid tumors (NCT03080311). A standard "3+3" design was applied to the dose-escalation stage. Palcitoclax was administered IV infusion for 30 minutes, twice a week (BIW) or once a week (QW) for 3 weeks in a 28-day cycle. Once the maximum tolerated dose / recommended phase 2 dose (MTD/RP2D) was determined, additional patients were treated in a dose-expansion stage. **Results:** The dose-escalation phase has been completed with 42 patients (31 on BIW and 11 on QW) who received palcitoclax at 8 dose cohorts ranging 10 mg - 400 mg. Most adverse events (AEs) were grade 1 or 2 (G1 or G2), and 26.2% patients had ≥ G3 TRAEs. The most common TRAEs were platelet count decreased (14.3%), aspartate aminotransferase increased (9.5%), and alanine aminotransferase increased (7.1%). Rapid platelet drop was observed in patients treated at 320 mg and 400 mg, which was transient and resolved rapidly within 2-6 days. Palcitoclax at 240 mg once weekly was determined to be MTD/RP2D. Of 36 efficacy-evaluable patients, 3 patients with SCLC, neuroendocrine prostate cancer, and ovarian cancer respectively achieved partial response (PR) and 8 patients had stable disease (SD) as their best overall response. One patient with SCLC had a PR that lasted over 21 cycles. Preliminary PK analyses showed that C_{max} and AUC were approximately dose proportional over the range of 10 mg to 320 mg following the IV infusion on Day 1, with a mean $T_{1/2}$ of 3.0-13.0 hours. **Conclusions:** Palcitoclax is safe and well tolerated, with a favorable platelet toxicity profile. Its promising antitumor effect supports its further development in combination therapies for treatment of patients with SCLC and other solid tumors. Clinical trial information: NCT03080311. Research Sponsor: Ascentage Pharma Group Inc., Rockville, MD.

Safety and efficacy of pyrotinib in patients with NSCLC and other advanced solid tumors with activating *HER2* alterations: A phase I basket trial. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pyrotinib is a potent, irreversible tyrosine kinase inhibitor (TKI) that blocks signal transduction through the erythroblastic leukemia viral oncogene homolog (erbB) receptors, which has previously demonstrated promising antitumor activity in patients (pts) with breast cancers. We studied the safety and efficacy of pyrotinib in pts with non-small cell lung cancer (NSCLC) and other solid tumors with activating human epidermal growth factor receptor 2 (*HER2, ERBB2)* alterations. **Methods:** This is an open-label, multicenter phase 1 dose expansion basket trial of pyrotinib given 400mg oral daily at 28-day cycles. Expansion cohorts included pts with *HER2*-mutant NSCLC and advanced solid tumors with *HER2* mutation or amplification. *HER2* testing was conducted using next generation sequencing or fluorescence *in situ* hybridization. Primary endpoints included toxicities as evaluated by NCI CTCAE v5.0, and overall response rate (ORR) as evaluated by RECIST v1.1. Secondary objectives included progression-free survival (PFS). **Results:** A total of 62 pts were enrolled. The median age was 67 (range 40 – 86 years), 61% were female and the median lines of prior systemic therapy was 3 (range 1-11). There were no treatment related deaths. The most common adverse events were diarrhea (96.8%), nausea (82.3%) and vomiting (41.9%). The only ≥ grade 3 treatment related toxicity was diarrhea (24.2%). Prophylactic anti-diarrhea treatment was introduced to facilitate continuation of pyrotinib. At the Jan 13, 2020 cut-off, 24 pts with *HER2*-mutant NSCLC (20, i.e. 65% of which were the A775_G776insYVMA mutation) and 18 pts with *HER2*-mutant or amplified solid tumors completed end of Cycle 2 imaging scan and were evaluable for tumor responses. The ORR was 19% (8/42, 95% CI 7-31%); confirmed responses include a complete response (CR) and 3 partial responses (PRs) in *HER2*-mutant NSCLC, and 4 PRs in *HER2*-amplified cholangiocarcinoma, ovarian, endometrial and salivary gland carcinomas. There were 7 stable disease ≥ 6 months. Median progression-free survival was 5.4 months (95% CI 4.4-7.3). **Conclusions:** Pyrotinib demonstrated a manageable safety profile and encouraging efficacy in pts with heavily pre-treated *HER2*-mutant NSCLC. Furthermore, it is the first TKI to produce durable responses in pts with *HER2*-amplified biliary tract, ovarian, endometrial and salivary gland cancers. These results warrant further clinical development of pyrotinib. Clinical trial information: NCT02500199. Research Sponsor: Hengrui Therapeutics Inc.

CodeBreak 100: Phase I study of AMG 510, a novel KRAS^{G12C} inhibitor, in patients (pts) with advanced solid tumors other than non-small cell lung cancer (NSCLC) and colorectal cancer (CRC). *First Author: David S. Hong, MD Anderson Cancer Center, Houston, TX*

Background: Kirsten rat sarcoma viral oncogene homolog (*KRAS*) p.G12C mutation occurs in approximately 13% of NSCLC and 1%–3% of CRC and other solid tumors. AMG 510 is a first-in-class small molecule that specifically and irreversibly inhibits KRAS^{G12C}. Previously, AMG 510 showed preliminary antitumor activity and favorable tolerability in pts with *KRAS* p.G12C mutant NSCLC or CRC in the phase 1, first-in-human trial. Here, we report results in pts with other tumor types from the same trial. **Methods:** This study evaluates AMG 510 in pts with locally-advanced or metastatic *KRAS* p.G12C mutant solid tumors. Key inclusion criteria: *KRAS* p.G12C mutation via local testing and prior systemic anticancer treatment (tx). Oral daily doses of 180, 360, 720, and 960 mg were tested in the dose escalation, and 960 mg was selected for expansion. Primary endpoint is safety; key secondary endpoints include pharmacokinetics and objective response rate as assessed per RECIST 1.1. Response is assessed every 6 weeks (wks) for 24 wks then every 12 wks thereafter. **Results:** As of January 8, 2020, 25 pts (9 female, median age 60 years [range: 40–75]) with tumor types categorized by investigators as histology other than NSCLC and CRC were enrolled and dosed (10 pancreatic cancer, 4 appendiceal cancer, 2 endometrial cancer, 2 unknown primary cancer, 1 bile duct cancer, 1 sinonasal cancer, 1 ampullary cancer, 1 small bowel cancer, 1 melanoma, 1 small cell lung cancer, and 1 esophageal cancer). 23 pts received 960 mg dose. 20 pts (80.0%) had ≥2 prior lines of tx. At data cutoff, 13 pts (52.0%) remained on tx; 9 (36.0%) and 3 (12.0%) pts remained on tx for ≥3 and ≥6 months, respectively. Median follow up was 4.3 months (range: 0.1–12.6). Tx-related adverse events (TRAEs) occurred in 9 pts (36.0%). 2 pts (8.0%) had grade 3 TRAEs, including diarrhea (1/25) and pneumonia (1/25, serious AE). No dose-limiting toxicities, grade ≥4, or fatal TRAEs were reported. No TRAEs led to tx discontinuation. 3 pts had not been followed up for ≥7 wks by the data cutoff. 22 pts were followed up for ≥7 wks, and their best overall responses were: 3 confirmed partial response (1 appendiceal, 1 melanoma, and 1 endometrial), 13 stable disease (6 pancreatic, 2 appendiceal, 1 ampullary, 1 bile duct, 1 endometrial, 1 sinonasal, and 1 unknown primary), and 6 progressive disease. **Conclusions:** AMG 510 was well tolerated and demonstrated clinical activity in pts with advanced *KRAS* p.G12C mutant solid tumors other than NSCLC and CRC. Clinical trial information: NCT03600883. Research Sponsor: Amgen Inc.

Phase Ib study of a novel, small-molecule MDM2 inhibitor APG-115 combined with pembrolizumab in U.S. patients with metastatic solid tumors. *First Author: Anthony W. Tolcher, NEXT Oncology, San Antonio, TX*

Background: APG-115 activates p53-mediated apoptosis in tumor cells retaining wild-type *TP53*. It also functions as a host immune modulator and enhances antitumor activities when combined with PD-1 blockade preclinically. MDM2 amplification is associated with hyperprogression in patients treated with checkpoint inhibitors. **Methods:** The Phase Ib / II study was designed to evaluate APG-115 combined with pembrolizumab in patients with metastatic solid tumors (NCT03611868). APG-115 was administered orally every other day for 2 weeks, at dose ranging from 50 mg – 200 mg, with pembrolizumab at 200 mg IV on Day 1 of a 21-day cycle. Study objectives were to assess safety including dose-limiting toxicity (DLT), serious adverse events (SAEs), treatment-related AEs (TRAEs), pharmacokinetics (PK), pharmacodynamics (PD), and efficacy (assessed by RECIST v1.1), to determine recommended phase 2 dose (RP2D). **Results:** As of December 25, 2019, the enrollment of phase 1b study was completed. Total 19 patients had been treated in four APG-115 cohorts: 50 mg (n = 3), 100 mg (n = 3), 150 mg (n = 6), and 200 mg (n = 7). No DLT was observed, The TRAEs (≥15%) were nausea (47.4%), fatigue (36.8%), decreased platelet count (26.3%), and decreased appetite (21.1%), as well as diarrhea, vomiting, decreased neutrophil or white blood cell count, and hypothyroidism in 15.8% each. Grade > 3 TRAEs included decreased neutrophil and thrombocytopenia in 15.8% each. Two SAEs were treatment related: G3 febrile neutropenia and G3 adrenal insufficiency. No new safety finding from combination with Pembrolizumab. The RP2D of APG-115 was 150 mg. One patient with ovarian cancer has a CR lasting for 15 months, 2 patients had PR for 8-9 months: one NSCLC failed IO therapy, another with appendix cancer, and 7 had SD for 1.5-7 months. The objective response rate was 15.8%, and the disease control rate (DCR) was 52.6%. PK data indicated an approximately dose-proportional increase in APG-115 exposure over the range of 50-200 mg on Day 1. PD-PK analyses showed that serum macrophage inhibitory cytokine-1 (MIC-1) increase was time and dose dependent, the MIC-1 elevation correlated with APG-115 exposure, indicating p53 activation in these patients. **Conclusions:** APG-115 in combination with pembrolizumab is well tolerated. Encouraging antitumor effects were observed in several tumor types. The phase II study is ongoing in the cancer patients with specific bio-marker profiling. Clinical trial information: NCT03611868. Research Sponsor: Ascentage Pharma Group Inc., Rockville, MD.

Phase I study of rucaparib and irinotecan in advanced solid tumors with homologous recombination deficiency (HRD) mutations. *First Author: Mallika Sachdev Dhawan, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) are approved for multiple tumor types with HRD mutations. In efforts to prolong durations of response, combination treatments of PARPi and chemotherapy are being explored. However, expected overlapping toxicities have previously limited the tolerability of PARPi-chemotherapy combinations. Preclinical studies suggest that the inhibition of PARP will prevent the repair of topoisomerase induced DNA strand breaks. In this Phase I trial, we test whether pulse dosing and alternate treatment schedules of rucaparib and irinotecan are safe and tolerable. **Methods:** Rucaparib and irinotecan were dose escalated in a 3+3 design. Patients with advanced solid tumors and somatic or germline known or suspected pathogenic mutations in HRD were accepted on trial. 15 patients have been enrolled in 3 cohorts and treated with rucaparib 400 mg BID (days 1-7) and irinotecan 65 mg/m2 (cohort 1) or 100 mg/m2 (cohort 2) every 2 weeks or 100 mg/m2 every 3 weeks (cohort 2i). **Results:** Tumor types on trial are heterogeneous and include pancreatic ductal adenocarcinoma (PDAC: 3), cholangiocarcinoma, neuroendocrine carcinoma of the pancreas, ovarian cancer/primary peritoneal carcinoma (3), prostate cancer, small bowel carcinoma, squamous cell carcinoma of the tonsil, testicular cancer, triple negative breast cancer, and urothelial carcinoma. 14/15 patients had 3+ prior lines of therapy. Mutation types include: 7 ATM, 3 BRCA1, 3 BRCA2, 1 CHEK2, and 1 PALB2. All patients were previously exposed to platinum chemotherapies; 8/15 had progressive disease while on platinum. 5/15 patients had prior PARPi with progression. There were 3 DLT events, all of which were related to grade 3 or 4 neutropenia. Of the 13 patients evaluable for response, there was one confirmed partial response (PR). 5 patients have remained on study for longer than 6 months and 3 patients with ATM mutations have remained on study for longer than one year (primary peritoneal cancer, small bowel carcinoma, PNET). 4/5 patients with clinical benefit had prior platinum progression and 1/5 had previously progressed on a PARPi. Our current recommended phase 2 dose is rucaparib 400 mg BID days 1-7 and irinotecan 100 mg/m2 every 3 weeks. **Conclusions:** The pulse dosing schedule of rucaparib and irinotecan has allowed for long term tolerability and exposure to both agents with encouraging efficacy in patients with ATM mutations. Further testing of PARPi and topoisomerase inhibitors at this schedule in patients with ATM mutations is planned. Clinical trial information: NCT03318445. Research Sponsor: Clovis.

Lurbinectedin (LUR) in combination with Irinotecan (IRI) in patients (pts) with advanced solid tumors: Updated results from a phase Ib-II trial. *First Author: Santiago Ponce Aix, Hospital Universitario 12 De Octubre, Madrid, Spain*

Background: LUR is a novel agent that exerts antitumor activity through inhibition of trans-activated transcription and modulation of tumor microenvironment. Preclinical synergism/additivity in combination with IRI has been reported, thus prompting the conduct of this clinical trial. **Methods:** Phase Ib-II trial to evaluate escalating doses of LUR on Day (D) 1 plus a fixed dose of IRI 75 mg/m^2 on D1 and D8 every 3 weeks (q3w) in pts with advanced solid tumors (+/- G-CSF, if dose-limiting toxicities [DLTs] were neutropenia). Starting dose was LUR 1.0 m/m^2 + IRI 75 mg/m^2. **Results:** 77 pts have been treated to date at 5 dose levels, 51 of them at the recommended dose (RD). Baseline characteristics of all 77 pts were: 48% females, 68% ECOG PS=1; median age 57 years (range, 19-75 years); median of 2 prior lines (range, 0−4 lines). The maximum tolerated dose (MTD) was LUR 2.4 mg/m^2 + IRI 75 mg/m^2 with G-CSF, and the RD was LUR 2.0 mg/m^2 + IRI 75 mg/m^2 with G-CSF. DLTs in Cycle 1 occurred in 2/3 evaluable pts at the MTD and 3/13 evaluable pts at the RD, and comprised omission of IRI D8 infusion due to grade (G) 3/4 neutropenia (n=3 pts) or G2-4 thrombocytopenia (n=2). At the RD (n=51), common G1/2 non-hematological toxicities were nausea, vomiting, fatigue, diarrhea, anorexia and neuropathy. G3 non-hematological toxicities (diarrhea 10%, fatigue 10%) and G3/4 hematological abnormalities (neutropenia 49%, thrombocytopenia 10%) were transient. **Conclusions:** The combination of LUR and IRI had acceptable tolerance, with no unexpected toxicities. Transient myelosuppression was dose-limiting. The RD is LUR 2.0 mg/m^2 on D1 + IRI 75 mg/m^2 on D1 and D8 q3w with G-CSF. Antitumor activity was observed at the RD in SCLC pts, as well as in endometrial carcinoma pts. Hints of activity were also observed in STS pts. Updated results will be presented. Clinical trial information: NCT02611024. Research Sponsor: PharmaMar SA.

Main efficacy data for selected tumors at the RD are shown below.

Tumor type evaluable	SCLC (n=13)	Endometrial Ca. (n=10)	STS (n=9)	Glioblastoma (n=13)
ORR (PR)	8 (61.5%)	3 (30%)	0%	0%
DCR (PR+SD)	84.6%	100%	88.9%	38.5%
PFS at 6 months (95% CI)	36.3% (4.1-68.4%)	66.7% (36.0-97.5%)	50.8% (16.2-85.4%)	0%

Ca, carcinoma; CI, confidence interval; DCR, disease control rate; n, number of evaluable patients; ORR, overall response rate as per RECIST v.1.1; PFS, progression-free survival; PR, partial response; RECIST, Response Evaluation Criteria In Solid Tumors; SCLC, small cell lung cancer; SD, stable disease; STS, soft tissue sarcoma.

Pen-866, a miniature drug conjugate of a heat shock protein 90 (HSP90) ligand linked to SN38 for patients with advanced solid malignancies: Phase I and expansion cohort results. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: PEN-866 is a miniature drug conjugate which links a HSP90 binding small molecule to a SN-38 cytotoxic payload. HSP90 is highly expressed in advanced malignancies. PEN-866 targets and binds to activated tumor HSP90 protein, releases its cytotoxic payload, and results in complete tumor regressions in multiple xenograft models. This first-in-human study assessed safety, tolerability, pharmacokinetics (PK), and preliminary efficacy of PEN-866. **Methods:** Patients (pts) with progressive, advanced solid malignancies were enrolled in escalating cohorts of 2-9 pts. The primary objective was to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of PEN-866 given weekly (3 out of 4 weeks in a 28-day cycle). **Results:** 30 pts were treated in 8 cohorts (range 30-360 mg flat dosing or 150–200 mg/m^2 BSA-based dosing). As of 9Jan20, the total median/mean exposure was 7.05/12.4 weeks. No dose limiting toxicities (DLTs) occurred in the first 4 cohorts (30-240 mg; 14 pts). In cohort 5 (360 mg), 1 of 3 pts had a DLT of grade (G) 3 transient diarrhea, and 2 other pts had G3 uncomplicated transient neutropenia. A change to BSA-based dosing was instituted for cohort 6 (175 mg/m^2), on which no DLTs were observed, although 1 pt experienced G3 uncomplicated transient neutropenia. At 200 mg/m^2, 2 of 5 pts experienced DLTs (G5 dehydration, G3 fatigue). The MTD and RP2D were determined to be 175 mg/m^2. The most frequent (≥20% pts) related adverse events were nausea (50%), fatigue (43%), diarrhea (40%), vomiting (27%), and anemia (23%). PK was nonlinear. Plasma exposures increased greater than dose proportionally. Median $t_{1/2}$ ~7 h. Cleaved SN38 never exceeded 3% of PEN-866 plasma AUC at all dose levels. Tissue PK confirmed tumor accumulation and retention of both the conjugate and released payload. As of 9Jan20, 26 pts were evaluable for response. 11 pts had stable disease at 8 weeks, of which 7 lasted 12–58 weeks. One pt with anal squamous cell carcinoma achieved a confirmed partial response. Decreased target lesion size was observed in 6 additional pts. **Conclusions:** PEN-866 was well tolerated and demonstrated preliminary evidence of antitumor activity. PEN-866 will be evaluated in Phase 2a expansion cohorts enrolling multiple solid tumors (NCT03221400). Clinical trial information: NCT03221400. Research Sponsor: Tarveda Therapeutics, Inc.

Utility of circulating tumor DNA (ctDNA) versus tumor tissue clinical sequencing for enrolling patients (pts) with advanced non-colorectal (non-CRC) gastrointestinal (GI) cancer to matched clinical trials: SCRUM-Japan GI-SCREEN and GOZILA combined analysis. *First Author: Akihiro Ohba, National Cancer Center Hospital, Tokyo, Japan*

Background: We recently reported that clinical assessment of genomic biomarkers using ctDNA had advantages over tumor tissue-based sequencing for enrollment into matched clinical trials across a wide range of GI cancers. Herein we investigated the utility of ctDNA in non-CRC cancers in a SCRUM-Japan GI-SCREEN and GOZILA combined analysis. **Methods:** In GI-SCREEN, tumor tissue samples of pts with non-CRC were analyzed by a next generation sequencing (NGS)-based assay, Oncomine Comprehensive Assay, since Feb 2015. In GOZILA, plasma samples of non-CRC pts were analyzed by an NGS-based ctDNA assay, Guardant360, since Feb 2018. **Results:** As of Apr 2019, 2,952 pts in GI-SCREEN and 633 pts in GOZILA were enrolled. Baseline characteristics between the groups were well matched except that GOZILA included more pancreatic ($P < 0.0001$) and liver cancers ($P = 0.016$) but fewer gastric cancers ($P < 0.0001$) and GIST ($P = 0.020$) than GI-SCREEN. The success rates of the tests were 86.6% in GI-SCREEN and 87.3% in GOZILA ($P = 0.649$). Median turnaround time (TAT) was 37 days in GI-SCREEN and 12 days in GOZILA ($P < 0.0001$). The proportion of cases with actionable alterations detected (tissue vs blood; 29.8% vs 46.8%, $P < 0.0001$) and enrolled into matched clinical trials (4.8% vs 6.5%, $P = 0.286$) for each group by cancer type are shown in the Table. Pts with upper GI cancers, especially those in GOZILA, were more often enrolled into matched trials; trial enrollment for those with hepatobiliary and pancreatic (HBP) or other cancers was similar regardless of testing method. Median time from GI-SCREEN or GOZILA enrollment to clinical trial enrollment was 5.0 and 1.0 months (mo), respectively ($P < 0.0001$). Objective response rates (ORR) and progression-free survival (PFS) were not significantly different (tissue vs. blood; ORR: 14.6 vs. 26.3%, P = 0.30: median PFS: 3.3 vs. 2.6 mo, P = 0.71). **Conclusions:** Clinical sequencing of ctDNA, with its shorter TAT, contributed to rapid enrollment of non-CRC pts into matched clinical trials compared to those tested by tumor tissue sequencing, particularly for those with upper GI cancer, without compromising efficacy. Clinical trial information: UMIN000029315.Research Sponsor: SCRUM-Japan.

	Actionable alterations-Tissue (n = 855)	Matched trial-Tissue (n = 41)	Actionable alterations-Blood (n = 292)	Matched trial-Blood (n = 19)
Upper GI	346 (23.4%)	24 (6.9%)	84 (35.3%)	14 (16.7%)
HBP	401 (36.6%)	14 (3.5%)	196 (56.8%)	5 (2.6%)
Others	108 (37.5%)	3 (2.8%)	12 (29.3%)	0 (0%)

Pan-tumor analyses of kinase fusions detected in circulating tumor DNA (ctDNA) and concordance with paired tissue. *First Author: Jessica Kim Lee, Foundation Medicine, Inc., Cambridge, MA*

Background: Oncogenic kinase gene fusions are targetable with approved and investigational therapies and can also emerge as acquired resistance (AR) to targeted therapy. To understand the clinical validity of liquid biopsy comprehensive genomic profiling (CGP) to detect kinase fusions, we compared patient-matched plasma and tissue-based CGP. **Methods:** Hybrid capture-based CGP was performed on 28,743 plasma and 325,131 tumor tissue samples in the course of clinical care. Complete exonic regions of 13 kinases involved in oncogenic fusions plus select introns in *ALK, EGFR, FGFR2/3, PDGFRA, RET,* and *ROS1* were sequenced to capture fusions with well characterized breakpoints. ctDNA fraction was estimated by maximum somatic allele frequency (MSAF). **Results:** 86% of cases had detectable ctDNA in plasma (MSAF > 0). Kinase fusions were detected in 2.1% of ctDNA cases (478/23,294) and were most prevalent in patients (pts) with bladder cancer (4.5%), non-small cell lung cancer (NSCLC) (4.3%), and cholangiocarcinoma (3.9%). The most commonly rearranged kinases were *ALK* (60%, 162/271) and *RET* (19%, 51/271) in NSCLC, *FGFR2* (85%, 11/13) in cholangiocarcinoma, and *FGFR3* (88%, 7/8) in bladder cancer. *ALK* fusions were detected in 26% (54/207) of fusion+ non-NSCLC cases. Paired tissue and ctDNA samples where ≥1 sample harbored a kinase fusion were available for 147 pts; median time between sample collection was 150 days (interquartile range: 444 days). Positive percent agreement (PPA) to tissue and liquid biopsies was 76% and 80%. Median MSAF in concordant and discordant ctDNA samples was 2.3% and 0.41% ($p = 0.04$) and median time between specimen collection for concordant and discordant pairs was 110 and 344 days ($p = 0.04$). PPA to tissue and liquid was 86% and 88% for pairs collected < 60 days apart (n = 53), versus 70% and 74% for pairs collected > 60 days apart. 6 pts with paired samples all collected > 196 days apart (median 593 days) had initial tissue samples with *EGFR* driver mutations and had an acquired kinase fusion (4 *ALK*, 1 *FGFR2*, 1 *FGFR3*) in the 2nd ctDNA sample, likely representing AR. **Conclusions:** Kinase gene fusions identified by tissue-based CGP were detected by liquid biopsy CGP in 85% of temporally-matched plasma samples. Kinase fusion detection by liquid biopsy CGP is feasible and had high PPA to tissue-based CGP. Subsequent sampling by liquid biopsy identified acquired fusions in *EGFR* driver positive cases consistent with known mechanisms of resistance to EGFR inhibitors suggesting utility of liquid biopsy at progression to identify targetable mechanisms of AR. Early plasma circulating tumor DNA (ctDNA) changes to predict response to first-line pembrolizumab +/- chemotherapy in non-small cell lung cancer (NSCLC). *First Author: Biagio Ricciuti, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: ctDNA shedding into plasma can be prognostic in lung cancer, and changes in plasma ctDNA levels correlate with response to systemic therapy. However, is unknown whether early detection of ctDNA levels change predicts response to first-line pembrolizumab +/- chemotherapy. We hypothesized that serial assessment of plasma ctDNA by next generation sequencing would enable early detection of response to immunotherapy in NSCLC prior to radiological assessment. **Methods:** Patients (pts) with advanced NSCLC who received first-line treatment with pembrolizumab +/- platinum doublet chemotherapy at the Dana-Farber Cancer Institute were enrolled in this study. Plasma collected from pts prior to starting therapy and serially after starting therapy was analyzed by NGS using enhanced tagged-amplicon sequencing (eTAm-Seq) of hotspots and coding regions from 36 genes (InVisionFirst-Lung). ctDNA allele fractions (AF) change was correlated with treatment responses. **Results:** Among 38 pts who received first-line pembrolizumab +/- platinum/pemetrexed, 9 (23.7%) had no ctDNA detected at baseline while 29 had alterations detected. Pembrolizumab was administered as monotherapy in 19 of the 29 pts (65.5%) and in combination with chemotherapy in 10 (34.5%). The median time to the first ctDNA assessment was 21 days (IQR:21-24). Pts who had a decrease in the max AF at the first blood drawn compared to pre-treatment AF had a significantly higher response rate to treatment with pembrolizumab +/- platinum doublet chemotherapy than those with an AF increase (64.5% vs 7.7%, $P < 0.01$). The median PFS (mPFS) and median OS (mOS) were significantly longer among pts with early AF decrease compared to those with an AF increase mPFS: 13.7 vs 3.4 months, HR:0.20, $P < 0.01$; mOS: 32.8 vs 14.7 months, HR:0.06, $P < 0.01$). The median change in allele fraction at the first on-treatment blood draw was -90% (range: -100 to +65), -71% (range: -100 to +100) and +35% (range: +17 to +100) in pts with subsequent radiological response (N = 11), stable disease (N = 11) and progressive disease (N = 7), respectively ($P < 0.01$). Among the 9 cases with no detected ctDNA at baseline, 2 pts with emergence of cfDNA within 8 weeks developed progressive disease. In the other 7 cases, ctDNA remained undetected. **Conclusions:** In pts with advanced NSCLC, rapid decreases in ctDNA prior to radiological assessment correlated with clinical benefit. These results suggest a potential role for ctDNA as an early pharmacodynamic biomarker of response or resistance to immunotherapies. Research Sponsor: None.

Acquired genomic alterations in circulating tumor DNA from patients receiving abemaciclib alone or in combination with endocrine therapy. *First Author: Matthew P. Goetz, Mayo Clinic, Rochester, MN*

Background: An understanding of the mechanisms of acquired resistance to CDK4 & 6 inhibitors, either alone or with endocrine therapy (ET), is an unmet need. Abemaciclib is a CDK4 & 6 inhibitor approved for treatment of HR+, HER2- advanced breast cancer (ABC). Here we evaluated acquired genomic alterations detected in circulating tumor DNA (ctDNA) from patients (pts) treated with abemaciclib + nonsteroidal aromatase inhibitor (AI) or placebo + AI in MONARCH 3 or abemaciclib monotherapy in nextMONARCH 1. **Methods:** MONARCH 3 randomized postmenopausal women with HR+, HER2- ABC with no prior systemic therapy in the advanced setting to abemaciclib (150 mg Q12H) or placebo + AI. nextMONARCH 1 randomized women with HR+, HER2- metastatic breast cancer who had progressed on or after prior ET and CT to abemaciclib (150 mg Q12H) + tamoxifen, abemaciclib (150 mg Q12H), or abemaciclib (200 mg Q12H) + loperamide. Plasma from pts in the abemaciclib or placebo + AI arms (MONARCH 3) or abemaciclib monotherapy arms (nextMONARCH 1) was analyzed by the Guardant360 assay to identify potential tumor-related genomic alterations including point mutations, indels, amplifications, and fusions acquired at EOT in comparison with baseline. **Results:** For MONARCH 3, commonly acquired alterations at EOT included *ESR1* (17%), *TP53* (10%), *EGFR* (8%), *FGFR1* (7%), and *PDGFRA* (7%) in the abemaciclib + AI arm, and *ESR1* (31%), *TP53* (10%), and *BRCA1* (7%) in the placebo + AI arm. Acquired alterations more frequent for abemaciclib + AI pts included *RB1* (6%), *MYC* (5%), and *AR* (5%), compared to 0% in the placebo + AI arm ($p = 0.008$ *RB1*; $p = 0.015$ *MYC* or *AR*). In contrast, acquired *ESR1* alterations were less frequent with abemaciclib + AI vs placebo + AI (17% vs 31%, $p = 0.038$). In nextMONARCH 1, the most commonly acquired alterations with abemaciclib monotherapy were in *TP53* (10%), *EGFR* (9%), *RB1* (9%), *MYC* (9%), and *MET* (8%). In addition, acquired alterations in *ESR1* (6%) and *AR* (3%) were also found. *PIK3CA* alterations were not frequently acquired (abemaciclib + AI 1%, placebo + AI 6%, abemaciclib monotherapy 5%). **Conclusions:** Acquired genomic alterations potentially associated with emerging mechanisms of resistance to abemaciclib alone or in combination with AI may include *RB1*, *MYC*, or *AR* alterations, while the acquisition of *ESR1* alterations was less common in pts treated with abemaciclib + AI compared to placebo + AI. These findings are hypothesis-generating and provide insight into mechanisms of resistance to abemaciclib vs ET. Clinical trial information: NCT02246621, NCT02747004. Research Sponsor: Eli Lilly and Company.

3520 Poster Session (Board #250), Fri, 8:00 AM-11:00 AM

An open-label, multicenter, phase II study of ceritinib in patients with advanced ALK+ non-lung solid tumors and hematological malignancies (ASCEND-10). *First Author: Victor Moreno, START Madrid-FJD, Fundación Jiménez Díaz University Hospital, Madrid, Spain*

Background: Prior studies have confirmed the efficacy and safety of ceritinib in patients (pts) with advanced *ALK*+ non-small cell lung cancer (Soria, et al, Lancet 2017; Shaw et al, Lancet Oncol 2017; Cho et al, JTO 2019). Ceritinib also demonstrated antitumor activity in pediatric pts with *ALK*+ inflammatory myofibroblastic tumor (IMT) and ALCL (Georger et al, ASCO 2015 [abstract#10005]). Long-term clinical benefits of ceritinib treatment were shown in pts with anaplastic large cell lymphoma (ALCL) (Richly et al, Blood 2015). The aim of the current study was to examine ceritinib efficacy and safety in pts with advanced *ALK*+ non-lung solid tumors and hematological malignancies. **Methods:** In this open-label, multi-arm, phase 2 (NCT02465528) trial, adult pts with *ALK* gene abnormalities who had received ≥1 prior systemic therapy were administered oral ceritinib 750 mg/day, under fasted conditions. Primary endpoint: investigator assessed disease control rate (DCR); secondary endpoints: investigator assessed overall response rate (ORR), duration of response (DOR), time to response (TTR), progression-free survival (PFS), and safety. **Results:** Overall, 22 pts (ALCL [n = 1], IMT [n = 4], glioblastoma multiforme [GBM, n = 12] and others [n = 5]) were enrolled; median (m) age: 52.5 years; male: 50%; Stage ≥IV: 95.4%. Key efficacy results are shown in the Table. mTTR in pts with confirmed complete response (CR) or partial response (PR) [n = 4] was 7.4 (range, 6–25) weeks. mDOR was not reached. mPFS (95% CI) was 2.6 (1.6, 3.7) weeks. Most common adverse events (AEs; ≥30%) were: diarrhea and nausea (59.1% each), vomiting (50.0%) and increased alanine aminotransferase (31.8%). Most common grade ≥3 AEs (≥10%): hyperglycemia (18.2%), increased gamma-glutamyl transferase, thrombocytopenia, and anemia (13.6% each). Clinical trial information: NCT02465528. **Conclusions:** Ceritinib 750 mg/day under fasted conditions showed antitumor activity in pts with *ALK*+ ALCL and IMT; however, data interpretation is limited due to the small sample size. Safety findings were consistent with the known ceritinib safety profile.Research Sponsor: Novartis.

3522 Poster Session (Board #252), Fri, 8:00 AM-11:00 AM

Longitudinal cumulative dose: A novel measure to assess multiple dimensions of chemotherapy adherence over time. *First Author: Michael Webster-Clark, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Adjuvant chemotherapy regimens take months to complete. Despite this, trials and observational studies evaluate chemotherapy adherence via measures assessed at the end of treatment (e.g. number of patients missing any dose, relative dose intensity [RDI]). This approach misses information that impacts outcomes, like treatment delays. We propose longitudinal cumulative dose (LCD) as a way to integrate the impact of dose reductions, missed doses, and dose delays at each cycle over time. **Methods:** We obtained data from the 2,246 participants in the Multicenter International Study of Oxaliplatin/5FU-LV in the Adjuvant Treatment of Colon Cancer (MOSAIC). We evaluated proportions of patients stopping treatment early and reducing (based on protocol), missing, or delaying a dose in each arm for each chemo agent at each visit. We obtained LCD, the fraction of the final standard dose a participant reached by a given day, for each participant and each chemo agent. We compared LCD medians over time and at the end of a standard regimen (24 weeks) between treatment arms and by age and performance status. We assessed agreement between oxaliplatin LCD and RDI with Fleiss' kappa (Table). **Results:** Participants randomized to FOLFOX were more likely than those randomized to 5FU to stop treatment, reduce doses, miss doses, or delay visits; these differences increased over time. Median LCD for oxaliplatin in the FOLFOX arm at 24 weeks was 77%. Graphs of median LCD for 5FU showed a clear difference between arms (FOLFOX arm median LCD: 81%; 5FU arm median LCD, 96%). While 5FU LCD decreased with age in the FOLFOX arm (median LCD in those age <40: 85%; 40-64, 82%; 65-75, 76%), it was similar across ages in the 5FU arm (median LCD 94%, 96%, and 96%, respectively), with smaller performance status trends. RDI and LCD showed fair agreement (Fleiss' kappa=0.34); 19% of those with RDI over 85% had LCD under 60%. **Conclusions:** Visualizing LCD highlighted the timing and scale of deviations from standard administration, with major differences in 5FU LCD across arms. Next steps include evaluating if LCD predicts clinical outcomes. Research Sponsor: Patient Centered Outcomes Research Institute.

Comparison of oxaliplatin LCD versus RDI.

	RDI <60%	RDI 60%-85%	RDI > 85%
LCD <60%	133	62	84
LCD 60%-85%	55	165	25
LCD >85%	10	244	332

3523 Poster Session (Board #253), Fri, 8:00 AM-11:00 AM

A phase Ib study of simmitecan (LP) single-agent and in combination with 5-fluorouracil/leucovorin (5-FU/LV) or thalidomide (T) in patients with advanced solid tumor. *First Author: Jifang Gong, Gastrointestinal Medical Oncology, Beijing Cancer Hospital, Beijing, China*

Background: Simmitecan (LP), a novel 9-substituted lipophilic camptothecin derivative, is a potent inhibitor of topoisomerase I with anti-tumor activity single agent or in combination with other anti-tumor agents, i.e. thalidomide or anti-PD-1 antibody in xenograft models. In this phase Ib study (NCT02870036), we evaluate the safety and anti-tumor effects of LP as monotherapy or in combination therapies in patients (pts) with advanced solid tumors. **Methods:** This open-label, multi-cohort phase Ib study was conducted at 3 academic centers in China. Eligible pts had advanced cancer without standard treatment options. Prior irinotecan treated failure pts was eligible. In the single agent study, enrolled pts was allocated to received intravenous(iv) 50, 80, or 120 mg/m^2 of LP Q2W to determine the safety of LP. After single agent study finished, enrolled pts allocated in LP+5-FU/LV cohorts received 50, 65, or 80 mg/m^2 of LP then LV 400 mg/m^2 and 5-FU bolus at 400 mg/m^2 followed by 5-FU continuous iv of 2400 mg/m^2 Q2W; pts in LP+T cohorts received LP 65 mg/m^2 Q2W + thalidomide 50mg QD or thalidomide 100mg QD, or LP 80 mg/m^2 Q2W + thalidomide 50mg QD. Treatment repeated in 28-day cycles until disease progression or unacceptable toxicity. **Results:** Between October 2016 to February 2019, 41 pts, median age of 55.1 (range 29-69) years, were enrolled, 13 in LP monotherapy, 10 in LP + 5-FU/LV and 18 in LP + T. Over all, no dose limited toxicity (DLT) occurred. The most common (≥20%) grade 3/4 AE among three regimens was neutropenia (44%, 70% and 89% respectively in LP, LP+5FU/LV and LP+T),and treatment related SAEs were similar, i.e. anemia and febrile neutropenia (11.1% each) in LP, diarrhea (10%) in LP+5-FU/LV, febrile neutropenia (5.6%) in LP+T. Majority of enrolled pts (24/41, 59%) had progressed on prior irinotecan, nevertheless, partial response (PR) was observed in 1 colorectal cancer pt treated with LP 80 mg/m^2 + thalidomide 50mg. Disease control rate (DCR, SD≥12 weeks or CR or PR) were 60%, 80% and 61% and median progress free survival were 2.71, 4.17 and 2.76 months respectively in LP, LP + 5-FU/LV and LP+T cohorts. **Conclusions:** This study showed the safety profiles are manageable, either LP monotherapy or combination therapies, no DLT or safety concern was elicited in combination compared to single agent, and the LP + 5-FU/LV regimen showed higher DCR. A phase II study in pts with metastatic NEC is on-going to explore safety and efficacy of LP + 5-FU/LV regimen combined with toripalimab, an anti-PD-1 antibody. Clinical trial information: 02870036. Research Sponsor: Shanghai HaiHe Pharmaceutical Co.,Ltd.

3524 Poster Session (Board #254), Fri, 8:00 AM-11:00 AM

Intratumoral exposure levels of pentaglutamated pemetrexed following treatment with LEAF-1401 and pemetrexed. *First Author: Gwangseong Kim, L.E.A.F. Pharmaceuticals LLC, Woburn, MA*

Background: The activity of pemetrexed is highly dependent on the intracellular enzyme folypolyglutamate synthase (FPGS) which adds glutamates to pemetrexed and yields very potent pemetrexed polyglutamates. Pemetrexed pentaglutamate (tetraglutamated pemetrexed) is 80-fold more potent than pemetrexed in inhibiting thymidylate synthase. Yet it is a poor drug candidate because it cannot readily cross the negatively charged cell membrane due to its own negative charge. We are developing LEAF-1401, a novel nanoliposomal encapsulation of gamma L-pentaglutamated pemetrexed. Because liposomes can readily be taken up by tumor cells, for its anti-tumor effect, LEAF-1401 can directly deliver pentaglutamated pemetrexed into tumor cells, bypassing the need for transmembrane folate carriers and FPGS which are both downregulated in resistant tumors. **Methods:** To measure drug levels in tumor, blood and various tissues (biodistribution), *in vivo* testing of LEAF-1401 and pemetrexed was conducted in a CT-26 murine colorectal carcinoma xenograft model. Animals were treated with a single dose of either LEAF-1401 (80mg/kg; equivalent to 32 mg/kg pemetrexed) or pemetrexed (118mg/kg). Tumor growth inhibition and clinical assessments were conducted. Animals were sacrificed: 5 mice per timepoint in each group and tumor, blood, liver, spleen and other tissues were harvested. Pentaglutamated pemetrexed levels were quantitatively analyzed by LC/MS/MS. **Results:** Compared to pemetrexed, LEAF-1401 treatment resulted in a 19-fold increase in exposure levels of pentaglutamated pemetrexed in the tumor and significant tumor growth inhibition. Plasma levels of pentaglutamated pemetrexed were high with LEAF-1401, but undetectable with pemetrexed. Like other liposomes, LEAF-1401 also resulted in accumulation of pentaglutamated pemetrexed in the liver and spleen (See Table below). Treatment appeared to be generally well tolerated. **Conclusions:** LEAF-1401, given at approximately a quarter of the equivalent pemetrexed dose, resulted in a 19-fold increase in pentaglutamate pemetrexed in tumor tissue compared to regular pemetrexed. LEAF-1401 represents a promising new class of novel nanoliposomal antifolates, that enhance the intratumoral delivery of potent polyglutamate antifolates, and improve antitumor activity while retaining an acceptable safety profile. Liquid biopsies to enable non-invasive real-time functional chemoresistance profiling in solid organ cancers. *First Author: Dadasaheb B Akolkar, Datar Cancer Genetics Limited, Nasik, India*

Background: Despite the development of targeted therapy agents and immune checkpoint inhibitors (ICI), cytotoxic anticancer agents remain the mainstay of treatment in several solid organ cancers. However, instances of innate and acquired resistance towards these anticancer agents can lead to treatment failures, which remain undetectable until clinical or radiological manifestation of symptoms suggestive of disease progression. There are presently no viable means or markers to detect or monitor for chemoresistance in real time. Owing to this unmet need, cancer treatment strategies face risks of failure and poor outcomes. **Methods:** We obtained 15 mL blood from 3,662 patients with various solid organ cancers, of various states and including treatment-naïve and pretreated patients. Circulating Tumor Associated Cells (C-TACs) were enriched and harvested from PBMCs using an epigenetically activating medium that is cytotoxic towards non-malignant epithelial and hematolymphoid cells in blood, but confers survival benefit on apoptosis resistant cells of tumorigenic origin (Circulating Tumor Associated Cells, C-TACs). In a subset of patients, fresh tumor tissue was also obtained from which viable tumor derived cells (TDCs) were obtained. Viable TDCs and C-TACs were treated with a panel of anticancer agents and the surviving cell fraction estimated to determine chemoresistance. **Results:** Among the 1,325 therapy naïve patients, resistance towards treatment agents was observed in C-TACs from 56.3 % of samples. Among 2,201 pretreated patients' samples, resistance towards treatment agents was observed in C-TACs from 77.8% of samples. The increased resistance in C-TACs from pretreated patients indicated that the C-TACs had been resistance-educated by prior therapies. In a subset of patients, Chemoresistance profile of C-TACs was observed to be 96.9% concordant with that of tumor derived cells (TDCs) which were concurrently obtained from tumor tissue indicating that C-TACs accurately represent chemo-antecedents of the tumor. **Conclusions:** Non-invasive chemoresistance profiling of C-TACs is a viable strategy to monitor treatment efficacy in real time. Adoption of this strategy in the clinic will not only guide treatment selection with reduced risk of failure, but will also enable timely therapeutic course correction upon detection of acquired chemoresistance. 3526 Poster Session (Board #256), Fri, 8:00 AM-11:00 AM

Pharmacokinetics, safety, and early activity of a nanoparticle micellar formulation of docetaxel in women with metastatic breast cancer: Results of two randomized trials (phase I and II). *First Author: Markus Joerger, Department of Oncology/Hematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland*

Background: Docetaxel micellar (DM) is a nano-sized particle formulation of docetaxel in which a retinoic acid derivative is used as solubilizer with a high drug to excipient ratio possibly resulting in reduced systemic toxicity or hypersensitivity reactions due to the excipient. DM is given without standard use of premedication, avoiding steroid-associated immunosuppression. Here we present the pharmacokinetics (PK) after a single dose of DM or polysorbate-solubilized docetaxel (D) as well as safety and early activity including overall response rate (ORR) in female patients with metastatic breast cancer. **Methods:** The PK study was a two-cycle, cross-over study where 30 patients were included and randomized to either DM followed by D or D followed by DM, both given as a 1-hour intravenous infusion at a dose of 100mg/m^2. The phase II study was a prospective, multicenter, open-label, third-party blinded, randomized, parallel group, active-controlled study including 200 patients to compare the early activity and safety of DM and D, both given as 100 mg/m^2 1-hour intravenous infusion every 21 days (1 cycle) for a total of 6 cycles. **Results:** Bioequivalence of total docetaxel in plasma, AUC0-last and Cmax, was demonstrated for DM compared to D. The incidence of adverse events was higher in the D arm than in the DM arm for the majority of SOCs and PTs in the phase II study. Overall, Grade 3 or 4 AEs were reported for 82.7% of patients from DM arm and 99.0% of patients from D arm. Twelve (12.2%) patients in the DM arm and 24 (24.0%) patients in the D arm needed at least one dose reduction due to AEs. The primary efficacy endpoint in the phase II study was based on the assessment according to Response Evaluation Criteria in Soldid Tumors (RECIST) 1.1 and non-inferiority was not reached based on the pre-defined non-inferiority margin. A post-hoc analysis investigating the ORR based on tumour assessment at the end of chemotherapy, and non-inferiority of DM as compared to D was shown (ITT population). **Conclusions:** DM is bioequivalent to D regarding total drug in plasma and provides a docetaxel formulation that spares patients steroid premedication. An improved safety profile for DM compared to D was shown while additional efficacy data is needed for future development of DM. Eudra CT: 2012-005161-12 and 2013-004889-33. Clinical trial information: 2012-005161-12 and 2013-004889-33. Research Sponsor: Oasmia Pharmaceutical AB.

3527 Poster Session (Board #257), Fri, 8:00 AM-11:00 AM

Liquid biopsy: A community-based oncology practice experience. *First Author: Khalil Choucair, Kansas University School of Medicine, Wichita, KS*

Background: Liquid biopsy is a promising and minimally invasive genetic test examining plasma circulating tumor DNA. Coupled with the rapidly developing next-generation sequencing (NGS) technologies, it holds the potential for implementation in selecting signal-matched therapeutic options. **Methods:** A retrospective chart review was conducted on adult patients with advanced solid tumors whose tumors were tested with Guardant360 assay, between December 2018 and December 2019. A total of 178 patients were referred for testing by 12 oncologists within a single community cancer center. **Results:** Referral rates varied widely (2.25% - 22%). The majority of patients (98%) were tested upfront for molecular marker evaluation, in either newly diagnosed advanced cancer patients, or in recurrent patients without enough tissue for testing. Other patients (2%) were evaluated after failure of 1 st line therapy to assess for acquired mutations. A total of 18 histological types were tested, with lung (LCa; n = 90; 50.56%), breast (BCa; n = 31; 17.42%), and colorectal (CRCa; n = 14; 7.87%) cancers being the most common types. In 86.11% of all tests (n = 180), $\geq$ 1 alteration was detected, while 13.89 % of tests did not reveal any tumor-related mutation, and were considered negative. The average number of alterations per test was 3.1 ($\pm$2.14; n = 481), and varied across types: CRCa (4.36), prostate cancer (2.73), BCa (2.97), and LCa (2.59), had the highest average number of alterations per test. Similarly, LCa (48.44%), BCa (19.13%), and CRCa (12.68%), harbored most of the detected somatic alterations (n = 481). Of all the alterations of practical significance (n = 457), *TP53* (32.17%), *PIK3CA* (8.53%), *EGFR* (7.66%) and *KRAS* (7.22%), were the most commonly altered genes. Only 1 patient had a positive MSI-H status, amenable to immune-therapy. Of those with positive test results (n = 155), 31 (20%) had $\geq$ 1 FDA approved, target-matched therapeutic opportunity. Similarly, 71 patients (45.81%) had $\geq$ 1 target-matched therapeutic opportunity, outside current indications. Lastly, when no FDA-approved target-matched therapy was available (n = 39), results from liquid biopsy testing offered signal-based clinical trial opportunity in 39/39 patients. **Conclusions:** Implementation of NGS-based liquid biopsy testing is feasible within a community practice. In the era of precision oncology, such assays have the potential to expedite the efforts towards target-matched therapies and signal-based clinical trial opportunities. Further studies are warranted to identify the most-cost effective testing strategies. Research Sponsor: None.

3528 Poster Session (Board #258), Fri, 8:00 AM-11:00 AM

Exosomal circular RNAs derived from serum: Promising biomarkers for therapeutic targets and prognosis of triple-negative breast cancer (TNBC). *First Author: Sujin Yang, Department of General Surgery, the First Affiliated Hospital with Nanjing Medical University, Nanjing, China*

Background: Exosomes are well known by the "exosomal shuttle" that delivers oncogenic microRNAs (miRNAs), mRNAs, circular RNAs (circRNAs) and proteins to the recipient cells and tumor microenvironment, and may be used as promising biomarkers for disease diagnosis. This study aims to provide a theoretical basis to use stable exosomal circRNAs as new biomarkers for predicting the development, metastasis and therapeutic targets of TNBC. **Methods:** A strategy combining RNA-sequencing technique, bioinformatic analysis and RT-qPCR was used to determine the level of differential expressed circRNAs in serum exosomes samples (n = 43) from TNBC patients compared with non-TNBC patients. The expression of circHSDL2 were also detected in tumor tissues (n = 20) from TNBC patients and breast cancer cell lines by qRT-PCR. Cell cycle analysis, the wound healing assays and transwell assays were used to investigate the function of circHSDL2 in proliferation, invasion and metastasis of TNBC cells. FISH, dual-luciferase reporter and functional assays were performed to confirm the interaction between circHSDL2 and let-7a-2-3p in TNBC cells. **Results:** We profiled the circRNAs in the serum exosomes samples from TNBC patients and non-TNBC patients by RNA sequencing and detected 803 significantly differentially-expressed circRNAs. After bioinformatic analysis, circHSDL2 was chose to further study. RT-qPCR results showed that higher expression of circHSDL2 in TNBC cell lines and tumor tissues from TNBC patients. Moreover, overexpression of circHSDL2 promoted TNBC cells proliferation and invasion, while knockdown of circHSDL2 inhibited TNBC cells proliferation and invasion. Mechanistically, circHSDL2 acted as a "miRNAs sponge" to absorb let-7a-2-3p; let-7a-2-3p inhibited TNBC cell invasion and metastasis. Kaplan-Meier plots showed lower expression of let-7a-2-3p was connected to poor prognosis in TNBC metastasis patients from TCGA database. **Conclusions:** The expression of circHSDL2 was found significantly upregulated in serum exosomes and tumor tissues from TNBC patients. Moreover, circHSDL2 could promote cell proliferation, invasion and metastasis in TNBC cells. CircHSDL2 might be function as competing endogenous RNAs (ceRNAs) by targeting let-7a-2-3p in the progression of TNBC. Therefore, this study provides a fresh perspective on novel therapeutic targets and potential biomarkers for TNBC from exosomal circRNAs. Research Sponsor: National Natural Science Foundation of China (No. 81872365).

3529 Poster Session (Board #259), Fri, 8:00 AM-11:00 AM

MSK-ACCESS for noninvasive somatic mutation profiling of lung cancers utilizing circulating tumor DNA. *First Author: Emily S. Lebow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Circulating cell-free DNA (cfDNA) next-generation sequencing (NGS) is a promising strategy for non-invasive molecular profiling of cancers. MSK-ACCESS (Analysis of Circulating cfDNA to Evaluate Somatic Status) is a hybridization-capture targeted NGS assay that detects somatic variants in select exons of 129 genes with matched white blood cell sequencing. We present the initial clinical experience with MSK-ACCESS among patients with advanced non-small cell lung cancer (NSCLC). **Methods:** Patients with stage IV NSCLC underwent prospective MSK-ACCESS testing at initial diagnosis or progression of disease on targeted therapy between June 2019 and January 2020. A subset of patients had matched tissue-based NGS testing with the MSK-IMPACT 468 gene assay. We assessed oncogenic driver detection, turnaround time, plasma-tissue concordance, and matching to therapy. National Comprehensive-Cancer Network designated driver alterations were included in evaluation of tissue-plasma concordance (EGFR, ALK, KRAS, MET, RET, BRAF, HER2, ROS1, NTRK). Turnaround time was compared by a two-sided Wilcoxon signed-rank test. **Results:** A total of 201 patients with NSCLC had MSK-ACCESS testing at initial diagnosis (n = 79) or following progression of disease (n = 122). The median turn-around-time from plasma collection to MSK-ACCESS report was 16 days (range: 9 – 36 days) compared to 19 days from lab receipt of tissue to report (range: 12 – 57) for MSK-IMPACT ($p < 0.001$). Among patients with a driver detected on MSK-ACCESS, 100% (92/92) had an identical driver detected on MSK-IMPACT. Among patients with a driver detected on MSK-IMPACT, 75% (92/123) had an identical driver detected on MSK-ACCESS. This rate was similar among patients who were treatment-naive (74%; 64/86) and had disease progression (76%, 28/37) at the time of MSK-ACCESS. MSK-ACCESS identified driver alterations that directly guided first-line targeted therapy (n = 18) with response in all patients with available radiographic follow-up (n = 10), including a patient without confirmatory tissue testing. MSK-ACCESS identified resistance alterations among patients with disease progression including EGFR T790M, EGFR C797S, ROS1 G2032R, as well as a BRAF fusion. **Conclusions:** MSK-ACCESS successfully identified driver alterations with high concordance to tissue-based testing, directly guided patients to therapy with clinical responses, and detected known and novel resistance mechanisms. This assay warrants further clinical development to guide and facilitate precision oncology. Research Sponsor: None.

3530 Poster Session (Board #260), Fri, 8:00 AM-11:00 AM

Exploitation of treatment induced tumor lysis to enhance sensitivity of ctDNA analysis: A first-in-human pilot study. *First Author: Daniel Adam Breadner, London Regional Cancer Program, London, ON, Canada*

Background: Blood based liquid biopsies examining circulating tumour DNA (ctDNA) have increasing applications in non-small cell lung cancer (NSCLC). Limitations in sensitivity remains a barrier to ctDNA replacing tissue-based testing. There is a paucity of data regarding the dynamics of ctDNA levels in the hours to days following a new treatment. We hypothesize that chemotherapy or radiation will yield an increased abundance of ctDNA in plasma by inducing tumor lysis, allowing for the detection of genetic alterations that were occult in baseline testing. **Methods:** Two prospective cohorts of 20 patients (pts) with stage III/IV NSCLC were enrolled. Cohort 1 (C1) contained pts starting the first cycle of platinum doublet chemoradiation (C1a, n=10) or the first cycle of platinum doublet cytotoxic chemotherapy ± immunotherapy without radiation (RT) (C1b, n=10). Cohort 2 (C2) contained pts receiving palliative RT alone. Two baseline samples were collected, the first ≤ 14 days prior to starting treatment and one immediately prior to treatment. In C1, subsequent samples were collected 3, 6, 24 and 48 hours post initiation of chemotherapy. Pts in C2 had samples collected immediately prior to RT fractions 2, 3, and 4. Samples were analyzed for ctDNA using the 36-gene amplicon-based NGS Inivata InVisionFirst-Lung assay. **Results:** Complete results were available for the first 35 of 40 enrolled pts, C1a – 10 pts, C1b – 9 pts, C2 – 16 pts. Detectable ctDNA was present at baseline in 27 pts (77%), 4 additional pts (11%) had detectable ctDNA in post treatment samples. Four of the patients with detectable ctDNA at baseline (15%) had new genetic alterations detected in post treatment samples. A total of 8/35 pts (23%) had new genetic alterations detected in the post treatment samples. Mutant molecule numbers increased with treatment in 23 of 31 (74%) pts with detectable ctDNA, C1 - 13 of 19 pts (68%) and C2 - 10 of 16 pts (63%). ctDNA levels peaked a median of 2.2 hours (IQR: 1.5 – 2.9 hours) after the initiation of chemotherapy and a median of 1 day (IQR: 1-2 days) after radiation was commenced. The percentage increase in ctDNA levels was a median of 29% (IQR: -18 to +112%) in C1. C2 had a median increase of 16% (IQR: 0 to +131%). **Conclusions:** ctDNA levels increase in the hours to days after starting treatment. ctDNA testing in the acute post treatment phase can yield results that were not evident in pretreatment testing. Application of this principle could improve ctDNA utility as an alternate to tissue-based testing and improve sensitivity for the detection of treatment-resistant clones. Research Sponsor: None.

3531 Poster Session (Board #261), Fri, 8:00 AM-11:00 AM

Longitudinal and personalized detection of circulating tumor DNA (ctDNA) for monitoring efficacy of atezolizumab plus bevacizumab in patients with unresectable hepatocellular carcinoma (HCC). *First Author: Chih-Hung Hsu, National Taiwan University Cancer Center, Taipei City, Taiwan*

Background: ctDNA has emerged as a promising biomarker for noninvasive monitoring of treatment response and disease progression in many tumor types. However, the clinical use of ctDNA in patients with HCC has not been established. Here, we evaluated longitudinal and personalized detection of ctDNA for monitoring the treatment response to atezolizumab (atezo) + bevacizumab (bev) in patients with unresectable HCC not previously treated with systemic therapy. **Methods:** A subset (n = 48) of 104 patients with HCC who enrolled in Arm A of GO30140 (NCT02715531; Phase 1b) and received atezo + bev treatment were included in this study. These patients had 10 CR, 11 PR, 12 SD and 15 PD per IRF-assessed RECIST 1.1. Serial plasma samples were collected at baseline (Cycle [C]1 Day [D]1), during treatment (C2D1, C4D1) and at disease progression. Somatic mutations in individual tumors were identified via whole exome sequencing of archival tumor tissues or fresh biopsies collected before treatment. Personalized ctDNA assays (Signatera 16-plex multiplex PCR next-generation sequencing assay) specific to each patient's tumor mutational signatures were successfully designed for 47 of 48 patients. **Results:** At C1D1, a median of 25.7 ng of cell-free DNA was extracted from 2-mL plasma samples. ctDNA was detected in 45 of 47 patients (96%), with a median of 70.6 mean tumor molecules/mL of plasma (MTM/mL) and a median of 1.8% mean variant allele frequency (mean VAF) in plasma. Higher ctDNA levels detected at C1D1 appeared to be associated with increased tumor burden ($P < 0.03$). Dynamic changes in ctDNA levels post-treatment were associated with response at C4D1. ctDNA status changed from positive at baseline to negative in 7 of 10 CR (70%), 3 of 11 PR (27%), 1 of 11 SD (9%) and 0 of 11 PD (0%) patients. Longer PFS was observed in patients whose ctDNA became undetectable post-treatment. The median PFS in patients with ctDNA present vs cleared at C4D1 was 6.5 months and not reached, respectively (HR, 12 [1.7-93], log-rank $P < 0.00029$). **Conclusions:** Our study showed that Signatera, a personalized and tumor-informed ctDNA assay, could be used as a sensitive method for detecting ctDNA in patients with unresectable HCC. More importantly, our results illustrate the promise of ctDNA as an emerging biomarker that may potentially help to monitor treatment responses and disease progression in patients with HCC. 3532 Poster Session (Board #262), Fri, 8:00 AM-11:00 AM

Comprehensive genomic profiling of 216 Chinese patients with renal cell carcinoma. *First Author: Congwang Zhang, GloriousMed Technology Co., Ltd., Shanghai, China*

Background: Renal cell carcinoma (RCC), a global public health problem, has exhibited a gradual rise in incidence. Unfortunately, the scarcity of effective biomarkers in the clinical became a major limitation of the progress of biological therapies. Therefore, it is imperative to accurately comprehend RCC genomic profiling for exploring its clinical treatment strategies. **Methods:** Formalin Fixed Paraffin Embedded (FFPE) tumor and matched blood samples of 216 Chinese RCC patients were obtained for next-generation sequencing (NGS)-based 620 cancer genes panel assay and RCC genomic profiling was evaluated. **Results:** In our Chinese RCC cohort, multiple histological subtypes, encompassing clear cell (96/216, 44.44%), papillary (14/216, 6.48%), chromophobe (2/216, 0.93%), and undefined subtypes (104/216, 48.15%) were included. The top ranked genomic alterations in Chinese RCC patients were VHL (45.83%), PBRM1 (17.1%), BAP1(13.89%), TP53 (10.65%), SETD2 (9.29%), MTOR (8.67%), ARID1A (5.6%), PTEN (5.09%). Interestingly, BAP1, PBRM1 were co-mutated with VHL, and MET, NF2 were mutually exclusive with VHL (all $p < 0.05$). Of these patients, 87.9% (190/216) of RCC patients had at least one genomic alteration, indicating the potential clinical benefits of targeted therapies. Out of 15 most common canonical pathways, potentially targetable genomic alterations were mainly identified in HIF (45.83%), chromatin remodeling (42.59%), PI3K/AKT (24.07%), DNA damage response (19.44%), RTK-RAS (18.06%), TP53 (15.74%), NOTCH (9.72%), Hippo (9.72%), and WNT (5.56%) pathway. Additionally, HIF pathway was commonly co-altered with chromatin remodeling pathway, and WNT and NOTCH pathways were significantly co-altered with TP53 pathway. Rare mutation types such as CDKN2A-DMRTA1 and HOOK1-ALK were also detected. Across samples, the median TMB was 2.2 (0-18.6) mutations/Mb. Only 2 Chinese RCC patients had TMB-high (> 10 mutations/Mb). **Conclusions:** Our results displayed the landscape of genomic alterations in 216 Chinese RCC patients. The genomic alterations identified in our study may provide an opportunity to discover potential strategies for targeted and immunotherapy in RCC. Future studies should account for these genomic alterations. Research Sponsor: None.

3533 Poster Session (Board #263), Fri, 8:00 AM-11:00 AM

Genomically informed longitudinal monitoring of circulating tumor DNA (ctDNA) to predict outcomes of cancer therapy. *First Author: Mohamed Alaa Gouda, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Short fragments of ctDNA can be detected and quantified from blood samples of patients with cancer. We hypothesize that dynamic changes in quantity of ctDNA in patients with advanced solid cancers during the first few weeks of therapy can predict treatment outcomes reported by standard imaging. **Methods:** We enrolled patients with advanced cancers treated with experimental therapies, who had blood collection for ctDNA isolation and testing at baseline, mid-cycle and at the time of restaging imaging. Patients who were treated with multiple treatment lines were included with separate record for each therapy. Genomically informed molecular testing of ctDNA was performed using unamplified droplet digital PCR (QX200, Bio-Rad) designed based on known molecular profile of tumor tissue and ctDNA was quantified as aggregate variant allele frequency (VAF%) for detected molecular aberrations. Patients were classified based on results of their first restaging imaging as responders (complete [CR] or partial response [PR]) vs. non-responders (stable disease [SD], progressive disease [PD]) and progressors (PD) vs. non-progressors (CR, PR, SD). **Results:** Total of 85 patients who received 132 courses of therapies between May 2012 and June 2019 were analyzed. Breast (N = 21), melanoma (N = 14) and cholangiocarcinoma (N = 14) were most frequent tumor types. Aggregate VAF at mid-cycle was higher in non-responders (3.98%) compared to responders (0.40%, P = 0.016) and in progressors (4.40%) compared to non-progressors (2.10%, P = 0.019) as measured by 5% trimmed mean. Similarly, aggregate VAFs at first imaging restaging was higher in non-responders (5.10%) compared to responders (0.10%, P = 0.001) and in progressors (10.80%) compared to non-progressors (0.90%, P < 0.001). Progressors demonstrated increase in ctDNA VAF at the time of the first imaging restaging compared to decrease in non-progressors (0.7% vs. -4%, P = 0.015). In addition, increase in ctDNA VAF at the first imaging restaging was associated with more PD (44% vs. 8%, P = 0.019) and less PR/CR (0% vs. 31%, P < 0.001). Median time-to-treatment failure was shorter in patients with increase in ctDNA VAF at the time of the first imaging restaging (52 days vs. 89 days, P = 0.002). **Conclusions:** Dynamic changes in quantity of blood-derived ctDNA within the first few weeks of therapy correspond with treatment outcomes reported by the first restaging imaging and time-to-treatment failure. 3534 Poster Session (Board #264), Fri, 8:00 AM-11:00 AM

Subcellular partitioning of Kaiso (ZBTB33) as a biomarker to predict overall breast cancer survival. *First Author: Sandeep K Singhal, Department of Pathology, School of Medicine and Health Sciences, University of North Dakota, Grand Forks, ND*

Background: The epigenetic transcriptional regulator, Kaiso (ZBTB33) has been identified as a member of the C2H2 zinc finger proteins containing a BTB/POZ -zinc finger family of transcription factors that are implicated in development of cancer. Although, our understanding of clinical relevance of subcellular distribution (cytoplasmic/nuclear) Kaiso in the growth and survival of human Breast cancer (BC) is limited. **Methods:** We examined a cohort of 555 BC patients who underwent surgery for their primary BC in Greenville, NC using AI and SM approach. **Results:** The sub-classification BC shows, cytoplasmic Kaiso is differentially enriched in ER- BC (p=0.001) compared nuclear Kaiso (p=0.8) and is significantly enriched in the more aggressive classes LumB (p=0.0017), HER2+ (p=0.05) and TNBC (p=6.1e-07) with respect to LumA BC patients. Additionally, the survival analysis of different compartments of Kaiso demonstrates that high cytoplasmic Kaiso (HR = 16.29 (7.6 – 34.8), p = 5.5e−13) is much more predictive of poor survival compared to nuclear Kaiso (HR = 2.83 (2.02 – 3.8), p = 6.1e−11). At gene expression level, ZBTB33 mRNA levels do not correlate with either nuclear (Spearman correlation: -0.03157, p= 0.7267) or cytoplasmic levels (Spearman correlation: -0.03526, p= 0.6962) of Kaiso. Surprisingly, ZBTB33 mRNA abundance is predictive of poor overall BC survival as demonstrated in two independent publicly available BC cohorts Metabric (HR = 2.14 (1.49 − 3.08), p = 2.7e−05) and Gyorffy B et al. (HR = 1.81 (1.55 − 2.12), p = 2.5e−14). Nuclear and cytoplasmic levels of Kaiso do not show significant differences based on race p=0.27 and p=0.1 respectively. **Conclusions:** Our data suggest subcellular distribution of high Kaiso is associated with poor prognosis of BC survival and subcellular localizations of Kaiso may play differential biological roles in BC prognosis. Circulating stromal cells as a potential blood-based biomarker for screening invasive solid tumors. *First Author: Daniel Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Peripheral blood allows for a simple non-invasive method for isolating various cancer associated circulating stromal cells (CStCs) which may predict for cancer presence. Cancer Associated Macrophage-Like cells (CAMLs), a specific CStC, are phagocytic myeloid cells that derive from an immunological response to cancer and emanate from primary tumors. Using a filtration platform we screened the peripheral blood of untreated newly diagnosed cancer patients (n = 308) for CAMLs. In parallel, we screened patients with newly diagnosed non-malignant diseases, i.e. lupus, benign cysts, etc. (n = 39), and healthy control samples (n = 76). We found that CAMLs are highly prevalent (87%) in the blood of cancer patients, but uncommon in non-malignant conditions (20%) & absent in healthy individuals (0%). **Methods:** Anonymized peripheral blood were taken from 308 cancer patients after confirmation of invasive malignancy [stage I (n = 76), stage II (n = 73), stage III (n = 72), stage IV (n = 65) and unstaged non-metastatic (n = 22)] with pathologically confirmed lung (n = 65), pancreas (n = 53), breast (n = 52), prostate (n = 40), esophageal (n = 30), renal cell (n = 18), hepatocellular (n = 15), neuroblastoma (n = 10), melanoma (n = 8), and other (n = 17). Further, anonymized blood was taken from patients with untreated non-malignant conditions including benign breast masses (n = 19), lupus (n = 11), liver cirrhosis (n = 5), benign prostatic hyperplasia (BPH) (n = 3), and viral infection (n = 1); or from healthy control volunteers (n = 76). CAMLs were isolated from whole peripheral blood by the CellSieve™ microfiltration technique and defined as enlarged, multinuclear cells with cytokeratin and/or CD45/CD14 positive. **Results:** CAMLs were found in 87% of all cancer patients regardless of stage, ~5.4 CAMLs/7.5mL blood. Specifically, CAMLs were found in 80% of Stage I, 90% Stage II, 89% Stage III, and 97% Stage IV patients. No CAMLs were found in any healthy controls, but were found in 26% of benign breast masses, 18% of lupus, 0% of BPH and 0% of cirrhosis. In total, CAML sensitivity in cancer vs healthy was 87% (CI95% 82-90%), specificity = 100% (CI95% 95-100%), PPV = 100% (CI95% 100%), NPV = 67% (CI95% 58-71%). CAML sensitivity in cancer vs benign was 87% (CI95% 82-90%), specificity = 80% (CI95% 64-91%), PPV = 97% (CI95% 95-98%), NPV = 43% (CI95% 35-51%). **Conclusions:** CAMLs, a Circulating Stromal Cell subtype, is a sensitive blood based biomarker found in all stages of cancer that is rare in non-malignant conditions and absent in healthy individuals. 3536 Poster Session (Board #266), Fri, 8:00 AM-11:00 AM

Clinical potential of ctDNA-based TMB in small cell lung cancer recieving chemoradiotherapy. *First Author: Ying Jin, Institute of Cancer and Basic Medicine, Chinese Academy of Sciences, Department of Medical Oncology, Cancer Hospital of the University of Chinese Academy of Sciences & Zhejiang Cancer Hospital, Zhejiang Key Laboratory of Radiation Oncology, Hangzhou, China*

Background: Small cell lung cancer (SCLC) is an aggressive tumor with poor prognosis. Chemotherapy and / or radiotherapy is the main choice of SCLC treatment. Circulating tumor DNA (ctDNA) has received substantial attention in recent years owing to the potential of patient stratification and monitoring. Here, we assessed the value of prediction and prognosis using ctDNA in SCLC. **Methods:** SCLC patients (pts) with limited-stage disease (LD) receiving chemoradiotherapy and extensive-stage disease (ED) receiving chemotherapy were enrolled. Baseline plasma samples were collected for NGS using a 1021-gene-panel. Mutational features and blood-based tumor mutation burden (bTMB) were analyzed using ctDNA. pyClone software was used to cluster the mutations. The mutations in the cluster with the highest cancer cell fraction (CCF) were defined as clonal mutations. Progression-free survival (PFS) was followed. **Results:** 58 SCLC pts (35 LD and 23 ED) and 58 plasma samples were enrolled. Smoking pts accounted for 84% (49/58). In all samples, recurrent genes were TP53 (86%), RB1 (57%), LRP1B (34%), CREBBP (26%), and MLL3 (22%). The median of bTMB and clone count were 7.9 [0-26] and 7 [0-25]. Significant higher bTMB and clone count were observed in ED pts compared with LD (Mann Whitney test, p = 0.019 and p = 0.041, respectively). Mutated *CREBBP* (10/23 ED versus 5/35 LD) was enriched in ED (Fisher exact test, p = 0.017 and OR = 0.223). Mutations in NOTCH signaling pathway were enriched in ED (l6/23 ED versus 13/35 LD, p = 0.031, OR = 0.265). In LD group, there were trend toward prolonged PFS in pts with higher bTMB(p = 0.065), and pts with higher clonal bTMB (cbTMB) exhibited significant longer PFS (p = 0.016, HR 0.37, 95% CI [0.12-1.11]). Patients with alteration in PIK3CA showed shorter PFS than wild type (p < 0.001, HR 0.11, 95% CI [0-2.86]). There were no significant difference in median PFS in LD stage pts with any detectable pathway alterations. Whereas, LD pts whose ctDNA contained RTK-RAS signaling pathway alterations exhibited shorter PFS than pts without those alterations (p = 0.135). In ED pts, NOTCH1 gene wild type displayed longer PFS than mutant type (p = 0.036, HR 0.38, 95% CI [0.1-1.53]). There were no difference in PFS between pts with higher and lower bTMB and cbTMB. **Conclusions:** ctDNA can characterize the mutational feature of SCLC. There are differences in the molecular characteristics between ED and LD pts. Clonal bTMB is a potential prognostic biomarker for LD SCLC chemoradiotherapy. The prognostic marker of ED chemotherapy is different from LD. Research Sponsor: None.

3537 Poster Session (Board #267), Fri, 8:00 AM-11:00 AM

Circulating tumor DNA dynamics to predict cancer recurrence/metastasis in Chinese pathologic stage I lung adenocarcinoma. *First Author: Chao Cheng, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Pathologic(p)stage I lung adenocarcinoma (LUAD) patients exhibit high levels of genetic heterogeneity and the association between the genomic characteristics of (p)stage I LUADs and tumor recurrence remains poorly understood. Circulating tumor DNA (ctDNA) monitoring after resection represents a useful tool to predict response to therapy and tumor recurrence but its application in (p)stage I LUAD patients remains controversial. In addition, it is of great clinical interest to decipher the difference of genetic features between ground-glass opacity (GGO) and solid nodules (non-GGO) subgroups. **Methods:** Tumor tissues and matched post-operative plasma samples were collected from a total of 86 Chinese (p)stage I LUAD patients who were enrolled in a clinical study (NCT03172156). Comprehensive genomic profiling was performed using capture-based hybrid next generation sequencing by targeting 422 cancer relevant genes. **Results:** *EGFR* and *TP53* represent commonly mutated genes in this cohort of (p) stage I lung adenocarcinoma, followed by alterations in *ALK*, *PIK3CA*, *STK11*and *MYC*. For a median follow up period of 21.54 months after surgical resection, we observed that ctDNA positivity significantly correlated with an increased probability of early tumor recurrence or metastasis (P= 0.03, HR = 7.9), and in particular, the *EGFR* mutation status of ctDNA samples rather than that of primary tumor samples significantly correlated with shorter disease-free survival (DFS). Further comparison between GGO and non-GGO subgroups indicated that the frequency of *TP53* mutations in non-GGO was markedly higher than that in GGO (48% vs 20%, $P<$ 0.05). In addition, pathway analysis showed that the epigenetic regulation pathway was more frequently affected in the GGO subgroup, while impaired apoptosis/cell cycle pathway was more enriched in the non-GGO LUADs. **Conclusions:** Our data show that ctDNA positivity, including the *EGFR* mutation status, significantly correlated with early relapse or metastasis after surgery, representing a useful tool to predict treatment response and tumor relapse in (p)stage I LUAD patients. Mutated *TP53* was more abundant in non-GGO comparing to GGO (p)stage I LUADs that may act as potential oncogenic driver in LUAD development and/or disease progression. Clinical trial information: NCT03172156. 3538 Poster Session (Board #268), Fri, 8:00 AM-11:00 AM

Evaluation of Genexus system that automates specimen-to-report for cancer genomic profiling within a day using liquid biopsy. *First Author: Siew-Kee Kee Low, Cancer Precision Medicine Center, Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Genomic profiling of patients' tumors using NGS system help in facilitating molecular-guided therapy. The turnaround time from specimen to report by the NGS system is important to deliver result timely for clinical decisions. The Genexus Integrated Sequencer automates all steps of the targeted NGS workflow starting from nucleic acid of formalin-fixed paraffin-embedded tissues or plasma that significantly reduce laborious procedures. Importantly, the whole specimen-to-report workflow delivers results in a single day. In this study, we evaluated detection rate of alteration using Oncomine Precision Assay (OPA) on Genexus system with cell-free DNA (cfDNA) from non-small cell lung cancer (NSCLC). **Methods:** Among the cfDNA from 48 plasma samples of NSCLC were evaluated, 19 were newly-diagnosed cases with *EGFR* mutations in cancer tissues and 29 cases were patients who experienced progression of disease after first line of EGFR, ALK or ROS1-targeted therapy. 13-20ng of input cfDNA were subjected to automated Genexus Integrated Sequencer for library construction using OPA panel, templating and sequencing. OPA panel covers actionable hotspot mutations, copy number gains or loss, fusion drivers. The concordance of mutation profiles between the tumor tissue and cfDNA and detection of a resistance mutation(s) during molecular-targeted therapy were evaluated. **Results:** The sequencing resulted in median overall reads of 8,698,358, median overall depth of 30,648 (range 15,069-48,707) and median molecular coverage of 1,595 (range 859-2,550). Among 48 samples examined, 44 were detected to carry at least one somatic mutation, giving the detection rate of 92%. A total of 17 of 19 newly diagnosed EGFR-positive patients were also detected to carry *EGFR* mutations. Importantly, these 17 patients carry the same mutation that was found in tissue samples implying complete concordance. In addition, we found novel resistance mutations in plasma of the patients who were under EGFR, ALK or ROS1 targeted therapies. **Conclusions:** Genexus Integrated Sequencer is a fully automated and highly accurate NGS system with a 1-day turnaround time that could assist clinicians to make more timely decision. Novel actionable, resistance mutations were detected using OPA panel that provide potential options for molecular-guided therapy and may help the better understanding of resistance mechanism of targeted therapy. 3540 Poster Session (Board #270), Fri, 8:00 AM-11:00 AM

A pan-cancer analysis of ARID1A as a potential biomarker for immune checkpoint therapy. *First Author: Dongyong Yang, Department of Pulmonary and Critical Care Medicine, Second Affiliated Hospital of Fujian Medical University, Quanzhou, China*

Background: AT-rich interactive domain 1A (ARID1A), encoding a subunit of the BAF (SWI/SNF) chromatin remodeling complex, is correlated with the origination and progress of tumor. Previous research on ARID1A gene revealed that ARID1A deficiency was associated with mismatch repair (MMR) and higher tumor mutation burden (TMB) level in cancer, which might cooperate with immune checkpoint blockade therapy. **Methods:** Next generation sequencing (NGS) data of 10336 pan-cancer patients were obtained from the MSK-IMPACT Clinical Sequencing cohort (MSKCC). NGS data of 15849 pan-cancer patients from Chinese clinical dataset were analyzed to explore the association between ARID1A gene mutation and TMB. TMB was defined as total number of somatic non-synonymous mutations in coding region. 853 advanced NSCLC patients from two independent cohorts (OAK study cohort and POPLAR study cohort) were used to analyze the correlation between ARID1A alteration and the efficacy of immune checkpoint blockade immunotherapies (ICIs). **Results:** In total, 8.62% (891/10336) of pan-cancer patients in MSKCC harbored ARID1A mutation and 8.47% (3188/37628) in Chinese cohort. In MSKCC cohort, the highest ARID1A mutation frequency tumor type was endometrial cancer (31.64%, 69/218), bladder cancer (26.95%, 114/423) and hepatobiliary cancer (17.18%, 61/355) come in second and third, respectively. While in Chinese cohort, the top three ARID1A mutation frequency tumor types were endometrial cancer (39.29%, 88/224), gastric carcinoma (17.80%, 318/1787) and urothelial carcinoma (17.18%, 83/483), respectively. ARID1A gene mutation was also associated with higher TMB in the Chinese pan-cancer cohort ($P < 0.0001$). The highest medium TMB level of ARID1A mutation tumor type was Urothelial carcinoma with 18.63 Muts/Mb (n = 65). In addition, the TMB level and prognositic analysis were performed on patients in two independent NSCLC cohorts with ICIs, TMB level of ARID1A mutant group was higher than wild-type group with significant difference ($P < 0.0001$). The overall survival (OS) of ARID1A mutation group were significantly shorter than wild-type group (OS, median, 6.80 vs 10.28 months; HR, 1.47; P = 0.0474), and a decreasing trend on progression-free survival (PFS) without significant difference (median, 1.46 vs 2.99 months; HR, 1.27; P = 0.1584). **Conclusions:** The results indicated that ARID1A gene mutation was associated with a higher TMB level in Chinese pan-cancer patients, and patients harboring these genes mutations might easily benefit from ICIs. Research Sponsor: None.

3541 Poster Session (Board #271), Fri, 8:00 AM-11:00 AM

The predictive role of plasma mutant allele fraction to antiangiogenic drugs in patients with mCRC: An expanded analysis of surrogate biomarkers of response to first-line treatment with bevacizumab. *First Author: Giulia Martini, Medical Oncology, Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy*

Background: So far, no biomarkers of response to anti-angiogenic drugs are available in colorectal cancer (CRC) treatment. Liquid biopsy tracks dynamic mutational changes in CRC patients (pts). RAS mutant allele fraction in plasma (plMAF) is an independent prognostic marker in metastatic CRC (mCRC). We explored the predictive value of plMAF in RAS mutant pts treated in 1st line with chemotherapy +/- bevacizumab (bev). **Methods:** A multicentric prospective/retrospective analysis was conducted. We collected data from 226 mCRC pts and selected the subset not eligible for metastasis resection with basal plMAF sample evaluable for RAS mutant MAF quantification with digital PCR (BEAMing). Pts were stratified as high ($\geq$ 5.8%) or low ($<$ 5.8%) plMAF. We investigated associations between clinicopathological variables and progression-free survival (PFS) stratified by plMAF RAS levels using Cox regression models and survival data were calculated by Kaplan-Meier method. Computational analysis of baseline CT scan data extracted 93 radiomics features of all the lesions per patient including 1) 1st class from density histogram distribution and texture analysis by 2) 2nd order and 3) higher order feature classes. The radiomic features distribution between pts with high and low plMAF was assessed with Student's t-test analysis. **Results:** From October 17 to May 19, 63 basal plasma samples were analysed with BEAMing. 42 pts (67.7%) were classified as high and 21 pts (32,3%) as low plMAF. In high plMAF subgroup, a statistically significant longer PFS favouring FOLFOX+bev was observed, compared to FOLFOX alone (10.7 vs 6.9 mts; HR: 0.30; p = 0.002). In low RAS plMAF subgroup, no differences in terms of PFS were observed in either arm (8.9 vs 8.7 mts; HR: 0.7; p = 0.6). Multivariate PFS model showed no association between RAS plMAF and clinicopathological variables, except for high RAS plMAF and treatment benefit with FOLFOX+bev. The CT-radiomics signature, that may translate tumor vascularization, differentiated patients with high vs low plMAF (p = 0.002). 58 patients (92%) had similar radiomic score; 5 patients with high plMAF (8%) presented very heterogeneous radiomic score distribution. **Conclusions:** Tumor-borne RAS plMAFs may constitute a potential predictive biomarker of efficacy for anti-angiogenic drugs in mCRC. Next steps will include the identification of -histological, transcriptomic and radiomic- surrogate biomarkers of response that reflect tumor irrigational status. Research Sponsor: aecc.

3542 Poster Session (Board #272), Fri, 8:00 AM-11:00 AM

Analytical validation of digital cytometry (iSort) for leukocyte enumeration using stored blood. *First Author: Aaron M. Newman, Stanford Cancer Institute, Stanford, CA*

Background: Blood leukocyte enumeration is a cornerstone for clinical diagnosis and immune monitoring of diverse cancers and immunotherapies. Existing methods rely on intact/living cells and can thus be limiting due to handling time constraints and need for predefined antibody panels. While indirect cytometry methods including digital cytometry can overcome this limitation on archival specimens, their clinical performance has not been extensively characterized. We developed iSort, a novel transcriptome deconvolution method based on CIBERSORTx. Here, we comprehensively evaluated iSort and validated it against established diagnostic standards. **Methods:** We recruited 36 healthy adult blood donors and characterized their blood leukocyte profiles. We used several established clinical cytometry methods requiring intact cells in a CLIA laboratory including Complete Blood Count [CBC] and 6-color TBNK [TBNK]. We also immunophenotyped leukocytes by a research flow cytometry panel (FACS) and by mass cytometry (CyTOF). We then used these techniques as standards for validating leukocyte populations enumerated by iSort. iSort was performed on whole blood through deconvolution of 22 subsets from RNA-Seq. We assessed iSort's analytical detection performance by spiking purified lymphocyte subsets into lymphodepleted human blood and by simulating blood mixtures using defined leukocyte mixtures within latin square designs. We assessed iSort concordance with an FDA approved IVD assay (TBNK) comparing distinct RNA-Seq library preparation chemistries. **Results:** iSort was highly correlated with TBNK/CBC across CD4 T, CD8 T, B cells, NK cells, monocytes, and neutrophils ($r \geq 0.95$). When comparing correlations to TBNK/CBC, we found no significant differences between iSort, CyTOF, and FACS, nor between RNA-Seq library chemistries. iSort demonstrated high linearity at low abundance levels (0.1 - 1%, $r = 0.99$, B-cells spiked into lymphodepleted blood samples after Rituximab) and at higher abundance levels (0.5 - 90%, $r > 0.99$) across lymphoid and myeloid subsets. iSort also showed high reproducibility among triplicate blood tubes for each population (median CV = 11%). **Conclusions:** iSort digital cytometry achieves highly accurate and robust leukocyte enumeration for diverse hematopoietic subsets. Given its favorable performance against existing clinical standards that require intact/living cells, iSort is a promising approach for the development of immunotherapy biomarkers. Research Sponsor: CiberMed, Inc.

3543 Poster Session (Board #273), Fri, 8:00 AM-11:00 AM

Noninvasive identification of lineage-specific circular RNA for ER-positive breast cancer. *First Author: Jason Brown, Department of Internal Medicine, University of Michigan, Ann Arbor, MI*

Background: Non-invasive testing in plasma using RNA biomarkers has been limited by exoribonuclease-mediated degradation of RNA. Circular RNA (circRNA) are covalently closed RNA structures that resist this degradation due to their circular structure. Therefore circRNA are more stable than their linear counterparts. CircRNA are formed by alternative backsplicing of the 3' end of a downstream exon to the 5' end of an upstream exon. Here, we propose a novel method for non-invasive identification of circRNA and demonstrate circularized forms of several lineage and cancer specific targets for estrogen receptor-positive breast cancer. **Methods:** Capture RNA sequencing on cancer tissue was previously performed to determine the relative expression of potential circRNA isoforms in breast cancer patients. These isoforms as well as those predicted by intron length were screened using a quantitative PCR-based assay on ER-positive breast cancer cells. RNA extracted from breast cancer cells are exposed to ribonuclease R to demonstrate stability of circRNA. CircRNA derived from targets with known universal expression are used as positive controls as well as for analysis on plasma. **Results:** We identify the circRNA isoforms with highest expression for five genes, including ESR1, that are differentially expressed in ER-positive breast cancer compared to other cancers and normal breast tissue. We determine that the circRNA corresponding to all five targets is specifically expressed in breast cancer cell lines with at least 1000-fold higher expression than in non-ER positive breast cancer cell lines. We demonstrate that the highest expressing circRNA isoforms are resistant to degradation by ribonuclease R, whereas corresponding linear mRNA is susceptible. We also demonstrate the presence and stability of positive control circRNA in plasma from patients without cancer. **Conclusions:** CircRNA are promising biomarkers for early non-invasive detection of cancer due to their stability in plasma. This assay reliably detects ER-positive breast cancer specific circRNA, and exoribonuclease resistance has been validated. Application of this diagnostic assay to plasma from breast cancer patients is underway. Research Sponsor: U.S. National Institutes of Health.

3544 Poster Session (Board #274), Fri, 8:00 AM-11:00 AM

Circulating microtumors: A functional hallmark for cancer detection and management. *First Author: Vineet Datta, Datar Cancer Genetics Limited, Nasik, India*

Background: There are presently no accepted non-invasive means for detection of cancers in asymptomatic individuals or suspected cases. Radiological and serological investigations, though non-invasive, are not confirmatory and necessitate an invasive biopsy to establish malignant status of suspected findings. Invasive biopsies, in turn, face challenges due to non-representative tumor tissue or in cases where biopsy is impossible or unviable. We hypothesized that Circulating Microtumors (also called as C-ETACs: Circulating Ensembles of Tumor Associated Cells) in peripheral blood are universally present in solid organ cancers and their detection can be linked to malignant status. **Methods:** We obtained peripheral blood from 14,138 patients with various solid organ cancers as well as 10,625 asymptomatic individuals with age associated elevated risk of cancer. Out of the 14,138 patients with cancer, 25.1 % had local (non-metastatic) disease and 56.4% had metastatic disease as confirmed by radiological evaluation. C-ETACs were enriched and harvested from PBMCs using an epigenetically activating medium that is cytotoxic towards non-malignant epithelial and hematolymphoid cells in blood but confers survival benefit on apoptosis resistant circulating cells of tumorigenic origin and their heterotypic clusters (C-ETACs) in peripheral blood. Viable C-ETACs were identified and further characterized by immunocytochemistry (ICC) profiling. **Results:** C-ETACs were detected in 89.7% of samples from solid organ cancers irrespective of stage, treatment or present radiological status. C-ETACs were rarely detected (3.0%) in asymptomatic individuals. The asymptomatic individuals where C-ETACs were detected are being followed up periodically so as to enable detection of cancer based on clinical or radiological manifestation of symptoms. **Conclusions:** C-ETACs are ubiquitous in cancers and unexpected in asymptomatic individuals. Detection of C-ETACs in asymptomatic individuals may be indicative of risk of latent undiagnosed malignancy. The non-invasiveness of this approach makes it convenient for screening large populations for cancer. Research Sponsor: None.

3545 Poster Session (Board #275), Fri, 8:00 AM-11:00 AM

Identification of *FGFR2/3* fusions from clinical cfDNA NGS using a de novo fusion caller. *First Author: Arielle Yablonovitch, Bioinformatics, Guardant Health, Redwood City, CA*

Background: *FGFR2/3* rearrangements are promising therapeutic targets, especially in advanced urothelial cancer (aUC) with FDA-approved erdafitinib. Liquid biopsy is an attractive non-invasive method to identify these fusions, but detection in cfDNA is technically challenging due to low tumor shedding levels, short molecules, and wide variation in gene partners. To address this, we developed an assembly-based fusion detection algorithm to call rearrangements in a *de novo* fashion without reliance on a fixed partner set and applied it to $>$ 15,000 clinical samples. **Methods:** A cohort of 15,218 patients with mixed cancer types (including 698 aUC patients, as well as breast, cholangiocarcinoma, colorectal, and gastric), plus 276 healthy control samples were previously tested with Guardant360(R), a clinical 74-gene cfDNA NGS-based assay. The median unique molecule coverage was approximately 3,000 molecules sequenced to 15,000x read depth. Samples were reanalyzed *in silico* using the novel algorithm: in brief, reads aligned to candidate fusion breakpoints were assembled into de Bruijn graphs. Resulting contigs were aligned to the reference and filters were applied to remove technical artifacts. **Results:** The majority of *FGFR2* (86%) and *FGFR3* fusion partners (73%) in the mixed cancer cohort were observed only once, consistent with previous reports (Helsten 2016). *FGFR3-TACC3* was the most common fusion, occurring in 72% of *FGFR3* fusion-positive patients. In 37% of *FGFR2* fusion positive patients, the *de novo* caller detected partners not previously described. In the aUC cohort, *FGFR3* fusions were detected in 3.3% of patients, with 8/10 (80%) partner genes/intergenic regions occurring only once, which is in line with previous reports (Nassar 2018). No fusions were identified in 276 healthy control samples. In the mixed cancer cohort, common mutations co-occurring with *FGFR2* fusions were *FGFR2* N549K, *PIK3CA* H1047R, and *TP53* R175H (5.6% each); *KRAS* Q61H was observed in 28% of patients with *FGFR3* fusions. **Conclusions:** *FGFR2/3* fusion partners detected by a highly specific assembly-based *de novo* fusion caller were heterogeneous and individually rare, highlighting the importance of a *de novo* approach. We observed an *FGFR3* fusion prevalence in cfDNA from aUC patients that is comparable to previous reports for tissue testing, demonstrating an ability to capture targetable genomic rearrangements with plasma-based NGS in this patient population. Research Sponsor: Guardant Health.

3546 Poster Session (Board #276), Fri, 8:00 AM-11:00 AM

Demonstrating the value of liquid biopsy for lung cancer in a public health care system. *First Author: Rosalyn A. Juergens, Juravinski Cancer Centre, McMaster University, Hamilton, ON, Canada*

Background: Given the challenges of molecular profiling in patients with advanced lung cancer, this prospective study examines clinical outcomes and utility of liquid biopsy in treatment naive stage IV lung adenocarcinoma patients (Cohort 1) and in the setting of resistance to targeted therapy (Cohort 2; not reported here). **Methods:** This study is being conducted at 6 Canadian centres (NCT03576937) using Guardant 360 (G360), a validated cell-free DNA next-generation sequencing assay that identifies variants in 74 cancer-associated genes, including fusions and copy number gain. Cohort 1 (N = 150) includes patients with treatment-naïve advanced non-squamous lung carcinoma, ≤10 pack-year smoking history, and measurable disease. Patients received standard of care tumour tissue (TT) molecular profiling (*EGFR, ALK +/- ROS1*) and liquid biopsy (LB). The primary endpoint was response rate to first-line therapy (RECIST 1.1); secondary endpoints include incremental targetable alterations identified through G360 (*EGFR, ALK, BRAF, ERBB2, KRAS (G12C), NTRK, MET (amplification, exon 14 skipping), RET, ROS1*), turn-around time (TAT) and successful molecular profiling rates. **Results:** To date, 84 eligible patients with clinical data have been accrued to Cohort 1. Median age is 64 (range 23-91), 64% are female, 85% never smokers, 96% have adenocarcinoma. Actionable targets have been identified in 55% of patients using G360 (*EGFR/ALK* in 37%), 39% using standard TT profiling. Eight *EGFR/ALK* aberrations were identified in TT but not LB, while 6 were identified in LB but not TT. TT profiling for *EGFR/ALK* was unsuccessful in 8% of patients (insufficient tissue, failed biopsy). Fourteen patients (17%) had no ctDNA alterations detected by G360 (low disease burden vs. non-shedding). Of 75 patients receiving first-line treatment, 57% received targeted therapy, 28% chemotherapy combinations, 11% checkpoint inhibitors and 4% were observed. Treatment decisions were informed by G360 alone in 37% and by G360+TT results in 27% (by physician report). Among 46 evaluable patients, ORR was 54% (25/46). Using G360, ORR was 75% (15/20) in those with actionable alterations and 38.5% (10/26) in those without. Using TT, ORR was 67% (14/21) in those with actionable alterations and 44% (11/25) in those without. Mean TAT was 7.9 days (SD+/-1.7) for LB vs 19.9 days (SD+/- 9.8) for TT. **Conclusions:** Liquid biopsy using G360 identifies actionable targets beyond tissue profiling alone in newly diagnosed lung cancer patients, has faster TAT and yields similar outcomes with targeted and non-targeted therapy. Clinical trial information: NCT03576937. Research Sponsor: Guardant Health, Other Foundation.

3547 Poster Session (Board #277), Fri, 8:00 AM-11:00 AM

The prevalence of $KRAS^{G12C}$ mutations utilizing circulating tumor DNA (ctDNA) in 80,911 patients with cancer. *First Author: Kyaw Thein, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Kirsten rat sarcoma viral oncogene homolog (KRAS) is the most commonly mutated proto-oncogene identified in cancer and still remains an arduous therapeutic challenge. Recently, $KRAS^{G12C}$ mutation has become special interest since it has now been considered potentially druggable after the introduction of covalent small-molecule $KRAS^{G12C}$ inhibitors. Advances in next-generation sequencing (NGS) and embracing utilization of ctDNA have uncovered more genetic alterations in many cancers. We present a comprehensive analysis on the prevalence of $KRAS^{G12C}$ mutations identified by ctDNA. **Methods:** We conducted a 5-year (July 2014 to June 2019) retrospective review of ctDNA NGS analysis in the Guardant360 CLIA database inclusive of treatment-naïve and previously treated patients with metastatic solid tumors. Data were retrieved from the 80,911 unique patients with ctDNA detected. Clonality and co-occurrence of cancer type were analyzed. Clonality was defined as variant allele fraction(AF) / maximum somatic AF in the sample. **Results:** 80,911 patients, which included more than 100 tumor histologies, were identified. 2,985 patients (3.7%) with > 40 tumor types had $KRAS^{G12C}$ mutations identified in ctDNA. $KRAS^{G12C}$ prevalence by cancer type were as follows: sarcomatoid lung carcinoma (13.5%), lung cancer NOS (9%), large cell lung carcinoma (9%), lung adenocarcinoma (7.4%), NSCLC (6.9%), carcinoma of unknown primary (CUP) (4.1%), lung carcinoid (4%), CRC (3.5%), squamous cell lung carcinoma (2%), small cell lung carcinoma (1.5%), pancreatic ductal adenocarcinoma (PDAC) (1.2%), cholangiocarcinoma (1.2%), bladder cancer (0.6%), ovarian cancer (0.6%) and breast cancer (0.3%). 53 additional patients with $KRAS^{G12C}$ were identified across 24 other tumor types. The $KRAS^{G12C}$ mutation was found to be clonal (clonality > 0.9%) in the majority of patients with lung adenocarcinoma, NSCLC, CUP, squamous cell lung carcinoma, and PDAC, compared to patients with CRC and breast cancer who had bimodal distribution of clonal and sub clonal mutations. **Conclusions:** To our knowledge, this is the largest analysis on the prevalence of $KRAS^{G12C}$ mutations identified by ctDNA. Our study demonstrated the feasibility of utilizing ctDNA to identify $KRAS^{G12C}$ mutations across solid tumors with the highest prevalence in lung cancer as previously reported in tissue. The clonality information available from ctDNA-based genotyping may provide insights into the clinical efficacy of targeting $KRAS^{G12C}$ in different tumor types. Research Sponsor: None.

3548 Poster Session (Board #278), Fri, 8:00 AM-11:00 AM

Exploring the Cancer Genome Atlas (TCGA) for the molecular profile of young onset colorectal cancers. *First Author: Seyed Ali Khalessi Hosseini, NYU Langone Medical Center, New York, NY*

Background: Colorectal cancer (CRC) incidence and mortality has been declining, in part due to increased implementation of screening, but the incidence among patients under 50 (young onset, YO) is increasing at a rate of 2% per year. The cause of this increasing incidence remains poorly understood, but differences in mutation profiles can help understand pathogenesis, prognosis, and identify targets for therapy. **Methods:** Genomic and clinical data for 488 TCGA CRC patients was used to evaluate differences in genetic alterations between YO and patients over 50. Chi-squared tests were used to determine differences in somatic mutation frequency in critical pathways implicated in CRC: DNA MMR, P53, WNT, RAS-MAPK, PI3K/AKT/mTOR, and TGF-B pathways. For 85 of the patients, proteomic data via RPPA was also available and analyzed. **Results:** The average age of included patients was 66 (SD 12.8). 76 (12.2%) were under 50 at time of diagnosis. When comparing YO with those over 50, there were no differences in microsatellite instability, histologic type (adeno or mucinous), location (colon or rectal), tumor size, or metastasis. YO patients were more likely to have nodal involvement (p = 0.007) and higher histological grade (p = 0.022). YO patients were more likely to have mutations in the MMR pathway (43% vs 23%, p = 0.002) and the PI3K/AKT/mTOR pathway (70% vs 54%, p = 0.024). Specifically, YO were more likely to have mutations in MSH2 (7% vs 1%, p = 0.001), MSH6 (24% vs 7%, p = 0.000); ATM (46% vs 30%, p = 0.015); FZD10 (7% vs 2%, p = 0.007); ERBB2 (15% vs 7%, p = 0.027); PIK3R1 (20% vs 9%, p = 0.014), PTEN (61% vs 35%, p = 0.000), and TGFBR2 (13% vs 4%, p = 0.004). When looking at proteomic data, YO were more likely to have decreased expression of MSH2 (p = 0.003) and MSH6 (p = 0.005). **Conclusions:** Patients with YO CRC are more likely to have somatic mutations in genes involved in the MMR pathway and the PI3K/AKT/mTOR pathway. Specifically, in MSH2, MSH6, ATM, FZD10, ERBB2, PIK3R1, PTEN and TGFBR2. When including proteomic data, significant differences were only seen in expression of MSH2/6. Some of these genes (e.g. ERBB2/HER2) are targets for existing therapies, and others are being actively investigated as potential therapeutic targets. Establishing differences in tumor genetic profiles is a first step towards understanding the increase in YO CRC, and simultaneously identifies targets for therapy. However, because of post-transcriptional changes (e.g. RNAi, methylation), genetic profiling alone cannot always reliably establish differences in protein expression, and thus therapy targets. Research Sponsor: None.

3549 Poster Session (Board #279), Fri, 8:00 AM-11:00 AM

Phase I expansion study of XMT-1536, a novel NaPi2b-targeting antibody-drug conjugate (ADC): Preliminary efficacy, safety, and biomarker results in patients with previously treated metastatic ovarian cancer (OC) or non-small cell lung cancer (NSCLC). *First Author: Debra L. Richardson, Stephenson Cancer Center/Sarah Cannon Research Institute at the University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: XMT-1536 is a first-in-class ADC targeting the sodium-dependent phosphate transport protein NaPi2b, broadly expressed in NSCLC and ovarian cancer. XMT-1536 utilizes the Dolaflexin platform to deliver 10-12 DolaLock auristatin payload molecules per antibody. In the dose-escalation portion of the Phase I study (NCT03319628), XMT-1536 showed clinical activity at doses >20mg/m^2 with confirmed responses and prolonged stable disease in heavily pretreated OC and NSCLC patients, without preselection for NaPi2b expression. XMT-1536 was generally well-tolerated without the severe toxicities observed with other ADC platforms such as neutropenia, peripheral neuropathy, or ocular toxicity (Tolcher et al., ASCO 2019; Richardson et al., SGO 2020). Here, we report on the expansion (EXP) cohort, which included patients with fewer prior lines of therapy, in the ongoing Phase I study. **Methods:** Doses administered intravenously every 4 weeks (q4w) of 36 and 43 mg/m^2 were evaluated in two cohorts (1) high grade serous ovarian, fallopian tube, or primary peritoneal cancer (OC) with up to 4 prior lines of therapy and (2) NSCLC adenocarcinoma; prior treatment with a platinum-based therapy, immune checkpoint inhibitor, and TKI, if indicated. Archival tumor tissue and tissue from a new tumor biopsy were required for retrospective evaluation of NaPi2b expression. **Results:** As of 10 February 2020, 23 patients (19 OC and 4 NSCLC) were enrolled in the EXP cohort: 16 dosed at 36 mg/m^2 and 7 dosed at 43 mg/m^2. Adverse events were generally similar to those previously reported, including transient AST elevation, fatigue, nausea, and pyrexia. Clinical responses and stable diseases have been observed. Efficacy data (objective response rate) and initial correlation of NaPi2b score with clinical response will be reported. Available data from all patients with data cutoff in May 2020 will be included. **Conclusions:** Overall, XMT-1536 treatment demonstrated clinical activity in high grade serous ovarian cancer and NSCLC adenocarcinoma and was generally well-tolerated with no new safety signal trends identified in the EXP. Clinical efficacy and the relevance of NaPi2b expression for treatment with XMT-1536 will be presented. Clinical trial information: NCT03319628. Research Sponsor: Mersana Therapeutics.

3550 Poster Session (Board #280), Fri, 8:00 AM-11:00 AM

First-in-human dose-escalation study of anti-EGFR ADC MRG003 in patients with relapsed/refractory solid tumors. *First Author: Rui-hua Xu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: MRG003 is a novel antibody drug conjugate (ADC) composed of a fully human anti-EGFR IgG1 monoclonal antibody conjugated to a microtubule disrupting agent monomethyl auristatin E (MMAE). MRG003 is presently being tested in an ongoing phase I study for safety, pharmacokinetics, and preliminary antitumor activity in patients (pts) with solid tumors (CTR20180310). **Methods:** In the phase I dose escalation study of a traditional (3+3) design, pts with relapsed or refractory cancers received single agent MRG003 once every 3 weeks (Q3W) for a maximum of 8 treatment cycles. The starting dose of MRG003 is 0.1 mg/kg, followed by 0.3, 0.6, 1.0, 1.5, 2.0, 2.5, and 3.0 mg/kg. Observations included adverse events (AEs), dose-limiting toxicity (DLT), and antitumor activity which is assessed every two cycles. **Results:** A total of twenty-two pts with colorectal (CRC, n = 15), nasopharyngeal (NPC, n = 3), head and neck (H&N, n = 2), esophageal (EC, n = 1), and duodenal (DC, n = 1) cancer were enrolled in the dose escalation. The median age of pts was 56.5 years. The MTD identified was 2.5 mg/kg. Commonly observed adverse events were anemia (50%), AST increase (41%), decreased appetite (41%), rash (36%), pruritus (36%), asthenia (36%), and proteinuria (32%). Majority of AEs were mild to moderate in severity. EGFR expression in patients' tumor samples was determined retrospectively by a validated IHC method in a central laboratory. Nine out of 22 pts tested were EGFR positive. Among these 9 EGFR positive pts, one with NPC in the 2.5 mg/kg cohort had partial response, four had stable disease (one with H&N in the 1.5 mg/kg, one each with NPC and H&N in the 2.0 mg/kg, and one with EC in the 2.5 mg/kg cohorts). The disease control rate (DCR) at doses ≥1.5 mg/kg was 100% for the EGFR positive pts. **Conclusions:** The dose escalation study of MRG003 showed manageable safety profiles and encouraging preliminary antitumor activity in pts with EGFR-positive solid tumors. MRG003 is currently being evaluated as a single agent in phase I dose expansion cohorts to further assess safety, PK, and antitumor activity. Clinical trial information: CTR20180310. Research Sponsor: Shanghai Miracogen Inc.

3551 Poster Session (Board #281), Fri, 8:00 AM-11:00 AM

First-in-human phase I study of ALT-P7, a HER2-targeting antibody-drug conjugate in patients with HER2-positive advanced breast cancer. *First Author: Yeon Hee Park, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: ALT-P7 is an antibody-drug conjugate, in which two molecules of monomethyl auristatin E (MMAE) are site-specifically conjugated to a cysteine-containing peptide motif of trastuzumab variant. This is the first-in-human study evaluating safety and pharmacokinetics of ALT-P7 in patients with HER2-positive advanced breast cancer. **Methods:** This was an open label, 3+3 dose-escalation phase 1 trial. Eligible patients were with HER2-positive advanced breast cancer progressive to at least two kinds of prior anti-HER2 treatment. ALT-P7 at doses from 0.3mg/kg to 4.8mg/kg were intravenously administered once every 3 weeks. Dose limiting toxicities were evaluated over the first cycle of 21 days. Primary objective was to define the maximum tolerated dose. **Results:** ALT-P7 were administered in 27 patients (n=4 at 0.3mg/kg, n=3 at each of 0.6, 1.2, 2.4, 3.6, 4.2, 4.5 mg/kg, n=5 at 4.8mg/kg) between Jan 2018 and Feb 2020. The median number of previous line of systemic therapy was six, including median four prior anti-HER2 agents. The most common grade (G) 3/4 adverse event (AE) was neutropenia (n=4). The other common drug-related AEs of all grade were myalgia (n=9), fatigue (n=7), sensory neuropathy (n=6), alopecia (n=6), pruritus (n=6), and neutropenia (n=6). Dose limiting toxicities(DLTs) were observed in three patients at 4.8mg/kg (G4 febrile neutropenia, G4 thrombocytopenia, G4 hyperbilirubinemia, G3 myalgia, G4 hyponatremia). No DLTs have been observed up to 4.2mg/kg, and safety evaluation at 4.5mg/kg is currently ongoing. Toxicokinetic analysis for total antibody, drug-conjugated antibody, and free payload suggested that there were no accumulation of ALT-P7 upon repeated injection. In 22 patients with response evaluation, disease control rate at 6 weeks of ALT-P7 treatment was 77.3%(17/22) and partial response was achieved in two out of fifteen patients with measurable lesion. The median PFS at doses from 2.4 to 4.8mg/kg was 6.2 months (95% CI 2.5-9.9 months). **Conclusions:** ALT-P7 was well tolerated to a dose of 4.2mg/kg in heavily pretreated HER2-positive advanced breast cancer. DLTs were observed at 4.8mg/kg, and 4.5mg/kg is under evaluation. The observed clinical activity warrants further evaluation in a phase 2 trial. Clinical trial information: NCT03281824. Clinical trial information: NCT03281824. Research Sponsor: Alteogen, Inc., Korea Drug Development Fund (KDDF) funded by MSIT, MOTIE and MOHW

3552 Poster Session (Board #282), Fri, 8:00 AM-11:00 AM

A phase I/II study of rovalpituzumab tesirine in delta-like 3-expressing, advanced solid tumors. *First Author: Aaron Scott Mansfield, Mayo Clinic, Rochester, MN*

Background: Delta-like 3 (DLL3) is highly and specifically expressed in solid tumors, such as neuroendocrine carcinomas (NECs), malignant melanoma (MM), and medullary thyroid carcinoma (MTC). Rovalpituzumab tesirine (Rova-T) is a DLL3-targeting antibody-drug conjugate. **Methods:** This Phase 1/2 study (NCT02709889) enrolled patients with relapsed/refractory DLL3+ (>1% by IHC) advanced solid tumors and ECOG performance status of 0-1. Rova-T was given IV at 0.2, 0.3, or 0.4 mg/kg on d 1 of each 6-wk cycle (q6wk) for dose escalation (3+3 design) in disease-specific cohorts in Phase I. The recommended Phase 2 dose (RP2D) was tested in Phase II. Safety and dose-limiting toxicities (DLTs) were primary endpoints; efficacy outcomes were secondary endpoints. **Results:** The study enrolled 200 patients; 101 had NECs (large cell NEC [n=13], neuroendocrine prostate cancer [n=21], high-grade gastroenteropancreatic NEC [n=36], other [n=31]) and 99 had other solid tumors (MM [n=20], MTC [n=13], glioblastoma [GBM; n=23], other [n=43]). The median age was 61 y (range, 28-84); 63% were male. The RP2D was 0.3 mg/kg q6wk for 2 cycles in all cohorts. There were 7 DLTs in 5 patients: 2 with 0.2 mg/kg (Grade [Gr] 3 photosensitivity reaction, Gr 3 dyspnea), 2 with 0.3 mg/kg (1 with Gr 2 effusion, Gr 3 tumor lysis syndrome, and Gr 3 rhabdomyolysis; 1 with Gr 4 kidney injury), and 1 with 0.4 mg/kg (Gr 4 thrombocytopenia). Despite only 1 DLT identified with 0.4 mg/kg, the totality of the safety data suggested that this dose is not well tolerated. Common adverse events (AEs) in patients given 0.3 mg/kg (n=145) are shown (Table). Serious AEs occurred in 77/145 patients (53%), most commonly (≥3%) malignant neoplasm progression (n=18; 12%), pleural effusion (n=7; 5%), pericardial effusion (n=6; 4%), and dyspnea (n=5; 3%). The objective response rate (ORR) was 11% (21/200): 14 had NEC, 2 had MM, 2 had MTC, 2 had small cell carcinoma (SCC) not of lung origin (all partial responses), and 1 had GBM (complete response). In patients with NECs given 0.3 mg/kg, ORR, clinical benefit rate, and progression-free survival trended in favor of those with high DLL3-expressing tumors (≥50% by IHC) which represented 51% of NECs. **Conclusions:** Rova-T was tolerable in patients with advanced solid tumors at 0.3 mg/kg q6wk for 2 cycles. Antitumor activity was observed in patients with NEC, MM, MTC, SCC, and GBM. Clinical trial information: NCT02709889.Research Sponsor: Abbvie, Inc.

AEs in ≥30% of patients given 0.3 mg/kg q6wk Rova-T (n=145).

AE, n (%)	Any Gr	Gr ≥3
Any	144 (99)	99 (68)
Fatigue	75 (52)	6 (4)
Nausea	53 (37)	5 (3)
Thrombocytopenia	48 (33)	22 (15)
Pleural effusion	48 (33)	4 (3)
Peripheral edema	44 (30)	1 (1)

3553 Poster Session (Board #283), Fri, 8:00 AM-11:00 AM

Phase I study of mesothelin-targeted immunotoxin LMB-100 given as a long infusion with or without nab-paclitaxel. *First Author: Guillaume Joe Pegna, National Cancer Institute Center for Cancer Research, Bethesda, MD*

Background: LMB-100 recombinant immunotoxin consists of a mesothelin-binding Fab for targeting a modified *Pseudomonas* exotoxin A payload. Previous Phase 1 clinical testing of a 30-minute LMB-100 "short" infusion format identified a serum half-life of ~1 hour. Pre-clinical data suggested that extending infusion time could improve anti-tumor efficacy by increasing tumor cell duration of exposure to LMB-100. The primary objective of this study was to determine the safety and tolerability of administering LMB-100 in a long infusion format over 24-48 hours alone or with nab-paclitaxel chemotherapy in patients with mesothelin-expressing solid tumors. **Methods:** Patients (n = 15) with pancreatic adenocarcinoma and other mesothelin-expressing solid tumors (n = 3; mesothelioma, colon, and ampullary cancers) treated on 3 dose levels received long infusion of LMB-100 (65 or 100 mcg/kg/day) for 24 hour on Days 1 and 4 (n = 6) or 48 hour on Day 1 (n = 9) with or without a loading dose (40 mcg/kg over 30 minutes) for up to 2 cycles. In the second arm, patients (n = 5) with pancreatic adenocarcinoma were treated with LMB-100 over 24 hours on Day 1 concurrently with nab-paclitaxel (125 mg/m^2) for up to 3 cycles. **Results:** DLT of proteinuria (grade 3) in one patient and acute kidney injury (grade 1) in one patient were observed amongst patients receiving 100 mcg/kg/day over 48 hours and 24 hours, respectively. No objective responses were seen but all patients receiving nab-paclitaxel had > 50% decrease in CA 19-9. Patients at all single agent dose levels (8 of 10 evaluable) developed high titer anti-drug antibodies (ADAs) against LMB-100. Those with ADAs (8 of 8) had undetectable cycle 2 peak plasma LMB-100 concentration. Development of high titer ADAs occurred more frequently with long infusion than seen previously with "short" infusion LMB-100. Most long infusion patients (19 of 20) developed increased serum IL-6 within 24 hours of LMB-100 infusion. However, the systemic inflammatory response to LMB-100 (as measured by increased serum CRP) which occurs in most "short" infusion patients was not observed. **Conclusions:** Long infusion format LMB-100 is generally well tolerated but immunogenicity limits treatment to 1 effective cycle. No antitumor efficacy of the single agent was observed. Clinical trial information: NCT02810418. Research Sponsor: U.S. National Institutes of Health.

3555 Poster Session (Board #285), Fri, 8:00 AM-11:00 AM

Anaplastic lymphoma kinase (ALK) partners identified by next-generation sequencing in Chinese patients with solid tumors. *First Author: Sheng Yang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Anaplastic lymphoma kinase (ALK) rearrangement is a validated therapeutic driver gene in non-small cell lung cancer (NSCLC). More than 30 different fusion partner genes of ALK in NSCLC have been reportedand most of these ALK fusions respond well to ALK inhibitors crizotinib. With the development of next-generation sequencing (NGS), more novel partners for ALK rearrangement have been identified. Here, we aimed to report the landscape of ALK rearrangement in Chinese patients with solid tumors. **Methods:** Tissue or blood samples were subjected to NGS in a College of American Pathologists-certified and Clinical Laboratory Improvement Amendments-accredited lab for ALK arrangement. **Results:** In total, we profiled more than 40,000 patients, among which 72 cases with 52 ALK fusion partner, harboring 17 reported partners and 35 novel partners. The average ALK rearrangement patients' age was 53 years (range, 17-76 years). Among all the ALK fusion cases (n = 72), lung cancer were the largest proportion with 77.8% (n = 56), colorectal cancer accounted for, 5.5% (n = 4), liver cancer accounted for 4.2% (n = 3), biliary cancer, melanoma, carcinosarcoma and inflammatory myofibroblastic tumor accounted for 2.8% (n = 2) respectively, and only one case (n = 1) was malignant peritoneal mesothelioma. The most common ALK fusion partners were KIF5B (n = 6), DCTN1 (n = 5) and STRN (n = 5). In 38 cases, 35 novel ALK fusion partners were discovered. The novel CLIP4-ALK, EHBP1-ALK, PLB1-ALK occurred twice in 6 patients, which were two lung cancer patients with CLIP4-ALK fusion, two lung cancer patients with PLB1-ALK fusion, one hepatic cellular cancer patients with EHBP1-ALK, and one melanoma patients with EHBP1-ALK. There were two special lung cancer cases with two ALK fusions. One case detected the novel LRIG1-ALK fusion and novel PLB1-ALK fusion, the other case detected novel GLI3-ALK fusion and reported HIP1-ALK fusion. **Conclusions:** Novel ALK fusions are detected in patients with not only NSCLC but also other solid tumors. NGS fusion assay is an optional method for screening novel fusions. Research Sponsor: None.

3556 Poster Session (Board #286), Fri, 8:00 AM-11:00 AM

High intratumoral tryptophan metabolism is a poor predictor of response to pembrolizumab (pembro) in metastatic melanoma (MM): Results from a prospective trial using baseline C11-labeled alpha-methyl tryptophan (C11-AMT) PET imaging for response prediction. *First Author: Jorge D. Oldan, Department of Radiology, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Molecular imaging of metabolic pathways critical for effector T cell response other than glucose could predict response to PD1 inhibitors. We have previously shown that high expression of tryptophan metabolic pathway enzymes in stage III/IV melanoma correlates with reduced abundance of tumor-infiltrating lymphocytes (TILs, ASCO 2019, e21014). Here we investigated C11-AMT, a PET tracer that images tryptophan metabolism, as a predictor of response to pembro in patients (pts) with PD1 inhibitor-naïve MM. **Methods:** In this trial (NCT03089606) pts must have had measurable MM by RECIST, have undergone IV contrast CT, FDG-PET, and C11-AMT PET scan (30-40 min dynamic imaging), plus a mandatory tumor biopsy prior to pembro treatment. **Results:** 21 pts (16 males; 15 stage IV; median age 61) had all 3 baseline scans and evaluable research biopsies. 13 pts were non-progressors (CR = 4, PR = 6, and SD = 3). At a median f/u of 13.7 mons (2.8-25.1+), 6 pts are dead from MM, 11 are alive without MM and 4 are alive with MM. 46 tumor lesions were assessed by all 3 scans. Of the pts with tumor lesion, C11-AMT PET $SUV_{max} < 7$ and skewness $< +0.3$ of the tumor lesion with the highest C11-AMT SUV_{max} was associated with non-progression by RECIST ($SUV_{max} < 7$/skewness $< +0.3$ in progressors vs. non-progressors; Fisher's 2-tail test $p = 0.055$). The corresponding association between baseline FDG-PET ($SUV_{max} < 14$ and skewness $< +0.3$) with treatment response was insignificant ($p = 0.08$). There was a weak (Spearman $\rho = 0.33$) but significant correlation ($p = 0.001$) in SUV_{max} between FDG-PET and C11-AMT among the 46 tumors analyzed. There was no significant correlation between melanoma-specific expression of the tryptophan- (TPH1, TPH2, IDO1, TDO2, LAT1) and glucose-metabolizing enzymes (GLUT1, HK1, HK3) by immunohistochemistry. Response to pembro trends to associate with present TILs (Fisher's $p = 0.087$). **Conclusions:** Baseline C11-AMT PET imaging using simple radiomics measures (highest metabolic activity, SUVmax, and tumor heterogeneity, skewness) may better predict clinical benefit from pembro in MM than FDG PET. Variability in C11-AMT's SUV_{max} cannot be solely explained by FDG-PET's SUV_{max}, suggesting that these two imaging modalities may provide complementary information about intratumoral metabolic dysregulation that may relate with pembro response. Texture analysis using LifeX v4.0 will be presented at the meeting. Clinical trial information: NCT03089606. Research Sponsor: Merck.

3557 Poster Session (Board #287), Fri, 8:00 AM-11:00 AM

First in-human study of in vivo imaging of ex vivo labeled CAR T cells with dual PET-MR. *First Author: Ritu Singla, Cell Therapies, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: This is a first in human in-vivo biodistribution of ex-vivo labelled CAR T cells assessed in a cohort of patients. Cells were labelled with novel Cu-64 labelled superparamagnetic iron oxide nanoparticles (SPION) and infused IV into patients with solid tumors & tracked using clinical dual PET-MR. The study validates the clinical translation of CAR T cell in-vivo tracking in real time. **Methods:** Cu-64 radioisotope was bound to silica coated SPION using electrolysis plating with tin & palladium seeding. Cellular uptake of Cu-64 SPION was facilitated with a transfecting agent. Functional assays including ^{51}Chromium release, cytometric bead array demonstrated that labelling process did not affect cytotoxicity & cytokine secretion (TNFα & IFN-g). T cells were transduced with retroviral vector constructs encoding for second-generation chimeric T-cell receptor specific for carbohydrate Lewis Y antigen. Modified T-cells were expanded ex-vivo & were labelled with Cu-64 (~300 MBq) prior to re-infusion (3 $x10^8$ labelled cells). Scanning is performed with Siemens 3T dual PET-MR scanner. **Results:** In this first in human in-vivo study (HREC/16/PMCC/30) a cohort of patients received ex-vivo labelled CAR T cells to determine how many labelled cells distribute to solid tumor sites within 3-5 days. Our results demonstrate that cells can be efficiently labelled (≤60%) with high cell viability (≥85%) at a sensitivity sufficient to detect labelled cells at tumor site for up to 5 days. An observed trend in SUV_{mean} & SUV_{max} provided insight into efficacy & individual response to therapy. Early time points showed moderate uptake of labelled cells in lungs posterior basal segments without increased activity over next few days, suggesting a transient process. Mild, diffuse bone marrow & relatively intense uptake of labelled cells in liver & spleen suggests margination of cells to reticulo-endothelial system. Distinct PET signal at some of the tumor sites at 24 h suggests antigen specific localization & time taken to reach these sites. Excretion via hepatobiliary indicated reabsorption from GI tract & re-circulation of labelled cells. Minimal uptake in brain & heart supported safety profile of labeling agent. **Conclusions:** This is first in human in-vivo study to provide highly valuable visual and dynamic data in real time and provides insight into individual responses to therapy. CAR T cell functionality largely remain unchanged due to labeling process. The findings indicate that labelled cells traffic to tumor sites at later time points & remain persistent for extended period of time. Research Sponsor: Juno Therapeutics, Australian Global Innovation Linkage Grant.

3558 Poster Session (Board #288), Fri, 8:00 AM-11:00 AM

Clinically aggressive malignancies associated with STK11 germline mutations (STK11GCa): A comprehensive genomic profiling (CGP) study. *First Author: Ethan Sokol, Foundation Medicine, Inc., Cambridge, MA*

Background: Germline mutations in the *STK11* (*LKB1*) mTOR pathway gene are associated with Peutz-Jehger's Syndrome and a variety of malignancies of variable clinical aggressiveness. Recent evidence also links *STK11* inactivation with failure to benefit from anti-cancer immune checkpoint inhibitor (IO) therapy in NSCLC. **Methods:** Using hybrid capture based CGP on extracted tumor DNA and a published "somatic-germline-zygosity" SGZ data analysis algorithm on 212,470 samples of clinically advanced malignancies, we identified 103 (0.05%) STK11GCa inactivating base substitutions or indels. Tumor mutational burden (TMB) was determined on up to 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined on 114 loci. PD-L1 expression was determined by IHC (Dako 22C3). **Results:** 57 (55%) STK11GCa cases were NSCLC, 7 (7%) STK11GCa cases each were CRC, breast, pancreatic and unknown primary carcinomas, and 3 (3%) were gynecologic cancers. Amongst all samples included in this analysis, *STK11* germline alterations were found in 0.15% NSCLC, 0.03% CRC, 0.03% breast, 0.08% pancreas, 0.06% unknown primary carcinoma and 0.03% of gynecologic cancers. Additional malignancies harboring STK11GCa included melanoma, gastroesophageal, HNSCC, bladder, HCC, lymphoma and mesothelioma. In STK11GCa, the median patient age at sequencing was 61 years (range 2 to > 89 years); gender distribution was 52% female and 48% male. STK11GCa cases had a median of 6.5 genomic alterations (GA)/tumor and *KEAP1*, another IO resistance gene, was co-altered in 10%. Currently untargetable GA were detected in *TP53* (50%), *KRAS* (38% with 9% in potentially targetable G12C), *CDKN2A* (32%), *CDKN2B* (22%), *SMARCA4* (19%), *MYC* (11%), and *APC* (10%). Potentially targetable GA, which have also been linked in some studies to IO efficacy, included GA in *BRAF* (10%), *EGFR* (9%) and *PBRM1* (4%). No targetable gene rearrangements or fusions were identified. No MSI High cases were identified. The median TMB was 5 mut/Mb with 23 % >10 mut/Mb and 4% >20 mut/Mb. 15% of 20 evaluated STK11GCA cases were PD-L1 high (>50% tumor cell staining). **Conclusions:** STK11GCa include a wide variety of primary tumors with a paucity of co-occurring targetable GA. Although these tumors have significant PD-L1 staining and a subset harbor other markers of potential IO efficacy, the inactivated *STK11* in these tumors may contribute to IO resistance and lack of responsiveness to immunotherapies. 3559 Poster Session (Board #289), Fri, 8:00 AM-11:00 AM

A prospective study of prognostic role of plasma circulating tumor DNA (ctDNA) in patients (pts) with early-stage malignancies. *First Author: Mikhail Fedyanin, Federal State Budgetary Institution N.N. Blokhin National Medical Research Center of Oncology of the Ministry of Health of the Russian Federation (N.N. Blokhin NMRCO), Moscow, Russian Federation*

Background: Recently, conflicting evidence has emerged showing the association of ctDNA level and cancer progression. The aim of our study was the development of a method for detecting ctDNA in plasma and the investigation of the prognostic value of ctDNA retention after surgery in the prospective way. **Methods:** This prospective, single-center, sample collection study; pts with early-stage malignancies of the different origin were included. Tumor somatic mutations were determined by target sequencing of DNA from FFPE tumor blocks. Sequencing was performed using the custom NGS panel covering regions of frequent somatic mutations in 50 genes. Tumor-specific mutations were monitored in plasma samples taken before and after surgery. The median time between surgery and plasma collection was 7 days (5-15). Mutations of plasma ctDNA were determined by ddPCR. The plasma sample was considered "positive" if the content of ctDNA was more than 0.5 copies of mutant DNA in ml plasma. We needed 265 pts for improving 1-year disease free survival (DFS) from 60% to 80% with α=0.01, β=0.1, 10% loss of f.-up and duration of the study for 2 years. **Results:** The study comprised 271 pts with various cancers including colorectal – 91 (33,6%), pancreatic – 37 (13,7%), breast – 66 (24,4%), lung – 35 (12,9%) and gastric cancer – 42 (15,5%). Pts with stage I was 50 (18,5%), stage II – 118 (43,5%) and stage III – 103 (38%). The median time of the f.-up was 9 mos. (1-37). No significant association was found between the level of ctDNA before surgery and DFS either in the general group or in groups stratified by tumor sites (HR 2.4, 95%CI 0.8-7.1, p=0.12 and HR 1.5, 95%CI 0.4-6.3, p=0.5, correspondingly). ctDNA was detected in the plasma after surgery in 57 (10%) pts: 9 (9.9%) cases of colorectal, 10 (27%) - pancreatic, 9 (13.6%) - breast, 19 (54.3%) - lung, and 10 (23.8%) - gastric cancer. Progression of the disease was detected in 28/57 (49%) pts with ctDNA(+) and 17/214 (8%) - in ctDNA(-) pts ($p<0.001$). One-year DFS in ctDNA(+) and ctDNA(-) pts were 57% and 87%, respectively (HR 6.1, 95%CI 3.3-11.2, $p<0,001$). ctDNA positivity after surgery was an independent negative prognostic factor according to Cox regression model fitted to T, N, and adjuvant chemotherapy (HR 5.7, 95%CI 3.1-10.8, $p<0.001$). **Conclusions:** These results demonstrate the prognostic significance of ctDNA persisting after surgery in pts with the early stage of the different malignancies. Further clinical validation of this approach is required in trails with modifications of the adjuvant treatment, according to the content of ctDNA. Research Sponsor: This research is conducted under the auspices of the experimental governmental assignment of the Ministry of Health of the Russian Federation and coordinated by the FSBI "Center for Strategic Planning and Management of Biomedical Health Risks".

3560 Poster Session (Board #290), Fri, 8:00 AM-11:00 AM

Validation of RecurIndex (RI) for patients with early-stage breast cancer enrolled in a Taiwanese multicenter study. *First Author: Yi-Hsuan Lee, Departments of Pathology, National Taiwan University Hospital, Taipei, Taiwan*

Background: Numerous prospective studies, predominantly in Caucasian population, have proven the clinical utility of using multigene expression tests to prevent over-treatment in early breast cancer (EBC) patients. Since racial and ethnic disparities exist in genetic and biological factors that could influence the disease, the primary purpose of this study is to access the clinical utility of RecurIndex, a recurrence risk test, that is based on a genomic profiling derived from Asian women. **Methods:** A total of 298 patients with EBC, luminal subtype (85.6%), HER2 subtype (7.7%) and triple-negative subtype (6.7%), were enrolled in a retrospective study across Taiwan medical centers. Kaplan Meier and Cox Proportional Hazards model were used to, respectively, identify independent prognostic factors and calculate the survival rates. The prediction model was then tested using the area under the receiver operating characteristic curve (AUC). The primary endpoint was distant recurrence-free survival (DRFS). **Results:** The 10-year DRFS was significantly higher in the good-prognosis group than the poor-prognosis group (92.0% [95% CI, 86.1-98.2] versus 63.0% [95% CI, 49.9-79.5]) (Table). The overall hazard ratio for distant recurrence was 1.031 (95% CI, 1.017 ± 1.046) per RI score increment. In addition, in a subset of 179 cases (60.1%), the model yielded an 82.3% correct classification rate for predicting DR with a sensitivity of 87.0%, a specificity of 68.6% and negative predictive values of 97.3%. **Conclusions:** The present study provides robust evidence of the clinical utility of RI-DR to predict clinical outcomes. RecurIndex could be used to determine the utility of chemotherapy in Asian patients, especially in hormone-receptor positive and HER2 negative disease, leading to a meaningful reduction in adjuvant chemotherapy recommendations. Research Sponsor: Amwise Diagnostics Pte. Ltd.

Kaplan-Meier estimates of distant recurrence-free survival rates by RI-DR risk classification.

Risk group	10-year DRFS (%)	P value	Crude hazard ratio (95% CI)
All patients (n=298)		0.0011	
Good prognosis (n=145)	92.0		----
Poor prognosis (n=153)	63.0		3.621 (1.59 - 8.27)
Luminal patients (n=255)		0.0200	
Good prognosis (n=141)	91.6		----
Poor prognosis (n=114)	65.4		2.729 (1.13 - 6.58)
HER2/TNBC patients (n=43)		0.2500	
Good prognosis (n=4)	100.0		----
Poor prognosis (n=39)	61.2		----

Key words: Early breast cancer, Asian women, genomic assay, clinical utility, recurrence index (RI), distant recurrence (DR).

3561 Poster Session (Board #291), Fri, 8:00 AM-11:00 AM

Molecular profiling of metastatic breast cancer (MBC) and target-based therapeutic matching in an Asian tertiary phase I oncology unit. *First Author: Robert John Walsh, Department of Haematology-Oncology, National University Cancer Institute, National University Health System, Singapore, Singapore*

Background: Somatic profiling of MBC has highlighted actionable mutations and driven trials of matched targeted therapy (tx). Previous phase I studies have reported improved outcomes following matched therapies with tumour molecular profiles. Here, we review next generation sequencing (NGS) and treatment outcomes of Asian MBC patients (pts) in the phase I unit of a tertiary centre. **Methods:** Pts with MBC referred to a phase I unit underwent NGS (n = 152). Tumour tissue was sequenced via the amplicon based Ion Ampliseq Cancer (IAC) v2 (50 genes) platform from 2014-2017 prior to institutional change to Foundation Medicine 1 (FM1) (324 genes) 2017-2019. Patients were counselled on findings and enrolled onto matched therapeutic trials where available. **Results:** NGS was successfully performed in 107 pts (IAC 46%, FM1 54%) of which tumour subtypes include hormone receptor positive 63%, triple negative breast cancer (TNBC) 28% and Her2 positive 19%. Median lines of prior tx for MBC was 4 (range 0-12). 89% had prior chemotherapy (CT), 57% prior endocrine therapy (ET). 72/107 (67%) sequenced patients had further treatment and 18 (25%) were matched to tx based on NGS findings (15 clinical trial, 3 off trial). Matching rates on both NGS platforms were similar (IAC 22% *vs* FM1 28%). Mutated pathways with potential matched tx included PIK3CA/AKT/PTEN (52%), DNA damage response (DRR) (15%), and FGFR (11%) pathways. *PIK3* mutations were seen in 43% and associated with higher number of metastatic sites (p = 0.03); most prevalent aberrations were *PIK3CA H1047R* (41%) and *PIK3CA E542K* (13%). Matched cases were more heavily pretreated (mean lines of prior tx 5.3 matched *vs* 3.7, unmatched p = 0.05), and showed a median progression free survival (mPFS) of 24 weeks [w] and clinical benefit rate (complete/partial response or stable disease $\geq$ 12 weeks) of 53% on matched tx. Comparison by NGS platform showed improved mPFS for matched vs unmatched pts sequenced on FM1 *vs* IAC (FM1: 26 *vs* 19w, HR = 0.76 [95% CI: 0.3-1.9]; IAC: 8 *vs* 12w; HR = 1.21 [95% CI: 0.5-2.8]). Interestingly, 1 pt with *SMARCB* mutation, reportedly associated with the FGFR pathway, had a PFS of 70w on tx with a pan-FGFR inhibitor after progressing on 3 prior lines of tx (ET and CT). **Conclusions:** Molecular profiling of MBC in a phase I unit led to matched tx in 25% of cases. Matched pts showed encouraging mPFS with a suggestion of benefit in those matched after sequencing on a broader gene panel (FM1). Research Sponsor: NCIS Centre Grant - NMRC/CG/M005/2017_NCIS.

3562 Poster Session (Board #292), Fri, 8:00 AM-11:00 AM

Exomes and transcriptomes to reveal actionable findings in patients with negative-targeted panel sequencing. *First Author: Eric Y. Zhao, Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada*

Background: Next generation sequencing targeted panels increasingly inform clinical decisions, but may miss actionable findings detectable by whole exome sequencing (WES) and RNA-seq. There has been no direct comparison of WES plus RNA-seq against targeted panel sequencing to determine its added utility. To address this, we performed WES and RNA-seq analysis in a cohort of 100 patients with no actionable findings on prior panel sequencing. **Methods:** Ontario-wide Cancer Targeted Nucleic Acid Evaluation (OCTANE; NCT02906943) has sequenced 2,106 patients using a 161-gene Oncomine or 555-gene Hi5 panel. 100 patients (98 Hi5, 2 Oncomine) were chosen for further sequencing. Tumor (100x coverage) and normal (50x) exomes and tumor transcriptomes were sequenced on Illumina HiSeq2500 or NextSeq550. Interpretation included knowledgebase annotation (e.g. OncoKB, CIViC), mutation signatures, homologous recombination deficiency (HRD) scores, gene expression, and pathway analysis. Findings were deemed "actionable" if they could directly inform management or trial eligibility. **Results:** WES and RNA-seq identified one or more novel actionable findings in 38 patients. Of these, the main actionable finding was tumor mutation burden (TMB), mutation signature, or HRD score in 19 (50%), a copy number variant in 16 (42%), a fusion in 2 (5%), and a point mutation in 1 (2.6%). WES identified a *MALAT1-GLI1* fusion in a cancer of unknown primary (CUP) whose transcriptome was consistent with gastric cancer, together suggesting the diagnosis of a rare gastroblastoma. To date, two cases have received exome-supported targeted therapy: (1) a metastatic high grade serous ovarian cancer, HRD-high, treated with olaparib then cisplatin for a combined 15 months, and (2) a metastatic neuroendocrine rectal tumor with RICTOR amplification treated with everolimus starting in Dec 2016 until last follow-up in Sep 2019. Of 62 patients with no actionable finding, expanded sequencing identified one or more known cancer drivers in 25 (40%): 17 CNVs, 3 fusions, and 5 point mutations or indels. In 16 patients, an oncogenic variant found on panel was not captured by WES, and may represent artifacts, germline mutations, or subclonal/localized variants. **Conclusions:** WES and RNA-seq expanded detection of actionable biomarkers and oncogenic mutations, especially CNV, TMB/signatures, and HRD. Two cases have undergone exome-supported targeted treatment. We performed the first WES of a rare gastroblastoma, originally a CUP but reclassified by expanded fusion detection and RNA-seq. Research Sponsor: The Government of Ontario and The Princess Margaret Cancer Foundation.

3563 Poster Session (Board #293), Fri, 8:00 AM-11:00 AM

Machine learning radiomics signature on magnetic resonance imaging associated with phenotypes and disease-free survival in patients with breast cancer (RBC-01): A registry-based, multicenter cohort study. *First Author: Herui Yao, Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Department of Oncology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: The early stage breast cancer patients can vary in disease-free survival (DFS), innovative predictors evaluate the prognostic capacity are urgently needed. We aimed to develop and independently validate a radiomics signature based on MRI associated with phenotypes and DFS in patients with breast cancer and to establish a radiomics nomogram that incorporates the radiomics signature and clinicopathological findings using computational algorithms. **Methods:** In this multicenter, retrospective, cohort study, we analyzed preoperative contrast–enhanced MRI data from the prospective cohort study (n = 123) of patients who had been treated with neoadjuvant chemotherapy in phase 3 trials and independent cohort (n = 438) at the Sun Yat-sen Memorial Hospital as training cohort to develop the radiomic signature, and validated it in validation cohort (Foshan cohort, n = 121; Dongguan cohort, n = 89) between November 17, 2011, and September 21, 2019, and validated in TGCA cohort (n = 84). Machine-learning algorithm to identify robust imaging subtypes and evaluated their clinical and biologic relevance. A nomogram combining the radiomic signature and clinicopathological findings to predict individual survival based on Cox regression model. The primary endpoint was disease-free survival (DFS). This study is registered with ClinicalTrials.gov, number NCT04003558, and Chinese Clinical Trail Registry, number ChiCTR1900024020. **Results:** A total of 855 breast cancer patients were included. Radiomics signature was generated to classify patients into high-risk and low-risk groups in the Guangzhou training cohort. Patients with low-risk scores in the training cohort had higher DFS (hazard ratio [HR] 0.55, 95% CI 0.31 to 0.99; *P*= 0.045) than patients with high-risk scores, and validated in in validation cohort (HR 0.14, 95% CI 0.03 to 0.62; *P*= 0.003). The nomogram combined radiomics score with clinicopathological factors could accurately predict DFS benefits in training cohort (C-index = 0.83; AUC, 1, 2, 3-year were 0.80, 0.85, 0.82, respectively) and validated in validation cohorts. **Conclusions:** The radiomics signature are significantly associated with the DFS in patients with breast cancer. Combining the radiomics nomogram improved individualized DFS pretiction. Clinical trial information: NCT04003558. Research Sponsor: None.

3564 Poster Session (Board #294), Fri, 8:00 AM-11:00 AM

Comparison of the clinical interpretation of high-dimensional molecular data by two molecular tumor boards. *First Author: Damian Tobias Rieke, Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: The clinical interpretation of molecular data is a bottleneck of precision oncology. High-dimensional molecular data, such as RNA sequencing (RNA-seq) and whole-exome sequencing (WES), will likely increase the complexity of clinical interpretation. We compared the recommendations by two molecular tumor boards (MTBs) that independently interpreted the same high-dimensional molecular profiles. **Methods:** Patients with advanced solid tumors, no available standard therapy, an ECOG performance status of 0-1, and available fresh-frozen tissue underwent WES of tumor tissue and normal blood as well as RNA-seq of tumor tissue within the MASTER (Molecularly Aided Stratification for Tumor Eradication Research) precision oncology program of the German Cancer Consortium (DKTK). Data from 46 patients (WES and RNA-seq, n = 41; WES alone, n = 5) were independently discussed by two MTBs. Treatment recommendations were compared with regard to levels of evidence, therapeutic baskets, and types of biomarkers. **Results:** A total of 51,610 aberrations (median, 393 per patient) were considered for clinical interpretation (34,314 mutations/single-nucleotide variants, 7,115 mRNA expression changes, 6,144 DNA copy number variations, 4,037 gene fusions). 110 and 132 treatment options were identified by the two MTBs, respectively, with an overall agreement rate of 44.1%. The highest agreement rates were identified for treatment options based on clinical levels of evidence (Level 1, 60%; Level 2, 49.6%) and for poly(ADP-ribose)-polymerase inhibition (57.1%). The lowest agreement rates were identified when MTBs opted for traditional chemotherapy (0%), combination therapies (6.9%), therapies based on preclinical levels of evidence (Level 3, 35.9%; Level 4, 32%), and MAPK inhibition (35%). Similar agreement rates, ranging from 39% (gene fusions) to 54% (loss of heterozygosity), were observed for different types of biomarkers. **Conclusions:** Reproducible, evidence-based annotation of high-dimensional molecular data is feasible. Our experience provides a basis for ongoing harmonization and standardization efforts within the MTBs of the DKTK. Research Sponsor: Deutsches Konsortium für translationale Krebsforschung.

3565 Poster Session (Board #295), Fri, 8:00 AM-11:00 AM

ERBB2 amplifications and mutations in 109 advanced breast cancer patients by next-generation sequencing. *First Author: Ami N. Shah, Northwestern University, Chicago, IL*

Background: In advanced breast cancer (ABC) HER2 status is based on ASCO/CAP immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) criteria. Next generation sequencing (NGS) of tissue and blood can detect aberrations in *ERBB2* such as copy number gain/amplifications (cng/amp) and mutations. **Methods:** We retrospectively identified patients (pts) seen at Northwestern University between 2015 and 2019 with ABC and an alteration in *ERBB2* identified by tissue and/or circulating tumor DNA (ctDNA) NGS. We included pts with testing by Guardant360, TempusX, and/or FoundationOne platforms. NGS reports were evaluated for non-synonymous mutations and cng/amp. HR and HER2 status were determined based on the most recent pathologic assessment. Mutations were categorized as pathologic if they were consider oncogenic (level 1-2 evidence with direct functional data), likely oncogenic, or predicted oncogenic, based on OncoKB (Chakravarty et al., JCO PO 2017). **Results:** 109 cases of ABC (6 locally advanced, 103 metastatic) with *ERBB2* alterations were identified. Tissue NGS was available from 43%, ctDNA from 72%, and both from 19%. The positive predictive value (PPV) of *ERBB2* amp/cng by tissue NGS to predict HER2+ using the gold standard as IHC/FISH was 94% (33/35). The PPV of *ERBB2* amp by ctDNA was 93% (40/43). *ERBB2* mutations were detected in 52 pts. Of these, 23 pts were considered to harbor pathologic *ERBB2* mutations, (19 oncogenic, 2 likely oncogenic, 1 predicted oncogenic) detected by ctDNA and tissue in 4, ctDNA in 16, and tissue in 3 pts. The most frequently detected mutations were V777L and S310. Four pts had co-mutations of *ERBB2* V777L and S310F. Disease subtype among those with *ERBB2* pathologic mutations was HR+ HER2- in 57%, HER2+ in 26%, and triple negative in 17%. In all patients with serial ctDNA analysis and pathologic *ERBB2* mutations, the mutation was detected on the first analysis. Pathologic *ERBB2* mutation represented the mutant with the highest mutant allele frequency (MAF) in 30% and top 3 highest MAF in an additional 35%. *PIK3CA* was co-mutated in 48%. **Conclusions:** The PPV of *ERBB2* amp/cng by tissue and ctDNA NGS was high, and has potential utility for cancers where HER2 IHC/FISH is not standardly assessed or cases where biopsy is challenging. *ERBB2* pathologic mutations were found in all breast cancer subtypes. When present, they were identified on the initial ctDNA analysis and often represented a significant clone, supporting its role as a 'driver mutation'. Research Sponsor: None.

3566 Poster Session (Board #296), Fri, 8:00 AM-11:00 AM

Platform comparison of HTG EdgeSeq and RNA-Seq for gene expression profiling of tumor tissue specimens. *First Author: Di Ran, HTG Molecular Diagnostics, Tucson, AZ*

Background: Clinical biomarker studies are often hindered by the availability of tissue specimens of sufficient quality and quantity. While RNA-Seq is often considered the gold standard for measuring mRNA expression levels in cancer tissue, it typically requires multiple formalin-fixed paraffin-embedded (FFPE) tissue sections to extract a sufficient amount of quality RNA for subsequent gene expression profiling analysis. The HTG EdgeSeq technology is a gene expression profiling platform that combines quantitative nuclease protection assay technology with next-generation sequencing detection. Unlike RNA-Seq, the HTG EdgeSeq technology does not require RNA extraction, and can use small amounts of tissue material, typically several mm^2, to generate reproducible gene expression profiles. **Methods:** This study compares the performance of RNA-Seq and HTG's profiling panel, the HTG EdgeSeq Precision Immuno-Oncology Panel (PIP), which is designed to measure expression levels of 1,392 genes focused on tumor/immune interaction. Approximately 1,200 samples from three tumor indications (gastric cancer, colorectal cancer and ovarian cancer) were tested using both technologies. **Results:** Up to four FFPE slides were used for RNA extraction to support RNA-Seq testing; out of the 1,202 samples processed, 1,099 generated extracted RNA of sufficient quality and quantity (as measured by RNA concentration, RIN score and %DV200) to proceed to sequencing, which resulted in a pass rate of 91.4% for RNA-Seq. The HTG EdgeSeq PIP panel resulted in a pass rate of 97.3% (samples passing QC metrics) when the same 1,200 samples were tested, and required only a single FFPE section owing to the small sample requirement. The t-SNE (a non-linear dimensionality reduction method) analysis of the common 1,358 genes revealed similar clustering of the three cancer indications between the two methods. Correlations across individual genes by sample resulted in the mean Spearman correlation coefficient of 0.73 (95% confidence interval of 0.61 - 0.80). Additionally, gene-wise comparisons across all samples were also evaluated. **Conclusions:** These data demonstrate that HTG EdgeSeq gene expression panels can be used as a competitive alternative to RNA-Seq, generating equivalent gene expression results, while offering the added benefits of a small sample size requirement, lack of RNA extraction bias, and fully automated data analysis pipeline. Research Sponsor: HTG Molecular Diagnostics and Oncologie, Inc.

3567 Poster Session (Board #297), Fri, 8:00 AM-11:00 AM

Diagnosis of leptomeningeal metastasis (LM) through identification of circulating tumor cells (CTCs) in cerebrospinal fluid (CSF). *First Author: Kathleen Fenn, Department of Medicine at Columbia University Medical Center, New York, NY*

Background: Diagnosis of LM from solid tumors can be challenging. The TargetSelector (TS) CTC detection assay has demonstrated highly specific and sensitive CTC capture both for epithelial (CK+) and non-epithelial (CK-) subsets. The assay utilizes a ten-antibody (ab) capture cocktail followed by biotinylated secondary abs that bind to CTCs, enriched in a microfluidic device. TS targeted next-generation sequencing (NGS) assay detects somatic mutations in 12 breast cancer-related genes. The aim was to determine whether TS can improve sensitivity in the diagnosis of LM compared to CSF cytology by lumbar puncture (LP). **Methods:** CSF was collected prospectively from patients (pts) with a prior solid tumor diagnosis and suspicion of LM. CTCs were isolated from CSF using the TS platform. Cells were stained with cytokeratin (CK), CD45, streptavidin and DAPI. CTCs captured in a microchannel were classified as CK + or -. Peripheral blood samples obtained at time of LP underwent similar CTC analysis. Cell-free total nucleic acids (cfTNA) were extracted from plasma and CSF followed by NGS. Data analysis used the Ion Torrent Suite with annotation and report curation by Ion Reporter and Oncomine Knowledgebase Reporter software respectively. **Results:** There were 14 pts (13 women and 1 man), median age 56 years (range 32-75) with cancers of the breast (10), lung (1), colon (1), CNS lymphoma (1) or glioma (1). Pts had received a median of 2.5 lines of systemic metastatic therapy (range 0-8). CSF cytology was not sent for 1 pt and TS was not performed for 1 pt. TS and standard cytology had 89% agreement in pts with metastatic breast cancer (MBC, 8/9). Of the 6 pts for whom CTCs were detected in CSF by TS, 3 pts had + cytology (all MBC), 2 pts had - cytology and 1 pt with MBC was not tested by cytology. Of the 3 pts with + CSF by cytology (all MBC), all were detected by TS (Table). Among 5 MBC pts with CTCs present in CSF, ER status was concordant in 2 of 5 (40%). HER2 status was concordant in 3 of 4 (75%) evaluable pts and not determined in 1 pt. Analysis of cfDNA from CSF identified somatic mutations in 3 pts (TP53, PIK3CA, CCND1, respectively). In 1 of 3 pts, the mutation identified in the CSF (PIK3CA) in HR+/HER2- MBC was also identified in the blood. **Conclusions:** TargetSelector is a viable platform for the detection of breast cancer CTCs in the CSF. NGS performed on CSF samples can identify potentially actionable mutations. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

3568 Poster Session (Board #298), Fri, 8:00 AM-11:00 AM

The utility of blood-based molecular tools-the NETest-to monitor and evaluate the efficacy of PRRT in neuroendocrine tumors. *First Author: Lisa Bodei, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Peptide receptor radionuclide therapy (PRRT) is an effective therapy for metastatic/inoperable neuroendocrine tumors (NETs). Tools to predict and monitor the efficacy of therapy are important adjuncts in the radio-oncology armamentarium. Standard blood biomarkers are not effective by new molecular based assays such as the PRRT Predictive Quotient (PPQ) and NETest are effective as real-time predictors and monitors of therapy. We aimed to prospectively evaluate whether: 1) the NETest functioned as a surrogate biomarker for image-based per RECIST evaluation of PRRT efficacy; 2) there was a correlation between changes in NETest levels during therapy, PPQ prediction and treatment efficacy. **Methods:** Three independent ^{177}Lu-PRRT-treated GEP-NET and BPNEN cohorts (Rotterdam, Netherlands: n= 41; Bad-Berka, Germany: n= 44; Meldola, Italy: n= 72). Treatment response: RECIST1.1 [Responder (stable, partial/complete response) vs Non-Responder]. Blood sampling: pre-PRRT, prior to each cycle and 6 months (median) after completion of all cycles. PPQ (positive/negative) and NETest (0-100 score) by PCR. Stable$<$40; progressive $>$ 40). CgA (ELISA) as comparator. Samples deidentified, measurement and analyses blinded. Kaplan-Meier survival and Mann-Whitney analyses. **Results:** 122 of 157 were evaluable. RECIST stabilization or response in 67%; 33% progressed. NETest significantly ($p<$ 0.0001) decreased in RECIST-"responders" (-47$\pm$3%); in "non-responders" it elevated (+79$\pm$19%, $p<$ 0.0005). NETest monitoring accuracy 98% (119/122). Follow-up levels $>$ 40 (progressive) vs stable ($<$40) significantly correlated with mPFS (not reached vs. 10 months; HR 0.04, 95%CI: 0.02-0.07). PPQ response prediction was accurate in 118 (97%); 99% accurate positive and 93% accurate negative prediction. NETest significantly ($p<$ 0.0001) decreased in PPQ-predicted responders (-46$\pm$3%) and remained increased in PPQ-predicted non-responders (+75$\pm$19%). Follow-up NETest categories stable vs progressive significantly correlated with PPQ prediction and mPFS (not reached vs. 10 months; HR 0.06, 95%CI: 0.03-0.12). In comparison, the standard biomarker, CgA, failed to predict or correlate with response to PRRT (p= NS). **Conclusions:** NETest accurately (98%) monitors PRRT response and is an effective surrogate marker for radiological response (image concordance 98%). A NETest decrease identified responders (99%) and correlated ($>$ 97%) with the pretreatment PPQ response predictor. Research Sponsor: None.

High-risk breast cancer genes at 8q22-24 and their role in over 5,000 patients evaluated with the 70-gene risk of recurrence assay. *First Author: Sami Diab, Rocky Mountain Cancer Center-Aurora, Aurora, CO*

Background: Previous studies have shown that *CCNE2* expression is higher in patients' cancers resistant to CDK4/6 inhibitors. Increased expression of *CCNE2*, *MTDH,* or *TSPYL5*, genes contained within the 70-gene risk of distant recurrence signature (70GS), has also been implicated in breast oncogenesis, poor prognosis, and chemoresistance. These genes are located on chromosome region 8q22.1, one of the most recurrently amplified regions out of all 70GS genes in breast tumors (Fatima et al. 2017). *MYC*, located on 8q24, is overexpressed in 40% of all breast cancers (BC). Here we examined the expression of *CCNE2*, *MTDH,* and *TSPYL5* in relation to 70GS risk and the 80-gene molecular subtype signature (80GS), and their correlation with *MYC* expression in early stage BC patients. **Methods:** *CCNE2*, *MTDH*, *TSPYL5,* and *MYC* mRNA expression was measured in 5022 BC samples sent to Agendia (Irvine, CA) for 70GS and 80GS testing, which included FFPE microarray full-transcriptome data. 70GS was used to stratify patients into Ultra Low Risk (UL), Low Risk (LR), High Risk (HR), and Ultra High Risk (UH). Both 70GS and 80GS were used to classify patient samples into Luminal A, Luminal B, HER2, or Basal type. Wilcoxon rank sum test was used to assess expression differences. **Results:** The expression of *CCNE2*, *MTDH*, and *TSPYL5* significantly correlated with each other and was higher in HR patients compared to LR patients ($p < 0.001$) and higher in UH patients compared to HR patients ($p < 0.001$). Expression of these genes was highest in Basal type tumors, 83% of which were UH, followed by Luminal B type tumors, and lowest in Luminal A type tumors. *CCNE2* and *MYC* expression was elevated in LR compared to UL patients ($p < 0.001$ and $p = 0.0043$). There was no difference in *MYC* expression between HR vs. LR or UH vs. HR. Lastly, there was no association between the expression of 8q22.1 genes and *MYC* in any 70GS subgroup. **Conclusions:** Within the 70GS, *CCNE2, MTDH,* and *TSPYL5* have similar expression patterns and when overexpressed may identify an UH cohort of BC. This observation, in addition to their physical proximity at 8q22.1 suggests a possible amplicon in this region. The highest expression of *CCNE2*, *MTDH,* and *TSPYL5* associated with UH patients and is concordant with previous studies that support the role of these genes in BC metastasis. Furthermore, this analysis suggests *MYC* may not stratify patients based on metastatic potential. These data may be clinically relevant for stratifying patients in ongoing clinical trials evaluating response and resistance to targeted therapies in early stage BC. Research Sponsor: Agendia, Inc.

Adding precision to 2018 ASCO/CAP HER2 testing guidelines in breast cancer with genomic profiling. *First Author: Adam Brufsky, Magee-Womens Hospital of UPMC, Pittsburgh, PA*

Background: Biological heterogeneity of HER2 positive breast cancers has been suggested by a modest benefit of HER2-targeted therapies reported in the APHINITY and ExteNET trials. This highlights the need for improved biomarkers that more precisely identify patients who benefit from HER2-directed agents. The 80-gene molecular subtyping signature (80GS) classifies breast tumors into Luminal, HER2 or Basal type based on the gene expression of downstream signaling pathways. Previous work showed a substantial proportion of tumors identified as HER2 equivocal or HER2 positive by 2013 ASCO/CAP guidelines may be reclassified as non-HER2 type by 80GS. In 2018, ASCO/CAP HER2 IHC/ISH classification guidelines were revised to reduce the frequency of HER2 equivocal cases, for which treatment recommendations have been ambiguous. Here we evaluated concordance between HER2 status by 2018 ASCO/CAP guideline classification and 80GS molecular subtyping. **Methods:** Pathology reports are provided by physicians for samples that are tested with the 70-gene risk of distant recurrence signature (70GS) and 80GS as part of routine diagnostic care. This analysis includes data sent to Agendia (Irvine, CA) from January 2019 to January 2020. HER2 IHC/ISH results based on ASCO/CAP 2018 guidelines were available for 1453 samples. **Results:** Of 1453 samples, 1336 (92%) were HER2 negative, 99 (7%) were HER2 positive, and 18 (1.2%) were HER2 equivocal under 2018 guidelines. 80GS reclassified 57 of 99 (58%) HER2 positive tumors as Luminal and 11 of 99 (11%) as Basal; the remaining 31% were confirmed HER2. Furthermore, 55 of 99 (55%) HER2 positive tumors were also ER and PR positive by IHC, with 48 (87%) of these reclassified as Luminal type. Of HER2 negative tumors, 80GS classified 94 of 1336 (7%) as Basal and 2 of 1336 (0.15%) as HER2. Of HER2 equivocal tumors, 16 of 18 (89%) reclassified as Luminal and 2 of 18 (11%) as Basal. **Conclusions:** In this real-world diagnostic dataset, 2018 ASCO/CAP guidelines resulted in few HER2 equivocal tumors overall, confirming the positive impact of the revised guidelines. However, 80GS reclassified 69% of HER2 positive tumors to non-HER2 molecular subtypes, suggesting these tumors may have suboptimal responses to HER2-directed therapy compared to HER2 enriched. All HER2 equivocal tumors reclassified to non-HER2 subtypes. Molecular classification by 80GS adds further precision in classifying HER2 positive patients and potential to predict responsiveness to HER2-targeted therapies. Further studies are warranted to validate the utility of HER2 status based on 80GS. Research Sponsor: Agendia, Inc.

Genomic analysis of driver-negative lung adenocarcinoma (LA) in lifetime never smokers. *First Author: Aline Fusco Fares, Princess Margaret Hospital, Toronto, ON, Canada*

Background: Genomic events giving rise to driver negative LA in never smokers remain elusive. Here we report results of whole exome sequencing (WES) and targeted RNA sequencing in NS who had no mutation drivers found on routine clinical testing by targeted next generation sequencing (NGS). **Methods:** The cohort of never smokers with EGFR/ALK negative LA by clinical biomarker testing at Princess Margaret Cancer Centre, were first subjected to various clinical NGS profiling platforms (table). Where tissue was available, those negative for potential drivers in the clinical NGS then underwent WES (mean coverage > 200x) and Oncomine comprehensive v.3 RNA sequencing. We analyzed mutational signatures (MS) of the driver negative cohort based on the COSMIC catalog and assessed the median tumor mutation burden (mTMB mut/Mb -Megabase) in cases without a smoking MS, to avoid confounders. **Results:** Of 159 never smokers profiled with clinical NGS, potential drivers were found in 86 (54%): 75 (87%) with mutations in known LA driver genes and 11 (13%) with fusions. Among the remaining never smokers that tested negative by clinical NGS, 35 (48%) had available tissue for further testing. The Oncomine panel identified 9 cases (25%) with fusions or MET exon14 mutation (n = 7). Within the driver negative group, 24 (92%) underwent WES. Three tumors had WES base substitution patterns that were consistent with a smoking-related MS (MS4). Twenty-one patients exhibited signatures found common across all cancer types (MS 5), associated with DNA mismatch repair (MS 6, MS 20) or APOBEC over-activation (MS 2, MS13). In the driver-negative group, we identified 7 pts with somatic mutations in the KMT2 family (4 KMT2C, 4 KMT2A, 1 KMT2D), known for putative tumor suppressors and histone methyltransferases. mTMB on the driver negative group was 1.92, while one outlier with APOBEC MS and KMT2C/A mutations had a TMB of 16.8. **Conclusions:** Never smokers with driver negative LA are a heterogeneous group, with different MS and a wide TMB range. Mutations on KMT2 family are frequently found in driver negative LA in never smokers and warrant further investigations. Research Sponsor: Alan Brown Chair.

Never smokers EGFR/ALK negative with routine clinical NGS	**Drivers on NGS** N = 86 (54%)	**Mutations:** KRAS (35%) HER2 (33%) BRAF (9%) METex14 (7%) FGFR (4%)

3572 Poster Session (Board #302), Fri, 8:00 AM-11:00 AM

Ultrasensitive multiplex detection of structural rearrangements in *ALK*, *RET*, *ROS1* and *PD-L1* using a comprehensive next-generation sequencing assay. *First Author: Kao Chin Ngeow, Lucence Diagnostics, Singapore, Singapore*

Background: Oncogenic structural rearrangements (SR) in *ALK*, *RET* and *ROS1* are well-described in lung cancer, and confer sensitivity to targeted therapy. SR disrupting the 3'UTR of *PD-L1* gene have been reported in multiple cancer types and can potentially predict response to checkpoint immunotherapy. An amplicon-based next-generation sequencing (NGS) platform technology (AmpliMARK), previously optimized for detection of single nucleotide variations (SNVs), microsatellite instability and viral DNA, was extended to the multiplex detection of SR in *ALK*, *RET*, *ROS1* and *PD-L1* in cell-free DNA (cfDNA) and tumor tissue DNA. **Methods:** A hybrid primer-extension and adapter-ligation based method allowing detection of SR in a fusion-partner agnostic manner was utilized for multiplex target capture of genomic regions of *ALK*, *RET*, *ROS1* and *PD-L1* SR. Analytical validation was performed using admixtures of fragmented genomic DNA from an *ALK* SR-positive cell line, commercial standards containing *RET* and *ROS1* SR, and synthetic *PD-L1* SR gene constructs. Clinical performance was assessed in cfDNA samples from lung cancer patients and tumor tissue DNA samples from natural killer(NK)/T-cell lymphoma patients. **Results:** Detection of SR could be achieved to an allele frequency detection limit of 0.5% with sensitivity of 89.5% and specificity of 100% in admixture samples mimicking cfDNA. In an unselected series of 374 lung cancer cases, actionable SR for *ALK*, *RET* and *ROS1* were detected in cfDNA of 9 samples, for an overall detection rate of 2.4%, and 1.8% (3 out of 168) when restricted to treatment-naive lung cancer cases only. In 29 NK/T-cell lymphoma tumor tissue samples, 9 samples were positive for *PD-L1* SR, which were orthogonally confirmed by whole-genome sequencing, targeted sequencing or Sanger sequencing for a concordance rate of 100% across all samples. For 1 NK/T-cell lymphoma tumor tissue sample where matched plasma was available, the same *PD-L1* SR was also detected in cfDNA. **Conclusions:** We have demonstrated and validated a comprehensive amplicon-based NGS assay for ultrasensitive multiplex detection of structural rearrangements in *ALK*, *RET*, *ROS1* and *PD-L1* across both cfDNA and tumor tissue DNA in analytical and clinical contexts. Ongoing studies will further evaluate the performance and utility of this assay across a larger number of clinical samples for the detection of these SR as well as additional cancer-associated SR involving *NTRK1/2/3*, *FGFR2/3* and *TMPRSS2*. ^{89}Zr-durvalumab PD-L1 PET in recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck. *First Author: Sarah Verhoeff, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Immune checkpoint inhibitors (ICI) targeting programmed cell death protein-1/ligand-1 (PD-1/PD-L1) have shown activity in R/M squamous cell carcinoma of the head and neck (SCCHN). Positron-emission-tomography (PET) with ^{89}Zr-labeled anti-PD-L1 antibodies could aid in predicting response to ICI. We present the dose-finding results of the first-in-human ^{89}Zr-durvalumab PD-L1 PET-imaging in patients with SCCHN participating in the ongoing phase II PINCH study (NCT03829007). **Methods:** Following baseline [^{18}F]FDG-PET and CT/MRI imaging, patients with incurable R/M SCCHN received 37 MBq ^{89}Zr-durvalumab and protein dose 2mg, 10mg or 50mg durvalumab. ^{89}Zr-durvalumab PD-L1 PET-scan was acquired day 5 post-injection. Plasma pharmacokinetic analyses were performed at day 0 and 5. Standardized uptake values (SUV, mean ± SD) were measured in [^{18}F]FDG-positive tumor lesion, liver, spleen, bone marrow and bloodpool. PD-L1-expression was assessed on archival tumor tissue using the Ventana PD-L1 (SP263) assay. **Results:** 14 patients were enrolled and no adverse events were reported. High tracer-retention was observed in liver and spleen, most prominent in patients receiving 2 or 10mg durvalumab. ^{89}Zr-durvalumab accumulation within tumors and between patients was heterogeneous and not all [^{18}F]FDG-positive lesions showed ^{89}Zr-durvalumab uptake. Tumor lesions were visualized best using 10 or 50mg durvalumab (SUV_{peak} 2mg: 3.86 ± 0.79, 10mg: 7.46 ± 2.18, 50mg: 5.57 ± 1.74). Tumor-to-blood-ratios for 10mg durvalumab were highest (2mg: 2.27 ± 0.33, 10mg: 3.44 ± 0.76, 50mg: 1.73 ± 0.99; p = 0.019). PK-analyses confirmed visual prolonged tracer-retention in bloodpool with increasing protein dose. PD-L1-expression was equally distributed amongst dose-groups. **Conclusions:** This is the first study to show feasibility of ^{89}Zr-durvalumab PD-L1 PET in SCCHN patients, demonstrating the highest tumor-to-blood radio with a total dose of 10mg durvalumab. So far, no correlation of tumor PD-L1 expression with ^{89}Zr-durvalumab-uptake and PD-L1 expression on archival tissue was found. Next step will be to correlate ^{89}Zr-durvalumab PD-L1 PET tumor uptake with durvalumab treatment response in the phase 2 part of the PINCH study. Clinical trial information: NCT03829007. Research Sponsor: Astra Zeneca, Radboud Institute for Health Sciences, Junior research project.
