Background: Tropomyosin receptor kinase A (TrkA) is a protein encoded by the NTRK1 gene. Upregulation of TrkA signal transduction pathways, which can be caused by either NTRK1 gene fusions or intact TrkA protein overexpression, are oncogenic for multiple tumor types. This is clinically validated by demonstrated efficacy of ATP-competitive pan-TrkA/B/C inhibitors, larotrectinib and entrectinib for treatment of advanced solid tumors harboring NTRK1/2/3 gene fusions. VMD-928 is the first oral small-molecule TrkA (NTRK1) selective inhibitor with differentiated allosteric (ATP non-competitive) and irreversible mechanisms of action, acting as a molecular glue which sticks two TrkA proteins together and dose-dependently inhibits TrkA functions and downstream effectors, e.g. activated ERK, a hallmark of cancer. We conducted a first time in human phase 1 trial and completed the dose escalation phase. **Methods:** This is an open label, Phase 1 study investigating oral VMD-928 in adults with advanced solid tumors or lymphoma. The primary objective is to assess the safety and tolerability of VMD-928 and determine the recommended phase 2 dose. Secondary objectives include characterizing the pharmacokinetics (PK) and pharmacodynamics as well as assessing antitumor activity. **Results:** Non-biomarker-selected patients (n = 20) were accrued to 4 dose escalation cohorts ranging from 300 mg/day to 2400 mg/day. Three patients were accrued to the 2400 mg dose level with one DLT of elevated bilirubin, AST and ALT. The trough concentrations (Ctrough, ng/mL) ranged from 5.3 to 727. The dose was de-escalated to 1200 mg per day in divided doses and fifteen heavily pretreated patients were accrued with the following tumor types: adenoid cystic carcinoma, cholangiocarcinoma, lung cancer, pancreatic cancer, parotid, and squamous cell carcinoma of head and neck. There were no DLT's at this dose and one patient with adenoid cystic carcinoma had prolonged stable disease. Common adverse events related to therapy were dark stool (35%), elevated liver enzymes (25%, primarily at 2400 mg/day), fatigue, nausea or vomiting, and decreased appetite (20% each). **Conclusions:** VMD-928 was well tolerated with mainly gastrointestinal side effects. The recommended phase 2 dose (RP2D) is 600 mg twice (1200 mg) per day. The study is currently accruing in expansion cohorts to evaluate efficacy in biomarker-selected patients with tumors of TrkA protein overexpression. Tumor types with reported high TrkA protein expression including thymic carcinoma (98% with TrkA protein expression without NTRK1/2/3 gene fusions), mesothelioma (81%), squamous cell carcinoma of head and neck (80%), ovarian (80%), hepatocellular (72%), and squamous cell carcinoma of the lung (71%) are being accrued. Clinical trial information: NCT03556228. Research Sponsor: VM Oncology, LLC.

High-intensity focused ultrasound ablation for treatment of chemotherapy-induced thrombocytopenia and hypersplenism. *First Author: Min Yuan, Department of Oncology, Shanghai Tenth People's Hospital, Tongji University, Shanghai, China*

Background: Chemotherapy-induced thrombocytopenia (CIT) contributes to treatment dose delay and/or modification, often resulting in poorer survival and disease progression. Compared with partial splenic embolization (PSE) and drugs, high-intensity focused ultrasound has the advantages as following: (1) it is a noninvasive treatment modality with potentially fewer adverse effects and complications; (2) the hospital stay and recovery time after treatment are short; (3) its cost is relatively low compared to surgery. The purpose of this work was to preliminarily investigate the efficacy and safety of high intensity focused ultrasound treatment of chemotherapy-induced thrombocytopenia (CIT) and hypersplenism. **Methods:** 26 patients with chemotherapy-induced thrombocytopenia and hypersplenism (15 male and 11 female; median age, 56 years; range, 51-66 years) were treated with ultrasound guided high-intensity focused ultrasound. Complications were recorded. Laboratory examination and magnetic resonance imaging were used to evaluate the efficacy. The spleen volume and ablation volume rate of the spleen were calculated by MRI after treatment. They were followed closely for at least 6 months. **Results:** After high-intensity focused ultrasound treatment, the MRI showed that the ablation area had turned into a non-perfused volume, the mean percent spleen ablation volume was 18.76% ± 6.1% (range, 11.17%-32.34%). After 6 months of HIFU ablation, the ablated area shrank evidently; the sunken spleen formed a lobulated shape and the splenic volume decreased. The platelet count increased 3-7 days after treatment and remained for 1-2weeks higher than baseline ($53.33 \pm 15.80 \times 10^9$/L). The white blood cell count and platelet count of the patients were substantially improved during the follow-up period. No substantial difference was observed in RBC counts between baseline and after treatment. In addition, symptoms such as epistaxis and gingival bleeding were ameliorated or even eliminated, and the quality of life was improved. Follow-up imaging showed a nonperfused volume in the spleen. **Conclusions:** For the first time to our knowledge, high-intensity focused ultrasound ablation was used to treat Chemotherapy-induced thrombocytopenia (CIT) and hypersplenism. High-intensity focused ultrasound ablation of the spleen may cause damage to a certain volume of the spleen parenchyma to achieve the purpose of hypersplenism treatment. High intensity focused ultrasound may be an effective and safe alternative for treatment of CIT and hypersplenism. Research Sponsor: None.

Phase 1 trial of a novel, first-in-class G protein-coupled estrogen receptor (GPER) agonist, LNS8801, in patients with advanced or recurrent treatment-refractory solid malignancies. *First Author: Carolyn Muller, University of New Mexico, Albuquerque, NM*

Background: The G protein-coupled estrogen receptor (GPER) is a broadly expressed G protein-coupled receptor that is tumor suppressive. LNS8801 is an oral, highly selective small molecule agonist of GPER. GPER activation results in c-Myc depletion, inhibition of tumor proliferation, and enhancement of tumor immune recognition. Preclinically, LNS8801 demonstrates potent single-agent and combinatorial anti-cancer activity and can overcome established resistance to standard-of-care anti-cancer therapies including immune checkpoint inhibitors. **Methods:** The primary objective of this phase 1/1B first-in-human, open-label, multicenter study (NCT04130516) was to determine the safety and tolerability and recommended phase 2 dose (RP2D) of LNS8801 in patients (pts) with locally advanced or metastatic solid tumor malignancies, both as monotherapy and in combination with the anti-PD-1 antibody, pembrolizumab. Dose levels were escalated in a 3+3 fashion and included 10, 40 and 125 mg dosed 3/7, 125 mg daily, and 125 and 250 mg twice daily. Dose limiting toxicity (DLT) was defined via NCI CTCAE v5.0 during the first 21 days of treatment. An increase in prolactin over the initial 12 hrs of dosing was measured to assess systemic GPER signaling. Tumor c-Myc expression was measured as a surrogate of treatment-related biologic response. Radiographic response (RECIST v1.1) was evaluated every 8 weeks until progression. **Results:** 33 pts (19 M/14 F) with median age 58.8 y and 4 (1-9) prior therapies enrolled. Median duration of treatment was 66 d (1–367+). With monotherapy (n = 28), no DLTs, treatment-related SAEs, or treatment-related study discontinuations were observed up through the maximum administered dose (250 mg bid). Possibly related AEs were grade 1 or 2 and did not correlate with dose level. Exposure was above that predicted for efficacy and $t_{1/2}$ was ~10 hr at all doses. Of 26 evaluable monotherapy pts, 8 (27%) experienced stable disease (SD) for up to a year. All SD pts had a prolactin response. Among tumors expressing GPER, c-Myc depletion was observed in 100% (5/5) of paired pre and on-treatment biopsies. In the combination cohort (n = 5), 2/2 evaluable pts demonstrated net tumor reductions on initial f/up scans, including one RECIST partial response. Based on PK/PD data, 125 mg daily has provisionally been identified as the monotherapy and combination RP2D. **Conclusions:** LNS8801 is well tolerated and demonstrates signals of anti-tumor activity when administered both as monotherapy and in combination with pembrolizumab. Confirmation of RP2Ds and updated efficacy data will be presented in June. A phase 2A expansion study to evaluate these RP2Ds in clinical settings of high unmet need is now in development. Clinical trial information: NCT04130516. Research Sponsor: Linneus Therapeutics.

3085 **Poster Session**

A phase II study investigating biological effects of maintenance usage of hydroxychloroquine on Par-4 levels in patients with resected tumors. *First Author: Peng Wang, University of Kentucky Markey Cancer Center, Lexington, KY*

Background: Hydroxychloroquine (HCQ) is an inducer of the tumor suppressor Par-4 (prostate apoptosis response-4) secretion from normal cells. Secreted Par-4 causes paracrine apoptosis of tumor cells in mice. Established dosing of HCQ 200 mg bid induces Par-4 secretion but not the autophagy-inhibition marker p62 and correlates with apoptosis induction in patients' tumors. **Methods:** This is a single-arm, single institute phase II study to characterize the biological effects of 3-months of HCQ at fixed-dose (200 mg p.o. twice a day) on plasma Par-4 levels in adults with resected solid tumors. The primary endpoint is proportion of patients who will exhibit a two-fold increase in Par-4 levels from baseline compared to 3 months of follow-up. 12-month progression free survival (PFS) is one of the secondary endpoints. A Simon's two-stage design was used to test the null hypothesis that the proportion of patients exhibiting a two-fold increase in Par-4 is equal to 50% compared to 70% using a one-sided alternative. These hypothesized assumptions are based on a small pilot human data and from a phase I clinical trial on a small number of patients (n = 9). The first stage of interim analysis will be performed after a total of 15 patients have been accrued. If there are eight or fewer responses occurred, the study will be stopped. Otherwise, 28 additional patients will be accrued for a total of 43 subjects. **Results:** A total of 19 patients were enrolled in the trial. Per protocol, the interim analysis and stopping boundary is based on the first 15 patients. A total of 4 out of 15 patients (26.7%) 95% CI: 8% - 55% exhibited a >2-fold increase in Par-4 levels at 3 months. This did not surpass the stopping bound for futility and thus indicates stopping of patient accrual based on the assumptions used for the Simon's two-stage design. 7 out of 19 patients (36.8%) 95% CI: 16% - 62% who exhibited at least a 2-fold increase at either 2 or 3 months of follow-up, 50% (95% CI: 26% - 74%) and 56% (95% CI: 31% -79%) exhibited a 1.5-fold and 1.25-fold increase respectively. To date, 10/19 patients finished 12-month follow-up, 4/19 and 5/19 finished 6-month and 3-month follow up respectively. 2 of 12 patients with less than 2-fold increase of Par-4 developed disease progression. None of 7 patients with 2-fold increase of Par-4 showed disease progression. **Conclusions:** Despite that the study was terminated prematurely, to our knowledge this is the first study in human to identify dynamic changes of serum Par-4 while on long-term of usage of HCQ. We also demonstrate trend of PFS benefit especially for subjects having 2-fold increase of Par-4 induction. Identification of tumors more Par-4 sensitive and predictive biomarkers of Par-4 induction are necessary to continue our investigation. Clinical trial information: NCT02232243. Research Sponsor: Markey Cancer Center CCSG pilot grant.

3086 **Poster Session**

Safety and preliminary efficacy from the phase 1 portion of MasterKey-01: A First-in-human dose-escalation study to determine the recommended phase 2 dose (RP2D), pharmacokinetics (PK) and preliminary antitumor activity of BDTX-189, an inhibitor of allosteric *ErbB* mutations, in patients (pts) with advanced solid malignancies. *First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: BDTX-189 is an orally available, ATP-competitive and irreversible inhibitor directed against families of allosteric *HER2* and *EGFR* oncogenic mutations. In preclinical studies BDTX-189 achieved potent inhibition of 48 allosteric *HER2* and *EGFR/HER2* exon 20 insertion mutant variants with selectivity versus *EGFR* wild-type (WT) and demonstrated tumor growth inhibition and regression *in vivo*. The primary objective of the Ph 1 portion of this trial (NCT04209465) is to determine the RP2D and schedule of monotherapy BDTX-189 in pts with advanced solid tumors. **Methods:** Eligibility includes pts with relapsed or refractory locally advanced or metastatic solid tumors with no standard therapy available whose tumor harbors an allosteric *HER2* or *HER3* mutation; *EGFR* or *HER2* exon 20 insertion mutation; *HER2* amplification or overexpression; or *EGFR* exon 19 deletion or L858R mutation. BDTX-189 is dosed continuously orally in 3-wk cycles QD and BID in separate dose escalation cohorts. A separate cohort is also evaluating the high- and low-fat food-effect (FE) on BDTX-189 PK. **Results:** As of 1/11/21, 46 pts have been dosed, with 36 in the QD (fasting) schedule (25-1200 mg), including pts from the FE cohort who received 800 mg QD fasting after FE evaluation: 58% female; 67% white; median age 63.5 yrs; 53% received ≥ 3 prior tx lines. Cancer types: 12 NSCLC, 5 breast, 4 ovary, 3 biliary, and 12 other. Genomic alterations: 23 HER2 amplification and the following mutations: 11 allosteric *HER2*, 5 *EGFR* exon 20 insertion, 5 *HER2* exon 20 insertion, 3 *EGFR* exon 19 del./L858R, and 2 *HER3*. At ≥ 800 mg QD, 3 and 2 pts had EGFR or HER2 exon 20 mutations, respectively. The maximum tolerated dose (MTD) for QD (fasting) was 800 mg, with 2/6 pts with DLTs at 1200 mg. DLTs: gastrointestinal (G3 diarrhea; G1/2 nausea/vomiting). The most frequent (≥20%) related adverse events were diarrhea (36%, 8% G3), nausea (28%, 0% G3), and vomiting (25%, 3% G3). The rate of skin disorders was 11% with the highest severity of G2 in 1 pt. Dose-dependent exposure increases were observed, with the exposure at 800 mg QD fasting within the projected efficacious range. Pilot FE data suggest possible increased exposure with food. 27 pts were evaluable for efficacy, 15 at ≥ 800 mg QD, with 2 partial responses observed: 1 PR confirmed and ongoing (800 mg QD, CUP, HER2 amp, 3 prior lines of chemo) and 1 PR unconfirmed (NSCLC with brain mets, 1200 mg QD, HER2 amp + exon 19 del., 2 prior EGFR TKIs). 3 pts had a best response of SD and 10 with progressive disease. **Conclusions:** BDTX-189 has a generally manageable safety profile with early evidence of anti-tumor activity. Enrollment is ongoing in non-fasting QD and BID cohorts, and the FE cohort, prior to RP2D identification. Clinical trial information: NCT04209465. Research Sponsor: Black Diamond Therapeutics.

A phase 2 study of defactinib (VS-6063) in patients with NF2 altered tumors: Results from NCI-match (EAY131) subprotocol U. *First Author: David Michael Jackman, Dana-Farber Cancer Institute, Boston, MA*

Background: The NCI-MATCH trial assigns patients (pts) with solid tumors, lymphomas, or multiple myeloma to targeted therapies based on genetic alterations identified in tumor biopsies. Neurofibromatosis 2 (NF2)-inactivated tumors demonstrate increased sensitivity to FAK inhibition in preclinical models. Arm U evaluated the FAK inhibitor defactinib in pts with NF2 altered tumors. **Methods:** Patients found to harbor an inactivating NF2 mutation on NGS were assigned to the ARM U substudy MATCH. Defactinib 400 mg was given by mouth twice daily until progression or intolerable toxicity. The primary endpoint was objective response rate (ORR). Secondary endpoints included toxicity, progression-free survival (PFS), and 6-month PFS. **Results:** Of 5,548 cases with sufficient tissue for genomic analysis, 51 pts were found to have NF2 alterations (< 1% of the total analyzed). While NF2 alterations are known to occur more commonly in meningiomas and mesotheliomas, alterations were also detected in an array of other tumor types, including renal cell carcinomas and ovarian cancers. Thirty-five pts were ultimately enrolled; 33 patients were started on therapy, with 2 of those determined to be ineligible for outcome analysis. All pts had received at least one prior therapy, with 52% (16/31) having received 3 or more prior lines of therapy. Median follow-up was 35.9 months. ORR [90% CI] was 3% (1/31, [0.16, 14.86]), with the one partial response in a pt with choroid meningioma. Of the twelve pts whose best response was stable disease (39%, 12/31), 8 demonstrated some degree of tumor shrinkage (Table) with a disease control rate of 42% (13/31). Median PFS was 1.9 months for the 31 eligible pts who received study treatment, with median PFS of 9.3 months for the 9 patients who had a best response of stable disease or better. Six pts achieved a PFS of greater than 5.5 months. Among all treated pts (n=33), the most common treatment-related toxicities were fatigue (36%), nausea (33%), and hyperbilirubinemia (27%). There were no grade 4 or 5 toxicities; 27% of pts had grade 3 toxicities. No correlation could be made between clinical outcomes and tumor histology or specific NF2 genotype. **Conclusions:** Defactinib monotherapy had limited clinical activity in this cohort of previously treated patients with solid tumors exhibiting NF2 loss. Clinical trial information: NCT04439331. Research Sponsor: U.S. National Institutes of Health.

Patients with any evidence of tumor reduction.

Case	Histology	Maximum tumor reduction (%)	PFS (months)
16490	Choroid meningioma	–30%	14
11705	Papillary renal cell carcinoma	–27%	7
11988	Undifferentiated pleomorphic sarcoma/myxoid	–12%	4

15738	Schwannoma of right forearm	–2%	21

3088 **Poster Session**

Phase I trial of 5-aza-4'-thio-2'-deoxycytidine (Aza-TdC) in patients with advanced solid tumors. *First Author: James Nguyen, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis (DCTD), National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, MD*

Background: The nucleoside analog Aza-TdC inhibits DNA methyltransferase 1 (DNMT1), which regulates methylation-mediated silencing of tumor suppressor genes. Aza-TdC offers an improvement over traditional DNA methyltransferase inhibitors by virtue of a higher incorporation rate into DNA at lower levels of cytotoxicity. Aza-TdC has also shown improved preclinical antitumor activity compared to other hypomethylating agents in some solid tumor xenograft models. In an ongoing phase I trial, we evaluate the safety and activity of Aza-TdC in patients (pts) with advanced solid tumors. **Methods:** Adult pts with solid tumors whose disease has progressed on standard therapy or for which there is no standard therapy were treated with Aza-TdC administered orally once a day for 5 days of each week for 2 weeks in 21-day cycles. The study followed Simon accelerated titration design 3, with 1 pt per dose level at 100% dose increments. Accelerated titration continued until 1 pt experienced a dose-limiting toxicity (DLT) or 2 pts experience drug-related grade 2 toxicity at any dose level, after which, a 3 + 3 dose escalation design was used. Intrapatient dose escalation was allowed. Correlative studies included pharmacokinetic assays and pharmacodynamic assays in circulating tumor cells. **Results:** As of January 2021, a total of 18 pts have been enrolled on study. Median pt age is 61.5 years (range 35-84). Tumor types included colorectal adenocarcinoma (5 pts), sarcoma (3), breast carcinoma (2), and ovarian carcinoma (2). The DLTs at 48 mg were grade 3 rash and grade 3 acute kidney injury in one pt and < 75% of dosing completed in another pt due to grade 3 myelosuppression. Among the 10 pts treated at 32 mg, 1 pt experienced a DLT: grade 4 neutropenia. The maximum tolerated dose (MTD) is 32 mg. Grade 3 or 4 toxicities across all cycles possibly attributable to study drug were leukopenia (6), lymphopenia (6), neutropenia (4), rash (2), febrile neutropenia (1), anemia (1), thrombocytopenia (1), acute kidney injury (1), elevated AST (1), elevated ALT (1), diarrhea (1), and dehydration (1). Of the 14 pts evaluable for response, 11 had a best response of stable disease, and 3 had a best response of progressive disease. Median cycles on study is 4 (range 1-10+). A pt with clear cell ovarian carcinoma has been on study for > 10 cycles with stable disease. **Conclusions:** At the MTD of 32 mg, Aza-TdC is safe and well tolerated with a toxicity profile similar to currently approved hypomethylating agents. Global DNA methylation profiling, RNAseq, and DNMT immunohistochemical analyses of tumor biopsies are planned for the currently accruing dose expansion cohort. Funded by NCI Contract No. HHSN261200800001E. Clinical trial information: NCT03366116. Research Sponsor: U.S. National Institutes of Health.

3089 **Poster Session**

Evaluating clinical activity of MAPK targeted therapies (TT) in cancer patients (pts) with non-V600 BRAF mutations: A systematic scoping review and meta-analysis. *First Author: Matthew Dankner, McGill University, Montréal, QC, Canada*

Background: Oncogenic nonV600 BRAF mutations (muts) can be classified according to distinct molecular characteristics. TT strategies for class 2 and 3 BRAF muts have not been established. In recent years there have been numerous reports of clinical activity for various TT in pts with nonV600 muts. We performed a systematic scoping review and meta-analysis to assess treatment outcomes with MAPK TT according to BRAF class, cancer type and TT type. **Methods:** An extensive literature search was conducted from 2010-20. All studies were independently reviewed and extracted by 2 reviewers and in accordance with PRISMA guidelines. Individual patient level data were collected and analyzed from studies that met the following inclusion criteria: published reports of 1) advanced cancer pts with; 2) class 2 or class 3 nonV600 BRAF muts; 3) who received MAPK TT; 4) with treatment response (TR) data available. Primary outcome was overall TR rate (TRR). To assess differences between groups, odds ratios (OR) were calculated using a multi-level mixed-effects logistic regression model. **Results:** 15,171 studies were screened and 168 were included for data extraction. We identified 100 studies with a total of 396 pts that met inclusion criteria. There were 17 reports (161 pts) of prospective clinical trials and 83 retrospective studies (235 pts). RECIST criteria were used for TR assessment in 183 (46%) pts. The entire study included 280 pts with class 2 and 116 pts with class 3 BRAF muts. Overall, 111 (28%) pts achieved a TR. TRR according to primary tumor type, BRAF class, and TT type is indicated in Table. TRR was lower in reports of prospective studies compared to retrospective studies (OR 0.14, P = 0.002), and in studies that employed RECIST criteria vs. those that didn't (OR 0.29, P = 0.044). TRR was higher among pts with class 2 muts vs. those with class 3 muts (OR 2.21, P = 0.042). **Conclusions:** These data establish that MAPK TT have demonstrated clinical activity in cancers with oncogenic nonV600 mutations, and that BRAF mutation class may dictate responsiveness to different TT strategies. TRR may be over-estimated in the retrospective literature. This analysis will be valuable for molecular tumor boards and to guide future clinical trial design. Prospective clinical trials of TT in this pt population are warranted. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Phase I study of TT-00420, a multiple kinase inhibitor, as a single agent in advanced solid tumors. *First Author: Sarina Anne Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: TT-00420 is a spectrum-selective multi-kinase inhibitor that targets cell proliferation, angiogenesis, and immune-oncology pathways by inhibiting Aurora kinases A/B and Janus kinases (JAK) involved in cytokine signaling and receptor tyrosine kinases (FGFRs and VEGFRs) involved in the tumor microenvironment. TT-00420 has demonstrated anti-tumor activity in both *in vitro* and *in vivo* preclinical models of solid tumors, including triple-negative breast cancer (TNBC) and cholangiocarcinoma (CCA). **Methods:** The phase I, first-in-human dose escalation and expansion study of TT-00420 is enrolling adult patients with advanced or metastatic solid tumors. TT-00420 capsules in 1 mg or 5 mg formulation are administered orally once daily in 28-day cycles. Dose escalation is guided by Bayesian modeling with overdose control. The primary safety endpoints are to determine dose limiting toxicities (DLTs) and a dose recommended for dose expansion (DRDE). Secondary endpoints include pharmacokinetics (PK) and preliminary efficacy evaluated per RECIST v1.1 criteria. **Results:** As of February 17, 2021, 40 advanced solid tumor patients were enrolled in dose escalation cohorts and received at least one dose of TT-00420 in 7 dose levels: 1 mg *q.d.* (N=1), 3 mg *q.d.* (N=1), 5 mg *q.d.* (N=4), 8 mg *q.d.* (N=10), 10 mg *q.d.* (N=6), 12 mg *q.d.* (N=12), and 15 mg *q.d.* (N=6). DLTs were observed in 3 out of 32 DLT-evaluable patients, including 1 patient at 8 mg *q.d.* who had grade (Gr) 3 palmar-plantar erythrodysaesthesia syndrome and 2 patients at 15 mg *q.d.* who both had Gr 3 hypertension. Suspected adverse events (AEs) reported in ≥ 20% of patients across all tested dose levels include hypertension (any grade: n=17, 42.5%; Gr 3: n=8, 20.0%), diarrhea (n=10, 25.0%; Gr 3: n=1, 2.5%), vomiting (n=9, 22.5%; Gr 3: n=0), palmar-plantar erythrodysaesthesia syndrome (n=9, 22.5%; Gr 3: n=1, 2.5%), and nausea (n=8, 20.0%; Gr 3: n=1, 2.5%). No Gr 4 AEs, regardless of causality, were reported. Out of 26 patients who had at least one post-baseline scan, 4 (15.4%) had a best overall objective response of partial response (PR) and 13 (50.0%) had stable disease (SD). Of the patients who achieved PRs are 2 CCA patients (8 mg *q.d.*, n=1; 10 mg *q.d.*, n=1), 1 HER2-negative breast cancer patient (12 mg *q.d.*), and 1 TNBC (10 mg *q.d.*). Both CCA patients with PRs had disease control for ≥ 8 months. Of the patients who achieved SD, 1 salivary gland patient (5 mg *q.d.*) and 1 CCA patient (10 mg *q.d.*) had disease control for 8 months, and 2 TNBC patients (5 mg *q.d.*, n=1; 8 mg *q.d.*, n=1) had disease control for 6 months prior to disease progression. **Conclusions:** Toxicities observed in dose escalation cohorts were manageable with concomitant treatment and/or dose interruptions of TT-00420. 12 mg *p.o. q.d.* was recommended as the dose for dose expansion cohort for further safety and efficacy evaluation of TT-00420 capsules with focus on enrollment of TNBC and CCA patients. Clinical trial information: NCT03654547. Research Sponsor: Nanjing TransThera Biosciences Co., Ltd.

Incidence of *ERBB* gene fusions (*EGFR*, *ERBB2*, *ERBB4*) across tumor types. *First Author: Laura Schubert, University of Colorado School of Medicine, Denver, CO*

Background: Gene fusions often represent critical therapeutic targets across cancer subtypes. Fusions within the ErbB family of receptor tyrosine kinases, including *EGFR*, *ERBB2* (*HER2*) and *ERBB4* (*HER4*), have been previously described and represent potentially actionable alterations. Here, we report the relative incidence and functional characterization of these rare genomic events. **Methods:** Tumor samples (n = 64,354; representing > 40 tumors types) submitted to Caris Life Sciences (Phoenix, AZ) were molecularly profiled by next-generation sequencing of DNA (NextSeq, 592-gene panel; or NovaSeq, whole exome) and RNA (whole transcriptome). Gene fusion partners, in/out-of-frame status, retention of *ERBB* kinase domain, and topology of fusion breakpoints were characterized for each *ERBB* fusion transcript detected. Fusion prevalence was further examined in public data sets (TCGA, MSK-IMPACT and AACR GENIE). **Results:** From the Caris database, a total of 64 *EGFR* fusion isoforms were detected in 59 tumors (incidence 0.09%); 83% were in-frame and 91% retained the *EGFR* kinase domain. 206 *ERBB2* fusion isoforms were detected in 114 tumors (0.18%); 37% were in-frame and 34% retained the *ERBB2* kinase domain. 131 *ERBB4* fusion isoforms were detected in 108 tumors (0.17%); 62% were in-frame and 51% retained the kinase domain. All fusions were detected at low incidence across all tumor types. *EGFR* fusions were most common in high grade glioma (1.7%, n = 35), largely driven by recurrent *EGFR-SEPT14* fusions (n = 20). *ERBB2* fusions were most common in esophageal/gastroesophageal junction carcinoma (1.1%, n = 20), with recurrent fusion to *PGAP3* observed in multiple tumor types (n = 37). *ERBB4* fusions were most common in ovarian (0.7%, n = 40) and bladder (0.7%, n = 15) cancers, which often resulted from recurrent fusion with *IKZF2* (n = 36). *EGFR* and *ERBB2* fusions were generated predominantly (44-48%) from inversion events, while *ERBB4* fusions arose more frequently and at similar rates (27-32%) from deletions, duplications, or translocations. Mining of public data sets corroborated the prevalence of *ERBB* gene fusions: the frequency of *EGFR* fusions was 0.63%, *ERBB2* was 0.14% and *ERBB4* was 0.04%. *TP53* mutations frequently co-occurred with *ERBB2* and *ERBB4* fusions (> 60% average across public data sets), with higher co-mutation rates (> 70%) observed for samples in the Caris database. **Conclusions:** *ERBB* gene fusions are detectable at low frequency in various tumor types and may represent a unique genomic subset of cancer. Identification of novel *ERBB* gene fusions warrants further investigation to determine the potential pathogenicity and actionability of these fusions. Research Sponsor: None.

Association of high gene expression levels of *ARF6* with the immune microenvironment and prediction of poor outcomes. *First Author: Natsuko Kawanishi, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: ADP-ribosylation factor 6 (*ARF6*) is a small GTPase in the RAS superfamily, which regulates membrane trafficking, remodeling and tumor progression. Preclinical study shows that *TP53* and *KRAS* cooperatively activate the *ARF6-AMAP1* pathway which serves as a link by which pancreatic driver mutations promote tumor invasion, PD-L1 dynamics and immune evasion properties in pancreatic ductal adenocarcinoma (PDAC). The clinical impact of *ARF6* on cancer progression and prognosis remains unclear. **Methods:** A total of 2,948 PDAC samples were analyzed using next-generation sequencing of RNA (whole transcriptome, NovaSeq) and DNA (NextSeq, 592 genes or NovaSeq, whole exome sequencing) and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ). QuantiSeq (Finotello 2019, Genome Medicine) was used to quantify immune cell infiltration. Overall survival (OS) was obtained from insurance claims, and Kaplan-Meier estimates were calculated for molecularly defined cohorts. Significance was determined as p values adjusted for multiple correction (q) of < .05. **Results:** Median *ARF6* expression was higher in metastases (33.69 transcriptions per million) compared to primary/local tumors (27.59, q< .05). Specific metastatic sites showed higher expression than did primary tumors (q< .05 for liver and p< .05 for skin, bone and lymph nodes). Dividing into quartiles by *ARF6* expression (the highest expression quartile, QH; the lowest, QL), *KRAS* mutations were significantly more prevalent in QH than QL (93.4 vs 87.2%, q< .05), and *TP53* mutations had similar trends (81.0% in QH vs 74.7% in QL, p= .0078). The mutation rates of *KDM6A*, *FANCD2* and *TFEB* amplifications trended higher in QH than QL; the *STK11* mutation rate tended to be lower in QH (p< .05). PD-L1 expression by IHC was significantly higher in QH than QL (20.9 vs 13.1%); immune checkpoint genes by RNA expression: *IFNG*, *IDO1*, *PDCD1G2*, *CD274*, *PDCD1* and *PDCD2L* were significantly higher in QH than QL (all q< .05). Macrophages, neutrophils, NK cells, fibroblasts and endothelial cells were more abundant in QH than QL (all q< .05); whereas CD4+ and CD8+ T cells were lower in QH (q< .05), and monocytes had similar trends (p< .05). High expression of *ARF6* was significantly associated with unfavorable outcomes in OS (HR = 1.83, 95% CI [1.51–2.22], p< .0001); the effect on OS was seen when primary (HR = 1.47, [1.06–2.05], p= .02) and metastatic tumors (HR = 0.608, [1.29–2.10], p< .0001) were investigated separately. **Conclusions:** This is the first report showing that high gene expression of *ARF6* in PDAC indicates a different immune profile, is enriched in cancer metastases, and is associated with poor survival. Our results provide the first clinical evidence supporting the *ARF6* pathway as a major downstream target of *KRAS* and *TP53* mutations promoting immune evasion, suggesting *ARF6* is a novel marker for prognosis and a potential target for immune therapeutic strategies in PDAC. Research Sponsor: None.

Optimal dose selection in oncology biologics development: Need for a paradigm shift. *First Author: Rajendar K Mittapalli, Pfizer, Inc., San Diego, CA*

Background: In oncology, the recommended phase 2 dose (RP2D) is typically selected from the first-in-patient (FIP) dose escalation and then carried forward to late stage trials. The RP2D is often informed by limited data from a relatively small number of patients. Further dose optimization in late stage trials is rare as these trials often evaluate only one dose/dosing regimen. Traditionally oncology development relied on establishing an MTD with the expectation this dose would ultimately provide an optimal benefit/risk profile. However, for biologics there are clear examples suggesting a need to reconsider this approach to dose selection during drug development. The present review attempts to evaluate the dose selection approaches for approved oncology biologics to identify opportunities for improved dose optimization of future oncology drugs. **Methods:** The dose selection steps for oncology biologics approved by the USFDA from 2010 to 2020 were reviewed. The primary focus of the review was RP2D selection based on early clinical data, doses tested in pivotal trials, exposure-response and dose justification for the proposed dose, and post-marketing requirements (PMR) or post-marketing commitments (PMC) related to dose optimization. **Results:** The dose selection process for a total of 22 biologics was analyzed. Among these, 17 (77%) did not identify MTD during the FIP trial, and 6 (27%) tested more than one dose in the registration trials. In the initial approval, 2 (10%) had PMR or PMC for further dose optimization. For majority of the biologics the dose justification was based on 1) receptor occupancy 2) biomarker response 3) early clinical activity and 4) target efficacious concentration based on xenograft data. The majority of biologics had shown a shallow exposure-response relationship in safety or efficacy end points which partly can be attributed to the common practice of testing single dose level in the registrational trial. The dose recommended in the FDA label appears to be highly correlated to the RP2D determined in FIP studies. **Conclusions:** Oncology biologics have heavily relied on pharmacodynamic, early signs of efficacy, and safety data from the limited number of patients in the FIP dose escalation to identify the dose for pivotal trials. In most cases, there have been no dose ranging or optimization based on the final therapeutic outcome. While integration of relevant biomarker, PK, and PD data for optimal dose selection is an important aspect, there is a need to change the paradigm to consider more robust dose optimization, especially in early stage development. Dose ranging assessments incorporating therapeutically relevant endpoints and adequate sample size should be considered, ideally prior to pivotal trials. Research Sponsor: Pfizer Inc.

Anticancer drugs associated with venous thromboembolic event: Analysis of the WHO pharmacovigilance database. *First Author: Angélique DA Silva, PICARO Cardio-oncology Program, Breast Cancer Unit, Centre François Baclesse, Caen, France*

Background: Venous thromboembolic event (VTE) is a frequent complication of cancer, as of some classical cancer therapy, like chemotherapy and surgery. The advent of new therapies such as immunotherapy and targeted therapies has meant that new therapies may be associated with VTE. Reliable data concerning the association between ADs and VTE are scarce. **Methods:** On March 1st, 2020 we utilized VigiBase (International pharmacovigilance database) and performed a disproportionality analysis using reporting odds ratios (ROR) to determine the association between the 206 FDA- or EMA-labeled ADs and VTE, defined as deep vein thrombosis and pulmonary embolism. RORs were adjusted (aRORs) on population characteristics including the cancer risk of VTE with the primary tumor site according to Khorana classification and metastatic status. **Results:** A total of 50,438 VTE cases associated with at least one AD were identified. Thirteen ADs were associated with higher reporting of VTE of which 2 represented new VTE associations not previously confirmed in the summary of product characteristics or literature including sipuleucel-t and megestrol. ADs more reported with VTE were lenalidomide (n:5,796), bevacizumab (n:2,780) and thalidomide (n:1,700). ADs associated-VTE occurred mainly during the first 6 months after AD initiation. **Conclusions:** Although cancer itself may generate VTE, we identified 13 ADs associated with VTE overreporting. Recognition of AD most likely to cause VTE can help raise practitioner awareness and lead to earlier diagnosis and treatment. Futures studies should include ADs in VTE risk evaluation and evaluate the management of VTE when recurrences occur under AD favoring VTE. ClinicalTrial registration number: NCT04696250. Research Sponsor: None.

Does oxaliplatin pharmacokinetics (PKs) explain associations between body composition and chemotherapy toxicity risk in older adults with gastrointestinal (GI) cancers? *First Author: Grant Richard Williams, Institute for Cancer Outcomes and Survivorship, University of Alabama at Birmingham, Birmingham, AL*

Background: Considerable inter-individual variability in oxaliplatin toxicity exists in older adults with GI cancers. Low lean body mass (LBM), commonly known as sarcopenia, influences toxicity and is not incorporated in standard body surface area-based dosing, which may affect oxaliplatin PK and tolerability, but has not been examined systematically. **Methods:** We examined oxaliplatin PK in 26 older adults (103 concentrations) with GI cancers (NCT03998202). Using the transverse section at L3, skeletal muscle area (SMA) and total adipose tissue (TAT) were quantified (Slice-O-Matic software) and LBM was calculated (LBM = 0.30 × SMA + 6.06). Noncompartmental methods (WinNonlin 7.0) were used for PK estimates and a one compartment population PK model (PopPK) was developed. Covariates included age, sex, LBM, TAT, weight, BMI, creatinine clearance, BSA, serum albumin, and body composition phenotypes (i.e. low LBM-high TAT, etc.). **Results:** Median age was 68yrs, 69% male, 88% white, and mostly colorectal (62%) and pancreatic (27%) cancers. There was wide variability in oxaliplatin volume of distribution (Vd: 12.5-259L), peak concentrations (Cmax: 404-3642ng/mL), and clearance (CL: 26.7-270L/hr). Participants with lower LBM had lower Vd (r = 0.51, $p< 0.01$); those with higher TAT had higher Cmax (r = 0.53, $p< 0.01$). Higher albumin was associated with lower Cmax (r = -0.49, $p= 0.01$) and higher CL (r = 0.47, $p= 0.01$). The phenotype of low LBM + high TAT had the lowest Vd (Relative Risk [RR] 0.32, $p= 0.01$), lowest CL (RR 0.39, $p< 0.01$), and highest Cmax (RR 3.3, 95% CI 1.7-6.5, $p< 0.01$). Eleven patients (44%) had grade 3-5 chemotoxicity. Vd (r = -0.46, $p= 0.02$) and Cmax (r = 0.44, $p= 0.03$) were associated with grade 3-5 chemotoxicity. The phenotype of low LBM + high TAT was associated with a 45% higher risk of grade 3-5 chemotoxicity (RR = 1.45, 95% CI 1.1-2.1, $p= 0.04$), while BSA was not (r = -0.04, $p= 0.9$). In the popPK model, body composition was associated with PK (TAT with Vd [p = 0.006] and CL [$p < 0.001$]), as was albumin (Vd p = 0.004; CL p = 0.002), while BSA was not (Vd p = 0.08; CL p = 0.2). Compared to BSA, an additional 11-17% in oxaliplatin PK variability was explained by LBM (11%), TAT (14%), and albumin (17%). **Conclusions:** Relationships between body composition, oxaliplatin PK, and severe chemotoxicity suggest the need for novel dosing strategies that incorporate body composition to reduce chemotoxicity and improve outcomes. Clinical trial information: NCT03998202. Research Sponsor: U.S. National Institutes of Health.

Pre-therapeutic dihydropyridimidine dehydrogenase (DPD) deficiency screening: Impact on fluoropyrimidine dose reduction at the second chemotherapy cycle and on early severe toxicity. *First Author: Côme De Metz, Hôpital Victor Provo, Roubaix, France*

Background: DPD deficiency screening before fluoropyrimidine is a matter of debate. To avoid lethal toxicity, French authorities impose DPD screening before fluoropyrimidine-based chemotherapy by dosing uracilemia since April 2019. **Methods:** We have included all consecutive adult patients receiving 5-fluorouracil (5-FU) or capecitabin from April 2019 to January 2020 in 6 cancer centers. During the study period, different methods for screening had been applied: *DPYD* complete sequencing, phenotype (uracilemia and/or dihydrouracilemia/uracilemia ratio - UH2/U -) or both. All sceening tests were conducted in the same laboratory. Association between the method of DPD screening and fluoropyrimidine dose reduction at second chemotherapy cycle or on severe ≥grade 3 early toxicity (between first and second cycle) was evaluated using multivariate logistic regression. Concordance between genotype and phenotype for DPD deficiency was explored using Cohen Kappa test. **Results:** We included 597 patients, the median age was 63 (range, 55-77). The most prevalent cancers were digestive (68.3%), head and neck (19.4%) and breast (9.2%). 12.3% of patients received capecitabine and 87.3% received polychemotherapy. DPD deficiency screening was done for most of patients (n=519, 86.9%). DPD screening method consisted in full sequencing of *DPYP* (n=41; 7.9%), phenotype analysis (n=44, 8.5%) or both (n=424, 83.6%). We did not identify any complete DPD deficiency. Uracilemia was dosed for 467 patients, the median was 6.5 ng/mL and for 21 patients (4.5%) uracilemia was > 16 ng/mL and/or UH2/U <6, suggesting DPD deficiency. Severe early toxicities were observed for 82 patients (14%), with two patients presenting grade 5 toxicity. Overall DPD screening and method of DPD screening were not associated with fluoropyrimidine dose reduction at second cycle or early severe toxicity. In multivariate analysis, the only predictor for fluoropyrimidine reduction at second cycle (n = 125 patients) was polychemotherapy (OR=2.8; p=0.012). Kappa between uracilemia and UH2/U was 0.23 (poor concordance). Kappa between *DPYP* sequencing and uracilemia or UH2/U was 0.09 (very poor concordance). **Conclusions:** No DPD deficiency screening method was associated with dose adaptation at second cycle or early severe toxicity. The optimal strategy for DPD screening requires further clinical evaluation. Research Sponsor: None.

Clinical pharmacokinetics of bdtx-189, an inhibitor of allosteric ErbB mutations, in patients with advanced solid malignancies in MasterKey-01 study. *First Author: Nigel Waters, Black Diamond Therapeutics, Inc, Cambridge, MA*

Background: Allosteric oncogenic mutations occur outside the canonical ATP-binding site of EGFR and HER2, and there are no approved therapies that target such mutations. BDTX-189 is a potent, selective, irreversible inhibitor of 48 allosteric EGFR and HER2 mutant variants under clinical evaluation in the ongoing MasterKey-01 trial (NCT04209465). BDTX-189 was designed to rapidly and irreversibly occupy the active site of targeted ErbB mutants, leading to sustained pharmacodynamic (PD) effects, and with selectivity over EGFR-WT in order to minimize EGFR-WT mediated toxicities. The pharmacokinetic (PK) profile was designed for rapid absorption and fast elimination to maintain target occupancy while minimizing prolonged drug exposure that could contribute to off-target associated toxicities. **Methods:** In MasterKey-01, BDTX-189 was administered orally once daily in continuous 21-day cycles, taken fasted. Dose escalation included cohorts of 1-2 patients receiving doses between 25 and 200 mg QD followed by 5-7 patients receiving 400 mg, 800 mg, or 1,200 mg QD fasted. The possible effects of a high fat meal on the PK of BDTX-189 were assessed in a subset of patients receiving single doses of 400 mg BDTX-189 fasted and immediately after a high-fat breakfast in a randomized crossover fashion with 3 days between doses. In addition, a dose escalation cohort investigating administration of BDTX-189 non-fasted was enrolled at 800 mg QD. Serial blood samples for analysis of plasma BDTX-189 concentrations were collected after each dose on C1D1 and C1D15. BDTX-189 levels were determined using LC-MS, and data analyzed using non-compartmental methods. **Results:** After single and multiple doses, BDTX-189 was rapidly absorbed (median tmax 1-2 h), with an elimination $t_{1/2}$ of 2-6 h. Dose-dependent increases in exposure from 200 to 800 mg QD fasted were observed, with no apparent accumulation or decline in exposures observed at steady-state. Administration of BDTX-189 with a high-fat meal increased AUC approximately 1.7-fold with minimal effect on Cmax, relative to administration in the fasted state. At 800 mg QD, mean AUC was similar in the non-fasting state relative to fasting and was within the target efficacious range defined by mouse models harboring allo-ErbB mutated tumors. Median tmax and $t_{1/2}$ values were similar after administration in the non-fasted and fasted states. **Conclusions:** BDTX-189 demonstrated rapid absorption and a short PK half-life consistent with the desired PK/PD profile, with exposures in the efficacious target range based on preclinical data. The pilot high fat food-effect data and non-fasting QD dosing regimen show similar or improved systemic exposure relative to dosing in the fasted state. The MasterKey-01 trial is ongoing, including refinement of the dosing regimen and identification of the recommended phase 2 dose. Clinical trial information: NCT04209465. Research Sponsor: Black Diamond Therapeutics.

A phase I study of a TGF-β receptor I kinase inhibitor YL-13027 in patients with advanced solid tumors. *First Author: Jin Li, Shanghai East Hospital, Shanghai, China*

Background: Transforming growth factor beta (TGF-β) is upregulated in the majority of tumors, promoting tumor cell proliferation, differentiation, and, modulation of the tumor microenvironment. YL-13027, a small molecule inhibitor of type 1 receptor of TGF-β, is a potent highly selective oral agent that downregulates TGFbR1-dependent pathways in tumor cells. YL-13027 dosed into tumor bearing animals drives tumor growth inhibition and interruption of metastasis. In this first-in-human phase1 study, we characterized the safety, tolerability, maximum tolerated dose (MTD), pharmacokinetics (PK) and preliminary efficacy of YL-13027 in patients with advanced solid tumors. **Methods:** YL-13027 tablets were administered orally, twice daily under fasted conditions for 28 days, for at least two 28 day cycles until disease progression, unacceptable toxicity or withdrawal from the study. Starting with an initial dose of 60 mg, dose escalation in a 3+3 design, and pre-determined PK assessments were applied. Adverse events (AEs) were graded by NCI-CTCAE v5.0. PK analysis was performed using a non-compartmental method. Efficacy was evaluated according to RECIST1.1. **Results:** As of January 18th 2021, thirteen patients were enrolled sequentially to Cohort-1 (60 mg, n = 2), Cohort-2 (120 mg, n = 1), Cohort-3 (180 mg, n = 3), Cohort-4 (240 mg, n = 4) and Cohort-5 (300 mg, n = 3), having gastrointestinal (n = 9), esophageal (n = 1), gallbladder (n = 1), lung (n = 1) and breast (n = 1) carcinomas. These patients had prior systemic antitumor standard therapies, including multi-line chemotherapy, radiation therapy, molecular targeted therapy, immunotherapy, or surgery. Twelve patients completed the cycle 1 safety observation period, with no cardiovascular toxicities or other DLTs observed. The MTD was not reached. Twelve patients experienced AEs possibly related to YL-13027. The most frequent related TEAEs (all grades/grade ≥3) were gamma-glutamyltransferase increased (38.5%/7.7%), haemoglobin decreased (38.5%/0%), blood alkaline phosphatase increased (23.1%/7.7%), aspartate aminotransferase increased (23.1%/0%) and blood phosphorus decreased (23.1%/0%). A maximum YL-13027 plasma concentration was reached within 2h post dose, and the mean elimination half-life was 4.2h in the steady state. Six subjects were evaluable for efficacy. One triple-negative breast cancer (TNBC) subject (Cohort-4) acquired a Partial Response (38.8% reduction of the target lesion), with the response exceeding 4 cycles, and YL-13027 treatment is continuing. The TNBC patient's tumor profile indicated genomic mutations of EGFL7p.Q256H(13.50%), TP53p.E51* (10.90%) and NF1p.L21V(8.70%) from the initial tumor specimen at diagnosis. **Conclusions:** YL-13027 is well tolerated and further clinical investigation is warranted. (Sponsor: Shanghai Yingli Pharmaceutical Co., Ltd.) Clinical trial information: NCT03869632. Research Sponsor: None.

3099 **Poster Session**

A phase Ib study of the PI3Kδ inhibitor linperlisib in patients with advanced solid tumors. *First Author: Jin Li, Shanghai East Hospital, Shanghai, China*

Background: Phosphatidylinositol-3 kinase (PI3K) pathways are important elements of tumor survival and progression, and PIK3C genes are often mutated or overexpressed in many cancers. Additionally, PIK3D (PI3Kδ) modulates immune cell functions in tumors, elaborating another PI3Kδ inhibition feature with a potential clinical benefit. Linperlisib, an oral and highly selective PI3Kδ inhibitor, demonstrated potent anti-tumor activity in syngeneic animals from previous research. In this Phase 1b study, the safety, tolerability, and efficacy of linperlisib is under investigation for patients with advanced solid tumors. **Methods:** Linperlisib was given orally once daily (QD) in 28-day cycle until disease progression, unacceptable toxicity, or withdrawal from the study. Adverse events (AEs) were graded by NCI-CTCAE v5.0. Efficacy was assessed according to RECIST1.1 criteria. **Results:** As of December 28, 2020, 70 patients were enrolled in the Phase1b study, with advanced cancers, including colorectal (n = 22), breast (n = 8), lung (n = 8), kidney (n = 5), liver (n = 4), ovarian (n = 1), head and neck (n = 5), and esophageal (n = 1) cancers; sarcomas, (n = 4), small intestinal stromal tumor (n = 3), thymic (n = 2), gallbladder (n = 2), gastric (n = 4), and pancreatic (n = 1) carcinomas. The patients were heavily pretreated with an average of 4 previous lines of therapy. Among the 70 patients, the most common nonhematologic TEAEs (all grades/grade≥3) were proteinuria (37.14%/0%), elevated aspartate aminotransferase (20%/0%), nausea (20%/0%), oral mucositis (2.8%/2.8%), diarrhea (2.8%/2.8%). The most common hematological TEAEs were leukopenia (24.28%/0%) and neutropenia (17.14%/4.28%). There were no unexpected toxicities in this study. Of 42 patients evaluable for response, the overall response rate was 2.38%. Notably, the disease control rate (DCR) was 45.24% from monotherapy treatment. One patient with thymic carcinoma obtained a partial response (80.8% reduction of the target lesion), with a duration of response of more than 6 cycles. The treatment of this subject is continuing. A lung adenocarcinoma subject reached radiological stable disease associated with 13.7% reduction in the target lesion and disease control for approximately 6 months. **Conclusions:** In this study, the PI3K inhibitor, linperlisib exhibited a favorable safety profile as was previously seen in lymphoma patients. Monotherapy treatment with linperlisib was observed to impart a high DCR in advanced solid cancers of many types. Available data from linperlisib and other PI3K inhibitors suggests that linperlisib may limit tumor growth directly, but also by affecting the tumor immune microenvironment. With these promising indications of clinical tolerability and activity, further investigation of linperlisib alone or in key therapeutic combinations is warranted. Antibiotic use reduces efficacy of tyrosine kinase inhibitors in patients with advanced melanoma and non-small cell lung cancer. *First Author: Nadina Tinsley, Christie Hospital, Manchester, United Kingdom*

Background: Antibiotic (ABX) use and disruption of the gut microbiome has been demonstrated to reduce the efficacy of immune checkpoint inhibitors and chemotherapeutics in cancer patients. Little is known about the impact of ABX use in patients treated with targeted therapies, such as tyrosine kinase inhibitors (TKI). **Methods:** Retrospective data analysis was performed on advanced melanoma and non-small cell lung cancer (NSCLC) patients treated with TKIs between January 2015 and April 2017 at The Christie NHS Foundation Trust, UK. Demographics, prior systemic treatment, extent of disease, lactate dehydrogenase level (LDH), presence of brain metastases, performance status, comorbidities, TKI agent and the use of ABX (class, route, duration) were collected. Progression free survival (PFS) and overall survival (OS) were compared between the ABX+ group (defined as patients treated with ABX within 2 weeks of TKI initiation or 6 weeks after) and the ABX$^-$ group (patients with no ABX during specified period). Statistical analyses were performed with univariate and multivariable models. **Results:** In total, 168 patients were included; 89 patients (53%) with advanced NSCLC and 79 patients (47%) with melanoma. Over a third of patients, (57/168, 34%) received ABX in the specified period (ABX+). On univariable analysis, ABX use was associated with shorter PFS (208 days vs 357 days, p = 0.008) and OS (294 days vs 438 days, p = 0.024). Increased age, poorer performance status, and higher LDH were also associated with shorter PFS and OS. On multivariable analysis, ABX use was independently associated with shorter PFS (HR 1.57, 95% CI 1.05-2.34, p = 0.028) and OS (HR 2.19, 95% CI 1.44-3.32, p = 0.0002). The negative impact of ABX on OS was particularly pronounced for patients with worse performance status (HR 3.82, 95% CI 1.18-12.36, p = 0.025). **Conclusions:** To our knowledge, this is the largest multivariable analysis showing ABX use independently reduces PFS and OS in patients treated with TKIs. It is the first analysis to demonstrate this phenomenon across two distinct tumour sites. The data suggests that ABX use could be an independent predictor of shorter PFS and OS in cancer patients treated with TKIs, and warrants further validation in a larger cohort. Research Sponsor: None.

A phase I study of an IDO inhibitor (SHR9146) plus camrelizumab and in combination with/without apatinib in patients with advanced solid tumors: Safety and efficacy analysis. *First Author: Ying Cheng, Jilin Cancer Hospital, Changchun, China*

Background: IDO is an enzyme of interest in immuno-oncology because of the immunosuppressive effects that result from its role in tryptophan catabolism. Clinical trials of IDO inhibitors with immunotherapy are under active investigation. The addition of angiogenesis inhibitor may further enhance the anti-tumor immune responses. Here we report the safety and efficacy results of SHR9146 (IDO inhibitor) plus camrelizumab (PD-1 antibody) with/without apatinib (VEGFR-2 inhibitor) in patients (pts) with advanced solid cancers who failed standard antitumor therapies. **Methods:** This was an open-label, phase I study. Eligible puts would receive SHR9146 (escalated dose) plus camrelizumab (200 mg IV, q2w) alone (Cohort A) or in combination with apatinib (250 mg p.o. qd) (Cohort B). Each cohort was conducted according to a 3+3 dose escalation design. The starting dose of SHR9146 was 100mg bid, followed by 200, 400, 600 mg bid. The two primary endpoints were Dose-limiting Toxicity (DLT) and Maximum Tolerated Dose (MDT). The secondary objective was to analysis the incidence of Adverse Events (AEs) and efficacy. **Results:** As of Oct 31, 2020, 23 pts have been enrolled (Cohort A:14, Cohort B: 9; median age: 54 years; median prior therapies: 2 lines;). Cohort A was escalating at 600mg, and Cohort B was escalating at 400mg. Two pts experienced DLTs: one DLT (G4 hypercalcemia) was observed at 600mg in Cohort A; the other DLT (G3 rash) was observed at 400mg in Cohort B. MDT was not reached and the study was still ongoing. In Cohort A, ORR and DCR in evaluable pts were 21.4% (3/14, all confirmed) and 42.9% (6/14) . Partial response was observed in 3 pts with liver cancer (1/3), renal cancer (1/3), and cervix cancer (1/3). In Cohort B, ORR and DCR in evaluable pts were 33.3%(3/9, all confirmed) and 77.8%(7/9). Partial response was observed in 3 pts with SCLC (1/3), prostate cancer (1/3) and renal cancer (1/3). The incidence of pts with TRAEs and grade>=3 TRAEs were 91.3% (21/23) and 39.1% (9/23) respectively. The most common grade>=3 TRAEs were hypercalcemia (26.1%, 6/23), fatigue (17.4%, 4/23) and nausea (13.0%, 3/23). No fatal AEs were observed. G3 nausea, G3 lipase increased and G2 GGT increased resulted in SHR9146 dose reduction in 3 pts (Cohort A). **Conclusions:** SHR9146 plus camrelizumab in combination with/without apatinib demonstrated promising anti-tumor activity with acceptable safety in pts with advanced solid tumors. Further study is needed to validate the efficacy and safety. Clinical trial information: NCT03491631. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

3102 **Poster Session**

Phase 1b/2 SEASTAR trial: Safety, pharmacokinetics, and preliminary efficacy of the poly(ADP)-ribose polymerase (PARP) inhibitor rucaparib and angiogenesis inhibitor lucitanib in patients with advanced solid tumors. *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Lucitanib is an oral, potent tyrosine kinase inhibitor that selectively inhibits VEGFR1–3, PDGFRα/β, and FGFR1–3. In preclinical studies, antitumor activity of rucaparib is enhanced by lucitanib through antiproliferative, antiangiogenic, and immunological mechanisms. We hypothesize that combining lucitanib and rucaparib is tolerable and can induce a higher hypoxic state and homologous recombination repair deficiency that may lead to greater sensitivity to PARP inhibition. **Methods:** Patients with advanced solid tumors who had ≥1 prior line of therapy were eligible. Patients with *BRCA1/2*-mutated ovarian cancer must have received prior PARP inhibitor. Rucaparib and lucitanib were escalated using a 3+3 phase 1b dose-escalation design from starting doses of 300 mg BID and 4 mg QD, respectively. Dose-limiting toxicities (DLTs) were assessed during the first 28 days of treatment. Plasma samples were collected for pharmacokinetic analyses. Genomic alterations were identified by local testing, or through central testing of plasma or tumor tissue. **Results:** As of February 1, 2021, 16 patients were treated with rucaparib + lucitanib and included in the analyses (Table). Patients had a median of 4 prior therapies; 1 patient had prior PARP inhibitor (olaparib) treatment. Median time on treatment was 58.5 days, with 2 patients ongoing as of the data cutoff date. A DLT of grade 3 proteinuria was seen in Cohort 1; no other DLTs have been reported. Across all cohorts, the most common any-grade treatment-emergent adverse events were nausea (n=9; grade ≥3, n=1), hypertension (n=8; grade ≥3, n=2) and ALT/AST increased (n=7; grade ≥3, n=3). Initial pharmacokinetic data indicated no drug interactions between the 2 agents. To date, 1 patient in Cohort 1 with *PALB2*-mutated advanced endometrial cancer had a confirmed partial response per RECIST v1.1, lasting 30 weeks; 6 patients had RECIST v1.1 stable disease (SD), including 1 patient each in Cohorts 1 and 3 with SD for ≥16 weeks. In addition, 1 patient in Cohort 2 with *BRCA2*-mutated castration-resistant prostate cancer continued to receive treatment despite initial progressing bone metastases, resulting in a prostate-specific antigen response (≥50% change) lasting 16 weeks and a best change in sum of target lesions of −46.3%. **Conclusions:** Initial findings suggest that rucaparib + lucitanib has an acceptable safety profile. The safety and efficacy of the combination are being further evaluated. Clinical trial information: NCT03992131. Research Sponsor: Clovis Oncology, Inc.

Cohort	n	Rucaparib (BID)	Lucitanib (QD)	HRR gene mutations identified
1	6	300 mg	4 mg	1 BRCA1, 1 BRCA2, 1 ATM, 1 PALB2, 1 RAD51B
2	4	400 mg	4 mg	1 BRCA2
3	3	400 mg	6 mg	2 CDK12
4	3	600 mg	6 mg	None*

*Based on local testing results only. BID, twice daily; QD, daily; HRR, homologous recombination repair.

3103 **Poster Session**

A phase Ib trial of ERK inhibition with ulixertinib combined with palbociclib in patients (Pts) with advanced solid tumors. *First Author: Alison L. Raybould, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Activating *KRAS* mutations are the most frequently detected aberrant oncogenes in pancreatic adenocarcinoma. Combination strategies to target the downstream RAF-MEK-ERK effector pathway are a rational approach. Preclinical data with ERK and CDK4/6 inhibition in both pancreatic cancer cell lines and xenografts demonstrates synergistic cell death and tumor growth suppression. Ulixertinib (BVD-523) is an oral small molecule inhibitor of ERK1/2. This phase 1b study evaluated the safety, pharmacokinetics, and early clinical efficacy of ulixertinib when combined with the oral CDK4/6 inhibitor palbociclib in pts with advanced solid tumors. **Methods:** Using a 3+3 design, pts received ulixertinib at a starting dose of 300mg (range 300-600mg) twice daily continuously with palbociclib at a starting dose of 75mg (range 75-125mg) on D1-21 out of a 28 day cycle. The primary objective was to establish the maximum tolerated dose (MTD) of the combination. Secondary objectives included characterizing safety and estimating progression free survival (PFS). Dose limiting toxicities (DLTs) were evaluated during the first cycle of treatment. Adverse events were graded by CTCAE v4.03. Response was evaluated after 2 cycles (8 weeks) by RECIST 1.1 criteria. **Results:** 26 pts were enrolled (13 colorectal, 9 pancreas, 2 melanoma, 1 cholangiocarcinoma, 1 GIST); 16 were evaluable for response. The MTD of the combination was ulixertinib 450mg BID and palbociclib 125mg daily. DLTs included grade 3 fatigue, grade 3 acute kidney injury and grade 3 hyponatremia (Table). Due to toxicity in cohort 3, the protocol was amended to include two additional cohorts (2A and 2B) with a reduced dose of ulixertinib and increasing doses of palbociclib. The most common treatment-related adverse events (TRAEs) (all grades) were fatigue (70%), rash (62%) and nausea (54%). The most common laboratory TRAEs were decreased lymphocyte count (77%), decreased WBC count (73%) and anemia (65%). Grade 3 TRAEs were decreased WBC count, decreased lymphocyte count, anemia and fatigue. No grade 4/5 TRAEs were reported. Three pts demonstrated stable disease (SD). For this heavily pre-treated pt population, PFS was 2.05 months (95% CI 1.87, not determined). PK analysis for ulixertinib and palbociclib was linear and consistent with previously reported data; no drug-drug interactions were observed. **Conclusions:** The MTD of this phase Ib study of advanced solid tumor pts was ulixertinib 450mg BID combined with palbociclib 125 mg daily. At this dosing, 2 pts demonstrated SD, one with pancreatic cancer and one with cholangiocarcinoma. An expansion cohort of metastatic pancreatic cancer pts is ongoing. Clinical trial information: NCT03454035. Research Sponsor: BioMed Valley Discoveries, Inc, Pharmaceutical/Biotech Company.

Dose Level	Ulixertinib (mg)	Palbociclib (mg)	Total Pts	DLT
1	300	75	4	0
2	450	100	3	0
3	600	75	8	2–Gr 3 fatigue Gr 3 AKI

3104 **Poster Session**

Phase 1/2 first-in-human (FIH) study of CPI-0209, a novel small molecule inhibitor of enhancer of zeste homolog 2 (EZH2) in patients with advanced tumors. *First Author: Nehal J. Lakhani, START Midwest, Grand Rapids, MI*

Background: Enhancer of Zeste homolog 2 (EZH2) is a histone methyltransferase and the catalytic subunit of Polycomb Repressive Complex 2 (PRC2). EZH2 is frequently overexpressed in cancers and correlates with poor prognosis. CPI-0209 is an oral, small molecule, second-generation, selective inhibitor of EZH2 designed to achieve comprehensive target coverage through extended on-target residence time. The compound demonstrates more potent anti-tumor activity in preclinical cancer models, compared to first-generation EZH2 inhibitors. CPI-0209 is currently being evaluated in a Phase 1/2, open-label, FIH study (NCT04104776). **Methods:** Patients (pts) with advanced tumors were enrolled in a 3+3 design. Primary objective is to determine maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D) of CPI-0209. Secondary objectives are to evaluate the safety, PK, and PD in pts who received CPI-0209 QD in 28 days cycles (C). **Results:** As of December 16, 2020, 33 pts were treated: pancreatic cancer (n = 6), mesothelioma, breast, colorectal, and ovarian cancer (n = 5 each), leiomyosarcoma, melanoma, cholangiocarcinoma, prostate, bladder, endometrial clear cell and gastric cancer (n = 1 each). Pts received CPI-0209 at 50 mg (n = 4), 100 mg, 137.5 mg, and 187.5 mg (n = 6 each), 225 mg (n = 7), and 275 mg (n = 4) daily dose. Median treatment duration was 43 days (range 1-239); 4 pts are ongoing. Median age was 64 yrs (range 24-79); 15 (45%) pts were male. Patients were heavily pretreated, with 67% of pts had ≥ 3 prior lines of therapy. No dose limiting toxicities have been observed. The most frequent treatment-emergent adverse events (TEAEs) (≥10%) were fatigue (27%), diarrhea (24%), nausea (21%), abdominal pain, alopecia, anemia, thrombocytopenia, and dysgeusia (15% each), and vomiting, headache, decreased appetite, and alkaline phosphatase increased (12% each); usually grade 1 or 2 in severity. Thrombocytopenia was dose-dependent and not associated with bleeding or clinical sequalae. Three pts (9%) discontinued CPI-0209 due to TEAEs. Comprehensive target engagement (assessed by global reduction in H3K27me3 levels in monocytes) was observed within the first cycle at all dose levels. CPI-0209 also increased the expression of PRC2-controlled gene sets in blood in a dose-dependent manner. Updated safety, PK, PD, and preliminary efficacy results from Phase 1 will be presented. **Conclusions:** CPI-0209 achieved robust PD effects and a PK-PD relationship has been established. CPI-0209 monotherapy was generally well tolerated, and treatment related AEs were manageable and reversible. The MTD has not been reached. Clinical trial information: NCT04104776. Research Sponsor: Constellation Pharmaceuticals.

3105 **Poster Session**

Inhibition of histone lysine demethylases with TACH101, a first-in-class pan-inhibitor of KDM4. *First Author: Chandtip Chandhasin, Tachyon Therapeutics, Houston, TX*

Background: The KDM4 family of histone lysine demethylases consists of four main isoforms (KDM4A, B, C, D), all of which have been identified as key oncogenic drivers. They function as epigenetic regulators and control transitions between transcriptionally silent and active chromatin states via removal of methyl marks on histone H3K9 and histone H3K36. KDM4 isoforms play an important role in the epigenetic dysregulation in various cancers and is linked to more aggressive disease and poorer clinical outcomes. Functional redundancy and cross-activity have been observed across KDM4 family members, thus, selective inhibition of one isoform appears to not be effective. TACH101 is a novel, first-in-class pan inhibitor of KDM4 that simultaneously targets multiple isoforms of KDM4. Here we present data that show TACH101 has promising pre-clinical and pharmacologic properties as a cancer therapeutic. **Methods:** TACH101 was evaluated in *in vitro* and *in vivo* studies including cell-proliferation assays in multiple cancer cell lines, apoptotic and cell cycle analyses, and efficacy studies in various xenograft tumor models and patient-derived organoid models. **Results:** *In vitro*, TACH101 was broadly effective in killing 67% (200 out of 300) of cancer cell lines screened. TACH101 demonstrated potent increase of H3K36me3 levels (EC50 < 0.001 mM, HTRF) in KYSE-150 cell line engineered to overexpress KDM4C and potent anti-proliferative activity in multiple cell lines in OncoPanel. TACH101 treatment increased cancer cell population in S-phase in multiple cancer cell lines indicating cell-cycle arrest. TACH101 induced apoptosis in human colorectal (HT-29), esophageal (KYSE-150), and triple negative breast cancer (MDA-MB-231) cell lines with EC50s ranging from 0.033-0.092 μM. *In vivo*, TACH101 triggered effective tumor control in xenograft models including colorectal, esophageal, gastric, breast, and lymphoma with tumor growth inhibition of up to 100%. Further evaluation using a panel of patient-derived colorectal models and patient-derived organoids showed a strong correlation of TACH101 sensitivity with MSI-H status (IC50 ranges 1-150 nM). TACH101 also reduced tumorigenic potential by 4.4-fold as determined by FACS analysis using sorted CD44High EpCAM+ population in Limiting Dilution Assays *in vivo*, suggesting that reduction of cancer stem cells by TACH101 may be effective in therapy-resistant settings. Pharmacologic studies showed TACH101 demonstrated favorable cell permeability, good oral bioavailability, and high metabolic stability. **Conclusions:** Extensive preclinical work on TACH101 KDM4 inhibitor shows compelling data and broad applicability as a potential anti-cancer agent. Further evaluation is ongoing to advance the molecule into clinical trials. Research Sponsor: Tachyon Therapeutics.

3106 **Poster Session**

WX390, a high-potent PI3K-mTOR dual inhibitor, first-in-human (FIH) phase I study in advanced relapsed or refractory solid tumor, and lymphoma. *First Author: Wenbo Tang, Department of Medical Oncology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China*

Background: WX390 is a high potent PI3K-mTOR dual inhibitor targeting pan-PI3K and mTOR. WX390 exhibited anti-tumor activity and high potency in xenograft models with inhibition of AKT phosphorylation. **Methods:** Patients (pts) with advanced lymphoma and solid tumors who have failed standard therapies were enrolled in dose escalation cohorts and received WX390 administered daily orally in 28-day cycles until confirmed progressive disease, intolerable toxicity or withdrawal of consent. Plasma samples were collected up to 7 days after the first dose and up to 24 hours at C1D28. **Results:** As of the cut-off date 2021 Feb 10, 25 patients (median age 52 years) were enrolled in 6 dose levels (0.1mg, 0.2mg, 0.4mg, 0.7mg, 1.1mg and 1.4mg) of the dose-escalation cohorts. Cohorts 0.1 mg to 1.1 mg were completed without dose-limiting toxicities (DLT), cohort 1.4 mg was completed with 1 DLT (Diabetic ketoacidosis combined with grade 3 hyperglycemia) out of 4 evaluable patients. Common treatment-related adverse events (TRAEs) (all grades, ≥20%) included hyperglycemia (20 pts, 80%), proteinuria (10 pts, 40%), creatinine increased (11 pts, 44%), hypophosphatemia (10 pts, 25%), anemia (8 pts, 33.3%), thrombocytopenia (7 pts, 29.2%), and aspartate aminotransferase increased (25%). Grade≥3 TRAEs were hyperglycemia (7 pts, 28%, 1 pt combined with diabetic ketoacidosis), hypophosphatemia (2 pts, 8%), neutropenia (2 pts, 8%), dermatitis (1 pt, 4%), and maculopapular rash (1 pt, 4%). PK showed fast absorption (Tmax 0.5-4 h) and dose proportionality for Cmax and $AUC_{0-\infty}$. The mean multiple dose $T_{1/2}$ was approximately 12.4 hours across all cohorts with minimum accumulation. Among 14 tumor response evaluable patients, there were 3 patients with confirmed PIK3CA mutation. All 3 patients experienced tumor shrinkage and were still on treatment by the cut-off date. 2 (1 pt with head and neck cancer and 1 pt with cervical cancer) of them have achieved partial response (PR). The head and neck cancer patient (PR) was treated with WX390 0.7mg/day without any severe AE and the duration of response was beyond 15 months. Stable disease (SD) was observed in 6 patients (n = 5 with unknown PIK3CA mutation status and n = 1 with confirmed PIK3CA mutation). Of note, 1 patient (follicular lymphoma) treated with 0.1mg experienced SD for 14 months. Another patient (SD, head and neck cancer with PIK3CA mutation) experienced tumor shrinkage for more than 8 months and was still receiving WX390 treatment by the cut-off date. **Conclusions:** the PI3K-mTOR dual inhibitor WX390 was well tolerated with manageable safety profile, and showed encouraging antitumor activity. A RP2D of 1.1 mg qd is selected to be explored for different indications in solid tumor clinical studies. Clinical trial information: NCT03730142. Research Sponsor: Shanghai Jiatan Pharmatech CO., LTD.

3107 **Poster Session**

First-in-human dose-finding study of venadaparib (IDX-1197), a potent and selective PARP inhibitor, in patients with advanced solid tumors. *First Author: Yong Man Kim, Asan Medical Center, University of Ulsan, Seoul, South Korea*

Background: Poly ADP-ribose polymerase (PARP) is an enzyme that is central to the repair of DNA replication errors known as single-strand breaks (SSBs). PARP inhibitors are currently approved for ovary, breast, pancreatic and prostate cancers which harbor germline or somatic BRCA1/2 mutations (g/sBRCAmt) and/or homologous recombinant repair mutation (g/sHRRmt). In this phase 1 dose finding study of venadaparib, we determined the maximum tolerated dose for venadaparib monotherapy and explored the safety, tolerability, pharmacokinetics, pharmacodynamics and anticancer efficacy of venadaparib in patients with advanced solid tumor which progressed after an attempt of standard-of-care therapy and for which effective therapy does not exist. **Methods:** Subjects who satisfied all of the inclusion/exclusion criteria and provided written informed consent were enrolled in this study. The investigational product was administered orally once daily continuously in a 3 weekly cycle. Enrolled subjects were assessed for safety and evaluated on tumor response using RECIST 1.1. The study was carried out in a conventional 3+3 design, starting from 2 mg up to 240 mg. Dose limiting toxicities (DLTs) and pharmacokinetics were assessed during the first cycle. **Results:** As of 08 Feb 2021, enrollment is completed with 32 patients enrolled. Most common tumor types enrolled are breast cancer (16 patients) and ovarian cancer (11 patients). Other tumor types include cancers of endometrium, fallopian tube, uterus and prostate. No DLTs were observed up to the maximum tested dose of 240 mg. Frequently observed adverse drug reactions were as follows – Anemia (56%), nausea (38%) and neutropenia (25%). Overall objective response rate (ORR) was 16% and clinical benefit rate (CBR) was 47%. Partial response was observed starting from 40 mg and clinical benefit was observed from the lowest dose of 2 mg. From optional tumor tissue samples, venadaparib exhibited ≥ 90% PAR inhibitory effect in pharmacodynamic analysis from 10 mg. For patients with known germline or somatic BRCA status either from local lab results or examined at a central lab retrospectively, ORR and CBR was 22% and 44% respectively for BRCAm(+) (9) patients. Interestingly, clinical efficacy was observed in BRCAm(-) (18) patients also, with ORR and CBR of 17% and 50% respectively. **Conclusions:** Safety and tolerability of the venadaparib monotherapy was confirmed with preliminary efficacy signals observed, even in BRCAm(-) patients. Clinical benefit was observed from the lowest tested dose, suggesting the potential to combine with other chemotherapeutic agents. Further studies to explore efficacy and safety of venadaparib in other tumor types and combinations, as well as to explore adequate biomarkers are warranted. Clinical trial information: NCT03317743. Research Sponsor: Idience Co. Ltd, Other Government Agency.

3108 **Poster Session**

Long-term efficacy and safety of larotrectinib in an integrated dataset of patients with TRK fusion cancer. *First Author: David S. Hong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions encode tropomyosin receptor kinase (TRK) fusion proteins, which are oncogenic drivers in various tumor types. Larotrectinib is a first-in-class, highly selective, CNS-active TRK inhibitor approved to treat adult and pediatric patients with TRK fusion cancer. Larotrectinib demonstrated an objective response rate (ORR) of 78% and a median progression-free survival (PFS) of 36.8 months in an integrated analysis of 175 patients with non-primary CNS TRK fusion cancer (McDermott et al, ESMO 2020). We report updated efficacy and safety data with longer follow-up in an expanded dataset. **Methods:** Data were pooled from three clinical trials of patients with non-primary CNS TRK fusion cancer treated with larotrectinib. Larotrectinib was administered until disease progression, withdrawal, or unacceptable toxicity. Response was assessed by investigators using RECIST v1.1. Data cutoff: July 20, 2020. **Results:** As of data cutoff, 218 patients were treated with larotrectinib, of which 206 were evaluable for efficacy. There were 21 different tumor types, the most common being soft tissue sarcoma (STS [46%], including infantile fibrosarcoma [20%] and other STS [26%]), thyroid (13%), salivary gland (11%), lung (9%), and colorectal (5%). The median age was 38.0 years (range 0.1–84.0). Patients were heavily pretreated with 45% having received 2 or more prior lines of systemic therapy; 27% had 0 prior lines of systemic therapy. The ORR was 75% (95% CI 68–81): 45 (22%) complete response, 109 (53%) partial response (PR), 33 (16%) stable disease (SD), and 13 (6%) progressive disease (PD). Nineteen patients had brain metastases at baseline, with 15 evaluable for efficacy. The ORR for patients with brain metastases was 73% (95% CI 45–92): 11 PR, 2 SD, and 2 PD. Among all evaluable patients, the median time to response was 1.8 months (range 0.9–9.1). With a median follow up of 22.3 months, the median duration of response was 49.3 months (95% CI 27.3–not estimable). Treatment duration ranged from 0.03+ to 60.4+ months. Median PFS was 35.4 months (95% CI 23.4–55.7) with a median follow up of 20.3 months. At a median follow-up of 22.3 months, median overall survival (OS) was not reached and 36-month OS was 77% (95% CI 69–84). Treatment-related adverse events (TRAEs) were mainly Grade 1–2, with 18% having Grade 3–4 TRAEs. Only 2% of patients discontinued due to TRAEs. **Conclusions:** These results highlight the importance of testing for *NTRK* gene fusions in patients with cancer because the majority of patients with TRK fusion cancer treated with larotrectinib had long-term clinical benefit. The safety profile continued to be favorable and no new safety signals were identified. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: Bayer HealthCare and Loxo Oncology.

PARALLEL 303: Phase 2 randomized study of pamiparib vs placebo as maintenance therapy in patients (pts) with inoperable locally advanced or metastatic gastric cancer that responded to platinum-based first-line (1L) chemotherapy. *First Author: Fortunato Ciardiello, Second University of Naples, Department of Clinical and Experimental Medicine, Naples, Italy*

Background: A subset of gastric cancers exhibits platinum sensitivity and genomic instability that is characteristic of homologous recombination deficiency (HRD). Cells with HRD are sensitive to poly (ADP-ribose) polymerase (PARP) inhibition. PARP inhibitor maintenance therapy following platinum-based chemotherapy has been a successful treatment strategy in pts with ovarian cancer. Pamiparib is an orally administered selective PARP protein 1 and 2 (PARP1/2) inhibitor that has shown potent DNA-PARP trapping activity and crosses the blood brain barrier in preclinical studies. In early phase clinical studies (NCT02361723; NCT03333915), pamiparib showed an acceptable safety profile and promising antitumor activity. PARALLEL 303 compared the efficacy and safety of pamiparib vs placebo as maintenance therapy in pts with inoperable locally advanced or metastatic gastric cancer that responded to platinum-based 1L chemotherapy. **Methods:** The primary endpoint of this double-blind, randomized, global phase 2 study (NCT03427814) was progression-free survival (PFS) as determined by the investigator per RECIST Version 1.1. Key secondary endpoints included time to subsequent treatment, objective response rate, duration of response, time to response, overall survival (OS) and safety. At the time of this analysis, OS data were immature due to the short duration of study. Data presented here will focus on PFS and safety. **Results:** 136 pts were randomized 1:1 to receive pamiparib 60 mg orally (PO) twice daily (BID) (n=71) or placebo PO BID (n=65) in 28-day cycles. The median PFS was longer with pamiparib vs placebo, but did not reach statistical significance (3.7 months; 95% CI, 1.94–5.26 vs 2.1 months; 95% CI, 1.87–3.75 months); hazard ratio 0.799 (95% CI, 0.534–1.193; P=0.1428). Treatment-emergent adverse events (TEAEs) of ≥ Grade 3 were experienced by 29 pts (40.8%) in the pamiparib arm, and 20 pts (30.8%) in the placebo arm. The most common TEAEs of ≥ Grade 3 were blood and lymphatic system disorders in the pamiparib arm, and gastrointestinal disorders in the placebo arm. TEAEs leading to treatment discontinuation were: 8 pts (11.3%) in the pamiparib arm and 2 pts (3.1%) in the placebo arm. TEAEs leading to death were: 2 pts (2.8%; 1 pneumonia, 1 unexplained) in the pamiparib arm, and 2 pts (3.1%; 1 hepatic rupture, 1 sepsis) in the placebo arm. **Conclusions:** Although pamiparib did not meet statistical significance for superiority vs placebo for its primary endpoint, it was generally well tolerated with few treatment discontinuations due to TEAEs. No new safety signals were identified with pamiparib, and its safety profile was consistent with that of other PARP inhibitors. Clinical trial information: NCT03427814. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Yasmin Issop, PhD, and Shannon Galgani, MSci, of Ashfield Medcomms, an Ashfield Health Company, and funded by BeiGene, Ltd.

3110 **Poster Session**

Biomarker results supporting selection of RP2D from a phase 1b study of ORIC-101, a glucocorticoid receptor antagonist, in combination with nab-paclitaxel in patients with advanced solid tumors. *First Author: Anneleen Daemen, 240 E. Grand Ave., South San Francisco, CA*

Background: Preclinical studies have shown that activation of the glucocorticoid receptor (GR) leads to resistance to chemotherapeutics (eg taxanes) and antiandrogens across multiple tumor types, while GR inhibition enhances therapeutic efficacy. ORIC-101 is a potent, selective, and orally bioavailable small molecule GR antagonist undergoing clinical development in combination with nab-paclitaxel in patients with advanced solid tumors and in combination with enzalutamide in patients with metastatic prostate cancer. **Methods:** 21 patients were enrolled in the dose escalation portion of the phase 1b study, which evaluated both intermittent (5 days on, 2 days off for 21 days) and continuous dosing regimens of ORIC-101 across 5 cohorts (NCT03928314). Tumor tissue was obtained pre-treatment for 19 out of 21 patients, and on study or at the end of treatment for 11 patients. GR protein status was retrospectively evaluated using a proprietary IHC assay optimized for staining nuclear GR in the epithelial compartment of major tumor type tissues. Biopsies were also profiled with RNA-seq to evaluate a proprietary GR activation signature as a potentially predictive and pharmacodynamic (PD) biomarker. Blood-derived peripheral blood mononuclear cells (PBMCs) were collected for 20 patients along with the pre-treatment biopsy, in the morning of days 1, 5 and/or 8 of Cycle 1, and 2.5 or 6 hours after ORIC-101 administration. Blood cortisol levels were also simultaneously measured. PD modulation in PBMCs was assessed by RT-qPCR for biomarkers FKBP5, GILZ and PER1, selected for their consistent stimulation by GR and reversal with ORIC-101 in preclinical studies and observed PD modulation in healthy volunteers administered ORIC-101. **Results:** Nuclear GR protein was detected in most pre-treatment biopsies regardless of tumor type, and on treatment reduction of GR protein was observed across dose levels. At physiological systemic cortisol levels, ORIC-101 demonstrated PD suppression in PBMCs on days 1, 5 and 8 in the majority of patients. Cortisol levels increased post-dose in these patients due to negative feedback between cortisol and GR. Steady-state target engagement was not consistently demonstrated with the intermittent regimen. In healthy volunteer studies of ORIC-101, steady-state target suppression was consistently achieved after 7 consecutive daily doses of 200 or 350 mg of ORIC-101. Thus, continuous ORIC-101 administration was selected as the recommended phase 2 dose (RP2D) regimen, aimed at achieving sustained GR suppression for optimal chemotherapy re-sensitization. **Conclusions:** Biomarker data from patients enrolled in the phase 1b study provide evidence of on-target tumor cell eradication and PD modulation and support the RP2D and the tumor types selected for the ongoing dose expansion portion of the study. Clinical trial information: NCT03928314. Research Sponsor: ORIC Pharmaceuticals.

Institutional experience with *nab*-sirolimus in patients with malignancies harboring *TSC1* or *TSC2* mutations. *First Author: Mark Andrew Dickson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *TSC1*/*TSC2* genes are tumor suppressors in the mTOR pathway; mutated at low frequency across tumor types (~1–2%). Retrospective analyses of patients (pts) with mTOR pathway mutations treated with everolimus did not show improved outcomes vs the wild type (Voss et al. Clin Cancer Res 2019. PMID 30327302). In NCT02201212, pts with *TSC1/TSC2* mutations treated with everolimus had a 7% (2/30) response rate. In the AMPECT study, pts with advanced PEComa treated with a novel mTOR inhibitor (mTORi), *nab*-sirolimus (*nab*-S, ABI-009), the subset of pts with *TSC1/TSC2* mutations had a response rate of 64% (9/14) (Wagner et al. CTOS 2020. #3463014). In a xenograft model, *nab*-S showed significantly higher tumor accumulation, target suppression (pS6) and antitumor activity vs everolimus or sirolimus (Hou et al. AACR 2019. #348). In an expanded access program (NCT03817515), pts with advanced tumors bearing *TSC1/ TSC2* mutations were treated with *nab*-S and outcomes in pts with malignancies other than PEComa are reported herein. **Methods:** Eligible pts (ECOG 0–2) received *nab*-S 100 mg/m^2 IV, once weekly for 2 of every 3 weeks at 3 US sites between 7/2019 and 11/2020. **Results:** 7 pts with *TSC1*/*TSC2* mutations have been consecutively enrolled and are reported here. 6/7 pts had multiple prior therapies including 2 pts previously progressing on an mTORi. 4/7 pts had partial response (PR), all in mTORi naïve pts. 2/7 pts had stable disease (SD). In 2 pts previously treated with an mTORi, 1 had SD and 1 came off treatment after 1 cycle (CA125 ↑) with no follow-up scan. Treatment-related serious adverse events (SAEs; hyperglycemia and infection) and dose reduction were reported in 1 pt with metastatic angiosarcoma; SAEs resolved and the pt continued Rx. No other SAE or dose limiting event was reported **Conclusions:** Patients with various malignancies bearing *TSC1* or *TSC2* mutations, most with progression on multiple prior therapies, showed evidence of response and manageable toxicities during treatment with *nab*-S. A basket trial of *nab*-S in malignancies with *TSC1/TSC2* mutations is planned. Clinical trial information: NCT03817515. Research Sponsor: Study sponsored by Aadi Bioscience, Inc.

Pt#	Tumor Type	Relevant mutation	Prior Therapy	Treatment, months	Best Response[1] to nab-Sirolimus
1	Endometrial stromal sarcoma	TSC2	Exemestane, letrozole, fulvestrant	9.8+	PR
2	Epithelial ovarian cancer	TSC1	Cisplatin/paclitaxel, bevacizumab, carboplatin, liposomal doxorubicin, gemcitabine	9.6+	PR
3	Angiosarcoma	TSC1	Doxorubicin, ifosfamide, paclitaxel	5.6+	SD[2]
4	High grade sarcoma	TSC2	Doxorubicin, ifosfamide, gemcitabine, docetaxel, pazopanib, pembrolizumab	4.3+	PR
5	Epithelial ovarian cancer	TSC2	Liposomal doxorubicin, carboplatin, bevacizumab, gemcitabine, enzalutamide, sapanisertib (mTORi)	0.7	No scan
6	Endometrial cancer	TSC2	Anastrozole, leuprolide, sirolimus	2.9+	Mixed response SD
7	Lymphangioleiomyoma	TSC2	None	4.3+	PR

Dosing, drug reduction, drug interruption, and drug discontinuation rates among U.S. FDA approved tyrosine kinase inhibitors. *First Author: Neha K. Reddy, Dell Medical School, The University of Texas at Austin, Austin, TX*

Background: The advent of tyrosine kinase inhibitors (TKIs) has altered the therapeutic landscape of multiple hematological and solid malignancies. FDA approved starting doses of TKIs are based on the recommended phase 2 dose (RP2D) in clinical trials. Since many of these drugs are continuously dosed, ongoing toxicities may lead to drug reductions and drug discontinuations. Hence in practice, many patients are started on lower doses due to tolerability concerns or are dose-reduced subsequently for toxicity. Herein, we assessed the dosing, drug reduction rates, and drug discontinuation rates among FDA approved TKIs. **Methods:** We established a database of all FDA approved TKIs from the FDA online label repository. We extracted descriptive data for indications and usage, type of approval, approval dosage, dose reduction recommendation, median age, dose reduction rates, drug discontinuation rates, dose modification, warnings, adverse reactions, clinical trial experience, and geriatric use above 65 yrs and 75 yrs. **Results:** TKIs were approved for 143 different indications, ranging from 1 indication to 11 indications (eg. Imatinib) from data arising from 7 patients to 2816 patients for a specific indication. Among all TKIs, median dose was 150 mg and average dose was 237 mg; 34 (23.8%) were approved bid vs 71 (49.7%) qd. Specifically for oncology, 54 indications were biomarker based (eg. EGFR mutant NSCLC) and 52 were non-biomarker based for specific diseases (eg. metastatic RCC). Among approved indications range of dose reduction rate (DRR), drug interruption rates (DIR), drug discontinuations rates (DDR) were 0.80-89%, 3%-89%, and 1-39% respectively. Most common reasons for DRR, DIR, and DDR were diarrhea, fatigue, nausea, vomiting, hepatotoxicity, rash, and hypertension. Geriatric use was listed in 99 indications ($>$ 65 yrs, 6-68%; $>$ 75 yrs, 0.50-24%). Patient reported outcomes were not available. **Conclusions:** TKIs have a variable dose reduction and drug discontinuation rate. Clinical trials should evaluate multiple dosing regimens and schedules to lessen the toxicity burden and improve QOL in patients. Future studies are warranted to look into flat dosing vs alternative dosing, like weight-based dosing for TKIs, and to report patient reported outcomes. Research Sponsor: None.

3113 **Poster Session**

A phase I dose-escalation and expansion study of JPI-547, a dual inhibitor of PARP/tankyrase in patients with advanced solid tumors. *First Author: Seock-Ah Im, Seoul National University Hospital, Seoul, South Korea*

Background: JPI-547 is an oral inhibitor of PARP 1/2 and Tankyrase 1/2. JPI-547 demonstrated anti-tumor activity in BRCA-deficient xenograft models as a single-agent and in combination with chemotherapy and immune checkpoint inhibitors. **Methods:** This is the first in human (FIH) phase I study of JPI-547 in patients (pts) with advanced solid tumors. For the dose escalation phase, a 3+3 design was used with 4 doses from 50 to 200 mg QD on 21-day cycles. Primary objectives were to assess safety and tolerability to determine RP2D, and secondary objectives included pharmacokinetics and preliminary antitumor activities. DLT monitoring period was 21 days. Pharmacodynamics and information of HRR mutation were also explored. For the dose expansion phase, pts with documented pathogenic germline or somatic BRCA/HRR mutations were enrolled to assess the preliminary efficacy and safety. Tumor response (RECIST 1.1) was evaluated every 6 weeks. Centralized germline BRCA testing was conducted to confirm pathogenic gBRCA mutations. Results available at the cut-off date of 31-Dec-2020 are presented. **Results:** For dose escalation phase, 22 pts were enrolled. JPI-547 was well absorbed with T_{max} of 0.25-8 h post-dose and apparent half-life of 18-31 h. Mean C_{max} and AUC increased proportionally (within the dose range of 50-200 mg). PAR level measured from PBMC was 53% inhibited at C_{max}. One DLTs was observed at 100 mg (elevated ALT, G3) and 200 mg (elevated ALT/AST, G3) respectively. MTD was determined as 200 mg after considering DLTs and myelosuppression observed from cycle 2. RP2D was determined to be 150 mg based on the pharmacokinetic data and safety. Thirteen pts (59.1%) had at least one grade 3/4 TRAE and 12 had dose interruption/reduction due to TRAE. The most common ($>$ 20%) TRAE were anemia, thrombocytopenia and neutropenia. In dose expansion phase, 40 pts were enrolled, and response was evaluable in 39 pts. The best overall responses were 11 confirmed PR (cPR) and 15 SD with ORR of 28.2% (11/39) and DCR of 64.1 % (25/39). The mPFS was 3.5 mos and mDoR was 3.4 mos. At the time of data cut-off, three pts were ongoing as following response and cancer types: cPR (breast, ATMm, 9.0 mos), cPR (NSCLC, gBRCA2m, 3.8 mos) and SD (breast, gBRCAm, 9.3 mos). Five pts (2 ovarian, 3 breast) previously treated with olaparib and discontinued due to progressive disease were enrolled in this JPI-547 trial and one ovarian cancer pt showed cPR with 37% tumor shrinkage. **Conclusions:** These results demonstrate that JPI-547 is adequately absorbed with acceptable safety profile. Preliminary efficacy results suggest that JPI-547 monotherapy is effective in pts with BRCA/HRR mutation. Further investigation is warranted in pts with solid tumor including PARP inhibitor resistant cases. Clinical trial information: NCT04335604. Research Sponsor: National OncoVenture (Korea).

Intra-patient comparison from larotrectinib clinical trials in TRK fusion cancer: An expanded dataset. *First Author: David S. Hong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Larotrectinib is a highly selective, CNS-active tropomyosin receptor kinase (TRK) inhibitor that demonstrated rapid and durable responses in three phase I/II single-arm studies of patients (pts) with TRK fusion cancer. In single-arm studies the growth modulation index (GMI) can be used to provide a comparative analysis. GMI is an intra-patient comparison that uses pts as their own control by comparing progression-free survival (PFS) on current therapy to time to progression or treatment failure (TTP) on the most recent prior therapy; namely the ratio of PFS/TTP (EMA Guidelines. Guideline on the Evaluation of Anticancer Medicinal Products in Man, EMA/CHMP/205/95 Rev.5). A GMI ratio $\geq$1.33 has been used as a threshold of meaningful clinical activity. In a previous analysis of 122 pts with TRK fusion cancer treated with larotrectinib, 84 pts (69%) had a GMI $\geq$1.33. Conversely, 38 pts (31%) had a GMI $<$ 1.33, but of these, 9 pts were ongoing treatment and censored for PFS as of July 2019 (Italiano et al, ESMO 2020). Here, we report the GMI of this initial group with a longer follow-up as well as an expanded dataset to more accurately assess the treatment effect of larotrectinib in pts with TRK fusion cancer previously treated with $\geq$1 line of therapy. **Methods:** Pts with TRK fusion cancer from three clinical trials on larotrectinib treatment with $\geq$1 prior line of systemic therapy were eligible for retrospective GMI analysis. TTP on the prior line of therapy was investigator-assessed. PFS on larotrectinib was determined by independent review committee per RECIST v1.1. Pts who had not progressed were censored as of date of last visit. Kaplan–Meier (KM) analyses were used to estimate median GMI, in addition to median PFS and TTP. The data cut-off was July 2020. **Results:** With an extended follow up of the original 122 pts, 90 (74%) pts had a GMI $\geq$1.33, including 6 of the 9 pts who were previously censored with a GMI $<$ 1.33 and ongoing treatment; 6 pts (5%) had a GMI $\geq$1 to $<$ 1.33 and 26 (21%) had a GMI $<$ 1. The KM estimated median GMI increased from 7.6 (95% CI 5.7–88.0) to 9.5 (95% CI 5.7–17.4). In the expanded dataset of 140 pts, 103 pts (74%) had GMI $\geq$1.33, 7 (5%) had a GMI $\geq$1 to $<$ 1.33 and 30 (21%) had a GMI $<$ 1. Six of the 37 pts with a GMI $<$ 1.33 were censored and still ongoing treatment. The KM estimated median GMI was 8.9 (95% CI 6.2–17.4). Among pts who had received 1, 2, or $\geq$3 prior lines of therapy, 74%, 65%, and 80%, respectively, had GMI of $\geq$1.33. Median TTP on the prior therapy was 3.0 months (95% CI 2.1–3.5) and median PFS on larotrectinib was 33.0 months (95% CI 16.6–34.9). **Conclusions:** With a longer follow-up, nearly three-quarters of pts with TRK fusion cancer treated with larotrectinib had a prolonged PFS compared to their most recent prior therapy. These results further validate the use of larotrectinib in treating patients with TRK fusion cancer. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: Bayer HealthCare and Loxo Oncology.

3115 **Poster Session**

Phase I expansion study of the first-in-class monocarboxylate transporter 1 (MCT1) inhibitor AZD3965 in patients with diffuse large B-cell lymphoma (DLBCL) and Burkitt lymphoma (BL). *First Author: Sarah E. R. Halford, Cancer Research UK Centre for Drug Development, London, United Kingdom*

Background: Tumours rely on lactate transporters (MCT1-4) to maintain glycolytic flux and avoid intracellular acidification. In haematological tumours the MCT1 transporter acts as a lactate and pyruvate exporter. AZD3965 is a potent and specific inhibitor of MCT1 causing intracellular lactate accumulation. *In vivo* efficacy was observed in xenografts of DLBCL and BL, expressing high levels of MCT1 and no or low levels of MCT4. In the AZD3965 phase I (NCT01791595) dose-escalation an oral recommended phase 2 dose (RP2D) of 10mg twice-daily (bd) was determined. Pharmacokinetic (PK) showed exposure estimated to produce a minimum MCT1 occupancy of 90% (based on modelling). DLTs were primarily on-target dose-dependent, reversible, asymptomatic alterations in retinal function seen on ERG. **Methods:** This expansion cohort enrolled patients with relapsed/refractory DLBCL and BL. Expression of MCT1/MCT4 was assessed by immunohistochemistry. Pharmacokinetic (PK) sampling was performed and pharmacodynamic assessments included [^{18}F]FDG-PET/CT imaging and plasma/urine metabolomics. **Results:** 11 DLBCL patients were treated with AZD3965 10mg bd. PK showed exposure to be broadly in line with the escalation cohort. No significant ERG changes were observed. One patient experienced a dose-limiting SUSAR of Troponin I increase. MCT1 is expressed in erythrocytes, however no serious events of anaemia were seen, with one non-clinically significant episode of grade 3 anaemia reported. Urine analysis showed increased excretion of lactate and ketone bodies post AZD3965 treatment consistent with renal target engagement. No alteration was detected in plasma. Ongoing stable disease at cycle 5 was observed in one patient and an additional patient had a confirmed complete response (CR) lasting 15 months, with no significant toxicity. In the patient showing CR a reduction in tumour FDG uptake was observed on day 3 of cycle 1. The other four patients who consented to research imaging did not have a clinical response and no changes were observed on FDG-PET. **Conclusions:** AZD3965 can be safely administered at 10mg bd. In one DLBCL patient monotherapy activity was observed with changes in FDG-PET providing evidence indicative of proof of mechanism. These changes in FDG uptake as early as on day 3 in the responding patient warrant further investigation of FDG-PET as a predictive biomarker. Further biomarker analysis and preclinical studies are ongoing to understand the biology and explore effective combinations with other agents targeting tumour cell metabolism Clinical trial information: NCT01791595. Research Sponsor: Cancer Research UK.

The next-generation pan-RAF inhibitor, KIN-2787, is active in class II and class III BRAF mutant models. *First Author: Aleksandra Franovic, Kinnate Biopharma Inc., San Diego, CA*

Background: Oncogenic *BRAF* gene alterations, leading to aberrantly activated BRAF monomers (Class I mutations) or dimers (Class II and Class III mutations), are observed in approximately 6% of all human cancers. First-generation BRAF inhibitors targeting Class I BRAF mutants, including dabrafenib, encorafenib, and vemurafenib, provide significant clinical benefit to patients with BRAF V600 mutation-driven melanoma and select solid tumors as monotherapies or in combination with other targeted therapies. The currently approved BRAF inhibitors have not, however, proven to be effective in patients with Class II or III *BRAF* alterations which account for a large proportion (34%) of *BRAF* mutations. KIN-2787 is an orally available, potent and selective small molecule pan-RAF inhibitor specifically designed to inhibit Class II and III BRAF dimers, in addition to Class I mutants. **Methods:** The efficacy and tolerability of the pan-RAF inhibitor, KIN-2787, was evaluated *in vitro* and *in vivo* in Class I, II, and III *BRAF* mutation-driven human cancer models. **Results:** In biochemical assays, KIN-2787 showed low nanomolar to picomolar potency against RAF1, BRAF, and ARAF (IC50 0.06-3.46 nM) with minimal activity towards non-RAF kinases. In cell-based assays, KIN-2787 inhibited RAF activity, as measured by inhibition of downstream ERK phosphorylation (pERK), across multiple BRAF mutant cancer cell lines. Class II and III BRAF mutant cell lines were the most responsive when treated with KIN-2787 (IC50 $<$ 50 nM); 19- and 7-fold more sensitive compared to cells harboring wild-type BRAF, respectively. Dose-dependent inhibition of A-375 (Class I), BxPC-3 (Class II), and WM3629 (Class III) BRAF mutant human xenograft tumor growth was attained with daily KIN-2787 treatment and was well-tolerated. A trend towards greater tumor responses was observed with twice daily (BID) compared to once daily (QD) dosing of KIN-2787; however, the two dosing regimens led to similar tumor growth inhibition (TGI) and regressions (mean TGI up to 101-118%; $p \leq 0.0001$) at equivalent total daily doses. Furthermore, KIN-2787 led to a significant *in vivo* pharmacodynamic response using either regimen, however, prolonged target coverage, as measured by pERK, was achieved with BID dosing. The impact of KIN-2787 treatment on additional biomarkers, including transcriptional changes and MAPK pathway modulation in cell-based models and patient-derived samples, will be presented at the meeting. **Conclusions:** KIN-2787 is a next-generation pan-RAF inhibitor with pronounced *in vitro* and *in vivo* activity against human cancers driven by Class II and III *BRAF* mutations. A phase 1 dose escalation and expansion clinical trial evaluating the safety and efficacy of KIN-2787 monotherapy in patients with advanced or metastatic solid tumors harboring *BRAF* gene alterations, including Class II and III mutations, is expected to initiate in 2021. Research Sponsor: Kinnate Biopharma Inc.

3117 **Poster Session**

Prognostic factors in RET dependent cancers treateded with RET inhibitors in early phase clinical trials. *First Author: Max Gordon, UT MD Anderson Cancer Center, Houston, TX*

Background: Activation of the RET proto-oncogene has been identified in multiple cancer types, for example, gene rearrangements in non-small cell lung cancer (NSCLC) and papillary thyroid cancer (PTC) and activating mutations in medullary thyroid cancer (MTC), amongst others. The recent FDA approval of two highly selective RET inhibitors, selpercatinib and pralsetinib has changed the treatment paradigm of RET-driven cancers, but the significance of historical prognostic factors is unknown. Herein, we analyzed the outcomes of patients with RET-altered cancers enrolled in phase I trials and assess the utility of prognostic scores. **Methods:** A retrospective analysis was performed of patients treated with selective RET inhibitors at the MD Anderson Cancer Center (MDACC). Baseline clinical factors and survival data were assessed. Overall and progression free survival (OS and PFS) were estimated using the Kaplan-Meier method and multivariable Cox models were constructed. For all a p-value of $<$ 0.05 was consider significant. **Results:** Among 126 patients, median age was 58 years (range, 15-82), most with ECOG 0-1 (n = 124). RET-mutant MTC was most frequent (n = 81), followed by RET fusion-positive NSCLC (n = 30) and RET fusion positive thyroid cancer (n = 9). RET fusion partners were KIF5B (n = 17), CCD6 (n = 12) and NCOA4 (n = 7). RET M918T mutation was the most frequent (n = 50, 63%). Most patients were treated in the relapsed/refractory (R/R) setting (n = 85) and received a median of 1 prior line of therapy (range, 0-11). Median follow up was 20 months (range, 1-43). The estimated median PFS and OS were 24 and 35 months, respectively. Overall objective response rate was 64% (81/126), 2 complete response, 79 partial response, 32 had stable disease (25%) and 13 had progressive disease (PD). The following were associated with shorter PFS and OS: age $\geq$50 years ($p < 0.05$), albumin $<$ 4 g/dL ($p < 0.01$), brain metastases ($p < 0.0001$), hemoglobin $<$ 12 g/dL (< 0.05), LDH $>$ normal ($p < 0.05$), WBC $\geq$8 ($p < 0.01$), PD ($p < 0.0001$) and NSCLC ($p < 0.01$). The M918T mutation and ECOG $>$ 0 were associated with shorter OS but not PFS ($p < 0.05$). $>$ 3 metastatic sites and R/R disease were associated with inferior PFS ($p = 0.04$ and $p = 0.01$, respectively) but not OS. The Royal Marsden Hospital (RMH) and MDACC prognostic scores were significantly associated with PFS and OS ($p < 0.01$). In multivariable models including all variables significantly associated with PFS and OS (excluding LDH as this was only tested in 58 patients) albumin $<$ 4 (HR 6.10, $p = 0.013$), brain metastases (HR 4.90, $p = 0.027$) and WBC $\geq$8 (HR 4.67, $p = 0.031$) were associated with inferior OS. NSCLC was significantly associated with inferior PFS (HR 5.45, $p = 0.02$). **Conclusions:** The RMH and MDACC prognostic scores predict OS in RET-aberrant cancers treated on early phase trials. Low albumin, WBC $>$ 8 and brain metastases are significantly associated with inferior survival. Research Sponsor: None.

Expression of end-binding protein 1 (EB1), a potential response-predictive biomarker for lisavanbulin, in glioblastoma and various other solid tumor types. *First Author: Magdalena Skowronska, Institute of Pathology, University of Bern, Bern, Switzerland*

Background: EB1, a protein located on the plus-ends of microtubules is involved in microtubule function and has been associated with glioblastoma (GBM) stem-cell-ness and more aggressive disease. Lisavanbulin (BAL101553) is a prodrug of the lipophilic small molecule BAL27862, that promotes tumor cell death by modulating the spindle assembly checkpoint and has been shown in rodents to efficiently penetrate the brain. Data from GBM mouse models and recent phase 1 clinical data (Lopez et al. ESMO 2020) suggest that EB1 is a response-predictive marker for lisavanbulin in GBM. A phase 2 study is ongoing to confirm this hypothesis (NCT02490800). A proof-of-concept in GBM would support an expansion of EB1-directed lisavanbulin clinical development in non-GBM tumors, which requires prevalence estimates of EB1-positivity in non-GBM tumor types. **Methods:** Tissue samples from GBM and other tumor types were stained for EB1 using a CE-marked immunohistochemistry Clinical Trial Assay (Targos Molecular Pathology GmbH, Kassel Germany). EB1-positivity was assessed by a board-certified pathologist based on the percentage of tumor cells showing moderate or strong staining for EB1, using thresholds of $\geq$50%, $\geq$60% and $\geq$70% of tumor cells with EB1 positivity. Whole transcriptome sequencing (WTS) using RNAseq was performed in a subset of tissue samples to develop a potential RNA-based predictive response signature for lisavanbulin. **Results:** 73 GBM tissue samples and 333 tissue samples from 13 other cancer types were stained for EB1. The strongest overall signal for EB1-positivity was obtained for medulloblastoma, neuroblastoma and GBM. In addition, moderate or strong EB1-staining in $\geq$50% of tumor cells was observed in samples from colorectal cancer (CRC), non small-cell lung cancer (NSCLC), metastatic melanoma, small-cell lung cancer (SCLC) and triple-negative breast cancer (TNBC). An expanded staining campaign is ongoing in these cancer types. Initial results from the ongoing WTS analyses show marked differences in gene expression profiles between EB1-positive and -negative cases. **Conclusions:** Strong EB1-positivity is infrequent but occurs in a variety of tumor types, with the strongest signals in medulloblastoma, neuroblastoma and GBM. A phase 2 study is ongoing to assess prospectively whether EB1 is a response-predictive biomarker for lisavanbulin in GBM. Research Sponsor: Basilea Pharmaceutica International Ltd.

		% EB1-positive tissue samples (moderate or strong EB1 staining based on % tumor cells threshold)

TP53 and CHEK2 germline mutations in malignant solid tumors. *First Author: Zhiye Zhang, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China*

Background: Li-Fraumeni syndrome (LFS, OMIM #151623) is an autosomal dominant cancer predisposition syndrome. Typical LFS tumors comprise adrenocortical carcinomas, sarcoma, breast cancer and central nervous system tumors. LFS is also associated with an increased risk of a multitude of other common types of cancer, such as prostate cancer, lung cancer, gastric cancer, colorectal cancer, ovarian cancer, melanoma, etc. TP53 germline mutations are the most common gene with LFS. Germline mutationsof CHEK2 have been identified as another predisposing gene and associated with a range of cancer types. However, the pattern of TP53 and CHEK2 germline mutations in malignant tumors remains unknown. **Methods:** We identified 8535 malignant solid tumors patients without selecting age or family history in a retrospective cohort. Germline mutations were categorized based on ACMG (American College of Medical Genetics and Genomics) guidelines in pathogenicity. The patients were divided into three groups, P group (with pathogenic mutations), LP group (with likely-pathogenic mutations) and Non_P group (neither pathogenic nor likely-pathogenic mutation). Statistical significance was defined as P-value less than 0.05. **Results:** A total of 461 (461/8535) patients carried TP53 or CHEK2 germline mutations were identified, in which 15 patients with pathogenic mutations and 17 patients with likely-pathogenic mutations. One patient with lung cancer in LP group carried TP53 homozygous mutation (p. Ser215Ile), and the remaining 31 patients all carried heterozygous mutations. Among these 31 carriers, 16 (51.6%) carried nonsense or missense mutations (10 for nonsense and 6 for missense mutations). 3 patients in the P group carried CHEK2p. Y139* (one liver cancer patient and two lung cancer patients) were identified. The median age of group P, LP and Non_P was 55 (39 for TP53, 61 for CHEK2), 63 (52 for TP53, 66 for CHEK2) and 59, respectively. Somatic mutation analysis found no significant difference in tumor mutation burden (TMB) among three groups. The SNV/INDEL mutation frequency of LRP1B in the P or LP group was significantly lower than the Non_P group. **Conclusions:** Our data showed that 0.375% (32/8535) malignant solid tumor patients carried TP53 (16/8535) or CHEK2 (16/8535) germline pathogenic or likely-pathogenic mutations. The relationship between germline mutations and cancer susceptibility will be studied in the future. Research Sponsor: None.

A comprehensive landscape of BRCA1 versus BRCA2 associated molecular alterations and survival outcome across 35 cancer types. *First Author: Alberto Puccini, Medical Oncology Unit 1, IRCCS Ospedale Policlinico San Martino, Genoa, Italy*

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) are effective therapies for some patients with both germline and somatic *BRCA1/2* mutations (MTs) or with homologous recombination repair deficiency (HRD). We aimed to characterize molecular differences between *BRCA1* and *BRCA2* MTs and their prognostic and/or predictive impact on PARPi outcomes in various cancer subtypes using real world data (RWD). **Methods:** Tumor samples obtained from patients with 35 types of cancer were analyzed by whole exome sequencing (WES, Novaseq) at Caris Life Sciences (Phoenix, AZ). High genomic loss of heterozygosity (gLOH-H) was defined as LOH-H in ≥16% of tested loci. MSI/MMR was tested by fragment analysis, IHC, and WES. Overall survival (OS) extracted from insurance claims was calculated from start of treatment or tissue collection until last contact or death using Kaplan-Meier curves. *P*-values adjusted for multiple comparisons (q-value of < 0.05 was considered to be significant). **Results:** In total, 17,640 tumors were included, of which 776 (4.3%) had tumor-based *BRCA1/2* MTs. *BRCA1/2* MTs were most commonly seen in ovarian (N = 221/2187, 10.1%), breast (138/2506, 5.5%), prostate (61/1131, 5.4%), pancreatic (48/1430, 3.4%), and non-small cell lung (100/4046, 2.5%) cancers. *BRCA2* MTs were more frequent than *BRCA1* except in ovarian cancers. *BRCA1* MTs were more common in younger pts (median age, 61 vs 65 years, $p < .001$). When compared to *BRCA2* MTs, *BRCA1* MTs were more often associated with gLOH-H (64% vs 51%, $p < .001$) and *TP53* MT (80% vs 53%, $p < .001$) in all tumor types. In NSCLC, *EGFR* mutations were exclusively seen in *BRCA2* compared to *BRCA*1 (10.3 vs. 0%, P = 0.038). The *EGFR* mutations that co-occurred with BRCA2 mutations were L858R (N = 1), Exon19del (N = 4), and L861Q (N = 1). *KRAS* was more frequently mutated in *BRCA*1-mutated NSCLC (*BRCA1*: 32% vs. *BRCA2*: 16%, p = .056). In univariate analyses, overall *BRCA1/2* MTs were associated with improved OS compared to wild type (HR 1.38, 95% CI [1.31-1.45], $P < .0001$). This effect was seen in ovarian (1.42 [1.29-1.57], $p < 0.0001$) and triple-negative breast cancers (TNBC) (1.18, [1.09-1.28], $p < .001$); but was not observed in prostate, pancreatic, or non-TNBC breast cancer subtypes. In all breast cancers, *BRCA2* MTs had a superior OS (0.68, [0.51-0.89], p = .005) compared to *BRCA*1, while no differences were seen in other cancers. Using RWD, PARPi treated-patients with *BRCA2* MTs had worse OS than *BRCA1* MTs (HR 1.4, [1.09-1.80], p = 0.009); but this was not significant when individual cancers were considered. **Conclusions:** *BRCA1* and *BRCA2* MTs had variable power to be prognostic and predictive for PARPi efficacy among different cancer types using RWD. About 2.5% of NSCLCs harbor BRCA1/2 MT. Additional genomic exploration may refine biomarkers predictive of response to PARPi and may highlight features within the tumor microenvironment of importance in the setting of HRD. Analysis of the MOSAIC correlative cancer database integrating molecular cancer classification and tumor profiling to identify targeted treatment options for metastatic cancer. *First Author: Li Ma, Biotheranostics, Inc., San Diego, CA*

Background: Unless tumor type and genetic alterations can be identified, metastatic cancer patients with unknown or uncertain diagnoses may be limited to empiric chemotherapy. The 92-gene assay (CancerTYPE ID) is a validated gene expression classifier of 50 tumor types and subtypes for patients with cancer of unknown primary (CUP) or ambiguous diagnoses. Multimodal molecular biomarker testing by next-generation sequencing (NGS), tumor mutational burden (TMB), fluorescent in situ hybridization (FISH), microsatellite instability (MSI), and immunohistochemistry (IHC) can identify genetic targets. A database integrating tumor typing with biomarker analysis in metastatic cases was utilized to identify the most prevalent genetic alterations by tumor type. **Methods:** MOSAIC (Molecular Synergy to Advance Individualized Cancer Care) is an IRB-approved database of cases with CancerTYPE ID testing plus multimodal biomarker testing. The current study determined molecular tumor type followed by molecular profiling by NGS for up to 323 genes, (NeoTYPE profiles, Neogenomics). **Results:** Tumor type was determined in 1992 of 2151 cases (92.7%), comprised of 27 different tumor types. 72% of cases were comprised of the 7 tumor types shown in the table,- which also shows the frequency of the 10 most commonly mutated genes by tumor type. Bolded are genes with actionable genetic mutations for which FDA-approved therapies are not currently indicated in the identified tumor type. **Conclusions:** Precise targeted treatment for many patients with CUP or ambiguous diagnoses requires accurate diagnosis of the cancer origin combined with multimodal molecular testing to identify actionable genetic alterations in the appropriate cellular context. Future studies will evaluate additional biomarker profiles, including TMB, FISH, MSI, and IHC for cases in the MOSAIC database. Research Sponsor: Biotheranostics, Inc.

Temporal and spatial topography of cell proliferation in cancer. *First Author: Sheheryar Kairas Kabraji, Dana Farber Cancer Institute, Boston, MA*

Background: Tumors are complex ecosystems where exogenous and endogenous cues are integrated to either stimulate or inhibit cancer cell proliferation. However, the nature of these complex cell cycle states, their spatial organization, response to perturbation, and implications for clinical outcomes, are poorly characterized in tumor tissues. **Methods:** We used multiplexed tissue imaging to develop a robust classifier of proliferation, the multivariate proliferation index (MPI), using 513 unique tumors across five cancer types. Next, we used dimensionality reduction analysis to assess how the patterns of cell cycle protein expression in tumors were altered in response to perturbation. **Results:** The MPI outperforms single markers, like Ki67, when classifying proliferative index across diverse tumor types and reveals the proliferative architecture of tumors in situ. We find that proliferative and non-proliferative cancer cells are organized across microscopic (cell-to-cell) and macroscopic (tissue-level) scales. Both domains are reshaped by therapy, and local clusters of proliferative and non-proliferative tumor cells preferentially neighbor distinct tumor-infiltrating immune cells. We further phenotyped non-proliferating cancer cells using markers of quiescent cancer cells, cancer stem cells, and dormant cancer cells. We found that these types of non-proliferating cancer cells can occupy distinct regions within the same primary tumor. In high-dimensional marker space, populations of proliferative cancer cells express canonical patterns of cell cycle protein markers, a property we refer to as "cell cycle coherence". Untreated tumors exist in a continuum of coherence states, ranging from optimal coherence, akin to freely cycling cells in culture, to reduced coherence characterized by either cell cycle polarization or non-canonical marker expression. Coherence can be stereotypically altered by induction and abrogation of mitogen signaling in a HER2-driven model of breast cancer. Cell cycle coherence is modulated by neoadjuvant therapy in patients with localized breast cancer, and coherence is associated with disease-free survival after adjuvant therapy in patients with colorectal cancer, mesothelioma and glioblastoma. **Conclusions:** The MPI robustly defines proliferating and non-proliferating cells in tissues, with immediate implications for clinical practice and research. The coherence metrics capture the diversity of post-treatment cell cycle states directly in clinical samples, a fundamental step in advancing precision medicine. More broadly, replacing binary metrics with multivariate traits provides a quantitative framework to study temporal processes from fixed static images and to investigate the rich spatial biology of human cancers. Multi-cancer detection and tissue of origin determination based on 5-hydroxymethylcytosine biomarkers in circulating cell-free DNA. *First Author: Zhou Zhang, Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Early detection may reduce cancer mortality. Systematic screening programs are available only for a limited number of cancers (e.g., colorectal cancer). The majority of common cancers are detected after the onset of signs and symptoms, making treatment difficult or less effective. We describe here a multi-cancer epigenetic approach for simultaneous cancer detection of common cancers (~70% of adult cancers) and determination of tissue of origin (TOO) using circulating cell-free DNA (cfDNA) from plasma. **Methods:** A total of 2241 cancer cases, including patients with newly diagnosed primary colorectal, gastric, esophageal, liver, lung, and breast cancer (stages I-III or equivalent) and 2289 non-cancer controls were recruited from participating hospitals in China. Study participants were randomly assigned into a training set (70%) and a testing set (30%), and patients were matched for cancer types and stages. Plasma samples were collected before radical treatment or surgery. The 5hmC-Seal, a highly sensitive chemical labeling technique, was used to profile genome-wide 5-hydroxymethylcytosines (5hmC) in cfDNA from ~5mL of plasma per person, followed by the next-generation sequencing, data summarization at gene-level, and normalization. We applied the elastic net regularization to establish a predictive rule based on the multivariable logistic regression model for cancer detection in the training set as well as a multiclass classification model for determining TOO. The final solution for simultaneous cancer detection and TOO determination was established by integrating the 5hmC-based models and protein markers (e.g., AFP). Overall sensitivity and specificity were computed and reported in the testing set of 670 cancer cases and 686 non-cancer controls. **Results:** For the primary scenario (i.e., stages I-III or equivalent), at specificity of 95%, the overall sensitivity achieved 79.3% for detecting a cancer patient in all six cancer types in the testing set, except stage I lung cancer, for which the multi-cancer detection solution showed a sensitivity of 51%. Notably, for individuals with a negative result from conventional protein markers (e.g., AFP, CEA), the 5hmC-only models showed 67.6% sensitivity at 98.2% specificity in the testing set, representing significant improvement. In the testing set, among the 500 cancer patients who were detected from the multi-cancer detection solution, 435 patients were assigned a TOO; of those, 362 (83.2%) TOO were correctly determined. **Conclusions:** The 5hmC-Seal in cfDNA shows the potential as a non-invasive tool that could be integrated into a screening program for simultaneous detection of common cancers and TOO localization. This approach can be expanded to additional cancer types and is currently undergoing validation in prospectively recruited cohorts. Research Sponsor: Shanghai Epican Genetech, Co. Ltd.

Frequency of longitudinal changes in *TP53* mutation status from gene sequencing of serial tumor biopsies from a large cohort of cancer patients. *First Author: D. Allen Allen Annis, Aileron Therapeutics, Inc., Cambridge, MA*

Background: The p53 pathway is one of the most important in cancer biology, with mutation of the *TP53* gene that encodes the p53 tumor suppressor protein observed in ≈50% of all cancers. We evaluated the frequency of changes in *TP53* mutation status in a large cohort of serial tumor biopsies. **Methods:** From a database of >200,000 next-generation gene sequencing results we identified 16,592 samples arising from repeat biopsies from 7840 patients (pts), average 2.12 per pt, 1007 pts with ≥3, max 11; over an interval up to 234 months (mos), average 11.0 mos. *TP53* mutations with known or unknown significance in successive biopsies and changes in assignment from *TP53*-Wild-Type (WT) to Mutant (Mut), or Mut to WT, were evaluated vs. cancer type and time between biopsies. **Results:** Table: N (%) of samples vs. change in *TP53* status from previous biopsy vs. mos from initial biopsy in all samples (7840 initial + 8752 successive, 46% *TP53*-Mut) and the three most represented cancers: non-small cell lung cancer (NSCLC, 1189 initial + 1268 successive, 60% Mut), breast (947 initial + 993 successive, 55% Mut), multiple myeloma (MM, 578 initial + 981 successive, 18% Mut). **Conclusions:** Changes in *TP53* status were rare (<10% of samples). Differences may occur in serial biopsy samples for pathophysiological reasons, e.g., a mutant clone becoming dominant and/or heterogeneity at different tumor biopsy sites, or analytical differences in biopsy tumor content or assay sensitivity between samples. In this analysis, WT-to-Mut changes were more frequent (5.9%) than Mut-to-WT changes (3.3%), suggesting a small selection pressure for *TP53* alterations later in oncogenesis and indicating that these alterations are truncal. Mut-to-WT changes are not readily explained physiologically and may suggest these infrequent changes are mostly due to sampling or analytical variability, and genuine changes in *TP53* mutation status are quite rare. Research Sponsor: Aileron Therapeutics, inc.

A comprehensive literature review and meta-analysis on prognostic value of BRCAm, HRRm and HRD+ across tumor types. *First Author: Changxia Shao, Merck & Co., Inc., Kenilworth, NJ*

Background: Poly (ADP-ribose) polymerase inhibitor (PARPi) may have broad application in the treatment of cancer patients with mutations of BRCA (BRCAm) or other homologous recombination repair genes (HRRm) or HR deficiency positive (HRD+). A literature review and meta-analysis were conducted to evaluate the clinical prognostic outcomes by total BRCAm, HRRm, and HRD+ status across tumor types among patients treated with non-PARPi treatment. **Methods:** Comprehensive searches for eligible studies in Ovid MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, and Cochrane reviews were performed in May 2020 to capture studies published in English within 10 years for manuscripts and 3 years for abstracts across geographic regions. A summary estimate with corresponding 95% CI was calculated using random-effects models due to varying effects sizes across studies. **Results:** A total of 135 eligible studies were included. Breast cancer (BC) patients with either BRCA1m or BRCA2m (BRCA1/2m) had a similar overall survival (OS) to those with wild-type BRCA1 and BRCA2 (BRCA1/2wt) across 18 studies reporting data on BRCA1m and BRCA2m. The pooled estimates of hazard ratio (HR) was 1.0 (95% CI: 0.8-1.3) overall and was 1.0 (0.7-1.5) for triple-negative BC (TNBC, 7 studies). Similarly, the HR was 1.1 (0.9-1.3) across all 10 studies reporting BRCA1m data and 1.1 (0.8-1.3) across all 7 studies reporting BRCA2m data. Ovarian cancer (OC) patients with BRCA1/2m had a significantly longer OS than those with BRCA1/2wt across 24 studies reporting BRCA1m and BRCA2m, with a HR of 0.7 (0.6-0.8). The HR was 0.6 (0.4, 0.8) across 4 studies on stage III-IV ovarian cancer. The HR was 0.8 (0.6-1.1) across 13 studies reporting BRCA1m and 0.5 (0.3-0.9) across 8 studies reporting BRCA2m. Less OS data were reported for other tumors, 6 studies for BRCA2m in prostate cancer with a HR of 1.9 (1.1-3.2) and 2 studies for BRCA1/2m in pancreatic cancer with a HR of 1.5 (0.8-3.1). Only 4 studies reported HRD+ by either BRCAm or genomic instability score (GIS) ≥ 42 and OS by HRD status; 3 on TNBC and 1 on high-grade serous ovarian cancer. The HR was 0.67 (0.43-1.02) for OS with HRD+ vs. HRD-. A total of 15 studies reported the association between HRRm and OS of cancers (5 on prostate, 4 on pancreas, 3 on ovary, 2 on breast and 1 on urothelial cancer), in which one or more HRR genes were examined. The HR was 1.0 (0.7-1.4) comparing patients with HRRm to those with HRRwt across tumor types. Due to the limited study number and inconsistent methodology/definitions of HRRm and HRD+, these results should be interpreted with caution. **Conclusions:** The effects of BRCA1/2m on OS in patients treated with chemotherapy varies by cancer type with no effect in BC and a positive association in OC. More study is required in other cancer types. There was no significant association found between HRD+ or HRRm with OS. These findings could help inform evidence-based treatment decisions. Research Sponsor: Merck & Co.

3126 **Poster Session**

The value of defining molecular resistance in patients with progressive *EGFR* and *ALK*-driven lung cancer in a public system. *First Author: Carly C. Barron, University of Toronto, Toronto, ON, Canada*

Background: Repeat molecular profiling, except to detect *EGFR* T790M, is not routinely performed in Canadian patients with lung cancer progressing on *EGFR* tyrosine kinase inhibitors (TKIs). We performed genomic profiling on post-progression biopsies in patients with stage IV non-small cell lung cancer (NSCLC) and known *EGFR/ALK* aberrations treated with TKIs to identify resistance mechanisms, evaluate options for subsequent treatment, and to assess clinical trial eligibility and costs. **Methods:** From Feb 2018-Aug 2020, post-progression tumour biopsies from consenting patients at a major cancer centre underwent genomic profiling (ThermoFisher OCA v3.0 including hotspots, fusions, and copy number variations in 161 cancer-associated genes). Outcomes of interest were the identification of resistance mutations, actionable targets, clinical trial eligibility (per clinicaltrials.gov), and costs. **Results:** Thirty-two patients consented to the study. Most, 84% (n = 27), had successful testing completed while 16% (n = 5) had insufficient tissue. Median age of the cohort was 56 yrs, 59% (n = 16) were female, 74% (n = 20) were never-smokers, 81% (n = 22) had ECOG performance status 0-1, and 67% (n = 18) were Asian. The majority, 81% (n = 22) had *EGFR* mutated NSCLC, and had progressed on EGFR TKIs (15 with previously identified T790M had progressed on osimertinib), and 19% (n = 5) had *ALK* fusions. Patients had received a median of 2 prior lines of targeted therapy prior to re-biopsy (IQR 1.5,3). One patient had evidence of small cell transformation and associated *TP53* and *RB1* mutations, 11% (n = 3) had acquired *EGFR* C797S mutations, and 11% (n = 3) had acquired *ALK* resistance point mutations (G1202R n = 2, I1171N n = 1). Genomic profiling identified additional actionable targets in 19% of patients (n = 5: *MET* exon 14 skip mutation n = 1, *MET* amplification n = 2, *BRAF* V600E n = 2). Overall, 33% (n = 9) patients had management-changing resistance mechanisms identified (small cell transformation n = 1, actionable targets n = 5, *ALK* inhibitor resistance = 3). New clinical trial options based on genomic profiling results were identified for 67% (n = 18) of patients. Incremental costs for repeat genomic profiling were approximately $880 CAD per case. **Conclusions:** Molecular profiling upon development of resistance to targeted therapy in our cohort revealed actionable resistance mechanisms for over a third of patients and clinical trial options for 67%. These incremental benefits for patients highlight the importance of routine molecular profiling in the setting of acquired TKI resistance in lung cancer. Research Sponsor: Princess Margaret Cancer Foundation OSI Pharmaceuticals Foundation Chair.

Landscape of *KRAS^{G12C}*, associated genomic alterations, and interrelation with immuno-oncology (IO) biomarkers. *First Author: Mohamed E. Salem, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Sotorasib has shown promising activity in cancer patients (pts) specifically harboring the *KRAS^{G12C}* mutation. Response rates vary significantly by tumor type, suggesting *KRAS^{G12C}* pathogenesis may be cancer-type-dependent. **Methods:** We retrospectively analyzed de-identified records of 79,004 pts with various cancer types that underwent Tempus xT and xF next generation sequencing assays. Fisher's exact test was used to analyze the association between cancer subtypes and *KRAS* variants. Logistic regression was used to study co-mutations between *KRAS^{G12C}* and other oncogenes, as well as the association between *KRAS* variants and IO biomarkers. False discovery rate-adjusted P-value (FDR *P*) was used for multiple testing. **Results:** In total, 13,578 (17.4%) tumors harbored *KRAS* mutations, of which 1,632 were G12C; 750 *KRAS* wild-type (WT) tumors gained *KRAS* mutation on follow-up testing, with 79 harboring G12C. The most frequent *KRAS* variants across all cancers were G12D, G12V, G12C, and G13D (see Table). The distribution of *KRAS* variants significantly varied by cancer type, with G12C and G12D being the most prevalent in non-small cell lung (NSCLC) and colorectal (CRC) cancers, respectively. G12C was most prevalent in NSCLC (9%), appendiceal cancer (3.9%), CRC (3.2%), tumors of unknown origin (1.6%), and pancreatic cancer (1.3%). Compared to non-G12C, G12C was more frequently identified in females (56% vs. 51%, FDR $P = 0.0005$), smokers/prior smokers (85% vs. 56%, FDR $P < 0.0001$), and pts > 60 years of age (73% vs. 63%, FDR $P = 0.0006$). While no G12C tumors exhibited *BRAF^{V600E}* co-mutations, *BRAF$^{non\text{-}V600E}$* co-mutations were seen in 3.1% of pts. Significant differences were observed in genomic alterations co-occurring with G12C compared to non-G12C (e.g., *STK11* (20.6% vs 6%), *KEAP1* (15.4% vs 4.6%), *SMAD4* (7.2% vs 19%), and *PDGFRA* (5.8% vs 3%); FDR $P < 0.0001$). However, G12C and oncogene co-mutations were not significantly different between NSCLC and CRC, except for *KEAP1* (FDR_$P = 0.04$). Compared to non-G12C and WT, G12C tumors were associated with TMB-High and PD-L1 over expression but were less likely to have MSI-H status (FDR $P < 0.0001$; Table). **Conclusions:** Our data suggest that *KRAS* variants significantly differ by cancer type. Tumors harboring KRAS^{G12C} were significantly associated with high TMB and PD-L1 overexpression. KRAS^{G12C} mutation appeared to be associated with smoking status. These results may guide future therapeutic strategies. Research Sponsor: None.

Cancer Type		KRAS Variant	Prevalence (%)	FDR P Value
		G12C	17.9

The impact of clinical decision making in a molecular tumor board at a tertiary care center. *First Author: Meena Sadaps, Cleveland Clinic, Cleveland, OH*

Background: Multidisciplinary molecular tumor boards were first established with the onset of precision oncology (PO), as many clinicians were unfamiliar with the interpretation and incorporation of the information into clinical practice. PO has since rapidly evolved and integrated itself into standard of care practices for most cancer patients, yet molecular tumor boards have not grown accordingly and in fact some have been discontinued. There remains a paucity of data in regards to the value and impact of molecular tumor board discussions themselves. We previously reported on our longitudinal experiences in PO (*Sadapset al*, 2018), focusing on the therapeutic impact of matched therapy. Here, we report on the utility of our molecular tumor board in clinical decision making. **Methods:** We conducted a retrospective review of patients seen at Cleveland Clinic with a solid tumor malignancy who had large panel, next-generation-sequencing (NGS) performed via any commercial platform from November 2019-January 2021. Cases were filtered through a local therapeutic algorithm and then reviewed individually. Initial review was performed by a core genomics committee comprised of 2 oncologists and 2 genetic counselors. Interesting and/or complex cases were flagged for discussion at our bimonthly molecular tumor board, which is regularly attended by medical oncologists, pathologists, genetic counselors, bioinformaticians, and patient care coordinators. Data analyzed included categorization of treatment recommendations and the percentage of cases for which initial recommendations were changed based on tumor board discussion. **Results:** Of 782 total cases, 575 (73.5%) had a clinically relevant genomics tumor board (GTB) recommendation as compared to 51.7% from our previously reported study. 16.7% of patients had on label recommendation(s) and 86.4% had off label/ clinical trial recommendation(s). 179 (22.9%) patients were recommended for genetic counseling (GC). During our bimonthly GTB, we discussed 173 (22.1%) of these cases. Of the discussed cases, the most common tumor types were hepatobiliary (18.5%), lower gastrointestinal (17.3%), and breast (16.2%). Topics of discussion at GTB included such things as pathologic/histologic/molecular testing, prioritization of available trials, appropriateness of an off label therapy, and need for a genetics consult. Discussion at GTB resulted in a change in treatment recommendation in 63 (36.4%) cases. **Conclusions:** Discussions from multidisciplinary molecular tumor board impacted treatment decisions for our patients. Referral to GC was also common and should be considered an integral part of somatic sequencing review. Molecular tumor boards remain a crucial platform for treatment guidance and clinical management, especially given the increase in "actionability" over the years due to newly discovered targets and targeted therapies in this rapidly evolving field. The mutational landscape of the sensitivity of cancer to ionizing radiation. *First Author: Priyanka Gopal, Northwestern University, Chicago, IL*

Background: The impact of common or rare gene mutations on the sensitivity of cancers to ionizing radiation remains largely unknown. We conducted a systematic, arrayed (single variant per well) profiling effort to identify gene mutations that alter cellular sensitivity to radiation and validated some of our findings using a clinical cohort of patients who received thoracic radiotherapy alone. **Methods:** Candidate mutations were prioritized on the basis of genotype-phenotype associations from our previously completed large-scale cancer cell line irradiation profiling study (doi: 10.1038/ncomms11428), location within conserved protein domains, and functional impact (MutationAssessor). We used site-directed mutagenesis to generate mutant clones (2 clones per variant) and transferred the ORFs into lentiviral vectors in SV40 lung primary immortalized cells (BEAS2B). For clinical validation, an IRB-approved study was used to identify patients treated with lung radiotherapy alone. 197 patients with primary (stage I–IV) or recurrent lung cancer and patients with other cancer types and solitary metastases or oligometastases to the lung were included. Death without evidence of local failure was treated as a competing event, and Fine and Gray regression modeling was used to examine potential predictors of local failure. **Results:** Over 600 cancer variants were tested in ~1200 experimental replicates, comprising 91 genes. We identified known and new radioresistant and radiosensitive variants involved in several cellular functional categories including cellular signaling, cytoskeleton, cell cycle, apoptosis, DNA methylation, and DNA repair. Variants that conferred resistance in BEAS2B cells were significantly more likely to confer resistance in TERT-HU1 and NCI-H520 cells, suggesting that most functional variants are cellular context indifferent. Variants under somatic oncogenic selection (hotspot mutants) were significantly more likely to confer resistance to radiation. Several infrequent cancer variants (< 1% prevalence in cancer), including those in ERBB3, SMAD4, TGFBR1, VHL, CTNNB1, and MAP2K1, conferred radiation resistance. Some genes (e.g. KEAP1) demonstrated significant intragenic allelic variation in the magnitude of conferred resistance and other genes (e.g. CTNNB1) displayed both resistance and sensitivity in a protein domain-dependent manner. KRAS (resistant; HR 2.23; $P = 0.02$) and CTNNB1 exon 3 (sensitive; HR 0.3; $P = 0.04$) mutants conferred resistance and sensitivity, respectively, to radiotherapy in our clinical cohort. **Conclusions:** We report on a large-scale profiling effort to identify mutant alleles that govern radiation survival. Our results reveal new insights into potentially actionable determinants of tumor sensitivity to radiotherapy and accelerate clinical validation of common and rare gene mutations that impact radiation sensitivity. Research Sponsor: U.S. National Institutes of Health.

Clinically advanced pelvic squamous cell carcinomas (pSCC) in men and women: A comprehensive genomic profiling (CGP) study. *First Author: Philippe E. Spiess, Moffitt Cancer Center, Tampa, FL*

Background: Given that the clinical manifestations, disease course, and treatment options for pSCC differ between tumor types, we performed CGP to examine possible genomic differences. **Methods:** 1,741 clinically advanced pSCCs including 230 penile (penSCC), 17 male urethral (murthSCC), 125 male anal (manSCC), 7 female urethral (furthSCC), 263 vulvar (vulSCC), 822 cervical (crvSCC), and 277 female anal SCCs (fanSCC) underwent hybrid capture-based CGP to evaluate all classes of genomic alterations (GAs). Tumor mutational burden (TMB) was determined on up to 1.1 Mb of sequenced DNA and microsatellite instability (MSI) was determined on up to 114 loci. PD-L1 expression was determined by IHC (Dako 22C3). **Results:** HPV-16/18 detection was lowest in murthSCC and vulSCC and highest in manSCC, fanSCC, and crvSCC. *TP53* GAs were inversely associated with HPV status. *PIK3CA* GA frequency varied (22-43%). DNA-damage response (DDR) GAs (e.g., *BRCA1/2*, *ATM*, others) were low (< 1-3%) throughout. Cell-cycle GAs were most frequent in external cases (penSCC, furthSCC, vulSCC). MTOR pathway GAs (*PTEN*, *FBXW7*) were the most frequently identified "actionable" GAs. *FGFR3* GA were present in >5% of murthSCC, crvSCC, and fanSCC; other receptor-tyrosine kinase (RTK) targeted options were 1% in *BRAF*/*ERBB2*. *NOTCH1* GAs were present in > 15% of penSCC and vulvSCC. TMB ≥10 mut/Mb was >15% in manSCC, fanSCC, and crvSCC. PD-L1 low expression was > 25% in all pSCC except crvSCC and high expression was > 18% in all pSCC except urthSCC and manSCC. **Conclusions:** Despite similar histology, pSCC differ widely in GAs and HPV status. *PIK3CA* is the most frequent "targetable" GA followed by MTOR pathway and cell cycle; RTK targets are extremely rare. PARP inhibitor options appear low given the infrequent finding of DDR GAs. Anti-PD(L)1 could be considered in a number of cases based on TMB>10 mut/Mb and PD-L1 expression. Partitioning of cancer therapeutics in nuclear condensates. *First Author: Isaac Klein, Dana Farber Cancer Institute, Milton, MA*

Background: The molecules of the cell are compartmentalized into membrane- and non-membrane-bound organelles. Many non-membrane-bound organelles are phase-separated biomolecular condensates with distinct physicochemical properties that can absorb and concentrate specific proteins and nucleic acids involved in discrete biochemical processes. We reasoned that selective condensate partitioning might also occur with small molecule drugs whose targets occur within condensates, and that the therapeutic index and efficacy of such compounds might therefore relate to their ability to partition into condensates. **Methods:** To study the behavior of drugs within condensates, these were modeled in cells and in vitro with purified proteins and visualized by fluorescent confocal microscopy. The functional outcomes of condensate partitioning were queried in cells. **Results:** We found that cisplatin, tamoxifen, JQ1, THZ1, and mitoxantrone are concentrated in specific protein condensates in vitro, and that this occurs through physicochemical properties independent of the drug target. A screen of a chemically diverse fluorescent probes and mutant-protein condensates demonstrated that pi-system interactions between aromatic moieties in the protein and small molecule govern concentration in condensates. These results show that clinically important drugs partition into specific protein condensates in vitro by virtue of defined chemical properties, thereby altering their local concentration. In vitro droplet assays revealed that cisplatin is selectively concentrated in transcriptional condensates, and that this ability is required for efficient platination of target DNA. In cell studies revealed that cisplatin preferentially targets DNA contained within MED1 condensates, and disrupts the genetic regulatory elements that compose phase-separated transcriptional condensates. Live cell imaging demonstrated that transcriptional condensates are dissolved by cisplatin, whereas other condensates remain intact. **Conclusions:** Our results show that antineoplastic drugs partition selectively into biomolecular condensates, that this can occur through physicochemical properties independent of their molecular targets, and that drug activity may occur through condensate-related mechanisms. These results have implications for development of efficacious cancer therapeutics; effective target engagement will depend on factors such as drug partitioning in condensates. Assays of the type described here may thus help optimize condensate partitioning, target engagement, and the therapeutic index of drugs for cancer treatment. The genomic landscape of gene fusions across solid tumors and clinical outcome of targeted therapies: A real-world retrospective analysis. *First Author: Yumeng Zhang, Hematology/Oncology Fellowship, Moffitt Cancer Center, Tampa, FL*

Background: Oncogenic gene fusions can be observed across numerous solid tumor types with therapies targeting fusion events emerging as important treatment modalities. The occurrence of rare fusion events and response to targeted therapy inclusive of off-label drug use has not been fully elucidated. We describe a real-world (RW) landscape of gene fusions in solid tumors and treatment outcomes of targeted therapies. **Methods:** Patients with solid tumors harboring a gene fusion or rearrangement were retrospectively identified through review of a clinical molecular database housing sequencing data on 6,800 patients from a single-center between 1/1/2015 – 12/31/2019. Patients who received targeted therapy for gene fusions were divided into three arms: off-label, on-label, and clinical trial use. Clinical characteristics were summarized using descriptive statistics. Overall survival (OS) and Progression free survival (PFS) between the three arms were compared using the Kaplan-Meier estimates. **Results:** A total of 336 (4.9%) patients had a fusion positive solid tumor with 197 (2.9%) having a fusion event predicted to be oncogenic and could be targeted with a drug. Thirty different cancer types had targetable fusions with the three most common types being lung adenocarcinoma (41%), glioblastoma (10.2%), and melanoma (7.1%). The most common observed targetable fusions included *ALK* (21.3%), *RET* (11.7%), *ROS1* (9.1%), and *FGFR2* (8.1%). A total of 71 patients received targeted therapy; 37 (52%) received therapies on-label, 20 (28%) off-label, and 14 (20%) on-trial (Table). The median PFS was 4 months for off-label, 16 months for on-label, and 9 months for on trial-therapy (p=0.02). The median OS was 8 months for off-label, 51 months for on-label, and 11 months for on-trial therapy (p=0.001). Seven out of twenty patients (35%) in the off-label group had PFS for at least 6 months. Three patients had a response for more than one year. However, higher toxicity related discontinuation rate was observed (30%, 8%, 7% for off-label, on-label, and on-trial, p=0.03). **Conclusions:** Off-label targeted therapy had shorter PFS and OS when compared to on-label therapy. However, 35% patients in the off-label group had at least 6 months PFS. Off-label therapy remained a valuable option for patients who were not candidate for clinical trials or with rare fusions. Further studies are needed to determine which patients are most likely to benefit from targeting gene fusion events. Research Sponsor: None.

Differential response rates in early-phase cancer clinical trials (EPCCT). *First Author: Rozana Abdul Rahman, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: The primary objective of EPCCT (phase I and non-randomised phase II trials) is to determine the safety and tolerability of new therapeutic agents. Response rates (RR) in these trials have typically been reported at around 10-15%. Increasingly RR and survival outcomes are now investigated in EPCCT as primary or secondary objectives. **Methods:** Retrospective data analysis was performed on patients (pts) enrolled onto an EPCCT between January 2018 and December 2019 at The Christie NHS Foundation Trust, UK. Data on demographics, prior systemic treatment, sites of disease, performance status, comorbidities, types of therapy, RR, progression free survival (PFS), and overall survival (OS) were collected. Statistical analyses were performed with univariable and multivariable models. Objective response rate (ORR) was defined as the proportion of pts with complete response (CR) and partial response (PR). Duration of response (DOR) was from initial response to progressive disease (PD). Disease control rate (DCR) was defined as CR+PR+ stable disease (SD). **Results:** A total of 247 pts were treated across 46 EPCCTs. Median age 61 years; 57% female. Sixty-six percent of pts had ≥2 lines of treatment and the majority were ECOG PS 0/1 (98%). Eighty-one percent of pts had ≥2 sites of metastatic disease, and 13 major tumour types were included. Monotherapy trials (159 pts) were predominantly targeted therapies (TT; 60%), or immunotherapies (IO; 20%). Combination therapy trials (88 pts) were TT-based (68%) or IO-based (32%). Data for RR analyses was available for 231 pts. ORR across all trials was 15% (CR 2%) and DCR was 63%. The median DOR was 8.3 months (mos) (95% CI: 7.0 – 9.7) with 28% of pts responding for >6 mos and 7% for >12 mos. ORR in pooled IO treated pts was 27%, DCR was 65% with sustained response >6 mos seen in 37% of these pts. ORR in pooled TT treated pts was 9.4%, DCR was 60% and sustained response > 6 mos seen in 25% of pts. ORR for IO v TT treated pts was significantly different, p=0.007 (pearson chi square), but no significant difference was seen for DCR. Median PFS for all patients was 5.0 mos (95% CI: 4.1 – 6.0) and OS was 10.4 mos (95% CI: 8.4 – 13.0). OS for those with a PR is not reached (HR for PR v PD, 0.006 (95% CI: 0.002 – 0.18). Pts with SD appear to have significantly better OS compared to those with PD (14.6 v 4.2 mos, HR 0.2 (95% CI: 0.1 – 0.3). Multivariable Cox proportional hazards analysis for OS was significant for male gender (HR 1.9, p=0.002), presence of liver metastasis (HR 2.0, p=0.001), low Hb (HR 0.8, p=0.03) and log (LDH) (HR 1.9, p<0.001). **Conclusions:** Two-thirds of pts enrolled on EPCCTs benefitted in terms of DCR with significant OS improvement in those with PR and SD. Higher ORR were seen in pts receiving IO-based treatments however DCR was similar in IO and TT pts. Gender, presence of liver metastases, Hb count and LDH level contributed significantly to survival differences. Research Sponsor: None.

A phase Ib trial of alpelisib and weekly cisplatin in patients with solid tumor malignancies. *First Author: Erica S Tsang, University of California San Francisco, San Francisco, CA*

Background: The PI3K pathway may represent a mechanism to overcome cisplatin resistance, particularly in human papilloma virus (HPV)-associated tumors. We conducted a phase Ib trial of alpelisib and cisplatin for patients with solid tumor malignancies and HPV-associated tumors in the dose expansion cohort. **Methods:** Patients with advanced solid tumors were enrolled in this phase Ib open label study (NCT02620839). Dose escalation followed standard 3+3 design. Two different weekly doses of cisplatin (30 and 35 mg/m^2) were evaluated with escalating doses of alpelisib, administered daily during a 21-day cycle. The primary objective was to determine the maximum tolerated dose (MTD) and recommended phase II dose. Secondary objectives included determining the objective response rate (ORR), median progression-free survival (PFS), and characterizing the safety profile. **Results:** 23 patients were enrolled in this study between September 2016-August 2018. Median age was 57 years (range 37-83), and 57% of patients were female. Tumor sites included prostate (22%), cervical (13%), endometrial (13%), breast (9%), anal (9%), penile (9%), and other (26%). 91% of patients had > 3 lines of prior therapy, with 74% who previously received a platinum. Median duration of treatment was 8.7 weeks (range 1-57.5). The MTD was alpelisib 250 mg daily with weekly cisplatin 30 mg/m^2. 9 patients discontinued the study during cycle 1 due to an adverse event without progression. There were 3 DLTs, all of which were grade 4 hyperglycemia: 2 at alpelisib 250 mg and 1 at alpelisib 300 mg. Treatment-related grade 3-4 toxicities included hyperglycemia (13%), rash (13%), neutropenia (9%), anemia (4%), thrombocytopenia (4%), neuropathy (4%), and diarrhea (4%). Any grade nephropathy occurred in 17%. Dose reductions and/or interruptions were required in 61% of patients. There was a significant decrease in administered cisplatin dose intensity (33.8%) with a planned weekly cisplatin dose of 35 mg/m^2 and alpelisib 250 mg. In contrast, dose intensity ranged from 55-85% for other dose levels with an intended cisplatin dose of 30 mg/m^2. Dose expansion was not conducted due to significant early and cumulative toxicity. Of the 14 patients with post-baseline assessment available, ORR was 29%, with all 4 patients demonstrating partial response and 7 patients (50%) with stable disease. Of the 4 responders, tumor sites included 2 endometrial cancers, cervical neuroendocrine carcinoma, and penile SCC, and 3 were platinum-refractory. Median PFS measured 3.1 months (95% CI 1.3-4.1). 5 of 21 patients had *PIK3CA* mutations, with no difference in PFS (p= 0.76). **Conclusions:** While alpelisib and cisplatin demonstrated responses among patients with solid tumor malignancies, the combined adverse event profile presented significant dose intensity limitations. Future prospective studies are planned using carboplatin and alpelisib to improve the toxicity and tolerability. Clinical trial information: NCT02620839. Research Sponsor: Novartis.

3135 **Poster Session**

Cancer and COVID-19: A proposed mechanism with therapeutic interventions. *First Author: Yan Leyfman, Penn State Hershey College of Medicine, Hershey, PA*

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a novel betacoronavirus that causes the respiratory illness coronavirus disease 2019 (COVID-19). COVID-19 ranges in severity from an asymptomatic viral infection to life-threatening cases of pneumonia, acute respiratory distress syndrome (ARDS), multi-organ damage and sepsis. Cancer patients are at an increased risk of severe SARS-CoV-2 infection due to their immunocompromised status. We propose a mechanism by which SARS-CoV-2 infection causes multiple organ damage through IL-6-mediated inflammation and hypoxia-induced cellular metabolic alterations leading to cell death. Hypoxia is also induced by malignancy due to alterations in metabolism, resulting in greater IL-6 secretion. **Methods:** To highlight the possible effect of active cancer on the likelihood of hypoxia in COVID-19, we analyzed the correlation between cancer status and the severity of COVID-19 from the COVID-19 and Cancer Consortium data registry. For cancer status, we looked at progressive cancer and remission of cancer only – those being the two extremes of presence and absence of uncontrolled cancer. Similar to prior studies, the severity of COVID-19 was used as an indication of hypoxia. **Results:** We observed a 24% positive deviation between expected and actual number of patients with actively progressing cancer who had hypoxic COVID-19 (moderate to severe), and a 26.9% negative deviation between expected and actual number of patients with active cancer who had no hypoxia with COVID-19 ($p<0.0001$). Conversely, for patients with cancer in remission, there was only a +5.8% and -5.1% deviation between expected and actual number of patients who did not have hypoxia and who had hypoxia, respectively. **Conclusions:** These results suggest that in the presence of poorly controlled malignancy, there is an increased likelihood of hypoxia in patients with COVID-19, thereby exacerbating downstream cytokine release syndrome and contributing to prolonged systemic inflammatory injury. Appreciating this pathway, future therapies can be developed to target the pathogenesis of both diseases and prevent progression, as seen with mesenchymal stem cells, which demonstrated a 91% overall survival and 100% survival in patients younger than 85 years old at one month after a single treatment. Research Sponsor: None.

	Cancer in Remission	Cancer Progressing
Expected Non-Hypoxic	526	113
Actual Non-Hypoxic	557	82
Expected Hypoxic	589	126
Actual Hypoxic	558	157

Genome-wide cfDNA fragmentation in patients with cancer and other diseases. *First Author: Jacob Carey, Delfi Diagnostics, Baltimore, MD*

Background: Genome-wide cfDNA fragmentation patterns have previously been demonstrated to distinguish with high sensitivity and specificity between plasma samples from individuals with and without cancer. **Methods:** To further evaluate cfDNA fragmentation as a blood-based screening test for cancer, we have evaluated these genomic features in patients with and without cancer who have been diagnosed with other common comorbidities. For this study, we have used low coverage (1-2x) whole genome sequencing to analyze plasma samples from 412 patients referred to an advanced diagnostic center due to unexplained signs and symptoms associated with cancer. **Results:** Seventy-seven of these patients were ultimately diagnosed with one of sixteen different solid cancers, 68 with cardiovascular disease, 48 with diabetes, as well as other comorbidities. We used the DELFI approach (DNA evaluation of fragments for early interception) to measure the cfDNA fragmentation in plasma from all 412 patients included in the study using a cross-validated machine learning model. Patients with cancer could be distinguished from non-cancer individuals with high sensitivity and specificity (AUC = 0.92), including for common cancers such as colorectal and lung cancer. **Conclusions:** These data support the hypothesis that abnormal cfDNA fragmentation is a consequence of unregulated mitoses in cancer cells and can be distinguished from fragmentation patterns of individuals with co-morbidities. Research Sponsor: Delfi Diagnostics.

Outcomes of active cancer patients with COVID-19 infection treated with COVID-19 neutralizing monoclonal antibodies. *First Author: Justin Shaya, University of California San Diego, Moores Cancer Center, La Jolla, CA*

Background: Treatment with COVID-19 (C19) neutralizing monoclonal antibodies (mAbs), including bamlanivimab and casirivimab/imdevimab, has been associated with decreased rates of C19-related hospitalizations in high-risk patients. Patients with active cancer are at high-risk for C19 complications and currently are candidates for C19-mAbs. Little is known about C19-related outcomes with mAb therapy in cancer patients. Here, we examine the outcomes of a cohort of active cancer patients infected with C19 who were treated with C19-neutralizing mAbs. **Methods:** Retrospective, single center cohort of patients with active cancer and mild-moderate C19 infection not requiring hospitalization who were treated with either bamlanivimab or casirivimab/imdevimab. Active cancer was defined as a solid or hematologic malignancy diagnosed within 90 days of C19 diagnosis or recurrent/metastatic disease. The primary endpoint was the rate of C19-related hospitalization. Secondary endpoints included the rate of C19-related mortality and adverse events associated with mAb therapy. **Results:** We identified 38 active cancer patients with C19 who were treated with mAbs. Median age was 65 years (range 20-89) and 47.4% (N = 18) had a hematologic malignancy. Among the cohort, 73.7% (N = 28) were on an anti-cancer therapy at the time of C19 diagnosis: targeted therapy (n = 18), cytotoxic chemotherapy (N = 5), immunotherapy (n = 3), or hormonal therapy (n = 2). 42.1% (N = 16) received bamlanivimab and 57.9% (N = 22) received casirivimab/imdevimab. Median time from C19 diagnosis to mAb infusion was 2 days (range 0-6 days). With a median follow-up of 21 days (range 7-71), 7.9% (N = 3) required hospitalization for C19-related complications. Median time from mAb infusion to hospitalization was 25 days (range 5-29). C19-related deaths occurred in 5.3% (N = 2) of the cohort. No significant adverse events were reported with either mAb formulation. **Conclusions:** Among a cohort of high-risk cancer patients treated with mAbs, rates of hospitalization and mortality due to C19 were low compared to previously described rates among active cancer patients. Key limitations of this analysis include the lack of a control group for comparison and a small sample size given the recent emergency use authorization of these agents. Given the high mortality rate of active cancer patients with C19, these data support the use of mAbs in cancer patients with C19. Research Sponsor: None.

Patients with advanced solid cancers treated with ERK inhibitors exhibit pseudo-progession in lymphatic nodes. *First Author: Reem Abo-Zahrah, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ERK1/2 signaling is often overactivated in cancer, especially in patients with molecular alterations activating the MAPK pathway. MAPK pathway inhibition can result in the increase of CD8+ and CD4+ T-cells and decreased expression of immunosuppressive cytokines. **Methods:** This is a retrospective study of 52 patients with advanced solid cancers and oncogenic alterations in the MAPK pathway, who were treated in phase I/II clinical trials with five different single agent ERK1/2 inhibitors at MD Anderson Cancer Center. We reviewed serial PET and/or CT imaging obtained before therapy, on therapy, and after therapy completion. We evaluated dynamic changes in the lymphatic nodes (LN) in the context of overall response per RECIST 1.1 and other outcomes. **Results:** Of the 52 patients, 19 (37%) patients were evaluated with serial PET/CT and 33 (63%) with serial CT imaging only. Of the 19 patients evaluated with PET/CT, 12 (63%) demonstrated increased FDG uptake in LN compared to pre-treatment imaging (LN enlargement, n = 9; no LN enlargement, n = 3) discrepant from the known target and non-target lesions. These 12 patients were on therapy with ERK inhibitors (11 at doses $>$ recommended phase 2 dose [RP2D]) for a median of 3.6 months (range, 1.8-12 months) with a best response per RECIST 1.1. as follows: partial response, n = 1; stable disease (SD), n = 10; progressive disease (PD), n = 1. Of interest, in 6 of those 12 patients, FDG uptake in LN decreased or resolved after treatment discontinuation. Further, one patient had a biopsy of an emerged LN, which showed lymphocytic infiltrate without tumor cells. Of the 33 patients evaluated with CT only, 5 (15%) demonstrated increased size of LN discrepant from the known target and non-target lesions compared to pre-treatment imaging. These 5 patients were on therapy with ERK inhibitors (all at doses $<$ RP2D) for a median of 1.4 months (range, 1.1-3.5 months) with a best response per RECIST 1.1. as follows: SD, n = 2; PD, n = 3. Of interest, in 2 of those 5 patients, size of LN decreased or resolved after treatment discontinuation. In addition, one patient had a biopsy of an emerged LN, which showed lymphoid aggerates without tumor cells. **Conclusions:** Our data suggest that treatment with ERK inhibitors can result in activation of the lymphatic nodes, which can manifest as pseudo-progression. This can lead to an inconclusive assessment of their therapeutic benefit and further suggests exploration of the potential synergistic effects with immune therapy. Research Sponsor: U.S. National Institutes of Health.

Germline polymorphisms in genes maintaining replication fork to predict the efficacy of oxaliplatin and irinotecan in metastatic colorectal cancer (mCRC) patients enrolled in MAVERICC trial. *First Author: Hiroyuki Arai, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Protection of replication forks is critical for the survival of cancer cells. Chemotherapeutic drugs such as oxaliplatin and irinotecan can impede the progression of replication forks by inducing DNA lesions, which cause fork collapse and generate double-strand breaks. We hypothesized that functional genetic variants in genes involved in the maintenance of replication forks may predict the efficacy of cytotoxic drugs in mCRC patients. **Methods:** We analyzed genomic and clinical data from MAVERICC, a phase II trial which compared mFOLFOX6 and FOLFIRI in combination with bevacizumab in untreated mCRC patients. Genomic DNA extracted from blood samples was genotyped using an OncoArray (Illumina, Inc., San Diego, CA, USA). Candidate six missense single nucleotide polymorphisms (SNPs) (*SLFN11* rs9898983, *SLFN11* rs12453150, *RPA1* rs5030749, *MCM3* rs2230240, *TIMELESS* rs2291739, and *TIMELESS* rs774047) were tested for association with progression-free survival (PFS) and overall survival (OS), using Cox proportional hazards model. To confirm the predictive value, the treatment-by-SNP interaction was tested. **Results:** A total of 324 patients were available for the SNP analyses (mFOLFOX6 plus bevacizumab arm [OHP arm]: $n = 161$; FOLFIRI plus bevacizumab arm [IRI arm]: $n = 163$). In the OHP arm, univariable analysis showed a significantly better PFS in patients with G/G genotype of *TIMELESS* rs2291739 compared to those with any A allele, and in patients with T/T genotype of *TIMELESS* rs774047 compared to those with any C allele. However, neither of these SNP's associations were confirmed by multivariable analysis: *TIMELESS* rs2291739 (any A allele vs G/G, hazard ratio [HR] = 0.60, 95% confidence interval [CI] = 0.31–1.17, $p = 0.12$) and *TIMELESS* rs774047 (any C allele vs T/T, HR = 0.74, 95% CI = 0.41–1.36, $p = 0.33$). In the IRI arm, univariable analysis showed a significantly worse OS in patients with G/G genotype of *TIMELESS* rs2291739 compared to those with any A allele, and in patients with T/T genotype of *TIMELESS* rs774047 compared to those with any C allele. Multivariable analysis confirmed the significant associations in these SNPs: *TIMELESS* rs2291739 (any A allele vs G/G, HR = 3.06, 95% CI = 1.49–6.25, $p < 0.01$) and *TIMELESS* rs774047 (any C allele vs T/T, HR = 2.95, 95% CI = 1.43–6.08, $p < 0.01$). Treatment-by-SNP interaction test confirmed the significant predictive value of both SNPs, both on PFS and OS. **Conclusions:** Germline polymorphisms in the *TIMELESS* gene involved in the protection of replication forks may predict efficacy of oxaliplatin and irinotecan in mCRC patients. Our novel findings warrant further validation studies. Initiative for Molecular Profiling and Advanced Cancer Therapy (IMPACT2): Challenges and Opportunities in Conducting an MD Anderson Randomized Study in Precision Oncology. *First Author: Henry Hiep Vo, The University of Texas MD Anderson Cancer Center, Department of Investigational Cancer Therapeutics, Houston, TX*

Background: Precision oncology is associated with favorable outcomes in selected patients with cancer. Our first IMPACT trial (IMPACT1) demonstrated that in sequential patients with advanced cancer who had tumor molecular testing and participated in phase I clinical trials, matched targeted therapy (MTT) was associated with superior rates of response, progression-free survival (PFS) and overall survival compared with those of patients who received non-MTT. Despite the statistical significance for these outcomes, the study was non-randomized. Recognizing that it would be difficult to randomize patients we nonetheless undertook IMPACT2, a phase 2 randomized study to determine whether patients treated on the basis of tumor genomic alterations have longer PFS compared to those whose treatment is not selected on the basis of molecular alteration analysis. **Methods:** Patients with metastatic cancer undergo a tumor biopsy and genomic profiling. Patients are presented at tumor board and are offered to be randomized between two arms: MTT or non-MTT, when criteria (biomarker present, available clinical trial, eligibility criteria met, insurance approval) are met. In April 2019, we amended the trial to include a "patient-preference" cohort for each arm. Patients who decline randomization are offered choice of arm (ClinicalTrials.gov: NCT02152254). The primary analysis will use both randomized and patient-preference cohorts based on a Bayesian hierarchical model that "borrows" from the patient-preference cohorts to the extent to which its PFS agrees with that in the randomization cohort. **Results:** The key barriers randomizing patients with actionable molecular alterations are patient-related (advanced, metastatic setting requiring immediate intervening therapy; decline in performance status, organ function; or death); drug-related (FDA-approved drug available; or unavailable MTT against key driver biomarker) or financial (no insurance coverage of MTT; lack of patient resources to participate in trials). As the study spans over a few years, some investigational agents that were considered non-MTT at the time of treatment assignment were later proven to be MTT (e.g., immunotherapeutic agents targeting high tumor mutational burden); and/or were approved by the FDA. **Conclusions:** Although randomized trials have been considered the gold standard in drug development, such studies in the advanced metastatic setting are complicated. The benefit of Precision Oncology has been exemplified in individual patients who were treated with biomarker-selected therapy. The adaptive design of IMPACT2 enables patient randomization despite the evolving tumor biomarkers and the plethora of investigational drugs. IMPACT2 provides insights for the development of cancer genome-based medicine. Outcomesfor randomized patients are awaited. Clinical trial information: NCT02152254. A phase 2 basket trial of combination therapy with trastuzumab and pertuzumab in patients with solid cancers harboring HER2 amplification (JUPITER trial). *First Author: Ryo Kudo, Tokyo Medical and Dental University hospital, Bunkyo-Ku, Japan*

Background: The human epidermal growth factor receptor 2 (HER2) gene amplification and mutations have emerged as oncogenic drivers and therapeutic targets not limited to breast and gastric cancers, but also in a variety of cancers. However, even if an actionable gene alteration is found, the incidence of HER2 amplification in these cancers is less than 5%. Despite its considerable therapeutic potential, the evidence is not yet mature enough for use as treatment in clinical practice. To address this unmet clinical need, we have designed an organ-agnostic basket trial, which covers a variety of solid cancers harboring HER2 amplification. **Methods:** JUPITER trial is a Japanese multicenter, single-arm, phase 2 basket study of combination therapy with trastuzumab and pertuzumab. Patients with solid cancers harboring HER2 amplification, who have progressed with standard treatment, or rare cancers for which there is no standard treatment, are eligible. Types of cancer include bile duct, urothelial, uterine, ovarian, and other solid cancers that HER2 amplification is detected by comprehensive genomic profiling using next-generation sequencing technology. Target sample size is 38. All enrolled patients receive combination therapy with trastuzumab and pertuzumab every 3 weeks until disease progression, unacceptable toxicity, death, or withdrawal of informed consent. Response assessment using RECIST version 1.1 is performed at weeks 9 and 17, followed by every 12 weeks. The primary endpoint is the objective response rate, and secondary endpoints are progression-free survival, overall survival, duration of response, and safety. In total, 40 patients were enrolled by June 2020. Data fix is scheduled in September 2021. Trial registration: jRCT2031180150 Clinical trial information: jRCT2031180150. Research Sponsor: Japanese Agency for Medical Research and Development.

TPS3142 **Poster Session**

A phase 1b, open-label, single-arm study of cofetuzumab pelidotin (a PTK7-targeting antibody-drug conjugate) in patients with PTK7-expressing, recurrent non-small cell lung cancer (NSCLC). *First Author: Eric S Schaefer, Highlands Oncology Group, Fayetteville, AR*

Background: Protein tyrosine kinase 7 (PTK7) is a highly conserved receptor tyrosine kinase involved in the Wnt signaling pathway and is overexpressed in multiple cancer types, including non-small cell lung cancer (NSCLC). Cofetuzumab pelidotin (ABBV-647) is an anti-PTK7 antibody-drug conjugate comprising the hu6MO24 monoclonal antibody, a cleavable cysteine-reactive linker, and Aur0101 (an auristatin microtubule inhibitor). It has shown promising preclinical anti-tumor effects (Damelin et al. Sci Transl Med 2017;9[372]:eaag2611) and clinical activity with a manageable safety profile in a Phase 1 study in patients with advanced solid tumors, with promising anti-tumor activity noted in NSCLC (Sachdev et al. DOI: 10.1200/JCO.2018.36.15_suppl.5565). **Methods:** This open-label, single-arm, multicenter Phase 1b study (NCT04189614) will assess the anti-tumor activity and safety of cofetuzumab pelidotin in approximately 40 patients with PTK7-expressing, recurrent NSCLC. The primary objective is to assess the objective response rate of cofetuzumab pelidotin according to Response Evaluation Criteria in Solid Tumors version 1.1. Secondary objectives include the duration of response, progression-free survival, overall survival, and safety and tolerability. Pharmacokinetic and biomarker samples will also be collected throughout for analysis. Patients must be aged ≥18 years with an Eastern Cooperative Oncology Group performance status of 0–1 and have recurrent histologically confirmed NSCLC with PTK7-expressing tumor (using a validated immunohistochemistry assay). Patients must have progressed after treatment with a platinum-based chemotherapy doublet and an immune checkpoint inhibitor (for tumors without targetable genetic alterations), or a platinum-based chemotherapy doublet and targeted agent(s) (for tumors with targetable genetic alterations). Patients must also have received ≤2 prior lines of systemic therapy (≤3 prior lines for tumors treated with targeted agent[s] for genetic alterations), including no more than 1 line of systemic chemotherapy. Cofetuzumab pelidotin (2.8 mg/kg) is administered intravenously every 3 weeks until the patient experiences disease progression, intolerable toxicity, or other study treatment discontinuation criteria are met. The study commenced on February 13, 2020 and enrollment is ongoing. Clinical trial information: NCT04189614. Research Sponsor: AbbVie.

TPS3143 **Poster Session**

TCF-001 TRACK (Target Rare Cancer Knowledge): A national patient-centric precision oncology trial for rare cancers. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Many rare cancers are understudied, and affected patients often have few if any standard treatment options and limited access to clinical trials. Comprehensive genomic profiling (CGP) is a robust tool to efficiently identify the genomic alterations of cancer and can be applied to study rare tumors. The promise of this technology is to simultaneously enhance our understanding of diverse rare tumors and find matched therapies to benefit the individual patient in real-time. The COVID19 pandemic has challenged the "trial-centric" clinical trial infrastructure. Novel "patient-centric" trials are needed, especially for rare cancers. TRACK is a decentralized, patient advocacy-initiated trial that aims to establish whether patients with rare tumors and cancer of unknown primary can benefit from matched molecular therapy as dictated by their CGP results. **Methods:** This is a national open label, non-randomized, multi-center (includes community and academic centers) pragmatic study in rare tumors (<6 cases per 100,000 persons per year) and cancer of unknown primary. All participants will have tumor tissue and blood analyzed by CGP (FoundationOneCDx and FoundationOneLiquidCDx). A Virtual Molecular Tumor Board (VMTB) will convene to identify targeted treatment recommendations for participants with genomic alterations. Overall, 400 participants will be enrolled to achieve the goal of 100 patients matched to genomically informed treatment, utilizing remote consenting to ensure study access regardless of geographic location. The primary feasibility endpoint is the percent of participants who receive a molecularly matched treatment after recommendation from the VMTB. The primary efficacy endpoint is the progression-free survival (PFS) among participants who received the molecularly matched treatment. Secondary endpoints include the percent of participants with genomic alterations, overall response rate, response duration, overall survival, clinical benefit rate (SD > 6 months; PR; CR), and high-grade toxicities (as available) of matched targeted therapy. Exploratory endpoints include matching rates; understanding genomic correlates of response; concordance rates between CGP from tissue and blood, time-to-treatment failure, and the impact of the cancer treatment from the patient perspective (via ESAS-FS, a validated patient-reported outcomes (PRO) instrument). All eligible and enrolled patients, regardless of whether receiving matched treatment or not, will be followed for a minimum of one year in a uniform way such that the treatment efficacy and outcomes can be assessed in standard formats. The study is open with six patients enrolled at time of submission. Clinical trial information: NCT04504604. Research Sponsor: TargetCancer Foundation, Inc, Pharmaceutical/Biotech Company.

TPS3144 **Poster Session**

A phase 1 study of SGN-B6A, an antibody-drug conjugate targeting integrin beta-6, in patients with advanced solid tumors (SGNB6A-001, Trial in Progress). *First Author: Amita Patnaik, START, San Antonio, TX*

Background: The extracellular matrix (ECM) plays an important role in solid tumor pathogenesis and is a major focus of research and therapeutic targeting. Integrin beta-6 is a cell surface receptor that interacts with the ECM to mediate cellular adhesion. Integrin beta-6 is overexpressed in numerous solid tumors and its expression is a negative prognostic marker in cancers including colorectal, non-small cell lung, gastric, and cervical cancers. SGN-B6A is an investigational vedotin, an antibody-drug conjugate directed against integrin beta-6 to selectively deliver the cytotoxic agent monomethyl auristatin E, which binds tubulin and induces apoptosis. In multiple xenograft models, treatment with SGN-B6A resulted in tumor growth delay and regression in tumor volume when compared to non-binding control. **Methods:** SGNB6A-001 (NCT04389632) is a phase 1, first-in-human, open-label, multicenter study designed to evaluate the safety, tolerability, pharmacokinetics (PK), and antitumor activity of SGN-B6A in adults with select advanced solid tumors. Primary objectives are to evaluate the safety and tolerability of SGN-B6A in patients with advanced solid tumors, identify the maximum tolerated dose, and identify a recommended dose and schedule. The study has 2 parts: dose escalation (Part A) and dose expansion with multiple disease-specific cohorts and a biology cohort (Part B). SGN-B6A will initially be given by intravenous infusion on Days 1, 8, and 15 of 21-day cycles. The dose escalation (Part A) will be conducted using the modified toxicity probability interval method to determine a dose that demonstrates a dose-limiting toxicity rate of 25% with a 5% margin. The dose and schedule for Part B will be determined based on evaluation of safety, PK, and pharmacodynamic biomarkers. Response evaluations will be based on RECIST v1.1. Patients must be ≥18 years old and have histologically or cytologically confirmed metastatic or unresectable solid malignancy within one of the following tumor types: non-small cell lung cancer, head and neck squamous cell cancer, breast cancer, esophageal cancer, ovarian cancer, cutaneous squamous cell cancer, exocrine pancreatic adenocarcinoma, bladder cancer, cervical cancer, or gastric cancer. After an appropriate dose and schedule are determined in Part A, safety and preliminary antitumor efficacy of SGN-B6A will be evaluated in indication-specific cohorts (Part B). This study is ongoing in sites across North America and Europe. Clinical trial information: NCT04389632. Research Sponsor: Seagen Inc.

TPS3145 **Poster Session**

Phase I trial of acoustic cluster therapy (ACT) with chemotherapy in patients with liver metastases of gastrointestinal origin (ACTIVATE study). *First Author: Udai Banerji, The Institute of Cancer Research and The Royal Marsden, London, United Kingdom*

Background: Response to existing chemotherapeutics (chemo) can be limited by exposure, itself limited by systemic toxicity. Interstitial fluid pressure can impede transport of drugs with, in some cases, <5% of systemic chemo penetrating the target tumour. ACT is an innovative platform technology using sonopermeation to induce ultrasound (US) mediated targeting of therapeutic agent of choice by co-administration of an emulsion of microbubble-microdroplet clusters (PS101) for intravenous injection. Dual-frequency US is applied to tumor tissue to concentrate the drug through expansion and oscillation of the clusters, increasing tumoral penetration. Early pre-clinical models of ACT indicate significant increase in uptake of co-administered product at the US targeted site and have demonstrated enhanced efficacy outcomes with co-administered ACT across a range of cancer models. All studies showed significant benefit in disease response and tumour regression/inhibition versus drug alone. The combination of US, microbubbles and chemo has been shown to be feasible in a clinical setting using commercially available equipment with no additional toxicities. This first in human study will primarily investigate the safety and tolerability of PS101 in combination with chemo together with any differential response in ACT-treated versus control lesions to identify the phase 2 recommended dose. **Methods:** This is an open label non-randomised study with central blinded assessment of tumor response. The study comprises two parts: Part 1, a dose escalation in a 3+3 design followed by dose expansion in Part 2. Patients with advanced solid tumors with liver metastases for whom FOLFOX/FOLFIRI is considered an appropriate treatment option are eligible for Part 1 (n=6-12); two separate cohorts of patients with liver metastases, one with metastatic colorectal cancer eligible for 1L or 2L standard of care (SOC) FOLFOX/FOLFIRI (n=25) and one with metastatic pancreatic ductal adenocarcinoma (n= 6) eligible for SOC gemcitabine-nab-paclitaxel will be treated in Part 2. The starting dose of PS101 is 20 μL/kg with a maximum feasible dose of 40 μL/kg. In Part 1, after sentinel administration of PS101 for PK profiling and toxicity assessment, patients receive PS101 (given as i.v. bolus x 3) in combination with FOLFOX or FOLFIRI and US (to one target lesion) in four q2w cycles. The DLT evaluation period comprises the PK-assessment period plus two cycles of ACT plus chemo. Patients receive a further two cycles of ACT and chemo prior to evaluation of tumor lesions by CT/MRI at the Week 8 timepoint. Assessment is made of the target lesion and the pre-defined control lesions outside of the US field. Part 1 has enrolled 5 patients without DLT, with part 2 expected to start in mid-2021. Clinical trial information: NCT04021277. Research Sponsor: Exact Therapeutics.

TPS3146 **Poster Session**

First-in-human phase 1 trial (DRAGON) of SRK-181, a potential first-in-class selective latent TGFβ1 inhibitor, alone or in combination with anti-PD-(L)1 treatment in patients with advanced solid tumors. *First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Transforming growth factor-beta 1 (TGFβ1) is a key mediator of primary resistance to programmed cell death protein 1 (PD-1) pathway blockade. SRK-181 is a fully human, highly potent and selective monoclonal antibody that inhibits latent TGFβ1 activation. SRK-181 has minimal or no binding to latent TGFβ2 and TGFβ3 isoforms or to active TGFβ growth factors. In mouse tumor models (bladder, melanoma, and breast cancer), SRK-181 in combination with anti-PD1 therapy overcame primary anti-PD-1 resistance and showed survival benefit. No cardiotoxicities (valvulopathy) were observed with SRK-181 in 4-week GLP nonclinical toxicology studies. Thus, the potency and selectivity of SRK-181 may overcome PD-1 inhibitor resistance and toxicity of non-selective TGFβ pathway approaches. **Methods:** The DRAGON trial NCT04291079 is an ongoing multicenter, open-label, phase 1 study of SRK-181 administered by IV infusion every 3 weeks (Q3W) alone or in combination with anti-PD-(L)1 in patients (pts) with locally advanced or metastatic solid tumors. The study comprises 3 parts: Part A of the study follows a standard 3+3 dose escalation trial design to evaluate safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and antitumor activity of SRK-181 alone (Part A1) or in combination with the anti-PD-(L)1 agent that is approved for the respective tumor indication (Part A2). Part A1 and Part A2 will determine maximum tolerated dose (MTD) or maximum administered dose and Recommended Phase 2 Dose (RP2D) for Part B. Part B (expansion phase) will evaluate combination treatment of SRK-181 with anti-PD-(L)1 in pts with non-small cell lung cancer, urothelial carcinoma (UC), melanoma or other advanced solid tumors, to confirm the tolerability of the RP2D and to evaluate the antitumor activity of combination treatment. Pts in Part A2 and Part B must have previously received an anti-PD-(L)1 therapy approved in their tumor indication and considered non-responders (best response of stable disease or disease progression) to anti-PD-(L)1 monotherapy. Pts in Part B must have received the most recent dose of the prior anti-PD-(L)1 within 6 months of study enrollment (9 months for UC cohort). Safety, PK, PD and efficacy data will be collected and monitored throughout the study. Detailed translational PD and predictive biomarker studies for SRK-181 will include a novel digital pathology analysis of CD8 to assess the alteration of immune profile in tumor microenvironment and TGFb pathway biomarkers, such as quantitative analysis of tumor phospho-Smad2 and circulating levels of TGFb1 ligand. As of Feb 01 2021, dose escalation has proceeded to the highest planned dose of 2400 mg Q3W in Part A1 (monotherapy) and to 800 mg Q3W in Part A2 (anti-PD-(L)1 combination). Additional planned doses in Part A2 are 1600 mg and 2400 mg Q3W. Clinical trial information: NCT04291079. Research Sponsor: Scholar Rock Inc.

TPS3147 **Poster Session**

Phase 1b dose escalation study to evaluate the safety, tolerability, pharmacokinetics, and preliminary efficacy of GS-3583, a FLT3 agonist Fc fusion protein, in patients with advanced solid tumors. *First Author: Joshua Brody, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Productive antitumor immune responses in nonclinical models depend on a type of dendritic cell (DC), conventional DC subtype 1 (cDC1), which in the context of cancer, primes tumor-reactive T cells through presentation of tumor-derived antigens. FMS-related tyrosine kinase 3 ligand (FLT3L) is a hematopoietic growth factor that binds to and activates FLT3 on terminally differentiated DCs. Activated FLT3 promotes proliferation, inhibits cell death, and is required for the differentiation, expansion, and maintenance of DCs in peripheral and lymphoid organs. GS-3583 is a fusion protein composed of the extracellular domain of recombinant human FLT3L fused to an engineered fragment crystallizable (Fc) region of human immunoglobulin G4. GS-3583 has PK properties that support sustained cDC in patients and potential combination with established immunotherapies. This phase 1b, open-label, multicenter, dose-finding study will evaluate safety, tolerability, PK, and preliminary efficacy of GS-3583 monotherapy in patients with advanced solid tumors (NCT04747470). **Methods:** Approximately 33 adults aged ≥18 years with a histologically or cytologically confirmed locally advanced or metastatic malignant solid tumor that is refractory to or intolerant of standard therapy or for which no standard therapy is available will be enrolled. The study employs a 3+3 dose escalation design in which GS-3583 is administered intravenously for up to 52 weeks or until progressive disease or unacceptable toxicity. Up to five dose escalation cohorts have been planned. The maximum tolerated dose is the highest dose with incidence of DLT in < 33% of 6 or more patients in the first 28 days of GS-3583 dosing; recommended phase 2 dose will be determined. Assessments include safety, PK, pharmacodynamics including cDCs, immunogenicity, and efficacy by RECIST 1.1 in CT/MRI imaging conducted every 8 weeks. Accrual at approximately 3-4 centers in the US is ongoing. Clinical trial information: NCT04747470. Research Sponsor: Gilead Sciences, Inc.

TPS3149 **Poster Session**

Phase 1 and phase 2a, first-in-human (FIH) study, of DRP-104, a broad glutamine antagonist, in adult patients with advanced solid tumors. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: Dependence of cancer cells on glutamine has made glutaminolysis an attractive therapeutic target in cancer. Prior clinical trials evaluating glutamine analogues for the treatment of cancer were abandoned due to lack of efficacy and/or tolerability. DON (6-Diazo-5-oxo-L-norleucine) is an irreversible inhibitor of several enzymes that utilize glutamine as a metabolic substrate. In addition to direct anti-tumor efficacy, inhibition of glutamine metabolism in the tumor microenvironment has been shown to improve T-cell activation and tumor infiltration, increasing anti-tumor immune responses. As such, combining DON with an immune checkpoint inhibitor (ICI), has strong preclinical rationale. The investigational product DRP-104 (sirpiglenastat) is an inactive prodrug of DON designed to limit systemic DON exposure while targeting glutamine dependence in tumor cells. **Methods:** A phase 1/2a, FIH, multi-center, non-randomized, multi-cohort, open-label study of DRP-104 is currently open to accrual for patients with advanced solid tumors. This study will be conducted in 4 parts: A) Dose Escalation of IV and subQ DRP-104 (Run-In phase followed by modified Continual Reassessment Method) to define MTD/RP2D. Primary objective of dose escalation is to assess the safety, tolerability, pharmacokinetics, pharmacodynamics and preliminary antitumor activity of DRP-104 as a single agent; B) Dose Expansion of IV and subQ DRP-104 for safety assessment while primary objective is to select and recommend phase 2 DRP-104 route of administration; C) Phase 2a at recommended MTD/RP2D of selected route of DRP-104 in 2 patient cohorts: patients with locally advanced/metastatic NSCLC with KEAP1, NFE2L2 and/or STK11 mutation and patients with unresectable or metastatic SCCHN, in order to assess the safety, tolerability and preliminary antitumor activity of DRP-104 as a single agent; D) Phase 2a at recommended MTD/RP2D of selected route of DRP-104 in combination with atezolizumab in adult patients with advanced solid tumors previously treated with an ICI, in order to assess the safety, tolerability and preliminary antitumor activity of DRP-104 in combination with atezolizumab; DRP-104 IV is infused TIW over 1 hour infusion for 2 consecutive weeks followed by 1 week off. DRP-104 subQ is administered BIW weekly. Study is currently open with 6 IV patients (Run-In Phase completed and at Dose Level 4) and 3 subQ patients at Dose Level 1 at time of submission. Clinical trial information: NCT04471415. Research Sponsor: Dracen Pharmaceuticals, Inc.

TPS3150 **Poster Session**

Subcutaneous delivery of amivantamab in patients with advanced solid malignancies: PALOMA, an open-label, multicenter, dose escalation phase 1b study. *First Author: Matthew Krebs, Division of Cancer Sciences, Faculty of Biology, Medicine and Health, The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: Amivantamab, an epidermal growth factor receptor (EGFR)-MET bispecific antibody with immune cell-directing activity, targets activating/resistance EGFR mutations and MET mutations/amplifications. Amivantamab has demonstrated antitumor activity in patients (pts) with EGFR-mutant NSCLC and also in pts with EGFR tyrosine kinase inhibitor-resistant disease. The recommended phase 2 dose (RP2D) is 1050 mg (1400 mg, ≥80 kg) administered as intravenous (IV) infusions weekly (QW) for the first 28-day cycle and every other week (Q2W) thereafter. A subcutaneous (SC) formulation of amivantamab has the potential to reduce pt and physician burden by reducing administration time. The safety and pharmacokinetics (PK) of amivantamab administered SC ± recombinant human hyaluronidase (rHuPH20) will be evaluated. **Methods:** PALOMA is an ongoing phase 1b dose escalation study of amivantamab SC in pts with advanced solid tumors that may derive benefit from EGFR or MET-directed therapy (NCT04606381). Pts must have progressed on standard of care therapy for metastatic disease, be ineligible for, or have refused current standard therapies. The primary endpoints are trough concentration at the end of QW dosing and safety of SC administration. The objective of part 1 is to evaluate the feasibility, safety, and PK of SC administration of a low concentration (50 mg/mL) formulation of amivantamab alone (Ami-LC) or admixed with rHuPH20 (Ami-LC-MD). Approximately 8 pts will be enrolled to receive either 1050/1400 mg amivantamab SC using Ami-LC-MD (Cohort 1a) or Ami-LC (Cohort 1b) QW in cycle 1 and Q2W thereafter. The objective of part 2 is to evaluate the safety and PK of SC administration of a high concentration (160 mg/mL) formulation of amivantamab alone (Ami-HC) or with rHuPH20 (Ami-HC-CF) and to determine a dose, schedule, and formulation for SC administration that achieves similar exposure as observed at the RP2D of amivantamab IV, with acceptable safety. Pts enrolled in part 2 will initially receive 1050/1400 mg amivantamab SC using Ami-HC-CF in Cohort 2a or Ami-HC in Cohort 2b. ≤10 pts may be enrolled in either cohort. Additional cohorts of ≤10 pts may be enrolled to support dose, schedule, and formulation selection as guided by safety and PK observations in earlier cohorts. To mitigate infusion related reactions (IRR), medication with steroid, paracetamol, and antihistamine will be given pre-infusion and as clinically indicated post-infusion. Safety assessments include monitoring adverse events, laboratory abnormalities, vital signs, IRR, and injection site reactions. Blood samples will be collected to assess PK, pharmacodynamics, and immunogenicity. A Study Evaluation Team composed of investigators and sponsor representatives will review safety and PK data to make decisions about dose escalation and cohort expansion throughout the conduct of the study. Clinical trial information: NCT04606381. Research Sponsor: Janssen R&D.

TPS3151 **Poster Session**

SGNTUC-019: Phase 2 basket study of tucatinib and trastuzumab in previously treated solid tumors with HER2 alterations (trial in progress). *First Author: Tom Stinchcombe, Duke Cancer Institute, Durham, NC*

Background: Tucatinib (TUC) is a highly selective HER2-directed TKI approved in combination with trastuzumab (Tras) and capecitabine (Cape) for HER2 overexpressed/amplified (HER2+) metastatic breast cancer (BC), based on a statistically significant and clinically meaningful PFS, OS, and ORR benefit over Tras and Cape. In xenograft models of HER2+ and HER2-mutated (HER2-mut) tumors, dual targeting of HER2 with TUC and Tras showed superior activity to either agent alone. While various HER2-directed agents have been evaluated in HER2+ and HER2-mut tumors, there are no approved HER2 therapies outside of breast and gastric cancers. The SGNTUC-019 basket study is evaluating TUC combined with Tras in patients (pts) with HER2+ or HER2-mut locally-advanced unresectable or metastatic solid tumors. **Methods:** SGNTUC-019 (NCT04579380) is a multi-cohort, open-label, international phase 2 study. Eligible pts must have progressed on or after the last systemic therapy for advanced disease. Metastatic cervical cancer: must have received platinum-based chemotherapy ± bevacizumab; hormone receptor positive (HR+) HER2-mut BC: must have received a prior CDK4/6 inhibitor. Pts must be ≥18 years old, with ECOG PS ≤1, adequate hepatic, hematological, renal, coagulation, and cardiac function, and no prior HER2-directed therapy (except Tras for uterine serous carcinoma). For eligibility, HER2 alterations can be demonstrated by HER2+ in tumor tissue by prior IHC/ISH (IHC 3+/signal ratio ≥2.0 or gene copy number >6), or by HER2 amplification/mutation in a prior or on-study NGS assay of ctDNA or prior tissue NGS assay. Pts with HER2+ disease will be enrolled in cohorts for cervical, uterine, biliary tract, and urothelial cancers, non-squamous NSCLC, and other solid tumors (except GEC, BC, and CRC). Pts with HER2-mut disease will be enrolled in cohorts for non-squamous NSCLC, BC, and other solid tumors. Except for solid tumor and BC cohorts, 12 RECIST 1.1 evaluable pts will be enrolled in each cohort. If ≥2 responses are observed, the cohort will be expanded to a total of 30 pts. Other solid tumor and BC cohorts will enroll 30 pts in a single stage. If justified, additional HER2+ or HER2-mut disease-specific cohorts may be opened. Approximately 162-270 pts are planned. The primary objective is antitumor activity in each cohort, with confirmed ORR per investigator as primary endpoint, and disease control rate, duration of response, PFS, and OS as secondary endpoints. Pts will receive TUC 300 mg orally twice daily and Tras 8 mg/kg IV on Cycle 1 Day 1 and 6 mg/kg q21 days from Cycle 2 Day 1. HR+ BC pts will also receive fulvestrant 500 mg IM every 4 weeks and C1 D15. Disease assessments per RECIST 1.1 will occur q6 weeks for 24 weeks, then q12 weeks. TUC PK will be evaluated in all pts in Cycles 2-6. QoL is evaluated q2 cycle using EQ-5D-5L. Sites are open in the US; EU and Asia will be opened. Enrollment began in Dec 2020. Clinical trial information: NCT04579380. Research Sponsor: Seagen Inc.

TPS3152 **Poster Session**

Trial in progress: Phase 1a/b study of PF-07284890 (brain-penetrant BRAF inhibitor) with/without binimetinib in patients with BRAF V600-mutant solid tumors. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BRAF inhibitors have transformed treatment (Tx) for patients (pts) with BRAF V600-mutant cancers, but long-term efficacy is limited by disease progression in the brain, due to poor brain penetration. PF-07284890 is a potent, selective, highly brain-penetrant, small-molecule inhibitor of BRAF V600 mutations. This first in human study will assess the PK, safety, and preliminary clinical activity of PF-07284890, as monotherapy and in combination with binimetinib (MEK inhibitor), in pts with BRAF V600-mutated advanced solid tumors with/without brain metastases. **Methods:** Phase 1a/1b open-label, multicenter, dose-finding study (NCT04543188). Pts will be ≥18 y with a histologically confirmed advanced/metastatic solid tumor including primary brain tumor (PBT), confirmed BRAF V600 mutation, and presence/absence of brain involvement. Pts will have disease progression despite prior Tx without alternative Tx options. Pts with brain metastasis/PBT > 4 cm and/or symptomatic brain disease will be excluded initially, but allowed based on emerging PK. Phase 1a is a dose escalation study of PF-07284890 (monotherapy and combination). ~35 pts will be enrolled to determine maximum tolerated dose (MTD) and/or recommended dose for expansion (RDE) of PF-07284890 (monotherapy and combination). Cohorts of 2-4 pts will be treated at each dose level of PF-07284890 until MTD/RDE determination (PF-07284890 starting dose: 50 mg QD; binimetinib 45 mg BID). Bayesian Logistic Regression Model will be used to inform dose level decisions. At least 6 pts each for monotherapy and combination will be treated at MTD/RDE. Phase 1a primary endpoints: Cycle 1 dose-limiting toxicities; MTD/RDE; AEs; lab abnormalities; and dose interruptions, modifications and discontinuations due to AEs. Secondary endpoints include PK parameters and overall response (RECIST; overall and intracranial; RANO for PBT). Phase 1b is a dose expansion and drug-drug interaction study to further evaluate PF-07284890 + binimetinib. Cohorts 1-4 (~40 pts each) will enroll pts based on tumor type, brain involvement (asymptomatic/symptomatic), and prior Tx. Cohort 5 (~20 pts) will include pts with any solid tumor including leptomeningeal metastases. Cohort 6 (~10 pts) will assess the effect of PF-07284890 + binimetinib on CYP3A activity using midazolam as a substrate. Phase 1b primary endpoint: overall response (RECIST; overall and intracranial; RANO for PBT). Secondary endpoints: duration of response; progression-free survival; disease control rate; time to response; overall survival; AEs; lab abnormalities; and dose interruptions, modifications and discontinuations due to AEs; and PK parameters. For both Phase 1a and 1b, Tx will continue until disease progression, unacceptable toxicity or patient refusal. Study began enrolling pts in January 2021 and is ongoing. Clinical trial information: NCT04543188. Research Sponsor: Pfizer.

TPS3153 **Poster Session**

A first-in-human phase I study of ATR inhibitor M1774 in patients with solid tumors. *First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ataxia telangiectasia and Rad3-related (ATR) protein kinase plays a critical role in the DNA damage response by sensing and responding to DNA replication stress, and by inducing cell cycle arrest to prevent aberrant replication and mitotic catastrophe. Based on extensive preclinical and limited clinical evidence, ATR inhibition is a promising treatment strategy as monotherapy for patients with advanced tumors harboring synthetically lethal conditions, such as alternative lengthening of telomeres (ALT) and inactivating mutations in *ARID1A* and *ATM*. M1774 is a potent, selective, orally administered ATR inhibitor that has been shown to exert antitumor activity in patient-derived xenograft tumors and acute myeloid leukemia xenograft tumors that express the ATR inhibition sensitizing mixed lineage leukemia fusion protein. This study (NCT04170153) aims to evaluate the safety and tolerability, maximum tolerated dose, recommended dose for expansion (RDE) and pharmacokinetics (PK) of M1774 (part A1), the effect of food on M1774 PK (part A2), and the efficacy of M1774 in patients with tumors harboring selected mutations (part A3). An additional objective is to assess the pharmacodynamics of M1774 by measuring relative changes in baseline p-CHK1 and γ-H2AX expression in paired tumor biopsies and serial blood samples. **Methods:** Patients aged ≥18 years, with an Eastern Cooperative Oncology Group performance status ≤1, adequate baseline hematological, renal and hepatic function, and with locally advanced or metastatic disease refractory to standard therapy are eligible. Patients with tumors bearing loss-of-function (LoF) mutations (determined by site testing or a central trial assay) in *ARID1A*, *ATM*, or *ATRX* and/or *DAXX* as ALT status surrogate markers; and measurable disease according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1, will be enrolled in part A3. In the dose escalation phase (part A1 [open]), 18–24 patients are due to receive M1774 at a starting dose of 5 mg once daily. Dose escalation is determined by the safety monitoring committee and guided by a Bayesian 2-parameter logistic regression model. The preliminary food assessment (part A2) will follow a randomized two-sequence two-period crossover design in which ≤12 patients will be randomized (1:1) to receive a single dose of M1774 on Day –7 at the RDE (determined in part A1) in either a fed or fasted condition. After the food assessment, patients will subsequently receive M1774 according to the part A1 dosing schedule. In the preliminary efficacy study (part A3), patients (n = 20–24 for each of the three planned cohorts) with tumors harboring LoF mutations in the genes for *ARID1A, ATM, ATRX* and/or *DAXX*, will receive M1774 at the RDE. The primary efficacy endpoint is overall response (RECIST). The study is open and currently recruiting. Patients have been enrolled to seven cohorts in part A1 with no DLTs observed; dose escalation is ongoing. Clinical trial information: NCT04170153. Research Sponsor: Merck KGaA, Darmstadt, Germany.

TPS3154 **Poster Session**

Tumor-agnostic precision immuno-oncology and somatic targeting rationale for you (TAPISTRY): A novel platform umbrella trial. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Actionable genomic alterations are found in many solid tumors in pediatric and adult populations. Identifying such alterations can match patients (pts) to genome-driven therapies. Although TRK and immune checkpoint inhibitor therapies have tumor-agnostic approval for *NTRK*-rearranged and tumor mutational burden (TMB)-high cancers, respectively, similar approvals remain an unmet need for other genome-driven cancers, limiting pt access to potentially active therapies. Platform master protocol studies leveraging comprehensive next-generation sequencing (NGS) are a pragmatic means of evaluating multiple genome-driven therapies in rare biomarker-selected populations. Contemporary study designs include adult and pediatric pts to expand care across age groups. **Methods:** TAPISTRY (NCT04589845) is a phase 2, global, open-label, multi-cohort study evaluating the efficacy and safety of targeted therapy or immunotherapy, as single agents or in combination, in pts with unresectable, locally advanced/metastatic solid tumors. Eligible pts have tumors that harbor genomic alterations or are TMB-high by NGS (Foundation Medicine or CLIA/equivalent-certified laboratory). General inclusion criteria: PD on prior treatment/no available acceptable treatment; measurable disease (by RECIST v1.1, RANO, INRC), adequate ECOG/equivalent PS and end organ function. Pts will be assigned to treatment according to eligibility criteria for biomarker-defined cohorts (Table). Pediatric pts may be enrolled if age-appropriate formulations/dosages are established. Samples will be taken for central NGS biomarker testing at baseline (tissue/blood), tumor assessments (blood) and at response/PD (optional tissue/blood). Tumor assessments (CT, MRI, PET) will be completed at baseline then every 6–8 weeks, depending on cohort. Primary endpoint: confirmed ORR by independent review committee (IRC; RECIST v1.1). Key secondary endpoints: ORR (by investigator [INV], per RECIST/INRC); DoR, CBR, PFS, time to CNS PD (by IRC and INV, per RECIST/INRC); intracranial efficacy (Cohorts A–D; per RANO [primary brain tumors]/RECIST [baseline CNS mets]); OS; patient-reported outcomes; safety; pharmacokinetics and immunogenicity (Cohorts D and F). Treatment will continue until PD, loss of clinical benefit, unacceptable toxicity, discontinuation or death. Target enrollment is 650 pts at 100+ sites based on screening 40,000+ pts; 3 pts enrolled as of 9 Feb 2021. Clinical trial information: NCT04589845. Research Sponsor: F. Hoffmann-La Roche Ltd.

Cohort	Biomarker	Drug	Age (yrs)	NSCLC	Primary CNS/mets
A	ROS1-f	Entrectinib	All	N	Y
B	NTRK1/2/3-f	Entrectinib	All	Y	Y
C	ALK-f	Alectinib	≥18	N	Y
D	High TMB	Atezolizumab	All	Y	Y
E	AKT1/2/3-m	Ipatasertib	≥12	Y	N
F	HER2-m	Trastuzumab emtansine	≥12	Y	N
G	MDM2-a, TP53 WT*	Idasanutlin	≥18	Y	N
H	Multiple PIK3CA-m	GDC-0077	≥12	Y	N

*Closed. Cohorts may be added/closed due to new evidence. a, amplification; f, fusion; m, mutation; WT, wild-type.

TPS3155 **Poster Session**

Alpha-T: An innovative decentralized (home-based) phase 2 trial of alectinib in *ALK*-positive (*ALK*+) solid tumors in a histology-agnostic setting. *First Author: Razelle Kurzrock, University of California San Diego, Moores Cancer Center, La Jolla, CA*

Background: Anaplastic lymphoma kinase (*ALK*) fusions are found in 3–8% of non-small cell lung cancers (NSCLC) and ~0.2% of other tumor types. Alectinib is a selective, CNS-active ALK tyrosine kinase inhibitor approved as first-line treatment for adults with advanced *ALK* fusion-positive (*ALK*-fp) NSCLC based on the phase 3 ALEX trial (NCT02075840; PMID 28586279). Preliminary evidence supports investigation of alectinib in a tumor-agnostic setting. ALK inhibitors have shown efficacy in *ALK*-fp tumor types other than NSCLC (PMIDs 29685646; 28977547; 30591488), with alectinib showing efficacy irrespective of *ALK* fusion partner and against *ALK*-activating mutations (PMIDs 29642598; 29559559). **Methods:** Alpha-T is a phase 2 open-label, single-arm trial (NCT04644315) with an innovative home-based remote design, currently enrolling adults with histologically confirmed, locally advanced/metastatic solid tumors (except lung cancer and cancers of unknown primary) harboring *ALK* fusions or selected mutations (*ALK*-mut; R1275Q, F1245C, F1174X). The decentralized design permits enrollment regardless of location, allows most assessments to be home-based and maintains the relationship between patients (pts) and their treating oncologist. Key inclusion criteria: no alternative or unsuitable to receive standard therapy; ECOG PS 0–2; adequate hematologic, renal and hepatic functions; no prior ALK inhibitor; measurable solid tumor (RECIST 1.1) or primary brain tumor (RANO); asymptomatic or stable CNS metastases permitted. Pts are identified via the Foundation Medicine Inc. (FMI) Precision Enrollment service. For any solid tumor identified as *ALK*+ (fusion/selected mutation) by next-generation sequencing in tissue/blood (F1 CDx/F1L CDx, FMI), the ordering oncologist is given trial details and can liaise with a Science 37 investigator. Pts receive 600mg oral alectinib twice a day with food until radiological PD, unacceptable toxicity, withdrawal of consent or death. Home-based assessments (eg, physical examination, blood sampling, questionnaire completion) are conducted in-person by a mobile nurse at baseline and every 4 weeks, with remote support from the Science 37 investigator via their telemedicine platform. Tumor assessments at screening and every 8 weeks are performed at a local radiology facility. Primary endpoint: confirmed ORR by investigator in pts with *ALK*-fp tumors (RECIST 1.1). Secondary endpoints: ORR by independent review facility (IRF); DoR and PFS; intracranial ORR and DoR (IRF); OS and safety. Descriptive analyses are planned for pts with *ALK*-mut tumors and primary brain tumors. Pharmacokinetics and biomarkers will be evaluated. Patient-reported outcomes will be assessed via the EORTC QLQ-C30 and EuroQoL EQ-5D-5L questionnaires. Target enrollment is 50 pts with *ALK*-fp tumors evaluable by RECIST. As of 9 Feb 2021, 1 pt is in screening. Clinical trial information: NCT04644315. Research Sponsor: F. Hoffmann-La Roche.

TPS3156 **Poster Session**

A phase 1/2 study with open-label, dose escalation phase followed by single-arm expansion at the maximum tolerated dose to assess the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy of NT219 injection alone and in combination with cetuximab in adults with advanced solid tumors and head and neck cancer. *First Author: Alberto Bessudo, California Cancer Care Associates for Research and Excellence, Encinitas, CA*

Background: NT219 is a small molecule, dual inhibitor of insulin receptor substrates (IRS) 1/2 and signal transducer and activator of transcription 3 (STAT3), effecting IRS1/2 degradation and inhibiting STAT3 phosphorylation. IRS1/2 and STAT3 are major signaling junctions regulated by various oncogenes, altered during epithelial to mesenchymal transition (EMT) and drug resistance, and play an important role in the tumor and its microenvironment. Patient derived xenograft (PDX) models have shown that inhibition of both IRS and STAT3 is essential to overcome targeted epidermal growth factor receptor inhibitor (EGFRi) resistance, and NT219 has demonstrated efficacy as monotherapy and in combination with immune oncology therapies. Particularly, both pathways have been found to be relevant in resistance to cetuximab in head and neck squamous cell carcinoma (HNSCC) PDX models. **Methods:** This phase 1/2 study (Clinical trial: NCT04474470) began in September 2020. The phase 1 component has a dose escalation arm of NT219 as a single agent at doses ranging between 3mg/kg and 50mg/kg in adult subjects with recurrent and/or metastatic solid tumors enrolled in sequential dose cohorts of 3 to 6 subjects, in a conventional 3+3 design aiming to establish the safety of single agent NT219. Following the conclusion of follow up on the third dose cohort, an additional dose-escalation arm of NT219 in combination with standard dose cetuximab will be opened in patients with recurrent and/or metastatic HNSCC and colorectal cancer, aiming to establish the safety of NT219 when combined with cetuximab. In the expansion phase, 29 patients will be enrolled at the recommended phase 2 dose in combination with standard dose cetuximab in patients with recurrent/metastatic HNSCC. The primary objectives of the trial are safety, tolerability, MTD, and RP2D and preliminary efficacy of NT219 alone and in combination with cetuximab. Measurements of STAT3 and IRS1/2 phosphorylation in biopsy specimens and TILs will be evaluated as potential biomarkers. NT219 provides a first-in-class treatment for patients with resistant neoplastic disease. The current trial will provide important data in patients with recurrent/metastatic cancers, particularly, HNSCC on the effects of the inhibition of STAT3 and IRS1/2 pathways as a novel therapeutic approach. Clinical trial information: NCT04474470. Research Sponsor: Purple Biotech Ltd.

TPS3157 **Poster Session**

Trial in progress: A phase 1-2 multicenter, open-label, dose-escalation and dose-expansion study to evaluate the safety, pharmacokinetics, pharmacodynamics, and antitumor activity of ABN401 in patients with advanced solid tumors. *First Author: Dae Ho Lee, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea*

Background: c-MET (hepatocyte growth factor (HGF) receptor) overexpression, either by gene amplification, or mutation is associated with oncogenic transformation in numerous malignancies including lung, gastric, skin, renal, colorectal, and pancreatic cancers. ABN401 inhibits the activation of c-MET by reversibly interfering with the binding of c-Met tyrosine kinase to adenosine triphosphate (ATP) and blocking the receptor's downstream signaling that has demonstrated efficacy in NSCLC and gastric cancer in mouse xenograft and PDx models. This clinical trial is in progress in patients with advanced cancers. **Methods:** ABN401 is being evaluated in an open-label, non-randomized, dose-escalation (phase 1) study in patients with advanced solid tumors, and dose-expansion (phase 2) in patients with targeted indications and c-MET biomarker expression (NCT04052971). The phase 1 explores ascending daily doses of oral ABN401 monotherapy in 21-day cycles to identify the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D). A preplanned extension (pilot expansion) study has been initiated based on predefined positive efficacy signals at intermediate doses up to 10 NSCLC patients who have c-MET alteration. Once RP2D is determined, the phase 2 expansion of up to 10-29 patients in four specific tumor-type cohorts is planned, utilizing a Simon's optimal two-stage design to evaluate the clinical activity of ABN401. ABN401-001 study began enrolling patients in August 2019 and is ongoing in Korean and Australia. Dose escalation up to cohort 4 has been completed, enrollment to cohort 5 began in November 2020. AEs are assessed according to CTCAE v5. Tumor response is determined according to RECIST 1.1 criteria and safety findings reviewed by the DRC, which will determine the RP2D and MTD. Key Phase 1 eligibility criteria include 1) histological or cytological diagnosis of melanoma or any type of carcinoma or sarcoma and 2) refractory metastatic disease, or refractory locally advanced disease not amenable to local therapy. For the extension (pilot expansion) study, patients must have NSCLC with MET exon 14 skipping, MET amplification and/or c-MET overexpression. An exploratory study is being conducted for co-development of a companion diagnostic (CDx) system including a CTC device and ddPCR kit through liquid biopsy. Clinical trial information: NCT04052971. Research Sponsor: ABION.

TPS3158 **Poster Session**

First-in-man phase I clinical trial evaluating TTI-101, an orally bioavailable, small molecule inhibitor of STAT3, in patients with advanced solid tumors. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Signal transducer and activator of transcription 3 (STAT3) is a transcription factor that is a key signaling node and a master regulator of the key hallmarks of cancer, including tumor angiogenesis, resistance to apoptosis, metastasis, and immune evasion. STAT3 activation is observed in ~70% of all cancers and up to 95% of hepatocellular carcinomas (HCC). Thus, inhibition of STAT3 signaling is expected to have a therapeutic effect against a wide range of cancers. TTI-101 is a first-in-class, orally bioavailable, selective small molecule that binds STAT3 and prevents phosphorylation, homodimerization, nuclear translocation, and ultimately, STAT3-mediated transcriptional activity. TTI-101 has demonstrated anti-tumor activity across a broad range of preclinical cancer models, including a Hep*Pten*$^{-}$ (hepatocyte-specific deletion of *Pten*) murine model of liver cancer, which recapitulates the pathogenesis of HCC in non-alcoholic fatty liver disease (NAFLD) with chronic inflammation and liver fibrosis leading to cancer at 11 months. TTI-101 treatment starting at 11 months arrested tumor growth as well as reversed liver injury and fibrosis (1). Given these findings, a clinical trial is being conducted examining the effect of this novel, targeted therapeutic agent in patients with advanced solid malignancies. **Methods:** This single-site Phase I trial (NCT03195699) is evaluating TTI-101 as monotherapy in patients with advanced solid tumors who are refractory to prior therapies. The primary objectives of this dose-escalation study include establishing tolerability and safety at each dose level, pharmacokinetics (PK), and establishing the recommended phase 2 dose (RP2D). The secondary and exploratory objectives include assessing clinical outcomes of patients and pharmacodynamics (PD) of TTI-101 via timed, paired tumor biopsies. The initial dose-escalation study is stratified by disease type (HCC and non-HCC) with independent dose-escalation schemas and will be followed by dose expansion cohorts where safety, PK and PD will be evaluated. TTI-101 is administered orally, twice daily for a 28-day cycle. Key eligibility criteria include: 18 years of age or older, having metastatic or unresectable solid tumor refractory to standard therapies, and measurable disease as defined by Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1, an Eastern Cooperative Oncology Group (ECOG) score of 0-2, and normal organ function. Additional criteria are specified for patients with HCC including Child-Pugh class A. HCC cohorts 1-4 and non-HCC cohorts 1-3 have been completed without dose limiting toxicities (DLTs). Enrollment to the HCC dose expansion began in February 2021. 1. Jung KH, et al. Multifunctional Effects of a Small-Molecule STAT3 Inhibitor on NASH and Hepatocellular Carcinoma in Mice. Clin Cancer Res. 2017;23(18):5537-46. Clinical trial information: NCT03195699. Research Sponsor: Cancer Prevention and Research Institute of Texas, Other Foundation.

TPS3159 **Poster Session**

A multicenter open-label phase 1 study evaluating the safety and tolerability of HMPL-306 in patients with locally advanced or metastatic solid tumors with IDH mutations. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Isocitrate dehydrogenase (IDH) is a rate-limiting tricarboxylic acid cycle enzyme with 3 isoforms. Mutations in IDH1 and IDH2 result in gain-of-function activity that can cause tumor formation and/or progression and have been associated with various tumor types. Therefore, selective, single mutant IDH (mIDH) isotype inhibitors (mIDH1 or mIDH2) can lead to insufficient efficacy and the potential for tumor resistance. HMPL-306 is an innovative, small-molecule, orally available, highly selective, potent inhibitor of both mIDH1 and mIDH2. Clinical development of a compound that concurrently targets, inhibits, and suppresses multiple mIDHs could lead to significant and durable clinical benefit for patients (pts) with solid tumors harboring IDH mutations. **Methods:** This is a phase 1, open-label, dose escalation (Part 1) and dose expansion (Part 2) study to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of HMPL-306 in pts ≥18 years with locally advanced or metastatic solid tumors with any IDH mutations. HMPL-306 will be administered orally, once daily in a 28-day continuous dosing treatment cycle. The HMPL-306 dose will be escalated in Part 1 according to the modified toxicity probability interval-2 (mTPI-2) design in 4 cohorts in approximately 15-20 pts: 50, 100, 150, and 200 mg. Eligible pts must have locally advanced or metastatic solid tumors with IDH1 or IDH2 mutations. The primary objectives are to evaluate safety, dose limiting toxicities (DLTs), tolerability, maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), and PK. Approximately 95 pts will be enrolled at the RP2D in Part 2 to further characterize the safety, tolerability, PK, PD, and preliminary anti-tumor activities of HMPL-306. Part 2 will include 5 dose expansion cohorts: cholangiocarcinoma (n = 20), skeletal chondrosarcoma (n = 20), low-grade glioma (n = 20), perioperative low-grade glioma (n = 15), any other solid tumor harboring an IDH1/2 mutation (n = 20). All pts will continue treatment until disease progression, unacceptable toxicity, withdrawal of consent, or at the investigator's discretion. Safety will be assessed based on reports of adverse events including clinical laboratory testing, vital signs, physical examinations, and electrocardiograms. All pts who receive any study treatment will be included in safety and efficacy analyses. Antitumor activity based on investigator-assessed overall response will be evaluated using descriptive analyses. Objective response rate will be calculated with 95% confidence interval using the Clopper-Pearson method. The Kaplan-Meier method will be used to summarize the time-to-event data such as progression-free survival and duration of response. No statistical hypothesis testing is planned. Enrollment started February 2021. Research Sponsor: Hutchison MediPharma Limited.

TPS3160 **Poster Session**

EPIK-P2: A prospective phase 2, double-blind, randomized, placebo-controlled study of alpelisib in pediatric and adult patients (Pts) with *PIK3CA*-related overgrowth spectrum (PROS). *First Author: Guillaume Canaud, Hôpital Necker, Université de Paris, Paris, France*

Background: Somatic gain-of-function mutations in the *PIK3CA* gene, encoding the phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K) catalytic α subunit (p110α), can result in PI3K pathway hyperactivation. PROS is an umbrella term for rare, phenotypically varied, but overlapping features driven by *PIK3CA* mutations. Disease onset is often congenital or in early childhood; presentation ranges widely from localized overgrowth to pleiotropic, severe overgrowth. Complications depend on anatomical site and extent of overgrowth. Management of PROS currently involves symptomatic treatment of its manifestations; an unmet need exists for targeted, systemic therapies. Alpelisib, a PI3Kα inhibitor, has demonstrated encouraging clinical observations and a promising safety profile; after 6 mo of treatment, pediatric and adult pts with PROS experienced improvements in symptoms without requiring surgery. A low rate of side effects was observed (Venot Q, et al. *Nature.* 2018;558:540-6). **Methods:** EPIK-P2 is a prospective, phase 2, multicenter study with an upfront 16-week, randomized, double-blind, placebo-controlled period. Key eligibility criteria include male or female ≥6 yr of age with PROS and symptomatic and/or progressive overgrowth; ≥1 PROS-related measurable lesion confirmed by a Blinded Independent Review Committee (BIRC) and documented somatic *PIK3CA* mutation. Pts with isolated cases of macrodactyly, epidermal nevus/nevi, or macrocephaly in absence of other PROS-related lesions; previous treatment with PI3K inhibitor(s); or debulking surgery within 3 mo are not eligible. Approximately 138 pts will be enrolled into 2 groups comprising adult (age ≥18 yr) and pediatric (ages 6-17 yr) pts. Pts will be randomized 2:1 to daily oral alpelisib or matching placebo; adults will receive 125 mg and pediatric pts 50 mg. After 16 weeks, pts randomized to placebo will switch to alpelisib in a blinded fashion; pts receiving alpelisib will continue alpelisib. Treatment will continue for up to 5 yr. The primary objective is to demonstrate the efficacy of alpelisib by the proportion of pts randomized to alpelisib with a response at Week 24 in each group. Response is defined as ≥20% volume reduction in the symptomatic target lesion(s) per BIRC. The key secondary objective is to demonstrate efficacy of alpelisib vs placebo based on the proportion of pts in each group with response at Week 16. Other secondary outcomes include safety and tolerability, duration of response, overall clinical response rates, changes in symptoms and comorbidities, patient-reported outcomes, pharmacokinetics, and healthcare utilization. An exploratory group of pts (n = 12) ages 2-5 yr will be later enrolled once a starting dose of alpelisib is confirmed in these pts. Enrollment of 150 pts is anticipated. Clinical trial information: NCT04589650. Research Sponsor: Novartis Pharmaceuticals Corporation.

TPS3161 **Poster Session**

Phase 1/2 study of eprenetapopt (APR-246) in combination with pembrolizumab in patients with solid tumor malignancies. *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The p53 pathway has been implicated in antitumor immunity, including antigen presentation and T-cell proliferation. Loss of p53 function can increase resistance to immunotherapy across many tumor types. Eprenetapopt (eprenet) is a small molecule that stabilizes the folded structure of p53, resulting in activation of mutant p53 and stabilization of wild-type (WT) p53. It also targets the cellular redox homeostasis, resulting in induction of apoptosis in tumor cells. *In vivo*, mice carrying supernumerary copies of the *TP53* gene harbor a pro-inflammatory tumor microenvironment, an effect recapitulated in *TP53* normal-copy mice treated with eprenetapopt. Combining eprenetapopt and anti-PD1 or anti-CTLA4 therapy resulted in enhanced tumor growth inhibition and improved survival in *TP53* WT mice inoculated with B16 melanoma and MC38 colon adenocarcinoma cells. Based on these results, we hypothesized that eprenet-induced p53 stabilization may augment response to immunotherapy. To test this hypothesis, we are conducting a phase 1b/2 study of eprenet in combination with pembrolizumab (eprenet+pembro) in pts with solid tumors. **Methods:** The primary objectives are to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) and to assess the safety and tolerability of eprenet+pembro in pts with advanced solid tumors. The secondary objectives are to estimate the anti-tumor activity and to describe the pharmacokinetics of the combination. Exploratory objectives include assessing predictive and pharmacodynamic markers of response. The study includes a safety lead-in with a 3+3 dose de-escalation design for pts with advanced solid tumors with known tumor *TP53* mutation status (*TP53* WT is acceptable) (max 18 pts), followed by expansion cohorts in pts with NSCLC, gastric/GEJ and urothelial cancer (max 100 pts). In expansion, pts with urothelial and gastric cancers must be naïve to anti-PD-1/ L1 therapy. Eprenet is given IV once daily on Days 1–4 while pembro is administered on Day 3 of each 21-day cycle. The RP2D of eprenet+pembro is considered the dose at which ≤ 1 of 6 pts in a cohort has a dose-limiting toxicity (DLT). Primary endpoints are occurrence of DLTs, adverse events (AEs) and serious AEs with eprenet+pembro. Key secondary endpoints are best objective response, progression free survival and overall survival. Exploratory endpoints include gene mutations by next generation sequencing (including *TP53*), mRNA expression, multiplex immunohistochemistry and transcriptomics, multiplex flow cytometry on peripheral blood mononuclear cells and cytokines in serum. Continuous monitoring of toxicity will be conducted. The trial opened in May 2020 and is actively enrolling patients. Clinical trial information: NCT04383938. Research Sponsor: Aprea Therapeutics.

TPS3162 **Poster Session**

A phase 2, multicenter, open-label study evaluating trastuzumab deruxtecan (T-DXd) for the treatment of solid tumors harboring specific HER2-activating mutations (DESTINY-PanTumor01). *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There are substantial data suggesting that a subset of human epidermal growth factor receptor 2 (HER2)–activating mutations induce ligand-independent constitutive HER2 signaling and promote oncogenesis. Direct therapeutic targeting of HER2 has transformed the treatment of patients with HER2-overexpressing breast and gastric cancers. However, currently no targeted treatments are approved for patients with tumors harboring HER2-activating mutations. T-DXd is an antibody-drug conjugate consisting of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a membrane-permeable topoisomerase I inhibitor payload that may be selectively internalized in tumors with HER2 mutations (Li BT, et al. *Cancer Discov.* 2020;10:674-687). In a phase 1 study (DS8201-A-J101), T-DXd demonstrated preliminary antitumor activity in patients with tumors harboring HER2 mutations, with confirmed responses observed in 9 of 19 patients (47.4%) (Tsurutani J, et al. *Cancer Discov.* 2020;10:688-701). Here we describe the DESTINY-PanTumor01 trial (NCT04639219). **Methods:** DESTINY-PanTumor01 is an open-label, multicenter, single-arm, phase 2 study evaluating T-DXd for the treatment of patients with unresectable and/or metastatic solid tumors (excluding non-small cell lung cancer) harboring prespecified HER2-activating mutations. Patients (N≈100) are required to have progressed following prior treatment for advanced or metastatic disease or have no satisfactory alternative treatment options. Prior HER2-targeting therapy is allowed. HER2 mutation status will be determined locally using next-generation sequencing or a validated nucleic acid–based methodology. The primary endpoint is confirmed objective response rate according to independent central review per Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. Secondary endpoints include duration of response, disease control rate, progression-free survival, investigator-assessed confirmed objective response rate, overall survival, safety, pharmacokinetics, and immunogenicity. Clinical trial information: NCT04639219. Research Sponsor: AstraZeneca.

3500 **Oral Abstract Session**

Final overall survival for the phase III KN177 study: Pembrolizumab versus chemotherapy in microsatellite instability-high/mismatch repair deficient (MSI-H/dMMR) metastatic colorectal cancer (mCRC). *First Author: Thierry Andre, Sorbonne Université and Hôpital-Saint Antoine, Paris, France*

Background: In the phase III, randomized open-label KEYNOTE-177 (NCT02563002) study 1L pembrolizumab (pembro) versus chemotherapy (chemo) provided superior progression-free survival (PFS) at second interim analysis (IA2) in patients (pts) with MSI-H/dMMR mCRC. The study continued to final analysis of overall survival (OS), planned after 190 OS events or 12 months after IA2, whichever occurred first. We present results of the final analysis of OS, 12 months after IA2. **Methods:** A total of 307 pts with MSI-H/dMMR mCRC and ECOG PS 0 or 1 were randomized 1:1 to 1L pembro 200 mg Q3W for up to 2y or investigator's choice of mFOLFOX6 or FOLFIRI Q2W ± bevacizumab or cetuximab. Treatment continued until PD, unacceptable toxicity, pt/investigator decision to withdraw, or completion of 35 cycles (pembro only). Pts receiving chemo could crossover to pembro for up to 35 cycles after confirmed PD. Primary end points were OS and PFS (RECIST v1.1, central review). Secondary end points included ORR, duration of response (DOR) (RECIST v1.1, central review), and safety. For OS significance, the p-value had to meet a prespecified α of 0.0246 (one-sided). Sensitivity analyses to adjust for crossover effect were performed. Data cut-off for final analysis was Feb 19, 2021. **Results:** Median (range) study follow-up was 44.5 mo (36.0-60.3) with pembro vs 44.4 mo (36.2-58.6) with chemo. 56 (36%) pts crossed over from chemo to pembro, with 37 more receiving anti-PD-1/PD-L1 therapies off study (60% effective crossover rate in the ITT). The HR for OS favored pembro vs chemo with a trend toward reduction in the risk of death (HR 0.74; 95% CI, 0.53-1.03; *P*=0.0359; median not reached [NR] vs 36.7 mo); this difference did not reach statistical significance. Sensitivity analysis by the rank-preserving structure failure time model and inverse probability of censoring weighting showed OS HRs of 0.66 (95% CI 0.42-1.04) and 0.77 (95% CI 0.44-1.38), respectively. Pembro vs chemo met the prespecified criteria for PFS superiority at IA2. At final analysis, median PFS was 16.5 mo vs 8.2 mo (HR 0.59; 95% CI, 0.45-0.79), but was not formally tested per analysis plan. Confirmed ORR was 45.1% (20 CR, 49 PR) vs 33.1% (6 CR, 45 PR). Median (range) DOR was NR (2.3+ to 53.5+) vs 10.6 mo (2.8 to 48.3+), respectively. Treatment-related adverse events (TRAEs) occurred in 79.7% vs 98.6% of pts; 21.6% vs 66.4%, respectively, had grade ≥3 TRAEs. **Conclusions**: As 1L therapy for pts with MSI-H/dMMR mCRC, pembro vs chemo provides statistically superior PFS with fewer TRAEs, and is associated with a trend toward reduced mortality that did not meet statistical significance likely due to the high crossover rate from chemo to anti-PD1/PD-L1 therapies. Together these data confirm pembro as a new standard-of-care in the 1L for pts with MSI-H/dMMR mCRC. Clinical trial information: NCT02563002. Research Sponsor: Merck & Co., Inc.

3501 **Oral Abstract Session**

The randomized phase II study of FOLFOXIRI plus cetuximab versus FOLFOXIRI plus bevacizumab as the first-line treatment in metastatic colorectal cancer with *RAS* wild-type tumors: The DEEPER trial (JACCRO CC-13). *First Author: Akihito Tsuji, Department of Medical Oncology, Kagawa University Hospital, Takamatsu, Japan*

Background: Triplet regimens, FOLFOXIRI, combined with bevacizumab (bev) or panitumumab have been shown to be superior in terms of early tumor shrinkage (ETS) and depth of response (DpR) compared to doublet combinations in patients with *RAS* wild-type metastatic colorectal cancer (mCRC), in the TRIBE trial (*N Engl J Med* 2014) or the VOLFI trial (*J Clin Oncol* 2019), respectively. There have been few studies which directly compared cetuximab (cet) with bev when combined with triplet regimen. Therefore, we investigated the efficacy and safety of bev vs. cet in combination with FOLFOXIRI in previously untreated mCRC patients with *RAS* wild-type tumors. **Methods:** This trial was a randomized phase II trial to evaluate modified (m)-FOLFOXIRI (irinotecan 150mg/m^2, oxaliplatin 85mg/m^2, 5-FU 2400mg/m^2) plus cet vs. bev as first-line treatment in terms of DpR during the entire course as the primary endpoint in 360 patients with *RAS* wild-type mCRC. The aim of the trial was to show that median DpR of cet arm was more than 12.5% higher than bev arm, with a power of 85% at a significance level of 0.05. Secondary endpoints included ETS rate at week 8, overall response rate (ORR), progression-free survival (PFS), overall survival (OS), secondary resection rate, and toxicity. **Results:** A total of 359 patients were enrolled between July 2015 and June 2019. For the full analysis set (median age 65y, 64% male, PS0/1: 91%/9%, left/right primary: 83%/17%), 173 and 175 patients were randomly assigned to the cet and bev arms, respectively. On the cutoff date of September 2020, the median number of cycles administered was 10 (range, 1-51) for the cet arm and 12 (range, 1-51) for the bev arm. Safety data was already reported at the ASCO GI symposium 2021 (J Clin Oncol 39, 2021 suppl 3; abstr 86). The primary endpoint was met (p = .001); 57.4% (-15.0~100) for the cet arm versus 46.0% (-0.6~100) for the bev arm. As for primary tumor sidedness, median DpR were 60.3% versus 46.1% (p = .0007) in the left-side and 50.0% versus 41.2% (p = .46) in the right-side. The ETS rate and ORR as the secondary endpoints were 77.8% and 69.1% in the cet arm versus 74.6% and 71.7% in the bev arm, respectively, with no statistical significance. Although the survival data were immature, PFS and OS of both arms were 12.7 months (95%CI 11.5-14.0) and 37.6 months (95%CI 30.8 to 43.0), respectively. **Conclusion:** The mFOLFOXIRI plus cet has been shown to be significantly superior to the mFOLFOXIRI plus bev in terms of DpR as the primary endpoint in first-line treatment for *RAS* wild-type mCRC. Clinical trial information: NCT02515734. Clinical trial information: UMIN000018217. Research Sponsor: Merck Biopharma Co., Ltd.

3502 **Oral Abstract Session**

Randomized study to investigate FOLFOXIRI plus either bevacizumab or cetuximab as first-line treatment of BRAF V600E-mutant mCRC: The phase-II FIRE-4.5 study (AIO KRK-0116). *First Author: Sebastian Stintzing, Medical Department, Division of Hematology, Oncology, and Tumor Immunology (CCM), Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: FIRE-4.5 (AIO KRK-0116) compared FOLFOXIRI plus either cetuximab or bevacizumab in BRAF V600E-mutant metastatic colorectal cancer (mCRC) patients not treated for metastatic disease before. **Methods:** Within this 1:2 randomized, controlled, open-label phase-II study, patients received FOLFOXIRI every two weeks at the following schedule: irinotecan 150mg/m^2 (30-90min, day 1), folinic acid 400mg/m^2 (120min, day 1), oxaliplatin 85mg/m^2 (120 min, day 1), followed by 5-fluorouracil 3,000 mg/m^2, 48h. FOLFOXIRI was combined with either bevacizumab (arm A) at a dose of 5mg/kg body weight, every 2 weeks or cetuximab (arm B) at a loading dose of 400mg/m^2 and subsequent weekly doses of 250mg/m^2. FOLFOXIRI was applied for a maximum of 12 cycles before maintenance treatment was recommended. Primary endpoint was superiority of Arm B with respect to overall response rate (ORR) according to RECIST 1.1 criterions. Secondary endpoints included PFS, OS, and tolerability. **Results:** From November 2016 to December 2020 108 patients were randomized in 90 German and 10 French centers (35 arm A and 73 in arm B). No new or unexpected toxicities were observed. Primary endpoint was not met with an ORR of 66.7% and 52.0% (p =0.23) in the respective arms. Median PFS was significantly longer in arm A vs arm B (8.3 months vs 5.9 months; log-rank p = 0.03; HR 1.8). While OS data is still immature, median OS time are comparable at the time of analysis. Patients with left-sided primary tumors had comparable results with either bevacizumab or cetuximab, whereas those with right-sided primary tumors showed a trend towards better efficacy of the bevacizumab combination. Updated results will be presented at the annual meeting. **Conclusions:** FIRE-4.5 is the first prospective and randomized study investigating efficacy of FOLFOXIRI combined with targeted therapy in the first-line treatment of BRAF V600E-mutant mCRC. FOLFOXIRI plus either bevacizumab or cetuximab have comparable efficacy with differential effects according to primary tumor sidedness supporting the heterogeneity of BRAF V600E-mutant subpopulation of mCRC. Clinical trial information: NCT04034459. Research Sponsor: MERCK.

3503 **Oral Abstract Session**

Maintenance therapy with 5-fluoruracil/leucovorin (5FU/LV) plus panitumumab (pmab) or 5FU/LV alone in RAS wildtype (WT) metastatic colorectal cancer (mCRC) - the PANAMA trial (AIO KRK 0212). *First Author: Dominik Paul Modest, Department of Medicine III, University Hospital, LMU Munich, Munich, Germany*

Background: Planned discontinuation or stop-and-go use of oxaliplatin are established strategies in the systemic therapy of mCRC. Consequently, and irrespective of antibody use, 5FU/LV represents the standard backbone of most maintenance strategies. Unlike VEGF-targeted substances, there is limited evidence that EGFR-antibodies add efficacy to 5FU/LV maintenance in *RAS* wildtype (*RAS* WT) mCRC patients. **Methods:** Following induction therapy with six cycles of 5FU/LV, oxaliplatin (FOLFOX) and pmab, the trial randomized maintenance therapy with 5FU/LV plus pmab vs. 5FU/LV alone in a 1:1 fashion in patients (pts) with *RAS* WT mCRC. The primary endpoint was PFS (progression-free survival: time from randomization until progression or death). With 218 events needed for PFS, the trial was designed to demonstrate superiority of the 5FU/LV+ pmab arm vs. 5FU/LV alone with a hazard ratio (HR) of 0.75, power of 80% and a significance level of 10%. Secondary endpoints included overall survival (OS), objective response to induction- and maintenance therapy as well as quality of life. The trial is registered with ClinicalTrials.gov, NCT01991873. **Results:** The full analysis set consists of 248 pts (125 pts 5FU/LV + pmab and 123 pts 5FU/LV) who were randomized and received maintenance therapy. Median age was 66 vs. 65 years, male patients were 69.6% vs. 63.4%, ECOG 0 was 56.8% vs. 60.2% in the respective trial arms (5FU/LV+ pmab vs. 5FU/LV). At data cut-off, with 218 events, PFS of maintenance therapy was improved with 5FU/LV+ pmab vs. 5FU/LV alone (8.8 (80% CI 7.6-10.2) months vs. 5.7 (80% CI 5.6-6.0) months, HR 0.72 (80%CI 0.60-0.85), p = 0.014). OS (event rate 54.4%) numerically favoured the 5FU/LV+ pmab arm (28.7 (95% CI 25.4-39.1) months) as compared to 5FU/LV alone (25.7 (95% CI 22.2-28.2) months), HR 0.84 (95% CI 0.60-1.18). **Conclusion:** In *RAS* WT mCRC, maintenance therapy with 5FU/LV+ pmab appears to be superior to 5FU/LV alone and should be regarded as standard of care maintenance regimen following induction therapy with FOLFOX plus pmab. Clinical trial information: NCT01991873. Research Sponsor: AMGEN, Arbeitsgemeinschaft Internistische Onkologie (AIO).

3504 **Oral Abstract Session**

Oral maintenance capecitabine versus active monitoring for patients with metastatic colorectal cancer (mCRC) who are stable or responding after 16 weeks of first-line treatment: Results from the randomized FOCUS4-N trial. *First Author: Richard Adams, Cardiff University and Velindre Cancer Centre, Cardiff, United Kingdom*

Background: There is extensive randomised evidence supporting the use of treatment breaks in mCRC, but breaks from treatment are not universally offered to patients despite reductions in toxicity, without detriment to OS. Prior trials have shown that the combination of Cp and bevacizumab extend PFS but not OS. FOCUS4-N explores oral maintenance Cp monotherapy in patients with disease control on first line therapy. **Methods:** FOCUS4 was a molecularly stratified trial programme registering patients with newly diagnosed mCRC from 88 hospitals in the UK. Whilst undergoing 16 wks of first line treatment, a sample of tumour was sent for laboratory testing to stratify their disease into molecular subtypes: MSI, BRAF, PIK3CA, TP53 and RAS mutations. For some molecular groups, a targeted therapy subtrial was available but entry into the FOCUS4-N trial was offered to those in whom a targeted subtrial was unavailable. Patients were randomised 1:1 between maintenance Cp therapy or AM. The primary outcome was PFS assessed using 8-wkly RECIST reported CT scans with quality of life (using EQ5D 8 weekly) and OS as secondary outcomes. Toxicity and tolerability were assessed 4-wkly. On progression, from the nadir, patients recommenced first line treatment. Cox regression was used to assess efficacy by intention-to-treat (ITT) with adjustment for tumour location, WHO status, metastatic burden, first line treatment and biomarker subtype. **Results:** Between March 2014 and March 2020, 254 patients were randomised (127 to Cp and 127 to AM). Baseline characteristics were balanced between groups but event rates were higher than anticipated in the AM group and the final analysis was triggered early as a result of the COVID-19 pandemic halting recruitment. The table presents results for PFS and OS. Compliance with treatment was good with per-protocol analysis results very similar to ITT (PFS HR=0.38 (95% CI 0.28-0.51)). Toxicity from Cp v AM was as expected with G≥2 fatigue (25% v 12%), diarrhoea (23% v 13%) and hand-foot syndrome (26% v 3%). Quality of life showed no statistically significant differences between the two arms. **Conclusions:** Despite strong evidence of prolongation of PFS with maintenance therapy, OS remains unaffected and FOCUS4-N provides additional evidence to support the use of treatment breaks as a safe management alternative for patients who are stable or responding well to first line treatment for mCRC. Cp without bevacizumab may be used to extend PFS, in the interval after 16 weeks of combination therapy. Clinical trial information: ISRCTN#90061546. Research Sponsor: Cancer Research UK, Other Government Agency.

	Cp		AM		
Outcome	Events/N	Median (IQR) survival time (mths)	Events/N	Median (IQR) survival time (mths)	Cox regression adjusted HR (95% CI) p-value

3505 **Oral Abstract Session**

Trastuzumab deruxtecan (T-DXd; DS-8201) in patients (pts) with HER2-expressing metastatic colorectal cancer (mCRC): Final results from a phase 2, multicenter, open-label study (DESTINY-CRC01). *First Author: Takayuki Yoshino, National Cancer Center Hospital East, Kashiwa, Japan*

Background: T-DXd is an antibody–drug conjugate of a humanized anti-HER2 antibody bound to a topoisomerase I inhibitor by a cleavable linker. The primary analysis of DESTINY-CRC01 (DS8201-A-J203; NCT03384940), a phase 2, open-label, multicenter study of T-DXd in pts with HER2-expressing mCRC showed promising antitumor activity and a manageable safety profile (cohort A median follow-up [FU], 27.1 weeks; Siena S, ASCO 2020). We present updated longer-term efficacy and safety data. **Methods:** Pts had centrally confirmed HER2-expressing, *RAS* wild-type mCRC that progressed after ≥2 prior regimens. 6.4 mg/kg of T-DXd was administered every 3 weeks (Q3W) in 3 cohorts (A: HER2 IHC3+ or IHC2+/ISH+; B: IHC2+/ISH−; C: IHC1+). The primary end point was confirmed objective response rate (ORR) by independent central review in cohort A. Secondary end points were disease control rate (DCR; CR + PR + SD), duration of response (DOR), progression-free survival (PFS), and overall survival (OS). **Results:** At data cutoff (Dec 28, 2020), 86 pts (A, 53; B, 15; C, 18) received T-DXd. Median age was 58.5 y (range, 27-79), 53.5% were male, and 90.7% had left colon or rectum cancer. Median prior regimens for metastatic disease was 4 (range, 2-11). All pts had prior irinotecan; 30.2% in cohort A had prior anti-HER2 therapy. Median (m) treatment duration (all pts) was 3.0 mo (95% CI, 2.1-4.1; cohort A, 5.1 mo [95% CI, 3.9-7.6]). In cohort A (median FU, 62.4 weeks), confirmed ORR was 45.3% (24/53 pts; 95% CI, 31.6-59.6), DCR was 83.0% (44/53 pts; 95% CI, 70.2-91.9), mDOR was 7.0 mo (95% CI, 5.8-9.5), mPFS was 6.9 mo (95% CI, 4.1-8.7) with 37 (69.8%) PFS events, and mOS was 15.5 mo (95% CI, 8.8-20.8) with 36 (67.9%) OS events. These results are consistent with the primary analysis. Confirmed ORR was 43.8% (7/16 pts; 95% CI, 19.8-70.1) in pts with prior anti-HER2 therapy, 57.5% (23/40 pts; 95% CI, 40.9-73.0) in pts with IHC3+ status, and 7.7% (1/13 pts; 95% CI, 0.2-36.0) in pts with IHC2+/ISH+ status. In cohorts B and C, mPFS was 2.1 mo (95% CI, 1.4-4.1) and 1.4 mo (95% CI, 1.3-2.1); mOS was 7.3 mo (95% CI, 3.0-NE) and 7.7 mo (95% CI, 2.2-13.9), respectively. Treatment-emergent adverse events (TEAEs) of grade (G) ≥3 occurred in 65.1% of pts (56/86); the most common TEAEs were hematologic and gastrointestinal. TEAEs leading to drug discontinuation occurred in 13 pts (15.1%). 8 pts (9.3%) had interstitial lung disease (ILD) adjudicated by an independent committee as related to T-DXd (4 G2; 1 G3; 3 G5). **Conclusions:** T-DXd at 6.4 mg/kg Q3W showed promising activity and durability with longer-term FU in this pt population. The safety profile was consistent with prior results; ILD continues to be recognized as an important identified risk that requires careful monitoring and intervention as needed. These results support continued exploration of T-DXd in pts with HER2-overexpressing mCRC. Clinical trial information: NCT03384940. Research Sponsor: Daiichi Sankyo, Pharmaceutical/Biotech Company.

3506 **Oral Abstract Session**

Phase II study of anti-EGFR rechallenge therapy with panitumumab driven by circulating tumor DNA molecular selection in metastatic colorectal cancer: The CHRONOS trial. *First Author: Andrea Sartore-Bianchi, Niguarda Cancer Center, Grande Ospedale Metropolitano Niguarda, University of Milano, Milan, Italy*

Background: Despite advances in molecular segmentation of metastatic colorectal cancer (mCRC), beyond *RAS* status therapeutic actionability remains confined to the limited subgroups of *ERBB2* amplified, *BRAF* mutated and MSI-H patients. Optimization of available treatments is therefore warranted. Rechallenge with anti-EGFR monoclonal antibodies is often empirically used with some benefit as late-line therapy. We previously found that mutant *RAS* and *EGFR* ectodomain clones, which emerge in blood during EGFR blockade, decline upon antibody withdrawal leading to regain drug sensitivity. Based on this rationale, we designed CHRONOS, a multicenter phase II trial of anti-EGFR therapy rechallenge guided by monitoring of the mutational status of *RAS, BRAF* and *EGFR* in circulating tumor DNA (ctDNA). To our knowledge, this is the first interventional clinical trial of liquid biopsy for driving anti-EGFR rechallenge therapy in mCRC. **Methods**: Eligible patients were PS ECOG 0-2 *RAS/BRAF* WT mCRC having first achieved an objective response and then progression in any treatment line with an anti-EGFR antibody containing regimen, displaying *RAS, BRAF* and *EGFR* ectodomain WT status in ctDNA at molecular screening after progression to the last anti-EGFR-free regimen. Clonal evolution in ctDNA was analyzed by ddPCR and next generation sequencing. Panitumumab 6 mg/kg was administered IV every two weeks until progression. The primary endpoint was objective response rate (ORR) by RECIST version 1.1 with independent central review. 27 total patients and 6 responses were required to declare the study positive (power = 85%, type I error = 0.05). **Results**: Between Aug 19, 2019 and Nov 6, 2020 52 patients were screened by liquid biopsy and 36 (69%) were negative in ctDNA for *RAS/BRAF/EGFR* mutations. Of these, 27 patients were enrolled in 4 centers. Median age was 64 years (range: 42-80). PS ECOG was 0/50%, 1/46%, 2/4%. Previous anti-EGFR was administered in 1st line in 63%, 2nd in 15% and $>$ 2nd in 22%. Median number of previous treatments was 3. The primary endpoint was met, with 8/27 partial responses (PR) observed (2 unconfirmed) (ORR = 30%, 95% CI: 12-47%). Stable disease (SD) was obtained in 11/27 (40%, 95% CI: 24-59%), lasting $>$ 4 months in 8/11. Disease control rate (PR plus SD $>$ 4 months) was therefore obtained in 16/27 (59%, 95% CI: 41-78%). Median progression-free survival was 16 weeks. Median duration of response was 17 weeks (1 ongoing). Maximal grade toxicity was G3, limited to dermatological and occurring in 19% of patients. ctDNA dynamics were studied in all patients. **Conclusions**: Liquid biopsy-driven rechallenge with anti-EGFR antibodies leads to further objective responses in one third of patients. Genotyping tumor DNA in the blood to direct therapy can be effectively incorporated in the management of advanced CRCs. Clinical trial information: 2016-002597-12. Research Sponsor: Associazione Italiana per la Ricerca sul Cancro (AIRC), Other Foundation, Amgen provided panitumumab.

3507 **Oral Abstract Session**

The TRUSTY study: A randomized phase 2/3 study of trifluridine/tipiracil plus bevacizumab versus irinotecan and fluoropyrimidine plus bevacizumab as second-line treatment in patients with metastatic colorectal cancer. *First Author: Yasutoshi Kuboki, Department of Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Chiba, Japan*

Background: The efficacy of trifluridine/tipiracil (FTD/TPI) plus bevacizumab (BEV) as a later-line treatment for metastatic colorectal cancer (mCRC) has been demonstrated in clinical trials. Therefore, we conducted a randomized phase 2/3 study to determine whether FTD/TPI plus BEV is non-inferior to either FOLFIRI or S-1 and irinotecan plus BEV in terms of overall survival (OS) as second-line treatment in patients with mCRC. **Methods:** Patients with histologically confirmed mCRC who failed first-line doublet chemotherapy including fluoropyrimidine plus oxaliplatin with either BEV or an anti-EGFR antibody (in cases of *RAS* wild-type) were eligible. Patients were randomized to receive either FTD/TPI plus BEV (experimental group, BEV 5.0 mg/kg on days 1 and 15, FTD/TPI 35 mg/m^2 twice daily on days 1–5 and 8–12 of each 28-day cycle) or either FOLFIRI or S-1 and irinotecan plus BEV (control group). The primary endpoint was the OS. The non-inferiority margin of a hazard ratio (HR) of 1.33 was based on the assumption of a median survival time of 19 months for the control (power 0.80, 1-sided alpha 0.025). The secondary endpoints were the progression-free survival (PFS), response rate (RR), disease control rate (DCR), time to treatment failure, time to post-study treatment failure, proportion of patients receiving post-study treatment, quality of life, and safety. **Results:** As a result of the interim analysis for futility, the study was terminated in July 2020, and 397 patients were finally enrolled at 65 institutions from October 2017. The baseline characteristics were similar between the groups. The median OS were 14.8 months in the FTD/TPI plus BEV group and 18.1 months in the control group [HR: 1.38; 95% confidence interval (CI): 0.99–1.93; p = 0.5920 for non-inferiority]; non-inferiority of FTD/TPI plus BEV was not demonstrated. The median PFS were 4.5 months in the FTD/TPI plus BEV group and 6.0 months in the control group (HR: 1.45; 95% CI: 1.14–1.84). The RR and DCR were 3.8% and 61.2% in the FTD/TPI plus BEV group, respectively, and 7.1% and 71.7% in the control group, respectively. The proportions of patients receiving post-study treatment in the FTD/TPI plus BEV and control groups were 59.9% and 52.3%, respectively. The main grade 3 or 4 adverse events in the FTD/TPI plus BEV and control groups were neutropenia (65.8% and 41.6%, respectively), diarrhea (1.5% and 7.1%, respectively), and grade 1 or 2 alopecia (3.6% and 24.9%, respectively). **Conclusions:** FTD/TPI plus BEV did not show non-inferiority to FOLFIRI or S-1 and irinotecan plus BEV as second-line treatment in patients with mCRC. *Post hoc* subgroup analyses are ongoing to investigate patients who likely benefit from FTD/TPI plus BEV. Clinical trial information: jRCTs031180122. Research Sponsor: Taiho Pharmaceutical Co, Ltd.

CCTG CO.28 primary endpoint analysis: Neoadjuvant chemotherapy, excision and observation for early rectal cancer, the NEO trial. *First Author: Hagen Fritz Kennecke, Providence Cancer Institute, Portland, OR*

Background: CO.28 (NCT03259035) is a phase II study designed to determine if patients with cT1-T3a/bN0 rectal cancer can be treated with induction chemotherapy (FOLFOX/CAPOX) and organ-preserving surgery. **Methods:** Patients with MRI staged cT1-3a/bN0 tumors and no pathologic (p) high risk features received 6/4 cycles of FOLFOX/CAPOX, repeat sigmoidoscopy/pelvic MRI and subsequent Transanal Endoscopic Surgery (TES) in the absence of tumor progression. ypT0/T1N0 tumors were treated with observation while ypT2+ or ypN+ stage were recommended Total Mesorectal Excision (TME). The primary endpoint was protocol specified Organ Preservation Rate (psOPR = ypT0/T1N0, no p high risk features) and actual Organ Preservation Rate (aOPR = ypT0/T1N0 stage plus higher yp stage patients who declined TME surgery). The study would be considered negative with an psOPR of 50% or lower (H0) and as promising if it is 65% or higher (H1). **Results:** Between 08/2017 to 05/2020, 58 eligible patients were accrued in Canada and the United States, median age was 67 years, 71% male. All had well-moderately differentiated, non-mucinous rectal adenocarcinoma and median tumor height was 6 cm (range 0-18). Median follow-up was 15.4 months. Chemotherapy with FOLFOX (32) or CAPOX (26) was administered, 90% completed all planned cycles. A total of 56/58 (97%) proceeded to TES, while one patient was ineligible due to tumor progression (1.7%) and one declined. In the intention to treat analysis, the psOPR was 57% (95% CI 43-70%) while the aOPR was 79% (95% CI 67% to 89%) due to 13/23 declining recommended TME surgery. Of 10 patients who proceeded to recommended TME, a complete R0 TME was performed in 9/10, and no p residual carcinoma was found in 7/10. Crude loco-regional (LR) and distant recurrence rates were 3.5% (95% CI 0.4 to 12%) and 0%, respectively. A recurrence occurred in 1/13 patients who initially declined TME surgery. **Conclusions:** In select patients with early stage rectal cancer, three months of induction CAPOX/FOLFOX followed by TES resulted in a high OPR without the use of pelvic irradiation. The observed high rate of pathologic downstaging may point to high chemo-responsiveness in early rectal adenocarcinoma with no p high risk features. Further trials to evaluate this approach are justified and updated results will be presented. Clinical trial information: NCT03259035. Survival and organ preservation according to clinical response after total neoadjuvant therapy in locally advanced rectal cancer patients: A secondary analysis from the organ preservation in rectal adenocarcinoma (OPRA) trial. *First Author: Hannah Thompson, Colorectal Service, Department of Surgery, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: Clinical response following neoadjuvant therapy is paramount to identifying locally advanced rectal cancer (LARC) patients suitable for Watch and Wait (WW). A 3-tier schema was devised to stratify clinical response. Patients with a complete clinical response (cCR) are considered for WW, while those with an incomplete clinical response (iCR) are recommended for total mesorectal excision (TME). A near complete response (nCR) tier captures patients with significant, but not complete, response to be considered for WW. This schema's efficacy has yet to be validated. We investigated survival and organ preservation (OP) rates based on this 3-tier clinical response assessment in patients with LARC who underwent total neoadjuvant therapy (TNT) in a prospective, multi-center clinical trial. **Methods:** Patients with MRI stage II and III rectal adenocarcinoma were randomized to either induction chemotherapy (FOLFOX or CAPEOX) followed by chemoradiation or chemoradiation followed by consolidation chemotherapy (FOLFOX or CAPEOX). At 8+/-4 weeks following TNT, response on digital rectal and endoscopic examinations was evaluated by the 3-tier schema. The date of this restaging clinical response assessment was used as time zero. The endpoints of rate of OP, disease-free survival (DFS), TME-free DFS, and overall survival (OS) were evaluated using the Kaplan-Meier method with differences analyzed by the log-rank test. **Results:** Clinical response assessments were available for 294 patients. The median time to assessment after neoadjuvant therapy was 7.9 weeks. Based on the 3-tier schema, 124 patients were categorized as cCR, 113 as nCR, and 57 as iCR. Baseline age, sex, average distance from the anal verge, clinical T classification, and clinical N classification were similar between the response groups. The table shows the 3-year rates of OP, DFS, TME-free DFS, and OS. The median follow-up was 2.36 years. Of the patients with a nCR, the 3-year TME rate was 48% compared with 21% in the cCR group. **Conclusions:** The 3-tier clinical response assessment has prognostic implications for OP and DFS in patients with LARC who underwent TNT. In patients with a nCR, more than half achieved OP at 3 years. This information should be utilized to counsel patients regarding their expected outcomes. Clinical trial information: NCT02008656. Research Sponsor: U.S. National Institutes of Health.

A multicenter, randomized, phase III trial of short-term radiotherapy plus chemotherapy versus long-term chemoradiotherapy in locally advanced rectal cancer (STELLAR): The final reports. *First Author: Jing Jin, Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: It's presented the results of a phase III trial of short-term radiotherapy (SCRT) combined with chemotherapy versus long-term chemoradiotherapy (LCRT) in patients with locally advanced rectal cancer (LARC). **Methods:** Patients with distal or middle third, T3-T4 and/or N+ rectal adenocarcinomas diagnosed by MRI, were randomly assigned to experimental group or control group. In experimental group, patients received SCRT (25 Gy / 5 fractions / 5 days), followed by four courses of CAPOX. In control group, patients received LCRT (50 Gy / 25 fractions / 35 days with concurrent capecitabine). Surgery was recommended in both groups and performed 6-8 weeks after preoperative treatment. Two or six courses of CAPOX was prescribed as the postoperative chemotherapy in experimental group and control group, respectively. This trial was a multicenter, open-label, randomized, noninferior, phase III study, and all the patients were from 16 hospitals of China. The primary endpoint for this study was 3-year disease-free survival (DFS). **Results:** From Aug 30, 2015 to Aug 27, 2018, 599 patients were enrolled and entered random. Finally, 591 intention-to-treat (ITT) populations were included in the analysis, 298 patients assigned to SCRT followed by chemotherapy and 293 to CRT. For the experimental group and control group, cT3 and cT4 accounted for 82.3% vs. 84.6% and 15.4% vs. 12.3%, respectively, and approximately 85% were mrN positive (85.6% vs. 84.0%). As a whole, the completion and full-dose completion rates of preoperative treatment were 82.6% vs. 95.2% ($p < 0.001$) and 74.8% vs 93.2% ($p < 0.001$) in the experimental and control groups, respectively. Among the 465 patients who received surgery, 16.6% and 11.8% of them achieved pCR (p=0.134), respectively. Accounting for cCR after preoperative treatment, the total rate of pCR+cCR in experimental group was 22.5% and significantly higher than control group (12.6%, p=0.001). With median follow-up 35.0 months, the HR between experimental and control of DFS was 0.883, with 1-sided noninferiority p-value <0.001, so the noninferiority hypothesis was confirmed. The probability of DFS and OS at 3 years was 64.5% and 86.5% in the experimental group compared with 62.3% and 75.1% in control group. It's observed the OS rate of the experimental group was significantly higher than that of the control group (p=0.036) and no significant difference in metastasis-free survival or loco-regional recurrence was observed. **Conclusions:** For LARC with high risk factors, SCRT combined with sequential chemotherapy was noninferior to CRT and could be used as an alternative to LCRT. Meanwhile, SCRT combined with chemotherapy presented a higher cCR+pCR and 3-year overall survival rates as compared with CRT. However, the long term results need to be further followed up. (ClinicalTrails No.: NCT02533271). Clinical trial information: NCT00833131. Research Sponsor: Collaborative Innovation Center for Cancer Medicine.

Phase II study of preoperative (PREOP) chemoradiotherapy (CTRT) plus avelumab (AVE) in patients (PTS) with locally advanced rectal cancer (LARC): The AVANA study. *First Author: Lisa Salvatore, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli–IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Preop CTRT is considered the standard of care in the management of LARC. RT can induce antigen release from a low neoantigen-burden tumor (such as a mismatch repair proficient colorectal cancer) and activate dendritic cells leading to a CD8+ T lymphocyte-mediated anticancer immune response. In LARC patients, neoadjuvant CTRT increases PD-L1 expression in tumor cells, strongly suggesting a neoadjuvant combinatory strategy with RT and PD-1/PD-L1 pathway blockade. Based on such considerations, we have designed the AVANA study to investigate the role of Ave in combination with preop CTRT in LARC. **Methods:** This is an Italian multi-center, phase II study. Pts with resectable LARC, defined by the presence of at least one of the following features: cN+, cT4, high risk cT3, received standard preop CTRT (capecitabine 825 mg/sqm/bid 5 days/week+ 50.4 Gy in 28 fractions over 5.5 weeks) plus 6 cycles of Ave 10 mg/Kg every 2 weeks. Surgery with total mesorectal excision was performed at 8-10 weeks after the end of CTRT. The primary end-point was the pCR rate, defined as complete histological regression with no available tumor cells ypTONO. Secondary end-points were R0 resection rate, tumor downstaging, local recurrence, sphincter preservation rate, progression-free survival, overall survival, safety profile, and the evaluation of exploratory predictive and/or prognostic biomarkers. Assuming as null hypothesis p0 a pCR rate of 15%, a significance level of 5% (one-side), and a power of 80%, a sample size of 101 pts was needed to detect an absolute increment of 10% in pCR rate (from 15% to 25%). The experimental regimen is considered for further studies if, in at least 22 pts, we observe a pCR. **Results:** From April 2019 to November 2020, a total of 101 resectable LARC pts were enrolled in 10 Italian Centers. The median age was 63 years (23-82), 62 (61.4%) pts were male, 93 (92%) had ECOG PS 0. At baseline, 94 (93%) and 16 (16%) pts had cN+ and cT4 LARC, respectively. All pts completed the induction phase. Out of 96 pts evaluable for pathological response, 22 (23%) pts achieved a pCR and 59 (61.5%) pts a major pathological response (a central review is ongoing). At this time, microsatellite status is available only in 39 pts, of which only one was instable. The rate of grade 3-4 non-immune and immune-related adverse events was 8% and 4%, respectively. Avelumab was early interrupted in 9 pts out 101, mainly due to toxicity. **Conclusions:** The combination of preop CTRT plus Ave showed a promising activity and a feasible safety profile. According to our statistical considerations, the experimental regimen will be considered for further studies. Updated results will be presented during the Congress. Sponsored by GONO and partially supported by Merck. EUDRACT 2017-003582-10. Clinical trial information: NCT03854799. Phase II trial of neoadjuvant mFOLFOX 6 with panitumumab (P) in T3 rectal cancer with clear mesorectal fascia (MRF) and *KRAS*, *NRAS*, *BRAF*, *PI3KCA* wild type (4WT). GEMCAD 1601 PIER trial. *First Author: Carlos Fernandez-Martos, Hospital Quironsalud, Valencia, Spain*

Background: Patients with advanced colorectal cancer with 4WT tumors achieve increased response rates with chemotherapy and anti-EGFR therapy as compared with chemotherapy alone. In clinically staged (c) T3 rectal cancer neoadjuvant oxaliplatin/fluoropyrimidine combination has shown to induce encouraging pathological complete response (pCR). We hypothesize that combining FOLFOX and P could improve outcomes in 4WT tumors. **Methods:** PIER was an investigator-initiated phase II, single-arm, multicentre clinical trial to evaluate the safety and efficacy of neoadjuvant mFOLFOX6 with P in pts < 75-y, with 4WT rectal cancer of the middle third staged as T3 by centrally-reviewed magnetic resonance imaging (MRI) and clear MRF, who were candidate for a R0 resection with sphincter preservation surgery. Pts received 6 cycles and underwent re-staging with MRI and sigmoidoscopy. Pts without progression underwent total mesorectal excision 4 weeks after the last cycle. Patients with progression were treated with pre-op chemoradiotherapy. The primary endpoint was pCR. The study followed a 2-Stage Simon's MiniMax design (P0 of 16%, P1 of 35%, alpha and beta of 0.1). The target sample size was 35 patients and if 9 or more achieved a pCR, the results would be compatible with efficacy. We present primary and early secondary endpoints. **Results:** Between 9/2017 and 6/2020, 90 patients were screened (56 excluded; 42 were excluded due to mutations, 12 were excluded due to discrepancies with central review of radiology) of whom 34 were enrolled. In the ITT population a pCR was observed in 11 pts (32.3%; [95% CI 17.39-50.53]) and a near-complete pathological response (Mandard 1+2) was observed 17 pts (52.9%). Clinical complete or near complete response was achieved in 50% and there were no progressions. R0 resection rate and pathological circumferential resection margin neg- were 100%. Full compliance with induction was 88%. Neoadjuvant G3/4 toxicity occurred in 54% and was consistent with FOLFOX/P safety profile. G3/4 postoperative related toxicity was 19% with one reoperation. **Conclusions:** The study met the threshold for efficacy. mFOLFOX6 with P as neoadjuvant therapy can be effective and safe without unexpected toxicities in mrT3, clear MRF and 4WT rectal cancer and resulted in a higher rate of pCR compared with our previous series (GEMCAD 0801; The Oncologist 2014) in a similar molecular-unselected population. This study was funded by Amgen S.A. Clinical trial information: NCT03000374. Research Sponsor: AMGEN.

Molecular correlates of clinical benefit in previously treated patients (pts) with *BRAF* V600E-mutant metastatic colorectal cancer (mCRC) from the BEACON study. *First Author: Scott Kopetz, MD Anderson Cancer Center, Houston, TX*

Background: Encorafenib + binimetinib + cetuximab (enco/bini/cetux; triplet) and enco + cetux (doublet) regimens improved overall survival and objective response rate vs standard of care in pts with previously treated *BRAF* V600E-mutant mCRC in the randomized phase 3 BEACON study. To identify molecular correlates of clinical outcome, we performed molecular profiling in tumors from pts in the study. **Methods:** Baseline tumor samples were retrospectively analyzed by whole-exome sequencing (WES) and whole transcriptome sequencing (WTS) using ImmunoID NeXT (Personalis, Menlo Park, CA, USA). *BRAF*-mutant (BM) and consensus molecular subtypes (CMS) were determined using published classifiers. Pathway activities were evaluated with gene set variation analysis. Objective tumor response was evaluated according to each subtype. Additional association and interaction analyses between molecular features and clinical outcomes by treatments are ongoing and will be presented. **Results:** Baseline tumor samples were analyzed by WES and/or WTS from 527 of 665 (79.2%) randomized pts. The biomarker analyses set is representative of the total pt population and had similar clinical outcomes. Of the 460 pts analyzed by WTS (165/224 [73.7%] in the triplet arm, 146/220 [66.4%] in the doublet arm, and 149/221 [67.4%] in the control arm), 84.6% were classified as either CMS1 (n = 225) or CMS4 (n = 164). The proportion of pts classified as BM1 was 32.2% (n = 148) and the majority (84.5%) of these were CMS4, whereas many of those classified as BM2 (67.8%, n = 312) were CMS1 (64.7%). In the BM1 and CMS4 tumors, expression of inflammatory response and epithelial mesenchymal transition genes were elevated, and expression of cell cycle genes was reduced. The response rate in pts with CMS4 and/or BM1 tumors was higher in the triplet arm (CMS4: 33.3% [95% CI: 21.7–46.7]; BM1: 33.3% [95% CI: 21.4–47.1]) compared with the doublet arm (CMS4: 19.2% [95% CI: 9.6–32.5]; BM1: 14.9% [95% CI: 6.2–28.3]). **Conclusions:** Molecular characteristics and biological properties observed in *BRAF* V600E-mutant mCRC suggest that a subset of pts with specific molecular features may derive greater clinical benefit from triplet than doublet therapy. Additionally, these findings support the utility of gaining further understanding of the biological landscape in *BRAF*-mutant mCRC to enable potential hypotheses for pt selection to improve clinical outcome in future studies. Clinical trial information: NCT02928224. Research Sponsor: Pfizer.

3514 **Poster Discussion Session**

Rarity of acquired mutations (MTs) after first-line therapy with anti-EGFR therapy (EGFRi). *First Author: Christine Megerdichian Parseghian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Colorectal cancers (CRC) lacking *RAS* MTs treated with EGFRi are thought to evolve by a repetitive process of genetic diversification and clonal evolution. Acquired MTs in *KRAS, NRAS, BRAF, MAP2K1*, and *EGFR* are known mechanisms of acquired resistance in the EGFRi refractory population. However, the prevalence of MTs in the first line (1L) setting is not well established as most experience with EGFRi has been beyond the 1L setting. **Methods:** We analyzed paired plasma samples from *RAS/BRAF/EGFR*^{WT} mCRC patients (pts) enrolled in 3 large randomized phase 3 trials who had been treated with EGFRi and in whom paired baseline (BL) and time of progression (PRO) plasma samples had been collected for sequencing of ctDNA on a platform optimized for very low allele frequencies (Plasma*Select*-R™ and Resolution Bio™). Prevalence of MTs at BL and PRO from a 1L study ('203; FOLFOX ± panitumumab) were compared with 2 studies in the third line setting (3L; '007; panitumumab + best supportive care [BSC] vs BSC; and 3L; '763; panitumumab vs. cetuximab), to assess the frequency of acquired resistance mutations via ctDNA analysis. **Results:** For pts with available paired plasma samples (n = 112 for '203; n = 89 for '007; n = 274 for '763), acquisition of at least one *KRAS, NRAS, BRAF, MAP2K1*, or *EGFR* MT was significantly less common in post-progression samples in the EGFR containing arms of the 1L '203 study compared to the 3L '763 and '007 studies (6.8% vs 50.4% vs 39.6%, respectively; p < 0.001). In the non EGFR containing arms of the '203 and '007 study, the rate of acquired MTs was 7.5% and 0%, respectively (p = 1). While this difference in the rate of acquired MTs between the EGFR and non EGFR containing arms was statistically significant for the 3L study (p < 0.001) it was not significant for the 1L study. Further, pts on both 3L studies treated with EGFRi who experienced CR, PR or SD acquired more MTs than those who had PD as best response (53.6% vs 33.3%, respectively; p < 0.001). This relationship was not significant in the 1L setting (7.7% vs 0%; p = 1). Subclonal MTs (rMAF < 25%) in *KRAS, NRAS, EGFR, BRAF* and *MAP2K1* were present at BL in 129 pts (27%). Based on the hypothesis that EGFRi is selecting for rare existing mutated cells in the tumor, we would expect expansion of any preexisting subclones in the BL samples. However, in contrast to expectations, these subclones rarely expanded to become clonal at the time of progression (12.4%). **Conclusions:** In contrast to expectations, acquired *KRAS, NRAS, BRAF, EGFR*, or *MAP2K1* MTs rarely develop after 1L therapy. While selective pressure appears to increase the frequency of acquired MTs in the 3L setting, preexisting subclonal MTs do not appear to be the dominant source of acquired MTs at progression, implying that there may also be a transient mutational process driving resistance rather than expansion of preexisting clones. These findings have significant implications for ongoing and planned EGFRi rechallenge studies. Research Sponsor: Amgen inc.

Immune signatures to affect overall survival (OS) and response to bevacizumab (Bev) or cetuximab (Cet) in patients (pts) with metastatic colorectal cancer (mCRC) of CALGB/SWOG 80405 (Alliance). *First Author: Federico Innocenti, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: CALGB/SWOG 80405 was a randomized phase III trial in first-line mCRC patients treated with Bev, Cet, or both, plus chemotherapy. No difference in OS was found between Bev and Cet. We tested the effect of immune signatures on OS in all the three arms of the study and analyzed differences in OS between the Cet and Bev arms. **Methods:** 578 primary tumors were profiled by RNAseq. Immune signatures of TGF-β, cytotoxic T cells, wound healing, macrophages, lymphocytes, and INF-γ, as well as relative frequencies of CD8+ T-cells, memory resting CD4+ T cells, memory activated CD4+ T cells, macrophages M1 and M2, and activated mast cells were measured. Multivariate Cox proportional hazard models were applied using elastic-net penalization with covariates (age, race, gender, all *RAS* and *BRAF* V600E mutations). For relevant signatures, optimal cut-offs for OS were calculated. **Results:** In all the three arms of the study, high expression of macrophages M2 (HR 6.81, 95% CI 3.56-30.16) and TGF-β (HR 1.37, 95% CI 1.03-2.10) conferred reduced OS compared to low expression; high expression of plasma cells (HR 0.52, 95% CI 0.27-0.83) and memory-activated CD4+ T cells (HR 0.34, 95% CI 0.10-0.65) conferred increased OS compared to low expression. Using optimal cut-offs from these 4 signatures, pts have been categorized as to whether they had either 4, 3, 2, 1, or 0 beneficial signatures associated with increased OS. In all arms of the study (N = 469, after accounting for covariates), the median (95% CI) OS decreased from 42.5 (35.8-47.8; N = 79), to 31.0 (28.8-34.4; N = 177), 25.2 (20.6-27.9; N = 144), and 17.0 (13.5-20.4; N = 69) months when the number of beneficial signatures decreased from 4, to 3, 2, and 0-1 (combined due to a low number of pts), respectively (p = 3.48e-11). In the Bev arm (N = 205), high expression of macrophages M2 conferred reduced OS compared to low expression (HR 6.6, 95% CI 2.7-67.1). In the Cet arm (N = 165), high expression of macrophages M2 conferred reduced OS compared to low expression (HR 4.3, 95% CI 2.1-79.8); high expression of plasma cells (HR 0.36, 95% CI 0.06-0.55) and memory activated CD4+ T cells (HR 0.37, 95% CI 0.03-0.98) conferred increased OS compared to low expression of either signatures. The plasma cell signature interacted with Bev and Cet on the OS of pts (interaction p = 0.009). **Conclusions:** Tumor immune signatures in mCRC pts are determinants of survival. In pts treated with Bev- and Cet-combination therapies that are standard of care, immune signatures affect response to therapy. These results, provide new markers for treatment selection and for the development of novel active combinations including immune checkpoint inhibitors. 3516 **Poster Discussion Session**

Examination of the tumor immune microenvironment (TIME) with multispectral immunofluorescence (m-IF): Association of markers with prognosis and bevacizumab (bev) benefit in NRG Oncology/NSABP C-08. *First Author: Katherine L. Pogue-Geile, NSABP/NRG Oncology, Pittsburgh, PA*

Background: The purpose of this study was to quantify different molecules of TIME including T cells, macrophages, and immune checkpoint proteins (ICPs), and determine their association with clinical outcomes and treatment benefit in pts enrolled in C-08, which tested the efficacy of adding bev to 5-fluoruracil+leucovorin+oxaliplatin. Our prespecified, NCTN-CCSC approved primary objective hypothesized that pts with more CD8 cells would have a better prognosis and receive benefit from bev. **Methods:** Tissue microarrays were used to assess TIME of 1,509 C-08 pts using m-IF and the Vectra Pathology System. Three m-IF panels were used to quantitatively assess T cells (CD3, CD8, CD45RO, FOXP3), macrophages (CD68, CD163), and ICPs (PD-1, PD-L1, CTLA4, TIM3, LAG3, OX40) in stromal and tumor (panCK) regions. The primary objective was to determine the association between overall survival (OS) and high (top 3rd) *v* low CD8 expression in both stromal and tumor regions. All markers were tested for associations with OS and recurrence-free interval (RFI) and with bev prediction using Cox models and median cut points. **Results:** Based on our pre-specified analysis, pts with high CD8 cells had better OS, HR=0.66 (95%CI: 0.49-0.88), p=0.005 but pts with high CD8 cells did not receive bev benefit. All T cells and double stained CD8/PD-1 were associated with better RFI. CD3, CD8, CD68, PD-1, PD-L1, and LAG3 cells were associated with better OS. PD-1 and CD8/PD-1 were associated with RFI in pts with deficient mismatch repair (dMMR) and proficient (p)MMR but TIM3, CD3/CD45RO and CD163 were only associated with RFI in dMMR. Association of CD8 cells with bev benefit (RFI) was seen in dMMR pts, HR 0.27 (95% CI: 0.1-0.73), p=.01 and OS, HR=0.27, (95% CI: 0.12-0.64), p=0.0028 but there was no significant interaction. Single staining CD8, PD-1, and double staining CD8/PD-1 cells were associated with bev benefit in dMMR pts but with bev harm in pMMR pts. However, pts with tumors having >1% of PD-1 and PD-L1 cells (n=197 including 76 dMMR, 100 pMMR, and 21 unknown), received significant bev benefit (int p=.0056). **Conclusions:** CD8 cells were associated with better OS but were not associated with bev benefit. All T cells and PD-1, PD-L1, and LAG3 cells, were associated with better prognosis in the entire cohort but when pts were stratified for MMR status differences in their association with prognosis and bev benefit emerged. PD-1, CD8, and CD8/PD-1 cells were associated with bev harm in pMMR but bev benefit in dMMR. A significant interaction for the association of high % PD-1 and PD-L1 with bev benefit regardless of MMR status may be a chance finding. However, VEGF has immunosuppressive effects and bev may block these effects in tumors with high PD-L1 and PD-1, regardless of MMR status. NCT: 00096278 PA DOH, U10CA-180868, -180822, -196067, Genentech, Sanofi; NSABP. Clinical trial information: 00096278. Early-onset stage II/III colorectal adenocarcinoma in the IDEA database: Treatment adherence, toxicities, and outcomes from adjuvant fluoropyrimidine and oxaliplatin. *First Author: Elisa Fontana, Sarah Cannon Research Institute, United Kingdom, London, United Kingdom*

Background: Incidence of early-onset colorectal cancer (eoCRC, age < 50) is steadily increasing. Decisions on adjuvant treatment (adjTx) regimen and duration should consider tx adherence, toxicity (tox) and expected outcomes in a population with life-expectancy longer than late onset CRC (loCRC, age ≥ 50). **Methods:** Individual patient data from stage II/III patients (pts) from 6 randomised trials in the IDEA database were used to compare characteristics, tx adherence, and adverse events of eoCRC to loCRC. To reduce the confounder of non-cancer-related deaths due to age/co-morbidities, time-to-recurrence (TTR) and cancer-specific survival (CSS) were compared by stratified Gay k-sample test. 5-year cancer-specific mortality (CSM) rate were estimated by adjusted cumulative incidence function. 3-year relapse-free survival (RFS) rate were compared by stratified and adjusted COX models. **Results:** Out of 16,349 pts included, 1564 (9.6%) were eoCRC. Compared to loCRC, eoCRC had lower percent of male pts (51% vs 57%, p < 0.01) better performance status (PS0 86% vs 80%, p < 0.01), similar T stage distribution (% T1-3/T4: 76/24 vs 77/23, p = 0.97), higher rate of N2 disease (24% vs 22%, p < 0.01), more likely to complete pre-planned duration of adjTx (83.2% vs 78.2%, p < 0.01) and received a higher tx intensity especially with 6 month tx (mean oxaliplatin dose intensity 75% vs 72%, p < 0.01; capecitabine 85% vs 78%, p < 0.01; 5FU 85% vs 82% p < 0.01). Gastrointestinal tox was more common in eoCRC (any grade nausea 58% vs 45%, p < 0.01; any grade vomiting 22% vs 16%, p < 0.01); haematological tox was more frequent in loCRC (62% vs, 69%, p = < 0.01); any grade neuropathy rate was similar (75%). Significant interaction was found between age and T stage for TTR (p = 0.04). Clinical outcome estimates and comparisons are shown in Table. Notably, high risk stage III (T4/N2) eoCRC had significantly lower 3-y RFS rate (54% vs 64%, HR_{adj} 0.74, p < 0.01). **Conclusions:** eoCRC have better tx adherence than loCRC, as expected. While in high risk stage II and low risk stage III, cancer-specific outcomes are not different, in high risk stage III young age is negatively prognostic and associated with significantly higher relapse rate and risk of CRC death; this is despite a higher administered adjTx-intensity, suggesting a more aggressive disease biology. Clinical trial information: NCT00749450 (SCOT); NCT00646607 (TOSCA); NCT01150045 (CALGB/SWOG 80702); NCT00958737 (IDEA France); Research Sponsor: EORTC GI Group supported the pooled analyses, ACHIEVE supported by the Japanese Foundation for Multidisciplinary Treatment of Cancer (JFMC) and funded by Yakult Honsha Co, Ltd; CALGB/SWOG 80702 was supported by grants (U10CA180821, U10CA180835, UG1C).

		eoCRC	loCRC	Adjusted Hazard Ratio (95% Confidence Interval)	p-value

3518 **Poster Discussion Session**

Prevalence of fertility discussions between young adult colorectal cancer survivors and their providers. *First Author: Julia Stal, University of Southern California, Los Angeles, CA*

Background: Clinical guidelines indicate that oncologists should discuss potential treatment-induced infertility with patients with reproductive potential. Due to tumor location and use of multimodal therapies, young adults with colorectal cancer (CRC) are at heightened risk for treatment-related infertility. **Methods:** An online, cross-sectional survey was administered in collaboration with a national patient advocacy organization for young adult CRC survivors (currently under age 50). Survivors were asked to indicate if a doctor had ever talked to them about potential problems with their ability to have children after treatment and if they banked eggs/embryos (females) or sperm (males) prior to their cancer therapy. Those who reported that they did not preserve fertility were asked to indicate why (*not sure; I chose not to; I did not know this was an option; I wanted to, but could not afford it;* and *I wanted to, but my treatment would not allow it*). **Results:** A total of 234 colon (N=86) or rectal (N=148) cancer survivors were included in the study (male [61.9%] and White [77.9%; table]). Most respondents were diagnosed with stage 2 cancer (55.8% colon, 61.6% rectal). Over half of male and female survivors reported that their doctor did not talk to them about problems with their ability to have children after treatment, and 75% did not bank eggs/embryos or sperm prior to their cancer therapy. Of those, over 20% endorsed 'I wanted to, but could not afford it' and over 20% endorsed 'I did not know this was an option'. **Conclusions:** Most CRC survivors in this study reported never having a fertility discussion with their provider, suggesting that survivors are not receiving, or cannot recall, comprehensive and guideline-concordant cancer care. In addition, one-fifth were not aware of preservation options, suggesting potential healthcare and/or provider-level barriers to appropriate fertility counseling. Fertility preservation cost is another barrier to the appropriate delivery of care. Providers must ensure that patients receive timely fertility discussions covering options to preserve fertility to mitigate this late effect of cancer treatment to ensure optimal quality of life for CRC patients with reproductive potential. Research Sponsor: The Aflac Archie Bleyer Young Investigator Award in Adolescent and Young Adult Oncology from the Children's Oncology Group. Additional support was provided by the NCI Cancer Center Support Grant from the USC Norris Comprehensive Cancer Center.

Microbiome signature, global methylation and immune landscape in early onset colorectal cancer. *First Author: Ning Jin, Univ of Wisconsin, Madison, WI*

Background: The incidence of colorectal cancer (CRC) in young adults (< 50 years old) has been rapidly increasing by 2% per year since early 1990. Approximately 20% of early-onset (EO) CRC cases are due to germline gene mutations. However, the etiology of sporadic EO CRC remains poorly understood. Research suggests that environmental factors such as the Western diet (high in fat and low in fiber) may be associated with an increased incidence of sporadic EO CRC. The gut microbiota decompose and ferment dietary fibers to produce microbial metabolites, which play pivotal roles in maintaining the integrity of intestinal epithelium as well as the immune cell homeostasis. Also, these microbial metabolites may influence the host epigenome by altering either the activity of epigenetic enzymes or by modifying the availability of cofactors needed for epigenetic modifications. The aim of our research is to associate intratumoral microbiota with methylation pattern and immune cell composition in EO CRC. **Methods:** A total of 358 CRC cases, including 54 cases of EO CRC (age < 50 years) and 304 cases of late onset (LO) CRC (age ≥ 50 years), with matched methylation array (Infinium HM450), RNA-sequencing (Illumina HiSeq) from colon adenocarcinomas (COAD) and rectal adenocarcinomas (READ), and clinicopathological information of each patient, were extracted from the Cancer Genome Atlas (TCGA). We characterized and compared the intra-tumoral microbiota composition, tumor-infiltrating lymphocytes (TILs), and methylation profile between EO and LO CRC. **Results:** We found that there is a distinct microbial distribution, gene expression and methylation pattern in the EO CRC when compared with LO CRC. Non-human sequences from several kingdoms including bacteria, fungi and viruses were found and the incidences were consistent with reported values by other methods, e.g. *Fusobacterium* incidence. The EO CRC cases showed global hypomethylation, even though hypermethylation pattern is expected in the young chronological age group (known as Horvath's clock). Pathway overrepresentation analysis of differentially expressed genes showed significant activation of p53 and pentose phosphate pathways and *de novo* nucleotide synthesis in EO CRC. Integration across datasets showed positive correlations between microbes and inflammasome pathway, positive correlation with regulatory T cells (Tregs), and negative correlations with CD4 memory T cells. **Conclusions:** These data suggest a mechanism by which the colorectal cancer-associated microbiota may be associated with epigenetic regulation and host immune response. HPV-mediated anal squamous cell carcinoma and precancerous lesions in HIV positive patients. *First Author: Omar Bushara, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Anal cancer affects over 8,000 patients per year in the United States and the incidence is increasing. A significant risk factor for anal cancer and precancerous lesions is human papilloma virus (HPV), with up to 90% of cases being associated with HPV infection. Another emerging risk factor is HIV co-infection. In the present study, we further address if CD4 count is a significant factor for driving higher-grade HPV-mediated anal squamous lesions in HIV/HPV co-infection patients with a single institution large cohort. **Methods:** A retrospective cohort of HPV-positive patients with anal biopsies was obtained from 2002-2020. Information on the grade of their anal lesion, HIV status, and CD4 count (cells/mm^3) were collected. In patients with HIV, the most recent CD4 count up to one year prior to or one month after their biopsy was utilized in our analysis. Lesions were grouped into low grade squamous intraepithelial lesions (LSIL) and higher grade squamous intraepithelial lesions (HSIL), carcinoma in situ (CIS), or squamous cell carcinoma (SCC). The Center for Disease Control CD4 count levels to define HIV status were utilized in our sub-analyses. The distribution of lesion grades was compared between HIV-negative and -positive patients, and between HIV-negative and three subgroups of HIV-positive patients using the Fisher's exact test. **Results:** Our cohort comprised of 3,354 total HPV-positive patients. 2,036 of these patients were HIV-negative and 1318 were HIV-positive. The proportion of higher grade lesions was significantly higher in HIV/HPV co-infected patients regardless of CD4 count (Table). The full cohort of HIV-positive patients had lower rates of LSIL (60.8% vs. 74.0%) and higher rates of higher-grade lesions (39.2% vs. 26.0%) ($p<0.001$) compared to HIV-negative patients. The distribution of lesion grades was also significantly different between HIV-negative patients and all HIV-positive patient subgroups, with all subgroups having higher rates of higher-grade lesions than HIV-negative patients (all $p<0.001$). **Conclusions:** Our data show that HIV-HPV co-infection is a risk factor for higher grade anal lesions, regardless of CD4 status. This suggests that CD4 count is not the only factor responsible for the increased risk of higher-grade anal lesions, as the groups of HIV-positive patients with CD4 counts between 200-499 and above 499 still had a higher rate of higher-grade lesions than HIV-negative patients. Further research into other HIV-related immunologic changes that increase risk for higher-grade HPV-driven anal lesions is warranted. Research Sponsor: None.

Final analysis of dose-finding and single-arm confirmatory study (phase I/II study) of definitive chemoradiotherapy (dCRT) with S-1/mitomycin-C (MMC) in patients (pts) with clinical (c) Stage II/III squamous cell carcinoma of the anal canal (SCCA): JCOG0903. *First Author: Yoshinori Ito, Department of Radiation Oncology, Showa University School of Medicine, Tokyo, Japan*

Background: dCRT with 5-FU/MMC is a standard treatment for cStage II/III SCCA. S-1 is an oral fluoropyrimidine and has a greater effect on radiosensitivity. We conducted this trial of dCRT with S-1/MMC to determine the recommended dose (RD) of S-1 in dose-finding (phase I) part and to evaluate the efficacy and safety in confirmatory (phase II) part for cStage II/III SCCA. We reported the RD of S-1 and the 3-year survival at 2019 Gastrointestinal Cancers Symposium. We report the final data after 5-year follow-up. **Methods:** Eligibility criteria included histologically proven SCCA, cStage II/III (UICC 6th), PS 0-1, and age 20-80 years. dCRT consisted of MMC (10 mg/m^2 on days 1, 29) and S-1 (60 mg/m^2/d in level 0 and 80 mg/m^2/d in level 1 on days 1-14, 29-42) with concurrent radiotherapy of 59.4 Gy/33fr. The dose-finding part adopted the 3+3 cohort design. The primary endpoint of confirmatory part was 3-year event-free survival (EFS). The sample size was 65 in the confirmatory part, with one-sided alpha of 5% and power of 80%, threshold and expected 3-year EFS as 60% and 75%. Key secondary endpoints were overall survival (OS) and progression-free survival (PFS) and colostomy-free survival (CFS), and adverse events. Final analysis was planned after 5-year follow-up for all pts. **Results:** From Feb/2010 to Mar/2015, 69 pts (3 in level 0 and 66 [7 in phase I and 59 in phase II] in level 1) were enrolled. Pts characteristics for level 1 were as follows: M/F, 12/54; Age, median 64 (range 33-80); cStage II/IIIA/IIIB, 29/9/28. Three in level 1 were ineligible and 63 eligible assigned to level 1 were included in efficacy analysis. In the dose-finding part, RD of S-1 was determined as 80 mg/m^2/d. The complete response rate was 81% (95% CI, 69.1-90.0%) on central review. With a median follow-up of 5.4 years, 3- and 5-year EFS was 65.0% (90% CI 54.1-73.9%) and 63.4% (95% CI 50.2-73.9%). 5-year OS, PFS, and CFS were 84.1% (95% CI 72.5-91.1%), 84.1% (95% CI 72.4-91.1%), and 73.0% (95% CI 60.2-82.3%), respectively. In a univariable analysis, male sex ($p = 0.045$) prognosticated for poor OS and cT3 or T4 ($p = 0.001$), male sex ($p = 0.019$) and, PS 1 ($p = 0.048$) prognosticated for poor CFS. Nine (14.3%) of 63 pts at a dose level 1 developed recurrence or disease progression. Locoregional recurrence only and distant metastasis were observed in 1 pts (1.6%) and 8 pts (12.7%) respectively. Among all treated 65 pts, only 5 pts (7.7%) showed grade 3 late toxicities including jejunum obstruction, jejunum ulcer, proctitis, lower gastrointestinal hemorrhage, anal pain, radiation dermatitis, and ureteral stenosis. No Grade 4 or 5 late toxicities were observed. **Conclusions:** dCRT with S-1/MMC showed acceptable toxicities and favorable 5-year survival and could be a possible treatment option for pts with locally advanced SCCA. Clinical trial information: jRCTs031180002. Research Sponsor: 26-A-4, 29-A-3, 2020-J-3, Grants-in-Aid for Clinical Cancer Research (H23Gann-012) from the Ministry of Health.

Association between cancer stem cell marker ALDH1 and clinical and morphological factors of colorectal cancer prognosis. *First Author: Elena A. Nikipelova, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Cancer stem cells (CSCs) capable of self-sustaining and multipotent differentiation are considered among the most important factors limiting treatment effectiveness. ALDH1 is a marker of colorectal cancer (CRC) CSCs; it is involved in cell differentiation and proliferation, determines resistance to alkylating chemotherapeutic agents, and also induces epithelial-mesenchymal transition (EMT), which increases the invasive and metastatic potential of tumors. The purpose of the study was to assess the association between the expression of the ALDH1 CSC marker in tissues of CRC of different stages and clinical and morphological factors of the disease prognosis. **Methods:** The study included 299 patients (aged 42-86 years, mean age 64.2±1.7) with stage II-IV CRC T1-4N0-2M0-1; histologically verified G1-G3 adenocarcinoma in all patients. Tissues of surgically removed tumors were studied with IHC analysis using mouse monoclonal anti-ALDH1 antibodies (clone B-5, Santa Cruz Biotechnology) diluted 1:1800 and the Reveal Polyvalent HRP-DAB Detection System. The percentage of cells positively stained for ALDH1 among all tumor cells was assessed. Statistical analysis was performed using the STATISTICA 13.0 program (StatSoftInc., USA). **Results:** Positive ALDH1+ expression was registered in 52.5% of all patients, negative expression – in 47.5%. Statistically significant association was observed between the ALDH1 expression and the CRC stage, since the ALDH1+ expression increased from stage II to stage IV ($p = 0.003$). The ALDH1 expression was statistically significantly associated with the depth of tumor invasion ($p = 0.018$) and the presence of distant metastases ($p < 0.001$). No significant relationship was observed between the ALDH1 expression and regional lymph node metastasis ($p = 0.788$). Statistically significant association was registered between the ALDH1 expression and the tumor grade ($p < 0.001$), perineural invasion ($p = 0.010$) and lymphocytic infiltration ($p < 0.001$). No significant relationship was observed between the tumor histological structure ($p = 0.979$), lymphovascular invasion ($p = 0.772$) and ALDH1 expression. Tumor site was not statistically significantly associated with ALDH1 expression ($p = 0.349$). **Conclusions:** The study demonstrated statistically significant association between the ALDH1 expression and clinical and morphological characteristics of CRC, determining invasive and metastatic potential of the tumor, and ALDH1 may be an independent prognostic factor and a new therapeutic target for the regulation of the progression process. Research Sponsor: None.

3523 **Poster Session**

Circulating tumor DNA-based genomic profiling of small bowel adenocarcinoma. *First Author: Pat Gulhati, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Small bowel adenocarcinoma (SBA) is a rare malignancy, with lower incidence, later stage at diagnosis, and worse overall survival compared to other intestinal cancers, such as colorectal cancer (CRC). Since the majority of small bowel tumors are not accessible to endoscopic biopsy, comprehensive genomic profiling using circulating tumor DNA (ctDNA) may enable non-invasive detection of targetable genomic alterations (GA) in SBA patients. In this study, we characterize the ctDNA GA landscape in SBA. **Methods:** Analysis of 299 ctDNA samples prospectively collected from 265 SBA patients between 2017 to 2020 was performed using a 73 gene next generation sequencing panel (Guardant360). A subset of patients underwent longitudinal analysis of changes in GA associated with systemic therapy. **Results:** Of the 265 patients, 160 (60.3%) were male; the median age was 66 (range: 21-93 years). The most common GA identified in SBA patients included TP53 [58%], KRAS [44%], and APC [40%]. MSI was detected in 3.4% of SBA patients. When stratified by primary tumor location, APC, KRAS, TP53, PIK3CA, and ARID1A were the most common GA identified in both duodenal and jejunal adenocarcinomas. ERBB2, BRCA2 and CDK6 alterations were enriched in duodenal adenocarcinoma, while NOTCH and BRAF alterations were enriched in jejunal adenocarcinoma. The most common currently-targetable GA identified were ATM [18%], PIK3CA [17%], EGFR [15%], CDK4/6 [11%], BRAF [10%], and ERBB2 [10%]. Unique differences in GA between SBA and CRC were identified: i) the majority of ERBB2 alterations are mutations (89%) in the extracellular domain and kinase domain, not amplifications (11%); ii) the majority of BRAF alterations are non V600E mutations (69%) and amplifications (28%); iii) there is a significantly lower rate of APC mutations (40%). Alterations in DNA damage response pathway proteins, including ATM and BRCA 1/2, were identified in 30% of SBA patients. ATM alterations were more common in patients ^{3}65 years old. The most common mutations predicted to be related to clonal hematopoiesis of indeterminate potential were TP53, KRAS and GNAS. Longitudinal ctDNA analysis in 4 SBA patients revealed loss of mutations associated with therapeutic response (TP53 R342*, MAPK3 R189Q) and acquired mutations associated with therapeutic resistance (NF1 R1968*, MET S170N, RAF1 L613V). **Conclusions:** This study represents the first large-scale blood-based ctDNA genomic profiling of SBA. SBA represents a unique molecular entity with differences in frequency and types of GA compared to CRC. Variations in GA were noted based on anatomic origin within the small intestine. Longitudinal ctDNA monitoring revealed novel GA associated with therapeutic resistance. Identification of multiple targetable GA may facilitate clinical decision making and improve patient outcomes in SBA, especially when a tissue biopsy is not feasible or sufficient for comprehensive genomic profiling. Association of HER2 expression with pathologic features and prognosis in stage II and III colon cancer. *First Author: Zehua Wu, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: We examined the frequency, tumor characteristics, and prognostic impact of HER2 protein expression in stage II and III colon cancer after curative resection. **Methods:** Paraffin-embedded tumors from consecutive primary stage II and III colon cancer patients were analyzed for HER2 protein expression by immunohistochemistry between April, 2013 and May, 2020. HER2 determination of immunohistochemistry scores (0/1+/2+/3+) was according to HERACLES diagnostic criteria. **Results:** A total of 2088 stage II and III colon cancer patients were included (53.8% stage II, 46.3% stage III). HER2 scored positive (3+) was detected in 48(2.3%) tumors, and was correlated with younger age ($P < 0.001$), well/moderate differentiation ($P = 0.026$), proficient mismatch repair (pMMR) ($P = 0.045$) and KRAS wild-type ($P < 0.001$). HER2 scored positive (3+) was not significantly associated with disease-free survival (DFS) compared with HER2 scored negative (0/1+), neither in stage III patients (multivariable HR, 0.86; 95CI, 0.38 to 1.94; $P = 0.717$), nor in stage II patients (multivariable HR, 1.68; 95CI, 0.74 to 3.84; $P = 0.218$). In a separate analysis involving stage II patients without any high-risk factor ($n = 741$), those with HER2 scored positive (3+) tumors ($n = 16$) showed significantly reduced DFS (multivariable HR, 2.91; 95CI, 1.04 to 8.81; $P = 0.041$) compared with patients with HER2 scored negative (0/1+) tumors, independent of sex, age and MMR status. **Conclusions:** HER2 scored positive (3+) was independently associated with poor DFS in stage II colon cancer patients without high-risk factors. HER2 expression determination may help to judge the prognosis of those patients and guide adjuvant chemotherapy. Research Sponsor: None.

Clinical utility of stool-based *SDC2* methylation test for the detection and screening of colorectal cancer in a Chinese population. *First Author: Yanmei Liu, The Qingyuan People's Hospital, Qingyuan, China*

Background: In 2020, colorectal cancer (CRC) ranks second in incidence and third in mortality among all types of cancers in China based on data from GLOBOCAN. Moreover, the rates of incidence and mortality have been continuously rising over the past several decades. In addition to conventional methods for detection and screening of CRC such as gFOBT, FIT, and colonoscopy, a stool-based methylation test of human *SDC2* gene was recently approved by National Medical Product Association (NMPA) of China. We hereby report the performance of this newly approved test in a hospital-based cohort of more than 10,000 patients in the real world of daily clinical practice. **Methods:** The methylation target, human *SDC2* gene, was extracted from stool and purified via sequence-specific capture technology. The isolated DNA was further treated with bisulfite before it was subsequently amplified by quantitative methylation-specific polymerase chain reaction (qMSP) to analyze the fecal level of *SDC2* methylation. Subjects were further examined by colonoscopy or CT imaging. Pathological examination would also be performed in cases deemed necessary. **Results:** A total of 11,284 individuals were tested using the novel *SDC2* methylation test. Among them, 858 and 10,426 were tested positive and negative, respectively. Follow-up visits, treatment, and medical information were complete for 429 positive and 780 negative patients who were included in this final analysis. Positive predictive value (PPV) of CRC and adenomas was 36.4% (156/429) and 24.5% (105/429), respectively. Stratified analysis implies that *SDC2* methylation level in CRC was significantly higher than those in adenoma and normal groups. In CRC, no significant correlation was observed between *SDC2* methylation and clinicopathological features including gender and grade of dysplasia. In < 65 and ≥ 65 age groups, the CRC detection rate in males was higher than that in females-almost two times higher in ≥ 65 age group. **Conclusions:** The stool-based *SDC2* methylation test demonstrated high accuracy in the detection of CRC and advanced adenomas. It is a sensitive and valid modality expected to play a significant role to aid diagnosis and screening of CRC and precancerous lesions in order to reduce the morbidity and mortality of this malignant disease. Patient-reported quality of life data from patients with pre-treated metastatic colorectal cancer receiving trifluridine/tipiracil: Interim results of the TALLISUR study. *First Author: Meinolf Karthaus, Klinikum Neuperlach/Harlaching, Munich, Germany*

Background: Compared to placebo, trifluridine/tipiracil (FTD/TPI) significantly improved overall and progression-free survival in patients (pts) with pre-treated metastatic colorectal cancer (mCRC) in the phase III RECOURSE trial. Although time to deterioration of ECOG performance status (PS) from 0/1 to ≥ 2 was significantly longer in pts treated with FTD/TPI, health-related quality of life (HRQoL) was not formally assessed by direct means. Therefore, a two-arm trial with best supportive care (BSC) as appropriate comparative treatment was designed to specifically address the effect of FTD/TPI on HRQoL. **Methods:** In this prospective, multi-center, German, open-label, phase IV study, pts with pre-treated mCRC could choose between BSC or oral FTD/TPI (35 mg/m^2 *bid* on days 1-5 and 8-12 of each 28-day cycle). EORTC QLQ-C30 and EQ-5D-5L questionnaires were employed to assess HRQoL. Primary endpoint was the rate of responders with stabilized (> -10 and < 10 scores) or improved (≥ 10 scores) response (RR). Response was calculated as the mean score of the EORTC QLQ-C30 global health status/QoL scale from the 2nd cycle until the end of treatment/ observation compared to the baseline score. **Results:** Of 194 eligible pts, 185 pts chose treatment with FTD/TPI (median 3 cycles), while 9 pts decided to receive BSC only. Questionnaires from 109 pts receiving FTD/TPI and from 6 pts with BSC were evaluable for RR. The primary endpoint (RR) was 59.6% (95% CI 49.8 – 68.9) in FTD/TPI-treated pts and 50.0% (95% CI 11.8 – 88.2) in pts receiving BSC. Analysis of the extended follow-up period, demonstrated that RR was 67.0% (95% CI 57.3 – 75.7) in FTD/TPI-treated pts. In the FTD/TPI-group, median time to deterioration of HRQoL was 121 days ($n = 61$; 95% CI 87 – 151) according to EORTC QLQ-C30 and 119 days ($n = 63$; 95% CI 85 – 138) according to EQ-5D-5L. **Conclusions:** If pts can choose between treatment and BSC in late-stage CRC, the vast majority opts for treatment. According to the present results, FTD/TPI-treatment induced prolonged stabilization of HRQoL, a highly desired attribute of therapies for pts with late-stage cancer. Clinical trial information: No 2017-000292-83. Research Sponsor: Servier Pharma Germany.

Globo H expression in metastatic colorectal cancer (CRC). *First Author: Priya Jayachandran, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Globo H is a carbohydrate antigen that is highly expressed on the cell surface of epithelial cancers but not in normal tissue, and has been reported to correlate with poor prognosis. An attractive therapeutic target, Globo H-targeted agents are being tested in early clinical trials (e.g., OBI-833, a Globo H antigen conjugated to a mutated diphtheria toxin with potential antineoplastic activities, and OBI-999, an antibody-drug conjugate (ADC) consisting of a Globo H monoclonal antibody with a synthetic antineoplastic agent). We aim to describe the molecular features associated with Globo H expression in CRC. **Methods:** A total of 7,604 CRC tumors were tested by Caris Life Sciences (Phoenix, AZ) by NextGen DNA and RNA sequencing. The expression of β3GalT5, FUT-1 and FUT-2 were evaluated as surrogates for Globo H expression as they are the key enzymes in its biosynthesis. An average z-score of the 3 genes (GloboH) and of β3GalT5 (B3) alone were calculated; tumors with top quartile z-scores were considered expression-high (Q4) and bottom quartile, expression-low (Q1). QuantiSEQ was used to assess immune cell infiltration in the tumor microenvironment (TME). Statistical significance was determined using chi-square/Fisher-Exact and adjusted for multiple comparisons ($q<0.05$). Consensus molecular subtype (CMS) was developed using RNA seq data. **Results:** When the 3 genes were considered, GloboH-H tumors showed higher prevalence of CMS1 and CMS4 (23.8% vs. 12%; 38.7% vs. 29.4%) and lower prevalence of CMS2 (40% vs. 18.7%) compared to GloboH-L. Similar patterns of CMS distribution were seen for B3 alone. B3-H tumors were significantly more frequently TMB-H ($>=10$) (11.4% vs. 8.3%), PD-L1 positive (5.7% vs. 3.4%) and MSI-H/dMMR (8.3% vs. 5.5%). Strong positive associations were seen with mutations in *BRAF*, *KRAS*, *RSPO3* fusion, and *cMYC* amplification with B3 alone and GloboH (all $q<0.05$). Anti-tumor CD4+ T cells and NK cells were increased in the TME with increased expression of GloboH and B3 ($q<0.05$). However, immune suppressive neutrophils and Tregs were also increased. Dendritic cells were negatively associated with B3 expression while endothelial cells and fibroblasts showed a positive association with GloboH and B3. **Conclusions:** The association with TMB-H, MSI-H, and PD-L1 status suggests that in some tumors Globo H may be a promising target for combination therapy with immune checkpoint inhibition. The association with different cell populations suggests manipulating the cellular balance in the TME as an approach to improve the efficacy of treatment. NK cell checkpoint inhibitors are in clinical trials and might be utilized in high Globo H cancers; treatments inducing DCs in tumors have been shown to enhance responses to *BRAF* and PD-L1 blockade and might be applicable in the context of Globo H immunotherapy to overcome Treg immune suppression. Anti-Globo H vaccines and ADCs might be particularly effective in *BRAF* and *KRAS*-mutant CRC patients. Research Sponsor: None.

Use of circulating tumor DNA in colorectal cancer patients to assess tumor burden and response to therapy: An observational study. *First Author: Erin L Symonds, Flinders University, Adelaide, SA, Australia*

Background: Residual disease after treatment for colorectal cancer (CRC) poses a risk for recurrence but imaging and CEA are limited in their capacity to detect residual disease. A simple test is needed for assessing treatment response. This study determined whether levels of methylated *BCAT1/IKZF1* DNA in blood correlate with tumor burden and whether post-treatment levels inform efficacy of different treatments for CRC. **Methods:** Patients with primary CRC had blood collected prior to treatment (n = 282, 59.9% males, median age 68.5y). Cell free DNA (cfDNA) was extracted from plasma and assayed for methylation in *BCAT1* and *IKZF1*. Detection of methylation in either gene deemed a sample positive; levels were expressed as %methylation (average methylation/average cfDNA). Positive patients had additional samples collected post-treatment for early stage CRC (surgery, n = 31), advanced/metastatic CRC (surgery + adjuvant chemotherapy, n = 15), and rectal cancer (neoadjuvant therapy, surgery +/- chemotherapy, n = 6), or following mid-therapy suspension of treatment in advanced CRC (n = 24). Tumor size was expressed as the maximum diameter of the primary (assessed surgically or by MRI). **Results:** Pretreatment results increased with CRC stage. Positivity by stage was: I, 23.7% (14/59); II, 62.1% (54/87); III, 68.6% (70/102); IV, 85.3% (29/34). Level by stage: I, 0.0%; II, 0.06%; III, 0.07%; IV, 4.07%, $p < 0.001$). Pretreatment levels correlated significantly with tumor size ($r = 0.372$, $p < 0.001$). Post-treatment blood was collected a median 2.4mo (IQR 1.7-3.9) after therapy completion. Positivity decreased after completing treatment (Table), with 88.4% of cases (46/52) becoming ctDNA negative. All cases with complete treatment had a reduction in biomarker levels, whereas in those with incomplete therapy, 54.5% (12/22) remained positive and the pre- and post-treatment levels were not significantly different. Of those positive after treatment, 13 had a further blood sample: 8 had become ctDNA negative and all but one remained disease free. Five remained positive and all had further suspected or confirmed disease. **Conclusions:** Levels of methylated *BCAT1* and *IKZF1* DNA in blood correlated with tumor burden; levels became undetectable in the majority of patients following completion of planned curative intent treatment. The methylated ctDNA blood test aids monitoring of responses to therapy and identification of those cases with residual cancer who might benefit from ongoing therapy. Research Sponsor: Clinical Genomics, NHMRC Australia.

	Post-treatment results	
Treatment	**No. positive (%)**	**No. that decreased in ctDNA level (%)**
Surgery (n = 31)	3/31 (9.7%)	31/31 (100%)
Surgery and complete adjuvant chemotherapy (n = 15)	3/15 (20.0%)	15/15 (100%)
Total neoadjuvant radiotherapy, plus surgery (+/- complete adjuvant chemotherapy) (n = 6)	1/6 (16.7%)	6/6 (100%)
Surgery, but incomplete or no adjuvant chemotherapy (n = 22)	12/22 (54.5%)	18/22 (81.8%)

Profiling plasma angiogenesis factors after use of biologics in metastatic colorectal cancer (mCRC): Update results from GI-SCREEN CRC Ukit study. *First Author: Yu Sunakawa, Department of Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: No predictive biomarkers have been validated to determine which patients (pts) with metastatic colorectal cancer (mCRC) benefit the most from angiogenesis inhibitors. Recent studies suggest that plasma angiogenesis factors and their dynamics may have some prognostic or predictive value. **Methods:** In this prospective longitudinal study, serial plasma sample collections were done at the time points of pre- and post-treatments in mCRC pts receiving biologics in either first- or second-line chemotherapy (chemo). Comprehensive measurements of 17 factors were performed by the multiplex assay with Luminex technology. Statistical analyses were conducted by using the Brunner-Munzel and Jonckheere-Terpstra test. **Results:** From Sep 2017 to Dec 2020, 789 plasma samples were collected from 498 enrolled pts [first-line chemo plus bevacizumab (BEV, n=102), first-line chemo plus anti-EGFR antibody (aEGFR, n=100), second-line chemo plus BEV (n=100), second-line FOLFIRI plus ramucirumab (RAM, n=99), second-line FOLFIRI plus aflibercept (AFL, n=85) and other treatment (n=7)]. 789 samples were evaluable for this analysis. In the analysis of first-line, level of VEGF-D was significantly higher in both post-BEV and post-aEGFR comparing with pre-first-line [pre-first-line; 264 pg/ml, post-first-line BEV; 354 pg/ml ($p<0.001$), post-first-line aEGFR; 380.5 pg/ml ($p<0.001$)], while PlGF was significantly higher only in post-BEV [pre-first-line; 6.7 pg/ml, post-first-line BEV; 23.4 pg/ml ($p<0.001$), post-first-line EGFR; 7.4 pg/ml ($p=0.650$)]. These dynamics were also observed in pts with paired samples (Table). In pts with paired samples who received second-line treatment, level of VEGF-A was significantly decreased in post-BEV, while it significantly increased in post-RAM and AFL. A significant elevation of VEGF-D level was observed in only post-RAM. PlGF level significantly increased in post all second-line angiogenesis inhibitors. In the distribution analysis of angiogenesis factors, there were no or weak correlations between VEGF-D and PlGF at the time points of all post-treatments ($r = 0.09$-0.26). **Conclusions:** Plasma levels of VEGF-D, VEGF-A and PlGF were independently changed by angiogenesis inhibitors as well as anti-EGFR therapy, suggesting the possibility of usefulness for selecting better biologics by measuring baseline angiogenesis-related factors in first- and second-line chemo. Clinical trial information: UMIN000028616. Research Sponsor: Japan Agency for Medical Research and Development.

The role of *HPSE* in *BRAF* V600E-mutant colorectal cancer. *First Author: Mengling Liu, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: *BRAF* mutations occur in about 10% of colorectal cancer (CRC), more than 90% of which are *BRAF* V600E mutation. Patients (pts) with *BRAF* V600E mutation present poor prognosis. Complex molecular biological mechanisms in this population have not been well annotated. *HPSE* plays a multifunctional role in cell proliferation, invasion and angiogenesis in cancer. Here we identified differentially expressed genes (DEGs) between pts with and without *BRAF* V600E mutation, and then focused on the function of *HPSE,* one of top DEGs, in *BRAF* V600E-mutant CRC. **Methods:** Clinical and transcriptional data of pts with CRC from The Cancer Genome Atlas (TCGA, n = 525) database and GSE39582 dataset (n = 510) were analyzed to explore the top overlapped DEGs between *BRAF* V600E mutant and wild-type pts. Records and tumor samples of 172 pts with *BRAF* V600E-mutant CRC diagnosed at Zhongshan Hospital Fudan University between 6/2015-12/2018 were collected. The HPSE protein expression status of tumor samples was evaluated by immunohistochemistry staining. Moderate or strong staining in > 25% of tumor cells was interpreted as HPSE positive. Overall survival (OS) was analyzed using Kaplan-Meier Curves with Log-rank test and multivariable Cox regression. Next, lentiviral shRNA-based silencing of *HPSE* was performed in two *BRAF* V600E-mutant CRC cell lines (HT-29, RKO). The effect of *HPSE* on tumor growth was investigated through colony formation assays, cell cycle assays and subcutaneous xenograft models. **Results:** The top overlapped genes of the DEGs list included *HPSE, TFF2, AXIN2, MLH1, RNF43, EPM2AIP1.* Among them, *HPSE* had significantly high expression in *BRAF* V600E-mutant group. Of 172 pts with *BRAF* V600E mutation, 83 were identified as HPSE positive and 89 were negative. Two groups were generally well balanced on age ($p = 0.096$), gender ($p = 1.000$), location ($p = 0.658$), stage ($p = 0.249$) and MMR status ($p = 0.129$). HPSE positive pts had a significantly worse OS in comparison to HPSE negative pts ($p = 0.037$, median OS not reached). The multivariate analysis showed that HPSE positive was independently associated with inferior OS [HR 1.97 (95%CI: 1.02 – 3.80), $p = 0.044$). Silencing *HPSE* gene impaired colony formation activity significantly and arrested more cells in G0/G1 phase of *BRAF* V600E-mutant CRC cell lines. Tumor growth was inhibited apparently in *HPSE*-silencing xenograft models. **Conclusions:** Pts with *BRAF* V600E-mutant CRC had a high *HPSE* expression level, while HPSE protein expression was an independent prognostic factor for this population. The silencing of *HPSE* expression in *BRAF* V600E-mutant CRC cell lines inhibited cell proliferation and tumor growth in vitro and in vivo. HPSE may contribute to the poor prognosis of *BRAF* V600E-mutant CRC and might be a promising therapeutic target for this subtype of CRC. Research Sponsor: National Nature Science Foundation of China (81772511, 81602038).

The impact of colorectal cancer screening on incidence and stage IV disease in the Netherlands. *First Author: Myrtle F Krul, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Population-based screening for colorectal cancer (CRC) aims to decrease incidence and mortality due to precancerous polyp removal, early detection and early treatment of CRC. In the Netherlands, phased introduction of a biennial fecal immunochemical hemoglobin test started in 2014 for individuals aged 55-75. This evaluation of the national data focuses on the initial effect of CRC screening on incidence and stage distribution and the impact on stage IV disease. **Methods:** All CRC patients diagnosed in the Netherlands between 2009 and 2018 were selected from the Netherlands Cancer Registry (NCR). Patients were linked to the Dutch national pathology registry (PALGA) to identify screen-detected tumors. **Results:** The NCR identified 137,717 CRC patients between 2009 and 2018. The incidence within screening age (55-75 yr) of all CRC stages showed an initial peak after introduction of screening in 2014, followed by a continuous decrease for all stages. CRC incidence outside the screening age did not show these explicit changes between 2009 and 2018. In 2018, the incidence of stage IV CRC within screening age was lower than the level at the start of the screening program. Stage distribution within screening age shifted towards earlier stages in the screening period (2014-2018) compared to the period before screening (2009-2012) (stage I: 31% vs. 18%, stage II: 22% vs. 26%, stage III: 29% vs. 31%, Stage IV: 18% vs. 25%, respectively). In the period 2014-2018 and within screening age, the ratio of screen-detected and symptom-detected tumors was highest in stage I (47%:53%) and lowest in stage IV (9%:91%). Screen-detected compared to symptom-detected stage IV patients diagnosed in the period 2014-2018 and within screening age had more frequently single organ metastases (74.5% vs 57.4%, $p < 0.001$), higher resection rate of the primary tumor (57.5% vs. 41.3%; $p < 0.001$) and higher local treatment rate of metastases (40.0% vs. 23.4% $p < 0.001$). The median overall survival of screen-detected stage IV patients was significantly longer than that of symptom-detected stage IV patients (31.0 months (95% CI: 27.7 – 34.3) vs. 15.0 months (95% CI: 14.5 – 15.5), $p < 0.001$). **Conclusions:** The initial results of the introduction of CRC screening in the Netherlands showed a favorable trend on CRC incidence and stage distribution. Screen-detected patients with stage IV disease had less extensive disease, resulting in better treatment options and improved survival. Research Sponsor: None.

Resectability, conversion and resections rates, and outcomes in *RAS*&*BRAF* wildtype (wt), *RAS* mutant (mt) and *BRAF*mt metastatic colorectal cancer (mCRC) subgroups in the prospective Finnish RAXO-study. *First Author: Pia J. Osterlund, Tampere University Hospital and University of Tampere, Department of Oncology, Tampere, Finland*

Background: Outcomes of metastasectomy varies with *RAS* and *BRAF*-status, but the effect on resectability, conversion and resection rates has not been extensively studied. **Methods:** The prospective Finnish RAXO study (NCT01531621) included 1086 patients 2011-2018 (Osterlund et al TLRHE 2021, Isoniemi et al BJS 2021) of which 906 were included in this secondary endpoint analysis. Excluded had missing *KRAS*/*NRAS*/*BRAF*-V600E test, were untreatable or had an atypical *BRAF* mutation. We studied repeated centralized resectability assessment, conversion and resectability rates in mCRC, and overall survival (OS) after resection and/or local ablative therapy (LAT) and systemic therapy. **Results:** Included were 289 *RAS*&*BRAF*wt, 529 *RAS*mt (overrepresented) and 88 *BRAF*mt, with median age 65.8/66.1/66.9 years. Demographics per *RAS*&*BRAF*wt, *RAS*mt and *BRAF*mt showed significant differences in male proportion (68/61/39%), ECOG PS 2-3 groups (16/14/25%), primary tumour location (right colon 16/30/69%, left colon 47/34/17%, rectum 38/36/14%), but not for Charlson comorbidity index, BMI, resection of primary, synchronous presentation or adjuvant therapy (Bonferroni corrected Chi-square). Metastatic profile was different for liver (78/74/61% per *RAS*&*BRAF*wt, *RAS*mt and *BRAF*mt), lung (24/35/28%) and peritoneal (15/15/32%) metastases, but not for lymph nodes or other sites, nor for number of metastatic sites (1 in 53/54/52%). Upfront resectability rates were different with 32/29/15% for *RAS*&*BRAF*wt, *RAS*mt and *BRAF*mt, respectively, as were conversion rates with 16/13/7%, and resection/LAT rates with 45/37/17%, respectively. Kaplan-Meier median OS estimate in R0/1/2-resected and/or LAT group (n = 342) was 83/69/30 months for *RAS*&*BRAF*wt, *RAS*mt and *BRAF*mt groups, respectively and 5-year OS-rates 67/60/24%, with Cox HR ref/1.53 (95% CI 1.04-2.25)/3.11 (1.49-6.49). In the "systemic therapy only" (n = 564) OS was 29/21/15 months and 5-year OS-rates 11/6/2% respectively, with HR ref/1.43 (1.15-1.76)/2.34 (1.73-3.17). Resection/LAT patients had improved OS over "systemic therapy only" patients in all subgroups, HR 5.74 (3.90-8.44)/5.06 (3.92-6.55)/2.89 (1.43-5.86). **Conclusions:** There were significant differences in resectability, conversion and resection/LAT rates according to *RAS*&*BRAF*wt, *RAS*mt and *BRAF*mt status. OS was also significantly longer for *RAS*&*BRAF*wt versus either mutant. Resected/LAT had better OS than "systemic therapy alone" patients in all subgroups. Clinical trial information: NCT01531621. A model combing an immune-related genes signature and an extracellular matrix-related genes signature in predicting prognosis of left- and right-sided colon cancer. *First Author: Min-Er Zhong, Department of Colorectal Surgery, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Primary tumor sidedness has been found to be prognostic in colorectal cancer (CRC), with right-sided colon cancer (RCC) having a worse survival than left-sided tumors (LCC), even after controlling for known negative prognostic factors. Our previous proteomic study identified differences in protein profiles between LCC and RCC. Immune-related proteins were found to be up-regulated in LCC while the differentially expressed proteins in RCC were mainly enriched in extracellular matrix-related proteins. Herein we aim to construct a prognostic prediction model for LCC and RCC patients by using immune-related genes (IRGs) and extracellular matrix-related genes (ECMGs). **Methods:** A total of 1,868 CRC patients with complete follow-up data from 1 training cohort (n = 562) and 3 independent validation cohorts (n = 622, n = 403, n = 281, respectively) were enrolled in our study. Tumors located in the splenic flexure, descending colon, sigmoid colon, and rectum are defined as LCC. In contrast, tumors located in the region from the hepatic flexure to the cecum are defined as RCC. The Least Absolute Shrinkage and Selection Operator (LASSO) algorithm was used to construct the multi-gene signatures. Univariate and multivariate analyses were used to test the prognostic value of these models. **Results:** Our biomarker discovery effort identified a 9-gene IRGs signature that significantly associated with poor DFS for LCC (HR = 3.46, 95%CI = 2.38-5.01, $P < 0.001$) and a 21-gene ECMGs signature associated with prognosis for RCC (HR = 4.53, 95%CI = 2.84-7.22, $P < 0.001$). For LCC, the IRGs signature was significantly correlated with worse prognosis in three independent validation cohort (Validation-1 cohort: HR = 2.08, 95%CI = 1.41-3.09, $P < 0.001$; Validation-2 cohort: HR = 2.19, 95%CI = 1.26-3.81, P = 0.004; Validation-3 cohort: HR = 2.94, 95%CI = 1.53-5.63, $P < 0.001$). Similarly, the ECMGs signature also robustly predicted survival for RCC in three independent validation (Validation-1 cohort: HR = 1.86, 95%CI = 1.22-2.83, P = 0.003; Validation-2 cohort: HR = 1.96, 95%CI = 1.18-3.26, P = 0.008; Validation-3 cohort: HR = 2.8, 95%CI = 1.27-6.17, P = 0.007). When compared with Oncotype DX, we found IRGs achieved an improved survival correlation in LCC (C-index, validation-3 cohort: 0.75 vs 0.64) and ECMGs got a better survival correlation in RCC (C-index, validation-3 cohort: 0.74 vs 0.58). **Conclusions:** Combing a 9-gene IRGs signature for LCC and a 21-gene ECMGs signature for RCC, we established a prognostic model that can robustly stratify CRC patients into high- and low- risk groups of tumor recurrence and predict prognosis. Automated computed tomography (CT)-derived skeletal muscle mass determination as a significant prognostic factor in colorectal cancer patients using deep neural network model. *First Author: Dongjin Seo, Yonsei University College of Medicine, Seoul, South Korea*

Background: Although recent evidence suggests skeletal muscle depletion predicts the survival of patients with cancer, the retrieval and manual measurement of the computed tomography (CT) images hinder clinical application in routine clinical practice. The advent of recent deep learning applications enables highly accurate noninvasive longitudinal evaluation of skeletal muscle mass (SMM) changes. Here, we evaluated the prognostic impact of DNN-measured skeletal muscle changes in colorectal cancer (CRC) patients. **Methods:** A total of 6,196 newly diagnosed CRC patients were analyzed in the Yonsei Cancer Registry Database between Jan 1, 2010, and Sep 30, 2020. SMM is measured by the Skeletal muscle index (SMI). The formula used was: L3 skeletal muscle cross-sectional area (cm^2)/height^2 (m^2). Patients' SMI patterns were grouped by difference ratio of initial and last SMI. Patients were also classified by BMI pattern with the result of K-means clustering. Association of baseline SMI, baseline body mass index (BMI), SMI changes, BMI changes, and demographic factors with overall survival (OS) were evaluated. Univariate and multivariate analyses were conducted. Concordance (c) statistics were used to test the predictive accuracy of survival models. **Results:** Fully automated UNet architecture-based deep learning algorithms were applied for the third lumbar transverse CT detection, skeletal muscle segmentation, and skeletal muscle area quantification in CRC patients undergoing abdominal CT between at the time of diagnosis and one year after the diagnosis. Baseline BMI distribution was 28% obese, 26% overweight, 42% normal weight, and 4% underweight. Patients in all SMI categories varied widely in BMI. Changes in SMI were categorized into three groups: SMI increase (33%), steady (45%), and decrease (22%) group. Similarly, BMI changes were categorized into three groups: BMI increase (24%), BMI stable (57%), and BMI decrease (19%) group. Low baseline SMI, low baseline BMI, SMI decrease, and BMI decrease were independently prognostic of survival. Intriguingly, BMI and SMI changes had a different prognostic impact in men and women. For women, the SMI increase group (hazard ratio [HR], 0.4; 95% CI, 0.3-0.7; $P = 0.001$) was associated with longer OS, while the SMI decrease group (HR, 1.2; 95% CI, 0.6-2.2; $P = 0.619$) was not associated with shorter OS, both compared with SMI steady group. **Conclusions:** Automated CT-derived SMM depletion had a negative prognostic impact independent of BMI and age in CRC patients. A noninvasive automatic deep learning algorithm provides a unique opportunity to apply to routine clinical practice and understand how and when cachexia impacts cancer prognosis. Genetic variants involved in the cGAS-STING pathway to predict outcome in patients (pts) with metastatic colorectal cancer (mCRC): Data from FIRE-3 and TRIBE trials. *First Author: Jingyuan Wang, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: The intracellular DNA sensor stimulator of interferon genes (STING) plays a vital role in anti-tumor immune responses by recognition of self-DNA from tumors and by-products of genomic instability. Activation of STING was reported to enhance cetuximab mediated natural killer cell activation and dendritic cell maturation. Previous reports suggested that polymorphisms of cGAS-STING can affect innate immune response. Therefore, we hypothesized that genetic variants in the cGAS-STING pathway may predict first-line treatment outcome in mCRC pts treated with bevacizumab/cetuximab-based chemotherapy. **Methods:** Genomic DNA from blood samples of pts enrolled in two independent randomized trials, FIRE-3 (cetuximab arm, n = 129; bevacizumab arm, n = 107) and TRIBE (bevacizumab arm, n = 215), was genotyped through the OncoArray, a customized array manufactured by Illumina including approximately 530K SNP markers. The impact on outcome of 7 selected SNPs in 3 genes involved in the STING pathway (cGAS, STING, IFNB1) was analyzed. **Results:** In the Cetuximab cohort, pts with STING rs1131769 any T allele (N = 29) showed significantly shorter overall survival (36.3 vs 56.07 months) compared to carriers of C/C (N = 95) in both univariate (hazard ratio [HR] = 2.08; 95% confidence interval [CI]: 1.06-4.07; p = 0.003) and multivariate (HR = 2.98; 95%CI 1.35-6.6; p = 0.00848) analysis; Pts carrying IFNB1 rs1051922 any A allele (N = 68) showed significant shorter progression-free survival (10.23 vs 14.1 months) than carriers of G/G (n = 59) in both univariate (HR = 1.87; 95%CI 1.26-2.78; p = 0.00163) and multivariate (HR = 2.03; 95%CI 1.25-3.3; p = 0.004) analysis. No association were observed in the bevacizumab cohort of TRIBE and FIRE-3. **Conclusions:** Our study demonstrates for the first time that STING and IFNB1 polymorphisms could predict outcomes of Cetuximab-based treatment in mCRC patients; These finding may provide insight for the combination of STING agonist and anti-EGFR treatment in mCRC patients. Multimodal circulating tumor DNA (ctDNA) colorectal neoplasia detection assay for asymptomatic and early-stage colorectal cancer (CRC). *First Author: Jeeyun Lee, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: To improve average risk CRC screening compliance, additional options are needed, especially options that address patient and provider reported barriers such as time and convenience. LUNAR-2 is a multimodal blood-based colorectal neoplasia detection assay incorporating ctDNA assessment of somatic mutations and tumor derived methylation and fragmentomic patterns, aimed to maximize sensitivity for early stage CRC detection. We evaluated this test in a large patient cohort with newly diagnosed CRC. **Methods:** Individuals diagnosed with CRC between 2013-2016 consented to provide blood samples prior to surgical resection. Those treated with neoadjuvant chemotherapy were excluded. Isolated plasma samples (median 3mL from EDTA) from 434 individuals were analyzed with LUNAR-2 (Guardant Health, USA) and included in the analysis. Median age at CRC diagnosis was 63 years (range 28 - 89) and 41% were female. Control samples were from 271 age-matched cancer free individuals. "ctDNA detected" and "ctDNA not detected" results were generated by a model trained on a separate sample set (N=614) from both cancer free individuals and those with CRC. Calling threshold was determined based on this held-out set to target 90% specificity. ctDNA results and clinical characteristics were correlated. **Results:** Overall CRC sensitivity was 91% (393/434), with high sensitivity across all stages; 88% Stage I/II, 93% Stage III (Table). Specificity was 94% (255/271). There was no difference in sensitivity when excluding those with early (<45 years) or late (>84 years) onset CRC (90% sensitivity; 388/429; p=0.95; 88% Stage I/II, 93% Stage III). There were no differences in sensitivity for asymptomatic CRC (88%) compared to symptomatic CRC (91%; p=0.4; Table). However, higher cell-free DNA tumor fractions were observed in the symptomatic cohort. Sensitivity for detection of right-sided and left-sided CRC was similar (93% vs. 90%; p=0.5; Table). **Conclusions:** In this large early-stage CRC cohort, multimodal ctDNA assessment has high sensitivity for CRC detection with high specificity. Equivalent sensitivity in the asymptomatic cohort suggests this test will have clinically meaningful performance in an average risk screening population. A prospective registrational study is ongoing to evaluate the test in an average risk CRC screening cohort. Research Sponsor: Guardant Health.

Cohort demographics.

		Overall Cohort (N = 434)	ctDNA Detected Cohort (N = 393) (N; %)
Stage	I / II	239	211; 88%
	III	195	182; 93%
Presentation at CRC diagnosis	Asymptomatic	139	123; 88%
	Symptomatic	233	212; 91%
	Unknown	62	58; 94%
Location of Primary Tumor	Right-Sided	83	77; 93%
	Left-Sided	334	302; 90%
	Transverse	17	14; 82%

Comprehensive characterization of neurotransmitters and neuronal signaling (NT) pathway alterations in colorectal cancer (CRC). *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Aberrant NT signaling has been shown to activate uncontrolled proliferation and dissemination in several gastrointestinal cancer types. Neurotransmitters have been shown to affect endothelial cells and immune cells in the tumor microenvironment to promote tumor progression. We previously showed that single nucleotide polymorphisms in the dopamine and GABA pathways are associated with outcome in patients with metastatic CRC receiving first-line treatment. Here we further evaluated the distribution and molecular context of NT pathway alterations in CRC. **Methods:** A total of 7,595 CRC tumors tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing on DNA (Next Seq, 592 genes or NovaSeq, WES) and RNA (NovaSeq, WTS) were analyzed. ssGSEA (single-sample gene set enrichment analysis) was used to calculate pathway enrichment scores (ES) of 7 NT gene sets (GABA, nicotinic, muscarinic, dopamine (DA), reelin, glial cell line-derived neurotrophic factor and neurotrophins). X2/Fisher-Exact was used for comparison and significance was determined as p-value adjusted for multiple comparison of (q) < 0.05. **Results:** ES based on sample sites showed a substantial heterogeneity in NT enrichment. Notably, when compared to primary tumors, all 7 gene sets were significantly enriched in brain metastases (mets; ES ratio 1.14-1.55), while abdomen, liver, and peritoneal mets displayed significant decreases in most NT gene sets. DA was enriched in ovarian and lung mets (ES ratio: 1.18 and 1.09, respectively), the latter also showing increased neurotrophins ES (1.06) (all $q < 0.05$). When investigating primary tumors grouped according to overall ES by unsupervised clustering, right-sided and CMS4 CRCs were more prevalent in the high ES cluster compared to the low ES cluster (32 vs 29%, $P = 0.02$ and 46 vs 30%, $P < 0.001$, respectively). In addition, tumors in the high ES cluster showed lower prevalence of TMB-H (≥ 10mt/MB) (7 vs 10%), MSI-H (6 vs 10%) and PD-L1 (2 vs 6%), while higher CNA rates were noted in 9 genes (all $q < 0.05$). High ES tumors showed significant positive associations with microenvironment infiltration of B cells, T cells (NK, CD4+ and CD8+ T cells, but not Treg), M2 Macrophages, Myeloid Dendritic Cell, Neutrophils, and an inverse association with M1 Macrophages, regardless of MSI status ($q < 0.05$). **Conclusions:** This is the first and most extensive molecular profiling study to investigate NT signaling pathway alterations in CRC. Our data show a distinct distribution of pathway enrichment according to metastatic site, distinct molecular features in high vs low ES clusters in primary tumors (including CMS subtypes, TMB, MSI and PD-L1 rates), and differential immune cell infiltration. These findings support the role of NT signaling in the metastatic spread of CRC and modulation of tumor immune microenvironment. KMT2C as a positive predictor for treatment of immune checkpoint inhibitor and correlation with immune infiltrates in colorectal cancer (CRC). *First Author: Ling Zhang, The First Affiliated Hospital of Nanchang University, Nanchang, China*

Background: Lysine Methyltransferase 2C (KMT2C), a member of the myeloid/lymphoid or mixed-lineage leukemia (MLL) family, possesses histone methylation activity and is involved in transcriptional co-activation. Present study has shown that KMT2C is positive correlated with better efficacy of Immune checkpoint inhibitor (ICI) in NSCLC. However, the role of KMT2C in treatment of ICI on colorectal cancer (CRC) is still unknown. **Methods:** NGS (Next Generation Sequencing) was performed on 1628 CRC patients. TMB of these patients were analyzed. A public accessible cohort (Samstein2018) with data from 130 CRC patients were used to investigate the correlation between KMT2C mutation and efficacy of ICI. WES and survival data of TCGA database (1099 CRC) was used to analyze prognostic effect of KMT2C mutation. Furthermore, CIBERSORT was used to analyze the tumor-infiltrating immune cells present in COAD (colon adenocarcinoma, 404 patients) from TCGA database. **Results:** Among 1628 CRC patient, 230(14.1%) had KMT2C mutation. TMB was positive correlated with KMT2C mutation (Mut vs. WT, 30.75 vs. 7.26 mut/Mb, $p < 0.0001$). The Samstein2018 cohort showed that KMT2C mutations (15.4%, 20/130) were significantly associated with better OS (Mut vs. WT, 11.5 vs. 7.5 month, HR = 0.29; 95% CI, 0.1-0.81; P = 0.012), and a higher TMB was also observed in KMT2C-Mut group (p = 1.98e-08). In TCGA, no association between KMT2C mutation and OS was observed (P = 0.23), suggesting that was not prognostic factor. Moreover, we analyzed the relationship between KMT2C mutation and immune cell infiltration through CRC TCGA database. The results showed, in COAD, KMT2C mutation was positively correlated with the abundance of CD8+ T cells (P = 0.0014), B cells (P = 0.014), M1 macrophages (P = 0.015), neutrophil (P = 0.0019) and NK cells (P = 0.043), and negatively correlated with Treg cells (p = 0.0063). **Conclusions:** KMT2C has an impact on the immune microenvironment and may be used as a potential positive predictor for treatment of ICI on CRC patients. The role of KMT2C in immunotherapy warrant further studies. Research Sponsor: None.

Multi-omics analysis to reveal the role of gut microbiome–associated serum metabolites in the detection of colorectal cancer and adenoma. *First Author: Feng Chen, State Key Laboratory of Molecular Oncology, Department of Clinical Laboratory, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Gut microbiome and their metabolites have been revealed to be associated with the initiation and progression of colorectal cancer (CRC), and gut microbiome produced or associated metabolites could enter the circulation system. **Methods:** Integrated analysis of untargeted serum metabolomics by liquid chromatography–mass spectrometry (LS-MS) and metagenome sequencing of fecal samples derived from matched individuals were used to profile serum metabolites that are both significantly affected by CRC and co-related with the gut microbiome. Targeted LC-MS was further used to test the ability of these metabolites for discriminating CRC and adenoma from healthy individuals. **Results:** More than 300 gut microbiome–associated serum metabolites with significantly altered abundance in both colorectal carcinoma (CRC) and adenoma patients have been identified. A panel of eight gut microbiome–associated serum metabolites (GMSM panel) was established and accurately discriminated CRC and adenoma from normal population. The GMSM panel–based CRC and colorectal adenoma prediction model yielded an area under the curve (AUC) of 0.94 (95% confidence interval: 0.90–0.99) and AUC of 0.91 (sensitivity 82%, specificity 91%) in the training and validation set respectively. This GMSM model shows significantly superior performance to the clinical marker carcinoembryonic antigen (CEA) (AUC 0.72), and more importantly, it suggests promising diagnostic potential in detecting adenoma (AUC = 0.81) and early-stage CRC (AUC = 0.91). **Conclusions:** Our results indicate that gut microbiome reprogramming in CRC patients is associated with the alterations of the serum metabolome, and these gut microbiome–associated serum metabolites has potential application for the detection of earlier CRC and adenoma. Serial circulating tumor DNA analysis to assess recurrence risk, benefit of adjuvant therapy, growth rate and early relapse detection in stage III colorectal cancer patients. *First Author: Tenna V Vesterman Henriksen, Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark*

Background: Challenges in the postoperative management of stage III colorectal cancer include: 1) selection of high-risk patients for adjuvant chemotherapy (ACT), 2) lack of markers to assess ACT efficacy, 3) assessment of recurrence risk after ACT, and 4) lack of markers to guide treatment decisions for high-risk patients e.g. additional therapy or intensified surveillance. Circulating tumor DNA (ctDNA) is a promising marker with potential to mitigate the challenges. Here we used serial ctDNA measurements to assess the correlation between recurrence and ctDNA detection: postoperative, during and after ACT, and during surveillance; and to assess growth rates of metachronous metastases. Uniquely, we also used concurrent CT scans and ctDNA measurements to compare the sensitivity for detecting recurrence. **Methods:** Stage III CRC patients treated with curative intent at Danish and Spanish hospitals in 2014-2019 were recruited (n = 166). Blood samples (n = 1227) were collected prior to and immediately after surgery, and every third month for up to 36 months. Per patient 16 personal mutations were used to quantify plasma ctDNA (Signatera, bespoke mPCR NGS assay). **Results:** Detection of ctDNA was a strong recurrence predictor, both postoperatively (HR 7.2, 95% CI 3.8-13.8, $P< 0.001$), directly after ACT (HR = 18.2, 95% CI 7.1-46, $P < 0.001$), and when measured serially after end of treatment (HR = 41, 95% CI 16-100, $P < 0.001$). The recurrence rate of postoperative ctDNA positive patients treated with ACT was 80% (16/20). Patients who stayed ctDNA positive during ACT all recurred. Serial post-treatment ctDNA measurements revealed exponential growth for all recurrence patients following either a SLOW (26%-increase/month) or a FAST (126%-increase/month) pattern ($P < 0.001$). From ctDNA detection to radiologic recurrence, ctDNA levels of FAST patients increased by a median 117-fold, and up to 554-fold. The 3-year overall survival was 43% for FAST patients and 100% for SLOW and non-recurrence patients (HR = 41.3, 95% CI 7.5-228, $P < 0.001$). Coinciding CT scans and ctDNA measurements (n = 113 patients, 235 coinciding events, median 2 per patient) showed a high agreement (92%) and ctDNA either detected residual disease before the CT scan (n = 7 patients) or at the same time (n = 14 patients). The median lead-time was 7.5 months. **Conclusions:** The study confirmed the prognostic power of serial postoperative ctDNA analysis. Moreover, it provided novel analyses demonstrating that ctDNA is more sensitive for recurrence detection than CT scans and can be used for tumor growth rate assessments. The difference between FAST and SLOW growing tumors suggest that growth rates could guide whom to start on systemic therapy rapidly and whom to send for diagnostic imaging. Altogether, the study highlights many potential utilities of ctDNA in guiding clinical decision-making. Research Sponsor: Danish Cancer Society, Other Foundation, Pharmaceutical/Biotech Company.

The effect of primary tumor location on second- or later-line treatment with anti-EGFR antibodies in patients with metastatic colorectal cancer: A single-center cohort study. *First Author: Anita Archwamety, Division of Medical Oncology, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand*

Background: The guideline recommends anti-EGFR monoclonal antibodies (anti-EGFR Ab) as first-line treatment only for patients with left-sided *RAS* wild type *(RASwt*) metastatic colorectal cancer (mCRC). However, there are no recommendations on tumor sidedness in subsequent lines. This study aimed to evaluate the effect of primary tumor location on second- or later-line treatment outcomes in patients with *KRASwt* mCRC. **Methods:** Medical records of patients diagnosed with mCRC at Siriraj Hospital between 2008 and 2019 were retrospectively reviewed. Patients with *KRAS*wt who received anti-EGFR Ab in second- or later-line treatment were included. The impact of tumor sidedness on progression-free survival (PFS) was determined using the Kaplan-Meier method and compared using the log-rank test. **Results:** Of 671 patients who had data on *KRAS* analysis, 396 patients (59%) had *KRASwt*. Of these, 210 patients received anti-EGFR Ab in second- or later-line treatment. Twenty-nine percent of patients (60 out of 210) had extended *RAS* analysis. Thirty patients (14%) had right-sided tumors, while 180 patients (86%) had left-sided tumors. Sixty-nine percent of patients (146 of 210) were treated in the third line, while 19% and 12% were treated in the second and the fourth line, respectively. Single-agent irinotecan was the most commonly used chemotherapy backbone (92%). Patients with right-sided tumors had non-significantly inferior PFS compared with patients with left-sided tumors (median PFS was 4.7 months, 95% CI 0.8–8.7 vs. 6 months, 95% CI 4.6–7.3; p = 0.55). Subgroup analysis on the impact of primary tumor location showed no difference in PFS when stratified by treatment lines. **Conclusions:** This study demonstrated that tumor sidedness has no impact on treatment outcomes in patients treated with anti-EGFR Ab in second- or later-line treatment. Therefore, there is not enough evidence to use tumor sidedness for treatment selection in these settings. A multi-center retrospective study is ongoing. Research Sponsor: None.

3542 **Poster Session**

Multi-omics characterization of left-right colorectal cancer. *First Author: John Marshall, Georgetown University, Washington, DC*

Background: Right (R) vs left (L) sided colorectal cancers are clinically distinguishable based on prognosis and response to certain therapies, but as of yet, limited data have emerged to explain these differences. The science of molecular testing has evolved rapidly. Enabled by improved technologies and computing power, it is now feasible to obtain to systematic multi-omic datasets covering DNA, RNA, proteins, phospho-proteins and metabolomics on large numbers of patients. Multi-omic analysis can further define disease specific subgroups but pre-analytic quality of the tissues (ischemia time) and comparison to normal tissue controls is paramount to optimize results. **Methods:** Following informed consent, 450 colorectal cancer primary tumors and paired normal tissues were collected following an SOP to minimize ischemia time, and were analyzed using comprehensive genomics, transcriptomics, proteomics, phosphoproteomics, morphology and annual clinical information. Right (C18.0,2,3) and left (C18.6,7) CRC tumors, normal tissue were compared using machine learning tools to unravel the molecular mechanisms that underpin these clinically distinguishable phenotypes as well as correlating with known genomic metrics such MSI and KRAS mutation status. **Results:** Through leveraging the tumor and paired normal patient samples, systematic differences between left and right tumor samples were observed including specific molecular events associated with these anatomical differences. The detailed results will be presented at the meeting. **Conclusions:** Progress in precision medicine requires the inclusion of multi-omics which in turn requires changes to our current SOPs of tissue collection. The ability to define molecular distinctions such as between R and L colon cancer will permit the rapid discovery of clinically useful prognostic and predictive markers, dramatically adding to our fundamental understanding to colon cancer biology. Future work will focus on the discovery of novel targets and signatures, creating innovative tools that depict multi-omic results for clinicians. Research Sponsor: Indivumed GmbH.

Genome-wide analysis indicating cancer associated fibroblast (CAF) impacts on colorectal cancer (CRC) prognosis via immunosuppression. *First Author: Yu-feng Chen, Department of Colorectal Surgery, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Cancer associated fibroblast (CAF) in tumor microenvironment is associated with poor prognosis and chemo-resistance in multiple solid tumors, however, there is lack of universal measure of CAF in colorectal cancer (CRC). The aim of this study was to assess fibroblast-signature for predicting outcome and analyze relevant mechanism. **Methods:** A dataset including 316 CRC patients without adjuvant chemotherapy was used as the discovery cohort for the identification of prognostic fibroblast-related genes (FRGs). A total of 1,352 CRC patients were then divided into one training cohort (n = 461) and two validation cohorts (n = 338, n = 553, respectively) for the construction of fibroblast-related gene signature (FRGS) and the verification of its prognostic value in stage II/III CRC patients. Functional annotation and analysis were performed to reveal the relevant mechanism. **Results:** A 11-gene signature was derived, which was prognostic for stage II/III CRC patients in two validation cohort (Validation-1 cohort: HR = 1.90, 95%CI = 1.16-3.12, $P< 0.01$; Validation-2 cohort: HR = 1.95, 95%CI = 1.39-2.73, $P< 0.001$). High CAF risk was correlated with worse prognosis in CRC patients without adjuvant chemotherapy (HR = 3.63, 95%CI = 2.24-5.88, $P< 0.001$), but not in patients who received adjuvant chemotherapy ($P= 0.154$). Similar trends were found in Validation-1 cohort. After integrated with clinical characteristics, FRGS was confirmed as an independent prognostic factor after adjusted for TNM stage of tumor in multivariate analysis (Training cohort: HR = 3.19, 95%CI = 1.88-5.41, $P< 0.001$; Validation-1 cohort: HR = 5.00, 95%CI = 1.58-15.85, $P= 0.007$; Validation-2 cohort: HR = 2.99, 95%CI = 1.44-6.21, $P= 0.003$). Furthermore, enrichment analysis found that anti-tumor immune response was suppressed in the high CAF risk group. **Conclusions:** The 11-gene FRGS had independent prognostic value for CRC patients, as well as in prediction of benefit from chemotherapy. CAF in tumor microenvironment might impact on the prognosis of CRC patients via inhibiting immune response. Research Sponsor: National Natural Science Foundation of China (NSFC) (No. 82003197).

***NTRK* fusion positive colorectal cancer as a unique subset of CRC with high tumor mutation burden and microsatellite instability.** *First Author: Hui WANG, Department of Medical Oncology, Beijing Hospital, National Center of Gerontology; Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Beijing, China*

Background: Neurotrophin receptor tyrosine kinase (*NTRK*) gene fusions are rare but actionable oncogenic drivers that are present in a wide variety of solid tumors. This study aims to identify the frequency and the clinicopathologic and genetic features of *NTRK*-driven colorectal cancers (CRC). **Methods:** Colonic and rectal tumor DNA specimen from colorectal cancer patients submitted for molecular profiling at a CLIA-certified genomics laboratory in China that performed *NTRK1/2/3* fusion detection by hybridization-based targeted next generation sequencing (NGS) were retrospectively reviewed. Patients' demographic, clinical characteristics, and treatment history were retrieved from the database for further evaluation. **Results:** A total of 2,519 unique Chinese colorectal cancer cases were profiled from April 2016 to May 2020, and 17 *NTRK+* fusion events were identified (0.7%, 17/2,519) consisting of 14 cases of *NTRK1+* and 3 cases of *NTRK3+* fusions. Furthermore, thirteen out of 17 *NTRK+* CRC tumors (76%) were microsatellite instability-high (MSI-H) tumors, a much higher rate than that of the molecularly unselected CRC population (8%) or *NTRK+* non-CRC tumors ($<$ 1%). *NTRK+* CRC patients also had increased tumor mutation burden (median TMB = 65 mut/MB) compared to that of non-*NTRK+* CRC (median TMB = 7.7 mut/MB) or *NTRK+* non-CRC tumors (median TMB = 4 mut/MB). *POLE/POLD1* mutations were also enriched in *NTRK+* CRC (8/17, 47%) relative to molecularly unstratified CRC patients (8%) with over half carrying concurrent *POLE* and *POLD1* mutations. *TPM3* was the most common fusion partner of *NTRK1* (78%, *N* = 14), followed by *LMNA* and *TRP*. Three *NTRK3+* CRC were identified *(ETV6-NTRK3, RUNX1-NTRK3, CSNK1G1-NTRK3). RNF43* (71%) was the most frequently mutated gene and the aberrations of *RNF43* and *ARID1* were significantly enriched in MSI-positive *NTRK+* tumors as compared to the MSS *NTRK+* subgroup. *TP53* (53%) and *APC* (35%) aberrations frequently co-occurred with *NTRK* fusions, whereas the majority of the *NTRK+* cohort were *RAS/BRAFwild-type*, except in one case that an oncogenic *KRAS* Q61R variant co-occurred with *RUNX1-NTRK3*. **Conclusions:** *NTRK+* colorectal cancer is rare. In addition to the absence of canonical driver mutations, *NTRK+* tumors demonstrated increased tumor mutation burden, higher frequency of microsatellite instability, and an enrichment of *POLE/POLD1* mutations relative to molecularly unselected CRC population. Research Sponsor: None.

A panel of DNA methylation markers for the classification of consensus molecular subtypes 2 and 3 in patients with colorectal cancer. *First Author: Inge van Den Berg, Erasmus MC, Rotterdam, Netherlands*

Background: Consensus molecular subtypes (CMSs) can guide precision treatment of colorectal cancer (CRC). Currently available assays can identify CMS1 and CMS4 cases well, while a dedicated test to distinguish CMS2 and 3 is lacking. This study aimed to identify a panel of methylation markers to distinguish between CMS2 and 3 in patients with CRC. **Methods:** Fresh-frozen tumor tissue of 239 patients with stage I-III CRC was included. CMS classification was performed on RNA-seq data using the single-sample-prediction parameter from the "CMSclassifier" package. Methylation profiles were obtained using the Infinium HumanMethylation450 BeadChip. We performed adaptive group-regularised logistic ridge-regression with post-hoc group-weighted elastic net marker selection to build prediction models for classification of CMS2 and CMS3 based on 15, 10 or 5 markers. Data from TCGAwas used for validation. **Results:** Overall methylation profiles differed between CMS2 and CMS3. Group-regularisation of the probes was done based on their location either relative to a CpG island or relative to a gene present in the CMS classifier resulting in two different prediction models and subsequently different marker panels. For both panels, even when using only 5 markers, sensitivity, specificity, and accuracy were $>$ 90%. Validation showed comparable performances. **Conclusions:** Our highly sensitive and specific methylation marker panel can be used to distinguish CMS2 and 3. This enables development of a qPCR DNA methylation assay in patients with CRC to provide a specific and non-invasive classification tool. Research Sponsor: None.

Clinical performance of methylation-based liquid biopsy test COLVERA after optimization of test interpretation rules. *First Author: Zivjena Vucetic, Clinical Genomics, Bridgewater, NJ*

Background: Clinical guidelines recommend surveillance for patients who complete primary treatment for colorectal cancer (CRC) with the aim of detecting recurrence when amenable to curative intent treatment. Currently recommended surveillance protocols, including imaging and CEA have limitations both in sensitivity and specificity, thus novel methods that detect circulating tumor DNA (ctDNA) have been introduced into clinical practice. COLVERA is a laboratory-developed, real-time PCR test that detects DNA methylation of BCAT1 and IKZF1 genes. These two genes are hypermethylated in 95% of CRC tissue and COLVERA showed improved sensitivity for detection of recurrent disease in comparison to CEA in several clinical populations. The current study evaluated the impact of optimizing the assay's qualitative reporting method on actionability and clinical performance for recurrence detection in CRC surveillance setting. **Methods:** Two previously described cohorts of CRC patients (N=322 and N=144) who completed primary treatment and were undergoing surveillance were evaluated. Imaging and blood collections were performed at, or adjacent to, a standard of care visit. cfDNA was extracted from whole blood, bisulphite-treated and assayed in triplicates for BCAT1/IKZF methylation. Previously, any positive replicate of either target gene was reported as COLVERA "detected". In the current study, COLVERA is "detected" when at least one replicate of IKZF1 or multiple replicates of either IKZF1 and/or BCAT1 are present. Sensitivity, specificity, and diagnostic odds ratio (DOR) for CRC recurrence detection from a single time-point blood sample was determined using radiological imaging as clinical reference standard. **Results:** In the first cohort (N=322), overall COLVERA test positivity was 6.5% (21/322) with a sensitivity of 59.3% (95% CI: 38.8 - 77.6) and specificity of 98.3% (96.1 - 99.5) for detecting recurrence at a time-point adjacent to imaging, representing improved specificity, from 91.5% (87.7 - 94.4%), with minimal decrease in sensitivity, from 63.0% (42.4 – 80.6). Similarly, in the second cohort (N=144) sensitivity was 62% (47.2 -75.4), compared to 66.0% (57.1 – 69.3) under the prior interpretation method, while specificity was 92.6% (85.3-97), compared to 90.4% (84.7 - 94.7). A high DOR of 84 (26 - 272) (previously 18 (7.6 – 44.4)) indicates that the revised COLVERA interpretation method is clinically more informative and differentiates with greater accuracy patients with and without the disease. **Conclusions:** This change in the COLVERA interpretation rule resulted in optimized clinical specificity with minimal impact on sensitivity. For an assay intended to aid in surveillance and early recurrence detection, improved accuracy allows the physician to have increased confidence in making actionable decisions based on test result, including further imaging or treatment. Effect of Medicaid expansion on incidence of early-onset colorectal cancer incidence among Hispanics. *First Author: Shafia Rahman, Albert Einstein College of Medicine/Montefiore Medical Center, New York, NY*

Background: Early onset colorectal cancer (EO-CRC, age $<$ 50 years) is an emerging public health crisis; especially in Hispanics. Access to healthcare is critical for timely detection and is tied to medical insurance. In 2010, the Affordable Care Act allowed for expansion of Medicaid eligibility across the country, however, states were permitted to opt out by the US Supreme Court ruling of 2012, which created an unintended experiment in the healthcare market. We evaluated the effects of Medicaid expansion on the incidence of EO-CRC among Hispanics with the hypothesis that it would lead to an increase in incidence and early detection EO-CRC. **Methods:** The National Cancer Data Base was used to collect data on newly diagnosed Hispanics with EO-CRC (40-49 years), across all stages, from 2010-2017. Data for 21 expansion states (ES) that expanded Medicaid in 2014, and 16 non expansion (NES) states was analyzed. The yearly state-wise Hispanic population was collected from U.S Census Bureau for 2010-17. Incidence was computed as number of new cases of CRC divided by size of the state's Hispanic population. Segmented Poisson generalized linear mixed effects model was used to analyze rate of change in yearly incidence of EOCRC before and after 2014, in ES and NES. **Results:** Average annual incidence (AI) of EO-CRC in Hispanics was 6/100,000 and 8/100,000 pre and post expansion, in ES, and 8/100,000 and 9/100,000 pre and post 2014 in the NES, respectively. Increase in AI of EO-CRC was 3.6% per year (2010-14) (95% CI: -0.1% to 7.4%), and 9.8% (2014-17) (95% CI: 5.2% to 14.7%) for ES states; and 6.4% (2010-14) (95% CI: 2.1% to 10.8%), and 1% (2014-17) (95% CI: -3.8% to 6.1%) in NES. ES showed greater change in EO-CRC incidence post expansion (2014) vs. pre-expansion, as compared to NES (p=0.078) table. There was no difference in stage at diagnosis between pre- and pos- expansion periods between ES and NES. **Conclusions:** Increase in incidence of EO-CRC in ES is likely due to greater access to health care due to Medicaid coverage as compared to NES. Other potential factor is migration of Medicaid eligible persons from NES to ES. However we need data past 2017 to confirm the current trend. Research Sponsor: None.

Rate of change in yearly incidence of early onset colorectal cancer.

	Pre- 2014	Post 2014	p=0.078
Non-expansion states	6.4% per year (95% CI: 2.1% to 10.8%)	1% per year (95% CI: -3.8% to 6.1%)	
Expansion states	3.6% per year (95% CI: -0.1% to 7.4%)	9.8% per year (95% CI: 5.2% to 14.7%)

PMC: A more precise classifier of POLE mutations to identify candidates for immune therapy. *First Author: Fadl Zeineddine, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Specific somatic mutations in DNA polymerase epsilon (*POLE*) can cause a hypermutant phenotype with tumor mutation burden (TMB) in excess of 100 mutations per megabase. It has been reported that *POLE* mutant tumors are enriched in response to immune therapy and this association is being tested in multiple active clinical trials. However, most *POLE* mutations are passenger mutations and have no pathogenic role. Current methods to classify *POLE* mutations are limited in both accuracy and completeness, which could lead to inappropriate use of immune agents in tumor such as MSS CRC, where response rate is 5% or less. Here we present a new classifier, *POLE* Mutation Classifier or PMC, based on the unique trinucleotide mutation signature caused by selective loss of the proofreading function (LOP) of POLE. **Methods:** cBioPortal was queried to identify all tumors with *POLE* mutation. TMB was calculated for each, additionally, trinucleotide mutation signatures were obtained for all *POLE* mutant tumors in TCGA. Using OncoKB to identify a gold standard of 12 functional *POLE* mutations (n = 98 tumors) a *POLE* mutational signature was created. A combination of mutational signature, amino acid location, and TMB was used to classify each POLE variant. **Results:** Among all 48035 unique tumors the overall frequency of *POLE* mutations was 2.5% (n = 1184), however only 9.2% (n = 110) were determined to cause the selective LOP. The incidence of LOP *POLE* mutation was highest in uterine carcinoma and CRC, these tumors also had the highest ratio of LOP to passenger mutations. In a pan-cancer analysis the overall survival of LOP *POLE* patients was significantly better than those with passenger mutations (not-yet-reached vs. 51 mo, HR = 4.4, $p < 0.0001$). A similar analysis performed using the polyphen-2 classifier to identify functional *POLE* mutations did not show a difference in overall survival (HR = 1.0, p-value = 0.57). To further validate the improved specificity of the PMC classifier TMB was used as a surrogate marker, using the PMC classifier 98% of tumors with LOP showed hypermutation (TMB $>$ 20mut/Mb), vs. 53% called functional by polyphen-2. A retrospective analysis of MD Anderson CRC patients identified 25 patients with LOP *POLE* mutation, who had improved OS relative to 267 CRC patients with passenger *POLE* mutation (not-yet-reached vs. 70 mo, HR:4.2, p = 0.028). Four metastatic CRC patients with LOP *POLE* mutation were treated with immune therapy (nivolumab, or ipilimumab/nivolumab) in 2nd or 3rd line, all four achieved objective response and remain on therapy (mean time on treatment 15 mo). **Conclusions:** The PMC classifier specifically identifies mutations in *POLE* that cause loss of the proofreading function, outperforming both manually curated databases and machine learning-based methods. Clinical trials that use *POLE* mutation as a selection criteria for immune therapy should be restricted to just those *POLE* mutations that cause LOP. Are current family-history based colorectal cancer screening guidelines adequate for early detection and potential prevention of young-onset cases? *First Author: Y. Nancy You, Department of Colon and Rectal Surgery, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Strategies to detect and prevent young-onset colorectal cancer (YOCRC, diagnosed under age 50) are critical. Established high-risk screening guidelines (SGs) aim to detect/prevent YOCRCs arising from hereditary syndromes. For non-hereditary YOCRCs, average-risk screening is being considered at an earlier age, but family history (FH)-based increased-risk screening has been poorly studied. We aimed to define the proportion of non-hereditary YOCRC with a FH, and to determine whether existing SGs could have detected/prevented these cases. **Methods:** 394 consecutive YOCRC patients presenting for surgical resection were reviewed for tumor MMR status, pedigree and genetic testing. Those with known/suspected hereditary syndrome (by phenotype, MMR status, and/or germline mutation) were excluded (N = 65). Pedigrees (N = 329) were analyzed for first- or second-degree relatives (FDR, SDR) with CRC and the ages of diagnosis. The gap between the recommended age for FH-based CRC screening and the age of YOCRC diagnosis was calculated. **Results:** 89 (27%) non-hereditary YOCRC patients had a FH of CRC. The median age of diagnosis was 45; the tumors were mostly from the distal colon (22%) and rectum (60%), and stage III (48%) and IV (27%). Twenty-one (24%) patients had 22 FDRs with CRCs diagnosed at age 64 (median); and 71 (80%) patients had 92 SDRs with CRCs diagnosed at age 65 (median). Thirteen (15%) had a FH of YOCRC. The existing SGs consider 39 patients (44%) at increased-risk, and the remaining, average-risk (Table). Screening would have begun prior to the YOCRC diagnoses in 28 (31% [or 46, 52%]) patients. But YOCRC diagnosis preceded the recommended screening age in the remaining 61(69% [or 43, 48%]) patients by a median of 5.3 [or 3.9] years (Table). **Conclusions:** FH is found in 27% of the non-hereditary YOCRC patients; 15% has a FH of YOCRC. In nearly half of the patients, YOCRC was diagnosed several years earlier than the recommended age for FH-based screening, even assuming perfect SG adoption and starting average risk screening at age 45. Refining existing FH-based SGs can potentially be impactful. Research Sponsor: University of MD Anderson Cancer Center Clinical Innovator Award.

A nationwide analysis of outcomes and healthcare utilization in HIV versus non-HIV patients with colon cancer. *First Author: Syed Ali Amir Sherazi, Department of Internal Medicine, John H. Stroger Jr. Hospital of Cook County, Chicago, IL*

Background: The incidence and mortality of Colon cancer (CC) is reportedly similar in HIV and non-HIV populations with same screening guidelines. The pathogenesis of HIV-CC may be multifactorial; related to chronic inflammation from AIDS colopathy, 2-fold increase in risk of polyps, smoking, elevation in proinflammatory cytokines, decrease in adiponectin, activation of b-catenin signaling pathway all of which may promote neoplastic growth of colonic mucosa. With increasing survival in HIV due to effective antiretroviral therapy, non-AIDS defining cancers are rising as population ages. We attempted to compare demographics and outcomes of HIV and non-HIV-CC patients in a national database. **Methods:** Healthcare Cost and Utilization Project (HCUP) National Inpatient Sample (NIS) was queried to identify all HIV and non-HIV-CC admissions. The groups were compared for socio-demographic differences, medical comorbidities, inpatient mortality, length of stay (LOS) and hospital charges (THC). Secondary outcomes studied included rates of sepsis, septic shock (SS), Anemia, transfusions, GI bleeding, colostomy rates, Acute Kidney Injury (AKI) and protein energy malnutrition (PEM). Statistics were performed using t-test, univariate and multinomial logistic regression. **Results:** A total 895 HIV-CC and 514,840 non-HIV-CC admissions were identified. HIV-CC were younger (mean age 56.3 vs 67.3 years, $p < 0.001$) with 76% $<$ 65 years old compared to 40% in non-HIV-CC. HIV-CC were more likely male (75.4% vs 50.5%, $p < 0.001$), African Americans (AA) (43% vs 14%, $p < 0.001$) and Hispanic (19% vs 9%, $p < 0.001$), were more likely from lowest income quartile zip codes (44% vs 28%, $p < 0.001$) from the Northeast region of US (27% vs 19%, $p < 0.001$) and on Medicaid (30% vs 10%, $p < 0.001$). HIV-CC had significantly lower rates of medical comorbidities (hypertension, diabetes, obesity, dyslipidemia, heart failure, all $p < 0.05$) compared to non-HIV-CC. The odds of adjusted inpatient mortality were significantly lower in HIV-CC (aOR = 0.46 CI = 0.24-0.87, p = 0.018), however HIV-CC had longer mean LOS (8.17 vs 6.66 days, $p < 0.01$) and higher mean THC ($88,305 vs $76,317, p = 0.051). Cancer pain and PEM were significantly higher in the HIV-CC group, but other secondary outcomes were similar. **Conclusions:** HIV-CC patients were significantly younger and minorities with significantly lower all-cause mortality compared to non-HIV-CC. The lower mortality may be explained by younger age, treatment of teaching hospitals for HIV-CC and lower incidence of medical comorbidities which may be driving mortality higher in non-HIV-CC. However, healthcare utilization of HIV-CC was higher with over $10 million in extra charges in 3 years compared to non-HIV-CC. The young age of HIV-CC compared to non-HIV suggests a need for studies to evaluate the role of starting colon-cancer screening at a younger age in the HIV population. Research Sponsor: None.

Investigating intra-tumor microbes, blood microbes, and CEA for development of non-invasive biomarkers in colorectal cancer. *First Author: Pannaga G. Malalur, The Ohio State University/Wexner Medical Center, Columbus, OH*

Background: The development of non-invasive biomarkers has the potential to revolutionize clinical care for colorectal cancer (CRC) patients. The presence of bacteria in CRC tumor biopsies has been shown to contribute to CRC development. In a previous study, our group showed some intra-tumor microbes in CRC tumor biopsies correlated with overall survival in CRC patients. However, the correlations between microbes in tumor vs blood, and between non-invasive serum marker carcinoembryonic antigen (CEA) and microbes are unknown. We hypothesize that tumor microbes will also be found in blood, and that CEA will correlate with certain microbes. **Methods:** We obtained RNA-seq data from CRC tumor biopsies from patients treated at The Ohio State University Comprehensive Cancer Center as part of the Oncology Research Information Exchange Network (ORIEN). Reads were aligned to human and exogenous genomes using TopHat2 and Kraken2/Bracken, respectively. RNA-seq from CRC tumor biopsies as well as peripheral blood at the Cancer Genome Atlas (TCGA) consortium were processed by the same method. **Results:** The analyzed ORIEN cohort included 93 CRC patients with an age range from 30-83 years, 60.2% male, 87.1% adenocarcinoma, and 47.3% with metastatic CRC. The TGCA cohort included 495 CRC patients with an age range from 31-90 years, 53.3% male, 85.1% adenocarcinoma, and 15.5% with metastatic CRC. Over fifteen exogenous phyla (including bacteria, viruses, fungi) were observed in both ORIEN and TCGA cohorts. Several of the samples were dominated by viral sequences while others by bacteria, suggesting considerable tumor microbiome heterogeneity. Evaluation of the fraction of microbes in tumor and blood showed that nearly all the microbes found in blood (97.6%) were also observable in tumor in the TCGA cohort. Microbial abundances of various taxa, including *Fusobacterium*, significantly correlated between blood and tumor. Several bacteria including members of the genera *Bacillus* and *Staphylococcus* were positively associated with tumor stage (metastatic vs non-metastatic), but microbial relative abundances were not correlated with the location of tumor in colon (right, left, transverse colon). Certain microbial species from the ORIEN cohort were found to positively correlate with CEA, (including from the genera *Fusobacterium, Lactobacillus, Pseudomonas, Vibrio, Clostridium)* and these associations remained when adjusted for alcohol and smoking by multivariate analysis. **Conclusions:** Nearly all the microbes found in blood were found in tumor and abundances of various taxa were significantly correlated, suggesting that blood-based cancer microbiome analysis has great potential. Serum CEA has a low diagnostic ability when used alone, but combining this with blood microbiome could improve diagnostic/prognostic utility as a non-invasive biomarker. Research Sponsor: Award Number UL1TR002733.

Consensus molecular subtypes and *RAS* status as biomarker of treatment intensity with fluoropyrimidine, bevacizumab, and irinotecan in metastatic colorectal cancer (XELAVIRI, AIO KRK 0110). *First Author: Arndt Stahler, Medical Department, Division of Hematology, Oncology and Tumor Immunology (CCM), Charité Universitaetsmedizin Berlin, Berlin, Germany*

Background: Prognostic biomarkers beside *RAS/BRAF* status are necessary to identify metastatic colorectal cancer (mCRC) patients who benefit from combined (COMB) versus sequential (SEQ) treatment with fluoropyrimidine, bevacizumab and irinotecan (randomized phase III XELAVIRI trial). **Methods:** mRNA was extracted from formalin-fixed paraffin embedded (FFPE) tumor tissue of 337 patients, gene expression was measured by the Nanostring PanCancer Progression Panel. Consensus molecular subtypes (CMS) classification was re-derived using a multinomial regression model. Data of Guinney et al. (Nat. Med. 2015. 21:1350-6) and FIRE-3 served as training and validation set. *RAS/BRAF* MUT were assessed by pyrosequencing. Median overall (OS) and progression free survival (PFS), hazard ratios (HR) and 95% confidence interval (CI) were estimated by Kaplan-Meier method and univariate Cox regression. **Results:** The multinomial regression model employed in the present analysis correctly predicted CMS labels in 98.3 % of the original Guinney- and 100.0 % of FIRE-3 population. In XELAVIRI, CMS subgroups were predicted as follows: CMS1: n = 62 (18.4 %); CMS2: n = 174 (51.6 %); CMS3: n = 9 (2.7 %); CMS4: n = 92 (27.3 %). A general prognostic impact of CMS was not observed when all patients were analysed. In *RAS/BRAF* WT mCRC patients, substantial benefit of COMB versus SEQ treatment was shown for OS and PFS in CMS2 and CMS4, but not in CMS1. Conversely, OS was significantly longer for COMB treatment in patients with *RAS* MUT and CMS1 mCRC, while SEQ treatment was not inferior in *RAS* MUT and CMS2 or CMS4 subgroups (see TABLE). Additional data for overall response rates, early tumor shrinkage and sidedness might be presented at the meeting. **Conclusions:** This retrospective analysis of XELAVIRI suggests that CMS may serve as biomarker that predicts response to initially combined versus less intensive sequential chemotherapy in patients with *RAS/BRAF* WT mCRC. Research Sponsor: Roche.

FOLFOX plus panitumumab or FOLFOX alone as additive therapy following R0/1 resection of RAS wild-type colorectal cancer liver metastases: The PARLIM trial (AIO KRK 0314). *First Author: Dominik Paul Modest, Department of Medicine III, University Hospital, LMU Munich, Munich, Germany*

Background: This trial investigates the addition of panitumumab to chemotherapy with fluorouracil/ folinic acid and oxaliplatin (FOLFOX) in a 2:1 randomized, controlled, open label, phase II trial in *RAS* wild-type colorectal cancer patients with R0/1-resected liver metastases. **Methods:** The primary endpoint was progression-free survival (PFS) two years after randomisation. The experimental arm (12 wks of biweekly mFOLFOX6 plus panitumumab followed by 12 wks of panitumumab alone) was considered active if the 2-year-PFS rate was ≥65%. Based on historical data, a 2-year-PFS rate of 50% was estimated in the control arm (12 wks of biweekly FOLFOX). The trial was performed with a power of 80% and an alpha of 0.05. Secondary endpoints included overall survival (OS) and toxicity. The trial is registered with ClinicalTrials.gov, NCT01384994. **Results:** The full analysis set consists of 70 patients (pts) in the experimental arm and 36 pts in the control arm. The 2-year-PFS rate was 34.3% with FOLFOX plus panitumumab and failed to meet the primary endpoint. The 2-year-PFS rate in the control arm was 25%. In the experimental arm, a more favourable outcome was observed with regard to PFS (HR: 0.72, 95%CI 0.45-1.17; P = 0.18) and OS (HR: 0.76 (95% CI 0.34-1.71, P = 0.51) which did, however, not reach the level of significance. Updated data including toxicity and subgroup analyses might be presented at the meeting **Conclusions:** The PARLIM trial clearly failed to demonstrate a PFS rate of 65% after resection of colorectal liver metastases 2 years after randomisation, potentially indicating that the generally high frequency of recurrence and the choice of primary endpoint did not correspond in this study population. However, a trend for improved PFS and OS by the addition of panitumumab to 12 wks of FOLFOX followed by 12 wks panitumumab maintenance therapy may support future trials with ant-EGFR antibodies in this specific treatment setting. Clinical trial information: NCT01384994. Research Sponsor: AMGEN, University of Munich (LMU).

Impact of a metastatic site on circulating tumor DNA (ctDNA) analysis in patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Hideaki Bando, Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: ctDNA genotyping has been used as an alternative to tissue genotyping for precision oncology. In mCRC, although low plasma *RAS* variant allelic frequencies (VAFs) and low concordance with tissue *RAS* tests have been reported in pts with lung-only metastasis (mets) (Kagawa Y. et al., Clin Cancer Res 2021), the association of ctDNA identified using the next-generation sequencing method with metastatic sites is still unknown. **Methods:** We investigated the association between metastatic site and ctDNA detection by using the Guardant360 (G360), a ctDNA assay which detects 74 gene alterations including mutations with the 95% of limit of detection of 0.2%, in mCRC pts with single organ mets in pts who had not received anti-EGFR therapy in the SCRUM-Japan GOZILA study. We also evaluated the correlations between the size/number of mets by CT and detected VAFs. **Results:** Of 1187 mCRC pts enrolled in GOZILA, 138 pts (49 with liver-only, 15 with lymph node-only, 27 with peritoneum-only, and 47 with lung-only mets) were eligible for this study. The concordance of *RAS*/*BRAF* status between G360 and tissue in-vitro diagnostic tests were 93.9% in liver-only, 80.0% in lymph node-only, 56.0% in peritoneum-only, and 65.9% in lung-only mets. The median maximum VAF (maxVAF) corresponding to the highest ctDNA fraction and the median numbers of detected variants were 23.1% and 5 in liver-only, 6.0% and 5 in lymph node-only, 0.4% and 3 in peritoneum-only, and 0.4% and 3 in lung-only (all $P<0.001$, Kruskal-Wallis test). A few pts with liver-only (2.0%) and lymph node-only mets (13.3%) had a maxVAF of <0.2%, but maxVAF was more frequently <0.2% in pts with lung-only (27.7%) or peritoneum-only mets (29.6%), especially in those with lung-only mets <20 mm as the longest diameter and <20 lesions (69.2%) or with peritoneum-only mets <20 mm as the longest diameter (87.5%). **Conclusions:** Lung-only and peritoneum-only mets had significantly lower maxVAF and lower numbers of detected variants, suggesting lower detections of subclonal variants. To ensure the sufficient clinical performance in G360 assay, inclusion of pts with lung-only mets ≥20 mm of longest diameter and/or ≥20 lesions, and ≥20 mm of the longest diameter in pts with peritoneum-only mets may be required. Research Sponsor: None.

Pertuzumab plus trastuzumab and real-world standard of care (SOC) for patients (pts) with treatment refractory metastatic colorectal cancer (mCRC) with *HER2* (*ERBB2*) amplification (amp) confirmed by tumor tissue or ctDNA analysis (TRIUMPH, EPOC1602). *First Author: Wataru Okamoto, Cancer Treatment Center, Hiroshima University Hospital, Hiroshima, Japan*

Background: *HER2* amp occurs in 1-4% of mCRC pts. Two single arm phase 2 studies, HERACLES and MyPathway, showed efficacy for dual HER2-targeted therapy in pts with *RAS* wild type (*RAS* wt) mCRC with *HER2* amp detected in tumor tissue; however, efficacy for pts prospectively enrolled with *HER2* amp identified in ctDNA is unknown. Furthermore, the efficacy of real-world non-HER2-targeted SOC for *HER2* amplified *RAS*wt mCRC pts is not clear. **Methods:** We conducted a phase 2 trial to evaluate the efficacy of pertuzumab (P) plus trastuzumab (T) in *RAS*wt mCRC pts with *HER2* amp centrally confirmed by tissue (IHC and/or FISH) and/or ctDNA (Guardant360) who had progressed on SOC including EGFR blockade. Pts received intravenous P (840 mg loading dose followed by 420 mg) and T (8 mg/kg loading dose followed by 6 mg/kg) every 3 weeks. The primary endpoint was confirmed objective response rate (ORR) by investigator assessment, analyzed for two primary populations: pts with *HER2* amp in tissue (tissue$^+$) or in ctDNA (ctDNA$^+$). Efficacy of real-world non-HER2-targeted SOC for *HER2* amplified *RAS*wt mCRC pts was prospectively assessed in a concurrent registry: the SCRUM-Japan registry. **Results:** Among 75 pts screened, concordance of *HER2* amp between tissue and ctDNA was 83%. The primary endpoint was met in each cohort of TRIUMPH, with confirmed ORR of 30% (95% CI 14-50%) in 27 tissue$^+$ pts and 28% (12-49%) in 25 ctDNA$^+$ pts. In contrast, ORR in first salvage SOC after EGFR blockade was 0% (0.0-24.7%) in the real-world cohort. Median progression free and overall survival were 4.0 months (1.4-5.6) and 10.1 months (4.5-16.5) in the tissue$^+$ pts and 3.1 months (1.4-5.6) and 8.8 months (4.3-12.9) in the ctDNA$^+$ pts. One pt withdrew due to an adverse event (grade 3 decreased ejection fraction), but no treatment related deaths occurred. In exploratory analyses, pts without ctDNA mutations of *RAS*/*BRAF*V600/*PIK3CA*/*HER2* were more likely to respond to P+T than those with a ctDNA mutation in at least one of these genes (ORR 44% vs. 0% in tissue$^+$ and 37% vs. 0% in ctDNA$^+$). Decreased ctDNA fraction and *HER2* plasma copy number at 3 weeks after treatment initiation corresponded to P+T response. At least one actionable alteration emerged after progression in 16 (62%) of 26 pts with ctDNA results at both baseline and progression. Among 5 pts who achieved response and had ctDNA results at both time points, 4 pts acquired actionable alteration at progression. **Conclusions:** We demonstrate promising efficacy and safety of P+T for *RAS*wt mCRC pts with *HER2* amp in either tumor tissue or ctDNA. Our results show that complete ctDNA genotyping identifies pts most likely to benefit from dual HER2 blockade and can be used to monitor response and detect actionable resistance biomarkers. Repeat sequential oxaliplatin-based chemotherapy (FLOX) and nivolumab versus FLOX alone as first-line treatment of microsatellite-stable (MSS) metastatic colorectal cancer (mCRC): Initial results from the randomized METIMMOX study. *First Author: Anne Hansen Ree, Akershus University Hospital, Lorenskog, Norway*

Background: Immune checkpoint blockade (ICB) has revolutionized patient outcome for the small mCRC subgroup with highly immunogenic disease. The majority of mCRC cases, however, are MSS without innate ICB susceptibility. In our ongoing METIMMOX study, we hypothesize that MSS mCRC can be transformed into an immunogenic condition by short-course oxaliplatin-based therapy (FLOX), enabling patients with unresectable, previously untreated metastases to obtain durable disease control when adding ICB therapy. Here we present the protocol-planned interim analysis. **Methods:** Eligibility criteria include infradiaphragmatic metastasis and C-reactive protein < 60 mg/L. At analysis 15 January 2021, 54 patients stratified according to primary tumor sidedness and mutational status and evaluable for the primary end point (progression-free survival; PFS) had been randomly assigned to a standard-of-care schedule of 8 FLOX cycles Q2W (control arm) or repeat sequential 2 FLOX cycles and 2 nivolumab cycles (240 mg Q2W) to a total of 8 cycles (experimental arm), for both arms before treatment break until disease progression and reintroduction of a new treatment sequence. Radiologic response assessment is every 8 weeks. Safety, tolerability, objective response rate, and duration of response are among secondary end points. **Results:** At median follow-up of 6.4 (range, 0.5-20) months, patients were well balanced between the treatment arms with regard to the predefined strata and single-organ or multiple-organ metastases. Median PFS for the entire groups of control and experimental arm patients was 5.6 (range, 0.5-15; $n = 26$) and 6.6 (range, 0.5-20; $n = 28$) months, respectively. The number of FLOX-related CTCAE grade 3 or higher adverse events, including 2 deaths after initial FLOX administration, was comparable in the two arms. Twelve immune-related grade 3-4 adverse events (no new safety signals) were recorded. In the experimental arm, 4 (16%) patients, all *RAS/BRAF*-mutant cases, had experienced complete response and 9 (32%) patients had ongoing objective response at 8 months. The control arm cases had 0 with complete response and 6 (23%) with ongoing objective response at 8 months, 1 of whom had proceeded to curative-intent liver surgery. **Conclusions:** MSS mCRC patients may hold the opportunity of ICB responsiveness evoked by short-course oxaliplatin-based chemotherapy. The search for predictive biomarkers of ICB responsiveness is ongoing in the specifically designed METIMMOX correlative study program. Clinical trial information: NCT03388190. Research Sponsor: Norwegian Cancer Society Grant 182496, Pharmaceutical/Biotech Company.

Impact of BRAF mutations on prognosis and immunotherapy response in microsatellite instability/mismatch repair deficient metastatic colorectal cancer: A systematic review and meta-analysis. *First Author: Robin Park, MetroWest Medical Center, Framingham, MA*

Background: Mismatch repair deficient/microsatellite instability high (dMMR/MSI-H) colorectal cancer (CRC) defines a molecular subtype with distinct clinicopathologic characteristics including an excellent response to immunotherapy. Although *BRAF* mutations are established as a negative prognostic marker in CRC, whether they retain their negative prognostic impact in or alter the response to immunotherapy in dMMR/MSI-H CRC remains unknown. Herein, we present a systematic review and meta-analysis of the impact of *BRAF* mutations on the overall survival (OS) and immune checkpoint inhibitor (ICI) response in dMMR/MSI-H CRC. **Methods:** Studies published from inception to 26 January 2021 were searched in PubMed, Embase, and major conference proceedings (AACR, ASCO, and ESMO). Eligible studies included the following: 1) observational studies reporting outcomes based on *BRAF* mutation status in dMMR/MSI-H CRC patients and 2) experimental studies of ICI reporting outcomes based on *BRAF* mutation status in dMMR/MSI-H CRC patients. A summary hazard ratio (HR) was calculated for OS in *BRAF* mutated (*BRAF*mut) vs. *BRAF* wild type (*BRAF*wt) patients (pts) with the random effects meta-analysis (REM). A summary odds ratio (OR) was calculated for objective response rate (ORR) in *BRAF*mut vs. *BRAF*wt pts treated with ICI with the REM. **Results:** Database search conducted according to PRISMA guidelines found 4221 studies in total. Initial screening identified 30 studies and after full-text review, 9 studies (N = 4158 pts) were included for the meta-analysis of prognosis (analysis A) and 3 studies (N = 178 pts) were included for the meta-analysis of ICI response (analysis B). The outcome measures are summarized in the table below. Analysis A showed that in stage I-IV dMMR/MSI-H CRC pts, *BRAF*mut was associated with worse OS than *BRAF*wt (HR 1.57, 1.23-1.99). The heterogeneity was low ($I^2 = 21\%$). Subgroup analysis showed no significant difference in the prognostic impact of *BRAF* mutation status between stage IV only and stage I-IV CRC pts. Analysis B showed no difference in ORR (OR 1.04, 0.48-2.25) between *BRAF*mut vs. *BRAF*wt dMMR/MSI-H pts who received ICI. The heterogeneity was low ($I^2 = 0\%$). **Conclusions:** *BRAF* mutations retain their negative prognostic impact in dMMR/MSI-H stage I-IV and stage IV CRC but are not associated with differential ICI response. Limitations include the following: analysis A was based on retrospective studies; also, the impact of *BRAF* status on the survival outcome of ICI could not be assessed due to limited number of studies. Research Sponsor: None.

***BRAF* mutated vs. *BRAF* wild type**	**Number of Studies (Pts)**	**Outcome**
Overall Survival (I-IV)	9 (N = 4158)	HR 1.57 [1.23-1.99]*
Overall Survival (IV only)	3 (N = 3247)	HR 2.02 [1.20-3.42]
Objective Response Rate to ICI	3 (N = 178)	OR 1.04 [0.48-2.25]**

**Lower HR favors BRAFmut **Higher OR favors BRAFmut.*

Phase II study of panitumumab monotherapy in chemotherapy-naïve frail or elderly patients with unresectable, *RAS* wild type colorectal cancer: OGSG 1602, survival update data. *First Author: Shingo Noura, Department of Surgery, Toyonaka Municipal Hospital, Toyonaka, Japan*

Background: We previously reported the result of the phase II OGSG1602 study in which single agent of panitumumab (Pmab) demonstrated 76.5% and 50% of disease control rate (DCR), primary endpoint, and response rate (RR), respectively, in chemotherapy-naïve frail or elderly patietns (pts) with wild-type (wt) *RAS* unresectable colorectal cancer (CRC). Here, we reports the survival analysis including overall survival (OS) and progression free survival (PFS) in terms of sidedness and early tumor shrinkage (ETS). **Methods:** Thirty-six pts aged ≥76 years, or ≥65 considered unsuitable for intensive chemotherapy were enrolled and received Pmab 6 mg/kg intravenously every 2 weeks. Primary tumors located in the cecum to transverse colon were coded as right-sided tumors (RST), while tumors located from the splenic flexure to rectum were considered left-sided tumors (LST). Early tumor shrinkage (ETS) was determined as tumor reduction of 20% at week 8 compared to baseline. **Results:** Of total of 36 enrolled pts, 34 pts were included in the efficacy analysis, with pts with LST vs. RST being 26 vs. 8 cases, while pts who achieved ETS (ETS+) vs. those who did not achieve ETS (ETS-) being 15 vs. 19 cases. Among the evaluable 34 pts, the median PFS (mPFS) and median OS (mOS) were 6.0 months (95% Confidence Interval [CI]: 5.4-10.0) and 17.5 months (95%CI, 13.8-24.3), respectively, with the median follow-up of 17.0 months. For PFS, there were no significant differences between pts with LST vs. RST [6.6 months (95%CI, 5.4-11.5) vs. 4.9 months (95%CI, 1.9-NA), p = 0.120] but between pts with ETS+ vs. ETS- [10.4 months (95%CI, 7.4-NA) vs. months (95%CI, 2.1-7.9), p = 0.001]. Furthermore, OS was significantly different either in pts with LST vs. RST [19.3 months (95%CI, 14.2-NA) vs. 12.3 (95%CI, 9.9-NA), p = 0.043] or in pts with ETS+ vs. ETS- [months (n = 15, 95%CI, 19.6-NA) vs. 10.1 months (n = 19, 95%CI, 6.8-21.8), p < 0.001]. **Conclusions:** Pmab monotherapy showed the favolable OS in the frail or elderly pts with *RAS* wt, unresectable CRC. Our data also confirmed the prognostic value of sidedness as well as predictive value of ETS in this setting. Clinical trial information: UMIN000024528. Research Sponsor: OGSG and Takeda Pharmaceutical Company Limited.

Phase Ib/II open-label, randomized evaluation of atezolizumab (atezo) + Imprime PGG (Imprime) + bevacizumab (bev) vs regorafenib (rego) in MORPHEUS: Microsatellite-stable (MSS) metastatic colorectal cancer (mCRC). *First Author: Marwan Fakih, City of Hope Comprehensive Medical Center, Duarte, CA*

Background: The MORPHEUS platform consists of multiple, global, open-label, randomized Phase Ib/II trials designed to identify early efficacy and safety signals of treatment (tx) combinations across cancers. Here, atezo (anti-PD-L1) was tested with Imprime and bev (anti-VEGF) for MSS mCRC, a poorly immunogenic cancer generally resistant to checkpoint inhibitors. Imprime acts as a pathogen-associated molecular pattern that, when bound to anti-β glucan antibodies (ABA), activates the innate immune system with the potential to 1) promote priming and expansion of tumor-specific T cells, 2) promote M2-M1 macrophage polarization and 3) enhance the immunomodulatory effects of atezo and bev. Therefore, we hypothesized that atezo + Imprime + bev would induce an antitumor response beyond that of rego, a standard-of-care multikinase inhibitor, in patients (pts) with MSS mCRC. **Methods:** Pts with MSS mCRC unselected for the Imprime-specific biomarker (ABA) and refractory to 1-2 prior lines of standard therapy received atezo (1200 mg IV every 3 weeks [q3w]) + Imprime (4 mg/kg IV on Days 1, 8, 15) + bev (7.5 mg/kg IV q3w) or control tx with rego (160 mg orally days 1-21; dose escalation to 160 mg during Cycle 1 allowed per institutional guidelines). The primary endpoint was objective response rate (ORR; investigator-assessed RECIST 1.1); secondary endpoints included disease control rate (DCR; response or stable disease ≥ 12 weeks), progression-free survival (PFS), overall survival (OS) and safety. **Results:** Pts were followed-up for ≥18 wk. 15 pts received atezo + Imprime + bev and 13 received rego. Grade (Gr) 3/4 tx-related adverse events (TRAEs) were seen in 13% of atezo + Imprime + bev and 62% of rego pts. No Gr 5 AEs occurred in atezo + Imprime + bev pts and 1 (8%) was reported in a rego pt. One pt in each arm (7% vs 8%, respectively) withdrew from tx due to a TRAE. No radiological responses were seen in either arm. Five pts (33%) receiving atezo + Imprime + bev and 8 (62%) receiving rego had stable disease as best response. DCR was 13% with atezo + Imprime + bev and 23% with rego. Median PFS was 1.5 mo (95% CI: 1.4, 2.8) and 2.8 mo (95% CI: 1.6, 3.1), and median OS was 5.7 mo (95% CI: 4.4, 10.5) and 10.2 mo (95% CI: 4.8, NE) with atezo + Imprime + bev and rego, respectively. There was no apparent correlation between baseline PD-L1 expression or CD8+ lymphocyte tumor infiltration and clinical benefit. Further, the systemic exposure of atezo, Imprime and bev and immunogenicity of atezo and bev are in line with previous clinical experience. Additional biomarker, pharmacokinetics and anti-drug antibody data will be shown. **Conclusions:** Atezo + Imprime + bev was well tolerated; toxicities were consistent with the safety profiles of the individual agents. No efficacy signal was identified with atezo + Imprime + bev in pts with MSS refractory mCRC. Clinical trial information: NCT03555149. Research Sponsor: F. Hoffmann-La Roche, Ltd.

Single-arm, phase 2 study of regorafenib plus nivolumab in patients with mismatch repair-proficient (pMMR)/microsatellite stable (MSS) colorectal cancer (CRC). *First Author: Marwan Fakih, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: The role of immunotherapy in the treatment of pMMR/MSS metastatic CRC is not established. A Japanese phase 1b trial in this setting showed the combination of regorafenib (multikinase inhibitor with immunomodulatory activity) plus nivolumab (anti PD-1) had encouraging activity and manageable safety (Fukuoka, 2020). This study further assessed the safety and efficacy of this combination. **Methods:** Patients (pts) from the US aged ≥18 years who progressed on/were intolerant to standard chemotherapy were enrolled. Regorafenib was given orally, once daily in 28-day (D) cycles (21D on/7D off) plus IV nivolumab 480 mg on D1. Regorafenib starting dose was 80 mg; if well tolerated, it could be escalated to 120 mg in Cycle 2. Primary endpoint was overall response rate (ORR; RECIST 1.1); secondary aims included disease control rate (DCR), overall survival (OS), progression-free survival (PFS), and safety (NCI-CTCAE v5.0 grade). Biomarker analysis was exploratory. **Results:** 70 pts (59% male) started treatment. At baseline, median age was 57 years (range 34–85), ECOG PS 0/1 was 51%/49%, 67% had liver metastases (mets), and the primary tumor site was right-sided colon in 36% and rectum in 17%. Median number of cycles was 3.0 (range 1–13); 41% of pts escalated regorafenib to 120 mg. Five pts (7.1%) had a partial response (PR) lasting ≥16 weeks (wks) and 22 (31.4%) had stable disease (SD); pts without liver mets had a higher ORR (21.7%). In pts with tumor samples (n = 40), higher baseline expression (IHC) of cytotoxic T cells (CD3+/CD8+/GranzymeB+), Tregs (FoxP3+), and macrophages (CD68+) trended with clinical benefit (PR/SD ≥16 wks/PFS); pts with liver mets had lower expression. Lower plasma levels of biomarkers of vascular biology (e.g. VEGF-D, Ang-2, VWF) trended with longer PFS. Grade (Gr) 3 treatment-emergent adverse events (TEAEs) occurred in 53% of pts and Gr 4 in 10%. Three pts had a Gr 5 TEAE: n = 1 related to the combination (sepsis); n = 1 related to nivolumab only by investigator (sepsis); n = 1 unrelated to treatment (respiratory failure). Most common Gr 3/4 TEAEs: maculopapular rash (14%), fatigue (7%), pneumonia (6%), increased bilirubin (6%). **Conclusions:** Combination treatment with regorafenib (up to 120 mg/day) and nivolumab (480 mg every 28D) has manageable safety. Efficacy of this combination in the North American population did not emulate results in the Japanese population. Absence of liver mets and expression of specific biomarkers indicate a better response and may warrant further analysis. Clinical trial information: NCT04126733. Research Sponsor: Bayer, Bristol Myers-Squibb, Ono.

Concurrent BRAFV600E and BRCA mutations in microsatellite stable (MSS) metastatic colorectal cancer (mCRC): Prevalence and case series of mCRC (pts) with prolonged overall survival (OS). *First Author: Timothy Lewis Cannon, Inova Schar Cancer Institute, Fairfax, VA*

Background: *BRAF* V600E+, MSS mCRC patients comprise up to 10% of advanced CRC. They have a poor prognosis with median survivals typically <1 year. Despite use of multi-agent first-line chemotherapy regimens and combination targeted therapies, outcomes are still poor. In our Institutional Molecular Tumor Board database, we identified 3 consecutive mCRC pts with MSS/*BRAF* V600E who also had a *BRCA1* or *BRCA2* co-mutation and had prolonged overall survival. Prior studies suggested that *BRCA* mutations are uncommon in CRC and we queried the Foundation Medicine (FM) genomic database to evaluate the prevalence of these cases as well as those with co-mutations in other homologous recombination genes. **Methods:** 36,966 CRC pts were sequenced by FMI using hybrid capture comprehensive genomic profiling (CGP) to evaluate all classes of genomic alterations (GA) for pathogenic *BRAF* mutations and/or a mutation in BRCA1/2 or a co-mutation in other homologous recombination (HR) genes (*BARD1, CDK12, FANCL, PALB2, ATM, RAD54L, CHEK2, BRAF, BRIP1, RAD51D, RAD51C, RAD51B, CHEK1*). Selected cohort analysis were *BRAF* V600E co-mutated with *BRCA1* and *BRCA2,* separated into MSI-H and MSS cohorts. The clinicopathological features and genomic loss of heterozygosity (gLOH) of those with a *BRAF* V600E and a *BRCA1/BRCA2* mutation are described along with 3 consecutive cases of CRC patients, identified through the Inova Schar Cancer Institute (ISCI) molecular tumor board (MTB) registry, whom had prolonged OS. **Results:** Of 36,966 colorectal cancer pts, 6.6% were *BRAF* V600E+ and 1.5% had any co-occurring HR gene mutation(s) with 0.6% having co-mutations of BRAF V600E and *BRCA1/2.BRCA* co-mutations were higher in MSI-High *BRAF* V600E, however 24.1% of these occurred in MSS *BRAF* V600E. *BRCA1* co-mutated was more commonly associated with MSS BRAF V600E and was associated with a higher gLOH than MSI-H *BRAF* V600E (18.7% vs 2.8%; p <0.001). In our institutional MTB database, (3/241;1.2%) CRC patients were MSS, *BRAF* V600E+ with *BRCA1 or BRCA2* co-mutations, one confirmed germline and 2 somatic in origin, and had average gLOH of 21.4% with overall survivals of 72+(alive), 17+(alive), and 30 months, respectively. **Conclusions:** Co-existence of *BRAF* V600E/*BRCA1/2* may represent a unique subset of advanced MSS CRC that may have a better prognosis and represent an opportunity to test novel targeted therapies. Larger prospective clinical validation trials in this subset is warranted. Research Sponsor: None.

Summary of colorectal cancer with comutation of BRAFV600E and HR variants.

Increased neutrophil infiltration and lower prevalence of tumor mutation burden and microsatellite instability are hallmarks of RAS mutant colorectal cancers. *First Author: Emil Lou, University of Minnesota School of Medicine, Minneapolis, MN*

Background: The tumor microenvironment (TME) of colorectal cancers (CRC) is modulated by oncogenic drivers such as KRAS. The TME comprises a broad landscape of immune infiltration. How tumor genomics associates with the immune cell landscape is less known. We aim to characterize immune cell types in RAS wild-type (WT) and mutant (MT) CRC, and to examine the prevalence of immuno-oncologic (IO) biomarkers (e.g. tumor mutation burden (TMB), PD-L1, MSI-H/dMMR) in these tumors. We performed genomic and transcriptomic analysis to confirm associations of mutant RAS with immune infiltration of the TME conducive to metastasis vs. potential response to immunotherapies. **Methods:** A total of 7,801 CRC were analyzed using next-generation sequencing on DNA (NextSeq, 592 Genes and WES, NovaSEQ), RNA (NovaSeq, whole transcriptome equencing) and IHC (Caris Life Sciences, Phoenix, AZ). MSI/MMR was tested by FA, IHC and NGS. TMB-H was based on a cut-off of > 10 mutations per MB). Immune cell fraction was calculated by QuantiSeq (Finotello 2019, Genome Medicine). Significance was determined by X^2 and Fisher-Exact and p adjusted for multiple comparisons (q) was <0.05. **Results:** Mutant KRAS was seen in 48% of mCRC tumors; NRAS in 3.7%, HRAS in 0.1%. The distribution was similar in patients < or >= than 50 yrs. In MSS tumors, there was a significantly higher neutrophil infiltration in KRAS MT (median cell fraction 6.6% vs. 5.9%) and NRAS MT (6.9%) overall and also when individual codons were studied. B cells, M2 macrophages, CD8+ T cells, dendritic cells and fibroblasts were lower in KRAS mutant tumors; B cells and M1 macrophages are lower in NRAS (q<0.05). dMMR/MSI-H was significantly more prevalent in RAS WT (9.1%) than in KRAS (2.9%) or NRAS MT (1.8%) tumors, and highest in HRAS MT tumors (60%, q<0.05).TMB-H was more prevalent in RAS WT (11%) than KRAS (5.8%) or NRAS (5.1%) MT, and highest in HRAS MT tumors (70%, all q<0.05). In MSS tumors, KRAS MT tumors showed more TMB-H than WT (3.1% vs. 2.1%, q<0.05), especially in KRAS non 12/13/61 mutations (5.5%, vs. 2.1%, q<0.05) and G12C (4.4%, p<0.05). PD-L1 expression was studied: in MSS tumors, KRAS-G12D (10.4%) and G13 MT (11.8%) showed higher mutation rates than RAS WT tumors (q<0.05). **Conclusions:** KRAS & NRAS mutations are associated with increased neutrophil abundance, with codon specific differences, while HRAS shows no difference. Overall CD8+ T cells and B cells are less abundant in KRAS & NRAS mutants; substantial variability was seen amongst different protein changes. RAS mutations were more prevalent overall than generally reported, but did not vary by age. These results demonstrate significant differences in the TME of RAS mutant CRC that identify variable susceptibilities to immuno-oncologic agents, and provide further detailed characterization of heterogeneity between RAS variants, at the molecular as well as immunogenic levels. Research Sponsor: None.

LEAP-005: A phase 2 multicohort study of lenvatinib plus pembrolizumab in patients with previously treated selected solid tumors—Results from the colorectal cancer cohort. *First Author: Carlos A. Gomez-Roca, Institut Claudius Regaud, Toulouse, France*

Background: Pembrolizumab (pembro), an anti-PD-1 antibody, is approved for the treatment of patients (pts) with unresectable or metastatic microsatellite instability-high (MSI-H) or mismatch repair (MMR) deficient colorectal cancer, both as first-line treatment and after progression following treatment with fluoropyrimidine, oxaliplatin, and irinotecan. The combination of lenvatinib, a multiple receptor tyrosine kinase inhibitor, and anti-PD-1 treatment showed synergistic antitumor activity in preclinical models. LEAP-005 (NCT03797326) is evaluating the efficacy and safety of lenvatinib plus pembro in pts with previously treated advanced solid tumors. We present findings from the colorectal cancer cohort. **Methods:** In this nonrandomized, open-label, phase 2 study, adult pts (aged ≥18 y) with histologically/cytologically documented metastatic and/or unresectable colorectal cancer, non–MSI-H/pMMR tumor per local determination, previous treatment with oxaliplatin and irinotecan in separate lines of therapy, measurable disease per RECIST v1.1, ECOG PS of 0–1, and a tissue sample evaluable for PD-L1 expression were eligible. Pts received lenvatinib 20 mg QD plus pembro 200 mg Q3W for up to 35 cycles of pembro (~2 y) or until confirmed disease progression, unacceptable toxicity, or withdrawal of consent. Treatment with lenvatinib could continue beyond 2 y in pts with clinical benefit. Primary endpoints were ORR (per RECIST v1.1 by blinded independent central review) and safety. Secondary endpoints included disease control rate (DCR), duration of response (DOR), PFS, and OS. Tumor imaging was performed Q9W from treatment initiation for 54 wks, then Q12W to week 102, and Q24W thereafter. **Results:** 32 pts with colorectal cancer received treatment with lenvatinib plus pembro (median age, 56 y [range, 36-77]; male, 81%; 3L, 91%); median time from first dose to data cutoff (April 10, 2020) was 10.6 mo (range, 5.9-13.1). ORR was 22% (95% CI, 9–40; table). Grade 3–5 treatment-related AEs occurred in 16 (50%) pts. Treatment-related AEs led to treatment discontinuation in 3 pts (grade 2 ischemic stroke [n = 1], grade 3 increased liver transaminases [n = 1], grade 5 intestinal perforation [n = 1]). **Conclusions:** In pts with previously treated advanced non–MSI-H/pMMR colorectal cancer, lenvatinib plus pembro demonstrated promising antitumor activity and a manageable safety profile. Enrollment in the colorectal cohort was expanded to 100 pts. Clinical trial information: NCT03797326. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Efficacy results.

Outcome	N = 32
ORR (CR+PR), % (95% CI)	22 (9–40)
DCR (CR+PR+SD[a]), % (95% CI)	47 (29–65)
DOR, median (range), mos	NR (2.1+–10.4+)
PFS, median (95% CI), mos	2.3 (2.0–5.2)
OS, median (95% CI), mos	7.5 (3.9–NR)

NR, not reached.
[a]Confirmation was not required for best overall response of SD, but a final visit response of SD or better must have occurred ≥6 wks after starting study treatment.

Circulating tumor derived cell-free DNA (ctDNA) to predict recurrence of metastatic colorectal cancer (mCRC) following curative intent surgery or radiation. *First Author: Bryant Chee, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Over half of patients (pts) with oligometastatic CRC treated with curative intent surgery or radiotherapy experience cancer recurrence with or without adjuvant chemotherapy. ctDNA detection post-definitive treatment could identify high risk pts for additional intervention to eliminate molecular residual disease. Here we report results of a prospective observational study aiming to determine ctDNA detection rates using a sensitive liquid biopsy and to correlate post-procedure ctDNA detection (post-ctDNA (+)) with radiographic mCRC recurrence. **Methods:** Pts with mCRC intending to undergo a curative intent procedure were prospectively recruited at two US sites. ctDNA was collected pre-procedure, 3 weeks post-procedure, and at multiple structured follow-up timepoints. The presence of ctDNA was evaluated using a plasma-only integrated genomic and epigenomic assay (Guardant Reveal, Guardant Health). A bioinformatic classifier was applied to differentiate tumor derived versus non-tumor derived cell-free DNA. **Results:** Among 52 enrolled pts, post-ctDNA data is available for 45 pts (87%), with a median of 4 (range 1-10) timepoints per pt. The sample analysis failure rate was 1% (2/217). As of 1/1/2021, the radiographic recurrence rate was 60% with a median follow-up time of 50 (range 4-192) weeks. 23 of 25 pts with post-ctDNA(+) have had recurrence (Positive Predictive Value [PPV], 92%). On average, ctDNA was detected 28 weeks before radiographic recurrence (mean 12 vs. 40 weeks, respectively). The two pts with post-ctDNA(+) but no recurrence have $>$ 3 years follow-up; one pt received adjuvant chemotherapy and cleared ctDNA. With a median event-free follow-up time of 97 (range 4-192) weeks, 4 of 20 pts with no post-ctDNA detection (-) have recurred (Negative Predictive Value, 80%). 3 of 4 pts with recurrence despite post-ctDNA(-) also were pre-ctDNA(-). We observed a sensitivity of 85% and a specificity of 89% for the ctDNA assay. The median time to radiographic recurrence was 36 wks for ctDNA(+) vs. not reached for ctDNA(-) (Hazard Ratio, 7.7; 95% CI, 2.6-22.5; $P < .001$). **Conclusions:** In mCRC pts undergoing curative intent surgery or radiotherapy, detection of ctDNA post-procedure had a high PPV for cancer recurrence, with a median lead time of 6 months compared to surveillance imaging. Thus, ctDNA holds promise as a biomarker for pt enrollment on clinical trials and as an endpoint for monitoring of response to experimental therapies in this oligometastatic CRC population. Research Sponsor: Guardant Health.

RAMucirumab in combination with TAS102 versus TAS102 monotherapy in metastatic colorectal cancer: Safety results from the phase IIb part of the RAMTAS phase II/III trial of the German AIO (AIO-KRK-0316). *First Author: Stefan Kasper, University Hospital Essen, West German Cancer Center, Essen, Germany*

Background: Patients (pts) with mCRC progressing on standard chemotherapy have limited therapeutic options. Trifluridine/tipiracil (TAS102) significantly improved survival in patients with refractory mCRC. Ramucirumab (ram) is approved in combination with FOLFIRI for second-line treatment. There is a strong rationale to evaluate the efficacy and safety of ram in combination with TAS102 in pts with refractory mCRC. **Methods:** This is a randomized, open-label, multicenter, starting as phase IIb and extended to a phase III study in pts with advanced mCRC. Eligible pts were randomized to receive either ram (8 mg/kg on d1+15, q4w) and TAS102 (35 mg/m^2 on d1-5 and d8-12, q4w, arm A) or TAS102 alone (arm B). The primary endpoint is overall survival. A total of 145 pts were enrolled into phase IIb. Here, we present the data from an interim safety analysis comprising the first 80 treated pts. The trial was extended to phase III including a total of 426 pts. Enrolment of additional 281 pts started in Dec 2020. The trial endpoints remained unchanged. **Results:** Pts (40 arm A, 40 arm B) received a median of 2.5 treatment cycles in arm A and 2 cycles in arm B; 31 pts in treatment arm A and 32 pts in arm B discontinued participation prematurely, mainly due to cancer progression. Most patients developed adverse events (AEs): grade 3 AEs were observed in 28 pts (70%) in arm A (24 treatment-related) and 27 pts (67%, 17 treatment-related) in arm B. More grade 4 AEs were seen in arm A (13 pts, 32.5%) than in arm B (5 pts, 12.5%). In total, 46 Serious AEs (SAEs) occurred, 27 in arm A (10 treatment-related) and 19 in Arm B (2 treatment-related). Five SAEs (3 in arm A, 2 in arm B) had a fatal outcome (one in arm A treatment-related). Within the analyzed population, no SUSAR occurred. **Conclusions:** This safety analysis demonstrates a minor increase in AEs in the experimental arm but no unexpected events. There were no excessive toxicity or unacceptable risks. In summary, a favorable risk-benefit-profile was confirmed. Based on these safety results and the ongoing need for efficient treatment in the tested population, the trial was extended to phase III. Clinical trial information: NCT03520946. Research Sponsor: Lilly.

Neoadjuvant chemotherapy to improve colon cancer survival in resectable metastatic colon cancer: A real world NCDB data analysis. *First Author: Saurabh Parasramka, University of Kentucky, Lexington, KY*

Background: According to the SEER database, approximately 21% of colon cancer patients have synchronous metastatic disease at presentation with a five-year survival of only 14%. Liver is by far the most common site of metastasis. For resectable and borderline resectable metastatic lesions after conversion to surgical resection, five-year survival ranges between 40-70% in different series. Survival advantage of neoadjuvant chemotherapy is not clear. We present here an updated analysis of effect of different variables on survival of 3,247 patients from the National Cancer Database (NCDB) treated from 2010-2015. **Methods:** Adults 20 years or older with primary colon cancer and single organ metastatic disease either in the liver and/or lung at diagnosis were identified. All patients had received surgery to the primary site, resection of the distant site and chemotherapy within 1 year of diagnosis. Patients were categorized into 2 cohorts based on whether they received chemotherapy in the pre-operative/peri-operative setting (neoadjuvant chemotherapy –NAC) or post-operative setting (adjuvant chemotherapy AC). Descriptive analysis, Kaplan-Meier plots, Log-Rank tests and Cox regression models for multivariate survival analyses were performed. To assess uncertainty of estimates, a sensitive analysis was also performed based on the intention to treat principle by including additional surgery only and chemotherapy only cases. **Results:** A total of 3,247 patients with colon cancer with liver or lung metastases were identified. A large majority 2,527 patients (77.8%) received AC. 54.5% were males and 45.5% females. On multivariate analysis, patients who received NAC had overall survival (OS) advantage with hazard ratio (HR) 0.86 (0.75-0.98). Clinical factors associated with worse survival included age $>$ 75 HR 1.31; positive margin status with R1 HR 1.49 or R2 HR 2.33; Comorbidity index $\geq$ 2 HR 1.68; positive KRAS status HR 1.20; N2 disease HR1.95; ; having liver metastasis compared to lung HR 1.65 ;. Factors associated with improved survival were CEA less than 30 ng/ml at diagnosis and left sided tumor with HR of 0.64 (0.56-0.72) and 0.75(0.67-0.84) respectively. **Conclusions:** Metastatic colon cancer with single organ liver or lung lesions benefit from neoadjuvant chemotherapy based on our analysis of the real-world data. The survival advantage in this setting has not been shown before. Research Sponsor: None.

Influence of dietary insulin scores on survival in patients with metastatic colorectal cancer (mCRC): Findings from CALGB (Alliance) 80405. *First Author: Katherine DiNardo, Brigham and Women's Hospital, Boston, MA*

Background: Diets inducing an elevated insulin response have been associated with increased recurrence and mortality in patients with non-metastatic colorectal cancer, but it remains unknown if postprandial hyperinsulinemia also affects progression and mortality in mCRC patients. The goal of this study was to assess the influence of dietary insulin load (DIL) and dietary insulin index (DII) on survival of mCRC patients. **Methods:** This was a prospective cohort study of 1,177 patients with previously untreated mCRC enrolled in a phase III trial of systemic chemotherapy plus biologics who reported dietary intake within one month after chemotherapy initiation. DIL was calculated as a function of food insulin index and the energy content of individual foods reported on a food frequency questionnaire. DII was calculated by dividing DIL by total energy intake. The primary endpoint was overall survival (OS). Secondary endpoints were progression-free survival (PFS) and treatment-related adverse events (TRAEs). The primary statistical test was a test for trend, which was performed using the median value for each quintile of dietary insulin score as a continuous variable. Cox proportional hazards regression was used to adjust for potential confounders including assigned treatment arm, known prognostic factors, comorbidities, body mass index, and physical activity. **Results:** Higher DIL was significantly associated with worse OS (p_{trend} = 0.04); patients in the highest quintile survived 34.1 months, compared to 27.7 months in the lowest quintile (Cox hazard ratio [HR] 1.22, 95% confidence interval [CI] 0.99 - 1.51). Higher DII was non-significantly associated with worse OS (HR 1.18, 95% CI 0.94 - 1.48, p_{trend} = 0.09). There was no significant association between dietary insulin scores and PFS. The influence of dietary insulin scores on survival did not differ significantly by various molecular markers involved in the insulin signaling pathway, including C-peptide, adiponectin, IGF-1, IGFBP-3, and IGFBP-7. Higher dietary insulin scores were significantly associated with greater risk of any TRAE. Those with a DIL greater than the median had a 75.4% rate of any TRAE, compared to 70.8% in those with a DIL less than or equal to the median (HR 1.19, 95% CI 1.03 - 1.38, p=0.02); the most significant associations were with neutropenia (HR 1.30, 95% CI 1.05 - 1.61, p=0.01) and diarrhea (HR 1.43, 95% CI 1.00 - 2.06, p=0.05). **Conclusions:** Higher DIL was significantly associated with worse OS, and both higher DIL and DII were significantly associated with increased TRAEs, in patients with previously untreated mCRC. These findings may inform future dietary recommendations for patients with mCRC. Further investigation into the molecular mechanisms underlying these associations is warranted. Clinical trial information: NCT00265850. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Exploratory biomarker findings from cohort 2 of MODUL: An adaptable, phase 2, signal-seeking trial of fluoropyrimidine + bevacizumab ± atezolizumab maintenance therapy for BRAF^{wt} metastatic colorectal cancer. *First Author: Josep Tabernero, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), IOB-Quiron, UVic-UCC, Barcelona, Spain*

Background: MODUL is an adaptable, phase 2, signal-seeking trial testing novel agents as first-line therapy for predefined subgroups of patients with metastatic colorectal cancer (mCRC). Previously reported findings demonstrated that adding atezolizumab to fluoropyrimidine (FP)/bevacizumab as first-line maintenance treatment after induction with FOLFOX + bevacizumab did not improve efficacy outcomes in BRAF^{wt} mCRC. Given these efficacy results, exploratory assessments on tumour samples were conducted to provide insights into factors that might affect efficacy of maintenance treatment and provide guidance on appropriate therapeutic strategies for BRAF^{wt} mCRC. **Methods:** In patients with BRAF^{wt} tumours (Cohort 2), experimental treatment was FP/bevacizumab + atezolizumab. Primary efficacy endpoint: progression-free survival (PFS). Overall survival (OS) was a secondary endpoint. Archival tissue samples from 104 patients were analysed by immunohistochemistry (IHC) at HistoGeneX (PD-L1; CD8/GrB/FoxP3). SP142 antibody was used for PD-L1 IHC analysis, which evaluated PD-L1^{low} (IC 0–1) vs PD-L1^{high} (IC $>$ 1) in correlation with PFS and OS in the control and experimental arms. CD8/GrB/FoxP3 triplex staining was also performed to evaluate potential correlations with efficacy. **Results:** 445 patients with BRAF^{wt} mCRC were randomised (2:1 ratio) to maintenance treatment in Cohort 2. Archival samples from 104 patients were analysed: FP/bevacizumab + atezolizumab (n = 82); FP/bevacizumab (n = 22). The biomarker evaluable population (BEP) for PD-L1 was n = 81 for FP/bevacizumab + atezolizumab [PD-L1^{low} n = 35 (43%); PD-L1^{high} n = 46 (57%)] and n = 22 for FP/bevacizumab [PD-L1^{low} n = 16 (72%); PD-L1^{high} n = 6 (28%)]. The BEP for CD8/GrB was n = 50 for FP/bevacizumab + atezolizumab and n = 16 for FP/bevacizumab. No difference in PFS or OS was observed in the FP/bevacizumab + atezolizumab vs FP/bevacizumab arms for PD-L1^{high} [PFS: HR = 1.5 (95% CI 0.45−4.8), p = 0.51; OS: HR = 1.3 (95% CI 0.38−4.1), p = 0.71] or PD-L1^{low} [PFS: HR = 0.92 (95% CI 0.47−1.8), p = 0.81; OS: HR = 0.78 (95% CI 0.4−1.5), p = 0.48]. Similar results were observed with CD8/GrB^{high} [PFS: HR = 0.73 (95% CI 0.27−2.0), p = 0.55; OS: HR = 0.66 (95% CI 0.24−1.8), p = 0.44], CD8/GrB^{low} [PFS: HR = 1.0 (95% CI 0.42–2.5), p = 0.96; OS: HR = 0.73 (95% CI 0.3–1.8), p = 0.5], FoxP3^{high} [PFS: HR = 0.97 (95% CI 0.37−2.5), p = 0.95; OS: HR = 0.95 (95% CI 0.36−2.5), p = 0.91] and FoxP3^{low} [PFS: HR = 0.73 (95% CI 0.29−1.9), p = 0.53; OS: HR = 0.5 (95% CI 0.19−1.3), p = 0.18]. **Conclusions:** These findings suggest that PD-L1, CD8/GrB and FoxP3 might not be predictive biomarkers in BRAF^{wt} mCRC. Further analyses are needed to further evaluate potential predictive and prognostic factors of response in this setting. Clinical trial information: NCT02291289. Research Sponsor: F. Hoffmann-La Roche Ltd.

Treatment responses and disease dynamics in patients with untreated metastatic colorectal cancer receiving bevacizumab-based sequential versus combination chemotherapy: Analysis of a phase 3 trial (AIO KRK0110, XELAVIRI study). *First Author: Annika Kurreck, Charité University Medicine Berlin, Berlin, Germany*

Background: Early response parameters such as early tumor shrinkage (ETS), depth of response (DpR), and time to DpR represent exploratory endpoints that may serve as early efficacy endpoints and potential predictors of long-term outcome. We analyzed the association of these endpoints with bevacizumab-based sequential (initial fluoropyrimidines) versus combination (initial fluoropyrimidines plus irinotecan) chemotherapy within a randomized phase III trial. **Methods:** DpR (change from baseline to smallest tumor diameter), ETS (≥20% reduction in tumor diameter at first reassessment), and time to DpR (study randomization to DpR-image) were analyzed in the XELAVIRI-trial. Moreover, progression-free survival (PFS) and overall survival (OS) were evaluated with ETS as stratification parameter (ETS vs. no ETS) according to treatment arm, molecular subgroup, and sex. **Results:** 370 patients were available for analysis of early treatment response parameters. A higher rate of ETS (60.9% vs. 43.5%; p = 0.001) and significantly greater DpR (-40.0% vs. -24.7%; p $<$ 0.001) were observed in the initial combination compared to the sequential therapy arm, respectively. The improvement of ETS and DpR was pronounced in the subpopulation of *RAS*/*BRAF* wildtype patients. Male in contrast to female patients significantly benefitted from initial combination treatment in terms of median DpR (male: -40.0% vs. -22.2%; p $<$ 0.001; female: -34.0% vs. -24.4%; p = 0.13) and rate of ETS (male: 64.8% vs. 40.2%; p $<$ 0.001; female: 52.5% vs. 49.3%; p = 0.73). Achievement of ETS correlated with improved survival irrespective of treatment arm (PFS: p $<$ 0.001; OS: p = 0.012) and molecular subgroup (PFS: p $<$ 0.001; OS: p $<$ 0.001). Whereas the survival benefit in male patients achieving ETS was statistically significant (PFS: p $<$ 0.001, HR 0.532 (0.409-0.692); OS: p $<$ 0.001, HR 0.574 (0.437-0.756)), there were no significant differences in PFS (p = 0.107) and OS (p = 0.965) of female patients depending on ETS. **Conclusions:** In the XELAVIRI trial, initial irinotecan-based combination therapy with bevacizumab improves ETS and DpR in mCRC patients. Improvement in early response parameters appears pronounced in patients with *RAS*/*BRAF* wildtype tumors suggesting a high sensitivity to irinotecan-based treatment. ETS was predictive of PFS and OS regardless of treatment arm. This finding was rather driven by male than female patients, potentially indicating that ETS might be less predictive of long-term outcome in an elderly, female population. Research Sponsor: Arbeitsgemeinschaft Internistische Onkologie.

Serial circulating tumor DNA (ctDNA) monitoring in metastatic colorectal cancer (mCRC) reveals dynamic profile of actionable alterations. *First Author: Jonathan M. Loree, BC Cancer, Vancouver, BC, Canada*

Background: Serial ctDNA can measure dynamic changes in disease burden over time, however utility of serial profiling to detect changes in actionable alterations remains unclear. **Methods:** We evaluated 501 patients with ≥3 serial Guardant360 assays performed between 09/2016 and 11/2020 and compared MSI, fusion, amplification and single nucleotide variant (SNV) detection over time. This comprised 2147 assays with a median of 4 assays per patient (min 3, max 18) occurring an average of 163 days apart (+/- SD of 147 days). Maximum detected variant allele frequency in samples (maxVAF) was assessed for relation to changes in detected alterations as a surrogate for tumor volume. **Results:** Among 406 patients with assays assessable for MSI-status, 17 (4.2%) had MSI detected. New MSI detection on a subsequent assay always occurred with a rising maxVAF (3/3) that was also ≥0.7%, while loss of detectable MSI between assays always associated with falling maxVAFs (7/7) with 6/7 occurring when maxVAF fell below 0.4%. Fusions were noted in 9/501 (2%) patients. Among 3 patients who lost a detectable fusion, maxVAF decreased in 1 patient and changed ≤0.2% between assays in 2, while 2/3 patients with new fusions had rising maxVAFs and 1 patient had a falling maxVAF. Amplifications were detected in 242/501 patients (48%). While most genes had highly variable amplification detection between assays (9% serially detected), ERBB2 amplifications were more consistent and serially detected in 39% of detected cases (P $<$ 0.0001). New detection of amplifications occurred more commonly in cases with rising maxVAF (OR 11.70, 95% CI 7.61-18.00, P $<$ 0.0001) and loss of detectable amplifications occurred more between samples with falling maxVAF (OR 12.37, 95% CI 8.35-18.66, P $<$ 0.0001). Change in maxVAF correlated with change in number of detected amplifications (r = 0.62, P $<$ 0.0001), but only partially explained changes seen (R^2= 0.39). Between serial assays, SNVs changed a median of 0 variants (IQR -1 to 1), however some patients had significant changes (max gain 21/max loss 18). Among 1646 serial time points, 454 (28%) had no change in SNVs, 674 (41%) gained SNVs, and 518 (31%) lost SNVs on subsequent assays. Gains were more common in samples with rising maxVAF (OR 7.76, 95% CI 6.18-9.73, P $<$ 0.0001) while losses were more common when maxVAF fell (OR 6.90, 95% CI 5.47-8.66, P $<$ 0.0001). The correlation between maxVAF change and SNV change was significant (r = 0.29, P $<$ 0.0001), but minimally explained SNV changes (R^2= 0.086) and was a much weaker association than noted for amplification changes. **Conclusions:** We noted significant differences in detection of actionable alterations across serial ctDNA assays. Increased ctDNA volume (higher maxVAF) due to tumor progression may explain some variation over time, but variability also occurs outside these changes, likely reflecting clonal evolution following therapy. Research Sponsor: None.

Efficacy and safety of vactosertib and pembrolizumab combination in patients with previously treated microsatellite stable metastatic colorectal cancer. *First Author: Tae Won Kim, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Microsatellite stable metastatic colorectal cancer (MSS mCRC) represents a high unmet need since there are currently no approved immunotherapy options. Since the inhibition of the transforming growth factor-β (TGF-β) pathway is known to contribute to the enhancement of immunotherapy efficacy, here, we report the results of vactosertib, a potent and selective TGF-β receptor I kinase inhibitor, combined with pembrolizumab in patients with MSS mCRC. **Methods:** In this phase 2, open label trial, patients have received vactosertib (300 mg BID, 5 days on / 2 days off) and pembrolizumab (200 mg, every 3 weeks) until confirmed progressive disease (PD), unacceptable toxicity or consent withdrawal. Patients with histologically confirmed mCRC who had disease progression after treatment with all available therapies including fluoropyrimidine and oxaliplatin or irinotecan were enrolled. Eligible patients were ≥19 years old, had ECOG status ≤1, and had no prior exposure to immunotherapy. The objectives were to evaluate the safety and efficacy (objective response rate (ORR) per RECIST v1.1). **Results:** Thirty-three patients with MSS mCRC were enrolled. Median age was 60 (range 33-72), 55% were male, median number of previous lines of chemotherapy was 3 (range 1-7), and 82% were consensus molecular subtype (CMS) 4. The ORR was 15.2% including 5 partial responses (PRs), 7 stable diseases, and 17 PDs as best overall responses; 12 patients remain on treatment. Among 5 patients with PR, 3 patients had confirmed PR and median duration of response was not reached yet. As of 04 Jan 2021, the most common treatment related adverse events (AEs) were increased amylase (21.2%), pruritus (21.2%), rash (21.2%), and increased lipase (18.2%). There were 3 treatment-related SAEs reported; drug induced pneumonitis (3%), nausea (3%), and vomiting (3%). **Conclusions:** The combination treatment with vactosertib and pembrolizumab showed favorable safety profile with promising efficacy in patients with MSS mCRC. Updated data including pharmacodynamic markers will be presented at the meeting. Clinical trial information: NCT03724851. Research Sponsor: MedPacto.

Safety and pharmacokinetic analysis of *UGT1A1* genotype-guided dosing of irinotecan. *First Author: Emma C Hulshof, Department of Clinical Pharmacy, Catharina Hospital, Eindhoven, Netherlands*

Background: Irinotecan is commonly used in the treatment of advanced colorectal and pancreatic cancer. The polymorphisms *UGT1A1*28* (7 TA repeats) and *UGT1A1*93* (SNP -3156G > A) are significantly associated with increased systemic exposure of irinotecan's active metabolite SN-38 and subsequently severe irinotecan-associated adverse-events (AEs) including (febrile) neutropenia and diarrhea. Severe AEs may lead to hospitalization, loss of quality of life, treatment delay and/or treatment discontinuation. Nonetheless, prospective genetic screening is not yet routinely performed. The aim of this study was to determine the safety and pharmacokinetics of *UGT1A1* genotype-guided dosing of irinotecan in UGT1A1 poor metabolizers (PMs), i.e. *UGT1A1 *28/*28* and/or *UGT1A1*93/*93* individuals, in order to reduce the incidence of severe irinotecan-associated AEs. **Methods:** A prospective, multi-center, non-randomized study was conducted in patients intended to be treated with irinotecan at a dose of $\geq$ 180 mg/m^2 or 450-600 mg flat dose. All patients were pre-therapeutically genotyped for *UGT1A1*28* and *UGT1A1*93*. In UGT1A1 PMs, an initial 30% dose reduction in the first cycle was applied followed by further individual dose titration based on neutrophil count and clinical tolerability. The primary endpoint was the incidence of febrile neutropenia in the first 2 cycles of irinotecan treatment. UGT1A1 PMs were compared to 1] historical control patients, i.e. homozygous polymorphic patients treated with full dose therapy identified from systematic literature review and to 2] UGT1A1 non-PMs treated with standard dose therapy. In addition, systemic SN-38 exposure ($AUC_{0\text{-}500h}$) of reduced dosing in the UGT1A1 PM cohort was compared to a standard dosed irinotecan patient cohort [doi: 10.1200/JCO.2000.18.1.195] by an independent T-test. **Results:** A total of 349 patients were pre-therapeutically genotyped and included for analysis. Thirty-one (8.9%) patients were UGT1A1 PM, in whom an initial median 30% dose reduction was applied. The incidence of febrile neutropenia in this group was 6.5% compared to 24% in historical controls (n = 50) (p = 0.042) and comparable with the incidence (4.1%; p = 0.632) in UGT1A1 non-PMs treated with full dose therapy. The systemic exposure of SN-38 of reduced dosing in UGT1A1 PMs (n = 17) was comparable to the systemic exposure of the standard dosed irinotecan patient cohort (n = 46) with a relative difference of +24% (p = 0.054) with a geometric mean (CV) of SN-38 $AUC_{0\text{-}500h}$ of 391 (43.7%) versus 298 (75.3%) ng*h/mL, respectively. **Conclusions:** *UGT1A1* genotype-guided dosing significantly reduces the incidence of febrile neutropenia in UGT1A1 PM patients treated with irinotecan. In addition, systemic drug exposure remained adequate, despite the 30% dose reduction. Therefore, *UGT1A1* genotype-guided dosing of irinotecan should be considered standard of care in order to improve the individual patient safety. Clinical trial information: Trial NL6270 (NTR6612). Research Sponsor: Catharina Research Foundation.

Characteristics of patients (pts) and prognostic factors across treatment lines (TL) in metastatic colorectal cancer (mCRC): An analysis from the Analysis and Research in Cancers of the Digestive System (ARCAD) database. *First Author: Jean-Baptiste Bachet, Pitié-Salpêtrière Hospital, Paris, France*

Background: Pts with mCRC frequently receive $\geq$1 sequential treatment TL. Approximately 50%-60% of pts receive second-line (L2) and 20%-30% third-line (L3) regimens in routine practice. We investigated the pts clinical/tumor characteristics and their prognostic impact across TL. **Methods:** Data from 37,560 pts enrolled in 48 randomized trials (34 in first (L1), 9 in L2, and 5 in L3) were analyzed. Candidate variables (VAR) measured at enrollment were sex, age, body mass index, performance status (PS), bilirubin, hemoglobin (Hb), platelets (Pl), derived white blood cells-to-absolute neutrophil counts ratio (WBC/ANC), lactate dehydrogenase (LDH), alkaline phosphatase (ALP), primary tumor location, and number and location of metastatic sites (MS). Missing data were imputed. VAR with significant value at all TL were selected to construct a prognostic score of overall survival (OS) in training set (TS, n=30,050; 80%). For each TL, the score was calculated as the sum on the estimations of the VAR' coefficients from the common multivariate model; Cox's model was used to define risk groups. The discrimination capability was assessed using the Harrell's C-index. External validation was done in the validation set (VS, n=7,510; 20%). **Results:** A total of 26,974 pts in L1, 7,693 pts in L2 and 2,893 pts in L3 were analyzed. The following characteristics increased continuously over TL: $\geq$2 MS (57%, 72%, 82%), lung metastases (50%, 74%, 91%), lymph nodes metastases (51%, 61%, 80%), *KRAS* mutation (37%, 47%, 51%) and elevated ALP (46%, 52%, 61%). *BRAF* mutation decreased (9%, 7%, 5%). In L1 vs L3 trials, 70% vs 89% of patients had primary tumor resection, 10% vs 80% had at least one metastasectomy and 31% vs 78% had a late metachronous (>12 months) metastasis. 7 independent VAR were retained in the prognostic score (PS, Hb, Pl, WBC/ANC, LDH, ALP, and the number of MS); four pt groups with significantly different prognoses were defined (table). This score remained valid when excluding pts with PS 2. Third-line oral drugs (vs placebo) and subsequent line (L2/L1 or L3/L2) were effective in all prognostic groups. **Conclusions:** Clinical/tumor pt characteristics significantly varied over subsequent TL in patients included in randomized trials. The same prognostic model using practical clinical and biological variables can be used in all TL. Research Sponsor: ARCAD.

Liquid biopsy-driven anti-EGFR rechallenge in patients with metastatic colorectal cancer. *First Author: Stefano Mariani, University of Cagliari, Cagliari, Italy*

Background: The rechallenge with EGFR inhibitors represents an emerging strategy for anti-EGFR pre-treated patients with RAS wild type colorectal cancer (CRC). Unfortunately definitive selection criteria for anti-EGFR rechallenge in this setting are lacking. Very recently RAS wild type status on circulating tumor DNA (ct-DNA) at the time of rechallenge along with already known clinical criteria emerged as a potential watershed for this strategy. In the present study we explored liquid biopsy-driven anti-EGFR rechallenge strategy in the clinical practice for patients with metastatic colorectal cancer. **Methods:** Ct-DNA from RAS and BRAF wild type metastatic CRC patients previously treated with an anti-EGFR containing therapy was analyzed for RAS/BRAF mutations with the aim to evaluate the rechallenge strategy with anti-EGFR. The ct-DNA was analyzed for RAS-BRAF mutations using pyro-sequencing (PyroMark Q24 MDx Workstation) and nucleotide sequencing (Genetic Analyzer ABI3130) assays. Real-time PCR (Idylla) and droplet digital PCR (QX200 System) were performed to confirm the RAS-BRAF mutation status. Several clinical variables including previous response to anti EGFR containing therapy, tumor sidedness and anti-EGFR free interval were evaluated in relation to outcome. Tumor response evaluation was performed according to RECIST 1.1. Differences between categorical variables were evaluated using the Fisher's exact test. Survival probability over time was estimated by the Kaplan–Meier method. Significant differences in the probability of survival between the strata were evaluated by log-rank test. **Results:** Twenty patients were included in the study. All patients were tested for RAS-BRAF mutations in ct-DNA. Fourteen patients (70%) showed a RAS-BRAF WT molecular profile, six patients (30%) showed a KRAS mutation. All the patients with ct-DNA RAS-BRAF WT profile underwent rechallenge with anti-EGFR. In details 11 patients (78.6%) underwent irinotecan+ cetuximab treatment, whereas 3 patients (21.4%) underwent panitumumab monotherapy. As for the outcome results to the rechallenge strategy, the median OS was 7 months (95% CI 5.0 to 13.0), the median PFS was 3 months (95% CI 2.0 to 6.0), the ORR was 27.3% with a DCR of 54.5%. Among the clinical variables evaluated as putative predictive/prognostic factors, previous response to anti-EGFR treatment was related to a not statistically significant improved OS (12 months vs 5 months HR:0.19 p: 0.06) and to a statistically significant improved ORR (75% vs 0% p:0.03). **Conclusions:** The rechallenge strategy with anti-EGFR confirmed to be feasible in clinical practice. The clinical outcome resulted consistent with the literature data. In addition to the molecular selection through the analysis of ct-DNA for RAS, previous response to anti EGFR treatment is confirmed as a prospective selection criteria for this therapeutic option. Final results from the CAVE (cetuximab rechallenge plus avelumab) mCRC phase II trial: Skin toxicity as a predictor of clinical activity. *First Author: Giulia Martini, Medical Oncology, Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy*

Background: Promising antitumor activity of so called rechallenge treatment with anti-epidermal growth factor receptor (EGFR) drugs in patients with RAS wild type (RAS WT) metastatic colorectal cancer (mCRC) has been recently reported. Beside the absence of resistance mutations at plasma circulating tumor DNA (ctDNA) analysis, no biomarkers of response to anti-EGFR rechallenge strategy have been identified. **Methods:** We conducted the single arm phase II CAVE mCRC trial to evaluate the combination of cetuximab as rechallenge plus avelumab treatment in 77 RAS WT mCRC patients, with complete (CR) or partial response (PR) to first line chemotherapy plus anti-EGFR drugs, who developed acquired resistance and received a subsequent line of therapy. A post-hoc baseline analysis of circulating tumor DNA (ctDNA) for KRAS, NRAS, BRAF and EGFR-S492R mutations was performed for 67/77 (87%) patients. The correlation of skin toxicity (ST) and other clinical variables with OS, PFS and response rate (RR) was assessed. **Results:** Cetuximab plus avelumab provided in the intention to treat population (ITT) median overall survival (mOS) of 11.6 months [95% Confidence Interval (CI), 8.4-14.8] and median PFS (mPFS) of 3.6 months (95% CI, 3.2-4.1) with a manageable toxicity profile. Thirty-three (42.9%) patients experienced grade 2-3 ST with mOS of 17.8 months (CI 95% 14.9-20.7), whereas 44 (57.1%) patients with grade 0-1 ST exhibited mOS of 8.2 months (CI 95% 5.6-11), (HR 0.51, CI 95% 0.29-0.89, P = 0.019). mPFS was 4.6 months (CI 95% 3.5-5.8) in patients with grade 2-3 ST, compared to 3.4 months (CI 95% 2.8-4.1) in patients with grade 0-1 ST (HR 0.49, CI 95% 0.3-0.8, P = 0.004). Grade 2-3 ST and baseline RAS/BRAF/EGFR WT ctDNA were the only variables with statistically significant effect on OS both at univariate and multivariate analyses. ST, number of metastatic sites $\leq$2, surgery of primary tumor and RAS/BRAF/EGFR WT ctDNA were associated with an improvement in PFS only at univariate analysis. In the 33 patients with grade 2-3 ST, 1 (3%) CR, 2 (6.1%) PR and 24 (72.7%) stable disease (SD) were observed, with disease control rate (DCR) of 81.8%. In the 44 patients with grade 0-1 ST 0 CR, 3 (6.8%) PR, 20 (45.5%) SD, with 52.3% DCR were reported. **Conclusions:** Cetuximab plus avelumab is effective and well tolerated as rechallenge treatment in mCRC. ST is a clinical biomarker for the identification of RAS/BRAF mCRC patients that could benefit from anti-EGFR rechallenge. Clinical trial information: NCT04561336. Circulating tumor DNA and circumferential resection margin as key prognostic indicators for survival in rectal cancer. *First Author: Mia Shepherdson, Flinders University, Adelaide, SA, Australia*

Background: Recurrence of colorectal cancer has been linked to the presence of epigenetic circulating tumour DNA (ctDNA) in patient plasma after surgery. The prognostic significance of ctDNA prior to treatment remains unknown. This study investigated the correlation between pre-treatment ctDNA and current radiological (MRI) prognostic markers in patients with rectal cancer. **Methods:** Forty-two patients with rectal cancer were enrolled, with all having staging MRI prior to treatment. Plasma was taken for ctDNA at diagnosis. The presence of either methylated branched-chain amino acid transaminase 1 (BCAT1) or Ikaros family zinc finger (IKZF1) in cell-free DNA from plasma was deemed a positive ctDNA result. Correlation of MRI prognostic indicators and ctDNA results was assessed with chi-square tests. Univariable and multivariable cox regression analyses were performed to determine variables associated with overall survival (OS). **Results:** Mean age was 64.4 years (SD 12.5) and majority were male (30/42, 71.4%). 11, 13, 9 & 9 patients had stages I, II, III, IV respectively. Patients had a minimum follow-up of 36 months. Thirty-three (78.6%) patients received neoadjuvant chemoradiotherapy. 29 (69.0%) patients underwent surgical resection. 3-year survival rate was 64% in the overall group. 67% (n=28/42) of patients were positive for the methylated ctDNA at diagnosis. 11 out of 12 patients with a positive circumferential resection margin (CRM +) were ctDNA positive (p=0.03). Univariable analysis showed that prognostic indicators for OS were presence of extramural venous invasion (EMVI) (HR 3.0, 95% CI 1.1-8.4), CRM+ (HR 12.2, 95%CI 3.9-37.6), metastatic disease (HR 7.32, 95% CI 2.63-20.37) and ctDNA% methylation (HR 1.1, 95% CI 1.04-1.13) (Table 1). The presence of CRM+ and a positive ctDNA had a HR of 20.5 (95% CI 5.1-82.3). With multivariable analysis, including adjustment for age and EMVI, only CRM+/ctDNA+ variable was an independent predictor for poor survival (HR 20.2, 95% CI 4.5-90.9). **Conclusions:** In rectal cancer, almost all patients with CRM involvement have ctDNA, and these patients had the worst prognosis. Future studies with longitudinal ctDNA assessment pre and post treatment could potentially inform prognosis and help tailor patients' treatment. Research Sponsor: Clinical Genomics and Cancer Australia.

Parameters associated with outcomes in pretreated MSI/dMMR metastatic colorectal cancer (mCRC) treated with immune checkpoint inhibitors (ICI): Subgroup analysis of a prospective cohort. *First Author: Raphael Colle, Sorbonne Université, Department of Medical Oncology, Saint-Antoine Hospital, AP-HP, Paris, France*

Background: Immune checkpoint inhibitors (ICI) have demonstrated efficacy in patients (pts) with MSI/dMMR mCRC . We aimed to evaluate clinical, pathological and molecular factors associated with progression-free survival (PFS) and overall survival (OS) in ICI-treated pretreated mCRC patients (pts). **Methods:** Pts are drawn from a prospective cohort of all patients treated with ICI for MSI/dMMR mCRC at Saint-Antoine Hospital, Paris, France. All MSI/dMMR mCRC pts with disease progression after $\geq$ 1 prior systemic treatment (fluoropyrimidine and oxaliplatin or irinotecan ± targeted therapy) were included. MSI/dMMR status was centrally reviewed. Lynch syndrome or sporadic status was determined according to MMR gene germline mutational testing, *MLH1* methylation status and $BRAF^{V600E}$ mutation. PFS and objective response rate (ORR) were assessed using iRECIST criteria. The impact of Lynch syndrome on PFS was analyzed apart from the multivariate analysis due to the interaction with the $BRAF^{V600E}$ mutation status. **Results:** Of 130 included pts, 66 received anti-PD1 alone, 1 anti-PDL1 alone and 63 anti-PD1 plus anti-CTLA4. 71% have had at least 2 prior lines of treatment. 33 patients (25%) have $BRAF^{V600E}$mutation (mt) and 49 (38%) RASmt. The ORR for the whole population was 62.8 % IC95% [53.8; 71.1]. Median follow-up was 21.0 months, median PFS and OS were not reached. Results of PFS unadjusted and adjusted analysis are displayed in the table. $BRAF^{V600E}$ and RAS mutation were not associated with PFS and OS in multivariate analyses. After adjustment for the treatment type, Hazard Ratio (HR) for PFS between patients with proven Lynch syndrome (N=44) and patients with proven sporadic tumors (n= 44) was 0.57 (95%IC 0.26 -1.26). **Conclusions:** In this cohort, main known clinical, pathological and molecular factors do not influence the efficacy of ICI in pre-treated MSI/dMMR mCRC. Research Sponsor: None.

The role of PP2A variants to predict outcome in patients (pts) with metastatic colorectal cancer (mCRC): Data from FIRE-3 and TRIBE trials. *First Author: Jingyuan Wang, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Protein phosphatase 2A (PP2A) is a serine/threonine phosphatase with functions that counter-balance kinase-mediated phosphorylation throughout cell signaling networks. PP2A was reported to upregulate the angiogenesis, while negatively regulate the pathways downstream of receptor tyrosine kinases at multiple nodes. Previous studies showed PP2A variants were associated with the increased risk of cancer. Therefore, we hypothesized that PP2A variants may predict first-line treatment outcome in mCRC pts treated with bevacizumab (bev)/cetuximab (cet)-based chemotherapy. **Methods:** Genomic DNA from blood samples of pts enrolled in two independent randomized trials, TRIBE (bev arm, n=215, as discovery cohort) and FIRE-3 (bev arm, n=107, as validation cohort; cet arm, n=129, as control cohort), was genotyped through the OncoArray, a customized array manufactured by Illumina including approximately 530K SNP markers. The impact on outcome of 17 selected SNPs in 3 main PP2A core subunits (PPP2CA, PPP2R1B, PPP2R1A), one phosphatase activator (PPP2R4) and 2 endogenous inhibitors (TIPRL, CIP2A) was analyzed. **Results:** In the discovery cohort, pts with PPP2R4 rs2541164 A/A (N=16) showed significantly shorter overall survival (15.3 vs 27.3 months) compared to carriers of any G allele (N=198) in both univariate (hazard ratio [HR]=1.8; 95% confidence interval [CI]: 1.1-3.1; *p=0.02*) and multivariate (HR=2.4; 95%CI: 1.4-4.4; *p=0.006*) analysis. These data were validated in the FIRE-3 bev cohort in both univariate (A/A vs. Any G: 17.3 vs 39.9 months, HR=2.8, 95%CI: 1.4-5.9, *p=0.004*) and multivariate (HR=4.3, 95%CI: 1.5-12.2, *p=0.0095*) analysis. Conversely, pts carrying CIP2A rs13069780 C/C (N=24) only showed significantly longer progression-free survival (17.7 vs 12.3 months) than carriers of any T allele (n=105) in the FIRE-3 cet cohort in both univariate (HR=0.6; 95%CI 0.4-0.99; p=0.04) and multivariate (HR=0.5; 95%CI 0.3-0.94; p=0.02) analysis, but no association were observed in the bev cohort of TRIBE and FIRE-3. **Conclusions:** Our study demonstrated for the first time that PPP2R4 polymorphisms could predict outcomes of bev-based treatment in mCRC patients; Meanwhile CIP2A polymorphism could predict outcomes of cet-based treatment in mCRC patients. These findings support a possible role of the PP2A variants in contributing to resistance to anti-VEGF/EGFR treatment. The prognostic impact of *RAS* and *TP53* mutation according to primary tumor location in colorectal liver metastases. *First Author: Yongjun Cha, National Cancer Center, Goyang, South Korea*

Background: Somatic gene mutations have been suggested to impact survival following resection of colorectal liver metastases (CRLM). However, most studies included a selected population with known mutation data and did not employ homogeneous methods. This study aimed to determine the prognostic impact of somatic gene mutations and microsatellite instability (MSI) in CRLM using a standardized protocol and assess their survival effects according to primary tumor location. **Methods:** A total of 568 patients who underwent resection of CRLM during 2001-2014 were identified from a prospectively maintained registry of the National Cancer Center. MassARRAY based mutation profiling of cancer-related genes (*KRAS*, *NRAS*, *HRAS*, *BRAF*, *PIK3CA*, *MET*, *PTEN*, *APC*, *TP53*)/MSI analysis was made in primary tumors from 538 (94.7%)/526 (92.6%) patients. **Results:** Primary tumor locations were: right colon for 51 (9.0%); transverse colon for 42 (7.4%); left colon for 238 (34.5%); rectum for 279 (49.1%) patients. Right sided tumors were associated shorter overall survival (OS) after liver resection compared to left colon primary tumors (5-year OS, 31.4% vs. 54.0% [P = 0.011]). Mutation frequencies were: 45.9% for *RAS* ; 2.4% for *BRAF* ; 8.4% for *PIK3CA* ; 0.2% for *PTEN* ; 0.4% for *MET* ; 12.1% for *APC* ; 24.3% for *TP53*. *RAS* (5-year OS, 40.8% vs. 55.7% [P = 0.001], *PIK3CA* (5-year OS, 31.1% vs. 50.5% [P = 0.027]), and *TP53* mutation (5-year OS, 42.7% vs. 50.8% [P = 0.035]) were associated with worse OS after liver resection. On multivariable analyses, *RAS* (hazard rato [HR] 1.27; P = 0.033) and *TP53* mutation (HR 1.35; P = 0.014) were significantly associated with poor OS after adjustment for covariates. Co-mutation in *RAS*/*TP53* (12.4%) was associated with the worst oncologic outcome (HR 1.81; $P < .001$). Notably, while the negative prognostic impact of *RAS* mutation did not differ significantly according to primary tumor location, the adverse effect of *TP53* mutation was limited to rectal cancer (interaction P = 0.002). In this study, MSI-high (2.3%) was not associated with survival. **Conclusions:** Both *RAS* and *TP53* mutation are associated with worse survival following CRLM resection. In contrast to *RAS* mutation, the negative prognostic impact of *TP53* mutation appears to be limited to CRLM from the rectal origin. Research Sponsor: NCC-1910210.

Overall survival (OS) with encorafenib (enco) + cetuximab (cetux) in BEACON CRC: Effect of prior therapy for *BRAF* V600E-mutant metastatic colorectal cancer (mCRC). *First Author: Scott Kopetz, MD Anderson Cancer Center, Houston, TX*

Background: Enco + cetux (doublet) has been approved in the US, EU, and Japan for the treatment of *BRAF* V600E-mutant mCRC after progression on 1–2 prior regimens. In the BEACON CRC study (NCT02928224), median OS (95% CI) with the doublet was 9.3 months (8.0–11.3) compared with 5.9 months (5.1–7.1) with cetux + irinotecan or FOLFIRI (control) in patients (pts) with *BRAF* V600E-mutant mCRC (HR 0.61 [95% CI: 0.5–0.8]). This *post-hoc* analysis investigates OS by prior therapies to the doublet treatment in pts with *BRAF* V600E-mutant mCRC from the BEACON CRC study. **Methods:** OS of pts treated with the doublet or control were compared according to prior treatment with bevacizumab, oxaliplatin, or FOLFOXIRI and duration of prior anticancer therapy (ACT). **Results:** The proportion of pts in the doublet and control arms who received prior bevacizumab were 64% and 55%, respectively. Of pts who had one prior therapy, 95% and 88% received prior oxaliplatin and 20% and 14% received prior FOLFOXIRI, respectively. OS by prior treatment in the doublet and control arms is shown in the table. In the doublet arm, pts who had bevacizumab < 4 months before start of study treatment had a median OS of 8.3 months (95% CI: 6.2–11.2); those who had bevacizumab ≥4 months prior had a median OS of 10.7 (95% CI: 7.5–17.7). Within each treatment arm, OS was similar regardless of prior treatment with oxaliplatin or FOLFOXIRI. The duration of prior ACT was similar across study arms, ranging from 5.6–5.8 months for the first line of ACT. **Conclusions:** In the BEACON CRC study, pts treated with the doublet for *BRAF* V600E-mutant mCRC demonstrated similar OS regardless of prior therapies or duration of prior therapy use. This exploratory *post-hoc* analysis provides data that reflect the prior treatment landscape clinicians may face when deciding subsequent treatment regimens for pts with *BRAF* V600E-mutant mCRC. Clinical trial information: NCT02928224. Research Sponsor: Pfizer.

A phase 1 first-in-human study of the anti-LAG-3 antibody MK4280 (favezelimab) plus pembrolizumab in previously treated, advanced microsatellite stable colorectal cancer. *First Author: Elena Garralda, Vall d'Hebron Institute of Oncology (VHIO), Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: Patients (pts) with microsatellite stable (MSS) metastatic colorectal cancer (mCRC) that progressed on ≥2 prior therapies have limited treatment options, with median OS ranging from 6-9 months (mo). In the dose-escalation phase of this first-in-human multicohort study (NCT02720068), the anti-lymphocyte activation gene (LAG)-3 antibody favezelimab (fave) was well tolerated alone and with pembrolizumab (pembro) across all dose levels (Lakhani, SITC, 2018, abstract O26). Here, we evaluate the safety and efficacy of fave alone or in combination with pembro in pts with advanced MSS CRC from the dose confirmation phase. **Methods:** Eligible pts with MSS PD-1/PD-L1-treatment-naïve mCRC that progressed on prior standard-of-care (3L+) were enrolled (cohort A) to receive the RP2D of 800 mg fave alone (Arm 1), 800 mg fave + 200 mg pembro (Arm 2C), or 800 mg fave + 200 mg pembro (MK-4280A) co-formulation (Arm 5), all Q3W. Treatment continued for 35 cycles or until progression, unacceptable toxicity, or investigator/pt decision. Pts with confirmed progression per irRECIST v1.1 on fave alone could crossover to 800 mg fave + pembro. Safety was assessed in all treated pts; efficacy in the full analysis set (FAS) of all treated pts with baseline scan. Objectives included safety (primary), ORR (RECIST v1.1 by investigator [secondary]), and DOR, PFS, and OS (exploratory). Interim analysis data cut-off was: Oct. 23, 2020. **Results:** A total of 20 pts received fave (Arm 1); 89 pts (including 9 crossover) received fave + pembro (Arms 2C+5); 12 pts (Arm 1) and 36 pts (Arms 2C+5), had PD-L1 CPS ≥1 tumors. At data cut-off, median follow-up was 5.8 months (mo) in Arm 1 and 6.2 mo in Arms 2C+5. Treatment-related adverse events (TRAEs) were 65% with fave (Arm 1) and 65.2% with fave + pembro (Arms 2C+5). Grade ≥3 TRAEs were 15% (Arm 1), and 20% [Arms 2C+5]). No grade 5 TRAEs were reported. Common TRAEs (≥15%) included fatigue (20.0%), nausea (15%) with fave, and fatigue (16.9%) with fave + pembro. Confirmed ORR was 6.3% (4PR, 1CR) with fave + pembro (Arms 2C+5). No pt receiving fave alone responded. In Arms 2C+5, median DOR was 10.6 mo (range, 5.6-12.7). ORR, OS and PFS by PD-L1 status are reported in the Table. **Conclusions:** Favezelimab alone or in combination with pembrolizumab had a manageable safety profile, with no treatment-related deaths. Promising antitumor activity was observed with combination therapy, including with MK-4280A, compared with monotherapy most notably in pts with PD-L1 CPS ≥1 tumors. Clinical trial information: NCT02720068. Research Sponsor: Merck & Co., Inc.

Fave + pembro[a,b]	**Total N = 80[c]**	**CPS ≥1 N = 36**	**CPS < 1 N = 35**
ORR, n (%)	5 (6.3)	4 (11.1)	1 (2.9)

Differential impact of different TP53 gain-of-function mutations on overall survival of patients with metastatic colorectal cancer: Results from a large integrated healthcare system. *First Author: Minggui Pan, Kaiser Permanente, Dept of Medical Oncology, Santa Clara, CA*

Background: TP53 mutation is present in approximately 50% of metastatic colorectal cancer (CRC). The spectrum of the TP53 mutations is extremely broad including approximately 80% missense mutations. Several missense mutations have been found to possess gain-of-function (GOF) properties in cell line and animal studies, however, confirmation of the concept of GOF in human malignancies is still lacking. **Methods:** We investigated the impact of TP53 GOF mutations in patients with metastatic CRC using the NGS data within Kaiser Permanente Northern California (KPNC), a large integrated healthcare system. **Results:** From November 2017 to January 2021, genomic profiling by StrataNGS was performed on 8658 patients, with 1056 patients being metastatic CRC, among whom 740 patients harbored a TP53 mutation (TP53mut) and 316 patients had wild-type TP53 (TP53wt). Ras (KRAS and NRAS) and BRAF mutation appropriately discriminated the overall survival (OS) of patient populations with either TP53wt or TP53mut, confirming the validity of our dataset. We identified seven GOF TP53 mutations (R175H, R248W, R248Q, R249S, R273H, R273L, R282W) in these CRC patients. We show that different GOF mutation differentially impacts the OS. Patients whose CRC harbored TP53mut R248W, R249S, and R282W (poor prognostic TP53mut, N = 47) had significantly worse OS versus patients whose CRC harbored TP53mut R248Q, R175H, R273H and R273L (N = 160, median OS 29.4 vs 44.2 months, HR 0.47, p = 0.007). The OS of the poor prognostic TP53mut patients was also significantly inferior compared to patients whose CRC harbored all other TP53 mutations (N = 1099, median OS 50.1 months, HR 0.55, p = 0.01) or TP53wt (N = 316, median OS 47,5 months, HR 0.54, p = 0.01). The demographics and the percent of Ras, BRAF, and PI3KCA mutations were similar except that the patients with the poor prognostic TP53mut had significantly higher percent of Ras mutation compared to the rest of the GOF TP53mut patients (p = 0.035). When compared to R248Q alone, R248W confers worse OS (median OS 36.3 vs 63.2 months, p = 0.05). **Conclusions:** Our data suggest that different TP53 GOF mutations are associated with very different clinical outcomes. Additional studies identifying specific TP53 GOF mutations that impact outcomes may provide further insight for drug development and clinical trial design. Research Sponsor: None.

3586 **Poster Session**

Mucinous colorectal cancer: Disease characteristics, treatment outcomes and the impact of metastasectomy. *First Author: Darren Cowzer, Mater Misericordiae University Hospital, Dublin, Ireland*

Background: Mucinous colorectal cancer (CRC) differs from adenocarcinoma with regard to clinical and histological features and is reported to have inferior outcomes when compared to non-mucinous CRC. This study aims to evaluate the clinical features and outcomes of patients with mucinous CRC at our institution. **Methods:** Medical records of patients with CRC that were referred to medical oncology between September 1999 and September 2018 were retrospectively reviewed. Mucinous histology was defined as those containing > 50% mucin identified on histology specimens. Statistical analysis was performed using Prism V9.0. **Results:** We identified 1,115 patients with CRC that were referred to medical oncology during this period. The tumours of 81 (7.3%) patients were classified as mucinous. Median age was 65 (28-94 years) and 45 (55.5%) were male. Forty-one patients (51%) had right sided tumours, 27 (33%) had left sided tumours and 13 (16%) had rectal tumours. Twenty-three (28.4%) had *de novo* metastatic disease. Eleven of 24 patients (46%) with stage II disease relapsed and 18 of 33 (55%) of those with stage III disease relapsed. Radiological surveillance identified 20/29 (69%) of relapsed disease, 5 (17%) were symptomatic and 4 (14%) had a rise in CEA. Median follow up for patients with stage II disease was 53 months and 3 year and 5-year disease free survival (DFS) was equal in both groups at 60.9%. For stage III disease 3- and 5-year DFS was 58.1% and 48.4% respectively with a median follow up of 43 months. In the metastatic setting, we observed no significant difference in overall survival (OS) between left and right sided tumours (*p = 0.550*). Median OS for pts with stage IV mucinous CRC who received any treatment was 25 months. Metastasectomy was performed in 25/52 (48%) patients and was associated with a significant improvement in OS, 23 vs 51 months (*p < 0.005, HR 0.4*). **Conclusions:** Mucinous CRC has been associated with inferior responses to treatment and worse overall outcomes compared to non-mucinous histologies. Survival in advanced-stage disease in our cohort is higher than what has been reported in the literature. With an effective multi-disciplinary approach and the increasing use of metastasectomy as a treatment option, survival in the advanced disease setting may be comparable to non-mucinous CRC. Young-onset colorectal cancer treatment side effects: Infertility, sexual dysfunction, and quality-of-life outcomes. *First Author: Laura Diane Porter, Colorectal Cancer Alliance, Washington, DC*

Background: Colorectal cancer is the third-most commonly diagnosed cancer and the second-leading cause of cancer death in men and women combined in the United States. Young-onset colorectal cancer refers to individuals diagnosed under the age of 50. In recent years, the incidence has increased by 2.2% annually in individuals younger than 50 years and 1% in individuals 50-64, in contrast to a 3.3% decrease in adults 65 years and older. Young-onset (YO) CRC patients and survivors face unique clinical challenges with fertility and sexual dysfunctions, but this risk is not well quantified. There is limited data and public discussion on the long-term effects of colorectal cancer treatments on fertility and sexual dysfunction and the long-term impact on the quality of life. **Methods:** To explore the unique challenges and unmet needs of the young-adult patient population, a cross-sectional study was conducted. Colorectal cancer patients and survivors (N = 884) diagnosed between the ages of 20 to 50 years old (median age 42 ± 7.0) completed an online questionnaire based on established instruments EORTC-QOL-30, EORTC-CR-29, and EORTC-SHC-22. **Results:** Thirty-one percent of respondents stated that a medical professional spoke to them about fertility preservation at the time of diagnosis and during treatment. Only 31% were referred to a reproductive endocrinologist, even though 37% of women and 16% of men reported that treatment left them infertile or sterile. Among survey respondents, 12% of women had an egg retrieval procedure, and 36% of men had their sperm preserved prior to the start of treatment. Fifty-three percent of women reported treatment led to premature menopause. Sixty-five percent of respondents suffer from some level of sexual dysfunction due to treatment. In patients who received radiation therapy, women were 12% less likely than men to have discussed sexual side effects with the provider before treatment. Patients who have an ostomy reported more severe sexual dysfunction (17.8%). Rectal cancer patients were 2.5 times more likely than those with colon cancer to report severe dysfunction after their treatment. More than 25% of the respondents said they would have considered alternative treatment if they would have known the risks of sexual dysfunction. **Conclusions:** Our survey demonstrates inadequate communications between patients and providers about the irreversible fertility and sexual effects of colorectal cancer treatments. Younger patients and survivors face unique long-term challenges and require further information about fertility preservation options and emotional support regarding their sexuality post-treatment. Other studies are needed to assess the physical and psychological side effects endured by young-onset CRC patients and survivors. Research Sponsor: None.

Dietary fat in relation to overall and progression-free survival among patients (pts) with advanced or metastatic colorectal cancer (CRC): Data from CALGB 80405 (Alliance). *First Author: Erin Van Blarigan, University of California San Francisco, San Francisco, CA*

Background: Growing data suggest dietary factors are associated with survival among pts with non-metastatic CRC. However, data on diet and survival among pts with advanced or metastatic disease are very limited. **Methods:** We prospectively examined dietary fat intake assessed at initiation of treatment for advanced or metastatic CRC in relation to OS and PFS. This analysis was conducted among 1,149 pts in the CALGB 80405 randomized controlled trial who completed a validated food frequency questionnaire. We examined intakes of saturated, monounsaturated, and polyunsaturated (total n-3, long-chain n-3, and total n-6) fats as well as animal and vegetable fats. Based on data from non-metastatic CRC and other cancers, we hypothesized that higher intakes of long-chain n-3 fatty acids and vegetable fats would be associated with longer OS and PFS and higher intakes of saturated fat and animal fat would be associated with shorter OS and PFS. We used Cox proportional hazards regression to estimate adjusted hazard ratios (HR) and 95% confidence intervals (CI). **Results:** Over a median follow-up of 6.1 years [y; interquartile range (IQR): 5.3, 7.2 y], we observed 974 deaths and 103 events of progression without death during follow-up. Participants in this analysis had a median age of 59 y (IQR: 51 to 67 y); 41% were female and 86% identified as white. We observed no statistically significant associations between any type of dietary fat and OS. However, vegetable fat was non-linearly associated with longer PFS (HR comparing 4th to 1st quartile: 0.78; 95% CI: 0.64, 0.96; *p*-trend: 0.10). We also observed a linear association between continuous saturated fat and PFS (HR per 5% kcal/d: 1.21; 95% CI: 1.03, 1.42; *p*-value: 0.02), perhaps driven by pts with high saturated fat intake. **Conclusions:** We observed no statistically significant associations between types of dietary fat and OS among pts with advanced or metastatic CRC. However, a healthy diet that includes vegetable fat and is modest in saturated fat may be associated with longer PFS. Future studies to replicate these findings and examine diet in relation to cancer survival in racially/ethnically diverse populations are needed. Assessment of HER2 (*ERBB2*) amplification (HER2amp) using blood-based circulating tumor DNA (ctDNA) next generation sequencing (NGS) and correlation with tissue-based testing in metastatic colorectal cancer (mCRC). *First Author: Kanwal Pratap Singh Raghav, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: HER2 amplified mCRC has emerged as a unique clinical subset, characterized by resistance to anti-EGFR therapy and response to anti-HER2 strategies. Accurate identification and quantification of HER2amp has predictive value for efficacy of anti-HER2 therapies and appropriate patient selection. Despite availability and use of various tumor tissue-based and blood-based assays for detecting HER2amp, data on cross-performance of these platforms are lacking. **Methods:** Leveraging a multicenter international consortium (Italy, Japan and USA), we generated a large cohort (N = 353) of mCRC patients (pts), tested for HER2amp using both tissue and blood. Tissue testing was done using immunohistochemistry (IHC), in-situ hybridization (ISH) and (NGS). ctDNA NGS was performed using CLIA-certified Guardant360 ctDNA assay, capable of detecting HER2 copy number (CN) variations. The primary endpoint was to correlate HER2 gene CNs in tissue (tCN) and plasma (pCN). Descriptive statistics, spearman correlation (r) and Fisher's exact test were used. **Results:** Baseline tumors characteristics included right-sided primary in 234 (23%), proficient mismatch repair in 264 (98%) and *RAS/BRAF* wild type (WT) genotype in 194 (67%) pts. Tissue testing was done by IHC, ISH and NGS in 76%, 64% and 74% pts, respectively. A total of 177 pts had HER2amp detected by at least one test: 116 (66%), 157 (89%) and 96 (54%) of which had tissue +, ctDNA +, and both tissue and ctDNA + disease, respectively. Discordant cases consisted of 20 (6%) with positivity in tumor only and 61 (17%) in ctDNA only. Sensitivity, specificity, positive and negative predictive values of ctDNA assay (vis-à-vis tissue) were 83%, 74%, 61% and 90% respectively. Among HER2amp pts, median (range) HER2/CEP17 (ISH) ratio, tCN and pCN were 5.2 (2–12), 11.6 (2–700) and 3.5 (2–122), respectively. The pCN showed strong correlation with ISH ratio (r = 0.69) and tCN (r = 0.68) ($P < 0.001$). Median pCN differed significantly between pts with HER2 IHC 3+ (12.0), 2+ (2.2) and 0/1+ (2.0) tumors ($P < 0.001$). High HER2amp (pCN > 4.0) appeared to be enriched with tissue + cases (69% vs 8% [OR 24.6, $P < 0.001$]), tumor tissue HER2 + status (IHC3+ [75%] vs IHC2+ISH+ [50%] vs IHC2+/ISH- or IHC0/1+ [12%], $P < 0.001$), HER2 tCN > 6 (79% vs 31% [OR 8.7, $P < 0.001$]) and *RAS/BRAF* WT tumors (41% vs 17% [OR 3.5, P = 0.064) but not left sidedness (41% vs 38%; OR 1.1; P = 0.82). **Conclusions:** In this large diverse cohort of mCRC, we demonstrated correlation of HER2 tCN and pCN obtained by tissue-based and blood-based ctDNA assay. Further prospective efforts are needed to standardize this cross-platform quantification of HER2amp to facilitate robust clinical application of HER2 therapies. This effort shows the value of strategic international partnership in furthering research for rare cancer subsets. Research Sponsor: None.

XELOX or mFOLFOX6 chemotherapy combined with resection of primary lesion versus chemotherapy alone for colon cancer with unresectable metastases: A randomized clinical trial. *First Author: Weijian Guo, Department of Medical Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: It is still controversial for colon cancer patients with unresectable metastases whether to resect the primary tumor when there are no symptoms of primary lesion. **Methods:** This is an open-label, single-center, prospective, randomized, controlled phase II trial. Colon cancer patients aged 18-80 years with unresectable metastases at enrollment will be randomly allocated to either resection group (group A) or chemotherapy group (group B), and stratified by tumor response and number of organ metastases, after receiving induction chemotherapy with 4 cycles of XELOX or 6 cycles of mFOLFOX6, excluding those with disease progression, lesions radically resectable, or primary lesion unresectable. Patients in group A received resection of primary lesion and then continued chemotherapy, and patients in group B just continued chemotherapy, both up to 4 cycles of XELOX or 6 cycles of mFOLFOX6, and capecitabine maintenance afterwards. If progression occurs 3 months after discontinuation of oxaliplatin and toxicity has recovered to grade I, the original regimen can be applied again. The primary endpoint was TFS (time to failure of strategy, defined as the time from randomization to secondary progression in patients received re-introduce of the induction chemotherapy regimen, or to first progression in patients without re-introduce of the original regimen). The secondary endpoints included progression-free survival (PFS, the time from randomization to first progression), overall survival (OS, the time from enrollment to death), and adverse events (AEs). Efficacy data were analyzed on an intention-to-treat (ITT) basis. This study is registered with ClinicalTrials.gov, number NCT02291744. **Results:** Between April, 2015, and July, 2020, 140 patients were enrolled, and 54 patients withdrew due to colon obstruction (16), perforation (1), disease progression (22), death (1), radical resection (3), or other reasons (11). Finally, 86 patients were randomized into group A (n = 42) or group B (n = 44). The median TFS was 143 days (95%CI: 104.9-181.1) in group A, and 196 days (95%CI: 96.5-295.5) in group B (HR:0.930 95%CI:0.589-1.468, p = 0.755). The median PFS was 147 days (95%CI: 105.7-188.3) in group A, and 206 days(95%CI:180.9-231.1) in group B (HR:0.831, 95%CI:0.522-1.323, p = 0.436). The median OS was 530 days (95%CI: 308.9-751.1) in group A, and 779 days (95%CI:626.3-931.7) in group B (HR:0.948 95%CI:0.554-1.622, p = 0.845). The incidence of treatment-related AEs was similar between two groups. **Conclusions:** Resection of primary tumor after induction chemotherapy could not bring survival benefits. It's not recommended for patients without symptoms of primary lesion to receive primary tumor resection, but it also requires individualized treatment as colon obstruction or perforation occurred in some patients. Clinical trial information: NCT02291744. Research Sponsor: Foundation from Fudan University Shanghai Cancer Center.

3591 **Poster Session**

Association of plasma adiponectin with tumor infiltrating lymphocytes and survival in patients with stage III colon cancer (NCCTG N0147; Alliance). *First Author: Frank A. Sinicrope, Mayo Clinic, Rochester, MN*

Background: Adiponectin is a peptide hormone exclusively secreted by adipocytes that plays a role in immune regulation and in the host inflammatory response to cancer. We examined postsurgical adiponectin levels in relationship to tumor infiltrating lymphocytes (TILs), clinicopathological features, vitamin D status, and patient survival in participants in a phase 3 trial of adjuvant chemotherapy. **Methods:** Plasma adiponectin and 25-hydroxyvitamin D [25(OH)D] were analyzed by radioimmunoassay in 600 patients with stage III colon carcinoma who received adjuvant FOLFOX +/- cetuximab. TIL densities were determined at light microscopy in routine histopathological sections. The associations between adiponectin and 25(OH)D, TILs, other factors were evaluated by Fisher's Exact, Chi-squared, t-test, and Kruskal-Wallis tests where appropriate. The association between adiponectin or 25(OH)D with disease-free survival (DFS), time to recurrence (TTR) and overall survival (OS) were evaluated by multivariable Cox regression, adjusting for body mass index (BMI), race, T, N stage, performance status, tumor location, TILs, *BRAF/KRAS*, and mismatch repair status. **Results:** A statistically significant and inverse association between adiponectin level and BMI was observed with lower levels found with obesity (BMI > 30 kg/m^2) [$p < 0.001$]. The level of adiponectin was significantly lower in men vs women ($p < 0.001$), in blacks vs whites or Asians ($p < 0.032$), and in patients with fewer regional lymph node metastases (N1 vs N2 stage, $p = 0.011$). A significantly lower level of adiponectin was found in patients whose tumors had high vs low TIL densities ($p = 0.040$), but was unrelated to 25(OH)D. Insufficiency of 25(OH)D (< 30 ng/ml) was detected in 291 (49%) of patients and was not associated with TILs. By multivariable analysis, adiponectin was not associated significantly with patient DFS (HR_{adj}= 0.98, 95% CI 0.74-1.29, p_{adj}= 0.88) nor with OS nor time-to-recurrence (TTR). TIL densities were significantly prognostic, but 25(OH)D was not (DFS: HR_{adj}= 1.12, 95% CI 0.85-1.47, p_{adj}= 0.44). No significant interaction was observed for adiponectin with TILs for the association with DFS. **Conclusions:** Lower adiponectin levels were associated with significantly increased TIL densities in colon cancers, indicating an enhanced anti-tumor immune response. In contrast to TILs, adiponectin was not independently associated with patient outcome. Nearly one-half of stage III patients were vitamin D insufficient, although 25(OH)D was not prognostic. Research Sponsor: U.S. National Institutes of Health.

Young-onset colorectal: Emotional and psychosocial effects on patients, survivors, and caregivers. *First Author: Laura Diane Porter, Colorectal Cancer Alliance, Washington, DC*

Background: Colorectal cancer is the third-most commonly diagnosed cancer and the second-leading cause of cancer death in men and women combined in the United States. Young-onset colorectal cancer refers to individuals diagnosed under the age of 50. In recent years, the incidence has increased by 2.2% annually in individuals younger than 50 years, and 1% in individuals 50-64, in contrast to a 3.3% decrease in adults 65 years and older. The Colorectal Cancer Alliance launched the Never Too Young Survey and the Caregiver Survey to assess and better understand the unmet needs of the young-onset population and their caregivers. **Methods:** A cross-sectional study, conducted in the form of an online survey, was launched to better understand the experiences around YO-CRC patients and caregivers. YO-CRC patients and survivors (N = 885) and caregivers (N = 204) completed an online questionnaire that was based on established instruments including PROMIS, EORTC-QOL-30, and EORTC-CR-29. The final survey instrument and study plan were reviewed and approved by the Aspire Inc. Institutional Review Board. **Results:** Nearly 75% of patients/survivors shared that they have been concerned about their mental health, and 64% responded that they have needed help for their depression. Further, 67% of caregivers surveyed responded that they were also concerned about their mental health, and 68% responded that they needed help with their depression. Seventy-one percent of caregivers often felt sadness, and 30% indicated that they had lost hope. Emotional exhaustion was reported by 77% of caregivers, whether they were providing round-the-clock care or caregiving from a distance. The effect was more pronounced in the patient/survivor cohort, with 95% indicating that emotional exhaustion impacted their lives. As a result, 71% of caregivers and 29% of patients/survivors indicated that they had withdrawn from other people. These results indicate the emotional toll that colorectal cancer has on patients/survivors and caregivers and their need for further resources. **Conclusions:** The Colorectal Cancer Alliance is committed to meeting these needs and providing resources that support patients, survivors and caregivers. Information and services may assist the caregiver in helping the patient make decisions, including shifting roles and routines in response to changing demands of YO-CRC. Further studies should investigate psychological well-being and support strategies. Research Sponsor: None.

Doublet (FOLFOX or FOLFIRI) versus triplet (FOLFOXIRI) backbone chemotherapy regimen as first-line treatment of metastatic colorectal cancer: A meta-analysis and systematic review. *First Author: Vishal Jindal, Beaumont Health, Department of Hematology and Oncology, Oakland University William Beaumont School of Medicine, Royal Oak, MI*

Background: Doublet chemotherapy FOLFOX and FOLFIRI are standard for first-line treatment of metastatic colorectal cancer (mCRC). Recently, use of triplet chemotherapy FOLFOXIRI has shown an increased anti-cancer activity but still there is uncertainty regarding first line backbone chemotherapy. Therefore, we conducted this metanalysis to determine the efficacy, safety and outcome of triplet vs doublet chemotherapy. **Methods:** The study protocol was published at PROSPERO (CRD42020166745) and prepared as per PRISMA guidelines. Total 10 studies were included, with sample size of 1536 participants in triplet arm and 1535 participants in doublet arm. The primary outcome is Response rate (RR) and secondary outcomes are Progression-free survival (PFS), Overall survival (OS), post chemotherapy radical (R0) surgical resection rate of metastases. Quantitative synthesis was performed using "R" statistical package. Dichotomous outcomes were summarized using odds ratio (OR) and time to event data was summarized using hazard ratio (HR). **Results:** A total of 678 articles were retrieved. The Medline article search gave a result of 271 article, Embase 296, the Cochrane Library 100 and Clinical tral.gov 11, when searched through April 2020. Total 10 studies were included. All the studies were randomized, open-label, multicenter study. Out of the 10 trials 5 each were phase II and phase III studies. The pooled odds ratio for RR was 1.66 (95% CI 1.42 to 1.93) and PFS was (HR, 0.70; 95% CI, 0.63–0.78) in favor of triplet chemotherapy. There was significant improvement in radical resection (R0) of metastases (OR 1.59; 95% CI, 1.27–1.98) in triplet arm. Triplet arm was also associated with increased toxicity especially neurological events 2.51(0.88-7.16), diarrhea 2.40(1.74-3.31), neutropenia, 2.23(1.71-2.90) and thrombocytopenia 1.94(1.05-3.59). **Conclusions:** Findings in this meta-analysis showed that FOLFOXIRI significantly improves the PFS, RR, OS, and R0 resection rate of overall metastases over the doublet chemotherapy. The incidence of fatal adverse events was found to be more in triplet chemotherapy compared to doublet therapy. Therefore, we concluded that with moderate evidence FOLFOXIRI provide clinically meaningful efficacy benefit at cost of increased toxicity. Research Sponsor: None.

Outcome	Odds ratio (OR)/Hazard ratio(HR) (95% Confidence interval)	Number of studies	Number of participants	I^2 Value (%)
OS	HR - 0.81(0.73-0.89)	7	2235	0
PFS	HR - 0.70(0.63-0.78)	8	2568	19
RR	OR -1.66 (1.42-1.93)	10	2815	0

A novel clinical tool to estimate risk of false negative KRAS mutation in circulating tumor DNA testing. *First Author: Stefania Napolitano, Università Degli Studi Della Campania, "Luigi Vanvitelli", Naples, Italy*

Background: Recently, in metastatic colorectal cancer (mCRC), the detection of RAS mutations by circulating tumor (ct) DNA has recently emerged as a valid and non-invasive alternative approach, overall showing a high concordance with the standard tissue genotyping, giving information on response to EGFRi treatment and resistant mechanisms. However, RAS mutations may be missed due to low levels of any ctDNA in the blood (false-negative), and it has been difficult to distinguish this from patients without a RAS mutation in the tumor (true-negative). We propose a methodology that can be applied to multi-gene ctDNA testing panels to accurately distinguish true- and false-negative tests. **Methods:** 357 subjects with tissue and multi-panel ctDNA testing from MD Anderson (MDACC) were used as a training dataset and 295 subjects from Massachusetts General Hospital (MGH) dataset as the testing dataset. CtDNA panels contained between 65 and 70 genes, allowing evaluation of tumor ctDNA shedding from variant allele fraction (VAF) levels in the plasma from other genes (such as APC and TP53). Based on the relationship between KRAS and the VAFs of other gene, we established a Bayesian model providing a posterior probability of false negative in the ctDNA test, using thresholds of $< 5\%$ (low), 5-15% (medium), and $> 15\%$ (high). This model was validated on the MGH database. **Results:** Across both cohorts, 431 patients were ctDNA wild type for KRAS. Of those, 29 had tissue documenting a KRAS mutation for a false negative rate of 8%. The model provides the posterior probability that a KRAS mutation is indeed present in the tissue given the observed values of allele frequencies for other mutated genes in the plasma. In the validation cohort, a predicted low false negative had no false negatives (0/62, 95% CI 0%-5.8%), while a predicted medium false negative rate was associated with 3% false negative (1/32, 95% CI 0%-16%). In contrast, a high predicted false negative rate was associated with 5% false negative (5/100, 95% CI 1.6%-11%). The results demonstrate the ability of our tool to discriminate between subjects with true negative and false negatives, as a higher proportion of false negatives are observed at higher posterior probabilities. **Conclusions:** In conclusion, our approach provides increased confidence in KRAS ctDNA mutation testing in clinical practice, thereby facilitating the identification patients who will benefit from EGFR inhibition while reducing the risk of false negative tests. Extension of this methodology to NRAS and BRAF is possible, with clinical application enabled by a freely available online tool. Research Sponsor: None.

Impact of time to treatment initiation on real-world (RW) outcomes in metastatic colorectal cancer (mCRC) in the United States. *First Author: Olumide B. Gbolahan, Indiana University School of Medicine, Indianapolis, IN*

Background: The COVID-19 pandemic caused disruptions in cancer care delivery and forced oncologists to make recommendations about safely delaying initiation of therapy. Compared to the adjuvant setting, information about the impact of time to treatment initiation on outcomes in the palliative setting for CRCis scarce. We sought to determine the median time to initiation of systemic therapy (TIT) in mCRC in the US pre-pandemic, and to assess the impact of TIT on survival outcomes. **Methods:** We retrospectively analyzed de-identified data of patients (pnts) with mCRC in the Flatiron Health nationwide EHR-derived database (metastatic diagnosis dates 01/2013 - 04/202000. Demographics, treatments (tx), and outcomes were collected. TIT, the period between diagnosis and initiation of first-line systemic therapy was split into 3 categories (I: < 2 weeks, II: 2- < 4 weeks, and III: 4-8 weeks). Overall survival (OS) was defined from time of diagnosis to time of death. Post-chemotherapy survival (PCS) was time from initiation of first-line therapy to death. Adjusted and unadjusted multinomial logistic regression were used to evaluate the association of demographics and clinical factors with TIT. PCS and OS were estimated using Kaplan-Meier curves. Adjusted (demographics and clinical factors) Cox proportional hazard models were used to estimate the effect of TIT groups on PCS and OS. Category II was control group. **Results:** 7,108 pnts with mCRC who received at least one line of tx were identified. 16% (N = 1132), 34% (N = 2406), and 50% (N = 3570) were in TIT categories I-III. The mean age at diagnosis was 63.4 years, with no significant difference in age (P = 0.6) among categories. Median TIT was 28 days. Multinomial logistic regression showed that compared to TIT II, Hispanic pnts were more likely than Whites to receive chemotherapy in 4-8 weeks (OR 1.4, 95% CI 1.12- 1.7, P= 0.0022). Females were more likely to receive treatment in 4-8 weeks (OR 1.14, 95% CI 1.03- 1.27, P= 0.01). Pnts without documented KRAS testing were more likely to receive tx within 2 weeks (OR 1.3, 95% CI 1.05- 1.48, P= 0.01). Median RW OS favored group III (I: 18.1, II: 22.6, III: 26.9, P< 0.0001). Adjusted Cox regression analysis suggested that Blacks had a higher hazard of death compared to Whites, (HR, 1.14. 95% CI 1.03 -1.27, P = 0.01) Also, compared to TIT of 2-4 weeks, TIT < 2 weeks was associated with lower RW PCS (HR, 1.22, 95% CI 1.11-1.33, P= 0.0001), and RW OS (HR, 1.25, 95% CI 1.14- 1.37, P= <0.0001). In contrast, TIT 4-8 weeks was associated with higher RW PCS (HR, 0.81, 95% CI 0.75- 0.87, P= 0.0001) and RW OS (HR, 0.78, 95% CI 0.72- 0.83 P= <0.0001. **Conclusions:** This RW analysis suggests that pre-pandemic, 50% of patients with mCRC who receive first-line therapy were treated within 4 weeks of diagnosis. We observed disparities in TIT. Paradoxically, RW survival increased with TIT, with the best outcomes reported in those treated in 4-8 weeks. Research Sponsor: None.

Real-world survival outcomes associated with completion of adjuvant chemotherapy for stage III colon cancer. *First Author: Jemma Megan Boyle, London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: The optimal duration of adjuvant combination chemotherapy administered to patients with stage III colon cancer is debated. Our study assessed the effect of completed chemotherapy cycles on 3-year colon cancer-specific mortality, as well as the effect of dose reduction and early discontinuation of oxaliplatin in patients with 100% completion, within a real-world population. **Methods:** 4,147 patients undergoing major resection between 01 June 2014 and 30 April 2017 with pathological stage III colon cancer in the English National Health Service were identified. Chemotherapy data were obtained from linked administrative hospital records and a national chemotherapy dataset. Patients were stratified according to completion of < 50% (< 6 FOLFOX cycles or < 4 CAPOX cycles), 50-92% (6-11 FOLFOX cycles or 4-7 CAPOX cycles) or 100% of cycles (12 FOLFOX cycles or 8 CAPOX cycles). Competing-risk regression analysis for 3-year colon cancer-specific death was performed with adjustment for patient, tumour and hospital-level characteristics to estimate subdistribution hazard ratios (sHR) as a measure of relative risk. **Results:** Patients included within our study were less fit and had increased rates of high-risk disease (T4 and/or N2 pathological staging) compared to the IDEA study. For FOLFOX, the 3-year cumulative incidence of colon cancer-specific death in patients completing 100% of cycles was 15.1% (95% CI, 12.8% to 17.6%), 18.2% (95% CI, 15.3% to 21.3%) for 50-92% of cycles and 26.4% (95% CI, 20.6% to 32.5%) for < 50% of cycles. For CAPOX, this was 12.0% (95% CI, 10.2% to 14.0%) for 100% completion of cycles, 18.2% (95% CI, 15.6% to 21.0%) for 50-92% of cycles, and 19.8% (95% CI, 15.8% to 24.1%) for < 50% cycles. Compared to 100% completion of FOLFOX cycles, colon cancer-specific death was higher in patients recorded as completing < 50% (sHR 2.17; 95% CI, 1.56 to 3.03; $P = < 0.001$) and 50-92% of FOLFOX cycles (sHR 1.40; 95% CI, 1.09 to 1.78; $P = 0.007$). Compared to 100% completion of CAPOX cycles, colon cancer-specific death was higher in patients recorded as completing < 50% (sHR 2.02; 95% CI 1.53 to 2.67; $P< 0.001$) and 50-92% of CAPOX cycles (sHR 1.63; 95% CI 1.27 to 2.10; $P< 0.001$). Dose reduction and early discontinuation of oxaliplatin did not have a statistically significant effect on mortality. **Conclusions:** Patients within the real world setting were more likely to have poor prognostic factors. Those who completed adjuvant chemotherapy for stage III colon cancer had improved survival rates regardless of dose reduction or early discontinuation of oxaliplatin. Research Sponsor: None.

Clinicopathological and molecular characteristics of early-onset stage III colon adenocarcinoma: An analysis of 25 studies with 35,713 patients in the Adjuvant Colon Cancer End Points (ACCENT) database. *First Author: Zhaohui Jin, Division of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: Colon cancer (CC) incidence and mortality have decreased since the 1970s, but the incidence in young adults (20-49 years) is increasing. There are limited data suggesting that, as a group, patients with early onset CRC (eoCC) may have different phenotypic characteristics compared to those with late onset CRC (loCC, age ≥ 50 years). **Methods:** Individual patient data on 35,713 subjects with stage III CC from 25 randomized studies (recruiting between 1987 and 2009) in the ACCENT database were pooled. The distributions of demographics, clinicopathological features, biomarkers, and outcome data were summarized by age group. Overall survival (OS), disease-free survival (DFS), recurrence free rate (RFR), and survival after recurrence (SAR) were assessed by Kaplan-Meier curves and Cox models stratified by treatment arms within studies, adjusting for gender, race, body mass index, performance status, disease stage, grade, risk group, number of lymph nodes examined, disease sidedness and molecular markers. **Results:** Using a 5% difference between age groups as the clinically meaningful cutoff, patients with stage III eoCC (n = 6246) had similar distributions according to gender, race, PS, risk group, tumor sidedness and T/N stage compared to those with loCC (n = 29467). Patients with eoCC were significantly less likely to be overweight (30.2% vs 36.2%) but more commonly had ≥ 12 lymph nodes resected (69.5% vs 58.7%). The eoCC tumors were more frequently mismatch repair deficient (16.4% vs 11.5%), and less likely to have $BRAF^{V600E}$ (5.6% vs 14.0%), suggesting a higher frequency of Lynch syndrome in eoCC. In univariate analysis, patients with stage III eoCC had significantly better OS, DFS, and SAR; the difference between 3-year DFS and RFR strongly suggests the OS/DFS difference between these the eoCC and loCC may be due to increased competing risks and comorbidities in patients with loCC. In multivariate analysis, age at onset lost its prognostic value when outcome was adjusted for molecular markers. The clear relation between age of onset and KRAS/BRAF status was confirmed in the interaction analysis. **Conclusions:** Tumor biology was an important determinant of prognosis regardless of patient age. In multivariate analysis age of onset was not a statistically significant determinant of outcome. Research Sponsor: None.

Clinical efficacy and safety of early adjuvant chemotherapy for stage III colon cancer: Short-term outcomes of a multicenter, randomized, open-label, phase 3 trial. *First Author: Jun Seok Park, Colorectal Cancer Center, Kyungpook National University Medical Center, Daegu, South Korea*

Background: Adjuvant chemotherapy (AC) is recommended to commence within 8 weeks since after surgical resection of stage II or III colon cancer. Results of many retrospective studies showed inferior survival outcomes following delay of AC delay. Moreover, preclinical studies showed that the progression of disseminated cancer cells is profound during the postoperative period. This study is the first prospective trial to evaluate early (≤ 14 days postoperative) AC for patients (pts) with stage III colon cancer. **Methods:** This study is a prospective, multicenter, randomized phase III trial. Pts with pathological stage III colon cancer were enrolled and randomized 1:1 to early AC (starting AC ≤ 14 days after surgery) or conventional AC (starting AC > 14 days after surgery). Pts were recommended to receive 12 cycles of FOLFOX-6 for AC. The primary endpoint was disease-free survival. The secondary endpoints were overall survival, adverse events, surgical complication during AC, and patient-reported outcomes (quality of life) during 1 year after surgery. Herein, safety data, chemotherapy delivery, and quality of life are presented. **Results:** This study randomized 443 pts either early AC arm (221pts) or early AC arm (222 pts) to the during September 2011 to March 2020. 380 pts who received at least one cycle of FOLFOX-6 were included in the safety analysis (192 and 188 in the early and conventional AC arms, respectively). The baseline characteristics of the two groups were well-balanced except for the interval from the surgery to the initial AC. The early and conventional AC arms started their first chemotherapy at median of 13 (4-43 days) and 29 (17-53 days) after surgery ($p < 0.001$), respectively. No significant differences were seen in the median chemotherapy cycles, AC completion, and relative oxaliplatin dose intensity between groups. AC Completion without any change of dose or schedule delay was seen in 18% and 20% in early and conventional AC arms respectively, while dose reduction or delay was 65% and 61%, respectively. Toxicities of grade 3 or more were seen in 28% in both groups. One patient in the early AC arm underwent an emergent operation for anastomotic leakage on the second day of 5-fluorouracil infusion (postoperative day 14). However, the surgical complication was not seen in any other patient. The scores of the European Organization for Research and Treatment of Cancer Quality of Life core 30 questionnaire were similar in both arms at baseline (before starting AC), and 1 month, 3 months, 6 months, and 12 months after surgery. **Conclusions:** Early AC was safe and did not increase either chemotherapy-related adverse events or surgery-related complications during treatment. Moreover early AC did not reduce the quality of life of the pts during 1 year after surgery. This study continues to follow-up the patients for survival outcomes. Clinical trial information: NCT01460589. Research Sponsor: None.

3599 **Poster Session**

Patient-specific meta-analysis of 3 validation studies of the 12-gene colon cancer recurrence score assay for recurrence risk assessment after surgery with or without 5FU and oxaliplatin. *First Author: Greg Yothers, NSABP, NRG Oncology and the University of Pittsburgh, Pittsburgh, PA*

Background: The 12-gene Oncotype DX Colon Recurrence Score assay is a clinically validated genomic assay that evaluates recurrence risks in stage II and stage III colon cancer patients independent of clinical-pathologic features. Improved colon cancer care has reduced recurrence rates since the late 1990's. **Methods:** Pre-specified patient-specific meta-analysis methods were used to estimate 1-, 3- and 5-year recurrence risk combining the 12-gene colon recurrence score (RS) validation studies CALGB 9581, NSABP C-07 and SUNRISE. Cox models had effects for RS result, number of nodes examined (<12 or ≥ 12), T-stage, MMR status, and stage (II, IIIAB or IIIC). Baseline cumulative hazard estimates used the latest two studies to reflect current medical practice. Estimates for surgery, surgery+5FU and surgery+5FU+oxaliplatin treatment were provided by integrating stage-specific 5FU hazard ratios from a meta-analysis of the QUASAR study (2007) and a pooled analysis of NSABP studies (Wilkinson 2010), and oxaliplatin treatment effect estimates from NSABP C-07. Recurrence risk with 5FU alone was not estimated for MMR-deficient patients due to expected lack of 5FU efficacy in these patients (Sargent 2010). **Results:** In the overall population of 2,179 patients, 55%, 32% and 13% were Stage II, IIIA/B and IIIC, 63% had $\geq$12 nodes examined, 90% were T3, and 88% were MMR proficient. Median RS result was 31 (IQR 23–39). RS result and each clinical-pathologic factor contributed independent prognostic information (meta-analysis Wald tests, all $p<.001$). Risk estimates are generally lower than previous RS report risk estimates. For patients with pathological stage II, T3, MMR-proficient tumors with $\geq$12 nodes examined, approximately 40% are expected to have 5-year recurrence risk $\leq$10% with surgery alone based on the distribution of RS results. The table shows example 5-year recurrence risk estimates for specific RS results and clinical-pathologic characteristics. **Conclusions:** The new recurrence risk estimates provide more patient-specific information reflecting more current medical practice than previous reports using RS result, allowing better, more individualized treatment decisions. Research Sponsor: None.

Example 5-year recurrence risk estimates (95% confidence intervals).

T-stage	Nodes ex.	MMR status	Stage	RS result	Surgery alone	Surgery+5FU	Surgery+5FU+oxali
T3	$\geq$ 12	Proficient	II	10	7% (5%, 9%)	5% (4%, 7%)	4% (3%, 6%)
				30	10% (8%, 13%)	8% (6%, 10%)	7% (5%, 9%)
				55	17% (13%, 22%)	13% (10%, 18%)	11% (7%, 15%)
		Proficient	IIIAB	10	15% (11%, 20%)	9% (7%, 13%)	8% (5%, 11%)
				30	22% (17%, 29%)	15% (11%, 19%)	12% (8%, 17%)
				55	34% (26%, 44%)	23% (17%, 31%)	19% (13%, 27%)
		Deficient	IIIAB	10	9% (5%, 13%)	–	4% (3%, 8%)
				30	13% (8%, 20%)	–	7% (4%, 11%)
				55	20% (13%, 31%)	–	11% (6%, 18%)

56% of patients in the meta-analysis population were T3 with $\geq$12 nodes examined.

3600 **Poster Session**

Prognostic value of baseline and early changes of circulating-free (cf) and circulating tumor (ct) DNA in the neoadjuvant (NA) setting of early stage colon cancer (CC). *First Author: Giacomo Bregni, Institut Jules Bordet-Université Libre de Bruxelles (ULB), Brussels, Belgium*

Background: ctDNA is an indicator of minimal residual disease and negative prognostic factor in stage II-III CC treated with surgery +/- adjuvant chemotherapy (CT). No study, however, has ever analysed the prognostic value of this biomarker in CC patients (pts) treated with NACT. We sought to evaluate the prognostic value of baseline and early changes of cf/ctDNA in stage II-III CC pts who were treated with one cycle of NA FOLFOX CT followed by surgery +/- adjuvant FOLFOX CT in the PePiTA trial. **Methods:** PePiTA was a multicentre, single-arm, prospective phase II trial testing *in vivo* tumour chemosensitivity of early stage CC (as assessed by ^{18}F-FDG PET/CT-based metabolic response to one cycle of NA FOLFOX) and its association with long-term outcome (NCT00994864). Plasma samples were prospectively collected at baseline, 2 weeks after one cycle of NA FOLFOX CT, and before surgery. NPY and WIF1 were selected as universal methylation markers for ctDNA and analysed with digital droplet (dd)PCR technology. Data from ddPCR were processed with the QuantaSoft v1.6 software (Bio-Rad). Survival outcome measures were 5-year disease-free survival (DFS) and 6-year overall survival (OS). ROC curve analyses, Kaplan-Meier method, cox proportional hazards models and log-rank tests were used. Statistical analyses were carried out with SPSS v25.0 (SPSS Inc.). **Results:** 80 pts were included (44 ypStage I-II and 36 ypStage III). After a median follow-up of 52.5 months, 5-year DFS and 6-year OS were 68% (95%CI 52-84) and 84% (95%CI 74-94), respectively. Pts with high ($\geq$1600 ng/ml) baseline cfDNA had worse 6-year OS (HR 6.45, 95%CI 1.61-25.84; p = 0.008). Early changes of cfDNA after one cycle of NA FOLFOX CT failed to predict survival (HR DFS 0.96, 95%CI 0.38-2.43; p = 0.92; HR OS 0.62, 95%CI 0.16-2.50; p = 0.50). At baseline, 25 out of 60 (42%) ctDNA-assessable patients were positive. Detectable ctDNA at baseline (HR DFS 2.06, 95%CI 0.65-6.49; p = 0.22; HR OS 3.11, 95%CI 0.57-16.99; p = 0.19) or at any timepoint before surgery (HR DFS 1.65, 95%CI 0.54-5.04; p = 0.38; HR OS 2.80, 95%CI 0.54-14.44; p = 0.22) was not significantly associated with survival. A trend toward a significant association between ctDNA increase at surgery and 5-year DFS was found (HR 3.66, 95%CI 0.81-16.44; p = 0.09). Data on the correlation between early changes of cf/ctDNA and ^{18}F-FDG PET/CT-based metabolic response will be presented at the meeting. **Conclusions:** For the first time, we have shown that baseline cfDNA may predict survival outcome in early stage CC pts treated with NACT. Pending confirmation in larger series, testing for cfDNA at baseline could help select high-risk pts who may benefit from FOxTROT-like, NACT treatment strategies. While analysis of ctDNA in this setting did not appear useful to predict prognosis, these results might be secondary to the small sample size. Research Sponsor: Fondation Les Amis de Bordet.

Association of suboptimal lymph node yield with inferior survival in resected stage 1 colon cancer patients. *First Author: Alexander C. Chacon, University of Rochester Medical Center, Rochester, NY*

Background: A minimum of 12 lymph nodes are required during colectomy to accurately stage colon cancer. Prior studies in stage II colon cancer patients demonstrate association of inadequate lymph node examination (LNE) with worse overall survival (OS). No large-scale analogous studies related to LNE have been completed in stage I colon cancer patients. We evaluated patients with stage I colon cancer to determine the association between lymph node yield and OS. **Methods:** We reviewed the National Cancer Database between 2004-2015 to identify patients with pathologic stage I colon cancer (pT1N0 or pT2N0) who underwent definitive surgical resection. Patients who received radiation therapy or had missing values were excluded. Clinical and demographic characteristics were analyzed. Based on LNE, patients were stratified into 4 cohorts (LNE, 0-5, 6-11, 12-19, 20+) and 2 cohorts (0-11, 12+). Univariable and multivariable analyses were performed to identify variables associated with OS. Kaplan-Meier survival curves were computed to compare the cohorts. **Results:** We included 81,909 patients for analyses. Median age at diagnosis was 69. A majority were female (51.1%), white (83.8%), received care in a community cancer program (59.5%), and had a Charlson-Deyo score of 0 (66.6%). Only 0.7% of patients had a margin positive resection with a 2.5cm median tumor size. Patients were similarly split between pT1 and pT2. Suboptimal LNE was noted in 27.8% of patients. Patients with LNE were distributed - 10.7% (0-5), 17.1% (6-11), 43.4% (12-19) and 28.9% (20+). Postoperative 30-day mortality was 1.9%. 521 (0.7%) received systemic therapy. Ten-year survival in patients with 0-5 LNE was 52.8% compared to 60.1% with 20+ LNE. On multivariable analyses, patients aged $\geq$ 69, male sex, increasing tumor size (quartile), pT2 staging and a higher Charlson-Deyo score independently predicted worse OS ($p < 0.001$). LNE categories were significantly associated with OS ($p < 0.001$) (Table). On regrouping into 0-11 and 12+ LNE groups, 0-11 LNE group predicted worse OS (HR 1.22, $p < 0.001$). On multivariable analysis, the above variables continued to show similar association with OS ($p < 0.001$). **Conclusions:** Our study demonstrates that lymph node yield is associated with overall survival in patients with stage 1 colon cancer undergoing surgical resection. Furthermore, patients with suboptimal lymph node yield are associated with an inferior overall survival compared to those with optimal lymph node yield. Moreover, this study finds that a large number of patients ($>$ 25%) continue to have suboptimal lymph node yields. Future efforts should focus on improving the lymph node yield with optimal efforts by the surgeon and pathologist. Future studies should examine the role of systemic therapy in patients with inadequate lymph node yield. Research Sponsor: None.

Phase I study of transarterial chemoembolization of lung metastases. *First Author: Franz Edward Boas, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lung chemoembolization (via the bronchial or pulmonary artery) is a new treatment option for unresectable and unablatable lung metastases. **Methods**: 10 patients with unresectable and unablatable lung, endobronchial, or mediastinal metastases, who failed systemic chemotherapy, were enrolled in this single center, single arm, phase I trial. Pulmonary and bronchial angiography was performed in all patients, to determine the blood supply to the lung metastases. Based on the angiographic findings, bronchial or pulmonary artery chemoembolization was performed, using a lipiodol / mitomycin emulsion, followed by spherical particles. Technical success, safety, efficacy, and pharmacokinetics were evaluated. Wilcoxon signed-rank test was used to compare change in size of treated versus untreated tumors. **Results**: On angiography, all patients had lung metastases that were hypervascular compared to normal lung. 90% of patients had lung metastases supplied by the bronchial artery, and 10% were supplied by the pulmonary artery. Technical success rate of intra-tumoral drug delivery was 100% (95% CI: 76-100%). There were no severe adverse events, and all patients met criteria for discharge 4 hours post procedure. Response rate of treated lesions was 10% by RECIST and 40% by PERCIST. Treated tumors were mostly stable to decreased in size after chemoembolization (median change in size: 0%; IQR: -11% to 2%; mean: -4%), and untreated tumors were mostly increased in size (median change in size: 10%; IQR: 0% to 17%; mean 9%; p= 0.02). Intra-tumoral lipiodol retention at 4-6 weeks was correlated with decreased tumor size and metabolic activity. Pharmacokinetics showed that 45% of the mitomycin dose underwent burst release in 2 minutes, and 55% of the dose was retained intratumorally with a half-life $>$ 5 hours. Initial tumor-to-plasma ratio of mitomycin concentration was 380. Half-life of intratumoral lipiodol retention was 16 days. *In vitro* experiments showed 50% emulsion separation in 6.2 days, and 50% drug release in 7.1 hours. **Conclusions**: Lung chemoembolization can safely treat lung, mediastinal, and endobronchial metastases, with minimal systemic toxicity. High intratumoral drug concentrations after chemoembolization can overcome chemoresistance. Clinical trial information: NCT04200417. Long-term outcome of a phase III trial on neoadjuvant chemoradiation with capecitabine and irinotecan in patients with locally advanced rectal cancer: Updated results of the CinClare trial. *First Author: Ji Zhu, Fudan University Cancer Center, Shanghai, China*

Background: Adding UGT1A1-guided irinotecan to capecitabine-based neoadjuvant chemoradiotherapy (CRT) significantly increased the pathological complete response (pCR) rate nearly doubling [J Clin Oncol. 2020 Dec 20;38(36):4231-4239]. Here, results of long-term outcome are reported. **Methods:** Eligible patients with clinical stage II/III rectal adenocarcinoma, UGT1A1 genotype *1*1 or *1*28 were randomized to the control group: pelvic radiation of 50 Gy/25 fractions with concurrent capecitabine, followed by a cycle of oxaliplatin and capecitabine; or the experimental group: radiation with capecitabine combined with weekly irinotecan 80 mg/m2 for patients with *1*1 or 65 mg/m2 for patients with *1*28, followed by a cycle of irinotecan and capecitabine. Surgery was scheduled for 8 weeks after completion of CRT. Five cycles of adjuvant XELOX chemotherapy were administered regardless of the pathologic result. Patients were stratified by UGT1A1 genotype (*1*1 vs. *1*28) clinical T stage (cT3 vs. cT4) and tumor distance from the anal verge ($\leq$5 cm vs. $>$ 5 cm). The primary end point of pCR was reached. Survival time was calculated from the date of randomization to the date of event or the last follow-up. Secondary endpoints were defined as local failure for local control (LC), tumor recurrence or death from any cause for disease-free survival (DFS), and death from any cause for overall survival (OS). **Results:** Of the 360 patients initially enrolled, 356 were evaluated as the modified intention-to-treat population (n = 178 in both groups). A total of 311 patients underwent surgery and pCR was achieved in 80 patients, another 10 patients undergo a watch-and-wait approach after achieving cCR. With a median follow-up time of 48 months (Q25-Q75, 41-55 months), 57 deaths (33 and 24), 17 local failures (11 and 6) and 69 distant metastases (37 and 32) were observed, respectively. Overall, the 4y LC rate were 93% and 96% in control and experimental groups, with estimated LC HR of 0.53 (95% confidence interval [CI], 0.20-1.43), the 4y DFS rates were 69% and 74% (HR = 0.74, 95% CI 0.49-1.10), and the 4y OS were 80% and 85%, (HR = 0.70, 95% CI 0.42-1.19), respectively. In the subgroup analysis, irinotecan showed a significant improvement in DFS (HR = 0.77, 95% CI 0.61-0.98) and OS (HR = 0.71, 95% CI 0.51-0.98) in UGT1A1 *1*1 patients. **Conclusions:** The addition of irinotecan to standard capecitabine-based CRT had a tendency towards improving LC, DFS, and OS, but without reaching statistical significance. UGT1A1 *1*1 patients seem to benefit the most from irinotecan. Molecular studies and subsequent therapies should be considered. Clinical trial information: NCT02605265. Impact of radiotherapy for local control in T3 N0 rectal cancer managed with total mesorectal excision: A systematic review and meta-analysis. *First Author: Jesus C. Fabregas, Billings Clinic Cancer Center, Billings, MT*

Background: Total mesorectal excision (TME) significantly improved rectal cancer outcomes. Radiotherapy (RT) is recommended for T3N0 rectal cancers, though benefit has not been demonstrated in combination with TME for this specific population. This meta-analysis could provide evidence to ameliorate toxicities from treatment. **Methods:** Randomized clinical trials and observational studies published until October 18, 2020 were identified via PubMed and Embase. *Objective:* To determine whether RT decreased the risk of local recurrence (LR) in T3N0 rectal cancer managed with TME. *Study Selection and Extraction:* Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines were observed for literature search, extraction, and screening. Studies with LR data specific to T3N0M0 rectal cancer, treated with and without RT, were included. Reviews, non-English articles, and non-TME studies were excluded. Newcastle Ottawa Scale (NOS) evaluated quality. Meta-analysis was done with a random-effects model. *Main outcome:* Meta-analysis of the relative risk of LR was conducted. **Results:** 7,246 studies were screened, 134 full-text studies assessed for eligibility, 5 studies were included in the final analysis. No randomized data reported results specific to our study population. Five retrospective cohort studies involving 932 participants reported LR outcomes. The median follow-up ranged from 38.4 months up to 71 months. Four studies took place in Asia (797 participants) and one in North America (135 participants) (Table). Quality according to NOS ranged from 7–9. The estimated average relative risk for LR at 5 years was 0.63 (95% CI 0.31–1.29; I^2=41.8%) when RT was used. **Conclusions:** This meta-analysis' supports that there is no clear benefit to LR with the addition of RT in T3N0 patients with rectal adenocarcinoma undergoing TME. As meta-analysis was limited to retrospective cohort studies, there is concern for bias. Registration Prospero number CRD42020216058. Research Sponsor: None.

H101 treatment of hepatic metastasis of colorectal cancer with recombinant human adenovirus 5 injection: A phase I clinical trial-TROJAN 021. *First Author: Yang He, Shanghai Tenth People's Hospital, Tongji University, Shanghai, China*

Background: Recombinant human adenovirus serotype 5 injection (H101), obtained through genetic engineering to delete the E1B domain and part of the E3 domain and then selectively replicated in tumor cells, has been approved in 2005 for the local treatment of nasopharyngeal carcinoma and head and neck cancers. This trial aimed to evaluate the safety and the preliminary treatment efficacy of H101 combined with standard treatments in patients with liver metastases from colorectal cancer. **Methods:** In this phase 1, dose-escalation trial (ChiCTR1900027922), 17-75 years old colorectal cancer patients with unresectable liver metastases that failed to first-line therapy were included at The Tenth People's Hospital Affiliated to Tongji University between 2018.9 and 2020.12. All patients received H101 combined with standard therapy (bevacizumab + mFOLFOX6/FOLFIRI). Ultrasound-guided injection of H101 into the liver metastases was performed for all patients, with one of the following doses: 5×10^{11} vp/injection for the low, 1×10^{12} vp/injection for the moderate, 2×10^{12} vp/injection for the moderate-high, and 3×10^{12} vp/injection for the high dose groups. Intravenous infusion of bevacizumab (5 mg/kg) and administration of standard-dose mFOLFOX6 or FOLFIRI within 48 h after the intratumor injection was performed. The primary endpoint of the trial was the maximum tolerated dose (MTD). The secondary endpoints included safety, tumor responses, and tumor marker CEA. The adverse events (AEs) were monitored according to the NCI Common Terminology Criteria for Adverse Events (CTCAE, Version 3.0) and evaluated within 1 week after injection. Imaging examinations were performed for all patients to evaluate the tumor responses, according to the irRECIST. **Results:** Finally, 8 patients were included; the numbers of patients in the 4 groups were 1, 3, 3, and 1, respectively. MTD was not observed in this study. No grade $>$4 AEs were observed. The major AE included fatigue (5/8), fever (4/8), shiver (3/8), abdominal pain (3/8), and night sweat (3/8). The tumor responses included partial response in one patient (moderate dose group), stable disease in 6 patients (1, 1, 3, and 1 in the low, moderate, moderate-high, and high dose groups, respectively), and progressive disease in 1 patient (moderate group). No dose-effect response was found. The tumor marker CEA was reduced in 6 of the 8 patients, including 1 (1/1), 3 (3/3), 2 (2/3), and 0 patients in the low, moderate, moderate-high, and high-dose groups, respectively. **Conclusions:** The safety of H101 combined with standard therapy for liver metastases from colorectal cancer is acceptable, which also shows certain preliminary efficacy. The phase 2 trial is now ongoing. Clinical trial information: ChiCTR1900027922. Research Sponsor: Shanghai Science and Technology Commission Industry-University-Research Medical Project (No: 18DZ1910102).

Accurate early-stage colorectal cancer detection through analysis of cell-free circulating tumor DNA (ctDNA) methylation patterns. *First Author: James M. Kinross, Section of Biosurgery & Surgical Technology, Department of Surgery & Cancer, Imperial College London, London, United Kingdom*

Background: Colorectal cancer (CRC) screening programs suffer from poor uptake and biomarkers have limited diagnostic accuracy. The measurement of the methylation status of tumor-derived cell-free DNA in plasma may address these challenges. We used a targeted methylation panel, tumor-derived signal deduction and machine learning algorithm to refine a blood test for the detection of early-stage CRC. **Methods:** This was a prospective, international multicenter observational cohort study. Plasma samples were collected either prior to a scheduled colonoscopy as part of standard colorectal cancer screening or prior to colonic surgery for primary CRC. Differentially methylated regions (DMRs) were initially selected by analyzing CRC and control tissue samples with whole genome bisulfite sequencing. A targeted sequencing assay was designed to capture these DMRs in plasma ctDNA. Individual sequencing reads were evaluated for cancer-specific methylation signal and scores calculated for each DMR in a sample. A panel of methylation scores originating from 203 DMRs was used in a prediction model building and validated in a test cohort of patients. **Results:** Calculated scores were used to train a machine learning model on 68 ctDNA samples from 18 early stage (I-II) and 16 late-stage (III-IV) CRC patients and 34 age, BMI, gender and country of origin matched neoplasia-free controls (median age 63 [50-74], mean BMI 27 [19.5-37], female 50%, Spanish and Ukrainian population, distal cancers 50%). This model was then applied to an independent set of subjects from Spanish, Ukraine and Germany, including 36 stage I-IV cancer patients (median age 61.5 [55-82], BMI 28 [16-39], female 47%, 42% of the tumors were distal) and 159 age and sex matched controls. 87 of the control patients had a negative colonoscopy finding (cNEG), 19 had hyperplastic polyps (HP), 37 had small non-advanced adenomas (NAA) and 16 were diagnosed with other benign gastrointestinal diseases (GID). The model correctly classified 92% (33/36) of CRC patients. Sensitivity per cancer stage ranged from 83% (5/6) for stage I, 92% (11/12) for stage II, 92% (12/13) for stage III to 100% (5/5) for stage IV. Specificity of the model was 97% (154/159), with 100% (37/37) NAA, 94% (15/16) GID, 95% (18/19) HP and 97% cNEG patients correctly identified. Lesion location, gender, BMI, age and country of origin were not significantly correlated to prediction outcome. **Conclusions:** Methylation sequencing data analyzed using read-wise scoring approach combined with a machine-learning algorithm is highly diagnostic for early-stage (I-II) CRCs (89% sensitivity at 97% specificity). This method could serve as the basis for a highly accurate and minimally invasive blood-based CRC screening test with significant implications for the clinical utility of ctDNA in early-stage cancer detection. A phase II study of capecitabine plus concomitant radiation therapy followed by durvalumab (MEDI4736) as preoperative treatment in rectal cancer: PANDORA study first-stage.

First Author: Stefano Tamberi, Ospedale per Gli Infermi, Faenza, Italy

Background: The combination of capecitabine plus long course radiotherapy (RT) is the standard preoperative therapy in cT3-4 cN+ rectal cancer. Pathologic Complete remission (pCR) can be considered as surrogate end point of efficacy of treatment in terms of disease free survival (DFS). Preclinical data points heavily toward a strong synergy between RT and immune treatments. **Methods:** This is a prospective phase II, open label, single arm, multi-centre study, conducted with support from AstraZeneca, in patient with locally advanced rectal cancer who receive concomitant CT/RT therapy (825 mg/m2 twice daily capecitabine every day and 5040 cGy radiotherapy for 5 days per week for 5 weeks) followed by durvalumab (1500 mg Q4W for 3 administrations). Surgery is performed after 10-12 weeks from neoadjuvant therapy. The primary endpoint is pCR rate after at least 1 cycle of durvalumab. The sample size has been estimated by using the optimal Simon's two-stage design. If more than 4 complete responses are observed in the first 19 enrolled patients, 36 additional patients will be accrued for a total of 55 evaluable patients. **Results:** Between November 2019 and July 2020, 20 patients were accrued and 19 were evaluable for study objectives, concluding the first stage of the trial. Baseline characteristics of the first 19 evaluable patients enrolled are listed in the table. All patients received 3 infusions of durvalumab; 18 patients underwent surgery after a median of 13 weeks from CHT/RT end. Five complete pathological responses (ypTON0) were observed, allowing to proceed to the second stage. About toxicity, four patients had Grade 3-4 adverse events (AE); the most frequent G3-4 AE related to the neoadjuvant therapy were anemia (n=1), diarrhea (n=2) and neutrophenia (n=2). No grade 3 and 4 adverse events related to Durvalumab treatment were observed. Eight patients had G1-2 AE related to durvalumab, the most common being asthenia (n=2) and nausea (n=2). **Conclusions:** At the end of study's first stage the preoperative treatment with radiotherapy plus capecitabine followed by durvalumab showed a safe toxicity profile and promising activity in terms of pCR rate. The second part of the trial is ongoing, and the accrual is under completion (44 patients enrolled as of 10 February 2021). Clinical trial information: NCT04083365. Research Sponsor: None.

Minimal residual disease by circulating tumor DNA analysis for colorectal cancer patients receiving radical surgery: An initial report from CIRCULATE-Japan.

First Author: Hiroki Yukami, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Circulating tumor DNA (ctDNA) analysis can be used to predict the risk of recurrence by detecting molecular residual disease (MRD) in patients with colorectal cancer (CRC). We are conducting a prospective observational study to monitor MRD status in patients with clinical stage II–IV or relapsed CRC amenable to radical surgical resection (GALAXY study), as part of the CIRCULATE-Japan, a nationwide ctDNA-guided precision adjuvant therapy project. **Methods:** Analysis of ctDNA is being performed at pre- and post-surgery timepoints and will continue periodically for up to 2 years using Signatera, a personalized, tumor-informed ctDNA assay that is designed to track 16 patient-specific somatic variants based on whole-exome sequencing of tumor tissue. The association of peri-operative ctDNA status with clinicopathological characteristics was investigated. **Results:** As of January 13, 2021, 941 patients have been enrolled in the GALAXY study, of which 400 patients had their pre-operative ctDNA status evaluated. Of the 400 patients, baseline ctDNA was detected in 92% (367/400) of the patients: consisting of 35 patients with pathological stage (pStage) I, 135 with pStage II, 152 with pStage III, and 78 with pStage IV or relapsed disease (pStage IV/R). Patient-specific Signatera assays targeting 16 variants were designed for 100% of the patients. Out of the 6400 designed variants 99.3% passed quality control in the plasma analysis and produced the final results. Among 4425 genes selected for 400 patients, 3330 genes were selected for only one patient, while *TP53* was the most commonly selected in 113 patients (28%). Median ctDNA levels, measured in mean tumor molecules per mL of plasma and ctDNA detection rate, stratified by stage are presented in table. Positive ctDNA status post-surgery was significantly associated with advanced pStage, pT and pN, and lymphovascular invasion. Of the 13 patients with recurrence, 10 were detected with a positive ctDNA at 4-weeks post-surgery, before confirmation of recurrence by the radiological imaging. **Conclusions:** Preoperative ctDNA detection rates were observed to be in >90% in patients with pStage II–III by personalized ctDNA assay based on unique somatic variants, specific to each patient. ctDNA- based MRD detected post-surgery (4W) was significantly associated with certain known clinicopathological factors for recurrence with ctDNA positivity associated with a very short-term of recurrence. Clinical trial information: 000039205. Research Sponsor: Japan Agency for Medical Research and Development.

Pharmacologic ascorbate enhances the therapeutic index of ATM-inhibitor based chemoradiation for colorectal cancer.

First Author: Cameron Callaghan, University of Iowa Hospitals and Clinics, Iowa City, IA

Background: Ataxia telangectasia mutated protein (ATM) is one of the key sensors of DNA damage and specific inhibitors of ATM are potent radiosensitizers. However, their clinical utility with radiation (RT) is limited because they lack tissue specificity and increase normal tissue injury. Pharmacologic (high dose) ascorbate ($P\text{-}AscH^-$) selectively increases oxidative stress in tumors while functioning as a donor antioxidant and reducing RT damage in normal tissues. We hypothesized that $P\text{-}AscH^-$ could enhance the therapeutic index of ATM-inhibitor based chemoradiation (CRT) for colorectal cancer (CRC) by simultaneously enhancing efficacy and reducing RT bowel injury. **Methods:** Human HCT116, SW480, and HT29 and murine CT26 and MC38 CRC models were used. Clonogenic survival was assessed following single-fraction RT (2-8 Gy) +/- $P\text{-}AscH^-$ (5 pM/cell) +/- veliparib (PARP), VE821 (ATR), or KU60019 (ATM). Catalase expression was induced using HCT116 cells expressing a doxycycline inducible catalase transgene. DNA double strand breaks (DSBs) were quantified using neutral comet assays 0-24 hours post RT. Cell cycle phases were assessed using flow cytometry. ATM and pATM localization were assessed using IF. Jejunal toxicity was assessed using IHC in fixed tissues following single fraction (10 Gy) whole abdominal RT in c57blj/6 mice. Tumor growth delay was assessed following RT (5 Gy x 3) +/- drug treatment in unilateral flank tumors. **Results:** Veliparib, VE821, and KU60019 were potent radiosensitizers in HCT116, SW480, HT29, MC38, and CT26 CRC tumor models and $P\text{-}AscH^-$ further reduced clonogenic survival with DRIs in all lines except for HT29. In contrast, $P\text{-}AscH^-$ enhanced survival of cultured HUVEC and FHs-74 cells exposed to RT. Enhanced cell kill with $P\text{-}AscH^-$ is H_2O_2 mediated as it is completely attenuated by inducible catalase expression. $P\text{-}AscH^-$ significantly increased the number of DNA DSBs in tumors after RT *in vitro*. Despite the increase in DNA DSBs, $P\text{-}AscH^-$significantly decreased nuclear localization of activated P-ATM after RT and significantly decreased the fraction of cells in G2/M phases of the cell cycle. *In vivo,* RT + $P\text{-}AscH^-$ + KU60019 induced more tumor growth delay/clearance than all other combinations in unilateral MC38 or HCT116 flank tumors. Finally, $P\text{-}AscH^-$ significantly reduced loss of jejunal crypt cell density, epithelial architecture, and markers of lipid and protein oxidation following whole abdominal RT. **Conclusions:** $P\text{-}AscH^-$ selectively enhances the efficacy of ATM-based CRT in CRC tumor models while simultaneously decreasing RT-mediated small bowel toxicity. In tumors, $P\text{-}AscH^-$ enhances DNA DSBs by stimulating an H_2O_2 flux and prevents activation of DNA repair pathways and cell cycle checkpoints by inhibiting RT-induced activation of ATM. Selective radioprotectors like $P\text{-}AscH^-$ could facilitate the clinical translation ATM inhibitors as radiosensitizers. Research Sponsor: RSNA Resident seed grant #RR1914.

Evaluating longitudinal toxicity of cetuximab in patients with metastatic colorectal cancer (mCRC): A pooled analysis from 1,302 patients in the ARCAD database.

First Author: Guilherme Lopes, Mayo Clinic, Rochester, MN

Background: Chronic lower grade adverse events (AE) can negatively affect a patient's quality of life but it is difficult to capture using a traditional toxicity reporting approach. A novel AE reporting method was recently developed to describe, summarize, and present longitudinal AE profiles(Lopes et al, 2021). We leveraged this method to describe and compare the AE profiles of doublet chemotherapy (DC) + Cetuximab and DC alone in mCRC patients. **Methods**: This AE reporting method utilizes two additional AE metrics to complement the maximum (max) toxicity grade usually reported in clinical trials. Onset time indicates the time period in which max grade for an AE occurred for the first time, defined here as "early" (i.e. within first 42 days) and "late" (i.e. after the 42^{nd} day). AE Load (AEL) indicates the overall severity of an AE in the entire treatment. AEL varies from 0 to 1. Higher AEL indicates a worse overall severity of that AE over time. AEL is the key metric for describing chronic AE. We included patients receiving DC + cetuximab (n = 738) and DC alone (n = 564 [ref group]) from two randomized first-line trials in the ARCAD database. Diarrhea, rash, hand-foot syndrome (HFS), fatigue, anorexia, and mucositis were examined and adjusted for backbone (FOLFOX vs. FOLFIRI), ECOG PS, sex, site location, dose reduction, and treatment length. **Results**: For rash, DC + cetuximab had a higher risk of G3+ (21% vs. 0.5%; odds ratio {OR} [95% confidence interval {CI}] = 50 [16,157], $p < 0.001$), increased overall severity over the entire treatment (AEL = 0.257 vs. 0.069; Adjusted difference in means–M_{diff} [95% CI] = 0.22 [0.21,0.23] , $p < 0.001$), and increased risk of early onset (67% vs. 33%; OR [95% CI] = 4.3 [2.7,6.7] , $p < 0.001$). DC + cetuximab also had higher AEL for rash across max grades ($p < 0.001$ within G1, G2, and G3+). For HFS, DC + cetuximab had a higher risk of G3+ (OR [95% CI] = 6.0 [2.5,14], $p < 0.001$), increased overall severity (AEL = 0.139 vs. 0.087; M_{diff} [95% CI] = 0.03 [0.03,0.04], $p < 0.001$), and slightly earlier onset (12.4 vs. 13.9 weeks; M_{diff}, weeks [95% CI] = -4.9 [-0.80,-9.0], p = 0.021). Within each max grade, DC + cetuximab did not have higher AEL of HFS. No associations were found for diarrhea, fatigue, anorexia, or mucositis. **Conclusions**: The addition of cetuximab is associated with higher grade, more persistent, and more immediate rash. The higher severity in HFS with the addition of cetuximab appears to be related to higher grade but not chronic HFS. This method may be useful to describe different strategies, e.g. intermittent cetuximab. It provided a comprehensive view of acute and chronic toxicity profiles supporting its potential interest as new metrics in clinical trials. Lopes GS, Tournigand C, Olswold CL, et al. Adverse event load, onset, and maximum grade: A novel method of reporting adverse events in cancer clinical trials. Clinical Trials. 2021;18(1):51-60 Research Sponsor: None.

Influence of preoperative chemoradiation on tumor-infiltrating lymphocytes in locally advanced rectal cancer: The STAR-01 cohort. *First Author: Francesca Negri, University Hospital of Parma, Parma, Italy*

Background: Preoperative chemoradiotherapy may increase antitumor immunity through enhancing T-cell activation and tumor infiltration. These effects could possibly sensitize tumors to immunotherapies, including checkpoint inhibitors. We explored whether preoperative chemoradiation for locally advanced rectal cancer induces immunologic changes and if the post-operative biological parameters are associated with tumor regression grade (TRG sec. Ryan –AJCC Eight ed.). **Methods:** The multicenter STAR-01 study compared a standard preoperative chemoradiotherapy regimen (50.4 Gy in 28 daily fractions with concomitant infused fluorouracil at the dose of 225 mg/m^2/d) with the same regimen plus oxaliplatin given weekly at the dose of 60 mg/m^2 in patients with locally advanced rectal cancers. Paired pre- and post-operative specimens were available for 58 patients from this trial and were analyzed by immunohistochemistry. The immunoistochemical analysis was performed with a panel of immune cells and associated factors as CD3, CD20, CD4/CD8, PD1. The pattern of tumor infiltrating lymphocytes (TILs) and related infiltrating lymphocytes (RILs) was also evaluated. Response to pre-operative chemoradiotherapy was assessed according to TRG. **Results:** After therapy we observed a decreased CD4/CD8 ratio ($p < 0.001$) and reduced expression level of CD20 ($p < 0.001$). The expression level of CD3+ and PD-1+ cells after therapy did not change significantly. The relative increase of lymphocytes CD8+ inside CD4/CD8 ratio evaluated on post-operative samples was significantly associated with TRG 0 ($p < 0.001$). **Conclusions:** Our data suggest that chemoradiation may induce an enrichment of CD8+ T lymphocytes and this translates in better response to chemoradiation. The new frontier of best treatment could be the use of specific immune cells (T lymphocytes) to trigger the system's immune response against disease. Research Sponsor: SNUPI Onlus.

Impact of the COVID-19 pandemic in treating gastrointestinal (GI) cancer patients receiving systemic anticancer treatment (SACT): The Guy's Cancer Centre experience. *First Author: Jose Roca, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: The COVID-19 pandemic has hugely affected the spectrum of cancer care. Worldwide healthcare systems have rapidly reorganized cancer services to ensure patients continue to receive essential care whilst optimizing the use of systemic anti-cancer treatments (SACT) and minimizing exposure to SARS-CoV-2 infection. Our study aimed to identify the outcome of patients with gastrointestinal (GI) cancers in our Cancer Centre during the pandemic compared to the same period in 2019. **Methods:** Retrospective analysis of all GI patients receiving any SACT at Guy's Cancer Centre from the 1 March-31 May 2020 and 2019. Demographic data (age, ethnicity, socio-economic status (SES), Performance status, cancer and SACT characteristics (type, intent and treatment-line) were collected during both periods. Also we collated the number of COVID-19 infections confirmed by PCR and severity defined by the WHO classification. Patients with clinical or radiological diagnosis were excluded. **Results:** 567 patients received SACT in 2019 and 417 patients in 2020 (26.4% less). No differences were observed in the demographic or tumour type characteristics. Commonest cancers in both periods were similar: colorectal (47.1, 47%), oesophago-gastric (29, 27.6%), pancreatic-biliary and NET tumours (23.8, 25.4%). However, there were a higher proportion of patients with advanced disease treated in 2020 (70.3% versus 55.2%). Treatment intent was similar in both years: radical (3.5 vs 3.8%), adjuvant (18.2% vs 17.3%), neoadjuvant (15.3% vs 12.7%) and palliative (63% vs 66.2%). There was an increase in the proportion of patients treated in the palliative first line setting (63.8% in 2020 vs 47.6% in 2019) and a reduction in the proportion of third or more treatment (8.7% versus 16.2%) mainly in the colorectal patients. Of 417 GI patients receiving SACT, 14 (3.35%) were diagnosed with COVID-19 infection. Of these, 64.3% were male, 92.9% were low SES and 35.7% were of Caucasian ethnicity. Colorectal cancer was the commonest (57.1%) tumour-type in the COVID-positive group and 57.1% had advanced disease. All the patients that died from COVID-19 were male. 13 patients were on chemotherapy and 1 was on targeted/biological treatment. None was in immunotherapy (n=4). Only one patient was neutropenic (grade 1). 8 patients (57.1%) had severe infection and there were 3 (21.4%) COVID-related deaths. **Conclusions:** Our study shows the delivery of SACT through the COVID-19 pandemic is relatively safe with low COVID-related mortality rate. It also reflects how we tailored the delivery of anti-cancer treatments to reduce the possible detrimental myelo-suppressive toxicities that could potentially put GI patients at higher risk of severe SARS-CoV-2 infection. This is crucial data that can inform anti-cancer treatment decision making during the protracted COVID-19 pandemic. Research Sponsor: None.

3613 **Poster Session**

Multi-omics longitudinal analyses in stages I to III CRC patients: Surveillance liquid biopsy test to predict early recurrence and enable risk-stratified postoperative CRC management. *First Author: Xuanhui Liu, Guangdong Provincial Key Laboratory of Colorectal and Pelvic Floor Diseases, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: One-third of colorectal cancer (CRC) recurs following curative surgery and chemotherapy. Accordingly, novel methods are needed to predict recurrence to enable clinical course mitigating strategies. Serial monitoring of plasma by mass spectrometry (MS) and multi-omics modeling (MMO) of CRC relapse chronology provide the framework for liquid biopsy test development to supersede existing imaging modalities such as CT scans according to relapse related pathologies. We hypothesized that plasma MS and MMO analysis of relapse related pathologies can deconvolute high risk stratification for CRC recurrence within the cancer continuum of care pre/post-surgery and/or pre/post adjuvant chemotherapy (ACT). **Methods:** 189 CRC patients (Stage I-III) underwent one of three treatment modalities: Modality 1 (Surgery followed by ACT), Modality 2 (Surgery only), Modality 3 (Neoadjuvant chemotherapy followed by surgery and ACT). Plasma samples (n = 441) were collected from patients before surgery, 30 days post-op, and every 3 months until death or month 24 whichever came first. The MMO approach was used to analyze biological features encompassing native peptides, proteins, metabolites, lipids, and ceramides. MMO panels were developed comprising the significantly perturbed features as per the treatment modalities. These panels were used to predict relapse from plasma collected pre-op, 30-day post-op or after adjuvant chemotherapy. CEA levels were monitored in parallel. **Results:** Follow-up data was available for 135 patients (Stage I-III) and 25/135 had evidence of radiological recurrence. Irrespective of the treatment modality, longitudinal follow-up using the MMO panel was able to predict disease recurrence greater than 7 months before clinical progression was confirmed by CT scan. There was no significant correlation between longitudinal CEA levels and recurrence status, hence CEA levels alone did not provide any lead time advantage over the MMO panel or radiological surveillance. Kaplan-Meier (KM) survival analysis revealed that patients that were MMO panel positive had a poor survival irrespective of treatment modalities used: Modality 1 (HR = 6.2, p value = 0.003, test immediately post-surgery and immediately before ACT; HR = 31.6, p value = 0.01, test immediately after ACT); Modality 2 (HR = 11.2; p value = 0.01, test immediately after-surgery); Modality 3 (HR $>$ 40, p value = 0.08, test immediately after neo-ACT and before-surgery; HR $>$ 40, p value = 0.004, test immediately after-surgery). **Conclusions:** The MMO panel predicts CRC recurrence several months prior to detection by conventional CT scans, thus providing opportunity for alternative therapeutic strategies much earlier in the disease course. TPS3614 **Poster Session**

A randomized phase III study of immune checkpoint inhibition with chemotherapy in treatment-naive metastatic anal cancer patients: A trial of the ECOG-ACRIN cancer research group (EA2176). *First Author: Marc Thomas Roth, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Anal cancer is growing in annual incidence globally and human papillomavirus (HPV) remains the predominant risk factor underlying its development. Due to its relative rarity, clinical trials in anal cancer have historically been difficult to conduct and treatment options for metastatic disease remain limited. Carboplatin/paclitaxel (CP) was compared to cisplatin/5-fluorouracil (historical standard of care) in a recent randomized phase II clinical trial (InterAACT; EA2133) in treatment-naïve metastatic anal cancer, finding that response rates were equivocal, but that overall survival (OS) was significantly longer in the CP arm (20 months vs 12.3 months, p = 0.014). Additionally, reduced grade 3/4 toxicities were seen in the CP arm. NCI9673, a single-arm phase II study, established safety and efficacy of nivolumab in previously-treated metastatic anal cancer. Progression-free survival (PFS) was 4.1 months (95% CI 3.0-7.9) and OS was 11.5 months (95% CI 7.1-not estimable). Multiple randomized trials in lung cancer have demonstrated efficacy of platinum-based chemotherapy combined with checkpoint inhibitors. Together these studies form the rationale behind combining CP and nivolumab in treatment-naïve metastatic anal cancer. **Methods:** EA2176 (NCT04444921) is the first NCTN phase III randomized clinical trial in treatment-naïve metastatic anal cancer. Stratification factors include HIV status and history of chemoradiation for curative intent. Patients will be randomized to carboplatin (AUC = 5, Day 1) plus paclitaxel (80mg/m2, Days 1, 8, 15) +/- nivolumab 240mg IV (Cycle 1 = Days 1, 15; Cycle $\geq$2 = Day 1, 480mg) q 28-days until disease progression or treatment intolerance. CP will be given for up to 6 cycles, while nivolumab will be continued as maintenance for up to 2 years. The primary endpoint is PFS. Secondary objectives include OS, response rate, and toxicity. Goal enrollment is 205 patients and the study continues accrual. This sample size will provide 80% power at a two-sided α of 0.05 to detect a 4.8-month improvement in PFS assuming 8 months in the control arm. Novel correlative studies include sequential quantitative tumor-derived cell-free HPV ctDNA levels (serotypes 16 and 18; Sysmex-Inostics SafeSEQ NGS assay). Correlative funding provided in part by the Farrah Fawcett Foundation and Sysmex Inostics, Inc. Clinical trial information: NCT04444921. Research Sponsor: NCI/CTEP, Other Foundation, Pharmaceutical/Biotech Company.

TPS3615 **Poster Session**

Total neoadjuvant treatment versus standard chemoradiation to increase the sphincter preservation rate for distal locally advanced rectal cancer (TESS). *First Author: Weiwei Xiao, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China*

Background: Standard treatment of rectal cancer is neoadjuvant capecitabine chemotherapy with radiotherapy, followed by total mesorectal excision (TME). Total neoadjuvant treatment (TNT), a new concept, suggests organ preservation as an alternative to rectal excision in good responders after neoadjuvant chemoradiotherapy to decrease surgical morbidity and increase quality of life. RAPIDO and PRODIGE-23 trials showed that TNT strategy could improve the pathological complete response (pCR) rateand reduce the risk of distant metastasis. The objective of this trial is to increase the proportion of sphincter preservation rate for distal rectal cancer patients by optimizing tumor response, by using TNT regimen as compared to conventional chemoradiotherapy. TESS (clinicalTrials.gov, NCT03840239), a prospective, open label, multicenter, randomized phase 2 study, is underway. **Methods:** Main inclusion criteria include: cT3-4aNany or cTanyN+ rectal adenocarcinoma aged 18-70y; ECOG performance 0-1; distance≤5cm from anal verge. 168 patients will be randomized 1:1. Patients in the TNT group will receive 2 cycles of neoadjuvant chemotherapy Capeox (capecitabine + oxaliplation) before, during and after radiotherapy 50Gy/25 fractions, before TME (or other treatment decisions, such as watch and wait) and adjuvant chemotherapy capecitabine 2 cycles. Patients in the standard treatment group will receive neoadjuvant radiotherapy 50Gy/25 fractions combined with capecitabine 5 weeks before TME (or other treatment decisions, such as watch and wait), and adjuvant chemotherapy Capeox 6 cycles. Primary endpoint is the rate of sphincter preservation rate (absence of stoma). Secondary endpoints include: Ratio of sphincter preservation strategy; pathological complete response rate and tumor regression grade distribution; acute toxicity; surgical complications; long-term anal function; late toxicity; ECOG standard score; disease-free survival; overall survival. First site opened in January 24, 2019. Clinical trial information: NCT03840239. Research Sponsor: the 5010 Clinical Research Foundation of Sun Yat-sen University.

TPS3616 **Poster Session**

PERSPECTIVE: Tepotinib + cetuximab in patients (pts) with *RAS*/*BRAF* wild-type left-sided metastatic colorectal cancer (mCRC) and acquired resistance to anti-EGFR antibody therapy due to *MET* amplification (*MET*amp). *First Author: Tanios S. Bekaii-Saab, Mayo Clinic, Phoenix, AZ*

Background: *MET*amp is a secondary, or co-driving, genetic change in pts with mCRC and acquired resistance to anti-EGFR therapy, which can contribute to disease progression. In EGFR-resistant pts with mCRC and *MET*amp, MET inhibition + an anti-EGFR agent may achieve disease control by targeting emerging MET pathway activation and maintaining EGFR pathway inhibition. Tepotinib is an oral, once-daily, highly selective, potent MET tyrosine kinase inhibitor (TKI), recently approved in the US for NSCLC harboring *MET* exon 14 skipping. Tepotinib + gefitinib demonstrated improved outcomes in pts with *EGFR*-mutant *MET*amp NSCLC and acquired EGFR TKI resistance vs chemotherapy (INSIGHT: NCT01982955). In these pts, progression-free survival (PFS) was 16.6 vs 4.2 months (HR = 0.13; 90% CI: 0.04, 0.43) and overall survival (OS) was 37.3 vs 13.1 months (HR = 0.08; 90% CI: 0.01, 0.51). In pts with mCRC and acquired resistance to anti-EGFR antibody therapy due to *MET*amp, tepotinib + anti-EGFR antibody cetuximab may be active and provide an effective therapeutic option. **Methods:** This Phase II, multicenter, single-arm, open-label study will assess preliminary safety and tolerability, antitumor activity, and explore pharmacokinetic (PK) profiles of tepotinib + cetuximab in pts with *RAS/BRAF* wild-type left-sided mCRC and acquired resistance to anti-EGFR antibody-targeted therapy due to *MET*amp (NCT04515394). A safety run-in (6–12 pts) will evaluate the recommended Phase II dose of tepotinib to be used in combination with cetuximab (endpoint: dose-limiting toxicities). Enrollment is based on a confirmed advanced left-sided CRC diagnosis (*RAS/BRAF* wild-type), documented previous anti-EGFR therapy and acquired resistance on most recent anti-EGFR antibody and *MET*amp confirmed by liquid and/or tissue biopsy. Pts must be ≥18 years old, have ECOG PS of 0/1 and normal organ function. The study will screen sufficient pts to account for setting-specific heterogenecity in reported *MET*amp incidence. Approximately 42 pts are planned to receive study treatment: ~22 in Cohort A (second-line, outside US) and 20 in Cohort B (≥third-line, US only). Primary endpoint: investigator-assessed objective response (RECIST 1.1). Secondary endpoints are investigator-assessed duration of response (DoR), PFS (RECIST 1.1) and OS, tolerability and safety (NCI-CTCAE v5.0), and cetuximab immunogenicity (measured by antidrug antibody assays at the start and end of treatment). Additional endpoints include assessment of tepotinib and cetuximab PK profiles, and expression of biomarkers of resistance (from blood and/or tissue samples). Retrospective assessment of best overall response, DoR and PFS by an independent review committee may be conducted. No formal statistical hypothesis will be tested in this exploratory study. Clinical trial information: NCT04515394. Research Sponsor: Merck KGaA, Darmstadt, Germany.

TPS3618 **Poster Session**

Colorectal Cancer Metastatic dMMR Immuno-Therapy (COMMIT) Study: A randomized phase III study of atezolizumab (atezo) monotherapy versus mFOLFOX6/bevacizumab/atezo in the first-line treatment of patients (pts) with deficient DNA mismatch repair (dMMR) or microsatellite instability high (MSI-H) metastatic colorectal cancer (mCRC)—NRG-GI004/SWOG-S1610. *First Author: Michael J. Overman, University of Texas MD Anderson Cancer Center, and SWOG, Houston, TX*

Background: The superiority of inhibition of programmed cell death-1 (PD-1) pathway in dMMR/MSI-H over chemotherapy with either anti-vascular endothelial growth factor receptor (VEGFr) or anti- epithelial growth factor receptor (EGFr) antibodies in mCRC has been demonstrated in a phase III trial (N Engl J Med 2020; 383:2207). However, more patients had progressive disease as the best response in the anti-PD1 monotherapy arm (29.4% vs. 12.3%) with mean progression-free survival (PFS) of 13.7 months. Preclinical models have demonstrated synergistic interactions between FOLFOX, anti-VEGF, and anti-PD-1. We hypothesize that the dMMR/MSI-H mCRC patients may be more effectively treated by the combination of PD-1 pathway blockade and mFOLFOX6/bevacizumab (bev) rather than with anti-PD-L1 therapy (atezo) alone. **Methods:** Initially a three-arm study, the mFOLFOX6/bev arm was closed to new enrollment on 6-4-20 due to emerging data; the redesigned COMMIT trial was reactivated on 1/29/2021 as a prospective phase III open-label trial that randomizes (1:1) mCRC dMMR/MSI-H pts (N=211) to either atezo monotherapy or mFOLFOX6/bev+atezo combination. Stratification factors include BRAFV600E status, metastatic site, and prior adjuvant CRC therapy. Primary endpoint is PFS as assessed by site investigator. Secondary endpoints include overall survival (OS), objective response rate (RECIST v1.1), safety profile, disease control rate, duration of response, and centrally-reviewed PFS. Health-related quality of life is an exploratory objective. Archived tumor tissue and blood samples will be collected for correlative studies. Key inclusion criteria are: mCRC without prior chemotherapy for advanced disease; dMMR tumor determined by local CLIA-certified IHC assay (MLH1/MSH2/MSH6/PMS2) or MSI-H by local CLIA-certified PCR or NGS panel; and measurable disease per RECIST. Clinical trial: NCT02997228. Support: U10CA180868, -180822, -180888, -180819, UG1CA189867, U24CA196067; Genentech, Inc. Clinical trial information: NCT02997228. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS3619 **Poster Session**

BREAKWATER: Randomized phase 3 study of encorafenib (enco) + cetuximab (cetux) ± chemotherapy for first-line (1L) treatment (tx) of *BRAF* V600E-mutant (*BRAF*^{V600E}) metastatic colorectal cancer (mCRC). *First Author: Scott Kopetz, MD Anderson Cancer Center, Houston, TX*

Background: Approximately 10% of patients (pts) with mCRC have *BRAF* mutations (mostly V600E). 1L tx options for *BRAF*^{V600E} mCRC are limited to cytotoxic chemotherapy ± anti-VEGF or anti-EGFR, or immune checkpoint inhibitors in pts with MSI-H tumors. In Europe, Japan, and USA, the combination of BRAF inhibitor enco + EGFR inhibitor cetux is approved for tx of *BRAF*^{V600E} mCRC after prior therapy. In BEACON CRC, enco + cetux resulted in a median overall survival (OS) of 9.3 months (95% confidence interval [CI]: 8.0–11.3) and an objective response rate (ORR) of 19.5% (95% CI: 14.5%–25.4%) in previously treated pts with *BRAF*^{V600E} mCRC (median follow-up: 12.8 months); 57.4% of pts had grade 3/4 adverse events (AEs); 9% discontinued due to AEs. Given the poor prognosis of pts with *BRAF*^{V600E} mCRC and based on the efficacy and tolerability of enco + cetux from BEACON CRC, BREAKWATER will evaluate efficacy and safety of enco + cetux ± chemotherapy in tx-naive pts with *BRAF*^{V600E} mCRC. **Methods:** BREAKWATER is an open-label, global, multicenter, randomized, phase 3 study with a safety lead-in (SLI). Approximately 60 and 870 pts will be enrolled in the SLI and phase 3 parts of the study, respectively. Pts must have *BRAF*^{V600E} mCRC (determined using tumor tissue or blood); ECOG performance status 0/1; and adequate bone marrow, hepatic, and renal function. Pts in the SLI must have evaluable disease (RECIST v1.1) and have received ≤ 1 prior tx regimen; those previously treated with a BRAF or EGFR inhibitor, or both oxaliplatin and irinotecan, will be excluded. Pts in the phase 3 study must have measurable disease and be tx naive for metastatic disease. Study tx and endpoints are shown in the table. Enrollment began on 6 January 2021. Clinical trial information: NCT04607421. Research Sponsor: Pfizer.

	SLI	Phase 3
Tx*	Enco 300 mg QD + cetux 500 mg/m^{2†} + mFOLFOX6† or Enco 300 mg QD + cetux 500 mg/m^{2†} + FOLFIRI†	Arm A Enco 300 mg QD + cetux 500 mg/m^{2†} Arm B Enco 300 mg QD + cetux 500 mg/m^{2†} + mFOLFOX6† or FOLFIRI† (depending on SLI) Control (± bevacizumab) mFOLFOX6† or FOLFOXIRI† or FOLFIRI† or CAPOX (21-day cycle; oxaliplatin, Q3W; capecitabine, BID Days 1–14)
Endpoints		
Primary	Incidence of dose-limiting toxicities	Progression-free survival (PFS; by blinded independent central review [BICR]) (arm A vs control; arm B vs control)
Secondary	Incidence/severity of AEs, ORR, duration of response (DOR), PFS, time to response (TTR), OS, pharmacokinetic (PK) parameters, drug–drug interaction of enco with irinotecan/oxaliplatin	**Key:** OS (arm A vs control; arm B vs control) **Other**: ORR, DOR, PFS (arm A vs arm B by BICR; arm A vs control; arm B vs control; arm A vs arm B by investigator), OS (arm A vs arm B), TTR, progression after next tx line, incidence/severity of AEs, pt-reported outcomes, PK parameters, MSI status, *BRAF* V600E variant allele fraction

TPS3620 **Poster Session**

Trastuzumab deruxtecan in patients with HER2-overexpressing locally advanced, unresectable, or metastatic colorectal cancer (mCRC): A randomized, multicenter, phase 2 study (DESTINY-CRC02). *First Author: Kanwal Pratap Singh Raghav, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Trastuzumab deruxtecan (T-DXd) is an antibody–drug conjugate consisting of an anti-HER2 antibody (trastuzumab) linked to a potent topoisomerase I inhibitor (DXd). T-DXd has been approved to treat HER2-positive metastatic breast cancer (United States, Japan, Europe) and advanced gastric cancer (United States, Japan). It is currently being evaluated in other solid tumor types including colorectal cancer. The phase 2 DESTINY-CRC01 study included patients with *RAS* wild-type mCRC, with median 4 (range, 2-11) prior lines of therapy. Preliminary results in patients with HER2-overexpressing (IHC 3+ or IHC 2+/ISH+) mCRC showed T-DXd treatment (6.4 mg/kg intravenously [IV] every 3 weeks [Q3W]) resulted in a confirmed objective response rate (ORR) of 45.3% (24/53; 95% CI, 31.6%-59.6%) and a median progression-free survival (PFS) of 6.9 months (95% CI, 4.1 months-not evaluable; Siena *J Clin Oncol.* 2020;38[15]:4000). Activity was also seen in patients treated with prior anti-HER2 therapy. Although 5.4-mg/kg and 6.4-mg/kg doses of T-DXd have shown clinical efficacy in multiple cancer indications, the lower dose has not yet been tested in patients with HER2-overexpressing mCRC. Preliminary data also suggest T-DXd may be active in *RAS* mutant mCRC, unlike other anti-HER2 therapies. The DESTINY-CRC02 study aims to determine efficacy and safety of T-DXd in patients with HER2-overexpressing, *RAS* wild-type or mutant mCRC at 5.4-mg/kg and 6.4-mg/kg doses. **Methods:** DESTINY-CRC02 (NCT04744831) is a multicenter, randomized, double-blind, 2-arm, parallel phase 2 study that will be conducted in 2 stages. Eligible patients (≥18 years; ≥20 years in Japan, Taiwan, and Korea) will have HER2-overexpressing (IHC 3+ or IHC 2+/ISH+) locally advanced, unresectable or metastatic CRC and have previously received chemotherapy, anti-EGFR therapy, anti-VEGF treatment, and/or anti–PD-1/PD-L1 therapy, as clinically indicated. Prior anti-HER2 therapy will be allowed. In stage 1, patients will be randomly assigned 1:1 to receive T-DXd IV Q3W at a dose of 5.4 mg/kg (n = 40; arm 1) or 6.4 mg/kg (n = 40; arm 2). Randomization will be stratified by ECOG PS (0 or 1), HER2 status (IHC 3+ or IHC 2+/ISH+), and *RAS* status (wild-type or mutant). After stage 1 enrollment is complete, eligible patients in stage 2 (n = 40) will receive T-DXd 5.4 mg/kg until disease progression or other treatment discontinuation criteria are met. The study is actively enrolling and aims to enroll 120 patients across 60 sites. The primary objective is to assess efficacy of T-DXd at the 5.4-mg/kg and 6.4-mg/kg doses, with a primary end point of confirmed ORR by blinded independent central review. Secondary end points include investigator-assessed ORR, PFS, duration of response, disease control rate, clinical benefit rate, overall survival, pharmacokinetics, and safety. Clinical trial information: NCT04744831. Research Sponsor: Daiichi Sankyo, Inc, Pharmaceutical/Biotech Company.

TPS3621 **Poster Session**

JCOG1805 (PanDRa-BD study): A randomized controlled study of adjuvant chemotherapy for stage II colorectal cancer patients at high-risk of developing recurrence according to T-stage and three selected pathological factors (Pn, DR, and BD). *First Author: Megumi Ishiguro, Department of Chemotherapy and Oncosurgery, Tokyo Medical and Dental University, Tokyo, Japan*

Background: Adjuvant chemotherapy for stage II colorectal cancer (CRC) still remains controversial. Although the NCCN and ESMO guidelines recommend adjuvant chemotherapy for patients with "high-risk features," the survival benefit has not been confirmed. We reviewed the evidence levels for prognostic values of risk factors, because lack of their robustness is a major source of uncertainty regarding the optimal indication of adjuvant chemotherapy. Consequently, on top of the T-stage, three pathological factors—perineural invasion (Pn), tumor budding (BD), and desmoplastic reaction (DR)—were selected as robust risk factors of recurrence. Among the conventional factors, the prognostic value of Pn had been well validated in a multicenter study conducted by the Japanese Society for Cancer of the Colon and Rectum (JSCCR; Am J Surg Path 2013), but others were deemed suboptimal in terms of the prognostic value. BD and DR are novel tumor- and stroma-factors, respectively, associated with cancer microenvironment at the tumor front. According to the JSCCR and ITBCC 2016 criteria, tumors are graded as BD1, BD2, or BD3. The DR heterogeneity is categorized into Mature, Intermediate, and Immature patterns based on site-specific products of cancer-associated fibroblasts—keloid-like collagen and myxoid stroma. According to a recent prospective multicenter study, BD and DR characterization represent a higher level of prognostic value than other conventional factors (SACURA trial; J Clin Oncol 2019, Br J Cancer 2021). Based on the four selected risk factors, we can exclude the patient group with favorable prognosis (i.e., > 90% of 5-year RFS), which accounts for approximately 40% of the total population, resulting in enabling us to identify the concentrated population of high risk of developing recurrence. **Methods:** The Japan Clinical Oncology Group (JCOG) launched a randomized controlled phase III trial to evaluate the superiority of adjuvant chemotherapy in terms of relapse-free survival (RFS) over observation only in stage II CRC patients aged 20–80 years having one or more of the following risk factors: pathological T4, Pn, BD3, and non-Mature DR. Patients are randomised, in a 1:1:1 ratio, to [A] observation, [B] capecitabine monotherapy for 6 months, or [C] capecitabine and oxaliplatin (CAPOX) for 3 months. A total of 1680 patients will be accrued from 54 Japanese institutions assuming 3-year RFS with [A] to be 82% and expected 5% increase in 3-year RFS for [B] and [C] with one-sided alpha of 2.5% and power of 80% for each pair comparison. Patient enrollment was started in January 2020 and 170 patients have been enrolled until January 2021. This trial has been registered at Japan Registry of Clinical Trials as jRCTs031190186. Clinical trial information: jRCTs031190186. Research Sponsor: Japan Agency for Medical Research and Development.

TPS3622 **Poster Session**

Phase II/III study of Circulating tumOr DNA as a predictive BiomaRker in Adjuvant chemotherapy in patients with stage II colon cancer: NRG-GI005 (COBRA). *First Author: Van K. Morris, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There are currently no validated predictive biomarkers for stage II resected colon cancer (CC) after adjuvant chemotherapy. However, circulating tumor DNA (ctDNA) that is shed into the bloodstream represents a highly specific and sensitive approach for identifying microscopic or residual tumor cells. For patients (pts) with CC, the detection of ctDNA is associated with persistent disease after resection and may outperform traditional clinical and pathological features as a prognostic factor to assess risk for recurrence. We hypothesize that for pts whose stage II colon cancer has been resected and who have no traditional high-risk features, a positive ctDNA status may identify those who will benefit from adjuvant chemotherapy. **Methods:** In this prospective phase II/III clinical trial, pts (N = 1,408) with resected stage II CC without traditional high-risk features and whom the evaluating oncologist deems suitable for no adjuvant chemotherapy will be randomized 1:1 into 2 arms: standard-of-care/observation (Arm A), or prospective testing for ctDNA (Arm B). Postoperative blood will be analyzed for ctDNA with the GuardantHealth LUNAR panel, covering CC-relevant mutations and CC-specific methylation profiling. Pts in Arm B with ctDNA detected will be treated with 6 months of adjuvant (FOLFOX) chemotherapy. For all pts in Arm A, ctDNA status will be analyzed retrospectively at the time of endpoint analysis. The primary endpoints are clearance of ctDNA with adjuvant chemotherapy (phase II) and recurrence-free survival (RFS) for "ctDNA-detected" pts treated with or without adjuvant chemotherapy (phase III). Secondary endpoints will include time-to-event outcomes (OS, RFS, TTR) by ctDNA marker status and treatment, prevalence of detectable ctDNA in stage II CC, and rates of compliance with assigned intervention. Archived normal and matched tumor and blood samples will be collected for exploratory correlative research. The trial is actively accruing towards the phase II endpoint in North America. NCT#: 04068103. Support: U10-CA-180868, -180822; UG1CA-189867; GuardantHealth. Clinical trial information: NCT04068103. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS3623 **Poster Session**

Neoadjuvant chemoradiotherapy with sequential ipilimumab and nivolumab in rectal cancer (CHINOREC): A prospective randomized, open-label, multicenter, phase II clinical trial. *First Author: Johannes Laengle, Division of Visceral Surgery, Department of General Surgery, Comprehensive Cancer Center Vienna, Medical University of Vienna, Vienna, Austria*

Background: Immune checkpoint inhibitors (ICI), such as ipilimumab (anti-cytotoxic T-lymphocyte-associated protein 4) or nivolumab (anti-programmed cell death protein 1) have been proven to be an effective strategy in solid cancers. However, ICI seem not to be effective in microsatellite stable (MSS) cancers. As they might lack an immunogenic priming, radiotherapy (RT) is capable to induce an immunogenic cell death (ICD) and subsequently an immunogenic tumor immune microenvironment (TIME). Thus, RT might restore the susceptibility of MSS tumors to ICI and consequently leading to an effective anti-tumor immune response. **Methods:** This is a prospective, randomized, open-label, multicenter, phase II investigator-initiated clinical trial (IIT), including patients with locally advanced rectal cancer (LARC). Patients receive either neoadjuvant chemoradiotherapy (CRT) alone (50 Gy in 2 Gy fractions over 25 working days + capecitabine 1650 mg/m^2/d PO) or in combination with ipilimumab (1 mg/kg IV on day 7) and nivolumab (3 mg/kg IV on day 14, 28 and 42). Patients will undergo surgery within 10-12 weeks post CRT. The primary endpoint is incidence of treatment-emergent adverse events (AEs) assessed by the Clavien-Dindo classification of surgical complications and the common terminology criteria of adverse events (CTCAE). Secondary objectives are radiographic and pathological therapy response. Serial liquid (plasma, serum and peripheral blood mononuclear cells) and tissue biopsies will be taken before, during and after neoadjuvant treatment. Genomic, transcriptomic, epigenomic and proteomic pattern of liquid and tissue biopsies, as well as the immune cell infiltrate of resected specimen, will be correlated with therapy response and clinical outcome. Currently 8 of planned 80 patients have been enrolled. Registration numbers: NCT no. NCT04124601, EudraCT no. 2019-003865-17. Clinical trial information: NCT04124601. Research Sponsor: This is an investigator-initiated trial (IIT), which received a research grant and the study medications from Bristol-Myers Squibb (BMS).

4000 **Oral Abstract Session**

ESCORT-1st: A randomized, double-blind, placebo-controlled, phase 3 trial of camrelizumab plus chemotherapy versus chemotherapy in patients with untreated advanced or metastatic esophageal squamous cell carcinoma (ESCC).

First Author: Rui-hua Xu, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: The current standard first-line therapy for advanced or metastatic ESCC is doublet chemotherapy, and prognosis remains poor. Camrelizumab, a humanized anti-PD-1 monoclonal antibody, has shown promising antitumor activity in previously treated advanced or metastatic ESCC (Huang et al. *Lancet Oncol* 2019). Immunotherapy may work synergistically with chemotherapy, but lacking clinical evidences in ESCC. Here, we report the findings of the phase 3 ESCORT-1st study which evaluated the efficacy and safety of camrelizumab plus chemotherapy vs chemotherapy in patients with untreated advanced or metastatic ESCC. **Methods:** Eligible patients were randomized 1:1 to receive camrelizumab 200 mg or placebo, both combined with up to 6 cycles of paclitaxel (175 mg/m^2) and cisplatin (75 mg/m^2). All were given intravenously Q3W. Tumor response was assessed every 6 weeks according to RECIST v1.1. Co-primary endpoints were OS and independent review committee (IRC)-assessed PFS. Efficacy was assessed in all randomized patients and safety was assessed in all treated patients. Data cutoff date for the prespecified interim OS and final PFS analysis was Oct 30, 2020. **Results:** From Dec 3, 2018 to May 12, 2020, 596 patients were randomized. 298 patients were treated with camrelizumb-chemotherapy and 297 patients with placebo-chemotherapy. With a median follow-up of 10.8 months, camrelizumab plus chemotherapy significantly improved OS compared with placebo plus chemotherapy (median, 15.3 month [95% CI 12.8-17.3] vs 12.0 months [11.0-13.3]; HR, 0.70 [95% CI, 0.56-0.88]; one-sided P = 0.0010). Camrelizumab plus chemotherapy was also superior for PFS (per IRC) vs placebo plus chemotherapy (median, 6.9 months [95% CI, 5.8-7.4] vs 5.6 months [95% CI, 5.5-5.7]; HR, 0.56 [95% CI, 0.46-0.68]; one-sided P $<$ 0.0001). ORR per investigator was 72.1% in camrelizumab-chemotherapy group vs 62.1% in placebo-chemotherapy group, and median DoR was 7.0 vs 4.6 months. Incidences of grade $\geq$3 treatment-related AEs were comparable between the two groups (63.4% vs 67.7%), with decreased neutrophil count (39.9% vs 43.4%) as the most common one. Serious treatment-related AEs occurred in 30.2% vs 23.2% of patients, and treatment-related deaths occurred in 3.0% vs 3.7% of patients, respectively. **Conclusions:** Addition of camrelizumab to chemotherapy provided superior OS and PFS vs placebo plus chemotherapy, with a manageable safety profile. Camrelizumab in combination with paclitaxel and cisplatin has the potential to become a new standard first-line therapy in patients with advanced or metastatic ESCC. Based on this trial, we are submitting NDA to seek the approval from China National Medical Products Administration for camrelizumab plus chemotherapy in the treatment of untreated advanced or metastatic ESCC. Clinical trial information: NCT03691090. Research Sponsor: Jiangsu Hengrui Medicine.

Nivolumab (NIVO) plus ipilimumab (IPI) or NIVO plus chemotherapy (chemo) versus chemo as first-line (1L) treatment for advanced esophageal squamous cell carcinoma (ESCC): First results of the CheckMate 648 study.

First Author: Ian Chau, Royal Marsden Hospital, Sutton, United Kingdom

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 PM ET on Thursday, June 3, 2021.

4002 **Oral Abstract Session**

First-line (1L) nivolumab (NIVO) plus chemotherapy (chemo) versus chemo in advanced gastric cancer/gastroesophageal junction cancer/esophageal adenocarcinoma (GC/GEJC/EAC): Expanded efficacy and safety data from CheckMate 649.

First Author: Markus H. Moehler, Johannes-Gutenberg University Clinic, Mainz, Germany

Background: CheckMate 649 is the largest randomized, global phase 3 study of 1L programmed death (PD)-1 inhibitor–based therapy in GC/GEJC/EAC. 1L NIVO + chemo demonstrated superior overall survival (OS) vs chemo, with progression-free survival (PFS) benefit and an acceptable safety profile in pts whose tumors expressed PD-ligand (L)1 at combined positive score (CPS) $\geq$ 5 and $\geq$ 1, and in all randomized pts (Moehler et al. *Ann Oncol* 2020). We report additional data for all randomized pts. **Methods:** Eligible pts had previously untreated, unresectable advanced or metastatic GC/GEJC/EAC. Known HER2-positive pts were excluded. Pts were randomized to receive NIVO (360 mg Q3W or 240 mg Q2W) + chemo (XELOX Q3W or FOLFOX Q2W), NIVO + ipilimumab, or chemo. Dual primary endpoints for NIVO + chemo vs chemo were OS and PFS by blinded central review in PD-L1 CPS $\geq$ 5 pts. Hierarchically tested secondary endpoints were OS in PD-L1 CPS $\geq$ 1 and all randomized pts. **Results:** At 12-month minimum follow-up for 1581 randomized pts, NIVO + chemo had a statistically significant OS benefit vs chemo (HR 0.80 [99.3% CI 0.68–0.94; P = 0.0002]) in all randomized pts; PFS benefit was also seen (HR 0.77 [95% CI 0.68–0.87]). OS benefit was observed in multiple prespecified subgroups, consistent with the primary population. Grade 3–4 treatment-related adverse events (TRAEs) were reported in 59% (NIVO + chemo) and 44% (chemo) of pts. TRAEs with potential immunologic etiology (select TRAEs; sTRAEs) are shown in the table. Pts in the NIVO + chemo arm had decreased risk of symptom deterioration on treatment vs those in the chemo arm (HR 0.77 [95% CI 0.63–0.95; P = 0.0129]). Tolerability as measured by the FACT-Ga GP5 item was similar in both treatment groups. **Conclusions:** The addition of NIVO to chemo demonstrated improved OS and PFS benefit in all randomized pts, along with an acceptable safety profile and maintained tolerability as well as QoL, providing further support for NIVO + chemo as a standard 1L treatment for advanced GC/GEJC/EAC. Clinical trial information: NCT02872116. Research Sponsor: Bristol Myers Squibb.

sTRAEs (NIVO + chemo, N = 782).

Adjuvant nivolumab (NIVO) in resected esophageal or gastroesophageal junction cancer (EC/GEJC) following neoadjuvant chemoradiotherapy (CRT): Expanded efficacy and safety analyses from CheckMate 577.

First Author: Ronan Joseph Kelly, The Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX

Background: In CheckMate 577 (NCT02743494), NIVO demonstrated a significant and clinically meaningful improvement in disease-free survival (DFS; primary endpoint) vs placebo (PBO) and was well tolerated in patients (pts) with resected (R0) stage II/III EC/GEJC who received neoadjuvant CRT and had residual pathologic disease. Median DFS doubled with NIVO vs PBO (22.4 vs 11.0 months; HR 0.69; 96.4% CI 0.56–0.86; P = 0.0003). Serious treatment-related adverse events (TRAEs) and TRAEs leading to discontinuation were reported for $<$ 10% of pts with NIVO and 3% with PBO. **Methods:** Pts were randomized 2:1 to NIVO 240 mg or PBO Q2W for 16 weeks, followed by NIVO 480 mg or PBO Q4W. Here, we present additional efficacy, safety, and quality-of-life (QoL) data from CheckMate 577. **Results:** 794 pts were randomized (NIVO, 532; PBO, 262). Distant recurrence was reported for 29% vs 39% and locoregional recurrence for 12% vs 17% of pts in the NIVO vs PBO groups, respectively. Median distant metastasis-free survival was 28.3 vs 17.6 months with NIVO vs PBO (HR 0.74; 95% CI 0.60–0.92). Median progression-free survival 2 (PFS2; time from randomization to progression after subsequent systemic therapy, initiation of second subsequent systemic therapy, or death, whichever is earlier) was not reached with NIVO vs 32.1 months with PBO (HR 0.77; 95% CI 0.60–0.99). TRAEs with potential immunologic etiology (select TRAEs; sTRAEs) reported for NIVO are presented in the table. Results for the FACT-ECS and FACT-G7 showed similar trends for QoL improvement from baseline for NIVO and PBO during treatment and maintained benefit post-treatment. **Conclusions:** Adjuvant NIVO demonstrated clinically meaningful efficacy, an acceptable safety profile, and maintained QoL, providing further support for its use as a new standard of care for pts with resected EC/GEJC who received neoadjuvant CRT with residual pathologic disease. Clinical trial information: NCT02743494. Research Sponsor: Bristol Myers Squibb.

TRAEs with potential immunologic etiology in the NIVO group (n = 532).

	Pts with any grade sTRAEs,[a] n (%)	Median time to onset (range), weeks	Median time to resolution (range),[b] weeks	Pts receiving immune-modulating medication, n (%)	Pts with resolution of sTRAEs,[b] n (%)
Endocrine	93 (17)	9.7 (1.7–52.4)	21.1 (2.0–150.0+)	10 (11)	62 (67)
Gastrointestinal	91 (17)	7.4 (0.1–49.3)	3.5 (0.1–84.1+)	9 (10)	83 (94)
Hepatic	49 (9)	6.1 (1.1–49.3)	7.6 (0.4+ to 126.4+)	7 (14)	37 (80)
Pulmonary	23 (4)	12.7 (4.0–47.9)	5.9 (0.7–65.0)	17 (74)	17 (74)

Neo-AEGIS (Neoadjuvant trial in Adenocarcinoma of the Esophagus and Esophago-Gastric Junction International Study): Preliminary results of phase III RCT of CROSS versus perioperative chemotherapy (Modified MAGIC or FLOT protocol). (NCT01726452). *First Author: John V Reynolds, Cancer Trials Ireland and St James's Hospital, Dublin, Ireland*

Background: The optimum combination curative approach to locally advanced adenocarcinoma of the esophagus and esophago-gastric junction (AEG) is unknown. A key question is whether neoadjuvant multimodal therapy, specifically CROSS (carboplatin/paclitaxel, 41.4Gy radiation therapy), is superior to optimum peri-operative chemotherapeutic regimens including modified MAGIC (epirubicin, cisplatin (oxaliplatin), 5-FU (capecitabine)) and more latterly FLOT (docetaxel, 5-FU, leucovorin, oxaliplatin). Neo-AEGIS was designed as the first randomised controlled trial to address this question. **Methods:** 377 patients with $cT_{2\text{-}3}N_{0\text{-}3}M_0$ AEG were randomly assigned to CROSS or peri-operative chemotherapy (ECF/ECX/EOF/EOX pre-2018, FLOT option 2019/20) at 24 sites (Ireland, UK, Denmark, France, Sweden). The primary outcome was overall survival. The initial power calculation was based on CROSS superiority of 10%. This was modified after the first futility analysis (70 events) to a non-inferiority margin of 5%. Secondary end points included toxicity, pathologic measures of response, and postoperative complications as per the Esophageal Complications Consensus Group (ECCG) definitions and Clavien-Dindo severity grade. **Results:** Of 362 evaluable patients, 178 CROSS, 184 MAGIC/FLOT (157/27), 90% were male, median (range) age 64 (35-83), 84% were cT3, and 58% cN1. At a median (range) follow up of 24.5 (1-92) months, at the second futility analysis (60% of planned events), there were 143 deaths, 70 CROSS and 73 MAGIC/FLOT arm, with 3-year estimated survival probability of 56% (95% CI 47,64) and 57% (95% CI 48,65), respectively [(HR 1.02 (95%CI. 0.74-1.42))]. Based on the absence of futility evidenced in this data the DSMB recommended closure of recruitment in December 2020. **Conclusions:** This RCT reveals no evidence that peri-operative chemotherapy is unacceptably inferior to multimodal therapy, notwithstanding greater proxy markers of local tumour response in the CROSS arm. Oncologic and operative outcomes were consistent with optimum modern benchmarks. These data strongly suggest non-inferiority and support equipoise in decision making in modern practice. Clinical trial information: NCT01726452. Research Sponsor: Health Research Board Ireland, Cancer Research UK (C49462/A18483), Irish Cancer Society, Oesophageal Cancer Fund Ireland.

4005 **Oral Abstract Session**

Multicenter, randomized phase II study of neoadjuvant pembrolizumab plus chemotherapy and chemoradiotherapy in esophageal adenocarcinoma (EAC). *First Author: Manish A. Shah, Weill Cornell Medicine, New York, NY*

Background: Recent transformative studies in the treatment of EAC support adjuvant nivolumab for patients with residual disease following neoadjuvant chemoradiotherapy (CRT) (Checkmate 577) and pembrolizumab (P) with chemotherapy in untreated metastatic disease (Keynote 590). We hypothesized that pre-operative P combined with CRT can further improve outcomes in patients with locally advanced EAC. **Methods:** Patients with cT3-4Nx or T2N1 M0 EAC or gastroesophageal junction (GEJ) adenocarcinoma eligible for curative surgery were randomized (1:1) to receive either full-dose paclitaxel (T)/ carboplatin (C) or T/C + P induction therapy. All patients then received CRT with weekly T/C, RT 41.4Gy in 23 fractions, and P every 3 weeks. Following resection, patients received P for one year. The primary endpoint is rate of major pathologic response (MPR), defined as pathologic complete response or near complete response ($<$ 10% residual cancer), with 80% power and 0.1 one-sided significance level to detect the difference between a MPR proportion of 30% (historical control) and an alternative hypothesis of 47% (with preoperative P). Tissue was collected for tumor immune microenvironment (TIME) analysis including bulk and single cell RNA(scRNA) expression analysis, DNA sequencing, and flow cytometry. **Results:** From 8/4/17 to 10/26/20, 40 patients were enrolled: median age 68 [38-81], male 32, esophagus/GEJ type I (n = 16), GEJ II/III (n = 24). CRT was well tolerated, with no grade 3-4 adverse events attributed to P. Notable toxicity included grade 3-4 pneumonitis (13%), anastomotic leak (13%), infection (35%). In 31 evaluable patients to date, the MPR rate was 50.0% (95% CI, 32.7%-67.3%). 1-yr disease free survival was 100% for patients with MPR vs. 31.8% without MPR, p = 0.002. Esophageal/GEJ type I cancers had a significantly higher MPR rate when compared with GEJ type II/III (76.9% vs 37.5%, p = 0.03). scRNA seq on $>$ 100,000 tumor cells revealed EAC/GEJ type I had higher infiltration of activated dendritic cells (p = 0.12), whereas GEJ tumors have significantly higher infiltration of activated B cells (p = 0.02). **Conclusions:** The addition of P to preoperative CRT for EAC is safe and associated with a significantly higher MPR rate compared to historical data. We found MPR to be significantly enriched in EAC/GEJ type I tumors compared with GEJ II/III, associated with important differences in the baseline tumor immune microenvironment. Clinical trial information: NCT02998268. Research Sponsor: Merck Inc, GI Oncology Translational Research Fund - Weill Cornell Medicine.

4006 **Oral Abstract Session**

Liposomal irinotecan (nal-IRI) in combination with fluorouracil (5-FU) and leucovorin (LV) for patients with metastatic biliary tract cancer (BTC) after progression on gemcitabine plus cisplatin (GemCis): Multicenter comparative randomized phase 2b study (NIFTY). *First Author: Changhoon Yoo, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: There is no globally established second-line therapy after progression on GemCis in BTC. Although ABC-06 trial showed the clinical benefit of mFOLFOX compared to active symptom control, further investigation is needed. **Methods:** NIFTY is an investigator-initiated, multicenter, open-label, randomized, phase 2b study. Pts with $>$ 19 years, ECOG PS 0/1, histologically confirmed metastatic BTC, and disease progression on first-line GemCis were eligible. Pts were randomized 1:1 to nal-IRI (70 mg/m2, 90 min) plus 5-FU (2400 mg/m2, 46 hours)/LV (400 mg/m2, 30 min), every 2 weeks or 5-FU/LV, every 2 weeks until disease progression per investigator review or intolerable toxicities (stratification: primary tumor site, prior surgery and institution). Tumor response was evaluated per RECIST v1.1, every 6 weeks (fixed schedule). Primary endpoint is progression-free survival (PFS) per blinded independent central review (BICR). Secondary endpoints were PFS per investigator review, overall survival (OS) overall response rates (ORR), and safety. This study was designed to improve median PFS from 2 months (P0) to 3.3 months (P1; HR 0.6) with 2-sided alpha of 0.05, power of 80% and follow-up loss rates of 10%; a total of 174 pts were required. **Results:** A total of 178 patients were enrolled between SEP 2018 and FEB 2020; with exclusion of 4 pts who did not receive any study treatment, 174 pts (88 for nal-IRI plus 5-FU/LV group and 86 for 5-FU/LV group) were included in the Full Analysis Set. Median age was 64 yrs (range 37-84); 99/75 pts were male/female; 74/47/53 pts had intrahepatic/extrahepatic/gallbladder cancers. Pts characteristics were well balanced between two arms. With median follow-up duration of 6.1 mo (IQR 3.5-11.2), median PFS per BICR in nal-IRI plus 5-FU/LV group and 5-FU/LV group was 7.1 mo (95% CI, 3.6-8.8) and 1.4 mo (1.2-1.5), respectively (HR=0.56 [0.39-0.81], p=0.0019); median PFS per investigator review was 3.9 mo (2.7-5.2) and 1.6 mo (1.3-2.2), respectively (HR=0.48 [0.34-0.69], p$<$0.0001). Median OS was 8.6 mo (5.4-10.5) and 5.5 mo (4.7-7.2), respectively (HR=0.68 [0.48-0.98], p=0.0349). ORR was 14.8% and 5.8% per BICR, respectively (p=0.0684) and 19.3% and 2.3% per investigator review, respectively (p=0.0002). Grade $\geq$3 adverse events (AEs) were reported in 68 pts (77.3%) of nal-IRI plus 5-FU/LV group and 27 pts (31.4%) of 5-FU/LV group. Most common grade $\geq$3 AEs in nal-IRI plus 5-FU/LV group were neutropenia (n=21, 23.9%), fatigue (7, 8.0%), and nausea (5, 5.7%). **Conclusion**: Nal-IRI plus 5-FU/LV significantly improved PFS and OS compared to 5-FU/LV in BTC pts who progressed on prior GemCis. Nal-IRI plus 5-FU/LV should be considered as standard second-line therapy for advanced BTC. ClinicalTrials.gov identifier: NCT03524508 Clinical trial information: NCT03524508. Research Sponsor: Servier.

4007 **Oral Abstract Session**

Hepatic arterial infusion chemotherapy of oxaliplatin plus fluorouracil versus sorafenib in advanced hepatocellular carcinoma: A biomolecular exploratory, randomized, phase 3 trial (The FOHAIC-1 study). *First Author: Ning Lyu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Advanced hepatocellular carcinoma (HCC) with mega liver masses and macrovascular invasion were commonly observed at the first diagnosis, while with less extrahepatic metastases (77.5% vs. 37.9%). However, in clinical trials IMbrave150, SHARP, and Asia-Pacific SHARP, the percentage of extrahepatic metastases reached 63%, 53%, and 68.7%, respectively, while macrovascular invasion only accounted for 38%, 36%, and 36%. Unlike the previous and ongoing phase 3 clinical trials exploring the optimal systemic medication in the first-line treatment of advanced HCC, this study mainly focused on a population with a heavy intrahepatic tumor burden. **Methods:** In this open-label, phase 3 trial, patients were randomly assigned in a 1:1 ratio to undergo hepatic arterial infusion chemotherapy (HAIC) of FOLFOX regimens (HAIC-FO) or sorafenib treatment. Patients in the HAIC-FO group were recommended to receive tumor and normal tissue biopsy to search for the potential genomic biomarkers in predicting the response to treatment. **Results:** Between May 2017 and May 2020, 551 patients were recruited. Two hundred sixty eligible patients were randomly assigned to receive HAIC-FO (n = 130) or sorafenib (n = 132) and were included in the intention-to-treatment population. Macrovascular invasion with or without extrahepatic metastasis was present in 82.8% of patients (84.6% and 81.1%; P = 0.446). The median tumor diameter was 11.7 cm (IQR 8.3-14.0) of the HAIC-FO group and 10.8 cm (8.7-13.6) of the sorafenib group (P = 0.439). The percentage of patients with $>$ 50% tumor volume involvement of the liver was 41.5% and 39.4%, respectively (P = 0.724). At the time of data cutoff (Oct 31, 2020, at 190 deaths [79 of HAIC-FO and 111 of sorafenib]), patients receiving HAIC-FO had a median overall survival of 13.9 months (95%CI 10.6-17.2), compared with 8.2 months (7.5-9.0) for those receiving sorafenib (HR 0.408 [95%CI 0.301-0.552], P $<$ 0.001). Tumor downstaging occurred in 16 (12.3% of 130) patients of the HAIC-FO group, including 15 (93.8%) receiving curative surgery or ablation and finally achieving a median overall survival (progression-free survival) of 20.8 (16.4) months (95%CI 9.1-32.5 [7.5-25.3]) with a 1-year rate of 93.8% (68.8%). Analyses of predictive biomarkers based on the whole genome sequencing were ongoing in the HAIC-FO group. **Conclusions:** This randomized phase 3 study proved that HAIC-FO had superior efficacy and survival outcome than sorafenib in the first-line treatment of primary diagnostic, advanced HCC, indicating that patients with heavy intrahepatic tumor burden, HAIC-FO monotherapy might be a better strategy than sorafenib. Clinical trial information: NCT03164382. Research Sponsor: The clinical trial was supported by the Sun Yat-sen University Clinical Research 5010 Program of China (No. 2018013).

4008 **Oral Abstract Session**

Neoadjuvant transarterial infusion chemotherapy with FOLFOX could improve outcomes of resectable BCLC stage A/B hepatocellular carcinoma patients beyond Milan criteria: An interim analysis of a multi-center, phase 3, randomized, controlled clinical trial. *First Author: Shaohua Li, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The efficacy of operation, as the only radical option for resectable BCLC stage A/B hepatocellular carcinoma (HCC) patients beyond Milan criteria, is still unsatisfactory. This study aimed to investigate to efficacy and safety of preoperative neoadjuvant transarterial infusion chemotherapy (TAI) with FOLFOX regimen for these patients. **Methods:** In this multi-center, prospective, phase 3, randomized, open-labeled, controlled clinical trial, resectable BCLC stage A/B HCC patients beyond Milan criteria were randomly assigned (1:1) before hepatectomy to receive either neoadjuvant TAI (NT group) or operation directly without any neoadjuvant treatment (OP group). The primary endpoint was overall survival (OS), the secondary endpoints are progression-free survival (PFS), recurrence free survival (RFS), and safety. **Results:** Between March, 2016 and July, 2020, 208 patients enrolled from five Chinese hospitals were randomly assigned to NT group (n=104) or OP group (n=104) with 99 patients in NT group and 100 patients in OP group included in the efficacy and safety analysis. Clinicopathological characteristics were balanced between the two groups. The 1-, 2-, and 3-year OS rates for NT group were 92.9%, 78.6%, and 63.5%, and were 79.5%, 62.0%, and 46.3% for OP group, respectively. The 6-, 12-, and 18-month PFS rates for NT group were 77.6%, 50.4%, and 47.4%, and were 52.7%, 42.8%, and 34.8% for OP group, respectively. The OS and PFS were significantly better in NT group than in OP group (p=0.016 and 0.017, respectively). The 6-, 12-, and 18-month RFS rates for NT group were 63.8%, 47.3%, and 47.3%, and were 52.7%, 42.8%, and 34.8% for OP group, respectively. The RFS between the two group had no difference (p=0.385). No patients in NT group experienced grade 3 or more severe TAI related adverse events. The operation related adverse events were similar between two groups (p=0.300). **Conclusions:** Neoadjuvant TAI before hepatectomy may bring survival benefits for resectable BCLC stage A/B HCC patients beyond Milan criteria. Trial number: NCT03851913. Clinical trial information: NCT03851913. Research Sponsor: None.

4009 **Clinical Science Symposium**

***IDH1* and *IDH2* Driven Intrahepatic Cholangiocarcinoma (IHCC): A comprehensive genomic and immune profiling study.** *First Author: Shalini Makawita, MD Anderson Cancer Center, Houston, TX*

Background: *IDH1/2* genetic aberrations (GA) occur in 20% of IHCC cases and may be specifically targeted by IDH inhibitors. The genomic and immunologic profile of IHCC with *IDH1/2* GA remains undefined. *IDH1* mutations impair DNA damage repair (DDR), loss of heterozygosity (LOH) and may represent a biomarker for DDR in these patients. **Methods:** Comprehensive genomic profiling (CGP) was performed in 3,067 cases of advanced stage IHCC using a hybrid capture-based FDA-approved assay. Tumor mutational burden (TMB) was determined on 0.8 Mbp of sequenced DNA and microsatellite instability (MSI) was determined on 95 loci. PD-L1 expression in tumor cells (Dako 22C3) was measured by immunohistochemistry (IHC). Genomic LOH (gLOH) was assessed for samples meeting quality criteria. Densities of tumor associated immune cells and immune-checkpoint markers expressed in epithelial malignant cells and in the tumor microenvironment of 100 surgical samples from 96 patients were evaluated by IHC using digital image analysis of 14 markers (CD3, CD4, CD8, CD68, PD1,PD-L1, B7-H4, B7-H3, IDO1, ICOS, VISTA, OX40, TIM3, LAG3). Tissue microarrays were generated for multiplex immune panel analysis. A p value < 0.05 was considered statistically significant. **Results:** 426 (14%) of IHCC were *IDH1+* and 125 (4%) were *IDH2+* (Table) and were mutually exclusive. All *IDH1* GA occurred at the R132 locus and included R132C (69%) and R132L/G/S/H/F (16%/7%/4%/3%/ $< 1\%$) and 119Q ($< 1\%$) and *IDH2* GA at R172 (94.4%) and R140 (6.6%). *IDH1+* and *IDH2+* IHCC had fewer co-occurring targetable GA than *IDH1/2* wildtype (WT, *IDH*wt) cases including *FGFR2* rearrangements (RE) ($P < .0001$), *ERBB2* ($P = .0009$) and *BRAF* ($P = .04$). Median gLOH were not significantly different between *IDH1+IDH2+* IHCC vs. *IDH*wt IHCC ($p = 0.37$). Potential biomarkers of immune checkpoint inhibition (ICI) response including MSI High, TMB > 10 mut/Mb, and PD-L1 positivity were more frequent in *IDH*wt IHCC than *IDH1+* IHCC. 29/96 (30%) surgical patients were positive for *IDH1/2* mutation though mutational status did not confer a statistically significant difference in the 14 immune biomarker panel expression. **Conclusions:** CGP reveals significant differences in GA between *IDH1+*, *IDH2+* and *IDH*wt IHCC consistent with IDH1 and IDH2 being driver oncogenes for IHCC. Immune biomarker expression and gLOH did not differ significantly between *IDH* mutated and WT cases. Research Sponsor: None.

4010 **Clinical Science Symposium**

FIGHT: A randomized, double-blind, placebo-controlled, phase II study of bemarituzumab (bema) combined with modified FOLFOX6 in 1L FGFR2b+ advanced gastric/gastroesophageal junction adenocarcinoma (GC). *First Author: Daniel V.T. Catenacci, Gastrointestinal Oncology Program, University of Chicago, Chicago, IL*

Background: Bema is a first-in-class humanized IgG1 monoclonal antibody selective for fibroblast growth factor receptor 2b (FGFR2b). Results from the FIGHT study showed an improvement in progression-free survival (PFS), overall survival (OS), and overall response rate with the addition of bema to mFOLFOX6 in FGFR2b+, non HER2+ GC. This report provides updated analyses of patient (pt) subgroups, additional data on ocular adverse events (AEs), and the median OS result for the bema+mFOLFOX6 combination. **Methods:** Pts were treated with mFOLFOX6 and randomized 1:1 to bema (15 mg/kg) or placebo (pbo) every 2 weeks (wks) with an additional 7.5 mg/kg bema/pbo dose on cycle 1 day 8. Eligible pts had unresectable locally advanced or metastatic GC not known to be HER2+, and had FGFR2b overexpression (any 2+/3+ staining) by centrally performed immunohistochemistry (IHC+) or *FGFR2* amplification by circulating tumor DNA (ctDNA+). **Results:** Of the 155 pts who were randomized, 149 (96%) were FGFR2b+ by IHC, 26 (17%) by ctDNA, and 20 (13%) by both. 96 pts (62%) had tumors with FGFR2b IHC 2+/3+ in $\geq$10% of tumor cells. The proportion of pts with ctDNA+ or with $\geq$5% or $\geq$10% tumor cells FGFR2b+ by IHC was similar across geographic regions. Bema showed a benefit vs pbo across pre-specified subgroups including age, gender, geographic region, and prior adjuvant therapy. Patients with FGFR2b overexpression irrespective of ctDNA gene amplification benefited from bema: IHC+/ctDNA- PFS hazard ratio (HR) 0.63 (95% CI 0.4, 0.99), OS HR 0.66 (95% CI 0.39, 1.12); IHC+/ctDNA+ PFS HR 0.15 (95% CI 0.02, 1.18), OS HR 0.10 (95% CI 0.01, 0.83). Frequency and severity of ocular AEs were similar for the overall enrolled population and for pts with $\geq$5% or $\geq$10% FGFR2b+ by IHC. Corneal AEs in the bema arm increased in frequency and severity over time; 10.5% (0% G3) wk 1-8 vs 44.1% (15.3% G3) wk $\geq$25. Following discontinuation of study treatment, subsequent anti-cancer therapy was balanced in the 2 arms (bema 53%; pbo 49%). With a median follow-up of 12.5 months (mo), the bema arm had a median OS of 19.2 mo (95%CI: 13.6, not reached) vs 13.5 mo (95%CI: 9.3, 15.9) for placebo (HR:0.60 95%CI: 0.38, 0.94) for the intent-to-treat population; for the subset of pts with $\geq$10% FGFR2b+ by IHC, the median OS for bema was 25.4 mo (95%CI: 13.8, not reached) vs 11.1 mo (95% CI: 8.4, 13.8) for placebo (HR: 0.41 95%CI: 0.23, 0.74). **Conclusions:** The addition of bema to mFOLFOX6 improved the OS of 1L FGFR2b + GC pts vs mFOLFOX6 alone. Outcomes favored bema across pre-specified subgroups. Pts with overexpression of FGFR2b even without ctDNA amplification demonstrated a benefit from the addition of bema to mFOLFOX6, supporting further evaluation of bema in tumors with FGFR2b overexpression without the requirement for gene amplification. Clinical trial information: NCT03694522. Research Sponsor: Five Prime Therapeutics, Inc.

hENT1 gene expression as a predictor of response to gemcitabine and nab-paclitaxel in advanced pancreatic cancer. *First Author: Sheron Perera, Princess Margaret Cancer Centre/University Health Network/University of Toronto, Toronto, ON, Canada*

Background: Human equilibrative nucleoside transporter 1 (hENT1) belongs to a family of nucleoside transporters critical to entry of gemcitabine into cells. The prognostic and predictive characteristics of this biomarker in pancreatic ductal adenocarcinoma (PDAC) have primarily been evaluated by immunohistochemistry, with conflicting results. We explored the impact of hENT1 gene expression in the Comprehensive Molecular Characterization of Advanced Ductal Pancreas Adenocarcinoma for Better Treatment Selection (COMPASS) trial. **Methods:** Patients were enrolled on COMPASS from December 2015 to June 2020 and underwent a biopsy for whole genome sequencing (WGS) and RNA sequencing prior to first chemotherapy in the advanced setting. Biopsies underwent laser capture microdissection to enrich for tumour epithelium. Chemotherapy regimen was determined based on clinician preference. The cut-off thresholds for hENT1 expression were determined using the maximal chi-squared statistic. Response rates and overall survival (OS) were computed based on hENT1 expression and chemotherapy regimen. **Results:** 254 patients were included in the analyses with a median follow-up time of 18 months. 146 patients were treated with modified FOLFIRINOX (FFX), 104 with gemcitabine and nab-paclitaxel (GnP), and 16 received no systemic therapy. Based on gene expression levels, 133 patients were classified as hENT1 ^{high} and 121 as hENT1 ^{low}. hENT1 expression was significantly associated with the modified Moffitt classifier with higher expression seen in classical tumours ($p < 0.001$). In the entire cohort, median OS was 10.0 months in hENT1 ^{high} vs. 8.3 months in hENT1 ^{low} (adjusted HR 0.78, 95% confidence interval 0.59 - 1.03, $p = 0.08$). In patients receiving modified FFX, there was no difference in response rates (32% vs. 31%, $p = 1.00$) or OS (10.6 vs. 10.6 months, $p = 0.94$) between the hENT1 ^{high} and hENT1 ^{low} groups, respectively. However, in patient treated with GnP, response rates were significantly higher in hENT1 ^{high} patients compared to those with hENT1 ^{low} tumors (45% vs. 21%, $p = 0.035$). Median OS in this GnP treated cohort was 9.8 months in hENT1 ^{high} vs. 6.1 months hENT1 ^{low} ($p = 0.003$). In an interaction analysis, hENT was predictive of treatment response to GnP ($p = 0.0002$). **Conclusions:** Biomarkers predictive of response to GnP and FFX are urgently needed. Here we demonstrate that hENT1 gene expression is a predictor of response to GnP in advanced PDAC. Research Sponsor: This study was conducted with the support of the Ontario Institute for Cancer Research (PanCuRx Translational Research Initiative) through funding provided by the Government of Ontario, the Wallace McCain Centre for Pancreatic Cancer supported by the Prin.

4012 **Poster Discussion Session**

RATIONALE 302: Randomized, phase 3 study of tislelizumab versus chemotherapy as second-line treatment for advanced unresectable/metastatic esophageal squamous cell carcinoma. *First Author: Lin Shen, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital & Institute, Beijing, China*

Background: Tislelizumab (tisle) monotherapy or plus chemotherapy demonstrated antitumor activity in patients (pts) with solid tumors, including esophageal squamous cell carcinoma (ESCC) (NCT03469557 and CTR20160872). **Methods:** In this global phase 3 study (NCT03430843), adults with histologically confirmed advanced/unresectable or metastatic ESCC whose disease progressed following prior systemic therapy with ≥1 evaluable lesion per RECIST v1.1 and an Eastern Cooperative Oncology Group performance score (ECOG PS) of ≤1 were included. Pts were randomized (1:1) to receive tisle 200 mg intravenously every 3 weeks or investigator-chosen standard chemotherapy ([ICC]; paclitaxel, docetaxel, or irinotecan) and treated until disease progression, unacceptable toxicity, or withdrawal. Stratification factors included ICC option, region, and ECOG PS. The primary endpoint was overall survival (OS) in the intent-to-treat (ITT) population. The key secondary endpoint was OS in the programmed death-ligand 1 (PD-L1)+ population (visually-estimated combined positive score [vCPS] ≥10%, by VENTANA PD-L1 SP263 assay). Other secondary endpoints included (by RECIST v1.1) progression-free survival, overall response rate (ORR), duration of response (DoR), and safety. **Results:** Overall, 512 pts (median age: 62 years; range 35-86 years) from 132 sites in 10 countries in Asia (404 pts [79%]), Europe, and North America (108 pts [21%]) were randomized to tisle (n=256) or ICC (n=256) (ITT population). Of these, 157 pts (tisle [n=89], ICC [n=68]) had vCPS ≥10% (PD-L1+ population). On 1 Dec 2020 (data cut-off), median follow-up was 8.5 months (m) with tisle and 5.8 m with ICC. The study met its primary endpoint: tisle clinically and significantly improved OS vs ICC in the ITT population (median OS: 8.6 vs 6.3 m; HR 0.70, 95% CI 0.57-0.85, p=0.0001). Tisle also demonstrated significant improvement in OS vs ICC in the PD-L1+ population (median OS: 10.3 vs 6.8 m; HR 0.54, 95% CI: 0.36-0.79, p=0.0006). Survival benefit was consistently observed across pre-defined subgroups, including baseline PD-L1 status and region. Treatment with tisle was also associated with a higher ORR (20.3% vs 9.8%) and more durable response (median DoR: 7.1 vs 4.0 m; HR 0.42, 95% CI 0.23-0.75) than ICC in the ITT population. Fewer pts had ≥Grade 3 (46% vs 68%) treatment-emergent adverse events with tisle vs ICC. Of these, fewer ≥Grade 3 AEs were treatment-related (TR) with tisle vs ICC (19% vs 56%). Fewer pts discontinued tisle vs ICC (7% vs 14%) due to a TRAE. **Conclusion:** Tisle demonstrated statistically significant and clinically meaningful improvement in OS vs ICC in pts with advanced or metastatic ESCC who had disease progression during or after first-line systemic therapy. Tisle showed a higher and longer response vs ICC. The safety profile of tisle was more favorable than ICC. Clinical trial information: NCT03430843. Research Sponsor: This study is sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Yasmin Issop, PhD, and Kirsty Millar, MSc, of Ashfield MedComms, an Ashfield Health company, and was funded by BeiGene, Ltd.

4013 **Poster Discussion Session**

Pembrolizumab plus trastuzumab and chemotherapy for HER2+ metastatic gastric or gastroesophageal junction (G/GEJ) cancer: Initial findings of the global phase 3 KEYNOTE-811 study. *First Author: Yelena Y. Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Trastuzumab (tras) plus chemotherapy (chemo) is standard-of-care (SOC) 1L therapy for HER2+ metastatic G/GEJ cancer. In two phase 2 studies, tras, chemo, and pembrolizumab (pembro) in combination showed promising efficacy and manageable safety. The ongoing global, randomized, double-blind, placebo-controlled phase 3 KEYNOTE-811 study is assessing whether adding pembro to SOC improves efficacy vs SOC alone for HER2+ metastatic G/GEJ cancer (NCT03615326). **Methods:** Eligible patients (pts) with previously untreated, unresectable or metastatic HER2+ G/GEJ cancer and ECOG PS 0 or 1 are randomized 1:1 to pembro 200 mg IV Q3W or placebo IV Q3W. All pts receive tras and investigator's choice of 5-fluorouracil and cisplatin (FP) or capecitabine and oxaliplatin (CAPOX). Treatment is given up to 2 y or until intolerable toxicity or PD. Dual primary end points are PFS per RECIST v1.1 by blinded, independent central review (BICR) and OS. Secondary end points are ORR and DOR per RECIST v1.1 by BICR and safety. Planned enrollment in the global cohort is 692 pts; accrual is almost complete. The protocol-specified first interim analysis (IA1) was to occur when the first 260 pts enrolled had ≥8.5 mo of follow-up and tested whether pembro + SOC significantly improved ORR; the superiority boundary was $P = 0.002$. The ORR difference was calculated using the Miettinen and Nurminen method stratified by the randomization stratification factors of geographic region, PD-L1 status, and chemo choice. Efficacy is presented for the first 264 pts enrolled. Safety is presented for all treated pts enrolled as of Jun 17, 2020. **Results:** Among the first 264 pts enrolled, 133 were randomized to pembro + SOC, 131 to placebo + SOC; 0.8% had MSI-H tumors, CAPOX was chosen for 87.1%, and median study follow-up was 12.0 mo (range, 8.5-19.4). Confirmed ORR (95% CI) was 74.4% (66.2-81.6) for pembro + SOC vs 51.9% (43.0-60.7) for placebo + SOC (difference, 22.7 percentage points [95% CI, 11.2-33.7], $P = 0.00006$); CR rate was 11.3% vs 3.1% and DCR (95% CI) was 96.2% (91.4-98.8) vs 89.3 (82.7-94.0). Median (range) DOR was 10.6 mo (1.1+ to 16.5+) for pembro + SOC vs 9.5 mo (1.4+ to 15.4+) for placebo + SOC; KM estimates of DOR ≥6 mo and ≥9 mo were 70.3% vs 61.4% and 58.4% vs 51.1%. As of data cutoff, 433/434 enrolled pts were treated (217/217 pembro + SOC, 216/217 placebo + SOC). AEs were grade 3-5 in 57.1% of pts with pembro + SOC vs 57.4% with placebo + SOC, led to death in 3.2% vs 4.6%, and led to discontinuation of any drug in 24.4% vs 25.9%. **Conclusions:** Adding pembro to tras and chemo resulted in a substantial, statistically significant increase in ORR versus trastuzumab and chemo alone as 1L therapy for HER2+ metastatic G/GEJ cancer; responses were durable and safety was manageable. These initial data support pembro plus tras and chemo as a potential new treatment option for this population. Clinical trial information: NCT03615326. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4014 **Poster Discussion Session**

Phase III trial comparing XELOX regimen (oxaliplatin plus capecitabine) versus EOX regimen (epirubicin, oxaliplatin and capecitabine) as first-line treatment for advanced gastric cancer: EXELOX trial. *First Author: Weijian Guo, Department of Medical Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: At present, there is no standard chemotherapy regimen for advanced gastric cancer (AGC), and there is no consensus whether the three-drug combination is better than two-drug combination in first-line treatment. Both of XELOX regimen and EOX regimen are widely recommended as firs-line chemotherapy regimens for AGC. In this EXELOX trial, we aimed to compare the efficacy and safety of EOX and XELOX regimens. **Methods:** EXELOX is an open-label, multicenter, prospective, randomized phase III trial that enrolled 448 previously untreated patients with histologically confirmed advanced gastric adenocarcinoma from 7 hospitals in China. Patients were randomly assigned (1:1) to receive XELOX regimen (oxaliplatin 130mg/m^2 d1; xeloda 1000mg/m^2 bid d1-14) or EOX regimen (epirubicin 50mg/m^2 d1; oxaliplatin 130mg/m^2 d1; xeloda 1000mg/m^2 bid d1-14) in this study. Treatment was repeated every 3 weeks until disease progression, intolerable toxicity, patient death, withdrawal of informed consent, or up to eight cycles, followed by xeloda single-agent maintenance. We stratified randomization by Eastern Cooperative Oncology Group status, extent of disease(locally advanced/metastatic) and clinical trial center. Patients and clinicians were not masked to the allocated treatment. The primary endpoint was progression-free survival (PFS) on an intention-to-treat basis with a non-inferiority upper margin of 1.3 for the hazard ratio (HR). The clinical trial was a non-inferiority study that was registered with ClinicalTrials.gov, Number NCT02395640. The study is ongoing, but no longer recruit new participants. **Results:** Between Apr 10,2015 and Aug 20,2020, a total of 448 AGC patients were randomized to receive XELOX (n = 222) or EOX (n = 226). In ITT basis, the median PFS was 5.0 months (95%CI 4.5-6.0) in XELOX group and 5.5 months (95%CI 5.0-6.0) in EOX group (HR 0.989, 95%CI 0.812-1.203; $P_{\text{non-inferiority}} = 0.0032$). In Per-protocol population (n = 428), the median PFS was 5.0 months (95%CI 5.0-6.0) in XELOX group and 5.5 months (95%CI 5.0-6.0) in EOX group (HR 0.983, 95%CI 0.807-1.198; $P_{\text{non-inferiority}} = 0.0028$). The incidence of grade 3-4 adverse events (AEs) was 42.2% (90/213) in XELOX group and 72.5(156/215) in EOX group ($p = 0.001$). The most common grade 3-4 AEs were neutropenia (affecting 13.1% (28/213) in XELOX group and 48.4% (104/215) in EOX group ($p = 0.000$). The incidence of chemotherapy dose reduction was 35% (75/213) in XELOX group and 55% (120/215) in EOX group($p = 0.009$). One treatment-related death (lung infection) was observed in EOX group, and none in XELOX group. **Conclusions:** XELOX regimen is noninferior to EOX regimen in PFS with a better safety profile as first-line treatment for AGC patients, therefore XELOX is a more favorable choice and might be one of the standard first-line chemotherapy regimens. Clinical trial information: NCT02395640. Research Sponsor: This study was funded by The National Key Research and Development Program of China (grant no. 2017YFC1308900), Other Foundation.

Maintenance durvalumab after first-line platinum-based chemotherapy in advanced oesophago-gastric (OG) adenocarcinoma: Results from the PLATFORM trial. *First Author: Caroline Fong, The Royal Marsden NHS Foundation Trust, London and Sutton, United Kingdom*

Background: PLATFORM is a prospective, open-label, multicentre, adaptive phase II trial assessing maintenance therapy in patients (pts) with OG adenocarcinoma after platinum-based first-line induction chemotherapy. HER2 negative pts were initially randomised 1:1:1:1:1 to surveillance (A1), capecitabine (A2), durvalumab (A3), with rucaparib (A4) and capecitabine + ramucirumab (A5) added later as per adaptive design. Here we report the primary analysis of durvalumab maintenance vs. surveillance. **Methods:** Pts were randomised upon achieving response or stable disease following 18 weeks of platinum-based chemotherapy and were stratified by region, disease extent and performance status. A1 pts had 4 weekly surveillance visits and A3 pts received 10mg/kg durvalumab iv Q2W. Target accrual was 154 pts/arm; however, A3 was closed prematurely after cessation of industry support. The primary endpoint was progression-free survival (PFS) from randomisation post induction chemotherapy to disease progression according to RECIST 1.1 criteria, or death. Secondary endpoints were time to treatment failure (TTF), objective response rate (ORR), overall survival (OS) and toxicity. Survival analyses according to PD-L1 using the combined positive score (CPS, Ventana SP263 assay) was conducted. **Results:** A total of 205 pts were concurrently randomised into A1 (n = 100) and A3 (n = 105). At data cut-off (02 Feb 2021), median follow up was 24.2 months [95% confidence interval (CI) 21.6-36.8]. There was no significant difference in PFS between A1 and A3 [median PFS: 3.2 vs. 4.7 months (hazard ratio (HR) 0.79 (95% CI 0.59-1.06, p = 0.122) respectively]. Median OS was 11.4 vs. 11.3 months (HR 0.92, 95% CI 0.66-1.27, p = 0.60) in A1 and A3 respectively and no significant difference in TTF was detected between both arms (median TTF: 3.2 vs. 3.5 months (HR 0.92, 95% CI 0.69-1.23, p = 0.558)]. ORR was 6% in A3 (n = 2 complete and n = 4 partial responses) whereas no radiological responses were seen in A1. PD-L1 results were available for 76 pts in A1 and 77 pts in A3. PFS was comparable between subgroups using the PD-L1 CPS thresholds of ≥1, ≥5 and ≥10. The safety population consisted of 199 pts (A1: 98 pts and A3: 101 pts). Grade ≥3 treatment-related adverse events were reported in 18% of A3 pts and no new safety signals were identified. **Conclusions:** Although a survival advantage was not seen with maintenance durvalumab compared to surveillance, a subset of patients who received durvalumab demonstrated incremental radiological responses. Exploratory analysis of PD-L1 expression was not associated with improved survival outcomes. Clinical trial information: NCT02678182. Research Sponsor: The Royal Marsden NHS Foundation Trust, Pharmaceutical/Biotech Company.

4016 **Poster Discussion Session**

Preoperative chemoradiotherapy to improve overall survival in pancreatic cancer: Long-term results of the multicenter randomized phase III PREOPANC trial. *First Author: Casper H.J. Van Eijck, Department of Surgery, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, Netherlands*

Background: Preoperative chemoradiotherapy (CRT) may improve overall survival in resectable pancreatic cancer (RPC) and borderline resectable pancreatic cancer (BRPC). Long term results are presented. **Methods:** In this multicenter phase III trial, patients with RPC or BRPC were randomized between preoperative CRT, (gemcitabine 1000 mg/m^2 weekly for 7 of 10 weeks, and 15x2.4 Gy radiotherapy in week 4 to 6), followed by surgery and four cycles of adjuvant gemcitabine (1000 mg/m^2 weekly for 3 of 4 weeks), or immediate surgery followed by 6 cycles of adjuvant gemcitabine (1000 mg/m^2 weekly for 3 of 4 weeks). Primary endpoint was overall survival by intention-to-treat (ITT). **Results**: From April 2013 to July 2017, 246 eligible patients were accrued by 16 Dutch centers and randomized, 119 to preoperative CRT and 127 to immediate surgery. After a median follow up of 56 months (35.3-92.0 months), 210 patients have died, 93 (78%) in the preoperative CRT arm and 117 (92%) in the immediate surgery arm. Three- and five-year overall survival ITT was 27.7% and 20.5% after preoperative CRT versus 16.5% and 6.5% after immediate surgery (HR 0.73; 95% CI 0.56 to 0.96; p = 0.025). In addition, disease-free survival (HR 0.70; p = 0.009) locoregional failure-free interval (HR 0.57; p = 0.004) and distant metastases free interval (HR 0.74; p = 0.071) improved after preoperative CRT. Also in the stratified subsets RPC and BRPC, preoperative CRT improved OS: RPC (n = 133, HR 0.79; 95% CI 0.54 to 1.16; P = 0.23). BRPC (n = 113, HR 0.67; 95% CI 0.45 to 0.99; p = 0.045). We could not demonstrate a difference in treatment effect between these subsets (interaction test p = 0.56). **Conclusions:** Preoperative gemcitabine-based CRT for RPC or BRPC improves long term overall survival compared to immediate surgery with adjuvant gemcitabine. Clinical trial information: NTR3709. Research Sponsor: Dutch Cancer Foumdation (KWF).

4017 **Poster Discussion Session**

Randomized phase II study of modified FOLFIRINOX versus gemcitabine plus nab-paclitaxel combination therapy for locally advanced pancreatic cancer (JCOG1407). *First Author: Masato Ozaka, Department of Gastroenterology, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: FOLFIRINOX, consisting of leucovorin (LV), fluorouracil (FU), irinotecan (IRI) and oxaliplatin (L-OHP), and GnP, consisting of gemcitabine (GEM) plus nab-paclitaxel (nPTX), have shown superior efficacy over GEM in patients (pts) with metastatic pancreatic cancer. Although several studies have reported the efficacy of FOLFIRINOX or GnP for pts with locally advanced pancreatic cancer (LAPC), no randomized controlled trial to compare the two regimens has been conducted in those pts. To select the most promising chemotherapy for LAPC, a randomized phase II selection design trial (JCOG1407) was conducted to compare between modified FOLFIRINOX (FOLFIRINOX with dose reduction of IRI and without bolus FU; Arm A) and GnP (Arm B) for pts with LAPC. **Methods:** In Arm A, 85 mg/m^2 of L-OHP, 200 mg/m^2 of l-LV, 150 mg/m^2 of IRI, followed by 2,400 mg/m^2 of continuous FU over 46 hours are infused every 2 weeks. In Arm B, 125 mg/m^2 of nPTX followed by 1,000 mg/m^2 of GEM are infused on days 1, 8, and 15 every 4 weeks. The primary endpoint was overall survival (the proportion of 1-year OS), and secondary endpoints included progression-free survival (PFS), distant metastasis-free survival (MFS) and response rate in pts with target lesions. The planned sample size was 124 pts to select more effective regimen in 1-year OS with a probability of at least 0.85 and to test the null hypothesis of 53% in 1-year OS with a one-sided alpha of 5% and 80% **Results:** From 2015 to 2019, a total of 126 pts was enrolled from 29 Japanese institutions, and were allocated to Arm A (n = 62) or Arm B (n = 64). The median (range) age was 66 (44-75) years and 58.7% were male. At the analysis, after a median (range) follow-up of 1.52 (0.55-3.99) years, 75 (59.5%) pts died. The proportion of 1-year OS was better in Arm B, 77.4% [95% CI 64.9–86.0] vs. 82.5% [95% CI 70.7–89.9], but 2-year OS was better in Arm A, 48.2% [95% CI 33.3–61.7] vs. 39.7% [95% CI 28.6–52.5]. Median OS was 2.0 years [95% CI 1.6-2.7] in Arm A and 1.8 years [95% CI 1.5-2.0] in Arm B. 1-year PFS for Arm A/B was 47.5 % [95% CI 34.5-59.4]/40.2% [95% CI 27.8-52.3], and 1-year MFS was 64.2 % [95% CI 50.9-74.8]/57.3% [95% CI 43.9-68.6]. Arm A was better OS in pts with CA19-9 $<$1000 U/mL and the opposite trend was observed in pts with CA19-9$>$1000 U/mL. Response rate was 30.9% [95% CI 19.1-44.8] in Arm A, and 41.4% [95% CI 28.6-55.1]) in Arm B. Incidences of grade 3-4 non-hematological toxicities for Arm A and Arm B were 66.1% and 67.2%, respectively. There was no treatment-related death. **Conclusions:** This study was the first randomized trial comparing the two regimens. The 1-year OS of the primary endpoint in GnP was better than mFOLFIRINOX, but mFOLFIRINOX achieved longer survival in 2-year OS. It is required to confirm longer OS and safety profiles which regimen should be selected as a standard regimen in LAPC. Clinical trial information: jRCTs031180085. Research Sponsor: Japan Agency for Medical Research and Development.

4018 **Poster Discussion Session**

Masitinib plus gemcitabine as first-line treatment of pancreatic cancer with pain: Results from phase 3 study AB12005. *First Author: Joel Ezenfis, Centre Hospitalier Sud Francilien, Corbeil-Essonnes, France*

Background: Masitinib (MAS) is a small molecule drug targeting mast cell and macrophage activity, innate immune cells that are critical components of the tumor microenvironment. Proof of concept that MAS in combination with gemcitabine (GEM) improved overall survival (OS) in pancreatic cancer (PC) patients (pts) with pain, was previously shown [doi 10.1093/annonc/mdv133]. The presence of pain in PC is thought to identify pts whose disease is driven in part by a pro-tumoral immune response. **Methods:** AB12005 was a prospective, placebo (PBO) controlled, double blind, randomized (2:1 MAS:PBO, stratified by disease stage, ECOG and geographic region) phase 3 trial, evaluating oral MAS (6.0 mg/kg/d) in combination with GEM (1000 mg/m^2) against PBO plus GEM for the treatment of unresectable locally advanced PC (LAPC) and/or metastatic PC (mPC) pts with pain criteria; i.e. baseline visual analog scale of pain intensity (VAS) $>$ 20 and/or pt treated with an opioid analgesics dose $\geq$1 mg/kg/d at baseline. Eligible pts were chemo-nave with histologically or cytologically confirmed inoperable LAPC or mPC and an ECOG status $\leq$2. The estimated sample size was ~330 pts to detect an OS hazard ratio (HR) of 0.68 (80% power, 2-sided α = 0.025) after 310 deaths. The study was successful if improvement in median OS (primary endpoint) relative to control reached a 2.5% level of statistical significance for either a targeted subgroup of LAPC with pain criteria, or the overall study cohort. **Results:** A total of 384 pts were enrolled (safety population n = 383; mITT n = 379; target subgroup n = 92). In the predefined subgroup of unresectable LAPC with pain, MAS-GEM (n = 62) showed significant benefit over PBO-GEM (n = 30) with median OS of 13.0 months (97.5% CI [11.0;18.0]) vs 11.2 months (97.5% CI [7.4;13.0]); p = 0.007. The HR was 0.46 (97.5% CI [0.2;0.9], p = 0.0047), corresponding to a significant 54% reduction in risk of death for MAS-GEM pts relative to control. Secondary analyses in the same subgroup were convergent with this primary outcome. Median PFS showed a 1.8 month between group difference in favor of MAS-GEM (p = 0.039), with a HR of 0.47 (97.5% CI [0.3;0.9], p = 0.014). The 12-month and 18-month OS rates showed a 1.3 fold and 3.4 fold improvement, respectively, in favor of MAS-GEM (53.2% and 33.9% for MAS-GEM vs 40.0% and 10% for PBO-GEM, respectively). In the overall population, comprising LAPC and mPC pts with pain, no survival benefit was observed; median OS for MAS-GEM (n = 244) was 6.9 months vs 8.0 months for PBO-GEM (n = 135); p = 0.461. The MAS-GEM combination was well tolerated with no sign of add-on toxicity. The proportion of patients presenting at least one adverse event (AE) or serious AE was respectively, 96.3% and 19.1% for MAS-GEM (n = 246) vs 99.3% and 21.3% for PBO-GEM (n = 136). **Conclusions:** The combination MAS (6.0 mg/kg/d) plus GEM may provide a new first line treatment option for unresectable LAPC pts with associated pain. Clinical trial information: NCT03766295. Research Sponsor: AB Science.

Gemcitabine (Gem) and nab-paclitaxel (NP) ± nivolumab (nivo) ± CD40 agonistic monoclonal antibody APX005M (sotigalimab), in patients (Pts) with untreated metastatic pancreatic adenocarcinoma (mPDAC): Phase (Ph) 2 final results. *First Author: Mark H. O'Hara, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Results from a ph1b trial evaluating gem/NP with CD40 agonistic monoclonal antibody APX005M ± nivo demonstrated promising clinical activity in pts with untreated mPDAC (O'Hara 2021). Herein, we report results from the follow-on, randomized (rand) ph2 trial evaluating gem/NP ± nivo ± APX005M. **Methods:** Pts with untreated mPDAC were rand to 1 of 3 open-label arms: gem/NP/nivo (A), gem/NP/APX005M (B), gem/NP/nivo/APX005M (C). All pts were treated with 1000 mg/m^2 gem and 125 mg/m^2 NP. Patients received 240 mg nivo in arms A and C and 0.3 mg/kg APX005M (RP2D) IV in arms B and C. Ph1b pts were included in ph2 analyses. 1° endpoint: 1-year OS rate of each arm, compared to a 35% historical OS rate for gem/NP (Von Hoff 2013). Key 2° endpoints: ORR, DCR, DOR, PFS and safety. Tumor and blood were collected for biomarker analysis. Planned enrollment of 35 pts/arm provided 81% power for testing the alternative of 58% OS rate vs 35%, using a 1-sided, 1-sample Z test with 5% type I error. Trial was not powered for cross-arm comparison. **Results:** 93 pts were rand in ph2 (N = 34, 30, 29 to A, B, C); when ph1b pts included, a total of 105 pts (34, 36, 35) were analyzed for efficacy and 108 pts (36, 37, 35) for safety. Min follow-up was 14 months (mos). Baseline characteristics were balanced across arms, inclusive of tumor burden, presence of liver metastases and stage at initial diagnosis (stage 1-3 vs 4). 1-year OS rate was 57% (1-sided p = 0.007 vs 35% historical rate, 95% lower CI bound = 41%) for A, 51% (p = 0.029, 95% bound = 36%) for B and 41% (p = 0.236, 95% bound = 27%) for C. Median OS and secondary endpoints are listed in Table. TRAE rates were similar across arms and to ph1b. 8 (7%) pts experienced an AE leading to tx discontinuation (6, 1, 1 in A, B, C), 40 (37%) pts experienced a serious TRAE (14, 15, 11 in A, B, C) and 2 pts died due to TRAEs; 1 each in B (acute hepatic failure) and C (intracranial hemorrhage). **Conclusions:** In this ongoing, seamless ph1b/2 trial of gem/NP ± nivo ± APX005M in pts with mPDAC, antitumor activity was observed in all arms. 1° endpoint of 1-year OS $>$ 35% was met when combining gem/NP with either nivo or APX005M; however, not the combination. Safety was manageable; consistent with ph1b. Detailed multiomic immune and tumor biomarker analyses are underway to elucidate mechanisms of action and inform pt subsets that benefit most from these combinations. Clinical trial information: NCT03214250. Research Sponsor: Parker Institute for Cancer Immunotherapy, Other Foundation, Pharmaceutical/Biotech Company.

KG 4/2015: A randomized, controlled, multicenter, open-label phase III clinical trial of GV1001 with gemcitabine/capecitabine in previous untreated, eotaxin-high patients with advanced pancreatic ductal adenocarcinoma. *First Author: Jung Hyun Jo, Yonsei University Severance Hospital, Seoul, South Korea*

Background: In the TeloVac study, GV1001 with Gemcitabine/capecitabine (G/C) did not show increased overall survival (OS) than G/C in patients (pts) with advanced pancreatic ductal adenocarcinoma (PDA). But cytokine examination suggested high serum eotaxin level may predict improved survivals in pts received GV1001 with G/C. This phase III trial was designed to assess the efficacy of GV1001 with G/C for previous untreated eotaxin-high Korean pts with advanced PDA. **Methods:** Eligible pts with histologically proven locally advanced and metastatic PDA (except peritoneal carcinomatosis), age > 18 years, and ECOG PS 0–2 were recruited. Pts were randomly assigned (1:1) to receive either G/C or G/C with GV1001 (G/C/GV). All pts receiving G/C/GV were with high serum eotaxin level (≥81.02 ng/mL), and the pts receiving G/C were randomly assigned again (1:1) to eotaxin-high and eotaxin-low pts. Study was designed according to Korean MFDS guidance for approval of clinical trial. G/C treatment included G (1000 mg/m^2, 30 min IVF, D 1, 8, & 15) and C (830 mg/m^2 BID for 21 days per month (m). G/C/GV treatment included an intradermal injection of GM-CSF (75 μg) and GV1001 (0.56 mg; D 1, 3, & 5, once on week 2–4, & 6, then monthly thereafter) from the start of G/C. The primary endpoint was OS. The secondary endpoints included time to progression (TTP), objective response rate, and safety. Survival data was analyzed using the copula graphic estimate method under dependent censoring. The response was independently assessed per RECIST v1.1. Under the one-sided significance level of 2.5% and to achieve the power of 80% of the statistical significance with the median OS difference from 7.9 to 14.9 m (HR = 0.53), 85 events and 118 registrations needed. Considering 20% drop-outs, 148 registrations were required. **Results:** Between Nov 2015 and Apr 2020, of 511 pts screened in 16 centers, eotaxin-high pts were identified as 34.7% (174 / 502 pts). 148 pts randomly assigned to G/C/GV (n = 75; all eotaxine-high) and G/C (n = 73; 37 eotaxine-high, 36 eotaxine-low). Median OS was significantly improved in the G/C/GV group with 11.3m [95% CI 8.6-14.0] than G/C group with 7.5 m [95% CI 5.1-10.0] (p = 0.021). Also, median TTP was significantly improved in the G/C/GV group (7.3 m [95% CI 5.0-9.7]) than in the G/C group (4.5 m [95% CI 3.2-5.8], p = 0.021). In other secondary endpoints, no statistical significance was confirmed between the two groups. Grade 3-4 treatment-emergent adverse events were reported in 49 pts (73.13%) vs. 58 pts (77.33%) in the G/C and G/C/GV group, without significant differences (p = 0.562). **Conclusions:** G/C/GV treatments significantly extend OS and TTP in advanced PDA than G/C, and specific safety-related issues had not been found. GV1001 should be considered as one of the options in PDA pts with high serum eotaxin levels. Clinical trial information: NCT02854072. Research Sponsor: SAMSUNG PHARM CO., LTD.

High CXCR4 expression in pancreatic ductal adenocarcinoma as characterized by an inflammatory tumor phenotype with potential implications for an immunotherapeutic approach. *First Author: Andreas Seeber, Department of Internal Medicine V (Hematology and Oncology), Medical University of Innsbruck, Comprehensive Cancer Center Innsbruck, Innsbruck, Austria*

Background: Immunotherapy is considered ineffective in the majority of patients with pancreatic ductal adenocarcinoma (PDAC), a consequence of a highly immunosuppressive tumor microenvironment (TME). However, treatment induced inhibition of CXC chemokine receptor 4 (CXCR4) and programmed cell death protein-1 (PD-1) in the COMBAT trial caused T cell infiltration and tumor regression in a subset of PDAC patients. Elucidating a phenotype that predicts response is clinically relevant. We performed a comprehensive molecular landscape study in PDAC evaluating CXCR4 RNA expression. **Methods:** 3,647 PDAC specimens were centrally analysed. NextGen DNA sequencing (NextSeq, 592 gene panel or NovaSeq, whole-exome sequencing), whole-transcriptome RNA sequencing (NovaSeq) and immunohistochemistry (Caris Life Sciences, Phoenix, AZ) were performed. Gene expression is reported as TPM (Transcripts per million). Pathway gene enrichment analyses were done using GSEA (Subramaniam 2015, PNAS). Immune cell fraction was calculated by QuantiSeq (Finotello 2019, Genome Medicine). The cohort was stratified in quartiles according to CXCR4 RNA expression status. **Results:** Overall, CXCR4 expression was higher in primary tumors compared to distant metastasis (38 vs. 28 TPM, p < 0.0001). CXCR4-high (top quartile: > 59 TPMs), when compared to CXCR4-low (bottom quartile: < 17 TPM) PDACs, were characterized by a high prevalence of mutations in signal transduction pathway genes (e.g. *GNAS*: 3.6 vs. 0.5%), an increased infiltration of immune cells (e.g. $CD8^+$ T cells, M1 macrophages), and a higher expression of HLA-DRA and HLA-E (all p < 0.0001). We detected an upregulation of CXCL9, CXCL10, CXCL12, CCL5, IDO1 and LAG3 in CXCR4-high compared to CXCR4-low tumors. In contrast, lower PD-L1 expression (17.4 vs. 13.1%, p = 0.02), genomic loss of heterozygosity (17.4 vs. 10.8%), and a lower frequency of gene amplifications in *ERBB2* (2.1 vs. 0.1%), *TNFRSF14* (2.0 vs. 0.1%), and *TP53* (82 vs. 73%, all p < 0.0001) were observed. Moreover, CXCR4-high expression was associated with a better survival (HR: 1.417, 95% CI [1.168-1.72], p < 0.001). **Conclusions:** This is the first study comprehensively investigating the molecular landscape of PDACs according to CXCR4 RNA expression. High CXCR4 expression is associated with an improved survival and a pro-inflammatory phenotype that may identify a subset of tumors with greater responsiveness to immunotherapeutic approaches. Research Sponsor: None.

Identification and prognostic impact of *PBRM1* mutations in biliary tract cancers: Results of a comprehensive molecular profiling study. *First Author: Kai Zimmer, Department of Internal Medicine V (Hematology and Oncology), Medical University of Innsbruck, Comprehensive Cancer Center Innsbruck, Innsbruck, Austria*

Background: The prognosis of biliary tract cancers (BTC) remains dismal and novel treatment strategies are needed to improve survival. Polybromo-1 (*PBRM1*) is a subunit of the PBF chromatin-remodeling complex and preclinical studies suggest induction of synthetic lethality by PARP inhibitors in *PBRM1*-mutated cancers. Therefore, we aimed to describe the molecular landscape in BTC harboring *PBRM1* mutations. **Methods:** 1,848 BTC samples were included in this study. Specimens were analyzed using NextGen DNA sequencing (NextSeq, 592 gene panel or NovaSeq, whole-exome sequencing), whole-transcriptome RNA sequencing (NovaSeq) and immunohistochemistry (Caris Life Sciences, Phoenix, AZ). Pathway gene enrichment analyses were done using GSEA (Subramaniam 2015, PNAS). Immune cell fraction was calculated by QuantiSeq (Finotello 2019, Genome Medicine). Survival was calculated from time of tissue collection to last contact using Kaplan-Meier estimates. **Results:** *PBRM1* mutations were identified in 8.1% (n = 150) of BTC tumors and were more prevalent in intrahepatic BTC (9.9%) than in gallbladder cancer (6%, p = 0.0141) and in extrahepatic BTC (4.5%, p = 0.008). In *PBRM1*-mutated tumors, we found a higher rate of MSI-H/dMMR (8.7% vs. 2.1%, p < 0.0001) and a higher median TMB (4 vs. 3 mt/MB, p < 0.0001). When compared to *PBRM1*-wildtype cancers higher rates of co-mutations in chromatin-remodeling genes (e.g. *ARID1A,* 31% vs. 16%, p < 0.0001) and DNA damage repair pathway (e.g. *ATRX,* 4.4% vs. 0.3%, p < 0.0001) were detected. Within *PBRM1*-mutated tumors, a significant higher frequency of infiltrating M1 macrophages was observed (p < 0.0001). Gene set enrichment analysis revealed that genes associated with tumor inflammation (e.g. *HLA-DRA*, *HLA-DRB1*, *IFNGR1*) were enriched in *PBRM1*-mutated tumors (NES = 2.02, FDR = 1.3%, p < 0.0001). Overall survival analysis showed that *PBRM1* mutations were associated with a favorable outcome (HR 1.502, 95% CI [1.013-2.227], p = 0.041). This relationship was also present in MSS subgroup (HR: 1.667, [1.026-2.71], p = 0.037). **Conclusions:** This is the largest and most extensive molecular profiling study focusing on *PBRM1*-mutated BTC. Co-mutations in chromatin-remodelling and DNA damage repair genes might set the stage for clinical testing of PARP inhibitors in *PBRM1*-mutated BTC. Moreover, a distinct tumor microenvironment characterized by high M1 macrophages infiltration and an enrichment of inflammatory genes suggest a potential benefit of immunotherapy. Research Sponsor: None.

4023 **Poster Discussion Session**

Multimodal profiling of biliary tract cancers to detect potentially actionable biomarkers and differences in immune signatures between subtypes. *First Author: Kabir Mody, Mayo Clinic, Jacksonville, FL*

Background: Biliary tract cancers (BTC) are increasingly subtyped by molecular alterations, but little is known about the relationship between gain-of-function mutations and the RNA transcript expression of immune-related pathways. **Methods:** A sample of retrospective, clinicogenomic and transcriptomic data from de-identified records of patients with BTC in the Tempus database was selected. We then investigated the relationship between the mutational landscape and immune-related RNA signatures of different anatomic and genomic BTC subtypes. **Results:** The cohort included 455 samples of intrahepatic bile duct (IH) (n=267), gallbladder (GB) (n=153), and extrahepatic bile duct (EH) (n=35) cancer subtypes. Across all subtypes, we detected alterations in *TP53* (43.8%), *ARID1A* (19.8%), *KMT2C* (18.2%), *BAP1* (14.6%), *KRAS* (12.7%), *TERT* (12.0%), *IDH1* (11.4%), *KMT2D* (11.0%), *LRP1B* (11.0%), and *PBRM1* (10.7%), along with *FGFR2* fusions (2.6%). Potentially actionable biomarkers (*FGFR2* and *NTRK1-3* fusions, *IDH1* and $BRAF^{V600E}$ mutations, tumor mutational burden [TMB]>10, HER2 expression, and/or microsatellite instability) were identified in 21.1% of all BTC and 28.6% of IH samples. Mutually exclusive alterations observed between subtypes were *TP53* & *BAP1*, *KRAS* & *BAP1*, *TP53* & *IDH1*, *KRAS* & *IDH1*, and *SMAD4* & *BAP1* ($P < 0.001$ for all). GB was more inflamed based on RNA signatures and classical immune biomarkers, including PD-L1 and TMB. RNA signature analyses revealed a higher expression of immune-related pathways in GB than IH ($P = 0.001$) with no differences in comparison with EH. PD-L1 expression and continuous TMB were elevated in GB versus the other anatomical subtypes. Significant associations were noted between particular genetic mutations and immune profiling features (table). **Conclusions:** BTC subtypes are diverse in DNA alterations, RNA inflammatory signatures, and immune markers. Notably, potentially actionable biomarkers were identified in a sizable portion of the cohort and varied significantly between subtypes. These results provide guidance for targeted therapy development and support the use of multimodal immune profiling for BTC. For example, GB-specific clinical trials may be considered due to the relative increase in immune-related biomarkers observed in GB and the historically limited success of BTC trials. Research Sponsor: None.

The prognostic value of tumor markers in patients (pts) with resectable gastric cancer (GC) receiving perioperative therapy in the CRITICS trial. *First Author: Astrid E. Slagter, Antoni van Leeuwenhoek/Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Carcinoembryonic antigen (CEA) and carbohydrate antigen (CA) 19-9 are well-known tumor markers. Most studies on CEA and CA 19-9 in pts with GC were performed in Asia, and/or in the metastatic setting. The aim of this study was to investigate the prognostic value of blood derived laboratory parameters in a cohort of European pts with resectable non-metastatic GC. **Methods:** In the CRITICS trial, 788 pts with resectable GC underwent perioperative therapy (preoperative chemotherapy plus either postoperative chemotherapy or postoperative chemoradiotherapy). Blood levels of CEA, CA 19-9, alkaline phosphatase (AP), creatinine, neutrophils, hemoglobin (Hb) and lactate dehydrogenase (LDH) were determined prior to treatment. Data for these variables were available for at least 89% of the pts. Factors significant on univariable cox regression analysis were further explored in multivariable analysis. Probabilities to undergo potentially curative surgery was investigated for factors significant on multivariable analysis. The relationship between tumor markers and the presence of circulating tumor DNA (ctDNA) was explored in 50 pts with available ctDNA data. **Results:** CEA and CA 19-9 were identified as independent prognostic factors for survival (Table). Probabilities to undergo potentially curative surgery were 86%, 77% and 60% for pts with no elevated tumor makers *versus* those with elevated CEA or elevated CA 19-9 *versus* those with both tumor markers elevated, respectively ($p<0.001$). No relationship was found between elevated tumor marker(s) and the presence of ctDNA neither pretreatment nor preoperatively. **Conclusions:** Pretreatment blood levels of CEA and CA 19-9 were identified as prognostic factors for overall survival in a large cohort of European GC pts with potentially curable disease. These factors may guide treatment choices at an early phase and should be included in future trials to determine their role in clinical decision making. Research Sponsor: Dutch Cancer Society, Dutch Colorectal Cancer Groupp, Hoffman La Roche.

Phase 1 study of the liposomal formulation of eribulin (E7389-LF): Results from the advanced gastric cancer expansion cohort. *First Author: Kensei Yamaguchi, Department of Gastroenterological Chemotherapy, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Eribulin has proven efficacy in previously treated metastatic breast cancer and liposarcoma. E7389-LF is a new formulation that uses liposomes to encapsulate eribulin, which is anticipated to improve eribulin concentration in tumor tissues. In the dose-expansion part of a phase 1 study of E7389-LF, the safety profile was acceptable and 2 patients (pts) out of 10 with gastric cancer (GC) had an objective response. Thus, the GC cohort was expanded for further evaluation. Here, we report efficacy and safety data from the phase 1 expansion cohort of pts with advanced GC who were treated with E7389-LF. **Methods:** Eligible pts were those with GC who had no alternative standard or effective therapy options after ≥2 prior chemotherapy regimens. Target total enrollment was 32 pts (10 pts in the initial GC cohort plus an additional 22 pts in the expanded cohort). E7389-LF 2.0 mg/m^2 was administered intravenously once every 3 weeks. Tumor responses were assessed every 6 weeks (± 1 week) by RECIST v1.1. **Results:** At data cutoff (Oct 16, 2020), 34 pts with GC were enrolled (10 pts in the initial GC cohort; 24 pts in the expanded GC cohort) with a median of 5 prior therapies (range, 2–11). Previous immune checkpoint inhibitor (ICI) therapy was reported for 26 (76.5%) pts. All pts were evaluable for objective response rate (ORR) and progression-free survival (PFS), and 30 pts were evaluable for overall survival (OS). Among all pts with GC, the ORR was 17.6% (95% CI 6.8–34.5) and the disease control rate was 79.4% (95% CI 62.1–91.3). Median PFS was 3.7 months (95% CI 2.7–4.3) and median OS was 7.6 months (95% CI 6.7–15.4). The ORRs were 19.2% (95% CI 6.6–39.4) in ICI-pretreated pts and 12.5% (95% CI 0.3–52.7) in pts without prior ICI therapy. Median PFS was similar regardless of prior treatment with ICIs (3.7 months [95% CI 2.7–5.6] in ICI-pretreated pts vs 3.4 months [95% CI 1.0–4.3] in pts without prior ICI therapy); however, the PFS rate at 6 months in ICI-pretreated pts was higher vs the rate in pts without prior ICI therapy (35.9% [95% CI 17.2–55.1] vs 0%, respectively). Median OS was also longer in ICI-pretreated pts (evaluable pts, n = 23) vs pts without prior ICI therapy (evaluable pts, n = 7) (10.0 months [95% CI 6.7–not estimable] vs 6.7 months [95% CI 3.1–8.5], respectively). Common grade ≥3 adverse events included neutropenia (41.2%), leukopenia (29.4%), and anemia (26.5%). In cycle 1, there were no cases of febrile neutropenia among the 22 pts treated with prophylactic peg-GCSF; among pts who did not receive prophylactic peg-GCSF, 16.7% of pts had febrile neutropenia. **Conclusions:** E7389-LF had a manageable safety profile and encouraging activity in pts with heavily treated GC. In pts with GC, prior treatment with ICIs might enhance the potential efficacy of E7389-LF. These results support further development of E7389-LF for advanced GC. Clinical trial information: NCT03207672. Research Sponsor: Eisai Co., Ltd., Tokyo, Japan.

Neoadjuvant nivolumab monotherapy in patients with resectable gastric cancer: Preliminary results from a multicenter study. *First Author: Shuji Takiguchi, Nagoya City University, Nagoya, Japan*

Background: In recent years, several studies suggest that neoadjuvant treatment improve outcomes of patients with resectable advanced gastric cancer (GC). In addition, nivolumab has demonstrated clinical efficacy in multiple types of advanced cancer, and the efficacy of neoadjuvant nivolumab monotherapy has been suggested in a past clinical trial in patients with resectable non-small cell lung cancer (NSCLC). Therefore, this phase I study was planned to evaluate the safety and efficacy of neoadjuvant nivolumab monotherapy in patients with resectable GC or NSCLC. Here we report preliminary results from GC patients. **Methods:** This study is a phase I, multicenter, open-label, single arm study to evaluate the safety and efficacy of neoadjuvant nivolumab monotherapy in patients with resectable GC (stage I or II [cT2 or more advanced for both], or stage III) before standard surgery. Nivolumab 240 mg was administered twice every two weeks. The primary endpoint is safety. Efficacy endpoints include major pathological response (MPR) defined as residual disease < 10% and the response of primary lesion, and surgical endpoints include proportion of patients undergoing surgery with curative intent and R0 resection rate. Biomarkers such as PD-L1 expression and MSI status are also evaluated. **Results:** From November 2018 to December 2019, 31 GC patients were enrolled into this study. The median age was 69 years (range, 44-84) and 21 patients (67.7%) were men. According to UICC 8th, clinical stage was stage I in 7 patients (22.6%), stage IIA in 0 patients (0%), stage IIB in 14 patients (45.2%), and stage III in 10 patients (32.3%). MSI status was high in 7 patients (22.6%), low in 4 patients (12.9%), and stable in 20 patients (64.5%). Treatment-related adverse events (TRAEs) occurred in 7 patients (22.6%). The most frequent TRAE was rash which occurred in 2 patients (6.5%); the other TRAEs occurred in 1 patient each. Asymptomatic lipase increased was the only grade 3 TRAE; the other TRAEs were all grade 1 or 2 with no new safety signal. All enrolled patients completed 2 doses of nivolumab. Five patients (16.1%) had MPRs, of whom 1 patient had pathological complete response (pCR). Four of 5 MPRs, 1 pCR included, was observed in 7 MSI-H patients (57.1%) and the remaining case of MPR was observed among 20 MSS patients (5%), whereas no MPRs was achieved in 4 MSI-L patients. Among the 31 patients, 30 patients underwent surgery. The remaining 1 patient discontinued the study before surgery due to disease progression. A total of 27 patients (90%) had R0 resection. **Conclusions:** Neoadjuvant nivolumab monotherapy showed acceptable safety profile and antitumor activity in patients with resectable GC. Recurrence free survival and overall survival in these patients are under follow-up. Clinical trial information: JapicCTI-183895. Clinical trial information: JapicCTI-183895. 4027 **Poster Session**

A phase II study of chemoselection with docetaxel, cisplatin, and 5–fluorouracil as a strategy for organ preservation in patients with resectable esophageal cancer (CROC trial). *First Author: Chikatoshi Katada, Department of Gastroenterology, Kitasato University School of Medicine, Sagamihara, Japan*

Background: In patients with resectable esophageal squamous cell carcinoma (SCC), the outcomes of chemoradiotherapy (CRT) for good responders after three courses of induction chemotherapy (IC) with docetaxel, cisplatin, and 5–fluorouracil (DCF chemotherapy) were unclear. **Methods:** Patients with clinical stage IB–III (UICC 7th) resectable esophageal SCC were eligible. IC included docetaxel 75 mg/m^2 on day 1, cisplatin 75 mg/m^2 on day 1, and 5–fluorouracil 750 mg/m^2 on days 1–5, repeated every 3 weeks for 3 cycles. The response was evaluated after 2 and 3 courses of IC. Patients were considered to have a remarkable response (RR) if an endoscopic examination with a central review showed shrinking of the primary lesion equivalent to T1 and the short axis of the metastatic lymph nodes were all < 1 cm on computed tomography—in other words, down staging to T1N0M0 stage IA. Patients were considered to have a poor response (POR) if they had progressive disease or no signs of reduction. Patients who did not achieve RR or POR were deemed to have limited partial response (LPR). CRT was administered to patients who achieved RR, and surgery was performed in patients who achieved LPR or POR. CRT included cisplatin 75 mg/m^2 on day 1 and 5–fluorouracil 1000 mg/m^2 on days 1–4, repeated every 4 weeks for 2 cycles. Radiotherapy was administered as 50.4 Gy in 28 fractions. The primary endpoint was a 1–year progression free survival (PFS) for RR followed by CRT. **Results:** A total of 92 patients were enrolled. Two patients with non–SCC (n = 1) and distant metastasis (n = 1) were excluded. Therefore, 90 patients were included in the analysis group. Although 1 patient could not continue IC due to renal failure, the remaining 89 patients completed 3 courses of IC. The response after IC were RR in 58.4% (52/89), LPR in 41.6% (37/89), and POR in 0.0% (0/89). Three patients who achieved RR underwent surgery owing to renal dysfunction (n = 1), curative irradiation difficulty due to intestinal malrotation (n = 1), and CRT refusal (n = 1). Six patients who achieved LPR underwent CRT owing to surgery refusal (n = 3), unresectable tumors (n = 2), and respiratory dysfunction due to emphysema (n = 1). The complete response rate for RR followed by CRT was 89.8%. During the median follow–up period of 33 months (range: 1–85), the 1 and 3–years overall survival (OS) for the analysis group were 96.6% and 74.1%, respectively. The 1 and 3–years organ preservation survival for the analysis group were 56.8% and 45.3%, respectively. The 1 and 3–years OS for RR followed by CRT (n = 49) vs. LPR followed by surgery (n = 31) were 100% vs. 93.1% and 83.7% vs. 62.8%, respectively (p = 0.06). The 1 and 3–years PFS for RR followed by CRT were 89.8% and 70.0%, respectively. **Conclusions:** Three courses of DCF chemotherapy followed by CRT is an effective treatment for patients with resectable esophageal SCC who respond to the IC regimen. Clinical trial information: 8086. Research Sponsor: Yakult Honsha Co., Ltd.

4028 **Poster Session**

Camrelizumab plus chemotherapy as neoadjuvant therapy for resectable, locally advanced esophageal squamous cell carcinoma (NIC-ESCC2019): A multicenter, open-label, single-arm, phase 2 study. *First Author: Jingpei Li, Department of Thoracic Surgery/Esophageal Surgery, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China*

Background: Despite multidisciplinary therapies, prognosis of pts with resectable esophageal squamous cell carcinoma (ESCC) remains poor. Combining PD-1 blockade to neoadjuvant chemotherapy might be a feasible and effective strategy. Camrelizumab (an anti-PD-1 antibody) was approved for advanced or metastatic ESCC in the second-line setting and showed improved anti-tumor activity and survival benefit when combined with chemotherapy in multiple advanced tumors. **Methods:** In this NIC-ESCC2019 phase 2 study, histologically or cytologically confirmed ESCC pts (stage II-IVA) were enrolled to receive two cycles of neoadjuvant chemoimmunotherapy (NIC) with camrelizumab (200 mg on day 1) plus nab-paclitaxel (260 mg/m^2 in total on day 1 and day 8) and cisplatin (75 mg/m^2 in total on days 1-3) of each 21-day cycle, followed by esophagectomy. The primary endpoint was complete pathologic response (CPR) rate in the primary tumor. Besides, we also explored the relationship between the tumor genomic profile or primary-tumor microenvironment and the pathological response. **Results:** Between Jan 17, 2020 and Dec 8, 2020, 56 pts were enrolled. 51 pts underwent surgical resection, and all had complete tumor resection. CPR was achieved in 18 (35.3%; 95% CI, 21.7%-48.9%) pts; 12 (23.5%) pts had major pathologic response (MPR), and 21 (41.2%) had incomplete pathological response (IPR). Of note, 16 (31.4%) pts achieved CPR in both primary tumor and lymph nodes. The objective response rate was 66.7% (95% CI, 40.0-70.4). No in-hospital mortality occurred. The most common treatment-related adverse events (TRAEs) were decreased WBC (20 [36%] of 56 pts), vomiting (19 [34%]), and alopecia (18 [32%]). Grade 3 TRAEs only occurred in 6 (11%) pts, and there were no grade 4 or 5 TRAEs. The most common immune-related AEs included grade 1-2 rash maculo-papular (7 [13%]) and reactive cutaneous capillary endothelial proliferation (5 [9%]). Presence of mutations in CREBBP and KMT2D at treatment-nave time-point was correlated with non-response group (IPR and stable disease) (CREBBP, p = 0.046; KMT2D, p = 0.047). Among the immune populations, CD8+, CD8+PD-1+ and CD8+PD-L1+ T cells increased significantly after two doses of NIC, especially in the CPR+MPR group (CD8+, p = 0.013; CD8+PD-1+, p < 0.001; CD8+PD-L1+, p = 0.068). **Conclusions:** The addition of camrelizumab to neoadjuvant chemotherapy in ESCC demonstrated promising efficacy with acceptable toxicity, supporting the further investigation in a randomized phase 3 clinical trial. Clinical trial information: NCT04225364. Research Sponsor: Jiangsu Hengrui Medicine and BGI Genomics.

Correlation analysis of present of mutations in significantly mutant genes and response to PD-1 blockade.

	Non-response (n=10)	Response (n=41)	p value assessed by Pearson's Chi-squared test

Nivolumab and ipilimumab for second-line therapy in elderly patients with advanced esophageal squamous cell cancer: Safety interim analysis of the RAMONA trial. *First Author: Nicolai Hartel, Heidelberg University, Mannheim, Germany*

Background: Advanced esophageal squamous cell cancer (ESCC) is frequently diagnosed in elderly patients (pts) with additional comorbidities. Limited treatment options are available. We report the safety interim analysis of a phase II clinical trial evaluating nivolumab and ipilimumab as second-line therapy for advanced ESCC in elderly pts. **Methods:** RAMONA is a multicenter open-label phase II trial assessing nivolumab/ipilimumab combination therapy in elderly pts (≥65 years). The geriatric status of the pts was assessed using the G8 screening tool and the Deficit Accumulation Frailty Index (DAFI). After a run-in phase of 3 cycles nivolumab (240mg Q2W), cohort assignment was based on a safety assessment. Pts with toxicities grade ≤2 were considered eligible for escalation to nivolumab (240mg Q2W)/ipilimumab (1mg/kg Q6W) combination therapy (cohort B). Other pts remained on nivolumab monotherapy (cohort A). Primary endpoint is overall survival (OS). Key secondary endpoint is time to Quality of Life deterioration defined as a loss of ≥ 10 points in the EORTC QLQ-C30 compared to baseline. Adverse events were assessed according to NCI-CTCAE version 4.03. **Results:** From February 2018 until February 2020, 69 pts entered the study. 61 pts were eligible for safety interim analysis. Median age of the pts was 71.9 yrs (± 5.4), median KPS score was 80% (50-100%). In 73.8% of the pts, metastases were detected at the time of study inclusion. Most pts received the IO therapy in ≥ 2nd line (91.8%). The mean G8-score at screening was 11.9 points (46 pts ≤ 14 points, 75.4%) (mean DAFI: 0.19). Based on safety assessment, 42 pts were escalated to nivolumab/ipilimumab, while 9 pts remained on nivolumab monotherapy. 10 pts were not allocated at the time of analysis. Median numbers of cumulative doses were 3.0 [1.0 - 3.0] for the run-in phase (nivolumab), 6.0 [1.0 – 48.0] for nivolumab therapy (cohort A/B) and 2.5 [1.0 – 16.0] for ipilimumab (cohort B). Median treatment duration was 144.5 days (56-781 days) in cohort A and 231 days (85-484 days) in cohort B. Frailty indices remained stable after 3 cycles of nivolumab with limited toxicity at the time of the safety assessment. Drug-related treatment emergent adverse events (AEs) were observed in 42 pts (68.9%); 29/42 in cohort A, 8/9 in cohort B, and 5/10 pts not allocated at the time of analysis. Grade ≥3 AEs were detected in 9 pts of 42 in cohort A and 4 of 9 pts in cohort B. Drug-related treatment emergent serious adverse events (SAEs) were detected in 12 pts (19.7%); 8/42 in cohort A, 2/9 pts in cohort B, and 2/10 pts not yet allocated. **Conclusions:** Combined nivolumab/ipilimumab is a safe and feasible second-line therapy for elderly pts with advanced ESCC. Most pts could be escalated to nivolumab/ipilimumab. Treatment duration was exceptional long for a subset of pts. Clinical trial information: NCT03416244. Research Sponsor: Bristol-Meyers-Squibb.

4030 **Poster Session**

LEAP-005: A phase 2 multicohort study of lenvatinib plus pembrolizumab in patients with previously treated selected solid tumors—Results from the gastric cancer cohort. *First Author: Hyun Cheol Cheol Chung, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Lenvatinib, an anti-angiogenic multiple receptor tyrosine kinase inhibitor, in combination with the anti–PD-1 antibody pembrolizumab, has demonstrated promising antitumor activity with manageable safety in the first- or second-line in a phase 2 trial of patients with advanced gastric cancer. LEAP-005 (NCT03797326) is a phase 2, multicohort, nonrandomized, open-label study evaluating efficacy and safety of lenvatinib plus pembrolizumab in patients with previously treated advanced solid tumors; here, we present findings from the gastric cancer cohort of LEAP-005. **Methods:** Eligible patients were aged ≥18 years with histologically or cytologically confirmed metastatic and/or unresectable gastric cancer, received at least 2 prior lines of therapy, had measurable disease per RECIST v1.1, ECOG PS of 0–1, and provided a tissue sample evaluable for PD-L1 expression. Patients received lenvatinib 20 mg once daily plus pembrolizumab 200 mg Q3W for up to 35 cycles of pembrolizumab (approximately 2 years) or until confirmed disease progression, unacceptable toxicity, or withdrawal of consent. Treatment with lenvatinib could continue beyond 2 years in patients experiencing clinical benefit. Primary endpoints were ORR (per RECIST v1.1 by blinded independent central review) and safety. Secondary endpoints included disease control rate (DCR; comprising CR, PR, and SD), duration of response (DOR), PFS, and OS. Tumor imaging was performed Q9W from treatment initiation for 54 weeks, then Q12W to week 102, and Q24W thereafter. **Results:** 31 patients were enrolled in the gastric cancer cohort; 87% were male, 58% were aged < 65 years, and 71% had PD-L1 combined positive score (CPS) ≥1. Median time from first dose to data cutoff (April 10, 2020) was 7.0 months (range, 1.9–11.9); 19 patients (61%) had discontinued treatment. ORR was 10% (95% CI, 2–26); 1 patient had CR (3%), and 2 had a PR (6%). 12 patients (39%) had SD. Median DOR was not reached (range, 2.1+ to 2.3+ months). DCR was 48% (95% CI, 30–67). Median PFS was 2.5 months (95% CI, 1.8–4.2). Median OS was 5.9 months (95% CI, 2.6–8.7). 28 patients (90%) had treatment-related AEs, including 13 patients (42%) with grade 3–5 AEs. 1 patient had a treatment-related AE that led to death (hemorrhage). 8 patients (26%) had immune-mediated AEs: hypothyroidism (n = 5), hyperthyroidism (n = 2), and pneumonitis (n = 1). There were no infusion-related reactions. **Conclusions:** In patients with advanced gastric cancer who received 2 prior lines of therapy, lenvatinib plus pembrolizumab demonstrated promising antitumor activity and a manageable safety profile. Based on these data, enrollment in the gastric cancer cohort has been expanded to 100 patients. Clinical trial information: NCT03797326. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Frequency of homologous recombination-related (HRR) genes mutations in gastric cancer. *First Author: Wei Wang, Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China*

Background: Homologous recombination deficiency (HRD) might contribute to predict response of immunotherapy and Chemotherapy response and PARP inhibitor (PARPi) therapy. The HRD phenotype has been defined as the presence of a non-silent somatic mutation in homologous recombination-related (HRR) genes. We aimed to analyze the mutational pattern of HRR genes and the relationship between HRR-related genes and clinical outcomes in gastric cancer. **Methods:** We prospectively sequenced 386 Chinese patients with gastric cancer using next-generation sequencing techniques with 808 cancer-related genes. 440 patients with WES data from the TCGA project were included. The 15 HRR genes were selected on clinical evidence of sensitivity to PARP inhibitors and immunotherapy. Correlations between HRR genes and clinical outcomes were identified via bioinformatic analysis using TCGA datasets. **Results:** In the Chinese cohort, 10.4% (40/386) patients exhibited genomic alterations in HRR genes. The frequently mutated genes were BRCA2 (2.3%), ATM (1.8%), CDK12 (1.8%), BRCA1 (1.0%), CHEK2(1.0%), PALB2(0.8%), BARD1 (0.5%), RAD51B (0.5%), and RAD54L (0.3%). 8.3% patients had at least one somatic HRR genes mutation. Pathogenic germline variants were identified in 2.1% (8/386) patients. No participants carried both germline and somatic HRR gene mutations. In TCGA cohort, 19.1% (841/440) patients had at least one somatic mutation in an HRR gene. The frequently mutated genes were BRCA2 (6.4%), ATM (6.4%), CDK12 (3.2%), BRCA1 (3.2%), BARD1 (2.3%), PALB2 (2.3%), HEK2 (1.6%), CHEK1 (1.4%), BROP1 (1.1%), RAD54L (1.1%), FANCL (0.9%), RAD51D (0.9%), RAD51C (0.7%), PPP2R2A (0.5%), and RAD51B (0.5%). Chinese cohort had lower frequently somatic mutation of HRR genes compared to that in TCGA cohort (8.3% vs 19.1%, p < 0.001). Interestingly, in the TCGA cohort, patients with HRR-mut had significantly elevated tumor mutational burden, microsatellite instability status and enhanced immune activity than patients with HRR-wt. In the MSK-IMPACT cohort comprising 49 patients treated with ICIs, patients with HRR-mut had significantly better overall survival compared to those in patients with HRR-wt (p = 0.027). **Conclusions:** Our data suggest that patients with altered HRR genes may be rational candidates for precision oncology treatment and provide new opportunities to predict the tumor response to multiple treatments, such as immunotherapeutic combine PARP inhibitor (PARPi) therapy. Exploring other biomarkers of HRD to predict the response to PARPi and immunotherapeutic in GC is necessary. Research Sponsor: None.

ENSURE: An international multicenter study exploring whether surveillance after esophageal cancer surgery impacts oncological and quality-of-life outcomes. *First Author: Jessie A Elliott, St. James's Hospital, Dublin, Ireland*

Background: Although established and emerging therapies for recurrent esophageal cancer (EC) may impact on survival and health related quality of life (HRQL), surveillance protocols after the primary curative treatment of EC are varied and inconsistent, reflecting a limited evidence-base to guide an optimum approach. Specifically, whether advantages exist for an intensive surveillance protocol is unknown and was the focus of this study. **Methods:** European iNvestigation of SUrveillance after Resection for Esophageal cancer (ENSURE) is an international multicenter retrospective observational study of consecutive patients undergoing surgery with curative intent for esophageal and gastroesophageal junction cancers (2009 – 2015) across 20 European and North American cancer centers (NCT03461341). Intensive surveillance (IS) was defined as routine annual CT/PET-CT along with clinical assessment during the first three postoperative years, and compared with standard surveillance (SS) with investigation as clinically indicated. The primary outcome measure was overall survival (OS), secondary outcomes included treatment administered, disease-specific survival (DSS), disease-free survival (DFS), recurrence pattern, and HRQL. Multivariable linear, logistic and Cox proportional hazards regression analyses were performed to determine the independent impact of surveillance on oncologic outcomes and HRQL. **Results:** 4,682 patients were studied (72.6% adenocarcinoma, 69.1% neoadjuvant therapy). 45.5% underwent IS. At a median follow-up of 60 months, 47.5% developed disease recurrence. Oligometastatic recurrence occurred in 39% of cases, with 31% receiving best supportive care, 60% chemotherapy and/or radiation, and 8% surgical resection. IS was associated with reduced symptomatic recurrence (odds ratio [OR] 0.17 [0.12–0.25]), increased tumor-directed therapy (OR 2.09 [1.58–2.77]), and improved OS (HR 0.90 [0.82–0.98], 5-year OS 47.9±1.2% versus 43.2±1.1%). After adjusting for confounders, significantly improved overall survival with IS was maintained for patients who underwent surgery alone as initial therapy (HR 0.60 [0.47–0.78]) and in those with lower pathological (y)pT stages (Tis-2, HR 0.72 [0.58–0.89]). IS was associated with greater anxiety (P= 0.016), but similar overall HRQL. **Conclusions:** These data suggest that IS may improve oncologic outcomes, particularly in patients with early stage disease at presentation or with a favorable pathological stage post induction therapy. This may be relevant to guideline development and provide a framework and rationale for RCTs. It may also inform shared decision-making with patients at a time where therapeutic options for recurrence are expanding. Research Sponsor: Supported by a fellowship award from the Health Research Board, Ireland, to Jessie A Elliott (HPF 2015-1013) and a grant award from the Surgical Research Society, United Kingdom and Ireland.

Circulating tumor DNA (ctDNA) analysis by low-coverage whole genome sequencing (lcWGS) of resectable esophageal adenocarcinoma (rEAC) patients. *First Author: Tom van den Ende, Amsterdam UMC, University of Amsterdam, Department of Medical Oncology, Cancer Center Amsterdam, Meibergdreef 9, Amsterdam, Netherlands*

Background: ctDNA is becoming an established marker to assess tumor burden, relapse after surgery, and to identify responders in immunotherapy studies. In the phase II PERFECT trial rEAC patients were treated with neoadjuvant chemoradiotherapy (nCRT) and a PD-L1 inhibitor (van den Ende et al. CCR. 2021). Here we evaluated the potential of cell-free DNA (cfDNA) to predict pathological complete response (pCR) and recurrence. **Methods:** The cohort consisted of 40 patients and 145 plasma samples. EDTA blood samples were drawn at baseline (B, N = 40), in week 5 of nCRT (W5, N = 40), before surgery (OR, N = 33) and 3 months after surgery (FU, N = 32). cfDNA was isolated by affinity columns (CNAkit, QIAgen) quantified by spectrofluorometer (BioAnalyzer, Agilent), sequencing libraries were prepared for lcWGS (< 5-fold coverage, Tag-seq, Takara) and sequenced on a NovaSeq (S4, PE150). Sequencing data were processed with an in-house pipeline. Copy number aberrations (CNA) and the tumor fraction were estimated using the ichorCNA tool. Insert sizes were recovered and we determined a Tumor Enriched Fragment Fraction (TEFF), calculated by doing the ratio of fragments between 90-150 bp and 250-320 bp (enriched in tumor signal) and fragments between 150-250 bp and 320-360 bp (poor in tumor signal). ichorCNA and TEFF were used to quantify the ctDNA fraction in plasma samples. pCR was defined as ypT0N0. Residual tumor, progression or death before surgery were considered non-pCR. Relapse-free survival (RFS) was defined as the time after surgery until recurrence. **Results:** The pCR rate was 25% (10/40). The median fold change TEFF between B and W5 was -0.15 (range -0.67 to 0.44) in the pCR group and 0.16 (range -1.40 to 0.76) in the non-pCR group (Mann–Whitney U; p = 0.047). Of the 17 patients in whom ctDNA was detected (TEFF≥0.3 and/or ichorCNA≥0.03) in the FU sample, 13 (76%) showed a recurrence. Of the 15 patients with no ctDNA detected 5 (33%) showed a recurrence. Patients with ctDNA detected at FU had worse RFS, HR = 2.72 (95%CI 0.96-7.71; p = 0.050). Recurrences were detected earlier by FU ctDNA than by imaging due to physical complaints with a median of 312 days (163-798 days). **Conclusions:** lcWGS appears to be a useful tool to predict pCR and recurrence in resectable esophageal cancer. These lcWGS results will be further combined with fragmentomics analysis and targeted mutational data (Ion Torrent next-generation sequencing) in order to assess response to immunotherapy. Clinical trial information: NCT03087864. Research Sponsor: MLDS fund, Pharmaceutical/Biotech Company.

DNA and RNA sequencing analysis revealed alterations of *ANK3*, *PKHD1* and olfactory transduction as potential biomarker of three-year survival in gastric cancer. *First Author: Jian Wang, Department of Oncology, The First Affiliated Hospital of Nanjing Medical University, Nanjinng, China*

Background: Gastric cancer is the third leading cause of cancer related death worldwide. Although targeted and immune therapy have brought new benefit for patients, it still faces challenges of limited effective group and survival. Here we investigate the association of overall survival with DNA and RNA alterations to explore potential biomarkers of prognosis in gastric cancer. **Methods:** Whole-exome sequencing, RNA sequencing and clinical data of 442 patients with stomach cancer were downloaded from TCGA. Clinical factors and mutational landscape (insertion/ deletion/ single nucleotide variant) were compared between group of OS3+ (overall survival > 3 years) and OS3- (OS < 3 years). Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses were performed based on differentially expressed RNAs between the two groups. **Results:** 415 of 442 patients with stage information were included. The corresponding rates of OS3+ for patients in stage of I/II/III/IV was 15.5% (9/58), 10.8% (9/58), 10.9% (9/58), 13.6% (9/58), respectively. When comparing the 49 patients with OS3+ to others with OS3-, no difference of stage or sex distribution was discovered, except that OS3+ group had lower median age at diagnosis than OS3- group (63 vs. 71 years, *P = 0.029*). Tumor mutation burden was comparable between groups. Mutational landscape showed that the two groups shared 70% of top 20 mutations. Among the 20 hot genes, mutations of *ANK3(P = 0.006), PKHD1(P = 0.008)* were more frequent in OS3+ group, Studies in breast and prostate cancer inferred that, *ANK3* was involved in activity of androgen receptor signaling and cyclins, increased expression of ANK3 in cancer was probably associated with better survival. *PKHD1* was involved in calcium ion binding and actin binding and was identified as a protective factor for colorectal cancer. OS3- group tend to have higher mutation frequency of *HMCN1(P = 0.062)*. Previous reports showed that mutation of *HMCN1* was enriched in peritoneal metastasis of gastric cancer, it might contribute to progression in gastric cancer. Enrichment analysis revealed difference between the two groups in olfactory transduction ($P < 0.01$, KEGG analysis), neuroactive ligand-receptor interaction ($P < 0.05$, KEGG analysis) and detection of chemical stimulus in sensory perception of smell ($P < 0.01$, GO analysis). Numbers of discussions have inferred that genes involved in olfactory transduction may also participate in tumor cell proliferation, migration, and invasion. **Conclusions:** Patients with OS3+ was enriched with mutations of *ANK3* and *PKHD1* and present significant functional difference in olfactory transduction. These are potential biomarkers of better survival in gastric cancer. Further studies are needed to figure out their roles in tumor activity and provide insight for novel antitumor treatment development. Research Sponsor: None.

4035 **Poster Session**

The prognosis of gastric adenocarcinoma depends on the crosstalk between immune profiles and tumor genomic alterations. *First Author: Deqiang Wang, Department of Medical Oncology, Cancer Therapy Center, Affiliated Hospital of Jiangsu University, Zhenjiang, China*

Background: Gastric adenocarcinoma (GAC) is with a complex microenvironment of tumor cells. A better understanding of the immune landscape of GACs may lead to the improved treatment strategies with ICIs. **Methods:** To determine whether the molecular characteristics can serve in prognostic stratification of GACs, tumor tissue and blood samples were collected from 231 GAC patients. The median follow-up time was 34 months. The TCR profile was determined by TCR-β CDR3 sequencing while mutation and gene expression profiles were determined by whole exon and whole transcriptome sequencing, respectively. Tumour-infiltrating immune cells were characterized using immunofluorescence (IF) staining. **Results:** The results showed the OS of patients with high levels of TCR clonality (TCR clonal expansion) was significantly improved compared with patients with low levels (HR = 1.80 and 2.22, p = 0.022 and 0.008, respectively**)** in the whole group and in the subgroup of patients with stages IB to III disease. Furthermore, low local clonality was an independent risk factor for OS (adjusted-HR = 1.68 and 1.95, p = 0.049 and 0.029, respectively). Thus, TCR clonal expansion in tumour tissue had a strong prognostic value for GAC patients, independent of clinicopathological factors. Based on whole exon and whole transcriptome sequencing, RNF43/FBXW7/ARID2 mutations and local TCR clonality jointly impacted prognosis ($p < 0.001$), and functional changes in corresponding Wnt pathway/Notch pathway/SWI/SNF complex characterized a GAC subset with enhanced tumour immunogenicity and TCR clonal expansion. TCR CDR3 sequence similarity comparisons yielded clusters of TCR clones of likely similar functions. The most expansive TCR clusters negatively correlated with the percentage of subclonal mutations (Pearson r = -0.8183, $p < 0.001$), indicating that tumors with less genomic heterogeneity might induce a greater immune response. By IF staining and mutual correlation analysis, only M1 macrophages showed a significant positive correlation with local TCR clonality for epithelia, stroma, and total cell counts. Tumors were categorized according to the density of M1 macrophages, M1 macrophage infiltrated subtype was associated with favorable OS (p = 0.040 and 0.043) and its combination with the local TCR clonality improved prognosis stratification ($p < 0.001$). Finally, the scoring by local TCR clonality, RNF43/FBXW7/ARID2 mutations and M1 infiltration determined the best prognosis ($p < 0.001$). **Conclusions:** TCR profiles were associated with genomic alterations and may serve as a prognostic biomarker for GACs. A multi-omic model including TCR profiles might produce an improved stratification for treatments and outcomes. Research Sponsor: None.

Camrelizumab combined with FLOFOX as neoadjuvant therapy for resectable locally advanced gastric and gastroesophageal junction adenocarcinoma: Updated results of efficacy and safety. *First Author: Ying Liu, Department of Medical Oncology, Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China*

Background: Although anti-PD-1 antibody in combination with chemotherapy has shown promising antitumor activity in advanced gastric or gastroesophageal junction adenocarcinoma (GC/GEJC), the evidence of neoadjuvant therapy for locally advanced GC/GEJC is limited. Camrelizumab combined FOLFOX as neoadjuvant therapy for resectable locally advanced GC/GEJC was a prospective, single-arm, phase 2 study we conducted. Here, we updated the results of efficacy and safety of this study. **Methods:** Patients confirmed by endoscopic ultrasonography (EUS) and imaging with clinical stage≥T2 and/or positive lymph nodes were enrolled. They received 4 cycles of camrelizumab (200mg ivgtt on day1, q2w) plus FOLFOX (oxaliplatin 85mg/m^2 ivgtt, LV 200mg/m^2 ivgtt, 5-Fu 400mg/m^2 iv followed by 2.4mg/m^2 CIV 46 hours on day 1, q2w) as neoadjuvant therapy. Then patients without disease progression evaluated by imaging underwent gastrectomy of D2 lymph node dissection. The primary endpoint was pCR, the secondary endpoints were R0 resection rate and safety. **Results:** Between Jul 24 2019 and Nov 30 2020, 49 patients were enrolled. The median age was 57 years (29-72 years). All patients completed 4 cycles treatment. Unfortunately, 2 of them were confirmed PD by imaging. In addition, two patients refused gastrectomy and withdrew from the study. Eventually, 45 patients underwent gastrectomy, of which 3 patients had intraperitoneal metastases during the operation. A total of 42 patients were evaluable, all of them gained R0 resection (100%), 4 patients (10%) achieved pCR and 10 patients (24%) reached TRG1. Among the patients experienced pCR, one of them was Her-2 positive, one was MSI-H, the rest two of them were PD-L1-positive (CPS≥10). The most common ≥grade 3 adverse events (AEs) were neutropenia (35%) and leukopenia (16%). Only 1 patient (2%) experienced grade 3 immune-related AEs of alanine aminotransferase and aspartate aminotransferase increase. No serious AEs resulted in termination of treatment or death. **Conclusions:** Camrelizumab combined with FOLFOX was an effective and safe neoadjuvant therapy strategy for patients with resectable locally advanced GC/GEJC. Furthermore, the analysis of biomarkers with clinical benefits is undergoing. Clinical trial information: NCT03939962. Research Sponsor: None.

Randomized phase II study comparing docetaxel versus paclitaxel in patients with esophageal squamous cell carcinoma who are refractory to fluoropyrimidine and platinum-based chemotherapy: OGSG1201. *First Author: Takayuki Kii, Department of Cancer Chemotherapy Center, Osaka Medical College Hospital, Osaka, Japan*

Background: Fluoropyrimidine and platinum-based chemotherapy are considered first-line therapy options for patients with unresectable advanced or recurrent metastatic esophageal squamous cell carcinoma(ESCC). After fluoropyrimidine and platinum-based chemotherapy is failed, taxanes (docetaxel(DTX) and paclitaxel(PTX)) was mainly used as a second-line treatment for ESCC. Therefore, we conducted a trial to compare DTX and PTX in patients with unresectable advanced or recurrent ESCC who were failed to previous fluoropyrimidine and platinum-based chemotherapy. **Methods:** We did a randomized, an open-labeled and multicentre phase 2 study. Inclusion criteria included age 20 to 80 years with unresectable advanced or recurrent ESCC, Eastern Cooperative Oncology Group (ECOG) performance status score of 0 or 1. Patients who were refractory to fluoropyrimidine and platinum-based chemotherapy. Treatment consisted of DTX 70 mg/m2 repeated every 21 days or PTX 100 mg/m2 once weekly on days 1, 8, 15, 22, 29, and 36 of a 49-day cycle. **Results:** 80 patients were enrolled between May 2012 and April 2019. 41 patients received DTX and 39 patients received PTX. After assessment of eligibility, two patients proved uneligible (one for double cancer, one for contraindication to DTX) and were excluded from the analysis. But, 80 patients were evaluable for the toxicity analyses. A median follow-up time was 32 months. Overall survival was significantly longer in the PTX group than in the DTX group (median, 8.8 months vs. 7.3 months; hazard ratio, 0.62; 95% CI, 0.38 to 0.9998; P = 0.047). The median progression-free survival was significantly longer in the PTX group than in the DTX group (median, 4.4 months vs. 2.1 months; hazard ratio, 0.49; 95% CI, 0.30 to 0.78; P = 0.002). The median time to treatment failure was significantly longer in the PTX group than in the DTX group (median, 3.8 months vs. 2.1 months; hazard ratio, 0.45; 95% CI, 0.28 to 0.73; P 0.001). The most common adverse events of grade 3 or higher were a decreased neutrophil count (in 28% of the PTX group and in 80% of the DTX group). Febrile neutropenia was also more frequent in the DTX group than the PTX group (46 vs. 0%). There was one death from sudden death in which treatment-related mortality could not be ruled out. **Conclusions:** Secound-line treatment with PTX, as compared with DTX, reduced the risk of ESCC. Clinical trial information: UMIN000007940. Research Sponsor: None.

Real-world data (RWD) reveals benefit for adjuvant chemotherapy with docetaxel, oxaliplatin and fluorouracil/leucovorin (FLOT) is limited to those with tumour regression grade (TRG) ≥3 in oesophago-gastric cancer (OGC). *First Author: Brindley Sonal Hapuarachi, Weston Park Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*

Background: Despite potentially curative surgery, long-term survival from OGC remains poor due to high relapse rate. Neoadjuvant (naFLOT) and adjuvant (aFLOT) FLOT is currently standard treatment for resectable OGC based on data from the FLOT-4 trial. We explored whether TRG was associated with FLOT-outcome using RWD. **Methods:** Pts with OGC treated with naFLOT +/- aFLOT at a tertiary UK centre were identified following institutional board approval. Clinical and laboratory data were extracted from the patient record. TRG was evaluated by a histopathologist. Median overall survival (OS) and median progression-free survival (PFS) were evaluated using Kaplan-Meier and Log-rank tests; time taken from start of naFLOT, and associations between factors with Fisher's exact (FE) test. **Results:** 171 pts were identified, median FU 30 mths. 144 (84%) male; median age 66 (32-84); oesophagus 66 (38%), junctional (GOJ) 73 (43%), gastric 32 (19%); stage IB 3 (2%), stage IIB 26 (15%), stage III 91 (53%), stage IVA 47 (28%) and unknown 4 (2%). Pts had median of 2 comorbidities (range 0-6); performance status (PS) 0: 95 (56%), PS 1: 71 (41%), PS 2: 3 (2%) and PS unknown 2 (1%). 132/171 pts completed 4 cycles of naFLOT and this was significantly associated with undergoing surgery (p = 0.02). Those who had surgery (140/171) had significantly improved PFS (not reached (NR) vs. 6 mths; 95% CI 2-10; p < 0.001) and OS (NR vs. 12 mths; 95% CI 6-18; p < 0.001). TRG was reported for 126/140 patients who underwent surgery. TRG 1/2 (42/126) vs. TRG ≥3 was significantly associated with improved PFS (NR vs. 35 mths; 95% CI NR; p < 0.001) and OS (median NR either group; p < 0.001). Pts with TRG 1/2 who commenced aFLOT (≥1 cycle; n = 31/42) or completed 4 cycles of aFLOT (17/31) did not have improved PFS or OS vs. those who did not. Those with TRG ≥3 who commenced aFLOT (≥1 cycle; n = 62/85) had improved PFS (median NR vs. 22 mths; 95% CI 13-31 p = 0.006) and OS (median NR vs. 25 mths; 95% CI 18-32 p = 0.019). Those with TRG ≥3 who completed 4 cycles of aFLOT (n = 38/62) had significantly improved PFS (median NR vs. 25 mths; 95% CI 14-36 p = 0.016) and OS (median NR vs. 36 mths; 95% CI 16-55 p = 0.012). There was no difference in PFS or OS in pts with TRG ≥3 who had a dose reduction at any time during aFLOT. **Conclusions:** TRG is a predictor of outcome following naFLOT + surgery with superior outcomes in those with TRG 1/2. Our analyses suggest that only pts with TRG >3 following naFLOT + surgery benefit from adjuvant FLOT. Prospective randomised studies are required to confirm whether pts with TRG 1/2 require treatment with aFLOT. Research Sponsor: None.

SHARED: Efficacy and safety of sintilimab in combination with concurrent chemoradiotherapy (cCRT) in patients with locally advanced gastric (G) or gastroesophageal junction (GEJ) adenocarcinoma. *First Author: Jia Wei, The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: PD-1 inhibitor and chemotherapy have shown significant clinical benefits in 1L-treatment of G/GEJ. While it is not clear for locally advanced stage. The aim of this single-arm phase Ib trial is to assess the feasibility of sintilimab (PD-1 inhibitor) in combination with cCRT in locally advanced GC. **Methods:** Patients (pts) with initial histopathologically confirmed G/GEJ adenocarcinoma, diagnosed as locally advanced III-IVA per AJCC 8th and ECOG PS of 0-1 were eligible. Sintilimab (200mg, iv, Q3W) was given with CRT sandwich in sequence of one induction chemotherapy (S-1+Nab-PTX), weekly Nab-PTX(80-100mg/m^2, d1, d8, d15, d22), concurrent radiotherapy (45Gy/1.8Gy*25f), and one consolidation chemotherapy (S-1+Nab-PTX). Pts received three additional combinations of sintilimab and chemotherapy after surgery or investigator's best choice for unresectable pts after planned therapy. The primary endpoint was pCR and a Simon two-stage was employed at first 9 pts. This interim analysis was pre-planned after finishing stage I assessment. Accrual is ongoing with another 25 in next stage. **Results:** In the first stage, 5 out of 9 pts achieved pCR and passed to next stage. As of 7th Feb 2021, 28 pts met inclusion criteria with median age 67 yrs (range 47-81), men 86%, PS 1 25%, cT3/4a/4b 28%/54%/18%, cN1/N2/N3 7%/50%/43% and Borrmann II/III/IV 57%/18%/25% . The location on GEJ and G was 14% and 86%. Of 23 pts completed neoadjuvant, all were evaluated as D2-surgery feasibility. 19 pts had completed gastrectomy (4 pts waiting for surgery) with pCR 42.1% (8/19), MPR (≤10% viable tumor cells) 73.7% (14/19) and R0 resection 94.7% (18/19). Down-staging to pT0 and pN0 were both observed in 42.1%. The median follow-up was 5.8m unavailable for survival evaluation at present. Grade (gr) 3-4 TRAE occurred in 39.3% (11/28) pts with most common events as myelosuppression (39.3%) and increased transaminase (10.7%). IrAEs occurred in 21.4% (6/28) pts with one gr 4 hepatitis and others gr 1-2. Peri-operative complications occurred in 3 pts with gr 1-2 pneumonia, increased transaminase, and ileus. No death or unexpected toxicity observed. **Conclusions:** SHARED interim analysis demonstrated a promising feasibility of sintilimab in combination with cCRT with preliminary impressive pCR & MPR and acceptable toxicity in phase III-IVA G/GEJ cancer. These results warrant further accrual and evaluation. Clinical trial information: ChiCTR1900024428. Research Sponsor: Innovent Biologics.

4041 **Poster Session**

Final survival results from a multicenter, randomized phase II trial of intravenous paclitaxel plus FOLFOX (ivPOF) and/or intraperitoneal paclitaxel plus FOLFOX (ipPOF) versus mFOLFOX6 as first-line treatment of advanced gastric cancer (AGC): SYLT/FNF 004. *First Author: Shen Zhao, Gastrointestinal Medical Oncology, Fujian Cancer Hospital, Fuzhou, China*

Background: Progression-free (PFS) and overall (OS) survival for SYLT/FNF 004 were previously reported in ASCO and ASCO-GI 2019. At that time, PFS was statistically significantly improved with ivPOF or ipPOF compared to mFOLFOX6 as first-line treatment of AGC; however, there were no significant between-treatment differences in OS. Herein, we report final survival results for this trial. **Methods:** Subjects were randomly assigned to one of three treatments: intravenous paclitaxel 135 mg/m^2 + mFOLFOX6 omitting the 5-FU bolus (ivPOF); intraperitoneal paclitaxel 80 mg/m^2 + mFOLFOX6 omitting the 5-FU bolus (ipPOF); or mFOLFOX6 (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2 followed by 5-FU 400 mg/m^2 bolus and 5-FU 2400 mg/m^2 as a 46-hour continuous infusion). Treatment cycles were repeated every 14 days for up to 9 cycles. Thereafter, maintenance treatment with S-1 80 mg/m^2/day for 14 days every 3 weeks until disease progression, unacceptable toxicity, patient refusal, or physician decision. The original study objective was to compare ivPOF or ipPOF vs. mFOLFOX6 for PFS. Due to slow accrual, the protocol was later amended to compare POF (ivPOF and ipPOF) with mFOLFOX6 for PFS. **Results:** Between Nov 2015 and May 2018, 89 subjects (30 ivPOF, 29 ipPOF, 30 mFOLFOX6) were enrolled. As of the data cutoff on Dec 31, 2020, median follow-up was 41 (IQR: 37-43) months. The median number of cycles administered was 7 (IQR: 4-9) for POF; 6 (IQR: 4-9) for ivPOF; 9 (IQR: 4-9) for ipPOF; and 4 (IQR: 3-9) for mFOLFOX6. Median PFS and OS, respectively, were 6.23 (95% CI: 4.90 to 9.07) and 10.17 (95% CI: 8.97 to 16.4) months for POF and 4.55 (95% CI: 2.73 to 6.87) and 6.87 (95% CI: 5.83 to 13.6) months for mFOLFOX6. Both PFS and OS were statistically significantly better with POF, ivPOF or ipPOF versus mFOLFOX6 (Table). Safety was consistent with previous reports. **Conclusions:** POF, ivPOF or ipPOF improved both PFS and OS compared with mFOLFOX6, with similarly manageable adverse effects. Clinical trial information: NCT02845908. Research Sponsor: None.

Immunogenomic features of pathologic response to neoadjuvant immune checkpoint blockade in esophageal cancer. *First Author: Zineb Belcaid, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Improving immunotherapy efficacy remains an unmet need in esophagogastric cancer and a deeper understanding of tumor and immune system dynamics during therapy may tailor immuno-oncology approaches. **Methods:** We performed whole exome sequencing (WES) and bulk RNA sequencing (RNAseq) of 70 serial tumor samples from 23 patients with stage II/III esophageal/gastroesophageal junction (E/GEJ) cancer treated on a phase 1B clinical trial with neoadjuvant nivolumab with or without relatlimab (anti-LAG-3) and chemoradiation followed by surgery (NCT03044613; CA209-906). Pathologic response was measured by tumor regression at the time of resection. Median follow up was 23 months post-surgery. Serial tumor samples were collected prior to therapy, after 2 cycles of induction immune checkpoint blockade (ICB), and at the time of resection. Twenty-two baseline tumor/normal DNA pairs were analyzed by WES and 48 serial tumor samples were analyzed by RNAseq. WES data was analyzed to identify somatic mutations, generate tumor mutation burden (TMB) estimates and assess the fraction of expressed mutations in conjunction with RNAseq data. Immune cell subset composition was determined by RNAseq data deconvolution by CIBERSORT and gene set enrichment analyses were performed utilizing GSEA. B-cell density was inferred by immunoglobulin rearrangements detected by RNAseq. **Results:** Gene set enrichment expression analyses revealed an upregulation of effector pro-inflammatory cytokines after induction ICB. Interferon-gamma, interferon-alpha and TNF-alpha related genes were significantly upregulated after induction ICB compared to baseline ($p < 0.0001$). In contrast, significant downregulation of E2F targets ($p = 0.002$), G2M checkpoint genes ($p = 0.005$) and DNA damage repair genes ($p = 0.004$) was observed post ICB; enrichment analyses were independent of response to therapy and treatment arm. While TMB was not predictive of pathologic response ($p = 0.22$), patients with tumors harboring a higher number of expressed mutations were more likely to achieve a pathologic complete response (pCR; $p = 0.026$). RNAseq deconvolution analyses revealed a higher B-cell density post ICB induction in tumors with pCR ($p = 0.018$). Furthermore, an increased baseline content of intra-tumoral activated M1 macrophages differentiated tumors from patients achieving a pCR ($p = 0.0034$), which was further exemplified post induction ICB. **Conclusions:** Neoadjuvant immunotherapy induces an inflammatory immune response in the tumor microenvironment that is linked with tumor elimination and pathologic response. Our findings highlight the importance of nuanced multi-omics analyses to understand the wiring of response to immunotherapy and guide therapy for E/GEJ cancer. Research Sponsor: Bristol Myers Squibb.

4043 **Poster Session**

A multicenter phase II study of S-1 plus ramucirumab as first-line treatment in elderly patients with advanced/recurrent gastric cancer (KSCC1701). *First Author: Hiroo Katsuya, Saga University, Saga, Japan*

Background: Elderly patients are often intolerable in the combination with cytotoxic agents. Therapy with S-1 alone is a key option for initial chemotherapy for Japanese elderly patients with unresectable gastric cancer in clinical practice. However, there are some cases in which the antitumor effects with S-1 alone are insufficient. We aimed to investigate the efficacy and safety of S-1 plus ramucirumab therapy to elderly patients with advanced/recurrent gastric cancer. **Methods:** Patients aged 70 years and older with previously untreated unresectable or recurrent gastric cancer patients were included in Japan. They received S-1 therapy (40-60 mg twice daily for 28 days, every 6 weeks) plus ramucirumab therapy (8 mg/kg, every 2 weeks) until disease progression. The primary endpoint was the one-year survival rate and null hypothesis of one-year survival was set as 40%, which is the lower bound of the 95% confidence interval in previously reported studies on S-1 therapy. The secondary endpoints included progression-free survival (PFS), overall survival (OS), response rate (RR), and safety. **Results:** Between September 2017 and November 2019, 48 patients were enrolled in this study. The characteristics of patients were male/female: 34/14, median age: 77.5 years (range: 71-87), and PS (0/1): 20/28. The one-year survival rate was 65.2% (95% confidence interval 49.8-78.6%), which means this trial met the primary endpoint. The median OS and PFS were 16.4 months (95%CI:12.0–20.7) and 5.8 months (95%CI:4.0–7.2), respectively. The best RR (CR+PR) was 60.9%. The frequent grade 3 or grade 4 adverse events were neutropenia (27.7%), anorexia (23.4%), anemia (19.1%), hypertension (14.9%), leucopenia (12.8%) and hypoalbuminemia (12.8%). **Conclusions:** Based on the observed efficacy and safety, S-1 plus ramucirumab is an appropriate first-line treatment for elderly patients with advanced/recurrent gastric cancer. Clinical trial information: UMIN000028309. Research Sponsor: Eli Lilly and Company.

Survival analysis by tumor response from real-world data in advanced gastric cancer treated with nivolumab: The DELIVER trial (JACCRO GC-08). *First Author: Yosuke Kito, Department of Medical Oncology, Ishikawa Prefectural Central Hospital, Kanazawa, Japan*

Background: The phase III ATTRACTION-2 trial demonstrated survival benefit of nivolumab (Nivo) as third- or later-line treatment in previously treated advanced gastric or gastroesophageal junction (GEJ) cancer, with response rate (RR) of 11% (Kang YK, et al. *Lancet* 2017). It has been shown that some tumors grow rapidly after Nivo treatment, but the proportion and survival are still uncertain. We therefore prospectively investigated clinical outcomes from real-world data of Nivo treatment in advanced gastric cancer (GC). **Methods:** The DELIVER trial was a prospective, multicenter, observational study which assessed patients (pts) with advanced gastric or GEJ adenocarcinoma treated with Nivo alone and ECOG PS 0-2 (UMIN000030850). The aims were to evaluate the efficacy and safety of Nivo treatment in real world. Primary endpoint was overall survival (OS), secondary endpoints were RR, disease control rate (DCR), progression-free survival (PFS), tumor growth rate (TGR) at 1st evaluation, and safety. The sub-group analyses were performed for survival according to tumor response and clinical factors. The survival data was fixed at the timepoint of 1 year after the last enrollment. **Results:** In 501 pts enrolled from Mar 2018 to Aug 2019, 487 pts were evaluable (median age 70y, 71% male, ECOG PS0/1/2 42/44/14%, no. of prior regimen 1/2/≥3 2/39/59%, 21% HER2-pos, 42% pts with ascites). Median OS was 5.8 months (m) (95%CI 5.3-7.0) with 1y-survival rate of 30%, and median PFS was 1.8 m (95%CI 1.7-2.0), at 454 events for PFS and 389 events for OS. The DCR were 39.4%, and RR was 14.2% in 282 pts with measurable lesions. Median OS and PFS by tumor response (CR/PR/SD/PD) were Not Reached (NR)/NR/11.3/4.1m and NR/11.7/3.8/1.4m, respectively. A sub-group analysis of OS by clinical factors is the following: male/female; 6.5/5.0m (p= 0.002), tub/por/sig; 8.1/5.4/4.1m ($p<$ 0.0001), albumin < 3.5/≥3.5; 4.2/8.9m ($p<$ 0.0001), w/peritoneal mets/w/o; 4.9/8.4m ($p<$ 0.0001), and w/ascites/w/o; 3.7/8.9m ($p<$ 0.0001). These findings were also observed in PFS. In 219 evaluable pts for TGR, 20.5% pts were identified as hyper-progressive disease (HPD). An exploratory approach by logistic regression analysis indicated that level of free-T3 in blood before Nivo treatment was higher in the HPD compared to the non-HPD group (2.5 vs. 2.2 pg/ml, p= 0.005). Survival time was comparable between the HPD group and PD without HPD group. Median period from 1st evaluation to death was 2.8 m for HPD, 5.7 m for non-HPD, and 2.4 m for PD at 1st evaluation without HPD. **Conclusions:** The real-world data of Nivo treatment in advanced GC indicated comparable survival to previous result in a clinical trial. Differences in survival time by tumor response or some clinical factors were observed in Nivo treatment. In addition, our study revealed the rate of HPD and the prognosis in advanced GC pts treated with Nivo. Clinical trial information: UMIN000030850. Research Sponsor: Ono Pharmaceutical and Bristol-Myers Squibb.

ERBB2 copy number (CN) as a quantitative biomarker for real-world (RW) outcomes to anti-HER2 therapy in advanced gastroesophageal adenocarcinoma (adv GEA). *First Author: Samuel J Klempner, Massachusetts General Hospital, Boston, MA*

Background: HER2 (*ERBB2*) overexpression or amplification (amp) are biomarkers for approved anti-HER2 therapies. *ERBB2*amp may be a superior predictor of anti-HER2 therapy outcome compared to IHC/ISH, and degree of CN gain may further stratify patients (pts). We investigated the distribution of *ERBB2*amp in adv GEA and hypothesized that increased CN was associated with better outcome to trastuzumab (T). **Methods:** Genomic analysis was performed using the Foundation Medicine (FM) tissue database (DB) of 313,896 pts with solid tumors including 12,749 pts with GEA and 34,629 pts with breast cancer (BC) used for comparison. *ERBB2*amp was defined as predicted CN $\geq$5 with $>$ 80% of exons amplified. Using the nationwide US-based Flatiron Health-FM clinico-genomic DB linking de-identified EHR-derived clinical data to FM genomic data, pts with *ERBB2*amp adv GEA (01/2011 - 12/2020) were selected. RW progression (rwP) was obtained via technology-enabled abstraction of EHR. Multivariable Cox proportional hazard models were used for outcome comparisons. **Results:** *ERBB2*amp was detected in 15% (1,920/12,749) of GEA samples; median CN 22 (IQR 9-73), and 97% of cases had full gene amp. Median *ERBB2* amplicon size was 0.27Mbp (IQR 0.13-0.95). In comparison, *ERBB2*amp was detected in 9.2% (3,193/34,629) of BC samples; median CN 20 (IQR 9-40), median amplicon size 0.32Mbp (IQR 0.13-1.37). In both cancers, smaller amplicons were associated with higher CN ($P < 0.001$), excluding amplicons $<$ 0.1Mbp where less than 100% target amp was common. *ERBB2*amp was additionally seen in 2.7% of other solid tumors, and specifically in 2.3% of NSCLC and 3.1% of CRC. In the RW DB of 183 pts with *ERBB2*amp adv GEA, chemo + T (45%) and chemo alone (17%) were the most common first therapies after genomic report. In 101 evaluable first-line T treated pts *ERBB2* CN was a significant predictor of rwP free survival (rwPFS) as a continuous variable (aHR = 0.74 [95% CI: 0.61 - 0.89], P = 0.002) and a range of cutoffs were similarly predictive. For control, in *ERBB2*amp pts treated with chemo *ERBB2* CN was not predictive of rwPFS (aHR = 0.93, [95% CI: 0.72 – 1.20], P = 0.060). Among T treated pts, co-*PIK3CA* mutation was more common with lower CN (p = 0.03 by Wilcox test); no significant differences were observed for primary tumor location, age, stage at adv diagnosis, co-*KRAS*mut, *EGFR*amp or *FGFR1/2*amp. **Conclusions:** *ERBB2*amp was detected in 15% of GEA tissue samples, with significant diversity in *ERBB2* CN and amplicon focality, but with a similar CN distribution and amplicon focality seen in *ERBB2*amp BC. *ERBB2* CN was predictive of rwPFS as a continuous variable for pts with GEA treated with T in the RW setting. Further studies exploring the clinical utility of quantitative *ERBB2* CN, and extending to ctDNA, particularly in the setting of the evolving anti-HER2 landscape and combination therapies, are warranted. Phase II trial of perioperative chemotherapy + avelumab in locally advanced gastroesophageal adenocarcinoma: Preliminary results. *First Author: Thierry Alcindor, McGill University Health Centre, Montréal, QC, Canada*

Background: Perioperative chemotherapy improves cure rate in locally advanced gastroesophageal adenocarcinoma (GEA), and immune checkpoint inhibitors are active at the metastatic stage. This trial tests the hypothesis that the addition of avelumab to perioperative chemotherapy will increase the major pathologic response (MPR) rate in comparison with historical controls. **Methods:** Phase II study of avelumab + chemotherapy (docetaxel, cisplatin and 5-FU or mDCF) given every 2 weeks for 4 cycles before and after surgery. Main inclusion criteria: GEA, cT3 and/or cN+, M0, WHO PS 0-1. Main exclusion criteria: use of immunosuppressants, serious autoimmune disease, daily intake $>$10 mg prednisone. Staging studies: CT, PET-CT, endoscopic ultrasound, diagnostic laparoscopy. Surgical resection: D2 lymphadenectomy, en-bloc esophagectomy for type I/II gastroesophageal junction (GEJ) tumors. Aim of the study: MPR as defined as tumor regression grades 0-1 (modified Ryan scheme); as per hypothesis, this experimental regimen will result in a 20% rate of MPR, compared with 7% with chemotherapy alone. Simon 2-stage design: if less than 2 MPR are seen in the first 16 patients, the study will be closed. The study hypothesis cannot be rejected if at least 6 MPR are seen in the first 50 patients. All adverse effects are prospectively recorded per CTCAE guidelines in patients who have received at least one treatment cycle. Survival rates are calculated with Kaplan-Meier method. Preliminary results are presented since the study has met its primary endpoint. **Results:** Feb 2018-Feb 2020: 28 patients enrolled (25 M/3 F, age 45-78). Location: GEJ (23), stomach (5). Staging: cT3 (25), cT4 (1), cN+ (20). Biomarkers expression: mismatch repair (MMR) protein loss (3/28); PD-L1(clone 73-10) expression in 1% (TPS) or more of tumor cells seen in 12/28 samples, and $>$10% in 6 patients. Grade 3 toxicity: stomatitis (2/28); nausea (2/28); vomiting (1/28); diarrhea (1/28); hypothyroidism (1/28); arthralgia (3/28); neutropenia (1/28). Grade 4 toxicity: pneumonia (1/28); neutropenia (2/28). Postoperative 30-day mortality: 0%. One patient was excluded from efficacy analyses for M1 staging; 27 patients underwent surgery, 26 with R0 (96%). Six cases (22%) show MPR: 3 grade 0 (11%) and 3 grade 1 (11%) tumor regressions. No correlation was seen between MMR proteins or PD-L1 expression and tumor regression. With a median follow-up of 1.5 years (range 0.4-2.5), the disease-free survival rate is projected to be 0.92 (95% CI 0.83-1.00) at 12 months and 0.77 (95% CI 0.58-1.00) at 24 months. **Conclusions:** The combination of mDCF chemotherapy with Avelumab demonstrates a promising safety and activity profile. Ongoing laboratory investigations are underway to correlate our findings with tumor molecular features before exposure to treatment. Clinical trial information: NCT03288350. Research Sponsor: EMD Serono.

Neoadjuvant camrelizumab combined with chemotherapy and apatinib for locally advanced thoracic esophageal squamous cell carcinoma (ESCC): A single-arm, open-label, phase Ib study. *First Author: Zhen Wang, Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Neoadjuvant therapy with PD-1 blockade plus chemotherapy has been found to be effective in the first-line treatment of advanced esophageal cancer. However, evidence of PD-1 blockade combined with chemotherapy as neoadjuvant treatment is limited. This study was designed to investigate the safety and efficacy of camrelizumab, a PD-1 blockade combined with chemotherapy and apatinib as neoadjuvant therapy for locally advanced esophageal squamous cell carcinoma (ESCC). **Methods:** A regiment of 2–4 cycles of neoadjuvant camrelizumab (200 mg, intravenous, day 1), nab-paclitaxel (150 mg/m^2, intravenous, day 1), nedaplatin (50 mg/m^2, intravenous, day 1), and apatinib (250 mg, orally, day 2–4) was given to the treatment-naive patients with resectable locally advanced ESCC. The treatments were repeated every 14 days. In this study, six patients were planned to receive two cycles of neoadjuvant therapy as safety assessment, and then 24 patients received four cycles of neoadjuvant therapy, followed by esophagectomy after 4–8 weeks. The primary end points were safety and feasibility. The secondary end points were the rate of major pathologic response (MPR) and pathologic complete response rate (pCR). **Results:** A total of 30 patients were enrolled, among them, five patients received two planned cycles of neoadjuvant therapy, and one patient missed the second cycle of therapy due to grade 3 ALT elevations. Further, all other 24 patients received four planned cycles of neoadjuvant therapy. A total of 11 patients (11/30, 36.7%) experienced grade 3 neoadjuvant treatment-related adverse events (TRAEs). No grade 4 and grade 5 TRAEs were reported. The most frequent grade 3 TRAEs was neutropenia (7/30, 23.3%). Twenty-nine patients underwent minimally invasive esophagectomy (McKeown procedure) after neoadjuvant therapy. The reason for not undergoing surgery was due to bone metastasis. There were five treatment-related surgical delays that were caused by adverse reactions (hyperglycemia, arthritis, anemia, leukopenia, capillary endothelial proliferation in oral mucosa). Among the 29 patients undergoing esophagectomy, 15 patients (15/29, 51.7%) achieved MPR, including 7 patients with pCR (7/29, 24.1%). Among the 24 patients who received four cycles of neoadjuvant treatment, there were 7 patients with pCR (7/24, 29.2%), and 14 patients with MPR (14/24, 58.3%). No surgery related mortality was documented. **Conclusions:** Neoadjuvant camrelizumab combined with chemotherapy plus apatinib is a safe and tolerable treatment for patients with locally advanced ESCC, and the MPR and pCR rate are promising. Clinical trial information: ChiCTR1900023880. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

Trastuzumab deruxtecan (T-DXd; DS-8201) in patients with HER2-positive advanced gastric or gastroesophageal junction (GEJ) adenocarcinoma: Final overall survival (OS) results from a randomized, multicenter, open-label, phase 2 study (DESTINY-Gastric01). *First Author: Kensei Yamaguchi, The Cancer Institute Hospital of JFCR, Tokyo, Japan*

Background: T-DXd is an antibody–drug conjugate comprising an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a topoisomerase I inhibitor. DESTINY-Gastric01 (DS8201-A-J202; ClinicalTrials.gov, NCT03329690) is an open-label, multicenter, randomized, phase 2 trial of T-DXd in patients with HER2-positive advanced gastric cancer (GC) or GEJ adenocarcinoma. In the primary analysis (101 OS events; median survival follow-up, 12.3 mo), T-DXd showed statistically significant benefit vs standard chemotherapy in objective response rate (ORR) and OS (Shitara K, et al. *N Engl J Med.* 2020;382:2419-2430); here, we present the final OS analysis as well as updated efficacy and safety. **Methods:** Patients (pts) with locally advanced or metastatic, centrally confirmed HER2-positive (IHC3+ or IHC2+/ISH+ on archival tissue) GC or GEJ cancer that had progressed after $\geq$2 previous lines of therapy including trastuzumab were randomly assigned 2:1 (T-DXd 6.4 mg/kg Q3W or physician's choice [PC] irinotecan [I] or paclitaxel [P]). Pts were stratified by country, ECOG performance status (0, 1), and HER2 status. Primary end point was ORR by independent central review. Key secondary end points were OS, duration of response (DOR), progression-free survival (PFS), disease control rate (DCR), confirmed ORR, and safety. Final OS analysis was performed at 133 OS events. **Results:** 187 pts received T-DXd (n = 125) or PC (n = 62 [55 I; 7 P]); 79.7% of pts were Japanese and 20.3% were Korean. Pts had a median of 2 prior lines of therapy, and 44.4% had $\geq$3. At data cutoff (June 3, 2020), 8% of T-DXd and 0% of PC pts remained on treatment (median survival follow-up, 18.5 mo). OS was improved with T-DXd vs PC (median OS, 12.5 vs 8.9 mo; hazard ratio [HR], 0.60 [95% CI, 0.42-0.86]); 12-month OS, 52.2% vs 29.7%. ORR was 51.3% (61/119; 11 CR; 50 PR) with T-DXd vs 14.3% (8/56; all PR) with PC ($P < 0.0001$); confirmed ORR, 42.0% (50/119; 10 CR; 40 PR) vs 12.5% (7/56; all PR) ($P = 0.0001$); DCR, 86.6% vs 62.5% ($P = 0.0003$); confirmed median DOR, 12.5 vs 3.9 mo; median PFS, 5.6 vs 3.5 mo (HR, 0.47 [95% CI, 0.31-0.71]; $P = 0.0003$). Grade $\geq$3 AEs occurred in 85.6% of T-DXd pts vs 56.5% with PC; the most common were neutrophil count decreased (49.6%, 22.6%), anemia (38.4%, 22.6%), and white blood cell count decreased (20.8%, 11.3%). 16 pts (12.8%) had T-DXd–related interstitial lung disease (ILD; 13 grade 1/2, 2 grade 3, 1 grade 4, no grade 5) vs 0 with PC. As reported in the primary analysis, there was 1 T-DXd–related death from pneumonia (non-ILD). **Conclusions:** With additional follow-up after the primary analysis, T-DXd continued to demonstrate OS benefit and clinically relevant improvement in ORR compared with standard chemotherapy, and a manageable safety profile, in HER2-positive advanced GC or GEJ adenocarcinoma. Clinical trial information: NCT03329690. Research Sponsor: Daiichi Sankyo, Pharmaceutical/Biotech Company.

First-line pembrolizumab plus chemotherapy versus chemotherapy in patients with advanced esophageal cancer: Chinese subgroup analysis of KEYNOTE-590. *First Author: Zhigang Li, Shanghai Chest Hospital, Shanghai, China*

Background: In the randomized, double-blind, placebo-controlled, multicenter, phase 3 KEYNOTE-590 study (NCT03189719), pembrolizumab + chemotherapy provided superior OS, PFS, and ORR versus chemotherapy with a manageable safety profile in patients with untreated locally advanced/unresectable or metastatic adenocarcinoma or esophageal squamous cell carcinoma (ESCC) or Siewert type 1 esophagogastric junction (EGJ) adenocarcinoma. We present results from the subgroup of patients enrolled in China. **Methods:** Eligible patients were randomly assigned 1:1 to pembrolizumab 200 mg or placebo Q3W for ≤35 cycles (~2 years) + chemotherapy (cisplatin 80 mg/m^2 Q3W [d1; 6 doses] + 5-FU 800 mg/m^2 on d1-d5 Q3W). Randomization was stratified by region, histology, and ECOG performance status. Primary end points were OS in patients with ESCC PD-L1 combined positive score (CPS) ≥10 tumors and OS and PFS (RECIST v1.1; by investigator) in ESCC, PD-L1 CPS ≥10, and all patients; ORR (RECIST v1.1; by investigator) in all patients was the key secondary end point. Data cutoff was July 2, 2020. **Results:** Of 749 patients enrolled, 106 (14.2%) enrolled in China (51 in pembrolizumab + chemotherapy arm; 55 in chemotherapy arm); 88.7% were male and 49.1% had PD-L1 CPS ≥10. In Chinese patients, ECOG performance status 1 (81.1% vs 59.8%) and ESCC (98.1% vs 73.2%) were more prevalent than they were in all patients enrolled in the study. Additionally, in Chinese patients (pembrolizumab + chemotherapy vs chemotherapy), median OS was 10.5 months versus 8.0 months (HR, 0.51; 95% CI, 0.32-0.81), median PFS was 6.2 months versus 4.6 months (HR, 0.60; 95% CI, 0.39-0.92), ORR was 37.3% versus 20.0%, and median DOR (range) was 6.4 months (2.2+ to 18.9+) versus 4.0 months (1.5+ to 16.6+). Grade 3 or 4 treatment-related adverse events (TRAEs) were reported in 74.5% of patients in the pembrolizumab + chemotherapy arm and 66.7% in the chemotherapy arm; no grade 5 events were reported. Eight patients (15.7%) in the pembrolizumab + chemotherapy arm and 3 patients (5.6%) in the chemotherapy arm discontinued because of TRAEs. Immune-mediated AEs (defined for the safety profile of pembrolizumab as events with potentially treatment-related immunologic causes) were reported in 21.6% of patients in the pembrolizumab + chemotherapy arm and 13.0% in the chemotherapy arm; most were grade 1 or 2 and were manageable with interruption or discontinuation of study drug or standard medical therapy. **Conclusions:** In Chinese patients with advanced esophageal or EGJ cancer, pembrolizumab + chemotherapy improved OS, PFS, and ORR versus chemotherapy as first-line therapy, and safety was manageable. These findings were consistent with those in the global study population. Clinical trial information: NCT03189719. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4050 **Poster Session**

Phase II study of perioperative toripalimab in combination with FLOT in patients with locally advanced resectable gastric/gastroesophageal junction (GEJ) adenocarcinoma. *First Author: Hongli Li, Department of Gastrointestinal Medical Oncology, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China*

Background: FLOT is the standard perioperative treatment for resectable gastric /gastroesophageal junction (GEJ) adenocarcinoma. However, patient's outcome is still poor. Toripalimab, a humanized IgG4 monoclonal antibody against programmed cell death receptor-1 (PD-1), has shown remarkable clinical efficacy in various cancers. This trial evaluates the addition of Toripalimab to FLOT for resectable patients. **Methods:** This is a prospective, single-arm, investigator-initiated phase II trial. Patients with histologically confirmed, resectable, gastric and GEJ adenocarcinoma (≥cT2 or cN+) were enrolled to receive 4 pre-and post-operative cycles of toripalimab (240mg, q2w) plus FLOT (docetaxel 50 mg/m2; oxaliplatin 85 mg/m2; leucovorin 200 mg/m2; 5-FU 2600 mg/m2, q2w). The primary endpoint was pathological complete response rate (pCR). The secondary endpoints included major pathological (complete and nearly complete) response (MPR), and R0-resection rate, 3-year disease-free survival rate, overall survival, and adverse events. **Results:** In total, of 36 patients were enrolled from June 2019 through Dec 2020. Male, 66.7%; median age, 60y; cT3 8.3%, T4, 83.3%; cN+ 88.9%; GEJ 47%; MSI-H, 5.6%, Her-2neu-positive, 5.6%, EBER-positive, 5.6%). Two patients refused surgery, six patients have not yet completely neoadjuvant treatment. 100% of patients completed the 4 pre-cycle. Patients who had received gastrectomy after neoadjuvant treatment (n=28) were included in this analysis. 6 (21%) patients had operations involving a thoracic approach (oesophagogastrectomy with two field lymphadenectomy), 21 (75%) gastrectomy with D2 lymphadenectomy. 8 (29%) evaluable patients had Clavien-Dindo grade II post-operative complications and 2 (7%) grade IIIA complications; one patient had an anastomotic leakage that was treated endoscopically. There were no emergency re-operations. All 28 patients achieved R0-resection and were discharged home after a median of 12 days (range:7-63) in hospital. 7 25% patients achieved pCR (TRG1a) and 12 (42.9%) patients achieved major pathologic response (MPR, TRG1a/b). Treatment-related adverse events (TRAEs) to any drug were reported in 30 (94%) patients. Mostly TRAEs were grade 1-2, the grade 3 or 4 TRAEs included neutropenia (34%), neutropenia (25%), lymphopenia (3%), Alanine aminotransferase increased (3%), hypokalemia (3%) and anaemia (3%). **Conclusions:** Perioperative toripalimab in combination with FLOT showed promising efficacy with high pCR and MPR rate and well tolerated safety profile in patients with resectable gastric/GEJ adenocarcinoma. This combination regimen might present a new option for patients with locally advanced, resectable gastric/GEJ adenocarcinoma. Clinical trial information: NCT04354662. Research Sponsor: None.

The sequence of chemotherapy and anti-PD-1 antibody influence the efficacy of neoadjuvant immunochemotherapy in locally advanced esophageal squamous cell cancer: A phase II study. *First Author: Lingdi Zhao, Department of Immunology, Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou City, China*

Background: PD-1 blockade may result in expansion of tumor-specific T cells. However, traditional immunochemotherapy regimens usually designed to use chemotherapy drugs and anti-PD-1 antibody on the same day, which may make chemotherapy drugs kill activated T cells. The purpose of this study was to investigate the rate of pCR of chemotherapy plus anti-PD-1 therapy and the influence of sequence of chemotherapy and anti-PD-1 therapy on pCR in patients with locally advanced esophageal squamous cell cancer. **Methods:** Thirty esophageal squamous cell cancer patients with T3, T4, or lymph node positive were assigned into experiment group (anti-PD-1 antibody was administrated two days after chemotherapy) and control group (anti-PD-1 antibody and chemotherapy were administrated on the same day) according to the order of enrollment. There were fifteen patients in each group. The chemotherapeutic regimen was paclitaxel and cisplatin, paclitaxel was given at the dose of 150-175mg/m^2 on day 1 and cisplatin was given at the dose of 70-75mg/m^2 on day 1. The anti-PD-1 antibody was toripalimab at the fixed dose of 240mg on day 3 or day 1. Operation was performed four to six weeks after the second cycle of chemotherapy combined with toripalimab. **Results:** From July 2019 to September 2020, a total of 30 patients completed at least one cycle of immunochemotherapy. 11 in the experimental group received operation after two cycles of neoadjuvant chemotherapy plus toripalimab. Thirteen in control groupreceived operation aftertwo cycles of neoadjuvant chemotherapy plus toripalimab. Four patients in experimental group and one in control group got pCR, the rates of pCR in experimental group and control group were 36.4% and 7.7% individually. Although the difference was not significant in statistics, the experimental group had the trend of higher pCR rate(c^2= 3.092, p = 0.079). PD-L1 CPS examination before treatment was performed in fourteen patients, it was found that except one patient with PD-L1 CPS was 10, the left thirteen with PD-L1 CPS were all below one. The patient with PD-L1 CPS 10 was in control group and pCR was got in this patient. Except one patient in the experimental group had grade 3 immune-related enteritis, one patient in the control group died from immune-related myocarditis after operation, there were no more immune-related events more than grade 3. **Conclusions:** Toripalimab was delayed on day 3 when toripalimab plus chemotherapy was taken as neoadjuvant therapy regimen in locally advanced esophageal squamous cell carcinoma might achieve a higher pathological complete response than toripalimab and chemotherapy used on the same day. Clinical trial information: NCT 03985670. Research Sponsor: None.

Risk factors for recurrence in each pattern after curative gastrectomy for pStage II/III gastric cancer: An exploratory analysis of a randomized controlled trial (JCOG1001). *First Author: Tetsuro Toriumi, Division of Gastric Surgery, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Peritoneal, lymph node, and hematogenous recurrence are frequently observed as patterns of recurrence after surgery for gastric cancer. However, the clinicopathological characteristics associated with each recurrence have rarely been comprehensively reported in a multicenter study. Understanding the risk factors for each pattern of recurrence would be helpful for the early detection of recurrence and the initiation of optimal treatment. This study investigated the risk factors for the first recurrence in each pattern after curative gastrectomy, using data from a multicenter randomized controlled trial (JCOG1001) that was designed to investigate the efficacy of bursectomy. **Methods:** Patients of 20-80 years of age, with cT3(SS)-T4a(SE) gastric carcinoma according to the 14th Japanese Classification of Gastric Carcinoma, with an ECOG PS of 0-1, and a body mass index of < 30 kg/m^2, and without bulky lymph nodes, Borrmann type 4 or large type 3 carcinoma were eligible for inclusion in JCOG1001. Of the 1204 patients who were enrolled in JCOG1001, 932 pStage II/III patients with a common histological type were included in this study. Risk factors for hematogenous, lymph node, and peritoneal patterns of recurrence were estimated by a multivariable Fine and Grey model considering death or site of recurrence other than the first site of recurrence as competing risks. **Results:** The overall rate of recurrence was 27.1%. Hematogenous recurrence was the most frequent pattern (12.3%), followed by peritoneal (11.2%) and lymph node (7.5%) recurrence. Differentiated type (HR, 1.818; 1.237-2.674; p = 0.0024), pT4 (in comparison to pT1-3, HR, 1.511; 95% CI, 1.011-2.257; p = 0.0440), and pN3 (in comparison to pN0-2, HR, 2.431; 95% CI, 1.635-3.616; p < 0.0001) were associated with an increased incidence of hematogenous recurrence. Conversely, more than D2 lymphadenectomy reduced this pattern of recurrence (in comparison to D1+or D2 lymphadenectomy, HR, 0.575; 95% CI, 0.364-0.907; p = 0.0174). Peritoneal recurrence was significantly associated with large (≥5 cm) tumor (HR, 1.649; 95% CI, 1.034-2.629; p = 0.0356), pT4 (in comparison to pT1-3, HR, 3.222; 95% CI, 2.086-4.976; p < 0.0001), pN3 (in comparison to pN0-2, HR, 1.865; 95% CI, 1.275-2.727; p = 0.0013), and undifferentiated type (HR, 2.674; 95% CI, 1.628-4.394; p = 0.0001). Extended lymph node metastasis (pN3) was the only risk factor (in comparison to pN0-2, HR, 8.030; 95% CI, 4.605-14.002; p < 0.0001) for lymph node recurrence. **Conclusions:** The risk factors for recurrence differed according to the patterns of recurrence. Vigilant follow-up with an understanding of patterns of recurrence is required, especially for high-risk patients. Risk factors of metachronous peritoneal carcinomatosis after potentially curative gastric cancer resection in the CRITICS trial. *First Author: Irene A. Caspers, Antoni van Leeuwenhoek/Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Peritoneal carcinomatosis (PC) is accountable for over 50% of metastatic spread in gastric cancer (GC). Little is known about factors contributing to the risk of metachronous PC as a single site of metastases after preoperative chemotherapy and potentially curative resection. An accurate prediction model of risk factors identifying high risk populations may pave the way for new treatment strategies, such as intraperitoneal chemotherapy. In this analysis, risk factors for the development of isolated metachronous PC after preoperative chemotherapy and surgical resection were investigated. **Methods:** In the CRITICS trial, 788 patients with resectable GC were randomized for preoperative chemotherapy and gastrectomy followed by either chemotherapy or chemoradiotherapy. Patients who underwent a potentially curative resection without peritoneal metastases at time of surgery were included in this analysis. Univariate and multivariate analyses were performed using a competing risk model. **Results:** In total, 617 patients met the inclusion criteria. Overall, 97 of 617 (16%) patients developed metachronous PC. The peritoneum was the first site of recurrence in 64 of 617 (10%) patients. Diffuse or mixed type GC, ypT4 stage and ypN3 stage or a lymph node ratio (LNR) with >20% tumor positivity were independent predictors of isolated PC in both univariate and multivariate analyses with hazard ratios (HR) of 2.90, 2.63 and 2.31, respectively (Table). ypT4 and ypN3 stage or a LNR >20% were also independent predictors of distant recurrence or death with HR of 1.46 and 2.34, respectively. Patients in whom all predictors were present had the highest 2 year cumulative incidences of both isolated PC development and other events of 39.6% and 48.8%, respectively. **Conclusions:** Diffuse or mixed tumor type, ypT4 and ypN3 or a LNR >20% were identified as independent risk factors for metachronous PC as a single site of metastases in a large cohort of patients treated with preoperative chemotherapy followed by surgical resection. The combination of these factors might identify a subgroup that could benefit from preventive treatment strategies. Research Sponsor: None.

Uni-/multivariate competing risk analysis on isolated metachronous PC. Other events are competing risk.

Long-term quality of life and nutritional results after laparoscopic sentinel node navigation surgery versus laparoscopic standard gastrectomy for early gastric cancer: Secondary outcomes of a multicenter, randomized phase 3 trial (SENORITA). *First Author: Bang Wool Eom, National Cancer Center, Goyang-Si, South Korea*

Background: Laparoscopic sentinel node navigation surgery (LSNNS) has been suggested as an alternative to laparoscopic standard gastrectomy (LSG) in early gastric cancer patients to improve long-term quality of life (QOL) and nutritional outcomes. Here, we present 3-year results of patient-reported quality of life (QOL) and nutrition, secondary endpoints of SENORITA trial. **Methods:** SENORITA is a prospective multicenter randomized phase 3 trial. Patients diagnosed with early gastric cancer of 3 cm or less were randomly allocated (1:1) to LSNNS for stomach preservation or LSG. The primary endpoint was 3-year disease-free survival. In this study, we analyzed QOL assessed using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) and EORTC stomach module (STO22) and nutritional parameters at 3, 12, 24, and 36 months after surgery. Linear mixed model analyses was used to evaluate differences between the two groups. This trial is registered with ClinicalTrials.gov, NCT01804998. **Results:** From March 2013 to March 2017, a total of 580 patients were randomly assigned and 527 patients were included in the modified intention-to-treat analysis population (258 in LSNNS and 269 in LSG group). QOL questionnaires were available for 99.4% of patients at baseline and then for 92.2%, 83.2%, 72.8%, and 66.9% at 3, 12, 24, and 36 months after surgery, respectively. The LSNNS group had higher physical function score than the LSG group at all time points ($p = 0.002$). However, there were no significant differences in other scales of EORTC QLQ-C30. Regarding EORTC QLQ-STO22, pain, eating restriction, anxiety, and taste scores were lower (better QOL) at all time points in the LSNNS group than in the LSG group ($p = 0.002$, < 0.001, < 0.001, and < 0.001, respectively). The summary score of EORTC QLQ-STO22 was also higher in the LSNNS group representing better QOL ($p < 0.001$). Body mass index, hemoglobin and total protein were significantly higher in the LSNNS group compared with the LSG group. **Conclusions:** The LSNNS group had better physical function and less symptoms, including pain, eating restriction, anxiety, and taste change compared with the LSG group. Moreover, the nutritional parameters were better maintained in the LSNNS group than in the LSG group. These findings showed benefits of stomach preserving surgery in LSNNS and can be used to help decision making about treatment for patients with early gastric cancer. Clinical trial information: NCT01804998. Research Sponsor: Grant 1110550, 1410140, 1710160, 2010150-1.

Apatinib in combination with docetaxel and S1 chemotherapy in the first-line treatment of metastatic gastric cancer. *First Author: Ling Xia, Department of Radiation and Medical Oncology, Zhongnan Hospital, Wuhan University, Wuhan, China*

Background: First-line chemotherapy in metastatic gastric cancer, either doublet or triplet-regiment, the average OS is less than one year. Anti-VEGF target therapy is proven to be effective both in second and third line settings. As for apatinib, which is the tyrosine kinase inhibitor showed highly affinity for VEGFR2, is permitted by SFDA to be used in the third line treatment of gastric cancer since September 2014. The post-market stage IV clinic trial Ahead-G201 further confirmed it can improve the OS in chemotherapy-refractory gastric cancer. What's more, apatinib could reverse paclitaxel resistance and improve the R0 resection rate in conversion of unresected gastric cancer in neoadjuvant settings. However, the safety and efficacy of apatinib in combination with docetaxel plus S1 in the first line treatment of metastatic gastric cancer is unknown and worthy of investigation. **Methods:** With expectation to improve PFS from 5.3m (the START Study) to 7m, this investigator-initiated, single arm, multi-center, registered phase II prospective study was designed to enroll 48 eligible patients diagnosed with metastatic gastric cancer. Each participant was expected to finish six cycles of chemotherapy plus apatinib (docetaxel 75mg/m2, d1, Q3W; S1 according to BSA: <1.25 40mg po bid; 1.25~1.5 50mg po bid; >1.5 60mg po bid; d1-14, Q3W; apatinib 500mg po qd). The toxicity was determined according to CTCAE 4.0. Efficacy assessed every two cycles (6 weeks) during the study and every 2 months during the follow-up period. The primary endpoint was PFS. The secondary endpoint was OS, ORR, and DCR. The tumor response was determined according to RECIST 1.1 criteria. **Results:** Baseline characteristics (FAS population): From July 2017 to December 2020, 45 patients from 5 centers across Hubei province were enrolled. Among them, 44 are eligible for analysis. There are 15 females and 30 males, median age 55 years old, median metastasis sites is 2, yet 63.6% of them have involved at least 2 organs. Safety: 90.91% patients reported adverse events (AEs). The incidence of grade 3-4 AEs was 47.73%. Main 3-4 AEs were oral ulceration (13.64%), leucopenia (13.64%), neutropenia (13.64%), hand-foot syndrome (6.82%), hypertension (6.82%), and thrombocytopenia (6.82%). Efficacy: By Jan 31th, 2021, 44 patients were evaluable for response and survival, 26 of them achieved partial response (PR), 9 achieved stable disease (SD), and 8 experienced progression disease (PD). The ORR is 60.47%, the DCR is 81.4%. Median PFS is 7.46m, median OS is 12.42m. So we closed the study in advance. **Conclusions:** Adding apatinib to standard DS chemotherapy as the first line treatment would be well tolerant in patients with metastatic gastric cancer, the spectrum of toxicity were not exceeding expectation. This modality also exhibits prolonged PFS, which might provide an alternative therapeutic strategy for metastatic gastric cancer. Clinical trial information: NCT03154983. Research Sponsor: None.

Real-world outcomes of second-line ramucirumab plus paclitaxel in patients with advanced gastric or gastroesophageal junction adenocarcinoma: A nationwide retrospective study in Korea (KCSG-ST19-16). *First Author: Dae Young Zang, Division of Hematology-Oncology, Department of Internal Medicine, Hallym University Medical Center, Hallym University College of Medicine, Anyang, South Korea*

Background: Ramucirumab as monotherapy or in combination with paclitaxel is a second-line treatment option recommended for patients with locally advanced unresectable or metastatic gastroesophageal junction (GEJ) or gastric adenocarcinoma. However, real-world data of large samples focused on ramucirumab plus paclitaxel in gastric cancer are limited. We conducted a nationwide retrospective study to evaluate the efficacy, safety, and factors potentially associated with survival in patients with gastric or GEJ adenocarcinoma who received second-line ramucirumab plus paclitaxel in a real-world setting. **Methods:** The study population comprised all patients with gastric or GEJ cancer who received ramucirumab plus paclitaxel in South Korea between May 1, 2018, and December 31, 2018. We included patients with advanced gastric or GEJ adenocarcinoma and disease progression after first-line platinum and fluoropyrimidine-containing combination chemotherapy. **Results:** A total of 1,063 patients with advanced gastric or GEJ adenocarcinoma who received ramucirumab plus paclitaxel were included. The objective response rate and disease control rate were 15.1% and 57.7%, respectively; the median progression-free survival was 4.03 months (95% CI, 3.80–4.27), and the median overall survival was 10.3 months (95% CI, 9.33–10.73). The common treatment-related adverse events (TRAEs) at any grade were neutropenia (44.7%), anemia (41.8%), neuropathy (29.1%), fatigue (25.9%), and anorexia (25.0%). Grade 3 or higher TRAEs with incidences of ≥5% were neutropenia (35.1%) and anemia (10.5%). Adverse events of special interest were infrequent, including hypertension (2.1%) and proteinuria (3.0%). Based on multivariate analysis, overall survival was negatively associated with Eastern Cooperative Oncology Group performance status ≥2, weight loss in the previous 3 months ≥10%, GEJ of primary tumor, poor or unknown histology grade, number of metastatic sites ≥3, presence of peritoneal metastasis, no prior gastrectomy, and time to second-line since first-line treatment < 6 months. **Conclusions:** Our large-scale, nationwide, real-world data analysis of an unselected real-world population added evidence for the efficacy and safety of second-line ramucirumab plus paclitaxel in patients with locally advanced unresectable or metastatic gastric or GEJ adenocarcinoma. Clinical trial information: NCT04192734. Research Sponsor: Health Insurance Review & Assessment Service.

Quality-adjusted time without symptoms or toxicity (Q-TWiST) of trastuzumab deruxtecan (T-DXd) versus chemotherapy in patients with advanced gastric cancer from the DESTINY-Gastric01 trial. *First Author: David Cella, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

Background: DESTINY-Gastric01 (NCT03329690) is a randomized, phase 2 study evaluating trastuzumab deruxtecan (T-DXd) in patients with HER2-positive advanced gastric cancer who progressed after ≥2 regimens. T-DXd significantly improved objective response rate (51% vs. 14%; $P < 0.001$) and overall survival (median OS; 12.5 vs. 8.4 months; $P = 0.01$) relative to chemotherapy (irinotecan or paclitaxel), leading to regulatory approval in USA and Japan. This post hoc analysis evaluated the overall effect of treatment differences on the quality of survival after discounting for time spent with toxicities or disease progression by comparing the Q-TWiST for patients who received T-DXd versus those who received chemotherapy. **Methods:** Patients were randomized 2:1 to receive T-DXd or chemotherapy. For each treatment arm, OS, truncated at 10.1 months (the median OS for the entire analysis population, following Q-TWiST convention), was partitioned into three health states: time with grade ≥3 toxicities before disease progression (TOX), time before disease progression without symptoms of disease progression or toxicity (TWiST), and time following disease progression prior to death or censoring (PROG). Mean duration in each state was weighted by a utility score, determined first in a threshold analysis, using a range of hypothetical utility values to generate quality-adjusted states, and then based on observed EQ-5D-5L scores, for that state; the sum of the utility-weighted durations yielded the Q-TWiST value for the time until the end of 10.1 months' follow-up. In both threshold and observed utility analyses, 95% confidence intervals (CIs) and two-sided P values were calculated using the bootstrap method. **Results:** Relative to patients receiving chemotherapy (n = 62), patients receiving T-DXd (n = 125) had significantly longer unweighted durations of TOX (3.0 vs. 1.6 months; $P < 0.01$) and TWiST (3.1 vs. 2.1 months; $P < 0.05$) and a shorter unweighted duration of PROG (2.4 vs. 3.7 months; $P < 0.01$). Using a matrix of 25 hypothetical utility-weight combinations, with a TWiST utility of 1 and TOX and PROG utilities ranging from 0 to 1, Q-TWiST differences between treatment arms ranged from −0.5 to 2.3 months, favoring T-DXd in 22 combinations, of which 15 were statistically significant. Using observed EQ-5D-5L utility values, Q-TWiST was 0.9 months (95% CI, 0.2-1.5) longer for T-DXd than for chemotherapy (6.6 vs. 5.7 months), significantly favoring T-DXd ($P < 0.05$). **Conclusions:** Over a 10-month follow-up period, treatment with T-DXd was associated with a statistically significant gain in quality-adjusted OS versus chemotherapy among previously treated patients with gastric cancer. An analysis using observed EQ-5D-5L utility scores found a statistically significant advantage in Q-TWiST for T-DXd. Clinical trial information: NCT03329690. Research Sponsor: Daiichi Sankyo.

Early predictors of benefit to dual anti-PD1/HER2 inhibition: Biomarker analysis from phase 2 trial of pembrolizumab/trastuzumab in HER2-positive metastatic esophagogastric (mEG) cancer. *First Author: Steven Brad Maron, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pembrolizumab and trastuzumab (P&T) and chemotherapy demonstrated 27 month mOS, 13 month mPFS, and 91% response rate in first-line HER2-positive mEG cancer irrespective of PD-L1 status (Janjigian Lancet Oncology 2020). Biomarkers including ^{89}Zr-trastuzumab PET, blood, and tumor analysis were correlated with progression-free survival. **Methods:** Twenty-five patients received P&T once 3 weeks prior to addition of chemotherapy to P&T. Pre-treatment tumor biopsies, ^{89}Zr-trastuzumab PET scans, serial plasma ctDNA (Guardant360, Redwood City, CA) and CT scans were performed. Tumor-matched DNA alterations were identified by correlating ctDNA and tissue-NGS variant calls. Pre-, on-, and post-treatment biopsies were analyzed using WES and IHC (HER2, PD-L1). Biomarkers were correlated with mPFS and 6-month PFS, the primary endpoint. **Results:** Of patients with tumor-matched mutations ctDNA at baseline, 12 of 16 had a decline in their maxVAF by week 3, corresponding to a mPFS of 14.7 (11.0-NR) vs 5.9 (95% CI 4.1-NR) months (p=0.009) and a mOS of 29.7 (95% CI 27.2-NR) vs 7.71 (95% CI 6.6-NR) months (p=0.006). 9 of 12 (75%) patients with decline in ctDNA at 3 weeks post-P&T achieved the 6-month PFS primary endpoint while the 4 patients with no decline in ctDNA all progressed in under 6-months. Similarly, 7 of 9 (78%) patients who had a decline in CT-measurements in all disease sites achieved the 6 month PFS primary endpoint, versus 10 of 16 (62.5%) of patients who did not respond in all sites (p=0.66), suggesting that ctDNA is superior to CT as an early predictive biomarker of response. Lack of *ERBB2* amplification (amp) by NGS in ctDNA and/or tumor was associated with lack of response to P&T alone prior to addition of chemotherapy. Interestingly, no lesions from patients lacking *ERBB2* ctDNA amp (n=3) responded to induction P&T by CT, while lesions from 3/9 patients lacking *ERBB2* tissue amp responded to P&T by 3-week CT, suggesting intrapatient HER2 heterogeneity. Eight patients also underwent ^{89}Zr-Trastuzumab PET scans prior to P&T and up to 5 lesions per disease site were measured on serial CT scans. All 15 lesions with intense uptake (SUVmax>10) responded to P&T, but only 9/24 lesions with SUVmax<10. All 4 patients who had at least 1 intense lesion achieved a post-P&T CT response and later 6+ month PFS. All 3 of 3 evaluable patients with intense uptake had baseline ctDNA *ERBB2* amp. **Conclusions:** Patients with a decline in tumor-matched maxVAF after one dose of P&T were more likely to achieve durable PFS. Pre-treatment ctDNA *ERBB2* amp and/or intense ^{89}Zr-trastuzumab PET avidity are non-invasive predictive biomarkers of response to HER2-directed therapy. Evaluation of tumor immune environment digital spatial profiling is underway. Clinical trial information: NCT02954536. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company, MSK Society.

A phase II study of neoadjuvant immunotherapy combined with chemotherapy (camrelizumab plus albumin paclitaxel and carboplatin) in resectable thoracic esophageal squamous cell cancer (NICE study): Interim results. *First Author: Zhigang Li, Shanghai Chest Hospital, Shanghai, China*

Background: We conducted a phase II trial of preoperative chemotherapy with albumin paclitaxel and carboplatin combined with camrelizumab (NICE regimen), in patients with locally advanced esophageal squamous cell carcinoma (ESCC) with multiple lymph nodes metastasis. Initial results were analyzed to assess the efficacy and safety of this strategy. **Methods:** This was a prospective, multicenter, open, single arm, phase II trial. Eligible patients were histologically confirmed thoracic ESCC, staged as T1b-4a, N2-3 (≥ 3 stations), and M0 or M1 lymph node metastasis (confined to the supraclavicular lymph nodes) according to the 8th edition of American Joint Committee on Cancer. Patients received neoadjuvant treatment (NICE regimen) with intravenous camrelizumab (200 mg, day 1) plus albumin paclitaxel (100 mg/m2, day 1, 8, 15) and carboplatin (area under curve 5, day 1) of each 21-day cycle, for two cycles before surgery. The primary endpoint is pathological complete response (pCR) rate in the per-protocol population, which included all patients who had tumor resection and received at least one cycle of neoadjuvant treatment. Secondary endpoints include R0 resection rate, adverse events and disease-free survival. Safety was assessed in the modified intention-to-treat population. **Results:** Of the planned 60 patients enrolled, 55 (91.7%) patients have received the full two-cycles NICE regimen successfully, 4 patients didn't receive the complete neoadjuvant therapy due to intolerance (3 patients) and drop out (1 patient), 1 patient died due to pneumonia on the second cycle of neoadjuvant therapy. Grade 3-5 treatment-related adverse events (TRAEs) rate was 53.3% and TRAEs resulting in discontinuation rate was 6.7%. The common grade 3-5 TRAEs included lymphopenia (50%), thrombocytopenia (10%), pneumonia (5%) and thyroid dysfunction (3.3%). At the time of writing, 47 patients underwent surgery within 27-85 days (median 36 days) after NICE treatment, in which 7 patients had delays to surgery due to TRAEs. All patients achieved radical (R0) resection. There was no in-hospital and postoperative 30-day mortality. pCR (ypT0N0) was identified in 20 (42.5%) of 47 patients and 5 (10.6%) patients had complete pathological response of the primary tumor but residual disease in lymph nodes alone (ypTON+). **Conclusions:** Preoperative NICE regimen has achieved satisfatory initial results of disease response in locally advanced thoracic ESCC. A phase III randomized controlled trial is required to demonstarate the possible survival improvement. Trial registration: ChiCTR1900026240 Clinical trial information: ChiCTR1900026240. Research Sponsor: Hengrui Pharmaceutical Co., Ltd.

4061 **Poster Session**

A prospective, phase II, single-arm study of neoadjuvant/conversion therapy with camrelizumab, apatinib, S-1 ± oxaliplatin for locally advanced cT4a/bN + gastric cancer. *First Author: Song Li, Qilu Hospital of Shandong University, Jinan, China*

Background: The prognosis of cT4a/bN+ gastric cancer (GC) is poor due to low R0 resection rate and frequent recurrence. We evaluated the feasibility, safety, and efficacy of a combination of immunotherapy, anti-angiogenesis, and chemotherapy for neoadjuvant/conversion treatment of cT4a/bN+ GC. **Methods:** Patients with T4a/bN+ GC were enrolled to receive camrelizumab (200mg d1), apatinib (250mg d1-14), S-1 (50mg bid d1-10) ± oxaliplatin (85 mg/m^2 d1) for at least 2 cycles, followed by re-evaluation and operation. Peri-treatment samples were collected for whole-exome, transcriptome, and T cell receptor (TCR) sequencing. Pathological response (PR) and its relationship with genomic biomarkers are primary endpoints. **Results:** 25 patients were enrolled, with median age 63 (48-70), 19 male, 11 cT4aN2-3 and 14 cT4bN2-3. The radiological response (RR) rate of the treatments was 33.3% (8/24), and tumor downstaging rate 79.2% (19/24). 24 patients completed re-evaluation, with 3 failed conversion, 2 refused surgery, and 1 postponed surgery for immune-related pneumonia. Among the 18 patients with R0 resection, 3 got complete PR (CPR), 2 major PR (MPR, ≤10% residual cancer cells), and 3 partial PR (11~49% residual cancer cells), with a PR rate of 44.4% and MPR+ (MPR & CPR) rate of 27.8%. 62.5% patients with PR and 83.3% patients with RR overlapped with each other. At a median of 12.5 (3.4-19.5) months of follow-up, 13 of 17 patients (76.5%) with R0 resection were recurrence-free. No ≥3 toxicity was found. Besides high microsatellite instability, tumor mutation/neoantigen burden (TMB/TNB), mutation signatures (DNA damage repair and DNA mismatch repair) and related gene mutations (BRCA2, PRKDC, ATM, POLD1, POLE), several novel driver mutations (SSPO, TRPS1, and DOCK2) and copy number variants (DUSP15 loss, FDFT1 gain, and RBBP8NL loss) were related to MPR+ GC. The combination therapy decreased TMB/TNB, facilitated infiltration of active immune cells (CD4$^+$ memory T, CD8$^+$ T, activated and plasmacytoid dendritic cells, and M1 macrophage), and specifically boosted TCR clonality in MPR+ patients. Besides, numbers of mesenchymal stem cells decreased in MPR+ but increased in MPR- GC after the treatment. **Conclusions:** Combination of camrelizumab, apatinib, S-1 ± oxaliplatin is feasible, safe, and efficient in neoadjuvant/conversion therapy for cT4a/bN+ GC. It may remodel immune microenvironments and induce anti-tumor immune responses. Clinical trial information: NCT03878472. Research Sponsor: None.

	Total (n = 25)	cT4aN+ (n = 11)	cT4bN+ (n = 14)
Mean cycles of treatment(95% CI)	2 (2.07-3.21)	2 (2-2)	3.14 (2.16-4.13)
R0 resection rate	85.7% (18/21)	100% (11/11)	70% (7/10)
PR rate	44.4% (8/18)	54.5% (6/11)	28.6% (2/7)
RR rate	33.3% (8/24)	27.3% (3/11)	38.4% (5/13)
MPR+ rate	27.8% (5/18)	36.4% (4/11)	14.3% (1/7)
Tumor down-staging rate	79.2% (19/24)	81.8% (9/11)	76.9% (10/13)

Efficacy and safety of KN046 plus paclitaxel/cisplatin as first-line treatment for unresectable locally advanced, recurrent or metastatic esophageal squamous cell carcinoma (ESCC). *First Author: Jianming Xu, Affiliated Hospital Cancer Center, Academy of Military Medical Sciences, Beijing, China*

Background: The prognosis of pts with advanced esophageal squamous cell carcinoma (ESCC) remains dismal clinically. Paclitaxel and cisplatin were used as the standard first-line regimen in ESCC for almost two decades. Recently, the combination of PD-1/PD-L1 pathway blockades with chemotherapy has shown synergistic efficacy in a few clinical trials. KN046 is the world's first dual immune checkpoint inhibitor, which can block PD-1/PD-L1 and CTLA-4 pathways at the same time. The purpose of this ongoing phase II trial (NCT03925870) in China was to evaluate the efficacy and safety of KN046 monotherapy or combined with chemotherapy for unresectable locally advanced, recurrent or metastatic ESCC. **Methods:** This trial included 3 cohorts, one of which enrolled systemic treatment nave pts with histologically or cytologically confirmed unresectable locally advanced, recurrent or metastatic ESCC who have ECOG PS of 0-1. Eligible subjects were given paclitaxel (135-175mg/m^2, iv, d1, q3w) and cisplatin (75mg/m^2, iv, d2-4, q3w) plus KN046 (5mpk, iv, d1, q3w) for 4~6 cycles during initial therapy. For those without progressive disease, maintenance treatment was administrated with KN046 monotherapy (5mpk, iv, q2w) until progression or unacceptable toxicity. Tumour response was assessed according to RECIST 1.1 every 6 weeks. The primary endpoint was investigator-assessed ORR. Secondary endpoints included DCR, safety, PK profile, and immunogenicity. **Results:** As of December 14, 2020, 15 pts were enrolled, all of them were male, 52.3% ≥60 years, 64% ECOG 1, 80% with distant metastasis. Median exposure time to KN046 was 11.4 wks and average KN046 treatment was 2.4 cycles. 12 pts were included in the efficacy analysis and 15 pts in the safety analysis. The overall response rate (ORR) and disease control rate (DCR) were 58.3% and 91.6%, respectively. 7 pts (58.3%) had partial response (PR) including one complete response of target lesion. 4 pts (33.3%) had stable disease (SD) with 3 pts showing more than 20% of tumor burden reduction. The overall incidence of KN046 related adverse events was 80.0%, with 13.3% Gr 3 or above TRAE. Infusion-related adverse events occurred during 7.8% and most were mild. Immune related adverse events irAE were seen in 53.3% and the most common Gr 3 irAE were nausea (n 1, 6.7%) and rash (n 1, 6.7%). **Conclusions:** KN046 plus paclitaxel/cisplatin demonstrated clinical efficacy and acceptable safety as first-line treatment, and might be a favorable option for pts with advanced ESCC. Clinical trial information: NCT03925870. Research Sponsor: Jiangsu Alphamab Biopharmaceuticals Co., Ltd. Clinical trial information: NCT03925870. Multicenter phase Ib/II study of second-line trastuzumab, ramucirumab, and paclitaxel in patients with HER2-positive advanced gastric or gastroesophageal junction cancer (HER-RAM study). *First Author: Sun Young Rha, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: We evaluated the safety and efficacy of adding trastuzumab to ramucirumab and paclitaxel (TRP) as a second line treatment in human epidermal growth factor receptor 2 (HER-2)-positive advanced gastric or gastroesophageal junction (G/GEJ) cancer progressed from trastuzumab containing chemotherapy. **Methods:** Patients with HER-2-positive advanced G/GEJ cancer who progressed after first-line chemotherapy with trastuzumab in combination with fluoropyrimidine and platinum were eligible. Trastuzumab (Herzuma[CT-P6], Celltrion Inc.) 4mg/kg on day 1 followed by 2mg/kg on days 8, 15, and 22, ramucirumab 8mg/kg on days 1 and 15, and paclitaxel (dose level 1: 80mg/m^2, dose level -1: 70 mg/m^2) on days 1, 8, and 15 of a 28-day cycle was tested. After safety analysis of lead-in safety cohort (phase 1b), phase 2 part was conducted to evaluate the primary endpoint of progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety. **Results:** At the phase 1b part, as there was no dose limiting toxicity in 3 patients at the dose level 1, dose level 1 with full dose combination was determined as recommended phase 2 dose. At the time of data lock on Jan. 31, 2021, 45 patients among enrolled 50 patients were evaluable for response and safety including 3 patients from phase 1b part. Median age was 59 years old (range 30-82) and most patients were male (37/45). At baseline, 33 patients had tumors with HER-2 3+ by immunohistochemistry (IHC) and 12 had those with HER-2 2+ by IHC with *ERBB2* amplification by in situ hybridization. With median follow-up duration of 11.6 months, median PFS and OS were 7.2 months (95% confidence interval [CI]: 6.0-8.5 months) and 13.6 months (95% CI: 10.3-16.9 months), respectively. ORR was 55.6% (25/45, complete response = 1, partial response = 24) and DCR was 95.6% (43/45), respectively. Most common hematologic adverse event (AE) was neutropenia (all grade: 64.4%, grade 3/4: 51.1%) with 1 case of febrile neutropenia (2.2%). Most common non-hematologic AE was peripheral sensory neuropathy (all grade: 33.3%, grade 3: 2.2%). Gastrointestinal (GI) bleeding occurred in 4 patients (grade 3 upper GI bleeding: 6.7%, grade 1 lower GI bleeding: 2.2%), whereas GI perforation was not observed. Hypertension occurred in 3 patients (all grade: 6.7%, grade 3: 4.4%). No new or unexpected AEs resulting in treatment cessation were observed with this combination regimen. **Conclusions:** The continuous use of trastuzumab beyond progression in combination with ramucirumab and paclitaxel showed promising activity and manageable safety profile in HER2 positive G/GEJ cancer patients who progressed after trastuzumab containing chemotherapy. Updated outcomes for ongoing patients will be presented. Research Sponsor: None.

A phase II/III study of perioperative nivolumab and ipilimumab in patients (pts) with locoregional esophageal (E) and gastroesophageal junction (GEJ) adenocarcinoma: Results of a safety run-in—A trial of the ECOG-ACRIN Cancer Research Group (EA2174). *First Author: Jennifer Rachel Eads, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: E/GEJ adenocarcinoma has a high mortality rate despite curative intent therapy. The use of immune checkpoint inhibition is beneficial for treatment of this cancer in the metastatic and adjuvant settings but the role of these agents in the perioperative setting remains unclear. Here we report the results of an initial safety run-in of nivolumab when given in combination with neoadjuvant chemoradiation. **Methods:** Pts with a localized T1N1-3M0 or T2-3N0-2M0 E/GEJ adenocarcinoma with an ECOG PS of 0-1 and whom were deemed surgical candidates for an esophagectomy by a qualified surgeon were eligible. In step 1, pts were randomized to neoadjuvant therapy with carboplatin AUC 2 and paclitaxel 50 mg/m2 intravenously (IV) weekly x 5 along with 41.4-50.4 Gy radiation without (Arm A) or with (Arm B) nivolumab 240 mg IV during weeks 1 and 3 of treatment, followed by esophagectomy. Pts underwent a second randomization (step 2) to adjuvant nivolumab 240 mg IV every 2 weeks x 12 cycles with or without ipilimumab 1 mg/kg IV every 6 weeks during cycles 1, 4, 7 and 10. For the safety run-in, 30 pts were planned for accrual to allow for 12 evaluable pts per arm. Pts were followed for safety during neoadjuvant therapy through surgery and toxicities monitored per CTCAEv5. Pre-specified early stopping rules were defined to allow halting of the trial if deemed unsafe. Planned study accrual is 278 pts. Neoadjuvant primary endpoint is pathologic complete response rate, adjuvant primary endpoint is disease-free survival. **Results:** A total of 31 pts were enrolled to the safety run-in element of the study (Arm A, n = 16; Arm B n = 15). Male, 94%; White, 100%; median age, 62; esophageal adenocarcinoma, 52%; GEJ, 48%. Grade (G) 3 events occurring in more than one pt on Arm A—decreased lymphocytes (n = 5). G4 events occurring on Arm A—decreased lymphocytes (n = 1). G3 events occurring in more than one pt on Arm B—decreased lymphocytes (n = 2); anemia (n = 2); leukopenia (n = 4); hypotension (n = 2). G4 events occurring on Arm B—decreased lymphocytes (n = 3); cardiac tamponade and pericardial effusion (n = 1). Cardiac events were thought to be secondary to tumor location, not neoadjuvant treatment. On Arm B, notable G3 events seen in one pt each included colonic obstruction, wound infection and esophageal anastomotic leak. Of pts who have reached the time for surgery, 12/14 pts on Arm A and 13/13 pts on Arm B have proceeded to surgery. Of pts who have completed step 1, 7/14 pts on Arm A and 8/11 pts on Arm B have registered to step 2. **Conclusions:** The addition of nivolumab to carboplatin, paclitaxel and radiation in the neoadjuvant setting appears to be safe with no disproportionate level of toxicity observed between the two treatment arms. Accrual to the remainder of the trial continues with 43/278 patients accrued. Clinical trial information: NCT03604991. Research Sponsor: U.S. National Institutes of Health.

Intraperitoneal aerosolized nanoparticle albumin based paclitaxel (NAB-PTX) for irresectable peritoneal metastases: A first in human phase I study. *First Author: Wim Ceelen, Ghent University Hospital, Department of GI Surgery, Ghent, Belgium*

Background: Pressurized intraperitoneal aerosolized chemotherapy (PIPAC) was recently introduced in the palliative treatment of peritoneal metastases (PM). Results from preclinical experiments suggest that intraperitoneal (IP) Nab-PTX may result in superior efficacy compared to solvent based paclitaxel (PTX). We performed a phase I first-in-human trial of PIPAC using Nab-PTX in patients with PM from upper gastrointestinal, breast, or ovarian cancer. **Methods:** Eligible patients with biopsy-proven PM underwent up to three PIPAC treatments using Nab-PTX with a four-week interval at two university hospitals. Patients underwent laparoscopy with IP nebulization of Nab-PTX over 5 min; the procedure was completed after 30 min. The dose of Nab-PTX was escalated from 35 to 140 mg/m^2 using a Bayesian approach until the maximally tolerated dose (MTD) was reached. Secondary endpoints included surgical morbidity, pharmacokinetics (PK), histological treatment response, and overall survival. Blood and tissue samples were taken after each PIPAC procedure. Population PK analysis was performed using Monolix version 2020R1. Quality of life was measured using the EORTC QLQ-C30 questionnaire and visual analogue pain scales (VAS). **Results:** Twenty-three patients were included. The primary tumor was gastric cancer (55%), ovarian cancer (20%), hepatobiliary or pancreatic cancer (15%), breast cancer (5%), and miscellaneous (5%). No dose limiting toxicity was observed. Grade 3 thrombopenia was observed in one patient allocated to a dose of 90 mg/m^2. One patient allocated to the highest dose experienced grade 3 neutropenia one week after each PIPAC. The most frequent treatment-related toxicities were liver toxicity (grade 1 to 3, 75%) and anemia (grade 1 to 3, 70%). Eight patients (40%) showed surgical site infections including wound infection and wound dehiscence (grade 1 to 3), four of whom required treatment with antibiotics. Treatment was associated with histological response in 35% of patients, while stable disease and progressive disease were found in 35% and 30%, respectively. The absorption of PTX continued long after the end of the procedure (30 min), with the T_{max} reached between 2 and 6 h after initiation of the procedure. Median tumor PTX concentrations suggested accumulation: 9.37 ng/mg, 14.78 ng/mg and 25.75 ng/mg after the first, second and third PIPAC, respectively. EORTC global health, functional, and symptom scores as well as VAS scores remained stable throughout the treatment period. Overall survival after one year was 57%. **Conclusions:** PIPAC with Nab-PTX may be applied safely up to a dose of 140 mg/m^2 and results in a favorable PK profile and promising anticancer activity. At the MTD of 140 mg/m^2, considerable surgical site infections and liver toxicity were observed. Therefore, the recommended dose for future phase II trials is 112.5 mg/m^2. Clinical trial information: NCT03304210. Research Sponsor: Kom op tegen Kanker - Flemish Cancer League.

Health-related quality of life (HRQOL) in patients (pts) with advanced gastric cancer/gastroesophageal junction cancer (GC/GEJC) or esophageal adenocarcinoma (EAC): Interim results of nivolumab plus chemotherapy (N +C) versus (C) from CheckMate 649.

First Author: Lucjan Wyrwicz, Klinika Onkologii i Radioterapii, Narodowy Instytut Onkologii, Warsaw, Poland

Background: CheckMate 649 (NCT02872116) is a randomized, open label phase 3 study in first line (1L) GC/GEJC/EAC. Prespecified interim results showed statistically significant improvement in overall survival (OS) and progression-free survival (PFS) for N+C vs C in all randomized pts and pts whose tumors expressed programmed death-ligand 1 combined positive score (CPS) $\geq$ 5. We present interim HRQOL results for CPS $\geq$ 5 pts, included as exploratory in the study. **Methods:** HRQOL was assessed using EQ-5D-3L (EQ-5D) and Functional Assessment of Cancer Therapy–Gastric Cancer (FACT-Ga). Assessments were performed at baseline (BL), every 6 weeks during treatment, and during follow-up. Change from BL EQ-5D Visual Analog Scale (VAS), Utility Index (UI) and FACT-Ga scores were analyzed using mixed models. Time to first symptom deterioration (TTSD), time until definitive deterioration (TuDD), and time to improvement (TTI) were estimated with Kaplan-Meier estimators and stratified Cox models; deterioration/improvement was based on prespecified meaningful change thresholds. **Results:** 1,581 pts were randomized to N+C (n = 789) and C (n = 792); of those, 955 pts had CPS $\geq$ 5 (N+C [n = 473] and C [n = 482]). Among 821 pts with BL and post BL PROs (N+C [n = 421] and C [n = 400]), BL scores for FACT-Ga total were similar for N+C and C. Least-squares mean differences from BL favored N+C at most visits for EQ-5D and FACT-Ga total and GaCS, and were comparable for other FACT subscales (data not shown). TTI largely favored N+C (most hazard ratios (HR) > 1) but was not significantly different between treatments. For TTSD, pts treated with N+C had decreased risk of deterioration (HR < 1) in EQ-5D UI, FACT-Ga total, and GaCS. TuDD showed statistically significant delays in deterioration (HR with confidence intervals [CI] < 1) for all scores. **Conclusions:** Pts with 1L GC/GEJC/EAC experienced better HRQOL with N+C compared with C alone. Change from BL in EQ-5D and FACT-Ga total and GaCS favored N+C at most visits. N+C decreased deterioration risk compared to C with OS and PFS improvement, suggesting favorable benefits in 1L GC/GEJC/EAC pts with CPS $\geq$ 5. Clinical trial information: NCT02872116. Research Sponsor: Bristol Myers Squibb.

Individual patient data meta-analysis of neoadjuvant chemotherapy followed by surgery versus upfront surgery in esophageal or gastro-esophageal carcinoma.

First Author: Matthieu Faron, Gustave Roussy Cancer Campus, Villejuif, France

Background: Defining the optimal neoadjuvant treatment for resectable locally advanced esophageal carcinoma remains an open question. The debate is fuelled by the fact that most of the available randomized clinical trials (RCT) accrued two histological subtypes (adenocarcinoma (AC) and squamous cell carcinoma (SCC)) and two anatomical locations (TE and GEJ). The aim of this individual patient data (IPD) meta-analysis was to investigate the effect of preoperative chemotherapy on survival with a specific focus on histological subtypes and anatomical locations. **Methods:** Were eligible published or unpublished RCT closed to accrual before December 2015 and comparing neoadjuvant chemotherapy (CS) to primary surgery (S), identified by electronic database, conference proceedings and clinical trial register. All analyses were conducted on IPD obtained from trial Investigators. The Primary endpoint was overall survival (OS), Secondary endpoints were disease-free survival (DFS) with a 6-months landmark time, local/distant relapse/death without relapse as competing events. Two subgroup analyses were pre-planned one on the histological subtype and another on the anatomical location. A stratified logrank test was used for OS and DFS, and a stratified fine and gray model for competing events. HR, and risk ratios (RR) were combined using a random effect model. **Results:** IPD were obtained from 12 RCT (2601 patients) out of 16 identified (2863 patients) When compared to S, CS was associated with a significantly increased OS, (HR = 0.85[0.78-0.92], $p < 0.0001$), with a 5-year absolute OS benefit of 5.7%. However, the subgroup analysis by histological subtype showed an OS benefit from CS higher for AC (HR = 0.80[0.72-0.91], $p < 0.01$), when compared to SCC (HR = 0.90[0.80-1.01], p = 0.06), but with p for interaction = 0.2. In the subgroup analysis by anatomical location CS benefit was seen across both anatomical location with a trend in favor of GEJ (TE: HR = 0.89[0.81-0.98], p = 0.02 GEJ: HR = 0.71[0.57-0.88]), $p < 0.01$, p for interaction = 0.057). CS also improved DFS (HR = 0.81[0.74-0.88], $p < 0.0001$), with the same trend for the subgroup analyses, with apparent significant benefit for AC HR = 0.80 [0.72-0.91] when compared to SCC HR = 0.90[0.80-1.01], (p for interaction 0.045) and a similar benefit for both location (TE: HR = 0.89[0.81-0.98] $p < 0.01$, GEJ: HR = 0.71[0.57-0.88], p = 0.095, P for interaction 0.11). Local (HR = 0.76[0.63-0.92], p = 0.0045) and distant (HR = 0.87[0.76-0.99], p = 0.04) relapses were also significantly lower in the CS arm, with no significant variation according to histological subtypes or tumor location. **Conclusions:** Neoadjuvant chemotherapy significantly improves OS when added to upfront surgery and was equally effective in AC and SCC. A slightly more pronounced effect was observed for overall survival in the GEJ location vs. the TE. Research Sponsor: French Programme Hospitalier de Recherche Clinique (PHRC).

Imaging HER2-positive metastatic esophagogastric cancer with ^{89}Zr-trastuzumab PET and ^{18}F-FDG PET.

First Author: Melissa Amy Lumish, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Variations in HER2 expression between primary tumor and metastases may contribute to drug resistance in HER2-positive mEG cancer. Whole body imaging with ^{89}Zr-trastuzumab PET has a potential advantage over single site biopsies as it can non-invasively assess variations in HER2 expression and target engagement. ^{89}Zr-trastuzumab PK, biodistribution and dosimetry in mEG cancer were previously published by our group (O'Donoghue, *JNM* 2018). We now present lesion level analysis of baseline ^{18}F-FDG-PET and CT in comparison with baseline ^{89}Zr-trastuzumab imaging. **Methods:** Patients with metastatic HER2-positive (IHC 3+, IHC 2+/FISH > 2.0) mEG cancer and RECIST 1.1 measurable disease were consented and imaged with ^{89}Zr-trastuzumab PET, ^{18}F-FDG-PET and CT. All visualized lesions (maximum 5 per organ) were annotated in detail using RECIST 1.1 measurements (CT) and maximum standard uptake values (SUVmax) on ^{89}Zr-trastuzumab and ^{18}F-FDG PET scans. Correlation of visualized disease burden between imaging modalities with clinical and pathologic characteristics was performed. **Results:** 33 patients with mEG adenocarcinoma were imaged with ^{89}Zr-trastuzumab PET, ^{18}F-FDG-PET and CT (12% esophageal, 64% GEJ, 24% gastric). HER2 status (IHC 3+ 70%; IHC2+/FISH+ 27%, NGS 3%) was assessed from biopsy of primary (66.7%) or metastasis (33.3%). Median time from diagnosis to ^{89}Zr-trastuzumab PET was 12.6 months. At the time of ^{89}Zr-trastuzumab PET, 39% were treatment naive, while 61% had received prior therapy including trastuzumab (58%) and afatinib (median lines 2, range 0-6). 82% of patients had the primary tumor in place and all patients had metastatic disease at the time of enrollment with metastases to lymph nodes (70%) peritoneum (24%), liver (58%), lung (33%), and/or bone (9%). Median number of RECIST 1.1 lesions measured on baseline CT was 6 (range 1-15). PET analysis is complete in 18 of 33 patients. Median number of ^{89}Zr-trastuzumab PET positive (SUV > 3) lesions was 5.5 (range 1-11) with 5 patients having at least 1 (max 3) very intense lesion (SUV > 15). Median number of ^{18}F-FDG-PET-positive lesions was 8 (range 1-14). Three patients had at least 1 lesion positive on ^{89}Zr-trastuzumab-PET and negative on ^{8}F-FDG-PET (range 0-5), and 8 patients had at least 1 lesion positive on ^{18}F-FDG-PET and negative on ^{89}Zr-trastuzumab-PET (range 0-7). Of the total lesions identified on ^{89}Zr-PET but not CT, 40% were in bone. Of those identified on ^{89}Zr but not ^{8}F-FDG-PET, 40% were in bone, and of those on ^{18}F-FDG- but not ^{89}Zr-PET, 6% were in bone. **Conclusions:** ^{89}Zr-trastuzumab PET effectively identifies heterogeneity of HER2 expression and allows assessment of lesions throughout the whole body. Bone lesions were better identified and appeared earlier on ^{89}Zr-trastuzumab PET compared with CT. Additional analyses including correlation of baseline HER2 heterogeneity with overall and disease-free survival will be presented. Clinical trial information: NCT02023996. Research Sponsor: Department of Defense.

4069 **Poster Session**

Final results from ClarIDHy, a global, phase 3, randomized, double-blind study of ivosidenib (IVO) versus placebo (PBO) in patients (pts) with previously treated cholangiocarcinoma (CCA) and an isocitrate dehydrogenase 1 (*IDH1*) mutation.

First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center & Weill Medical College at Cornell University, New York, NY

Background: CCA is a rare cancer for which there are limited effective therapies. *IDH1* mutations occur in ~20% of intrahepatic CCAs, resulting in production of the oncometabolite D-2-hydroxyglutarate, which promotes oncogenesis. IVO (AG-120) is a first-in-class, oral, small-molecule inhibitor of mutant IDH1 (mIDH1). ClarIDHy aimed to demonstrate the efficacy of IVO vs PBO in pts with unresectable or metastatic m*IDH1* CCA. The primary endpoint was met with significant improvement in progression-free survival (PFS) by independent radiology center (IRC) with IVO vs PBO (hazard ratio [HR] = 0.37, $p < 0.0001$). Objective response rate (ORR) and stable disease for IVO were 2.4% (3 partial responses) and 50.8% (n = 63) vs 0% and 27.9% (n = 17) for PBO. IVO pts experienced significantly less decline in physical and emotional functioning domains of quality of life at cycle 2 day 1 vs PBO pts (nominal $p < 0.05$). **Methods:** Pts with m*IDH1* CCA were randomized 2:1 to IVO (500 mg PO QD) or matched PBO and stratified by prior systemic therapies (1 or 2). Key eligibility: unresectable or metastatic m*IDH1* CCA based on central testing; ECOG PS 0–1; measurable disease (RECIST v1.1). Crossover from PBO to IVO was permitted at radiographic progression. Primary endpoint: PFS by IRC. Secondary endpoints included overall survival (OS; by intent-to-treat), ORR, PFS (by investigator), safety, and quality of life. The planned crossover-adjusted OS was derived using the rank-preserving structural failure time (RPSFT) model. **Results:** As of 31 May 2020, ~780 pts were prescreened for an *IDH1* mutation and 187 were randomized to IVO (n = 126) or PBO (n = 61); 13 remain on IVO. Median age 62 y; M/F 68/119; 91% intrahepatic CCA; 93% metastatic disease; 47% had 2 prior therapies. 70% of PBO pts crossed over to IVO. OS data were mature, with 79% OS events in IVO arm and 82% in PBO. Median OS (mOS) was 10.3 months for IVO and 7.5 months for PBO (HR = 0.79; 95% CI 0.56–1.12; one-sided p = 0.093). The RPSFT-adjusted mOS was 5.1 months for PBO (HR = 0.49; 95% CI 0.34–0.70; $p < 0.0001$). Common all-grade treatment emergent adverse events (TEAEs, $\geq$ 15%) in the IVO arm: nausea 41%, diarrhea 35%, fatigue 31%, cough 25%, abdominal pain 24%, decreased appetite 24%, ascites 23%, vomiting 23%, anemia 18%, and constipation 15%. Grade $\geq$ 3 TEAEs were reported in 50% of IVO pts vs 37% of PBO pts, with grade $\geq$ 3 treatment-related AEs in 7% of IVO pts vs 0% in PBO. 7% of IVO pts experienced an AE leading to treatment discontinuation vs 9% of PBO pts. There were no treatment-related deaths. **Conclusions:** IVO was well tolerated and resulted in a favorable OS trend vs PBO despite a high rate of crossover. These data – coupled with statistical improvement in PFS, supportive quality of life data, and favorable safety profile – demonstrate the clinical benefit of IVO in advanced m*IDH1* CCA. Clinical trial information: NCT02989857. Research Sponsor: Agios Pharmaceuticals, Inc.

Adjuvant nivolumab for hepatocellular carcinoma (HCC) after surgical resection (SR) or radiofrequency ablation (RFA) (NIVOLVE): A phase 2 prospective multicenter single-arm trial and exploratory biomarker analysis.

First Author: Masatoshi Kudo, Department of Gastroenterology and Hepatology, Kindai University Faculty of Medicine, Osaka, Japan

Background: The NIVOLVE trial was designed to assess the efficacy and safety of nivolumab as an adjuvant therapy for HCC, and to identify biomarkers predictive of recurrence in patients after SR or RFA (Registration # UMIN 000026648). **Methods**: The trial involved 11 sites and was conducted in patients with HCC who showed a complete response after SR (n = 33) or RFA (n = 22) (ITT). Overall, 53 of 55 patients with Child-Pugh A received nivolumab (240 mg/body every 2 weeks (8 cycles)), followed by nivolumab (480 mg/body every 4 weeks (8 cycles)) within 6 weeks after SR or RFA. The primary endpoint was the 1 year recurrence-free survival rate (RFSR). The key secondary endpoint was RFS. Exploratory biomarker analysis included mutations, copy number alterations, and tumor mutation burden in tumor tissues. Techniques included next generation sequencing, immunohistochemical staining (IHC) of formalin-fixed paraffin-embedded tissues (n = 31, 13 with recurrence and 18 without) for CD8, PD-1, PD-L1, Foxp3, and β-catenin, and ctDNA analysis using pre-nivolumab whole blood by deep sequencing (CAPP-seq; Avenio). **Results**: The 1-year RFSR and median RFS were 76.7% and 26.0 months (95% confidence interval (CI), 23.9–28.1), respectively, with no difference between SR and RFA. Copy number gains (CNGs) in WNT/β-catenin related genes (*APC, CTNNB1, TCF7L1, TCF7L2*) (n = 8) correlated with shorter RFS (positive: 11.8 months *vs.* negative: not reached [NR]; p = 0.0003). IHC revealed that negative staining for PD-1 ($p < 0.0001$), a low combined positive score for PD-L1 (p = 0.0113), a low number of CD8+ tumor infiltrating lymphocytes (TILs) (p = 0.0130), and positivity for Foxp3+ cells (p = 0.0076) correlated with recurrence. Treatment-related adverse events (AEs) (n = 53) were as follows: all grades, 68%; grades 3–4 (18.9%); and immune related AEs, 25%. HCC cases with low numbers of CD8+ TILs or cases positive for Foxp3+ cells (n = 16) showed a significantly shorter RFS (16.8 months [95% CI, 8.7–25.1]) than those with high numbers of CD8+ TILs and those positive for PD-1/PD-L1 expression (n = 15) (NR [95% CI,26.2months–NR]) ($p < 0.0001$). HCC cases with activation of the WNT/β-catenin pathway assessed by IHC (n = 9) showed shorter RFS (17.0 months [95% CI,1.1–26.2]) than those without activation (n = 22) (NR [95% CI,24.7 months–NR]) (p = 0.0191). Patients positive for ctDNA (n = 10) before nivolumab tended to have shorter RFS than those without ctDNA (n = 30) (26.2 vs. NR). There was no correlation between TMB and RFS. **Conclusions**: The 1 year RFSR and RFS in the NIVOLVE trial were 76.6% and 26.0 months, respectively. No new safety signal was observed. CNG in WNT/β-catenin-related genes, activation of the WNT/β-catenin pathway, the presence of Foxp3+ cells, and low numbers of CD8+ TILs may predict recurrence after SR or RFA with adjuvant nivolumab. IMbrave150: Exploratory analysis to examine the association between treatment response and overall survival (OS) in patients (pts) with unresectable hepatocellular carcinoma (HCC) treated with atezolizumab (atezo) + bevacizumab (bev) versus sorafenib (sor).

First Author: Michel Ducreux, Gustave Roussy Cancer Center, Villejuif, France

Background: Based on IMbrave150 (NCT03434379) results, atezo + bev has been approved in > 60 countries for pts with unresectable HCC who have not received prior systemic therapy (Finn RS, NEJM 2020). OS and objective response rate (ORR) improvements with atezo + bev vs sor were maintained with an additional 12 mo of follow up since primary analysis. Updated median OS was 19.2 mo with atezo + bev vs 13.4 mo with sor (stratified HR, 0.66; 95% CI: 0.52, 0.85). Updated ORR was 30% with atezo + bev vs 11% with sor by independently-assessed (IRF) RECIST 1.1 (Finn RS, ASCO GI 2021). Here, we report an exploratory analysis examining the association of response by RECIST 1.1 with OS and independent predictors of survival. **Methods:** Pts in this Ph III study were systemic treatment–naive with unresectable HCC, ≥1 measurable untreated lesion (RECIST 1.1), Child-Pugh class A liver function and ECOG PS 0/1. Pts were randomized 2:1 to atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w or sor 400 mg bid until unacceptable toxicity or loss of clinical benefit per investigator. ORR was determined by IRF RECIST 1.1. Kaplan-Meier analyses of OS by response status were conducted without landmark and with 4- and 6-mo landmarks. Multivariate analysis was conducted using Cox modeling with time-dependent covariate (responder [yes/no]) with backwards elimination. These analyses only included pts treated with atezo + bev. **Results:** IMbrave150 enrolled 501 pts, including 336 treated with atezo + bev. Median follow-up was 15.6 mo. OS was longer in pts with confirmed response per RECIST 1.1 (responders, CR + PR) vs non-responders by Kaplan-Meier analyses without landmark and with 4- and 6-mo landmarks (Table). By multivariate analysis, in addition to responder (yes/no), 5 of the 10 initially included predictors of OS remained in the final Cox model ($P < 0.10$): ECOG PS (0/1), geographic region (Asia excluding Japan/rest of the world), etiology (hepatitis B/hepatitis C/non-viral), macrovascular invasion and/or extrahepatic spread (yes/no), and baseline alpha-fetoprotein (< 400 ng/mL/ ≥400 ng/mL). **Conclusions:** Atezo + bev is the new standard of care for pts with previously untreated, unresectable HCC. Here we showed that in IMbrave150 pts treated with atezo + bev, response by RECIST 1.1 was associated with OS, suggesting that confirmed response is an independent predictor of OS in these pts. Clinical trial information: NCT03434379. Research Sponsor: F. Hoffmann-La Roche, Ltd.

Kaplan-Meier analyses of the association between confirmed response by RECIST 1.1 and OS.

Analysis	Responders	n	Median OS (95% CI), mo	HR[a] (95% CI)

Pembrolizumab (pembro) versus placebo (pbo) in patients (pts) with advanced hepatocellular carcinoma (aHCC) previously treated with sorafenib: Updated data from the randomized, phase 3 KEYNOTE-240 study.

First Author: Richard S. Finn, David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: KEYNOTE-240 (NCT02702401) examined the antiPD-1 antibody pembro and showed improvement in OS and PFS vs pbo in pts with aHCC previously treated with sorafenib. The study did not meet prespecified statistical significance criteria for OS and PFS. Median OS (final analysis) was 13.9 mo for pembro vs 10.6 mo for pbo (HR 0.781; 95% CI 0.611-0.998). At the first interim analysis when testing for PFS and ORR was prespecified, median PFS was 3.0 mo for pembro vs 2.8 mo for pbo (HR 0.775; 95% CI 0.609-0.987) and ORR was 16.9% (CR, n = 3) for pembro and 2.2% (CR, n = 0) for pbo. AEs were consistent with the known safety profile of pembro. Longer term data from KEYNOTE-240 after ~1.5 y of additional follow-up are reported. **Methods:** Adults with confirmed aHCC for whom sorafenib therapy failed (progression or intolerance) were randomly assigned 2:1 to receive pembro 200 mg IV Q3W + best supportive care (BSC) or pbo + BSC for ≤35 cycles or until confirmed progression/unacceptable toxicity, pt withdrawal of consent, or investigator decision to withdraw pt. Dual primary end points were OS and PFS, assessed by blinded independent central review (BICR) per RECIST v1.1. Secondary end points included ORR, DOR, DCR, TTP (all assessed by BICR per RECIST v1.1), and safety. **Results:** Of 413 pts, 278 were randomized to receive pembro; 135, to pbo.As of July 13, 2020, median time (range) from randomization to data cutoff was 39.6 mo (31.7-48.8) for pembro and 39.8 mo (31.7-47.8) for pbo. Median OS (95% CI) was 13.9 mo (11.6-16.0) for pembro and 10.6 mo (8.3-13.5) for pbo (HR 0.771; 95% CI 0.617-0.964). Estimated OS rates at 24 and 36 mo for pembro and pbo were 28.8% and 20.4% and 17.7% and 11.7%, respectively. Median PFS (95% CI) was 3.3 mo (2.8-4.1) for pembro and 2.8 mo (1.6-3.0) for pbo (HR 0.703; 95% CI 0.559-0.885). Estimated PFS rate at 24 mo was 11.8% for pembro and 4.8% for pbo. ORR (95% CI) was 18.3% (14.0-23.4) for pembro and 4.4% (1.6-9.4) for pbo. Median time to response (95% CI) was 2.7 mo (1.2-16.9) for pembro and 2.9 mo (1.1-6.9) for pbo. Median DOR (range) was 13.9 mo (1.5+ to 41.9+) for pembro and 15.2 mo (2.8-21.9) for pbo; 53.7% of responders in the pembro arm and 50.0% of responders in the pbo arm had DOR ≥12 mo. DCR was 61.9% for pembro and 53.3% for pbo. Best overall responses were 10 CR, 41 PR, 121 SD, and 85 PD for pembro and 0 CR, 6 PR, 66 SD, and 54 PD for pbo. Median TTP (95% CI) was 4.0 mo (2.8-5.3) for pembro and 2.8 mo (1.6-3.0) for pbo. No new or unexpected AEs occurred. The frequency of sponsor-assessed immune-mediated hepatitis events did not increase with additional follow-up. There continued to be no HBV or HCV viral flare events. **Conclusions:** In previously treated pts with aHCC, improvement in OS and PFS was maintained over time with pembro vs pbo, and the safety profile remained consistent. These data support the benefit:risk profile of pembro. Clinical trial information: NCT02702401. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

IMbrave150: Exploratory efficacy and safety results of hepatocellular carcinoma (HCC) patients (pts) with main trunk and/or contralateral portal vein invasion (Vp4) treated with atezolizumab (atezo) + bevacizumab (bev) versus sorafenib (sor) in a global Ph III study.

First Author: Valeriy Vladimirovich Breder, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Atezo + bev has been approved in >60 countries for pts with unresectable HCC who have not received prior systemic therapy, based on IMbrave150 (NCT03434379; Finn RS *NEJM* 2020). Due to their poor prognosis and the hemodynamic changes from increased portal vein pressure, pts with main portal vein tumor thrombus are often excluded from pivotal HCC trials. Here, we report exploratory efficacy and safety results of pts with Vp4 (presence of a tumor thrombus in the main trunk and/or contralateral portal vein) using updated IMbrave150 data (Finn RS ASCO GI 2021). **Methods:** Pts were randomized 2:1 to atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w or sor 400 mg bid until unacceptable toxicity or loss of clinical benefit per investigator. IMbrave150 enrolled 501 systemic treatment (tx)–naive unresectable HCC pts, ≥1 measurable untreated lesion (RECIST 1.1), Child-Pugh class A liver function and ECOG PS 0/1, including 73 (15%) Vp4 pts. This post hoc exploratory analysis was conducted with a median follow-up of 15.6 mo in ITT pts. **Results:** Of the Vp4 pts, 48 received atezo + bev and 25 received sor. Median OS (mOS) was 7.6 vs 5.5 mo (HR, 0.62; 95% CI: 0.34, 1.11) and median PFS (mPFS) per independent review facility (IRF)–assessed RECIST 1.1 was 5.4 vs 2.8 mo (HR, 0.62; 95% CI: 0.35, 1.09) with atezo + bev and sor, respectively. ORR per IRF RECIST 1.1 was 23% (11/47) with atezo + bev (2 [4%] pts had CR) vs 13% (3/23) with sor (1 [4%] pt had CR). All-grade variceal bleeding was higher with atezo + bev in Vp4 (13.6%) vs rest of ITT pts (2.5%). See table for further efficacy and safety data. **Conclusions:** The benefits of atezo + bev over sor in Vp4 pts are consistent with those in ITT pts across all efficacy endpoints, despite the expected disease-intrinsic increase in variceal bleeding in Vp4 vs rest of ITT pts. The overall positive benefit-risk profile supports the use of atezo + bev in pts with Vp4. Clinical trial information: NCT03434379. Research Sponsor: F. Hoffmann-La Roche, Ltd.

Pembrolizumab (pembro) monotherapy for previously untreated advanced hepatocellular carcinoma (HCC): Phase 2 KEYNOTE-224 study. *First Author: Jean-Luc Van Laethem, Erasme Hospital, Brussels, Belgium*

Background: Results from cohort 1 of KEYNOTE-224, an open-label, single-arm, multi-country phase 2 trial, demonstrated that pembro monotherapy was efficacious and tolerable in patients (pts) with advanced HCC previously treated with sorafenib. Here, we report results from KEYNOTE-224 cohort 2, which enrolled pts with advanced HCC and no prior systemic therapy. **Methods:** Eligible pts in cohort 2 had radiologically, histologically, or cytologically confirmed, incurable HCC not amenable or refractory to locoregional therapy, Child Pugh A liver disease, measurable disease based on RECIST 1.1 by blinded independent central review (BICR), ECOG PS 0-1, and BCLC stage C or B. Pts received pembro 200 mg IV Q3W for ~2 years or until disease progression, unacceptable toxicity, consent withdrawal, or investigator decision. Primary endpoint was ORR (RECIST 1.1 by BICR). Secondary endpoints included DOR, DCR, TTP, PFS, OS, and safety/tolerability. Response was assessed every 9 weeks. Efficacy and safety were assessed in pts who received ≥1 dose of study treatment. DOR was assessed in responders. The estimate and 95% CI of the ORR and DCR were based on the Clopper-Pearson method. Kaplan-Meier method was used to estimate OS, PFS, and DOR. A sample size of ~50 pts was chosen to provide acceptable precision for the assessment of ORR. **Results:** Cohort 2 enrolled 51 pts. The median time from the first dose to data cutoff (July 31, 2020) was 21 (range, 17-23) mo. The median age of pts was 68 (range, 41-91) years, one pt was HBV+, 80% had alcohol use, 8% were HCV+, 18% had vascular invasion, 35% had extrahepatic disease, 33% had BCLC Stage B disease, and 67% had BCLC Stage C HCC. ORR was 16% (95% CI, 7-29) and was similar across most subgroups. Median DOR was not reached (range, 3-20+ mo); 70% were estimated to have response duration ≥12 mo. Best overall responses were 0 CR, 8 (16%) PRs, 21 (41%) SDs, and 17 (33%) PDs; response was not evaluable or not assessed for 5 (10%) pts. DCR was 57%. The median TTP was 4 (95% CI, 3-8) mo. The median PFS was 4 (95% CI, 2-6) mo, and median OS was 17 (95% CI, 8-NA) mo. PFS rate at 18 mo was 16%, and OS rate at 18 mo was 46%. Treatment-related AEs (TRAEs) occurred in 27 (53%) pts; the most common TRAEs were diarrhea, fatigue, hypothyroidism, and myalgia. Grade ≥3 TRAEs occurred in 7 (14%) pts. TRAEs led to treatment discontinuation in 6% of pts. Immune-mediated AEs and infusion reactions occurred in 11 (22%) pts. One treatment-related death occurred due to myocarditis, with associated immune-related hepatitis. **Conclusions:** In pts with advanced HCC and no prior systemic therapy, pembro monotherapy provided durable anti-tumor activity, promising overall survival, and demonstrated a safety profile consistent with that previously observed for pembro in advanced HCC. These findings support further evaluation of pembro-based regimens for the treatment of HCC in the frontline setting. Clinical trial information: NCT02702414. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4075 **Poster Session**

A phase Ib study of anlotinib plus TQB2450 as second-line therapy for advanced biliary tract adenocarcinoma. *First Author: Yongkun Sun, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Although with modest efficacy, mFOLFOX is recommended as standard second-line chemotherapy for advanced biliary tract adenocarcinoma. Several clinical trials are exploring the combination treatment of anti-angiogenic drugs and immune checkpoint inhibitors. Anlotinib is an oral small molecule inhibitor of receptor tyrosine kinases, with inhibitory effects on tumor angiogenesis and growth. Anlotinib plus TQB2450,an anti-PD-L1 mAb, have shown anti-tumor activity in preclinical study and here we investigate the efficacy and safety of different dosage of this regimen as second-line treatment for advanced biliary tract adenocarcinoma. **Methods:** Patients with advanced biliary tract adenocarcinoma who had progressed after first-line treatment received anlotinib (once daily for 2 weeks on/1 week off) plus TQB2450 (1200mg once) every three weeks. The planned anlotinib dose levels to be explored were 10mg (starting) and 12mg daily. Dose expansion was performed after the determination of the maximum tolerable dose. Response to treatment was evaluated using the RECIST 1.1 criteria, supplemented by iRECIST. The primary endpoints were MTD, ORR, and the secondary endpoints were PFS, OS and safety. **Results:** Both 10mg and 12mg of anlotinib were tolerable after the initial safety observation of different doses from May 2019 to April 2020. 34 patients (8 cases of gallbladder cancer [GBC], 22 of intrahepatic cholangiocarcinoma [ICC] and 4 of extrahepatic cholangiocarcinoma [ECC]) were enrolled, 22 patients in the 10mg dose group and 12 in the 12mg dose group. The median age was 57 (37-72) years and 55.9% (19) of the patients were female. At the analysis cut-off date of 31 December 2020, the median follow-up duration was 14.9 months. Of the 34 patients, 4 patients had partial response (PR, 2 cases in the 10mg group and 2 in the 12mg group), including 2 cases with GBC and 2 with ICC, 17 had stable disease (SD, shrinkage, 12 in the 10mg group and 5 in the 12mg group) and 5 SD (enlargement, 4 in the 10mg group and 1 in the 12mg group), 7 had progression disease (PD, 5 in the 10mg group and 2 in the 12mg group) and 1 patient of ECC could not be evaluated. In the overall population, the median PFS (mPFS) was 5.95 (95%CI: 3.78-11.50) months. The mPFS was 5.29 (95%CI: 3.45-10.32) months in 10mg group and 12.98 (95%CI: 1.38-NR) in 12mg group. The median OS was not reached and the 12-month OS rate was 64.71% (60.87% in the 10mg group and 72.73% in the 12mg group). Grade 3 or higher toxicities were observed in 8 patients, with elevated transaminase (n = 4, 11.8%), elevated bilirubin (n = 3, 8.8%), fatigue (n = 1, 2.9%), hypertension (n = 1, 2.9%) and prolonged QTc (n = 1, 2.9%). **Conclusions:** Anlotinib plus TQB2450 as second-line therapy for advanced biliary tract adenocarcinoma was well tolerated and showed promising efficacy. No unexpected adverse events were observed in both drugs. This regimen is worthy of further exploration. Clinical trial information: NCT03825705. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Update on overall survival (OS) of RESCUE: An open-label, phase 2 trial of camrelizumab (C) in combination with apatinib (A) in patients with advanced hepatocellular carcinoma (HCC). *First Author: Yun Zhang, The Fifth Medical Center, Chinese PLA General Hospital, Beijing, China*

Background: C+A combination therapy displayed high objective response rate, disease control rate, and durable response with a manageable safety profile in patients (pts) with advanced HCC. Here we performed an updated analysis of OS to characterize the OS benefit of C+A in HCC pts. **Methods:** 70 pts in first-line cohort and 120 pts in second-line cohort were enrolled. Median OS and 2-year OS rate were evaluated *via* updated data (data cutoff, 3 January, 2021). Median time from enrollment to data cutoff of the total population (N = 190) was 29.1 months (range, 24.0-33.7). **Results:** OS events had occurred in 58.6% pts in first-line cohort and 60.0% pts in second-line cohort. The median OS was 20.1 months (95% CI, 14.9-NR) and 2-year OS rate was 43.3% (95% CI, 31.3-54.7) in first-line cohort. The median OS was 21.8 months (95% CI, 17.3-26.8) and 2-year OS rate was 44.6% (95% CI, 35.5-53.3) in second-line cohort. **Conclusions:** Long-term follow-up of C+A demonstrated remarkable survival benefit in advanced HCC pts, which further suggested that C+A is a promising combination therapy in advanced HCC pts. Clinical trial information: NCT03463876. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

A randomized, double-blinded, phase III study of icaritin versus huachashu as the first-line therapy in biomarker-enriched HBV-related advanced hepatocellular carcinoma with poor conditions: Interim analysis result. *First Author: Yan Sun, Department of Medical Oncology, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Many advanced hepatocellular carcinoma (aHCC) patients (pts) are often with more complicated clinical conditions such as damaged liver or blood function, poor physical conditions. Those aHCC pts are not suitable for molecular target drug like sorafenib or systemic chemotherapy and no standard or generally accepted treatment. Icaritin, a single molecule (> 98% purity) derived from *Epimedii herba* (Traditional Chinese herbal medicine), is a novel immune-modulation anti-tumor agent. Preclinical studies demonstrated that Icaritin induced anti-HCC activities through targeting IL-6/JAK//STAT3 pathways and modulating inflammation-immune systems including Th1 cytokines, and down-regulation of alpha-fetoprotein (AFP). Prior phase II study demonstrated favorable overall survival (OS) improvement in aHCC pts with poor conditions and correlated with the combined serum biomarkers. The current phase III study was designed to confirm above clinical benefits and safety of Icaritin in those patients. **Methods:** An adaptive enrichment design was used in a multicenter randomized, double-blinded study of comparing Icaritin with Huachashu (a TCM formula commonly used in China) as first line therapy for those aHCC pts (NCT03236636). The primary endpoint was overall survival (OS) and secondary endpoints included time-to-progression (TTP), progression-free-survival (PFS), disease control rate (DCR), and safety. The pts were randomized (1:1) to receive either Icaritin at 600mg or Huachashu. Based on prior studies, a composite biomarker score (CBS) of AFP(≥400 ng/mL), TNF-a(< 2.5 pg/mL) and IFN-g(≥7.0 pg/mL) was used for pts selection and a CBS score of 2/3 was predefined positive. Patients with CBS-positive were applied in interim analysis according to the protocol and statistical analysis plan (SAP). **Results:** A total of 283 aHCC pts were enrolled and randomized from Sept. 2017, and 71 enriched pts was CBS-positive with combined risk/poor prognosis factors such as BCLC stage C, HBV infection, and thrombocytopenia etc.. Thirty-three and 38 CBS-positive aHCC pts were treated with Icaritin or Huachashu, respectively. With a median follow-up of 8.1 mo (cutoff date, Dec.30,2020), the treatment outcomes for Icaritin and Huachashu arm showed following, that is mOS, 13.54 vs. 7.06 mo (HR = 0.40, 95%CI 0.21-0.77, p = 0.0046), mTTP, 3.65 vs. 1.84 mo (HR = 0.67, 95%CI, 0.36-1.22), mPFS, 2.79 vs. 1.84 mo (HR = 0.75, 95%CI, 0.43-1.33), and DCR, 48.5% vs. 26.3, respectively. Treatment-related adverse event (AE≥3 grades) observed were 15.2% vs. 31.6%, respectively. **Conclusions:** Small molecule immunomodulation agent Icaritin could significantly improve the overall survival with favorable safety in a prospectively CBS-enriched HBV-related advanced HCC pts with poor conditions. Clinical trial information: NCT03236636. Research Sponsor: Beijing Shenogen Pharma.

4078 **Poster Session**

Updated results of a phase 1b study of regorafenib (REG) 80 mg/day or 120 mg/day plus pembrolizumab (PEMBRO) for first-line treatment of advanced hepatocellular carcinoma (HCC). *First Author: Anthony B. El-Khoueiry, University of Southern California, Los Angeles, CA*

Background: REG, a multikinase inhibitor, and PEMBRO, an anti-PD-1 mAb, are approved as monotherapies in advanced HCC after progression on sorafenib. This phase 1b dose-finding study investigated first-line REG plus PEMBRO in advanced HCC. **Methods:** Patients (pts) in the first cohort received a starting REG dose of 120 mg/day orally for 3 weeks (wks) on/1 wk off, which could be escalated (160 mg) or reduced (80 mg) in later cohorts, plus a fixed dose of PEMBRO 200 mg IV every 3 wks. Due to a high dose modification rate in the REG 120 mg cohort, an exploratory REG 80 mg cohort was introduced. Primary objective was safety and tolerability; secondary aims were to assess the maximum tolerated dose (MTD), recommended phase 2 dose, and anti-tumor activity. **Results:** 35 pts started on REG 120 mg/day and 22 on REG 80 mg/day. Median age was 66 yrs (range 29–81), 84% of pts were male, 70%/30% had ECOG PS 0/1, 26%/74% were BCLC stage B/C, 100% were C–P A, 46% had extrahepatic spread, and 32% had macrovascular invasion. MTD of REG was 120 mg/day. Grade (Gr) 3/4 treatment-emergent adverse events (TEAE) occurred in 86% of pts on REG 120 mg and 50% on REG 80 mg (Table). Most common Gr 3/4 TEAE for REG 120 mg/80 mg were AST increased (23%/9%), lipase increased (20%/5%), ALT increased (17%/9%), and hypertension (17%/9%). TEAE led to REG/PEMBRO dose reductions or interruptions in 71%/57% of pts on REG 120 mg and 59%/45% on REG 80 mg. Median treatment duration (range) was 3.0 months (mo; 0.2–20.5) for REG 120 mg and 3.5 mo (0.03–24.4) for PEMBRO, and 3.5 mo (0.7–10.8) for REG 80 mg and 3.5 mo (0.8–11.3) for PEMBRO. Of 32 evaluable pts on REG 120 mg, 10 (31%) had a partial response (PR) and 18 (56%) had stable disease (SD); disease control rate (DCR) was 88% (RECIST v1.1). Of 22 pts on REG 80 mg, 4 (18%) had a PR and 16 (73%) had SD; DCR was 91%. As of 17 Dec 2020, 16 pts remain on treatment (REG 120 mg n = 5; REG 80 mg n = 11); median follow up was 11.7 mo and 6.9 mo, respectively. REG pharmacokinetic exposure was as expected for 80 mg and 120 mg doses. Flow cytometry analysis of sequential peripheral blood showed changes in subsets of T-cells and monocytes, which may contribute to clinical benefit. **Conclusions:** First-line REG plus PEMBRO in advanced HCC showed no new safety signals and encouraging anti-tumor activity (DCR ~90%). The REG 80 mg cohort appeared to have lower rates of dose reductions and interruptions due to TEAE vs REG 120 mg. Efficacy data for the REG 80 mg cohort are preliminary due to short follow-up. Clinical trial information: NCT03347292. Research Sponsor: Bayer.

Association of cell-free DNA dominant clone allele frequency with poor outcomes in advanced biliary cancers treated with platinum-based chemotherapy. *First Author: Umair Majeed, Mayo Clinic, Jacksonville, FL*

Background: Cell-free circulating tumor DNA (ctDNA) holds significant promise and is being used for clinical decision making in multiple tumors. This study aimed to evaluate the prognostic value of pre-treatment ctDNA in metastatic biliary tract cancers (BTC) treated with platinum based first-line chemotherapy treatment. **Methods:** We performed a retrospective analysis of 67 patients who underwent ctDNA testing before platinum-based chemotherapy for first-line treatment for metastatic BTC. For analysis we considered the detected gene with highest variant allele frequency (VAF). Results of ctDNA analysis were correlated with patients' demographics, progression-free survival (PFS) and overall survival (OS). **Results:** The median age of patients was 67 y/o (27-90). 54 (80.6%) of 67 patients evaluated had intrahepatic cholangiocarcinoma; seven had extrahepatic cholangiocarcinoma and six gallbladder cancer. 46 (68.6%) of the patients were treated with cisplatin plus gemcitabine, 14 (21%) patients received gemcitabine and other platinum (carboplatin or oxaliplatin) combinations while 7 (10.4%) patients were treated on a clinical trial with gemcitabine and cisplatin plus additional targeted agents (CX4945 or PEGPH20). TP53, KRAS, APC, FGFR2 and IDH1 were the genes with highest frequency as dominant clone. The median dominant clone allele frequency (DCAF) was 3% (0-97%). DCAF >3% was associated with statistically significant worse PFS (median PFS: 4.05 vs. 7.70 months, p=0.046) and OS (median OS: 10.8 vs. 18.8 months, p=0.056). Each 1% increase in DCAF is associated with a hazard ratio of 26.21 in OS when adjusting for subtypes, age, treatment type, and CA19-9 [Table]. **Conclusions:** Patients with metastatic BTC with DCAF > 3% at diagnosis have worse PFS and OS compared to patients with low ctDNA when treated with upfront platinum-based chemotherapy. Research Sponsor: None.

Overall survival adjusted for tumor type.

	Hazard Ratio	95%CI	P value

Lenvatinib plus pembrolizumab for patients with previously treated biliary tract cancers in the multicohort phase 2 LEAP-005 study. *First Author: Luis Villanueva, Fundación Arturo López Pérez, Providencia, Santiago, Chile*

Background: Second-line treatment options for patients with biliary tract cancers (BTC) are limited. Lenvatinib, an anti-angiogenic multikinase inhibitor, in combination with the programmed death-1 immune checkpoint inhibitor pembrolizumab, has demonstrated promising antitumor activity with a manageable safety profile in patients with select advanced solid tumors. LEAP-005 (NCT03797326) is evaluating the efficacy and safety of lenvatinib plus pembrolizumab in patients with previously treated advanced solid tumors; here we present results from the BTC cohort of LEAP-005. **Methods:** In this nonrandomized, open-label, phase 2 study, eligible patients were aged ≥18 years with histologically or cytologically documented advanced (metastatic and/or unresectable) BTC with disease progression after 1 prior line of therapy, measurable disease per RECIST v1.1, ECOG PS of 0–1, and tissue sample evaluable for PD-L1 expression. Patients received lenvatinib 20 mg once daily plus pembrolizumab 200 mg Q3W for up to 35 cycles (approximately 2 years) or until confirmed disease progression, unacceptable toxicity, or withdrawal of consent. Treatment with lenvatinib could continue beyond 2 years in patients experiencing clinical benefit. Primary endpoints were ORR (per RECIST v1.1 by blinded independent central review) and safety. Secondary endpoints were the disease control rate (DCR; comprising CR, PR, and SD), duration of response (DOR), PFS, and OS. Tumor imaging was performed Q9W from treatment initiation for 54 weeks, then Q12W to week 102, and Q24W thereafter. **Results:** 31 patients were enrolled in the BTC cohort (ECOG PS 1, 55%; 84% ex-US). As of April 10, 2020, median time from first dose to data cutoff (DCO) was 9.5 months (range, 3.1–11.9), with 8 patients on treatment at DCO. There were 3 (10%) PRs and 18 (58%) SDs. ORR was 10% (95% CI, 2–26), and DCR was 68% (95% CI, 49–83). Median DOR was 5.3 months (range, 2.1+ to 6.2). Median PFS was 6.1 months (95% CI, 2.1–6.4). Median OS was 8.6 months (95% CI, 5.6 to NR). Treatment-related AEs occurred in 30 patients (97%), including 15 (48%) who had grade 3 AEs; there were no grade 4 or 5 treatment-related AEs. 2 (6%) discontinued treatment due to treatment-related AEs (myocarditis, pyrexia; n = 1 each). The most frequent treatment-related AEs were hypertension (42%), dysphonia (39%), diarrhea (32%), fatigue (32%), and nausea (32%). 14 patients (45%) had immune-mediated AEs and 1 patient (3%) had an infusion-related reaction. **Conclusions:** Lenvatinib plus pembrolizumab demonstrated encouraging efficacy and manageable toxicity in patients with advanced BTC who had received 1 line of prior therapy. Based on these data, enrollment in the BTC cohort has been expanded to 100 patients. Clinical trial information: NCT03797326. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Preliminary results of molecular screening for *FGFR* alterations (alts) in the RAGNAR histology-agnostic study with the *FGFR*-inhibitor (FGFRi) erdafitinib. *First Author: Christophe Massard, Gustave Roussy-Department of Therapeutic Innovation and Early Trials (DITEP), Paris, France*

Background: *FGFR* alts (mutations and fusions) have been reported in multiple advanced solid tumors at varying frequencies. These alts may function as oncogenic drivers of disease independent of the underlying tumor type. RAGNAR is an ongoing phase 2, histology-agnostic trial investigating the efficacy and safety of erdafitinib, a selective pan-FGFRi, in patients (pts) with advanced solid tumors and *FGFR* alts. Little is known about the incidence, diversity or predominant *FGFR* alts across solid tumors in the clinical setting. Here, we provide an update on molecular screening and enrollment in the primary analysis population. **Methods:** Pts with advanced solid tumors were molecularly screened for eligible *FGFR* alts via central next generation sequencing (NGS) or review of local NGS reports. Underlying tumor type, *FGFR* alts, demographics and key disease characteristics were collected at baseline. **Results:** From Nov 2019 to Jan 2021, 5758 pts were molecularly screened (central or local) in 15 countries. 191 pts (3.3%) fulfilled primary analysis molecular eligibility criteria; 110 pts were enrolled. Among pts enrolled, 14 (12.7%) had central screening and 96 (87.3%) had local NGS reports. Eligible *FGFR* alts were identified in 19 tumor types, including rare cancers and ones (eg, pancreatic) with a very low prevalence of *FGFR* alts in genomic databases (Table). Median age was 57 y, and 19 pts (17.3%) were < 40 y. Gender distribution was even. **Conclusions:** Findings from molecular screening in the RAGNAR study indicate a wide range of *FGFR*-altered tumor types, including a notable number of cancers where eligible *FGFR* alts were considered exceedingly rare (eg, pancreatic). These results demonstrate the feasibility of conducting clinical trials on pts with rare genetic alts by adopting a histology-agnostic design and using both central testing and local NGS reports for molecular screening. This approach also helps investigate rare tumors, where histology-specific trials are challenging. Efficacy and safety results from the RAGNAR study will help define the benefit of erdafitinib in *FGFR*-altered advanced solid tumors. Clinical trial information: NCT04083976. Research Sponsor: Janssen Research & Development, LLC.

Preliminary efficacy and safety of perioperative treatment of camrelizumab combined with apatinib in resectable hepatocellular carcinoma (HCC): A prospective phase II study. *First Author: Yongxiang Xia, Hepatobiliary Center, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Background: Although there is no standard perioperative treatment for resectable HCC characterized with high recurrence rate, the strategy of immunotherapy combined with targeted agents is promising in neoadjuvant/adjuvant therapy in various tumors. **Methods:** In this perspective, single-arm, exploratory phase II trial (NCT04297202), eligible patients (pts) were systemic treatment-naive resectable HCC in intermediate/advanced stage. Preoperative combined treatment of anti-PD-1 antibody camrelizumab (200 mg q2w for 3 cycles) and VEGFR-2 inhibitor apatinib (250 mg qd for 21 days) was started on day 1 cycle 1. On the 7th day after the 3 cycles, radiological imaging was assessed to confirm whether to conduct the hepatectomy. Four weeks after the surgery, combined treatment (camrelizumab 200 mg q3w, apatinib 250 mg qd, 3 weeks per cycle) was resumed for the postoperative 8 cycles. The primary endpoint was major pathologic response (MPR) defined as 50%-99% tumor necrosis in resected tissue. Gene expression profiles (GEPs) using immune-related RNA with pre-treatment specimens were analyzed. The association between immune signatures and pathological response (responders (R) vs. non-responders (NR)) was assessed. **Results:** A total of 20 pts were enrolled between Dec 5, 2019 and Jan 27, 2021, with a median follow-up of 5.7 months (range 0.7-9.0). All pts were ECOG PS 0-1 and Child-Pugh class A. There were 85% pts with hepatitis B and 10% with hepatitis C, and 55% in BCLC stage B, 35% in stage C and 10% in stage A. In preoperative phase, with 2 withdraw of informed consent form, partial response was reached in 3/18 (16.7%) and 8/18 (44.4%) pts per RECIST 1.1 and mRECIST, respectively, while disease progression was found in 1/18 (5.6%) pts impossible for hepatectomy, which made the resection rate 17/18 (94.4%). After the surgery, one was found to be combined hepatocellular-cholangiocarcinoma by histopathological examination and failed to proceed the postoperative study. The rates of MPR and pathological complete response (pCR) were 5/17 (29.4%) and 1/17 (5.9%), respectively. The preliminary analysis of GEPs (R:NR = 3:4) revealed higher levels of chemokines (*CXCL10* and *CXCL11*) in responders and higher *MS4A4A* (marker gene of macrophages) in non-responders. The most common TEAEs included hypertension (95%), proteinuria (40%), AST elevation (40%), and platelet count decrease (45%). Grade 3 TEAEs were hypertension (20%), rash (10%), and platelet count decrease (10%). No grade 4/5 TEAEs was observed. The most common surgical complications were ALT and AST increase each with the incidence of 70% (all grades) and 45% (grade $\geq$ 3). **Conclusions:** This study preliminarily demonstrated that the perioperative treatment of camrelizumab combined with apatinib improved the MPR and pCR with managable safety in intermediate/advanced resectable HCC. Clinical trial information: NCT04297202. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

A phase II trial of lenvatinib plus toripalimab and hepatic arterial infusion chemotherapy as a first-line treatment for advanced hepatocellular carcinoma (LTHAIC study). *First Author: MinKe He, Department of Hepatobiliary Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Combining systemic and locoregional therapies represents a promising treatment strategy for patients with advanced hepatocellular carcinoma (HCC). We investigated the efficacy and safety of combined lenvatinib and toripalimab (recombinant, humanized programmed cell death receptor-1 monoclonal antibody) plus hepatic arterial infusion chemotherapy (HAIC) as a first-line treatment in this patient population. **Methods:** This single-arm, phase II study included treatment-naive adult ($\geq$18 years) patients with advanced HCC, Eastern Cooperative Oncology Group performance status 0–2, and Child-Pugh Class A liver function (NCT04044313). Patients initiated lenvatinib (8 mg for bodyweight $<$ 60 kg or 12 mg for bodyweight $\geq$60 kg, orally once daily) 3-7 days prior to initial HAIC to confirm tolerability, and then received 21-day treatment cycles of lenvatinib (day 1 to day 21), toripalimab (240 mg by IV infusion, on day 1), and HAIC (day 1 to day 2) with the FOLFOX regimen (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2, 5-fluorouracil bolus 400 mg/m^2 on day 1, and 5-fluorouracil infusion 2400 mg/m^2 for 24 hours) until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS) at six months, evaluated using RECIST 1.1. Secondary endpoints were median PFS and overall survival (OS), objective response rate (ORR) per RECIST 1.1 and mRECIST, and safety. **Results:** Between August 2019 and May 2020, 36 patients (33 men and 3 women; median age, 49 years) were enrolled. The median tumor size was 11.2 cm, 86.1% of patients had portal vein invasion, and 27.8% had extrahepatic metastasis. The primary endpoint showed a 6-month PFS rate of 80.6%. After a median follow up of 11.2 months, the median PFS was 10.5 months (95% CI, 6.21−14.79), and the median OS was not reached. The ORR per RECIST was 63.9% (95% CI, 40.9−73.0), and per mRECIST was 66.7% (95% CI, 43.3−75.1) including five (13.9%) patients who achieved a complete radiological response. The median duration of response was 12.1 months (95% CI, 4.52−19.69). Furthermore, eight patients achieved sufficient downstaging to be converted to resectable disease. Among them, one patient received liver transplantation, and four received curative surgical resection. One of them achieved pathological complete response. Grade 3-4 treatment-related adverse events (AEs) occurred in 72.2% of patients, and the most common were thrombocytopenia (13.9%), elevated aspartate aminotransferase (13.9%), and hypertension (11.1%). All AEs were expected and manageable, and no treatment-related deaths were reported. **Conclusions:** Combination treatment with lenvatinib and toripalimab plus HAIC showed promising antitumor activity and manageable toxicity in patients with advanced HCC. Further randomized, controlled trials are warranted to validate our findings. Clinical trial information: NCT04044313. Research Sponsor: None.

Exploratory circulating biomarker analyses: lenvatinib + pembrolizumab (L + P) in a phase 1b trial in unresectable hepatocellular carcinoma (uHCC). *First Author: Andrew X. Zhu, Massachusetts General Hospital Cancer Center and Jiahui International Cancer Center, Boston, MA*

Background: In a phase 1b trial (NCT03006926), L + P had promising antitumor activity as first-line (1L) therapy in uHCC. We present exploratory biomarker analyses of circulating angiogenic factors and cytokines/chemokines related to the mechanism of action of L + P (ie, pharmacodynamic [PD] biomarkers), as well as biomarker correlations with clinical outcomes in patients (pts) with uHCC, from this trial. **Methods**: Pts received lenvatinib 12 mg/d (bodyweight [BW] $>$60 kg) or 8 mg/d (BW $<$ 60 kg) PO + pembrolizumab 200 mg IV Q3W. Tumors were assessed using mRECIST or RECIST v1.1 per independent imaging review. Peripheral blood samples were collected before administration of study drug at baseline, cycle (C) 2, day (D) 1, C3D1, C4D1, and off-treatment. 43 Biomarkers were assayed in serum from 100 1L uHCC pts (excluding 4 pts from the dose-limiting toxicity part of the trial with prior sorafenib). Of these 43, 31 biomarkers (for which $\leq$20% of samples had measurements above/below the quantification limit of the assay) were included in the analyses. Changes in biomarker levels from baseline were evaluated via 1-sample Wilcoxon signed-rank test. Associations were explored between changes in biomarker levels and maximum tumor shrinkage (MTS) via the Spearman's rank correlation test, objective response (OR; complete response + partial response) via the Wilcoxon rank sum test, and PFS via Cox regression analysis and log rank test. Data cutoff date for clinical endpoints was 7 August 2020. **Results**: Levels of PD biomarkers related to angiogenic signaling (VEGF increase/ANG2 decrease), FGF signaling (increase in FGF23/FGF19), and IFNγ signaling (increase in IFNγ, CXCL9/10/11) were changed significantly (adjusted $P<$ 0.05) with L + P (C2D1–C4D1; except for FGF19 at C3D1). Significant decreases of TIMP1 and increases of MCP1 were observed at C4D1 during treatment; these were associated with greater MTS. Greater decreases in TIMP1 and greater increases in MCP1 were observed in pts with OR vs others. Changes in levels of the PD biomarkers ANG2, IL10, and VEGFR2 were found to be associated with PFS by dichotomized analysis. With tertile 2 cutoff, median PFS for pts in the group with greater decreases of ANG2 was 13.9 months vs 9.6 months for pts in the group with lesser decreases of ANG2 (unadjusted P= 0.002; HR 2.65, 95% CI 1.39–5.08). **Conclusions**: These are the first exploratory biomarker analyses for the single-arm study of L + P in pts with uHCC. Changes in serum biomarkers associated with angiogenic-, FGF-, and IFNγ-signaling pathways indicated target engagement of L + P. Decreases in TIMP1 and increases in MCP1 were associated with MTS and OR. Associations were found between longer PFS and a greater decrease in levels of ANG2. Angiogenesis inhibition and modulation of cancer immune response were observed with L + P. Further validation from independent studies is warranted. Clinical trial information: NCT03006926. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Treatment-related toxicity and improved outcomes with immune checkpoint inhibitors in patients with hepatocellular carcinoma. *First Author: Alessio Cortellini, Department of Surgery and Cancer, Imperial College London, London, United Kingdom*

Background: The development of treatment-related adverse events (trAE) correlates favorably with clinical outcomes in multiple studies of patients receiving immune checkpoint inhibitors (ICI), however, this relationship is undefined in patients with hepatocellular carcinoma (HCC). This retrospective multi-center study aimed to examine whether trAEs are prognostic in HCC. **Methods:** We established an international consortium of 10 tertiary-care referral centers located in Europe (n = 67), United States (US, n = 248) and Asia (n = 42) to test whether the development of clinically significant trAE (i.e. graded $>$2, trAE2) predicted for improved overall (OS), progression-free survival (PFS), and overall response rates (ORR) following ICI, and subsequently validated this association in a separate cohort of 406 HCC patients receiving ICI therapy as part of international clinical trials submitted to the US Food and Drug Administration (FDA) in support of marketing applications. **Results:** In a multi-institutional cohort of 357 patients, 274 (77%) with Barcelona Clinic Liver Cancer (BCLC) stage C HCC mostly treated with ICI monotherapy (n = 304, 85%), trAE were reported in 146 patients (41%). Development of trAE2 were associated with longer OS (23.3 versus 12.2 months) and PFS (8.6 months versus 3.7 months). After adjusting for viral aetiology, gender, presence of cirrhosis, Child-Pugh class, BCLC stage, AFP levels, ECOG-PS, ICI regimen (mono/combination therapy) and receipt of corticosteroid therapy, trAE2 were confirmed predictors of improved OS (HR 0.55; 95% CI:0.34-0.88) and PFS (HR 0.51; 95%CI: 0.35-0.74). TrAE2 were associated with higher ORR (27% versus 16%) from ICI. The association between trAE2 and patients' OS (HR 0.49; 95%CI:0.34-0.70) and PFS (HR 0.43; 95%CI:0.32-0.59) was also observed in the FDA dataset. After a 6-weeks landmark selection, trAE2 were confirmed to be associated with improved PFS (HR 0.59; 95% CI:0.39-0.87); the additional analysis adjusted for tumour response and duration of treatment within the FDA cohort further confirmed the association with longer PFS (HR 0.67; 95%CI: 0.47-0.94). **Conclusions:** Development of trAE2 may correlate with response and survival in patients with HCC receiving ICI, a clinical setting where the lack of biomarkers still represents an unmet need. Prospective studies aimed at understanding the underlying immunologic foundations of such relationship are warranted to identify predictive biomarkers of toxicity and response. Research Sponsor: None.

Pemigatinib for previously treated locally advanced/metastatic cholangiocarcinoma (CCA): Update of FIGHT-202. *First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center, Weill Medical College at Cornell University, New York, NY*

Background: Pemigatinib (PEMI), a potent, selective, oral FGFR1-3 inhibitor, has shown efficacy and safety in patients (pts) with CCA and *FGFR2* rearrangements/fusions in FIGHT-202 (NCT02924376; objective response rate [ORR], 35.5%; duration of response [DOR], 7.2 months [mo]). Overall survival (OS: 21.1 mo) was not mature in the primary report (Abou-Alfa. *Lancet Oncol* 2020; cutoff: Mar 22, 2019); herein we report matured efficacy and safety data from FIGHT-202 (cutoff: Apr 7, 2020). **Methods:** Pts (≥18 y) with known *FGF/FGFR* alterations and progression after ≥1 prior therapy had *FGFR2* rearrangements/fusions (cohort A), other *FGF/FGFR* alterations (B), or no *FGF/FGFR* alterations (C). Pts received PEMI 13.5 mg QD (21-d cycle; 2 wks on, 1 wk off) until progression or toxicity. Primary endpoint: independent, centrally confirmed ORR (cohort A); secondary endpoints: ORR (cohorts B, C; cohorts A and B combined); DOR, disease control rate (DCR), progression free survival (PFS), OS, and safety. A *post-hoc* analysis in cohort A evaluated mOS in responders (pts with complete response [CR] or partial response [PR]) vs non-responders (pts with progressive disease [PD] or stable disease (SD]). **Results:** At cutoff, 147 pts were enrolled (cohort A, n=108; B, n=20; C, n=17; *FGF/FGFR* status undetermined, n=2); median follow-up was 30.4 (range, 4.9–38.7) mo and median treatment duration was 5.9 (0.2–36.5) mo. In cohort A, 9.3% of pts remained on therapy at cutoff; in cohorts B and C, all pts had discontinued. Pts discontinued mainly for PD (67.6%, 75%, and 64.7% in cohorts A, B, and C respectively). Independent, centrally confirmed ORR was 37.0%; mOS was 17.5 mo (95% CI, 14.4-22.9) in cohort A (Table 1). mOS for responders (n=40) vs non-responders (n=68) was 30.1 (95% CI, 21.5-NE) mo vs 13.7 (9.6-16.1) mo. Overall, most common all-cause treatment-emergent adverse events (TEAEs) were hyperphosphatemia (58.5%; grade ≥3, 0%), alopecia (49.7%; 0%), diarrhea (46.9%; 3.4%), fatigue (43.5%; 5.4%), nausea (41.5%; 2%), and dysgeusia (40.8%; 0%); 10.2%, 13.6% and 42.2% of pts discontinued, had dose reduction, and treatment interruption due to TEAEs, respectively. **Conclusions:** These results reinforce the primary data, showing continued, durable responses and sustained tolerability in pts receiving PEMI for CCA harboring *FGFR2* rearrangements/fusions. Notably, the matured OS is longer than historical data; OS for responders was more than twice as long vs for non-responders. Clinical trial information: NCT02924376. Research Sponsor: Incyte Corporation.

T-cell receptor pharmacodynamics associated with survival and response to tremelimumab (T) in combination with durvalumab (D) in patients (pts) with unresectable hepatocellular carcinoma (uHCC). *First Author: Patricia McCoon, Translational Medicine, AstraZeneca, Waltham, MA*

Background: Study 22, a phase 2 clinical study (NCT02519348) evaluating T (anti-CTLA-4) and D (anti-PD-L1) as monotherapies and in combination indicated the best efficacy-safety profile with a novel combination regimen containing a single, priming dose of T (T300+D). Additionally, an expansion of proliferative CD8+ lymphocytes at Day 15 was observed with T300+D that was associated with improved response. Here, an exploratory molecular analysis of peripheral blood T cell receptors is presented. **Methods:** Immune-checkpoint inhibitor-nave pts were randomized to 1 of 2 T+D combinations: T300+D (T 300 mg [1 dose] + D 1500 mg, then D every 4 weeks [Q4W]) or T75+D (T 75 mg Q4W + D 1500 mg Q4W [4 doses], then D Q4W); or single agent D (1500 mg Q4W) or T (750 mg Q4W [7 doses] then Q12W). DNA was isolated from PAXgene-preserved whole blood collected at baseline and on Day 29 during the first cycle of Q4W dosing, and then underwent CDR3 sequencing of T-cell receptor β using the immunoSEQ Assay (Adaptive Biotechnologies, Seattle, WA). Associations with objective response rate (ORR) and overall survival (OS) were evaluated. **Results:** The number of evaluable pts, samples, and overall ORR and OS are provided (Table). Immunosequencing analysis did not reveal significant differences in baseline T-cell clonality across arms. Increased T-cell clonal expansion at Day 29 appeared to be T dose dependent (Table), with no significant difference in the median expansion between the D and T75+D arms**.** Across all arms, responders had a larger median number of expanded T-cell clones on Day 29 than nonresponders (77.5 vs 40), and this greater expansion trended with longer OS (Table). Further evaluation by arm demonstrated an increase in T-cell clonal expansion in responders vs nonresponders in the T300+D arm. Pts with T-cell expansion above the median in the T300+D and T75+D arms also exhibited longer OS. Both newly expanded and total expanded clones on Day 29 vs Day 1 were associated with improved OS. **Conclusions:** The observed T dose-dependent increase in T-cell clonal expansion trended with improved ORR and longer OS, with the greatest overall benefit seen with T300+D vs T75+D, D and T. This is consistent with the previously reported observation that T300+D led to the highest median proliferating CD8+ T-cell counts and radiographic response. Further work is needed to differentiate the relative contributions of CD4 and CD8 clonal expansion to increased efficacy. T300+D and D are being evaluated in the phase 3 HIMALAYA study (NCT03298451) in uHCC vs sorafenib. Funding: AstraZeneca. Clinical trial information: NCT02519348. Research Sponsor: AstraZeneca.

Phase I trial of fourth-generation chimeric antigen receptor T-cells targeting glypican-3 for advanced hepatocellular carcinoma. *First Author: Weijia Fang, Department of Medical Oncology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: GPC3 is highly expressed in hepatocellular carcinoma (HCC) and is a promising target for HCC immunotherapy. Earlier phase I trial results demonstrated that second-generation GPC3-specific chimeric antigen receptor (CAR-GPC3) T cells were well tolerated in advanced HCC patients and showed clinical benefits (Shi D, Clin Can Res, 2020). Further preclinical studies showed that CAR-GPC3 T cells combined with multi-tyrosine kinase inhibitors (TKIs) were more effective in killing $GPC3^+$ HCC xenografts (Wu X, Mol Ther, 2019), and fourth-generation (4G) CAR-GPC3 T cells co-expressing a transcription factor more effectively killed $GPC3^+$ HCC xenografts. **Methods:** In this single-arm, open-label, first-in-human phase I trial (NCT03980288), we investigated the safety and antitumor activity of autologous 4G-CAR-GPC3 T cells for $GPC3^+$ heavily pretreated advanced HCC patients. Patients received 4G-CAR-GPC3 T cell infusion(s) after lymphodepletion pretreatment and 67% patients combined with TKIs. Adverse events (AEs) were graded by CTCAE 5.0. Cytokine release syndrome (CRS) was graded by American Society for Transplantation and Cellular Therapy criteria (2019). Tumor response was assessed by RECISTv1.1. **Results:** As of January 30th, 2021, 6 subjects with HBV-related metastatic HCC were enrolled. All had progressed on ≥ 2 lines of systemic therapy, with at least one TKI combined with anti-PD-1/PD-L1 immunotherapy or FOLFOX4 chemotherapy. After lymphodepletion, patients were treated with 1-2 cycles (totaling $2.5–5\times10^8$ CAR^+ cells) of 4G-CAR-GPC3 T cell therapy. Among them, 1 patient received half dose of sorafenib and 3 patients received half dose of regorafenib along with cell infusion. No dose limiting toxicity (DLT) occurred. The maximum tolerated dose (MTD) was not observed. No patient withdrew from the trial due to AE. No treatment-related death or neurotoxicity occurred. The most common ≥ grade 3 AEs were hematological toxicity, mainly due to lymphodepletion, and patients recovered within 2 weeks after therapy. All patients developed CRS including 3 at grade 2 and 3 at grade 3. Patients recovered from CRS after tocilizumab therapy with corticosteroid (4 patients) or without. One patient achieved partial response and continued after 18 weeks. The objective response rate (ORR) and disease control rate (DCR) were 16.7% and 50%, respectively. The median progression free survival (mPFS) was 4.2 months. The median peak CAR-GPC3 copies were 5067 copies/ug gDNA, and CAR-GPC3 copies were detectable on day 28 ranging 113–2071 copies/ug gDNA. **Conclusions:** Our study is the first to report that 4G-CAR-GPC3 T cell therapy in combination with TKIs has a manageable safety profile while demonstrating potential antitumor activity for heavily pretreated advanced HCC patients; however, CRS should be diligently managed. Clinical trial information: NCT03980288. Research Sponsor: Carsgen.

4089 **Poster Session**

Natural history of patients (pts) with advanced cholangiocarcinoma (CCA) with *FGFR2* gene fusion/rearrangement or wild-type (WT) *FGFR2*. *First Author: Rachna T. Shroff, University of Arizona Cancer Center, Tucson, AZ*

Background: CCA is a rare, heterogeneous malignancy with poor prognosis due to late onset of symptoms and relative resistance to available therapies. *FGFR2* fusions are common, occurring in 10–16% of intrahepatic CCA (iCCA). There is increasing awareness of the importance of molecular profiling to inform treatment choices, although real-world data (RWD) are lacking on the natural history of pts with CCA and *FGFR2* fusions/rearrangements receiving therapies for advanced disease. This retrospective, observational, natural history study used a nationwide (US-based) de-identified clinico-genomic database (CGDB) to compare overall survival (OS) in pts with advanced CCA and *FGFR2* fusions/rearrangements vs. those with wild-type (WT) *FGFR2*. **Methods:** This study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine CCA CGDB (FH-FMI-CGDB). The data originated from approximately 280 US cancer clinics (~800 sites of care). Pts were ≥18y of age, had chart-confirmed advanced CCA, comprehensive genomic profiling, and ≥2 visits within the Flatiron Health network since Jan 1, 2011. Primary objective: evaluate OS in pts with *FGFR2* fusions/rearrangements and WT *FGFR2* from the index date (date of diagnosis of advanced CCA) to date of death from any cause. A key secondary objective was to evaluate the influence of *FGFR* status on OS after adjusting for potential prognostic variables. Risk-set adjustment was used to account for left truncation for all time-to-event analyses. **Results:** As of May 2020, 571 pts from the CCA FH-FMI-CGDB met the inclusion criteria; 75 pts with *FGFR2* fusions/rearrangements (median age 63y; 64% female; 95% iCCA; 68% stage IV at initial diagnosis), and 496 pts *FGFR2* WT (median age 65y; 48% female; 74% iCCA; 55% stage IV at initial diagnosis). Median OS was numerically higher, but not statistically different, for pts with *FGFR2* fusions/rearrangements vs *FGFR2* WT (12.1m [95% CI 8.5−17.1] vs 7.1m [95% CI 5.7−8.8]; log rank p = 0.184). Median OS was also numerically higher, but not statistically different, for *FGFR2* fusions/rearrangements vs *FGFR* WT in the subset of 437 pts with iCCA (12.1m [95% CI 8.4−17.1] vs 7.8m [95% CI 6.1−10.0]; log rank p = 0.375). *FGFR2* status was not a significant factor contributing to OS in univariate, bivariate, or multivariate models after adjusting for potential prognostic covariates. **Conclusions:** This analysis of RWD did not demonstrate a clear survival advantage for pts with *FGFR2* fusions/rearrangements vs *FGFR2* WT CCA receiving therapies for advanced disease, although a non-significant trend towards longer OS was observed in pts with *FGFR2* fusions/rearrangements. *FGFR2* status was not a significant predictor of OS after adjusting for potential prognostic covariates. An additional sub-analysis is ongoing to determine OS from time of initiation of second-line therapy in pts with *FGFR2* fusions/rearrangements. Research Sponsor: QED Therapeutics Inc.

Phase I study of H3B-6527 in hepatocellular carcinoma (HCC) or intrahepatic cholangiocarcinoma (ICC). *First Author: Teresa Macarulla, Hospital Universitario Vall d'Hebron, Barcelona, Spain*

Background: Evidence suggests that hyperactivated fibroblast growth factor 4 (FGFR4) signaling pathway leads to enhanced tumor growth. Targeting FGFR4 may have therapeutic benefit in tumors with altered FGF19 signaling. A phase I study (NCT02834780) was undertaken to assess H3B-6527, a highly selective covalent FGFR4 inhibitor, in patients with HCC/ICC. **Methods:** Adults with advanced HCC/ICC, ECOG PS 0-1, well compensated liver function, who progressed after > one prior therapy, received H3B-6527 po daily (QD) or twice-daily (bid) on a 21-day cycle following a 3+3 design. Doses ranged from 300-2000mg QD or 500-700mg BID. Patients in dose escalation were treated regardless of FGF19 status. Patients in expansion had FGF19+ tumors by mRNA testing. Adverse events (AEs), and pharmacokinetics (PK) were assessed. Response was determined by RECIST 1.1/mRECIST imaging every 6 weeks. **Results:** Study enrollment is complete at 128 patients. Ninety HCC patients were treated (QD = 48, bid = 42). ICC enrollment was suspended after 38 patients due to limited efficacy. No dose-limiting toxicities were seen and no grade 4-5 treatment related AEs have been observed. Recommended Phase II dose for H3B-6527 is 1000mg QD based upon safety, efficacy, and PK data. Grade 3 TEAEs have occurred in 12.5% of patients on QD dosing. Treatment related TEAEs were seen in 62.5% of patients on the QD schedule, with diarrhea (45.8%), fatigue (12.5%), and nausea (12.5%) most frequent. Drug discontinuation due to AEs for QD dosing was 8.3%. Interim data analysis shows that, for HCC patients with >2 prior lines of therapy treated on QD schedule, overall survival was 10.6m, progression-free survival 4.1m, overall response rate 16.7% (all partial responses), and clinical benefit rate 45.8% (responders + durable stable disease >17 weeks). H3B-6527 Cmax and AUC were lower at 300 mg dose but then similar across 500–2000 mg doses. Following oral administration of 1000 mg fasted, H3B-6527 plasma concentration reached peak at a Tmax of ~2-3 hours and then decayed exponentially, with terminal half-life of ~4-5 hours. There was no accumulation following QD dose. Dosing with food did not meaningfully change H3B-6527 plasma exposure. **Conclusions:** H3B-6527 was well tolerated and demonstrated a favorable toxicity and safety profile and encouraging clinical activity in heavily pretreated HCC patients. Final trial results will be presented at conference. Clinical trial information: NCT02834780. Research Sponsor: H3 Biomedicine.

Relationship between *Helicobacter pylori* and development of hepatocellular carcinoma: A systematic review and meta-analysis. *First Author: Samragnyi Madala, Northwell Health, Staten Island, NY*

Background: The relationship between *Helicobacter pylori (H.pylori)* and hepatocellular carcinoma (HCC) was first proposed in 1994. Since then, several studies have been performed to explore the association. The role of Hepatitis C (HCV) viruses coexisting with *H.pylori* in causing HCC was also studied. With the emergence of data in this regard, a causal relationship has been postulated, but not confirmed, and hence the relationship remains controversial. Our meta-analysis aims to summarize the research on this topic and investigate if there exists a relationship between *H. pylori* infection and the development of HCC and if the presence of HCV along with H.pylori plays a role in liver carcinogenesis. **Methods:** Following PRISMA guidelines, we performed a systematic review of all relevant studies published in the literature using keywords Helicobacter pylori and Hepatocellular carcinoma on major literature databases, including PubMed, EMBASE, Web of Science, and Cochrane controlled trials register. A total of 656 studies were identified between 1994 to March 2020, out of which 26 studies qualified under our selection criteria. Patients positive for HCC are included as cases and patients that did not have HCC under control group. In both groups, *H.pylori* positive patients and their HCV status, was identified. **Results:** Out of the 26 studies included in the final analysis, the prevalence of *H. pylori* infection was 64.78% (561 of 866) amongst HCC cases and 47.92% (1718 of 3585) in the non-HCC control group. The summary odds ratio for the association of *H. pylori* infection with the risk for HCC using the random-effects model was determined to be 4.75 (95% CI, 3.06-7.37), I^2=63%. Subgroup analysis to determine the odds of developing HCC in the presence of *H.pylori* and HCV coinfection, was 13.97 (95% CI, 3.94-49.61), I^2=81%. Whereas, the odds of developing HCC in the presence of only HCV without *H.pylori* was found to be 2.21 (0.70-6.94), I^2=79. Subgroup analysis by study design showed no significant difference between the study groups (P= 0.5705). **Conclusions:** Our meta-analysis showed a positive association between *H. pylori* infection and the development of HCC. It showed a significantly higher risk of developing HCC in the presence of HCV infection along with *H.pylori*. Further prospective cohort studies are needed to prove the causal relationship, especially in cases of Hepatitis B, C coinfection, and cirrhotic patients. Research Sponsor: None.

Summary of the results.

	HCC positive	HCC negative	Odds ratio [95% CI]
Primary analysis			
Relationship between *H.pylori* and HCC	561/866	1,718/3,585	4.75 [3.06-7.37]
Subgroup analysis			
***H.pylori* and HCV coinfection**	168/422	372/1,275	13.97 [3.94-49.61]
***H.pylori* only without HCV**	36/325	275/719	0.54 [0.11-2.63]
HCV without *H.pylori*	84/262	141/485	2.21 [0.70-6.94]

4092 **Poster Session**

Phase I result of ICP-192 (gunagratinib), a highly selective irreversible FGFR inhibitor, in patients with advanced solid tumors harboring FGFR pathway alterations. *First Author: Ye Guo, Shanghai East Hospital, Shanghai, China*

Background: ICP-192 (gunagratinib), developed by InnoCare Pharma, is a novel pan-FGFR (fibroblast growth factor receptors) inhibitor that potently and selectively inhibits FGFR activities irreversibly by covalent binding. Preclinical data showed that gunagratinib overcomes the acquired resistance to the first-generation reversible FGFR inhibitors, e.g., infigratinib. ICP-CL-00301 is a phase I, first-in-human, clinical study which includes a dose escalation followed by dose expansion. The safety and tolerability as well as pharmacokinetics/pharmacodynamics (PK/PD) of gunagratinib were evaluated in patients with advanced solid tumors, and the preliminary anti-tumor activity was evaluated by RECIST1.1 in patients with FGF/FGFR gene aberrations. **Methods:** In the dose-escalation stage, patients with advanced solid tumors with or without FGF/FGFR alterations were treated with escalating doses (2, 4, 8, 10, 12, 14, 16 mg etc.) of gunagratinib once daily in 21-day cycles until disease progression or unacceptable toxicity. During the dose-expansion stage, patients with cholangiocarcinoma harboring FGFR2 gene fusion/translocation received the treatment of gunagratinib daily at 12 mg continuously. **Results:** As of February 2021, a total of 30 patients had received the treatment of gunagratinib. The median age of the treated patients was 55.0 (range: 28 to 75 years) with 56.7% male and ECOG performance status between 0-1. The maximum tolerated dose (MTD) had not been reached. The most common treatment-related adverse events (TRAEs) (> 20%) included hyperphosphatemia, hypercalcemia, increased ALT or AST, diarrhea and hypertriglyceridemia. Hyperphosphatemia is a commonly reported AE from other trials targeting FGFR and here serves as a PD biomarker of FGFR inhibition. This PD biomarker was observed in 73.3% of the patients treated with gunagratinib at all dose levels and was consistently observed at doses of 8 mg QD and above. Hyperphosphatemia was well managed with oral phosphate binders when necessary. The plasma exposure increased proportionally to the oral dosage levels of gunagratinib. Among the 12 patients with FGF/FGFR gene aberrations who have completed at least one tumor assessment, the overall response rate (ORR) was 33.3%, including 1 patient (8.3%) of cholangiocarcinoma with complete response (CR) and 3 patients (25%) with partial response (PR). The disease control rate (DCR) was 91.7% (11 of 12 patients). **Conclusions:** Gunagratinib is safe and well-tolerated in patients with advanced solid tumors. Anti-tumor activity was demonstrated in patients with FGF/FGFR gene aberrations in multiple tumor types, including cholangiocarcinoma (NCT03758664). Better response is expected with the increase of treatment durations. Clinical trial information: NCT03758664. Research Sponsor: Beijing InnoCare Pharma Tech Co., Ltd.

A multicenter randomized controlled trial to evaluate the efficacy of surgery versus radiofrequency ablation for small hepatocellular carcinoma (SURF trial): Analysis of overall survival. *First Author: Masatoshi Kudo, Kindai University Faculty of Medicine, Osaka, Japan*

Background: The initial report of the multicenter SURF trial (surgery vs. radiofrequency ablation [RFA] for small hepatocellular carcinoma [HCC]) showed that recurrence-free survival (RFS) did not differ significantly between patients undergoing surgery and RFA. The focus of the present report was to assess the effect on overall survival (OS). **Methods:** The SURF trial was a multicenter, open-label, randomized, controlled, phase 3 trial conducted in 49 institutions in Japan. Patients (aged between 29 and 79 years) with Child-Pugh scores ≤ 7, largest HCC diameter ≤ 3 cm, and ≤ 3 HCC nodules were considered eligible. Before enrollment, both liver surgeons and hepatologists who perform RFA confirm that all the patients can be treated using both surgery and RFA. Patients were then randomly assigned in a 1:1 ratio to undergo surgery or RFA, stratified by age, hepatitis-C virus infection, numbers of HCC, largest HCC diameter, and institution. The co-primary endpoints were RFS and OS. As per the protocol, RFS was reported previously at 3 years after the last accrual of patients. OS was planned at 5 years after the last accrual. This trial is registered in UMIN000001795. **Results:** During 2009–2015, 308 patients were enrolled. After excluding ineligible patients, the surgery and RFA groups included 150 and 152 patients, respectively. Baseline factors did not differ significantly between the groups. In both groups, 90% of patients had solitary HCC. The median largest HCC diameter was 1.8 cm (interquartile range, 1.5–2.2 cm) in the surgery group and 1.8 cm (interquartile range, 1.5–2.3 cm) in the RFA group. The median (range) follow-up period was 6.4 (0.4–10.8) years in the surgery group and 6.6 (0–10.7) years in the RFA group. OS did not differ significantly between the surgery and RFA groups as the 5-year OS (95% confidence interval [CI]) was 74.6% (66.5%–81.0%) in the surgery group and 70.4% (62.2%–77.3%) in the RFA group (hazard ratio (HR), 0.96; 95% CI, 0.64–1.43; *P*= 0.828). The analysis after long-term follow-up in the current report showed that RFS was not significantly different between the surgery and RFA groups: the 5-year RFS (95% CI), 54.7% (46.0%–62.5%) vs. 50.5% (42.1%–58.3%); HR 0.90; 95% CI 0.67–1.22; *P*= 0.498. **Conclusions:** SURF trial revealed that OS and RFS were not significantly different between patients undergoing surgery and RFA for small HCC (≤ 3 cm and 3 nodules). Clinical trial information: 000001795. Research Sponsor: the Japanese Foundation for Multidisciplinary Treatment of Cancer and the Health and Labor Sciences Research Grant for Clinical Cancer Research (Grant No. H21-015).

Gemox chemotherapy in combination with anti-PD1 antibody toripalimab and lenvatinib as first-line treatment for advanced intrahepatic cholangiocarcinoma: A phase 2 clinical trial. *First Author: Zhou Jian, Department of Liver Surgery and Transplantation, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: The outcome of advanced intrahepatic cholangiocarcinoma (ICC) remains poor with current gemcitabine-based chemotherapy. This study is to evaluate the safety and efficacy of anti-PD1 agent toripalimab, lenvatinib in combination with oxaliplatin and gemcitabine (Gemox) chemotherapy. **Methods:** Locally advanced or metastatic ICC patients (pts) were given 240 mg toripalimab Q3W via intravenous (IV) infusion, 8 mg lenvatinib QD orally, and 1g/m^2 gemcitabine on Day 1 and Day 8, and 85 mg/m^2 oxaliplatin Q3W by IV for 6 cycles. The primary outcome was objective response rate (ORR), which was evaluated according to RECIST v1.1. Secondary outcomes included safety, progression-free survival (PFS) and overall survival (OS). Treatment would be terminated by confirmed disease progression, unacceptable toxicity, or voluntary withdrawal. Whole exome sequencing was performed on available tumor tissues and PD-L1 expression was determined by immunohistochemistry staining. **Results:** From May 2019 to Oct 2019, 30 pathologically-confirmed advanced ICC pts with a mean age of 56.5 (range, 25-73) years, including 11 women (37%), were enrolled at Zhongshan Hospital, Fudan University (one pt withdrawn). At the end of last follow-up (February 1, 2021), the ORR was 80% (24/30; 95% CI: 61.4%-92.3%), and disease control rate (DCR) was 93.3% (28/30; 95% CI:77.9%-99.2%). Median follow-up was 16.6 months. One pt achieved complete response (CR). Three pts with locally advanced disease were down-staged and then underwent resection. They remained disease-free survival at the end of last follow-up. 23 pts experienced disease progression and 12 pts (including one pt withdrawn) have died. The median PFS was 10.0 months and median duration of response (DOR) was 9.8 months. The median OS have not been reached. 12-months OS rate was 73.3% (95% CI: 57.5%-89.2%). No grade 5 adverse event (AE) was observed in present study. Grade 3 or 4 neutropenia and thrombocytopenia observed in 3 (10%) and 1 (3.3%) patient, respectively. Non-hematological toxic effects were jaundice (10 %), rash (6.7 %), proteinuria (6.7 %), increased AST level (3.3%), vomiting (3.3%), upper gastrointestinal hemorrhage (3.3%), sepsis (3.3%), gastrointestinal fistula (3.3%), adrenocortical insufficiency (3.3%), interstitial pneumonia (3.3%), and hyponatremia (3.3%). High ORR was significantly associated with positive PD-L1 expression (p= 0.048) and DNA damage repair (DDR)-related mutations (p= 0.022) in tumor samples. **Conclusions:** Gemox chemotherapy in combination with Anti-PD1 antibody Toripalimab and Lenvatinib provided remarkable efficacy with reasonable tolerability in advanced ICC patients. These findings warrant further validation in a large randomized clinical trial. Clinical trial information: NCT03951597. Research Sponsor: None.

An armored GPC3-directed CAR-T for refractory or relapsed hepatocellular carcinoma in China: A phase I trial. *First Author: Zhongwei Zhao, Key Laboratory of Imaging Diagnosis and Minimally Invasive Intervention Research, Affiliated Lishui Hospital of Zhejiang University/the Fifth Affiliated Hospital of Wenzhou Medical University /The Central Hospital of Zhejiang Lishui, Lishui, China*

Background: HCC is a leading cause of cancer-related morbidity and mortality worldwide, of which glypican 3 is a highly specific marker. GPC3-directed CAR-T had shown promising safety but limited efficacy in the treatment of HCC. We developed an armored GPC3-directed CAR-T G3-CAR-ori2 by inserting of a novel and proprietary Ori2 element following the 4-1BB and CD3ζ domains in a second-generation CAR-T. Pre-clinical studies showed a significantly higher memory stem cell ratio and dramatically improved proliferation and persistence, compared with traditional CAR-T, thus offering prolonged efficacy *in vitro* and *in vivo* and potentiality leading to improved activity in the clinical setting (ChiCTR1900028121). **Methods:** This is an open-label, dose-escalation study of G3-CAR-ori2 cell HCC patients in two centers. Eligible patients were aged 18-70 years with histologically confirmed GPC3+ HCC, Child-Pugh score A or B, ECOG≤1, relapsed or refractory to standard therapies. Patients were pre-conditioned with fludarabine (25~30 mg/m2) and cyclophosphamide (200~300 mg/m2) daily for 3 days. G3-CAR-Ori2 was administered as a single infusion via intrahepatic or intravenous route with a total dose of 0.9 to 3x10e8 CAR-T. The objective was to assess the safety, preliminary efficacy, persistence and cytokine profiling of G3-CAR-ori2. Adverse events were graded using the Common Terminology Criteria for Adverse Events (version 5.0). Tumor responses were evaluated per RECIST (version 1.1). CAR-T cell expansion and persistence were measured by qPCR and flow cytometry. **Results:** As of Jan 21, 2021, 10 patients had received single infusion, in which 6 received G3-CAR-ori2 via intravenous route and 4 via intrahepatic route. 7 patients received the highest dose level of 3x10e8. 9 patients reached at least 1 month of follow-up and tolerated the treatment well with no dose-limiting toxicity. All patients experienced transient grade 4 decrease in lymphocyte count resulted from the lymphodepletion regimen. Cytokine release syndrome (CRS) was observed in 8 patients, in which 6 at grade 1 or 2 and 2 at grade 4 notably infused with 3 x10e8 both via intravenous route and reversed within 7 days by administering high-dose steroids and tocilizumab. Other grade 4 hematologic toxicities include thrombocytopenia (2/9) and neutropenia (1/9). No neurotoxicity was observed. Two subjects were not evaluable due to early withdrawal from the trial. Among the 7 evaluable subjects, the best responses achieved are 3 PR, 2 SD, 2 PD. The duration of remission of one patient with PR is more than 4 months, follow up is ongoing. CAR-T gene detected by q-PCR provide preliminary indication that G3-CAR-ori2 is able to expand and persist well in the clinical setting. **Conclusions:** These initial data provide evidence that G3-CAR-ori2 is safe and holds promising antitumor potential, and supports its continuing development in the treatment of r/r GPC3+HCC. Clinical trial information: ChiCTR1900028121. Research Sponsor: Shanghai Origincell Therapeutics Co., Ltd. Shanghai, 201210, China.

Regomune: A phase II study of regorafenib + avelumab in solid tumors—Results of the biliary tract cancer (BTC) cohort. *First Author: Sophie Cousin, Medical Oncology, Institute Bergonié, Bordeaux, France*

Background: Regorafenib (R) has shown promising efficacy in patients (pts) with BTC refractory to standard chemotherapy. Anti-PD1/PD-L1 antibodies have only limited clinical activity. Synergy between R and anti–PD-1/PD-L1 antibodies has been shown in pre-clinical solid tumor models. **Methods:** This is a single-arm open-label multicentric phase II trial (Bayesian adaptive design) assessing the efficacy and safety of R (160 mg QD 3weeks/4) + avelumab (A) (10 mg/kg every 2 weeks) combination in BTC pts. The primary endpoint was the objective response rate under treatment, based on central review according to RECIST 1.1. Secondary endpoints included: 1-year progression free survival (PFS), 1-year overall survival (OS), and Safety using NCI-CTCAE v5.0. Correlative studies were planned from pts tumor samples obtained at baseline. **Results:** Between Nov. 2018 and Nov. 2019, 34 BTC pts were enrolled in 4 centers. Median age was 63 (range 36 – 80). Median follow-up was 9.8 months. Median number of previous treatment lines for metastatic or locally advanced disease was: 2 (range 1 – 4). Twenty-nine (85.3%) pts experienced at least 1 dose modification or treatment interruption of R or A due to an adverse event (AE) related to the treatment. The most common grade 3/4 AEs were : Hypertension (17.6%), Fatigue (14.7%), and maculo-papular rash (11.8%). No death was related to the treatment. Among the 29 pts with at least one imaging tumor assessment, 4 (13.8%) achieved a partial response, and 11 (37.9%) demonstrated stable disease including 10 (34.5%) pts with tumor shrinkage. Fourteen pts (48.3%) had progressive disease. The median PFS and OS were 2.5 months (95%CI 1.9 – 5.5) and 11.9 months (95%CI 6.2 – NA) respectively. Baseline tumor samples were available for 27 pts. High IDO and PD-L1 expression at baseline was associated with better outcome. **Conclusions:** The R+A combination is associated with significant anti-tumor activity with promising survival rates in this heavily pre-treated population. Full Biomarkers analyses will be presented at the meeting. Clinical trial information: NCT03475953. Research Sponsor: Bayer, Merck.

FOENIX-CCA2 quality of life data for futibatinib-treated intrahepatic cholangiocarcinoma (iCCA) patients with *FGFR2* fusions/rearrangements. *First Author: Juan W. Valle, University of Manchester, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: In FOENIX-CCA2 (NCT02052778), a pivotal phase 2 study among iCCA patients (pts) with *FGFR2* fusions/rearrangements, the highly selective, irreversible FGFR1–4 inhibitor futibatinib demonstrated a confirmed objective response rate of 41.7%, with a 9.7-month median duration of response. Adverse events were manageable with dosing modifications that did not adversely impact on response. We report outcomes for the preplanned analysis of Patient-Reported Outcomes (PROs) during futibatinib treatment as a secondary objective of FOENIX-CCA2. **Methods:** Pts enrolled in FOENIX-CCA2 had locally advanced/metastatic unresectable iCCA with *FGFR2* fusions/rearrangements, ≥1 prior line of therapy (including gemcitabine/cisplatin) and ECOG PS 0-1. Pts received oral futibatinib 20 mg continuous QD dosing per 21-day cycle. PRO measures included EORTC-QLQ-C30 (1 global health, 5 functional, 9 symptom scales), EQ-5D-3L, and EQ visual analogue scale (VAS). PROs were collected at screening, cycles 2 and 4, every 3 cycles thereafter, and end of treatment. PRO data were evaluated up to cycle 13, the last visit before data were missing for >50% of the PRO population (PRO primary assessment time point). **Results:** 92/103 (89.3%) pts enrolled had PRO completion data at baseline and a minimum of 1 follow-up assessment (median age 58 y, 56.5% female), with 48 pts having PRO data at cycle 13. At baseline, mean (SD) EORTC QLQ-C30 global health status score was 70.1 (19.4) and EQ VAS score 71.7 (20.3). Mean EORTC QLQ-C30 global health status scores were maintained from baseline to cycle 13, corresponding to 9.0 months on treatment, with no clinically meaningful (≥10-point) changes in individual functional measures (Table). EORTC QLQ-C30 scores across individual symptom measures were also stable from baseline through cycle 13; only constipation showed an average of 10.0-point worsening at only cycle 4. Mean EQ VAS scores were sustained from baseline to cycle 13 (mean change ranging -1.8 to +4.8 across cycles), with values maintained within the population norm range from across 20 countries. **Conclusions:** Quality of life data from the phase 2 FOENIX-CCA2 trial show that physical, cognitive and emotional functioning, and overall health status were maintained among pts with advanced iCCA receiving futibatinib. Clinical trial information: NCT02052778. Research Sponsor: Taiho Oncology, Inc.

EORTC QLQ-C30 global health status and functional scales, mean (SD) change from baseline.

Functional scale	Cycle 2 n=84	Cycle 4 n=80	Cycle 7 n=66	Cycle 10 n=59	Cycle 13 n=48
Global health	-1.0 (22.0)	+0.4 (20.6)	-0.5 (21.6)	+1.9 (22.8)	+0.9 (21.5)
Physical	-1.1 (17.9)	+0.8 (15.0)	-0.4 (14.1)	-1.4 (15.4)	-2.0 (14.0)

The cost effectiveness of lenvatinib versus atezolizumab and bevacizumab or sorafenib in patients with unresectable hepatocellular carcinoma (uHCC) in Canada. *First Author: David Trueman, Source Health Economics, London, United Kingdom*

Background: Hepatocellular carcinoma (HCC) represents 72% of liver cancers in Canada. In the phase III REFLECT trial, lenvatinib met the primary endpoint of non-inferiority in overall survival (OS) versus sorafenib and demonstrated superiority in secondary endpoints of progression free-survival (PFS), time to progression and objective response rate. Based on the REFLECT trial, lenvatinib has become the standard of care in the treatment of Canadian patients with unresectable HCC (uHCC). In the Phase III IMbrave150 trial, the use of the combination of atezolizumab and bevacizumab (atezo+bev) resulted in statistically significant improvement in OS and PFS versus sorafenib for patients with uHCC. The aim of this analysis was to estimate the cost-effectiveness of lenvatinib versus atezo+bev or sorafenib as first-line treatment for patients with uHCC from the perspective of Ministry of Health in Canada. **Methods:** A cost-utility analysis was conducted using a partitioned survival analysis. Health state membership for lenvatinib and sorafenib were estimated based on patient level data and clinical inputs from REFLECT and extrapolated using parametric survival models. Relative efficacy for atezo+bev was estimated from a de novo network meta-analysis. In the base-case analysis, estimates from REFLECT used in the NMA were adjusted for imbalances in baseline characteristics. Sensitivity analyses included the use of alternative approaches to determine relative efficacy. Health state utility values were determined with EQ-5D data collected in REFLECT. Drug acquisition costs were obtained from publicly available sources and medical resource utilization was based on a survey of Canadian clinicians. The time horizon was 10 years. Results of the incremental analysis were calculated sequentially. **Results:** In the base case lenvatinib was associated with cost savings of CAD$4,640 and CAD$120,095 and a QALY difference of 0.15 and -0.28 vs sorafenib and atezo+bev, respectively. The base case deterministic analysis resulted in lenvatinib being dominant over sorafenib and cost-effective vs. atezo+bev (sequential ICER for atezo+bev was CAD$425,754 per QALY). Results of the probabilistic sensitivity analysis (PSA) were consistent with the base case findings with lenvatinib being the optimal treatment strategy in >99% of iterations. **Conclusions:** Results of this analysis demonstrate that lenvatinib represents the optimal use of healthcare resources as a first-line treatment for uHCC in Canada. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4099 **Poster Session**

Lenvatinib plus toripalimab as first-line treatment for advanced intrahepatic cholangiocarcinoma: A single-arm, phase 2 trial. *First Author: Zhou Jian, Department of Liver Surgery and Transplantation, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Lenvatinib monotherapy and lenvatinib plus PD-1 antibody have shown some clinical benefit for advanced intrahepatic cholangiocarcinoma (ICC) in the second-line setting. Our study assesses the role of lenvatinib plus toripalimab (PD-1 antibody) for advanced ICC patients as the first line therapy. **Methods:** Patients (pts) with locally advanced or metastatic ICC received 12 mg/day (Body Weight ≥60 kg) or 8 mg/day (Body Weight <60 kg) oral lenvatinib daily plus 240 mg intravenous toripalimab every 3 weeks. The primary endpoint was objective response rate (ORR) and evaluated according to Response Evaluation Criteria In Solid Tumors version 1.1 (RECIST v1.1). Secondary endpoints included safety, progression-free survival (PFS) and overall survival (OS). Treatment continued until confirmed disease progression, unacceptable toxicity, or voluntary withdrawal. This trial is registered with ClinicalTrials.gov (NCT04361331). **Results:** From March 2020 to Sep. 2020, 31 pathologically confirmed advanced ICC pts with a mean age of 58.4 (range, 25-73) years, including 18 women (58.0%), were enrolled at Zhongshan Hospital, Fudan University. At the end of last follow-up (February 10, 2021), the ORR was 32.3% (10/31; 95% CI: 16.7%-51.4%) and the disease control rate (DCR) was 74.2% (23/31; 95% CI: 55.4%-88.1%). Median follow-up was 6.9 months. Two pts with locally advanced disease were down-staged and then underwent resection. They remained disease-free survival at the end of last follow-up. 11 pts exerted disease progression and 7 pts died. The median PFS and OS have not been reached. Median duration of response (DOR) has not been reached and responses were ongoing in 9/10 (90.0%) pts at data cutoff. 6-months OS rate was 87.1%. No grade 5 adverse event (AE) was observed in present study. 32.3% (10/31) of pts experienced Grade 3 or higher AEs and 1 pts discontinued the treatment owing to severe fatigue. **Conclusions:** As the first-line therapy, lenvatinib plus toripalimab provided promising efficacy with reasonable safety profile in advanced ICC patients. It offered an alternative treatment for advanced ICC who cannot tolerate gemcitabine-based chemotherapy. Clinical trial information: NCT04361331. Research Sponsor: None.

Molecular markers of response to anti-PD1 therapy in advanced hepatocellular carcinoma. *First Author: Philipp K. Haber, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Checkpoint inhibition with anti-PD1 is able to elicit objective response rates (ORR) of ~ 20% in patients with advanced hepatocellular carcinoma (aHCC) but molecular biomarkers predicting response remain unknown. Here, we define biomarkers of response and primary resistance to anti-PD1 in aHCC by analyzing molecular features prior to systemic therapy. **Methods:** Through an international consortium of 13 referral centers, we gathered 111 fresh and archived tumor samples from patients with advanced HCC treated with single agent anti-PD1 therapy. Genomic analysis was performed with whole genome expression arrays, CTNNB1 exon 3 mutation assessment and histological evaluation. **Results:** Overall, we performed transcriptomic analysis in 83 patients, 28 of which were treated in first-line (ORR: 42.9%) while the remaining 55 patients were treated either in 2nd (41 patients, ORR 29.3%) or 3rd line (14 patients, ORR 7.1%) after prior therapy with tyrosine- kinase inhibitors (TKI) sorafenib or lenvatinib. In patients treated in frontline, response was associated with a significant upregulation in Interferon-γ signaling (IFNγ) and genesets relatedto the antigen presentation machinery (FDR < 0.05). Through differential expression analysis we defined an 11-gene signature that was significantly associated with both major pathways (FDR < 0.01) and was capable of predicting OR as well as progression-free- (PFS) and overall survival (OS) in patients with aHCC. The signature was validated in three independent cohorts of melanoma, lung cancer, and head and neck squamous cell cancer patients were high expression was associated with a significant increase in ORR and longer PFS. In HCC, high expression of the signature was associated with a distinct profile in the immune infiltrate, where an increase in M1 macrophages ($p = 0.003$), CD4 memory T cell ($p < 0.01$) and CD4 nave T cell-infiltration ($p = 0.026$) was observed. Conversely, low expression of the signature was associated with a marked upregulation of regulatory T cells ($p < 0.001$). No association was found, however, between either the overall immune infiltrate or CTNNB1 mutations and response. In patients that were treated with TKIs in frontline before receiving subsequent anti-PD1 therapy, the signature was no longer able to predict either OR or PFS/OS, suggesting that TKIs may reshape the microenvironment in a way that renders previously inflamed tumors no longer amenable to anti-PD1. **Conclusions:** Here, we define an 11-gene signature of response to anti-PD1 in first line aHCC. The signature was validated in patients with other solid cancer types, where it retained its predictive ability. Of note, the signature was not able to identify responders among HCC patients that were treated with TKIs prior to anti-PD1 therapy. The molecular changes induced by different treatment lines would, thus, require fresh biopsies prior to anti-PD1to enable biomarker-driven treatment. Research Sponsor: BAYER.

Phase 2 study of AK104 (PD-1/CTLA-4 bispecific antibody) plus lenvatinib as first-line treatment of unresectable hepatocellular carcinoma. *First Author: Li Bai, The General Hospital of the People's Liberation Army, Beijing, China*

Background: Anti–PD-(L)1 plus anti-CTLA-4 therapies (e.g. nivolumab/ipilimumab, tremelimumab/durvalumab) produce durable immune responses in patients (pts) with advanced hepatocellular carcinoma (HCC). More recent data suggests that the combination of immune checkpoint inhibitors (ICIs) with a multi-kinase inhibitor is efficacious against unresectable HCC (uHCC). AK104 is a humanized IgG1 bispecific antibody that simultaneously binds to PD-1 and CTLA-4. Early data suggests that AK104 possesses encouraging anti-tumor activity in selected tumour types and an improved safety profile compared to the co-administration of anti-PD-1 plus anti-CTLA-4 antibodies. Lenvatinib is a multi-kinase inhibitor and approved for first-line treatment of uHCC. Here, we report results from a phase 2 study of AK104 plus lenvatinib in pts with uHCC. **Methods:** In this single-arm, multicenter phase II study (NCT04444167), pts with uHCC, BCLC stage B or C, Child-Pugh class A, who had not previously received systemic treatment received AK104 (6 mg/kg IV q2w or 15 mg/kg IV q3w) and lenvatinib (8 mg [bodyweight < 60 kg] or 12 mg [weight ≥ 60 kg] PO QD). Primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints include disease control rate (DCR), duration of response (DOR), progression-free survival (PFS) and overall survival (OS). **Results:** As of February 1 2021, 30 pts (86.7% male, median age 52.5yrs [31-71], 30% was ECOG 1, 93.3% was HBV+) had received the combination therapy of (AK104 6 mg/kg q2w plus lenvatinib). Of 18 pts evaluable for antitumor activity (defined as pts with the opportunity to be followed for at least 2 scans [≥13 weeks]), ORR per RECIST v1.1 was 44.4% (8/18), DCR was 77.8% (8 PRs and 6 SDs including 2 pts who had 28.4% and 29.2% reduction in tumor size from baseline). Median PFS has not been reached. Treatment-related adverse events (TRAEs) occurred in 83.3% of pts (G3 TRAEs occurred in 26.7% [8/30], and no G4 TRAEs or TRAEs leading to death). Most common TRAEs (≥15%) were increased AST (36.7%) and ALT (36.7%), decreased platelet count (33.3%), decreased neutrophil count (30.0%), and increased blood bilirubin (26.7%), with the vast majority being grades 1 or 2. **Conclusions:** AK104 plus lenvatinib as first-line therapy for uHCC has showed promising antitumor activity and an acceptable safety profile. Toxicities were manageable, with no unexpected safety signals. Enrollment for AK104 15 mg/kg q3w plus lenvatinib is currently ongoing, and longer follow-up is needed to further evaluate the durability of response. Clinical trial information: NCT04444167. Comparative effectiveness of sorafenib, lenvatinib, and nivolumab as first-line systemic therapy for patients with advanced hepatocellular carcinoma and Child-Pugh class B cirrhosis treated at VA Medical Centers. *First Author: William Joseph Chapin, Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA*

Background: Up to 90% of cases of hepatocellular carcinoma (HCC) in the U.S. occur in patients with cirrhosis. As prognosis in patients with decompensated cirrhosis may be more related to liver function than tumor stage, patients with Child-Pugh (CP) class B and C cirrhosis are often excluded from randomized trials despite representing up to 30% of patients treated with systemic therapy in clinical practice. While prospective data such as the GIDEON registry and CHECKMATE-040 have demonstrated safety of sorafenib and nivolumab in CP B cirrhosis, studies of comparative effectiveness of sorafenib, lenvatinib, and nivolumab are lacking. **Methods:** We performed a retrospective cohort study of patients with HCC and CP B cirrhosis at U.S. Veterans Affairs Medical Centers who initiated first systemic therapy with sorafenib, lenvatinib, or nivolumab between 9/22/2017 and 2/13/2021. Overall survival (OS) by first systemic therapy was assessed with Kaplan Meier analysis and Cox proportional hazards modeling with prespecified candidate covariates and a backward elimination approach for variable selection. Missing data were imputed by multiple imputation with chained equations. **Results:** Among 401 CP B patients undergoing first systemic therapy, 98% were male, 29% had macrovascular invasion (MVI), 35% had extrahepatic spread (EHS), 57%/29%/13% had CP score 7/8/9, 5% had hepatic encephalopathy, 37% had ascites, 63%/2%/36% had HCV/HBV/non-viral cirrhosis, 63% had prior embolization or ablation, and 35% had ECOG performance status of $>=2$. Of these patients, 320 received sorafenib, 33 received lenvatinib, and 48 received nivolumab. In univariate analysis, median OS was 4.8 months (95% CI 3.8 – 6.0; 1 year OS 21.8%) in the sorafenib cohort, 6.9 months (95% CI 4.4 – 8.4 months; 1 year OS 27.8%) in the lenvatinib cohort, and 7.7 months (95% CI 3.9 – 9.1 months; 1 year OS 31.7%) in the nivolumab cohort. Covariates with at least one category significantly associated with survival that were retained in the multivariate model included CP score, MELD-Na, BMI, log(AFP), time from diagnosis to systemic treatment, ECOG performance status, Cirrhosis Comorbidity index, and VA complexity level (all $p < 0.05$); MVI, EHS, and age were retained in the model as pre-specified despite lack of statistical significance. Compared with sorafenib, nivolumab was associated with significantly lower hazard of death (adjusted HR 0.63; 95% CI 0.43 – 0.91; p = 0.015) while hazard of death for lenvatinib treatment was not significantly different (adjusted HR 0.83; 95% CI 0.54 – 1.28, p = 0.41). **Conclusions:** Among patients with HCC and CP class B cirrhosis undergoing first systemic therapy, nivolumab was associated with significantly lower hazard of death compared to sorafenib after adjusting for important covariates. Tumor-informed assessment of circulating tumor DNA and its incorporation into practice for patients with hepatobiliary cancers. *First Author: Pashtoon Murtaza Kasi, University Of Iowa, Iowa City, IA*

Background: Hepatocellular carcinoma (HCC) and biliary tract cancers [BTC - including cholangiocarcinoma (CCA) and gall bladder cancers (GBC)] represent a heterogeneous group of diseases. Glycoprotein-based tumor markers like alpha-fetoprotein (AFP) or carbohydrate antigen 19-9 (CA-19-9) though part of standard-of-care (SOC), lack sensitivity, and specificity. A fair proportion of these cancers do not produce these glycoproteins. Circulating tumor DNA (ctDNA) testing can fill this void and be used for the assessment of molecular residual disease (MRD), as well as for surveillance purposes in patients with HCC or BTC. Prospective evaluation of this methodology in clinical practice has been limited to date. **Methods:** A personalized and tumor-informed multiplex PCR assay (Signatera bespoke mPCR NGS assay) was used for the detection and quantification of ctDNA. Serial time points were collected on a subset of patients to monitor their ctDNA levels in response to treatment. **Results:** Here we analyzed 200 plasma samples from a total of 90 patients with HCC (n=27) and BTC (n=63), comprising 46 patients with CCA and 17 patients with GBC. Sample-level ctDNA positivity rates, determined using a tumor-informed assay are presented in table. ctDNA detection was significantly associated with the stage of disease (Wilcoxon rank-sum test, $p<0.05$). Serial time point analysis was performed on a subset of patients (n=56) that had 2-7 time points available and correlations between ctDNA levels and clinical response were noted and will be presented. **Conclusions:** Our study is the first to set the benchmark for the utility and feasibility of using a tumor-informed assay in this cohort of hepatobiliary cancers. With adjuvant chemotherapy already a SOC for BTC, and immunotherapy being studied for HCC alongside other novel agents for CCA and GBC, assessment of MRD or ctDNA clearance on therapy would be of value as an additional tool in identifying patients at high risk for recurrence/metastasis. The utility of this study would also lie in incorporation in clinical trials to enrich and study those who are at the highest risk of recurrence i.e. ctDNA positive. Research Sponsor: None.

Sample-level ctDNA positivity rates across biliary tract cancer and hepatocellular carcinoma.

Cancer Type	Baseline	MRD	On treatment and Surveillance
Cholangiocarcinoma (CCA) and Gall Bladder (GBC) , N=138	10/12 (83%)	9/44 (20%)	24/82 (29%)
Liver (HCC), N=62	1/1 (100%)	6/21 (29%)	20/40 (50%)

Does adjuvant chemoradiation benefit patients with lymph node-positive biliary tract cancer? A secondary analysis of SWOG S0809. *First Author: Sepideh Gholami, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Biliary tract cancers are rare tumors with a median overall survival (OS) of 16 months for node-positive (N+) and 37 months for node-negative (N0) disease despite resection. Lymph node status is a known strong prognostic factor for local recurrence with an average estimated 2-year disease-free survival (DFS): 65.5% for N0 and 29.7% for N+ tumors. The Phase II Intergroup Trial S0809 showed that adjuvant capecitabine and gemcitabine followed by radiotherapy and concurrent capecitabine improved OS in patients with extrahepatic cholangiocarcinoma (EHCC) and gallbladder cancer (GBC) compared to historical controls. We hypothesized that nodal status is a prognostic factor for local recurrence in this patient population who received adjuvant therapy. **Methods:** This analysis included patients with stage pT2-4, N+ or positive margin EHCC or GBC. Treatment included four cycles of gemcitabine (1,000 mg/m^2 intravenously on days 1 and 8) and capecitabine (1,500 mg/m^2 per day on days 1 to 14) every 21 days followed by concurrent capecitabine (1,330 mg/m^2 per day) and radiotherapy (45 Gy to regional lymphatics; 52.5 to 59.4 Gy to tumor bed). S0809 patients who did not receive radiotherapy were excluded from analysis. Correlations between nodal status, resection margin, and other clinicopathological factors, patterns of recurrence and survival were analyzed, and Cox regression models were used to estimate the prognostic significance of nodal status. A Z-test was used to compare DFS rates between these patients and historical data. **Results:** A total of 69 patients [EHCC n = 46 (66%); GBCA n = 23 (33%)] were evaluated with a median age of 61.7 (26.1-80.6). The majority of N0 patients were female (17/24, 70.8%), whereas most N+ patients were male (25/45, 55.6%; $p < 0.04$). Distribution of R0 (66.7%) and R1 (33.3%) resections was similar in the N0 and N+ groups. Thirty-four patients with EHCC had N+ disease (73.9%) compared with 11 patients with GBCA (47.8%, p = 0.03). Nodal status did not significantly impact OS (HR = 2.03, 95% CI 0.92-4.49, p = 0.08) or DFS (HR = 1.75, 95% CI 0.85-3.59, p = 0.13). Two-year OS was 70.6% for N0 and 60.9% for N+ disease (p = 0.11). Nodal status was not significantly associated with 2-year DFS: 62.5% for N0 and 49.8% for N+ (p = 0.20). N+ vs N0 tumors showed higher rates of distant failure (51.1% vs 25.0%, $p < 0.04$), but similar local recurrence (17.8% vs 12.5%, p = 0.88). The observed 2-year DFS in patients with N+ tumors was significantly longer compared to the historical rate of 29.7% (p = 0.004). **Conclusions:** This combination adjuvant treatment regimen following curative resection for EHCC and GBCA provides favorable outcomes regardless of nodal status. These data suggest that adjuvant chemoradiation may positively impact local control in N+ patients. These findings need to be validated in future clinical trials. Clinical trial information: NCT00789958. Research Sponsor: U. S. National Institutes of Health.

ARID1A mutation to predict disease progression during first-line chemotherapy in biliary tract cancer patients. *First Author: Sung Hwan Lee, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, South Korea*

Background: Biliary tract cancer (BTC) is a retractable disease showing a dismal prognosis with therapeutic resistance. There are clinical unmet needs on predicting therapeutic response and precise strategy for the patient classification according to clinically relevant tumor biology in the patients with BTC. We aimed to identify clinically detectable genomic alteration predicting therapeutic response after first-line chemotherapy in BTC using real-world data. **Methods:** A comprehensive genomic analysis of multi-institutional cohorts of BTC cases was performed using next-generation sequencing (NGS) with targeted DNA panel and patients' clinicopathologic data. **Results:** A total of 200 BTC patients with NGS panel tests from three cancer centers were included in this study. The genomic alteration of TP53 (55.5%), KRAS (23%), ARID1A (10%), and ERBB2 amplification (10%) were the most frequent alteration events in the BTC. Pathologically-proved BTC including extrahepatic (n = 52), ampulla of Vater (n = 4), gallbladder (n = 56), intrahepatic (n = 88) cancers showed a distinct pattern of genomic alterations in terms of ARID1A for extrahepatic BTC and ERBB2 amplification, RB1, ARID2 for GB cancer, and KRAS, IDH1, PBRM1, BAP1 for intrahepatic BTC respectively (chi-square test, $P < 0.05$). The oncologic outcomes for progression-free and overall survival were significantly stratified according to the best response after the first-line chemotherapy (log-rank test, $P < 0.001$). The logistic regression test revealed that ARID1A, BRCA2, and STK11 could significantly predict disease progression during first-line chemotherapy. ARID1A, especially, was the only independent predictive marker in the multivariate regression model in total BTC (OR 3.91, 95%CI 1.25-11.66, P = 0.015) and extrahepatic BTC (OR 5.71, 95%CI 1.23-28.98, P = 0.027). The predictive performance of significant genomic alteration was enhanced with the tumor marker CA19-9 (DeLong's test, Z = 1.933, P = 0.053, AUC 0.73, 95%CI 0.623-0.837). **Conclusions:** Clinically available NGS test showed distinct genomic alterations in terms of different deterioration patterns for oncogenic molecular pathways according to the anatomic locations of BTC. Integrative analysis using the data for genomic alteration and therapeutic response for the first-line chemotherapy uncover that the patients with ARID1A mutation show a significant disease progression rate during initial treatment for BTC, especially in the extrahepatic BTC. Prospective translational studies revealing underlying biology and precision strategy should be followed to improve the therapeutic response of BTC. Research Sponsor: None.

Clinical outcomes analysis of TP53-mutated advanced and metastatic biliary tract cancers. *First Author: Sunyoung S. Lee, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Advanced biliary tract cancers (BTC) are lethal cancers with limited treatment options and short survival. Median progression-free survival (mPFS) in the ABC-02 trial was 8.0 months with gemcitabine-cisplatin (GC) and 5.0 m with gemcitabine alone in the front-line setting. The ABC-06 trial showed mPFS of 4.0 m with second-line FOLFOX. TP53 mutation is known to be associated with poor prognosis in other cancers, but its impact on survival in advanced or metastatic BTC has not been detailed. **Methods:** Mutational profiles were obtained from a retrospective database collected via an institutional DNA/RNA sequencing panel, FoundationOne, or Guardant360. Out of 149 patients with TP53 mutations in BTC, 90 had advanced or metastatic BTC treated at a single institution between 2015 and 2021. These patients were not candidates for surgery, radiation, or liver-directed therapy. **Results:** Intrahepatic, hilar, distal, and gallbladder cancer diagnoses were confirmed in 66, 11, 10, and 3 patients. Median age was 63, with a male:female ratio of 1:1. Poorly, moderately, and well-differentiated adenocarcinomas were found in 62, 20, and 1 (not available in 7 patients). The most common TP53 mutations were R175H (n = 5) and R248Q (n = 4). Common co-mutated genes included KRAS (n = 15), ARID1A (n = 15), FGFR2 fusion (n = 14), IDH1 (n = 13), BAP1 (n = 10), CDKN2A (n = 9), and HER2 amplification (n = 8). Microsatellite unstable (MSI-H) tumors were found in 3 patients. The median tumor mutational burden was 2.5/Mb. Patients received front-line GC (n = 54), GC-nab-paclitaxel (GAP, n = 14), FOLFIRINOX (n = 3), and GC with targeted or trial therapy (n = 11, e.g. trastuzumab). mPFS with front-line therapy was 5.0 m (n = 90); it was 4.7 m with GC and 5.1 m with GAP. Patients who had co-mutated IDH1 or FGFR2 fusion had longer mPFS (9.5 and 6.9 m, respectively) than those who did not (n = 63, 3.7 m, $p < 0.05$) from front-line chemotherapy. mPFS after second-line FOLFOX (n = 17) and FOLFIRI (n = 10) was 2.1 and 1.9 m, respectively, and mPFS after third-line FOLFOX/FOLFIRI was 1.8 m (n = 8). The median overall survival (OS) of patients with co-mutated FGFR2, IDH1, or neither was 34.5, 22.0, and 13.1 m, respectively ($p < 0.05$). TP53-mutated BTC with mutations other than FGFR2/IDH1 did not show statistically significant difference in PFS or OS. **Conclusions:** Patients with TP53-mutated advanced BTC have shorter PFS than those without TP53 mutation in front and further-line settings. The presence of co-mutated FGFR2 or IDH1 is associated with improved PFS with chemotherapy (not FGFR/IDH1 inhibitors) and longer OS. Other co-mutations do not appear to have a survival benefit. It is crucial for clinicians to take into account the worse prognosis with TP53 mutation before starting front-line therapy in patients with advanced BTC and consider early clinical trial options. Research Sponsor: None.

Impact of cell density in lymphocyte-rich areas in the tumor microenvironment on prognosis and gene expression landscape in hepatocellular carcinoma. *First Author: Jeonghyuk Park, VUNO Inc., Seoul, South Korea*

Background: Cellular and non-cellular components in the tumor microenvironment (TME) impact prognosis and treatment in hepatocellular carcinoma (HCC). We previously reported a deep learning-based model of tissue segmentation in pathology images, showing an impact of stromal and malignant cell distribution with respect to gene expression on survival and molecular subtypes of cancer [1]. **Methods:** Clinical outcomes data, mRNA-seq, and histopathology images of 351 patients (pts) with HCC were obtained from TCGA. We established a combined algorithm of two deep learning models: ResNet-based model for tissue segmentation; YOLO-based model for cell detection, using published data sets [2, 3]. The tissue segmentation model defines six segments having following predominant components: malignant cells, lymphocytes, adipose, stromal, mucinous, and normal liver tissues. The cell detection model calculates density and mapping of cells in the TME. The immune landscape was analyzed via mRNA-seq of 770 genes enriched in TME. This comprehensive analysis defined parameters including the cell density per lymphocyte segmented area (CDpLA), representing the density of lymphocytes on a lymphocyte-rich area in TME. **Results:** Pts were clustered into two groups with high and low CDpLA (212 and 139 pts). High CDpLA was defined as lymphocyte density > 0.5 (13,618 cells/mm^2 lymphocyte area). Pts with high CDpLA showed significantly better median overall survival (OS) than those with low CDpLA (82.9 vs 37.8 month, $p < 0.005$). The hazard ratio of CDpLA in OS was 0.36 (95% CI 0.18-0.72, $p < 0.005$). Among pts with available clinical data, 29 and 21 pts were with hepatitis C (HCV) and hepatitis B (HBV). Out of 29 HCV pts, 23 and 6 pts were with high and low CDpLA; out of 21 HBV pts, 17 and 4 pts were with high and low CDpLA. Fifty three were with alcoholic abuse, and 26 and 27 pts were with high and low CDpLA. Of note, pts with high CDpLA had significantly better OS in HCV pts (61.7 vs 19.9 months, $p < 0.005$). Genomic analysis with mRNA-seq shows that HCV pts with high CDpLA have lower expression of genes related to myeloid-derived suppressor cells (TRANK1, MEGF9, HS3ST2, GPNMB) and higher in genes related to immune activation (PLD4, IL3RA, TNFRSF4). **Conclusions:** A deep learning-assisted model of TME segmentation and cell detection showed an impact on survival from CDpLA, rather than the total number of lymphocytes in the TME. HCV pts are more likely to have higher CDpLA, and CDpLA was a strong prognostic indicator in HCV pts. Pts with high CDpLA are those with elevated expression of genes related to immune activation and decreased expression of immunosuppressive genes. Retrospective and prospective analysis of clinical response to immunotherapy and tyrosine kinase inhibitors is underway. [1] Kim et al. Cancer Res 2020 (80) (16 Supp) 2631 [2] Kather et al. Should all pancreatic neuroendocrine tumors (PNET) over 1 cm be resected? *First Author: Diana Hsu, UCSF-East Bay, Oakland, CA*

Background: Pancreatic neuroendocrine tumors (PNET) are a heterogeneous group of tumors that represent 1-2% of all pancreatic neoplasms. Their biologic behaviors are unpredictable with high grade, nodal metastasis, or liver metastasis lending an unfavorable prognosis. Current guidelines recommend resection for functioning tumors and those 2 cm or larger but are less straightforward regarding tumors < 2 cm in size. Previous data show that observation for non-functioning tumors < 2 cm can be safe and feasible; however, a significant portion of these patients may have nodal involvement or metastatic disease. **Methods:** A retrospective review was undertaken to identify patients with pancreatic neuroendocrine tumors treated at Northern California Kaiser Permanente (KP-NCAL) between February 2010 and December 2018. Univariate and multivariate analyses were performed with the log-rank test and Cox regression. Chi-squared test of relevant clinicopathologic factors determined which factors were predictive for overall survival (OS). **Results**: Mean age was 61 years in our cohort of 354 patients, with 29% over the age of 70. Mean tumor size was 3.43 cm; 32% of tumors were 2 cm or smaller. 51% of the patients had localized disease; 32% of the patients presented with metastatic disease. The pancreatic tail was the most common tumor location (38%), followed by the head of the pancreas (24%). On multivariate survival analysis, stage, location of the tumor, and surgical resection were statistically significant in terms of overall survival ($p< .001$). Mean OS for patients with localized and metastatic disease was 93 months versus 37 months ($p< .001$). Surgery was utilized in 8.9% of patients with metastatic disease ($p< .001$). All patients with PNET smaller than 1 cm in our study group had localized disease only. However, in patients with tumor size between 1 and 2 cm, 11% had nodal or metastatic spread. **Conclusions:** PNETs are indolent but have malignant potential at any size. In our retrospective study, all of the patients with tumor size < 1 cm had localized disease. For those with PNETs 1-2 cm in size, 11% had nodal or metastatic spread. Based on our findings, we suggest a more aggressive surgical resection size criteria of 1 cm. Research Sponsor: None.

Tumor size (cm)	Localized disease (%)	Nodal disease (%)	Metastatic disease (%)	Overall survival at 60 months (%)
< 1	100	0	0	90
1-2	89	4	7	80
> 2	35	25	40	54

4109 **Poster Session**

Validation of a clinical score (CS) for patients (pts) with well-differentiated neuroendocrine tumors (WD NETs) under consideration for peptide receptor radionuclide therapy (PRRT) with Lu 177 dotatate. *First Author: Satya Das, Vanderbilt University Medical Center, Nashville, TN*

Background: Questions remain regarding when to sequence PRRT and how to categorize pts being considered for the treatment (tx). We previously developed a CS (comprised of 5 categories: available non-PRRT tx for tumor type, prior systemic tx, pt symptoms, tumor burden in critical organs and peritoneal carcinomatosis presence) at Vanderbilt Ingram Cancer Center (VICC) for pts being considered for PRRT to help answer these questions and demonstrated the score to be associated with progression-free survival (PFS) in pts receiving PRRT. Herein, we present the performance of the CS in a validation cohort (VC) and combined cohort (CC). **Methods:** Our original cohort (OC) included pts with progressive WD NETs (N = 122) under consideration for PRRT between 3/1/2016-3/17/2020 at VICC while our VC included pts under consideration for PRRT (N = 126) between 1/25/2017-11/18/2019 at Ochsner Medical Center (OMC) (N = 51), Markey Cancer Center (MCC) (N = 51) and Rush Medical Center (RMC) (N = 24). All pts in the OC were prospectively scored while pts in the VC were scored retrospectively, with the CS-assigning investigator blinded to patient outcomes. The primary outcome PFS, was estimated by the Kaplan-Meier method; a Cox proportional-hazards model adjusting for primary tumor site, tumor grade and number of PRRT doses administered (0, 1-2 or 3-4) was used to analyze effect of CS. Overall survival (OS) was a key secondary outcome. **Results:** In our VC, on multivariable (MV) analysis, for each 2-point increase in CS, the hazard ratio (HR) for PFS was 2.58 (95% confidence interval (CI) 1.62-4.11). On MV analysis, for each 2-point increase in CS, the HR for OS was 3.89 (95% CI 1.8-4.83). We combined the OC and VC for this analysis in order to increase the predictive power of our originally developed Cox proportional-hazards models. In our CC, of the 248 total pts, median pt age, CS and number of prior tx were 63.3 years, 4 (range 0-8) and 1 (range 0-7), respectively. The most represented primary tumor sites were small intestinal (N = 136), pancreatic (N = 58), unknown primary (N = 26) and lung (N = 14). A total of 140, 82 and 26 pts received 3-4, 0 or 1-2 doses of PRRT, respectively. On MV analysis, for each 2-point increase in CS, the HR for PFS was 2.52 (95% CI 1.90-3.35). On MV analysis, for each 2-point increase in CS, the HR for OS was 3.48 (95% CI 2.33-5.18). No interaction between PRRT doses administered and CS was observed. **Conclusions:** Increases in CS were strongly associated with worsening PFS and OS in our VC and CC, validating findings from our OC. Although we cannot determine whether the CS specifically predicts PRRT response or is prognostic based upon these data, it is the first presented clinical metric which can categorize pts with WD NETs under consideration for PRRT and estimate anticipated benefit from PRRT for pts. The safety and efficacy of PEN-221 somatostatin analog (SSA)-DM1 conjugate in patients (PTS) with advanced GI mid-gut neuroendocrine tumor (NET): Phase 2 results. *First Author: Daniel M. Halperin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PEN-221 is a small molecule drug conjugate composed of a SSTR2 binding somatostatin analog linked to the toxin DM1. PEN-221-001 was a study which assessed the safety, tolerability, pharmacokinetics (PK), and preliminary efficacy of PEN-221 in well differentiated neuroendocrine tumors (NETs) and small cell lung cancer. Here we present the efficacy outcomes for patients enrolled in the GI mid-gut cohort and the safety data for the entire study. **Methods:** Pts with advanced, SSTR2+ (by imaging) GI mid-gut NETs were enrolled in this cohort of the study. The primary objective was to determine the safety and efficacy of PEN-221 given intravenously, every (q) 3 weeks in patients with documented radiographic progression within the 6 months prior to enrollment. Patients previously treatment with cytotoxic chemotherapy were excluded. Preliminary efficacy was assessed using RECIST 1.1. A clinically meaningful efficacy result was defined as a Clinical Benefit Rate (CBR) $>$ 75% and a median progression-free survival (mPFS) $>$ 8 months. **Results:** 32 patients (17M/15F) were enrolled between January 2018 to June 2020 and the data cut-off for this report is July 31, 2020. The first nine patients were treated at the phase 1 determined Maximum Tolerated Dose of 18 mg. After review of the safety, tolerability, and PK data from these pts, the regimen was amended to 8.8 mg/m^2 for all subsequent pts to achieve more uniform exposures (AUC) across all pts and reduce toxicity in pts with lower body-surface areas (BSA). The mean number of cycles received by pts in this cohort was 7 (range 1-18), with 5 pts still on treatment at time of data lock. PEN-221 was well tolerated in all pts at the dose of 8.8 mg/m^2. The most frequent ($\geq$20% pts) PEN-221 related adverse events of any grade were fatigue (39%), nausea (38%), diarrhea (35%), decreased appetite (30%), infusion reaction (24%), AST/ALT/Alk Phos increase (24%), and peripheral neuropathy (21%). Only 14 (10%) of these events were grade 3 or greater. Grade 3 PEN-221 related adverse events which were reported in 2 or more pts included fatigue (7.6%), ALT/AST/Alk Phos increase (7.6%), and peripheral neuropathy (3%). PEN-221 plasma median $t_{1/2}$ was ~4.5 h, with exposures uniform using BSA based dosing. Of the 26 pts who were evaluable for response, 23 (88.5%) had stable disease (SD) reported as their best response with a CBR of 88.5%. Target lesion shrinkage was observed in 10 (38%) patients. The median PFS for this cohort was 9 months (CI 5 – 16.5 months). Tumor marker data (Neuron Specific Enolase, Chromogranin A, 5-Hydroxyindoleacetic Acid, and Circulating Tumor Cells) will also be presented. **Conclusions:** PEN-221 appears well tolerated at 8.8 mg/m^2 q 3 weeks and has demonstrated efficacy exceeding its clinical efficacy goals with a CBR of 88.5% and a mPFS of 9 months. A randomized trial of PEN-221 in GI mid-gut NET patients is now in development. Clinical trial information: NCT02936323. Research Sponsor: Tarveda Therapeutics.

Subgroup analysis by Ki-67 and baseline CgA of the randomized, placebo-controlled phase 3 study of surufatinib in advanced well-differentiated pancreatic neuroendocrine tumors (SANET-p). *First Author: Xianjun Yu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: In the phase 3 SANET-p trial (NCT02589821), surufatinib significantly increased progression-free survival (PFS) compared with placebo in patients with progressive, well-differentiated (grade 1 or 2), advanced pancreatic neuroendocrine tumors (NETs). Here we report the relationship of Ki-67 and baseline Chromogranin A (CgA) on efficacy outcomes. **Methods:** A total of 172 patients with advanced pancreatic NETs were randomized to surufatinib or placebo in a 2:1 ratio. Investigator-assessed PFS and objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 were used for the analysis. The *post-hoc* subgroup analyses were performed on Ki-67 subcategory: $<$ 5% (n = 40 vs 21), 5-10% (n = 57 vs 31), $>$ 10% (n = 16 vs 7), and baseline CgA subcategory: $\leq$ 2 times of upper limit of normal (ULN) (n = 59 vs 31), $>$ 2 $\times$ ULN (n = 44 vs 24). **Results:** In the intent-to-treat population, surufatinib was superior to placebo, median PFS (mPFS) of 10.9 vs 3.7 months (mo) (p = 0.0011), with a stratified hazard ratio (HR) of 0.491 (95% confidence interval [CI]: 0.319, 0.755). mPFS was statistically significantly longer in the surufatinib arm versus that in the placebo arm in subgroups of Ki-67 5-10% (11.0 vs 3.7 mo, HR = 0.33, p= 0.0002), Ki-67 $>$ 10% (11.1 vs 2.8 mo, HR = 0.04, p = 0.0003) and CgA $>$ 2 $\times$ ULN (11.0 vs 3.7 mo, HR = 0.36, p = 0.0036). There was numerical PFS improvement with surufatinib compared to placebo in subgroup of Ki-67 $<$ 5% (9.3 vs 5.6 mo, HR = 0.91, p = 0.8015) and CgA $\leq$ 2 $\times$ ULN (9.4 vs 3.7 mo, HR = 0.61, p = 0.0809). ORRs in the subgroups of Ki-67 $<$ 5%, 5-10%, and $>$ 10% with surufatinib were 15.8%, 24.0% and 12.5% respectively. There was only one partial response in the placebo arm (with Ki-67 $<$ 5%). ORRs in the subgroups of CgA $\leq$ 2 $\times$ ULN and $>$ 2 $\times$ ULN with surufatinib were 18.9% and 21.4%, while also only one partial response in the placebo arm with CgA $\leq$ 2 $\times$ ULN. **Conclusions:** Surufatinib showed statistically significant and clinically meaningful improvement in PFS compared to placebo in patients with advanced, progressive, well-differentiated pancreatic NETs. From this exploratory analysis, surufatinib demonstrated benefit irrespective of Ki-67 expression levels or baseline CgA. Clinical trial information: NCT02589821. Research Sponsor: Hutchison MediPharma Limited.

4112 **Poster Session**

Final overall survival in the phase 3 NETTER-1 study of lutetium-177-DOTATATE in patients with midgut neuroendocrine tumors. *First Author: Jonathan R. Strosberg, Moffitt Cancer Center, Tampa, FL*

Background: As demonstrated in the primary analysis of the phase 3 NETTER-1 trial, ^{177}Lu-DOTATATE significantly prolonged progression-free survival (PFS) versus high-dose long-acting octreotide, with a HR of 0.18 (95% CI: 0.11, 0.29; p $<$ 0.0001), in patients with advanced, progressive, well-differentiated, somatostatin receptor-positive midgut neuroendocrine tumors (NETs). Here we report final overall survival (OS) for NETTER-1. **Methods:** In this international open-label trial, eligible patients were randomized to receive either four cycles of ^{177}Lu-DOTATATE 7.4 GBq (200 mCi) every 8 ± 1 weeks plus long-acting octreotide 30 mg or high-dose long-acting octreotide 60 mg every 4 weeks (control arm), both on top of best supportive care. After disease progression on randomized treatment or completion of an 18-month treatment period, patients in both arms entered long-term follow-up and could receive further anti-cancer treatment as recommended by their physicians. The primary endpoint was PFS per RECIST 1.1 and OS was a key secondary endpoint. Primary intention-to-treat analysis of OS was prespecified to take place after 158 deaths or 5 years after the last patient was randomized, whichever occurred first. **Results:** Of 231 randomized patients, 101/117 (86.3%) in the ^{177}Lu-DOTATATE arm and 99/114 (86.8%) in the control arm entered long-term follow-up. Final analysis occurred 5 years after the last patient was randomized, following 142 deaths, with a median follow-up of more than 76 months. During long-term follow-up, 41/114 (36%) of patients in the control arm received subsequent radioligand therapy (cross-over), the majority (22.8%) within 24 months. Median OS was 48.0 months (95% CI: 37.4, 55.2) in the ^{177}Lu-DOTATATE arm and 36.3 months (95% CI: 25.9, 51.7) in the control arm. HR was 0.84 (95% CI: 0.60, 1.17) with p = 0.30 (unstratified 2-sided log-rank test). A total of 2/112 (1.8%) ^{177}Lu-DOTATATE treated patients in the study developed myelodysplastic syndrome (MDS). No new cases of MDS or acute leukemia were reported in the long-term follow-up. Overall, no new safety signals emerged during long-term follow-up. **Conclusions:** Median OS was 48.0 months in the ^{177}Lu-DOTATATE arm of the NETTER-1 trial and 36.3 months in the control arm. This difference was not statistically significant, potentially impacted by a high rate (36%) of cross-over of patients in the control arm to radioligand therapy after progression. In overall conclusion, the NETTER-1 study demonstrated that ^{177}Lu-DOTATATE yielded a clinically and statistically significant improvement in PFS as a primary endpoint (HR: 0.18, p $<$ 0.0001) as well as a clinically meaningful trend towards improvement in median OS of 11.7 months. No new safety signals emerged during the 5-year long-term follow-up. Clinical trial information: NCT01578239. Research Sponsor: Advanced Accelerator Applications, a Novartis Company.

4113 **Poster Session**

Plasma biomarker study of lenvatinib in gastroenteropancreatic neuroendocrine tumors reveals Ang2 and FGF2 as predictors of treatment response: Results from the international phase II TALENT trial (GETNE 1509). *First Author: Jaume Capdevila, Vall d'Hebron Institute of Oncology (VHIO), Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: Predictive biomarkers of response to antiangiogenics currently remain elusive, with several molecules discovered but not fully validated nor clinically applied. TALENT trial is a multicenter prospective phase II study of lenvatinib, a VEGFR1-3 and FGFR1-4 multikinase inhibitor (MKI), in advanced G1/G2 neuroendocrine tumors (NETs) from pancreatic (panNETs) and gastrointestinal (giNETs) origins, which has reported the highest overall response rate (ORR) by central radiology assessment with a MKI in this setting. Here we report the plasma biomarker study. **Methods:** Proangiogenic profiling of plasma samples from patients included in the trial were analyzed by multiplex ELISA (custom made Quantibody Array, RayBiotech). Quantitative determinations of VEGF-A, FGF2, FGF4, Ang2, IL8, PlGF, VEGF-C, VEGF-D and VEGFR2 were obtained from 85 samples of sufficient quality (out of 111 patients included in the study). Association and prediction of response were evaluated for each biomarker and correlated with PFS, OS and ORR in all patients and the different subgroups included in the trial. **Results:** While none of the factors were able to discriminate PFS or OS in the whole population, a significant association of high-Ang2 and low-FGF2 to ORR was observed. Subgroup analysis confirmed this association in the two cohorts of patients, giNETs (p = 0.003) and panNETs (p = 0.024). In the panNET cohort, prior targeted therapy was mandatory. Prior sunitinib exposure was observed in 8 patients. Of the factors studied, Ang2 and VEGFR2 were significantly decreased in plasma from sunitinib-pretreated patients (-73% p = 0.022 and -62% p = 0.042 respectively). Furthermore, in these sunitinib-pretreated patients Ang-2 and VEGFR2 levels associated to ORR (p = 0.029 and p = 0.029 respectively) and were able to discriminate PFS (log rank p = 0.027 and 0.007 respectively). ROC curve analysis defined Ang2 and VEGFR2 plasma levels with optimal predictive power to be 415pg/ml and 1770pg/ml respectively (p = 0.021). **Conclusions:** Plasma proangiogenic profiling of TALENT patient samples unraveled high-Ang2 and low-FGF2 as predictive biomarkers of response to lenvatinib in both cohorts. In antiangiogenic-pretreated patients, Ang2 and VEGFR2 levels significantly predict response to treatment in panNETs. Importantly, current studies with MKIs should confirm the value of these markers for advanced NETs not only to predict response, but also to stablish sequential treatment options for these patients. Research Sponsor: EISAI.

Interim analysis results of surufatinib in U.S. patients with neuroendocrine tumors (NETs). *First Author: Andrew Scott Paulson, Texas Oncology/The US Oncology Network, Dallas, TX*

Background: Surufatinib (S) is a targeted inhibitor of tyrosine kinases VEGFR1, 2, and 3; FGFR1; and CSF-1R. A manageable safety profile and statistically significant efficacy of S have previously been demonstrated in patients (pts) with advanced NETs of extrapancreatic (epNET) and pancreatic (pNET) origin in 2 phase 3 randomized trials conducted in China (SANET-ep, NCT02588170; SANET-p, NCT02589821). Pts with epNETs achieved a median progression free survival (PFS) of 9.2 v 3.8 months (mo) (hazard ratio [HR] 0.334; $p < 0.0001$), and pts with pNETs achieved a median PFS of 10.9 v 3.7 mo (HR 0.491; $p = 0.0011$), with S v placebo, respectively. S has recently been approved for the treatment (tx) of pts with epNETs in China. **Methods:** A phase 1, dose escalation (ESC)/expansion (EXP) trial was conducted to evaluate and confirm the efficacy and safety of S in US pts. ESC was completed, and the maximum tolerated dose and recommend phase 2 dose were determined to be 300 mg, same as previous trials. The EXP completed enrollment of the epNET and pNET cohorts, and the primary endpoint was investigator-assessed PFS rate at 11 mo. Secondary objectives included assessment of safety and PK. **Results:** 32 pts with heavily pretreated progressive NETs (16 epNET and pNET each) were enrolled in the dose EXP. The median age was 62.2 years (44-75) and 64.4 years (39-72) for epNET and pNET pts, respectively. 65.6% of pts received ≥3 prior lines of tx (median lines of therapy: epNET: 2 [2-5]; pNET: 4 [1-8]), and all pts previously received everolimus and/or sunitinib. As of the data cutoff of 30-Jun-20, 7 pts remained on tx (4 epNET; 3 pNET). The median number of tx cycles was 8.0 (2, 15) for epNET and 8.5 (2, 23) for pNET pts. The PFS rate at 11 mo was 51.1% (95% confidence interval [CI]: 12.8, 80.3) for pts with epNETs and 57.4% (95% CI: 28.7, 78.2) for pts with pNETs. The observed mPFS was 11.50 mo (95% CI: 6.47, 11.50) and 15.18 mo (95% CI: 5.19, NR) for pts with epNETs and pNETs, respectively. An objective response rate (ORR) of 6.3% was observed for pts with epNETs and 18.8% for pts with pNETs. A disease control rate of 90.6% (95% CI: 75.0, 98.0) was observed for all NET pts (93.8% epNET; 87.5% pNET). The safety profile of S remains consistent with previously completed trials. All pts (n = 32) had reported at least 1 adverse event (AE), and 24 pts (75%) reported AEs ≥grade 3. The most common AEs of any grade reported were fatigue (46.9%), hypertension (43.8%), proteinuria (37.5%), diarrhea (34.4%), vomiting (28.1%), and nausea (25.0%). The most commonly reported AEs ≥grade 3 (> 5%) were hypertension (37.5%); diarrhea (9.4%); and proteinuria, dysphagia, and anemia (6.3% each). AEs leading to tx discontinuation occurred in 21.9% of pts. **Conclusions:** S has demonstrated antitumor activity in heavily pretreated US pts with progressive NETs with a manageable safety profile that is consistent with 2 completed phase 3 studies. S continues to be studied in other ongoing clinical trials globally. Clinical trial information: NCT02549937. Research Sponsor: Hutchison MediPharma Limited.

Phase I study of autolytic immunotherapy of metastatic neuroendocrine tumors using intralesional rose bengal disodium. *First Author: Timothy Jay Price, Queen Elizabeth Hospital, University of Adelaide, Adelaide, Australia*

Background: Metastatic neuroendocrine neoplasms (mNEN) originating in the gastrointestinal tract are frequently slow growing yet both symptom and disease control remain important. Treatment options include resection, systemic somatostatin analogues (SSA), and systemic peptide receptor radionuclide therapy (PRRT). Additional options are needed; we have explored intralesional (IL) rose bengal disodium (PV-10), an investigational autolytic immunotherapy that can yield immunogenic cell death and disease-specific functional adaptive immunity. **Methods:** This phase 1 study evaluated safety, tolerability and impact on symptoms and biochemical markers resulting from IL PV-10 administered percutaneously to hepatic lesions in patients (pts) with progressive mNEN not amenable to resection or other potentially curative therapy. Eligible lesion(s) were 1.0 - 3.9 cm in longest diameter with amount of PV-10 administered proportional to size. Cohort 1 (n = 6 pts) received PV-10 to a single lesion per treatment cycle; Cohort 2 (n = 6) could receive injection to multiple lesions per treatment cycle. Pts could receive further PV-10 ≥6 weeks after prior injection. The primary endpoint was safety. Secondary endpoints included objective response rate (ORR) assessed by contrast enhanced CT (RECIST 1.1) and 68Ga-DOTATATE PET, biochemical response (CgA) and patient-reported outcome (EORTC QLQ-C30 and GI. NET21 QOL instruments). **Results:** Twelve pts were enrolled, 50% male, median age 66 yrs (range 47-79). Primary sites: 7 small bowel, 2 pancreas, 1 caecal, 2 unknown; grade: Gd1 = 5, Gd2 = 7. All pts had received SSA and PRRT as part of previous therapy and all had symptomatic, progressive disease. Median CgA was 1585 (range 35-10370). One lesion was injected per cycle for all 12 pts; none were suitable for multiple injections. One pt received 4 sequential PV-10 treatment cycles, 3 received 2 cycles, and 8 received 1 cycle. Toxicity was consistent with experience in other hepatic malignancies: post-procedure pain was reported by most pts; grade 3 photosensitivity reaction occurred in 1 pt; and grade 1 elevation of hepatic enzymes attributed to PV-10 occurred in 2 pts, resolving by day 7. Additionally, carcinoid flare occurred in 1 pt. ORR of injected lesions was 42%; patient-level disease control was 84%. Estimated PFS was 9.2 months; median OS was 22.5 months. CgA remained stable in 10 pts and upregulation of NK and activated CD4+ T lymphocytes was observed post-injection. QOL data at months 1 and 3 showed stable or improved carcinoid symptoms and global health status in 9 pts. **Conclusions:** PV-10 elicited no safety concerns with encouraging evidence of both local and systemic disease and symptom control in a heavily pre-treated population. Multiple cycles were delivered safely in suitable patients. Adaptive immune upregulation is consistent with other solid tumors and supports potential systemic benefit. Clinical trial information: NCT02693067. Research Sponsor: Provectus.

Efficacy and safety of ^{177}Lu-DOTATATE in patients (pts) with advanced pancreatic neuroendocrine tumors (pNETs): Data from the NETTER-R international, retrospective registry. *First Author: Dominique Clement, King's College Hospital, London, United Kingdom*

Background: Peptide receptor radionuclide therapy with ^{177}Lu-DOTATATE is indicated in somatostatin receptor (SSTR)-positive gastroenteropancreatic neuroendocrine tumours. The NETTER-R registry builds upon the existing evidence for pts with advanced pNETs, who have limited therapeutic options. **Methods:** NETTER-R is a retrospective registry of pts with unresectable or metastatic, well-differentiated, SSTR-positive, progressive pNETs treated with ^{177}Lu-DOTATATE in the UK, France and Spain. Pts who received ≥1 administration of ^{177}Lu-DOTATATE were included. The primary endpoint was progression-free survival (PFS) based on RECIST v1.1. Secondary endpoints included overall survival (OS), safety and tumour response. **Results:** A total of 110 pts with pNETs were identified. Median age was 58.0 years (range 28–89) and 52.7% were male. At baseline, 96.4% of pts had progressive disease. The Ki-67 index was ≤2% in 23.6%, 3–20% in 66.4% and >20% in 2.7% of pts (7.3% missing). Metastases were present in the liver in 95.5% and bone in 29.1% of pts. Nearly all pts (90.9%) had received at least one prior anticancer therapy (somatostatin analogues: 70.0%, chemotherapy: 61.8%, protein kinase inhibitors: 38.2%). The majority of pts (70.0%) received all four scheduled cycles of ^{177}Lu-DOTATATE. The cumulative activity was 26.6–32.6 GBq in 65.5% of pts (<26.6 GBq: 31.8%, ≥32.6 GBq: 2.7%). 12 pts were re-treated after disease progression and received 1–4 additional cycles of ^{177}Lu-DOTATATE. By RECIST v1.1, evaluable in 62 pts, median PFS was 24.8 months (95% CI 17.5–34.5) and objective response rate was 40.3% (95% CI 28.1–53.6); all responses were partial. The response rate, including radiological, clinical, metabolic and biomarker assessments, evaluable in 100 pts, was 54.0% (95% CI 43.7–64.0), including 2 pts with complete response. Over a median follow-up of 24.5 months (range 2.0–123.4), median OS in 110 pts was 41.4 months (95% CI 28.6–50.2). 71.8% (n=79/110) of pts had at least one treatment-emergent adverse event (TEAE). The most frequent were nausea (28.2%) and fatigue (22.7%), predominantly grade 1/2 in severity. No TEAEs led to treatment discontinuation. Grade 3 anaemia and lymphopenia occurred in 1 (0.9%) and 4 (3.6%) pts, respectively. No grade ≥3 thrombocytopenia or neutropenia were reported. Renal TEAEs occurred in 6 pts (5.5%; grade 1: n=1, grade 2: n=2, grade 3: n=3). Grade 3 renal events were transient (≤24 days) and did not lead to treatment modification. No acute leukaemia or myelodysplastic syndrome were reported within the follow-up. **Conclusions:** In a real-world population of pts with advanced pNETs, ^{177}Lu-DOTATATE was well tolerated with a safety profile consistent with the NETTER-1 trial. With limited follow-up, the OS and PFS compared favourably with cohorts of progressive pNET patients treated with other systemic agents. Phase I dose-escalation study of AlphaMedix for targeted-alpha-emitter therapy of PRRT-naive neuroendocrine patients. *First Author: Ebrahim Delpassand, Excel Diagnostics and Nuclear Oncology Center, Houston, TX*

Background: Peptide-receptor-radioligand-therapy (PRRT) has been shown to increase the progression-free-survival (PFS) of neuroendocrine patients, however the objective response rate is rather low. The targeted-alpha-emitter therapy (TAT) of NETs can increase the ORR and induce partial or complete tumor response. In this abstract, we present results of the safety and efficacy of AlphaMedix (^{212}Pb-DOTAMTATE) done in PRRT-nave patients with SSTR-expressing NETs (FDA IND 135150). **Methods:** The phase 1 dose escalation study (IND 135150) was designed according to a 3+3 dose-escalation scheme (30% increase of the dose in each subsequent cohort). We enrolled PRRT nave subjects with biopsy-proven unresectable or metastatic SSTR-expressing NETs from different primary sites (midgut, rectal, pancreas, and lung) with at least one measurable lesion. Response to treatment was measured per RECIST 1.1 criteria and the effect on quality of life was measured with the EORTC-QLQ-C30 QOL questionnaire. **Results:** A total of 20 PRRT nave subjects (10 men and 10 women; median age 60 (range 27-80)) have been treated to date. 10 subjects in MAD4 cohort received at least three cycles of ^{212}Pb-DOTAMTATE at the highest dose level of 67.6 μCi/kg/cycle. Of these, 6/10 subjects (60%) have completed all four-cycles of treatment. Radiographic evaluation of these six-MAD4 patients reveal an ORR in 5 out of 6 subjects (83.3%) per RECIST 1.1 criteria (1CR, 4PR, 1SD) in addition to a 100% response according to ^{68}Ga-DOTATATE-PET/CT-imaging, defined as complete resolution of SSTR-positive lesions (CR) or Partial Response (PR) defined as resolution of most active lesions or substantially decreased SUV (>25%). No progression of disease was noted in the first six subjects enrolled in the MAD4 cohort who have completed treatment. All six-patients have 100% PFS up to 22 months (for the first 3-subjects in MAD4) and up to 19 months (next 3-patients). Except for mild-to-moderate, reversible hair loss, there were no other clinically significant drug related AE, or SAE**.** The most frequent AEs of any grade (> 4 subjects) reported include fatigue (35%), hyperglycemia (30%), lymphopenia (30%) alopecia (30%), and diarrhea (20%). Five grade 3 AEs were reported (back pain, dysarthria, dyspnea, acute kidney injury), no grade 4 AEs, and one grade 5 AE was reported. There was a significant improvement in the quality of life, reduction of pain, shortness of breath in the majority of subjects, with increase of energy. **Conclusions:** This F-I-H clinical study of AlphaMedix shows that PRRT with ^{212}Pb is feasible, well tolerated, and provides substantial reduction in tumor burden to patients with unresectable, metastatic SSTR-expressing NETs. Dramatic improvement in tumor burden and a positive impact on quality of life were seen in all of the PRRT nave subjects who AlphaMedix at the highest dose tested. Clinical trial information: NCT03466216. Research Sponsor: U.S. National Institutes of Health, companies own funds.

Clinical impact of pathogenic germline variants in pancreatic cancer: Results from a multicenter prospective universal genetic testing study. *First Author: Pedro Luiz Serrano Uson Junior, Mayo Clinic, Phoenix, Brazil*

Background: Germline variations in cancer susceptibility genes have important implications on treatment and family counseling in pancreatic cancer (PC). We report the prevalence and clinical outcomes of unselected PC patients with pathogenic germline variants (PGV) detected using a universal testing approach. **Methods:** We undertook a prospective multi-site study of germline sequencing using an >80 gene next-generation sequencing platform among 250 PC patients (not selected for age or family cancer history) between April 1, 2018 and March 31, 2020. Demographic, tumor characteristics and clinical outcomes were compared between PGV carriers and non-carriers. **Results:** Of 250 patients, the mean age was 65 years (SD 8.7), 56% were male, 83.6% were white and 65.6% had advanced disease (Stage III and IV). PGV were found in 15.2% (N=38) of patients, two patients had more than one PGV. Variants of uncertain significance were found in 44.4% (N=111). Family history of cancer (OR 2.36, 95% CI: 1.14-5.19, p=0.025) was associated with a higher risk of PGV. In a median follow up of 16.5 months, median overall survival was 16.8 months in PGV carriers compared with 16.5 months in non-carriers (HR 0.51, 95 %CI, 0.25-1.01, p=0.05). Higher levels of CA 19-9 and advanced stages (III and IV) were associated with worse outcomes in both groups. Overall, 68% of PGV carriers had mutations in homologous recombination repair (HRR) genes, including *BRCA1, BRCA2, PALB2, ATM, CHEK2, NBN, RAD51C.* In 65% of HRR gene carrier's systemic therapy with platinum was used. **Conclusions:** Universal multi-gene panel testing in pancreatic cancer reveals that 1 in 6 patients are carriers of PGV and is associated with improved survival. Multi-gene germline testing should be used to aid in treatment selection, prognostication, and familial cancer counseling. Distribution of the 40 PGV by penetrance status. Research Sponsor: Mayo Practice Transformation Grant, Mayo Clinic Center for Individualized Medicine.

	PGV	Total (n=40)
High Penetrance	BRCA1	1 (2.5%)
	BRCA2	9 (22.5%)
	CDKN2A	1 (2.5%)
	MSH6	1 (2.5%)
	PALB2	2 (5.0%)
	SDHA	2 (5.0%)
	TP53	1 (2.5%)
Moderate Penetrance	ATM	7 (17.5%)
	CHEK2	4 (10.0%)
	HOXB13	1 (2.5%)
	NBN	2 (5.0%)
	RAD51C	1 (2.5%)

Modified FOLFIRINOX versus S-1 as second-line chemotherapy in patients with gemcitabine-failed metastatic pancreatic cancer: A randomized phase III trial (MPACA-3). *First Author: Se-Il Go, Division of Hematology/Oncology, Department of Internal Medicine, Gyeongsang National University Changwon Hospital, Gyeongsang National University College of Medicine, Changwon, South Korea*

Background: Modified FOLFIRINOX (mFOLFIRINOX) consisting of 5-fluorouracil/leucovorin, irinotecan, and oxaliplatin has been assessed as second-line treatment of patients with advanced pancreatic cancer in retrospective and phase II studies. However, the result was not confirmed by randomized controlled trial. **Methods:** A randomized, open-label, phase III trial was conducted at 9 institutions in Korea. Patients with metastatic pancreatic adenocarcinoma (mPAC) and Eastern Cooperative Oncology Group performance status of 0-1 who failed to first-line gemcitabine-based chemotherapy were randomly assigned to receive mFOLFIRINOX or S-1. The primary endpoint was overall survival. **Results:** A total of 80 patients were enrolled from March 2017 to December 2019. The accrual of patients was early terminated due to clear difference of efficacy in the interim analysis and expectation of poor recruitment due to conflicting adjuvant regimens. Objective response and disease control rates were 15.4% vs. 2.4% (p= 0.041) and 66.7% vs. 36.6% (p= 0.007) in the mFOLFIRINOX and S-1 arms, respectively. The median progression-free survival was 5.2 and 2.2 months in the mFOLFIRINOX and S-1 arms, respectively (p= 0.002). The median overall survival was 9.2 and 4.9 months in the mFOLFIRINOX and S-1 arms, respectively (p= 0.048). The adjusted hazard ratio of the mFOLFIRINOX arm to the S-1 arm for overall survival was 0.402 (95% confidence interval 0.223-0.725, p= 0.002). All grade 3-4 adverse events occurred in 56.5% and 17.1% in the mFOLFIRINOX and S-1 arms, respectively ($p< 0.001$). However, only one patient in each arm prematurely discontinued treatment due to toxicity and there was no treatment-related mortality in both arms. Minimally important differences in the health-related quality of life were not observed in both arms. **Conclusions:** mFOLFIRINOX as second-line treatment in mPAC patients failed to gemcitabine-based chemotherapy demonstrated a survival benefit versus S-1 alone with acceptable toxicities. Clinical trial information: KCT0003534. Research Sponsor: None.

A phase I/IIa trial of the RNA oligonucleotide STNM01 by EUS-FNI to investigate the safety and efficacy in patients with first-line refractory, unresectable pancreatic cancer. *First Author: Takayoshi Tsuchiya, Department of Gastroenterology and Hepatology, Tokyo Medical University, Tokyo, Japan*

Background: Carbohydrate sulfotransferase 15 (CHST15) is an enzyme that synthesizes heavily sulfated matrix glycosaminoglycan and shown to promote tumor invasion and correlate with poor prognosis in pancreatic ductal adenocarcinoma (PDAC). To explore the role of CHST15 blockage, we conducted a Phase I/IIa (P I/IIa) study to investigate the safety and efficacy of EUS guided locoregional injection of STNM01, a synthetic RNA oligonucleotide, in patients with unresectable PDAC, refractory to first-line chemotherapy. **Methods:** This was an open-label and dose-escalation study of STNM01 as second-line (2L) therapy in unresectable PDAC patients at 4 centers in Japan. One cycle consists of locoregional injection with STNM01 three times at 2 week-interval in 4 weeks (Days 0, 14 and 28 of dosing) in combination with systemic 2L chemotherapy. A 3+3 dose cohort escalation design initiated with 250 nM (n = 3) followed by 1,000 nM (n = 3), 2,500 nM (n = 3) and 10,000 nM (n = 4) was used for P I part. P IIa part (n = 9) was subsequently conducted with MTD or the highest dose level determined by P I. The primary outcome was incidence of DLT at the end of cycle 1. The secondary outcomes included overall survival (OS), local tumor response, histology and safety. This study was registered with jRCT (jRCT2031190055). **Results:** A total of 22 patients across 4 doses were enrolled in the study of which 21 were evaluable as per protocol population. All patients received S-1 as a systemic 2L chemotherapy and total 3 cycles were repeated at maximum. The most common AEs were abdominal pain and pyrexia. There were 9 grade 3 AEs. No drug-related SAE as well as DLT was observed. Since MTD was not reached in P I, P IIa was conducted with the highest dose, 10,000 nM. The 6-month survival rate in the entire population (n = 21) and in the highest dose population (n = 12; 3 for P I and 9 for P IIa) was 66.7 and 83.3%, respectively. In histological analyses, the % positive area of CHST15 tended to show dose-dependent suppression at the end of cycle 1, especially with 70.0% reduction from baseline in the highest dose population. Increased tumoral infiltrations of $CD3^+$, $CD8^+$ and $CD20^+$ cells were observed during study period in the highest dose population. Local tumor response for the entire population showed 14 patients (66.7%) with stable disease. Notably, one patient showed complete disappearance on the CT image of both primary and metastatic tumors in the regional lymph node. **Conclusions:** Repeated locoregional injection of STNM01 is safe and well tolerated in patients with unresectable PDAC as combined 2L therapy. The 6-month survival rate of 10,000 nM of STNM01 was 83.3%, which is remarkable compared with previously reported data. Unexpected mode of action for tumoral lymphocyte infiltration also suggests the promising potential of locoregional injection of STNM01 as a new therapeutic option for PDAC. Clinical trial information: jRCT2031190055. Research Sponsor: Japan Agency for Medical Research and Development.

Genomic profiling of *KRAS* wide-type pancreatic ductal adenocarcinomas identifies targetable genetic alterations. *First Author: Deng Wei, Department of General Surgery, Beijing Friendship Hospital;Capital Medical University;Beijing Key Laboratory of Cancer Invasion and Metastasis Research & National Clinical Research Center for Digestive Diseases, Beijing, China*

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal cancers and the 5-year survival of PDAC patients is below 10%. The oncogenic *KRAS*mutations account for about 90% of PDAC cases. Unfortunately, there is no FDA-approved targeted therapy for *KRAS* mutations. Therefore, the genomic profiling of *KRAS* wide-type PDACs can provide invaluable sights to the etiology of these patients and offer them the opportunity of precision therapy trials. **Methods:** To characterize actionable targets in 521 Chinese PDAC patients, deep sequencing of a 831-gene panel (OncoPanscan, Genetronhealth) was applied to assess somatic mutations of their tumor tissues including SNV, insertions/deletions, CNV and re-arrangements, as well as possible pathogenic germline variants of paired genomic DNA sample. **Results:** There were 89% (463/521) of patients in our PDAC cohort harbored *KRAS* mutations. Among the remaining 58 patients in *KRAS* wild-type subgroup, 33% (19/58) carried activating mutations in the RTK/Ras/MAPK pathway. Targetable *BRAF* mutations were seen in five (9%) patients: V600E (1/5), G464V (1/5), N486_P490del (2/5) and BRAF fusion (1/5). The frequency of *BRAF* mutations was 9% (5/58) in *KRAS* wild-type PDACs but only 0.4% (2/463) in *KRAS*-mutated PDACs ($P < 0.001$). We found one classic EGFR activing mutation (L747_A750delinsP) and one MAP2K1 activating mutation (F53_Q58delinsL), which can be targeted by EGFR-TKIs and MEK inhibitor trametinib, respectively. An oncogenic *ERBB3* mutation (V104L) was seen in one patient, who was eligible for HER2-targeted therapy clinical trials. We also found *STK11/TSC2* inactivating mutations and a dominant-negative mutation of *PTEN* (R130Q) which could be targeted by mTOR inhibitor everolimus and AKT inhibitor capivasertib, respectively. Additionally, we observed a patient with high level amplification of *MET* and another patient with the *NCOA4-RET* fusion gene which can be targeted by MET inhibitor carbozantinib. Interestingly, we also identified two patients with inactivating mutations in *ELF3* (one frameshift and one in splicing-site), which is a driver gene of ampullary carcinoma. Lastly, two patients carried deleterious germline mutations in *BRCA1* and *PALB2*, which may be targeted with PARP inhibitors. Overall, at least 29% (17/58) *KRAS* wide-type patients harbored potentially actionable genomic alterations to currently used anticancer drugs. **Conclusions:** The mutational landscape of our PDAC cohort provided compelling evidence that targetable driver mutations accounted for a significant portion of *KRAS* wide-type tumors. Our findings demonstrated that genomic profiling of PDAC patients can enable physicians to optimize their clinical management and enroll them into genomically matched clinical trials. Research Sponsor: None.

Baseline level and early on-treatment clearance of circulating mutant *KRAS* in metastatic pancreatic ductal adenocarcinoma treated with chemotherapy with or without immunotherapy. *First Author: Jacob E. Till, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Traditional imaging-guided therapeutic decision-making for patients with metastatic pancreatic ductal adenocarcinoma (mPDAC) may lag and, on occasion, be misleading. The concept of liquid biopsy-based molecular response holds promise for proximate and accurate therapy monitoring and assessment of emerging resistance to therapy. Here we investigate the association between baseline (pre-treatment) level and early, on-treatment changes in plasma circulating cell-free DNA (ccfDNA) mutant *KRAS* (ctKRAS) with progression-free survival (PFS) and overall survival (OS) in mPDAC. **Methods:** 189 plasma samples were analyzed from 123 total patients with mPDAC. An initial cohort included 54 patients treated at the University of Pennsylvania who received first-line standard of care (SOC) regimens and had a baseline plasma sample. Of these, 21 also had an on-therapy sample collected at ~8 weeks. We also analyzed an independent cohort of 69 patients enrolled in the PRINCE trial (NCT03214250) who had a baseline sample, of which 45 also had an on-treatment sample at ~8 weeks. PRINCE trial patients received gemcitabine/nab-paclitaxel with immunotherapy (I/O) agents (APX005M and/or nivolumab). ctKRAS variant allele fraction (VAF) was quantified by droplet digital PCR on pre-amplified ccfDNA. Baseline ctKRAS was dichotomized at 5% VAF. ctKRAS clearance was defined as detectable ctKRAS at baseline followed by ctKRAS becoming undetectable in the on-treatment sample. **Results:** Baseline ctKRAS (above/below 5% VAF) and ctKRAS clearance were associated with PFS and OS in both cohorts (Table). Further, in a multivariate cox regression model, ctKRAS clearance associated with improved PFS (HR 3.8, 1.4-10.9 or 3.6, 1.8-7.2) in both the SOC and I/O cohorts, respectively, and OS in the SOC cohort (HR 5.5, 1.5-20.8) after adjusting for baseline VAF. **Conclusions:** Baseline ctKRAS is significantly associated with OS and PFS in mPDAC in both independent cohorts. Further, early on-treatment ctKRAS clearance is strongly associated with improved PFS and OS, independent of baseline ctKRAS VAF. These data strongly support further investigation of ccfDNA as a biomarker of response and resistance to therapy. Research Sponsor: Parker Institute for Cancer Immunotherapy (PICI), Other Foundation, Pharmaceutical/Biotech Company, U.S. National Institutes of Health, Penn Pancreatic Cancer Research Center (PCRC).

Association of baseline and early on-treatment clearance of ctKRAS with PFS and OS. Cox Regression Hazard Ratios (HR) with 95% confidence intervals (CI) and log-rank P-values are presented.

ctKRAS	Cohort	N	PFS HR (CI); Log-rank P-value	OS HR (CI); Log-rank P-value
Baseline	SOC	54	2.5 (1.3-4.6); p=0.004	2.9 (1.5-5.7); p=0.001
Baseline	I/O	69	1.7 (1.0-3.0); p=0.04	2.4 (1.4-4.2); p=0.0002
Clearance	SOC	21	3.4 (1.2-9.4); p=0.01	5.6 (1.5-20.3); p=0.004
Clearance	I/O	45	3.3 (1.6-7.0); p=0.0009	2.2 (1.1-4.6); p=0.03

Gemcitabine plus nab-paclitaxel versus gemcitabine alone in elderly patients aged 76 years or older with unresectable pancreatic cancer: A propensity score-matched multicenter prospective observational study. *First Author: Satoshi Kobayashi, Department of Gastroenterology, Hepatobiliary and Pancreatic Medical Oncology Division, Kanagawa Cancer Center, Yokohama, Japan*

Background: Gemcitabine plus nab-paclitaxel (GN) demonstrated a significant improvement of OS over gemcitabine alone (G) in the MPACT trial for metastatic pancreatic cancer. However, since patients aged 75 years or older was less than 10% in the trial, data for the efficacy and safety of GN in that population have been limited. **Methods:** We prospectively enrolled patients who were 76 years or older if they had pathologically proven, clinically unresectable pancreatic cancer and no prior history of chemotherapy. Treatment regimen was based on physicians' choice. The primary endpoint was OS and secondary endpoints included PFS, objective response, and safety. Geriatric assessments including G8, IADL, CCI and Mini-COG were performed at the time of registration and 3 months after. To adjust confounding factors in the comparison of GN and G, propensity score-matched analyses were performed. **Results:** We enrolled 233 eligible patients from 55 centers in Japan between September 2018 and September 2019. GN, G, other therapy, and BSC were administered to 116, 72, 29 and 16 patients, respectively. With propensity scores adjusted for age, sex, clinical stage, ECOG PS, CA19-9, and neutrophil-lymphocyte ratio, 42 patients each in GN and G were compared. Patients characteristics in the matched pair were well-balanced; median age, 79/79 years; ECOG PS 0, 43/36%; stage IV, 69%/64%. With a median follow-up of 14.8 months and 50 observed deaths, OS in GN showed a longer tendency than that in G: 12.2 vs. 9.4 months in median with a hazard ratio (HR) of 0.65 (95% CI, 0.37-1.13; p= 0.120). PFS in GN was significantly longer than that in G: 9.2 vs. 3.7 months in median with a HR of 0.38 (95% CI, 0.23-0.64; p= 0.0002). The objective response rates were 29% and 11% (p= 0.082), and the disease control rates were 81% and 61% (p= 0.088), respectively. Decline of G8 scores at 3 months was observed in 35% and 28% of patients in GN and G, respectively (p= 0.610), and that in IADL scores was observed in 61% and 37%, respectively (p = 0.194). GN had higher incidence of adverse events than G though all were not statistically significant: grade 4 neutropenia (23%/8%); grade 3-4 malaise (13%/8%), fatigue (15 %/10%), peripheral sensory neuropathy (5%/0%). The incidence of the other adverse events was comparable between GN and G: grade 4 leucopenia (3%/5%) and thrombocytopenia (0%/3%); grade 3-4 nausea (3%/5%), vomit (3%/5%) and febrile neutropenia (0%/0%). Treatment discontinuation due to adverse events was more often in GN than G (39%/14%). **Conclusions:** Our data suggests GN is more efficacious than G even in patients aged 76 years or older, although GN have higher incidence of grade 3-4 adverse events and tends to decrease geriatric assessment scores. Clinical trial information: UMIN000034265. Research Sponsor: Pancreas Research Foundation of Japan.

Genomic alterations for novel targeted therapies in pancreatobiliary cancers from real-world data. *First Author: Kumiko Umemoto, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Cancers of the pancreas and biliary tract remain one of the unfavorable malignant tumors with few driver genomic alterations. Tumor-agnostic approaches are promising for cancers with poor prognosis, with some potentially actionable alterations, such as *BRCA1/2* mutations, *ERBB2* amplification, MSI-High, or tumor mutational burden (TMB)-High. However, co-existing alterations, clinical significance of other genomic alterations, or frequency of alterations by clinical and genomic background are unclear. Here we investigated the genomic profile in a large cohort of advanced pancreatobiliary cancers to help refine and discover new targets for improved cancer therapies. **Methods:** Comprehensive genomic profiling was performed at Foundation Medicine, on patients with RWD tested during the course of routine clinical care. Hybrid capture was carried out on up to 395 cancer-related genes and select introns from up to 31 genes frequently rearranged in cancer. 16,913 pancreatic cancer (PC) patients and 3,031 biliary tract cancer (BTC) patients were available for analyses and were stratified by age ($\geq$40/ $<$ 40), MSI status, TMB status (High $\geq$10/Low $<$ 10 Muts/Mb), and select gene alterations. Using a chi-square test with Yate's correction, frequencies of genetic alterations were analyzed according to clinical or genomic background. **Results:** *KRAS* (84.8%), *TP53* (73.3%), *CDKN2A* (51.2%), *CDKN2B* (26.5%), and *SMAD4* (23.2%) were frequently altered in PC patients, versus *TP53* (60.6%), *CDKN2A* (33.5%), *KRAS* (27.1%), *CDKN2B* (20.6%) and *SMAD4* (16.9%) in BTC patients. The frequency of MSI-High and TMB-High in BTC was 1.2% and 5.7%, respectively, while these were lower in PC (0.48% and 2.1%, respectively). In PC patients, the *KRAS* alteration rate was significantly lower in both MSI-High (57.3%, $P<$ 0.001) and TMB-High populations (51.3%, $P<$ 0.001). In BTC patients, the rate of *ERBB2* amplification was 6.4% in TMB-High and 8.6% in TMB-Low population. Interestingly, *CDK12* rearrangement was observed in BTC patients with *ERBB2* amplified tumors but not in those without *ERBB2* amplified tumors. In patients of pediatric/adolescents and young adults ($<$ 40 years old), the mutation rate of *KRAS*/*TP53*/*CDKN2A*/*SMAD4* was lower, and *FGFR2* rearrangement (4%) was observed in PC patients; *GATA6* amplification (11.1%) and rearrangement of *BRAF* (2.8%), *FGFR2* (5.6%) were observed in BTC patients. **Conclusions:** A large real-world dataset showed differences in genomic landscape according to clinical or genomic background, and some potential targets for the development of novel drugs in advanced pancreatobiliary cancers. These findings may lead to the improvement of cancer therapies in PC and BTC patients with poor prognosis. Research Sponsor: None.

4125 **Poster Session**

Alternating gemcitabine/nab-paclitaxel (GA) and 5-FU/leucovorin/irinotecan (FOLFIRI) as first-line treatment for *de novo* metastatic pancreatic cancer (MPC): Safety and effect. *First Author: Brett A Schroeder, Virginia Mason Medical Center, Seattle, WA*

Background: Both gemcitabine and 5FU-based chemotherapy have demonstrated efficacy in MPC. Alternating regimens may 1) reduce toxicity 2) slow resistant cancer biology emergence and 3) provide a broader platform for addition of other therapeutic agents. Alternating GA and FOLFIRI in MPC has been previously reported as part of the SEENA -1 trial ,our own institution , and elsewhere (Picozzi et.al. *GI Cancer Symposium 2017,* Picozzi et.al, *ASCO 2018* Assenat et,al, *ASCO 2018).* An extension of our institutional observations are reported here. **Methods:** Pt eligibility required the following: 1) biopsy proven *de novo* MPC, 2) no prior evidence MPC on CT, 3) ECOG performance status $\leq$ 2, and 4) bi-dimensionally measurable disease. Treatment (Rx) entailed gemcitabine 1000mg/m^2 and nab-paclitaxel 125mg/m^2 1, (8), 15 alternating every 8 wks (2 cycles) with FOLFIRI using standard dosing. Patients were radiographically re-staged every 8 wks. Rx was continued up to 48 wks; Rx thereafter decided by pt/MD. **Results:** 108 pts met eligibility requirements from 10/2015 and 12/2020. Pt characteristics included median age 68 (range 35-81), ECOG PS 0/$\geq$1 54%/46%, # diseases sites 1/$\geq$1 62%/38%, liver /non-liver 76%/24%, biliary obstruction yes/no 40%/60%, C 19.9 NL/ $<$ 59XNL/ $>$ 59X NL 12%/32%/56%; median Ca 19.9 4598 With median f/u of 19.7 mo, 17 pts remain on Rx $<$ 48 wks, 35/91 (38%) completed 48 wks Rx, 56/91 (62%) pts progressed prior to 48 wks. Median # mos on Rx was 8.9. $\geq$ grade 3 heme toxicity included anemia 7%, neutropenia 9%, thrombocytopenia 5%. Neutrophil growth factors were not used in this pt cohort. $\geq$ 3 non-hem toxicity included neuropathy1%, nausea/vomiting 2%, mucositis 2%, diarrhea 1%. Disease control at 16 wks was 81% (35% PR/46% SD/ 16% PD, 95% CI 72-87%). Median OS was 13.7 mo (95% CI 10.9-18.7 mo). 6 /12/18/24 mo OS were 87%/55%/41%/ 20% respectively. Prognostic significance was seen with Rx $>$ vs $<$ 48 wks (21.1 vs 8.0 mo, p $<$ .0001), and ECOG PS 0 vs. $\geq$1 (17.8 vs. 10.9 mo, p = 0.03) Age, # metastatic sites, liver involvement, biliary obstruction and magnitude of CA 19.9 elevation all failed to achieve prognostic significance at the p $<$ .05 level. **Conclusions:** 1) Alternating GA/ FOLFIRI in MPC has a more favorable toxicity profile than standard regimens 2) Med OS appears superior to GA and competitive with FOLFIRINOX ; longer term (18/ 24 mo) OS seemed particularly encouraging 3) $\geq$ 48 wks Rx and ECOG PS 0 were prognostically significant 4) Further investigation using this regimen including a) randomized comparisons, b) incorporation of molecular data and c) addition of additional agents seems indicated Updated survival data will be presented at the meeting Research Sponsor: None.

Impact of G-CSF during neoadjuvant therapy on outcomes of operable pancreatic cancer. *First Author: Pranav Murthy, Department of Surgery, University of Pittsburgh, Pittsburgh, PA*

Background: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive disease characterized by chronic inflammation and a tolerogenic immune response. Neutropenia is a common side effect of cytotoxic chemotherapy, managed with administration of recombinant granulocyte-colony stimulating factor (G-CSF, Filgrastim). The interleukin 17 – G-CSF – neutrophil extracellular trap (NET) axis promotes oncogenesis and progression of PDAC, inhibiting adaptive immunity. We evaluated the impact of G-CSF administration during neoadjuvant therapy (NAT) on oncologic outcomes in patients with operable pancreatic cancer. **Methods:** A retrospective review of all patients with localized PDAC treated with NAT prior to pancreatic resection between 2014 – 2020 was completed at a single institution. G-CSF administration, type, and dose were collected from inpatient and outpatient medical records. **Results:** Of 351 patients treated, 138 (39%) received G-CSF during NAT with a median follow-up of 45.8 months. Patients who received G-CSF were younger (64.0 vs 66.7, p = 0.008), had lower BMI (26.5 vs 27.9, p = 0.021), and were more likely to receive 5-FU based chemotherapy (42% vs 28.2%, p < 0.0001), NAT dose reduction (40.6% vs 25.4%, p = 0.003), or experience febrile neutropenia (8.7% vs 3.3%, p = 0.029). No differences were observed in baseline or pathologic tumor staging. In patients who received G-CSF, 130 (94%) received Pegfilgrastim with a median cumulative dose of 12 mg (IQR 6-12). Patients who received G-CSF were more likely to have an elevated post-NAT neutrophil to lymphocyte ratio (45% vs 29.6%, p = 0.004) and systemic immune-inflammation index (39.5% vs 29.6%, p = 0.061). Receiving G-CSF was an independent predictor of perineural invasion (HR 2.4, 95 CI [1.08, 5.5], p = 0.031) and margin positive resection (HR 1.69, 95 CI [1.01, 2.83], p = 0.043). Patients who received G-CSF had decreased overall survival compared to patients who did not receive G-CSF (median OS: 29.2 vs 38.7 months, p = 0.0001). Receiving G-CSF during NAT was an independent negative predictor of progression free (HR 1.38, 95 CI [1.04, 1.83], p = 0.022) and overall survival (HR 2.02, 95 CI [1.45, 2.79], p < 0.0001). In a subset of patients with available pre- and post-NAT serum specimens (n = 28), G-CSF administration resulted in an increased number of citrullinated histone H3 complexes following NAT (+1378±1502 vs -300.7±1147 pg/ml, p = 0.007), indicative of enhanced peripheral NET formation. **Conclusions:** In patients with localized PDAC receiving NAT prior to surgical extirpation, G-CSF administration is associated with worse oncologic outcomes and should be administered with caution. Prospective randomized as well as confirmatory clinical studies are in order. Research Sponsor: None.

4127 **Poster Session**

SBP-101, a polyamine metabolic inhibitor, administered in combination with gemcitabine and nab-paclitaxel, shows signals of efficacy as first-line treatment for subjects with metastatic pancreatic ductal adenocarcinoma. *First Author: Nimit Singhal, Adelaide Cancer Centre, Kurralta Park, SA, Australia*

Background: SBP-101, a polyamine metabolic inhibitor, inhibited growth in 6 human pancreatic ductal adenocarcinoma (PDA) cell lines and 3 murine xenograft tumor models of human PDA. SBP-101 monotherapy in heavily pre-treated PDA patients (> 2 prior regimens) showed a median survival of 5.9 months at the optimal dose level. Purpose: To assess the PK, safety and efficacy of SBP-101 in combination with gemcitabine (G) and nab-paclitaxel (A) in patients with previously untreated metastatic PDA. **Methods:** In a modified 3+3 dose escalation scheme, subcutaneous injections of SBP-101 were dosed at 0.2, 0.4 or 0.6 mg/kg days 1-5 of each 28-day cycle. G (1000 mg/m^2) and A (125 mg/m^2) were administered intravenously on Days 1, 8, and 15 of each cycle. PK was evaluated on day 1 of cycle 1 in cohorts 1-3. Safety was evaluated by clinical and laboratory assessments. Efficacy was assessed by CA19-9 levels, objective response using RECIST criteria, progression-free survival (PFS) and overall survival (OS). A fourth cohort using a modified dosing schedule of 0.4 mg/kg SBP-101 days 1-5 for cycles 1-2 and days 1, 8, and 15 every cycle thereafter was added to mitigate hepatic toxicity, and that dose and schedule were recommended for phase 1b expansion. Interim **Results:** Fifty patients were enrolled (N=25, phase 1a and N=25, phase 1b) and have received up to 12 treatment cycles. SBP-101 plasma C_{max} and $AUC_{0\text{-}t}$ increased in a slightly more than dose proportional manner and were unchanged by the addition of G and A. PK parameters of G and A were unaltered by increasing doses of SBP-101. The most common nonserious adverse events related to SBP-101 (>10%) are fatigue (N=15), LFT/transaminase abnormalities (N=15), vision abnormalities (N=6), injection site pain (N=13), dehydration (N=7), diarrhea (N=7) and nausea (N=6). Serious adverse events related to SBP-101 observed in some subjects include hepatic toxicity (N= 6) and retinal toxicity (N=6) both occurring after prolonged treatment and requiring dose reduction or discontinuation. There is no evidence of SBP-101-related bone marrow suppression or peripheral neuropathy. At the recommended dose and schedule (N=30), CA19-9 levels decreased 60-99% in 19 of 29 evaluable patients, with 12/28 evaluable patients achieving partial responses (43%) and 11/28 achieving stable disease at 8 weeks (39%). Nine subjects are ongoing. PFS was confounded by SBP-101 dosing holds implemented to investigate potential toxicity. Median OS has not been reached. **Conclusions:** Interim results suggest SBP-101 may enhance first-line treatment with G and A in patients with metastatic PDA. Hepatic toxicity can be mitigated with dose reduction or discontinuation. Retinal toxicity that occurred in some subjects is under investigation. Clinical trial information: NCT03412799. Research Sponsor: Panbela Therapeutics, Inc.

Randomized multicenter phase Ib/II study of neoadjuvant chemoradiation therapy (CRT) alone or in combination with pembrolizumab in patients with resectable or borderline resectable pancreatic cancer. *First Author: Osama E. Rahma, Dana-Farber Cancer Institute, Boston, MA*

Background: Pancreatic cancer (PC) is a challenging target for immunotherapy due to suppressive immune-microenvironment. Neoadjuvant chemoradiation (CRT) can increase the presence of tumor-infiltrating lymphocytes (TILs). We hypothesized that the combination of CRT and pembrolizumab can lead to further increase in TILs and their activation. **Methods:** Patients with resectable or borderline resectable PC were randomized 2:1 to the investigational treatment (Arm A) of pembrolizumab 200mg IV every 3 weeks concurrently with CRT (capecitabine 825 mg/m2 orally twice daily and radiation 50.4 Gy in 28 fractions over 28 days) or CRT only (Arm B) prior to surgical resection. The primary endpoints were treatment safety and density of TILs with the objective to estimate differences in TILs density between the investigational and the control arms. Immune cell densities were assessed using multiplexed immunofluorescence on resected tumor specimens. Densities of CD8+TILs were measured in 2-10 representative regions containing residual cancer per case and then averaged to obtain overall densities. The study was amended after enrollment of 37 patients to allow FOLFIRINOX prior to CRT, given changes in standard of care. **Results:** 37 patients were enrolled (24 Arm A and 13 Arm B). Post-neoadjuvant therapy, 13 patients had unresectable disease (9 on A and 4 on B), and 24 patients underwent surgery and were evaluable for the TILs primary endpoint (17 arm A and 7 arm B). The mean difference (A-B) in CD8$^+$ cell density was 36 cells/mm^2 (95% CI -85 to 157, stdev 130) (p 0.48). Additional analysis did not show significant differences in CD8$^+$Ki67$^+$ (activated cytotoxic T-cells), CD4$^+$, and CD4$^+$FOXP3$^+$ (regulatory T cells), M1- or M2-like polarized macrophages, or granulocytes. The median recurrence free survival (RFS) was 18.2 months on Arm A and 14.1 on Arm B (p 0.41) and Overall Survival was 27.8 months on Arm A and 24.3 on Arm B (p 0.68) with a median follow up of 2.2 years. The most common grade 3 treatment-related toxicities were lymphopenia reported in 29% on Arm A and 31% on Arm B followed by diarrhea in 8% on Arm A attributed to CRT. There was only 1 DLT of increased ALT attributed to the combination on Arm A that resolved after holding the treatment and receiving steroids. There were no major surgical complications reported within 30 days post-surgery. **Conclusions:** The combination of CRT and pembrolizumab is safe. Preliminary analysis shows that the addition of pembrolizumab to CRT has minimal effects on several immune cell populations including CD8+TILs in the PC microenvironment. The study is currently enrolling 25 more patients who receive FOLFIRINOX prior to randomization to CRT+/- Pembrolizumab, which will help to dissect the immune modulatory effect of chemotherapy followed by CRT. Clinical trial information: NCT02305186. Research Sponsor: Merck.

Fecal microbiome composition in pancreatic cancer cachexia and response to nutrition support. *First Author: Natalie Moshayedi, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Pancreatic ductal adenocarcinoma (PDAC) carries a poor prognosis with a 5-year survival rate of 10.0%. Previous studies in stool microbiome indicate that microbiome composition has been associated with therapy response and pathogenesis across multiple cancers, and PDAC patients (pts) with higher bacterial diversity have demonstrated greater long-term survival. The fecal microbiome has not previously been characterized for PDAC pts with cancer cachexia or associated interventions. The study addressed the changes in microbiome over the course of treatment and the association between baseline bacterial composition and outcome in PDAC pts with cachexia. **Methods:** Stool specimens were collected from the PNCX1 trial (NCT02400398), where all pts were given a semi-elemental diet—enzymatically hydrolyzed protein—with enteral tube feeding. Stool samples (n = 29) were collected at time points aligned with enteral feeding and chemotherapy cycles separated by 6 weeks (C1D1, C2D1, and C3D1) and analyzed using 16S v4 sequencing of the microbiome. Microbiome changes from C1D1 to C3D1, weight stability, and overall survival (OS) were measured alongside microbiome characterization. **Results:** Pts with a complete set of stool samples were analyzed (n = 6) for differences in microbiome composition across treatment cycles. C3D1 samples were significantly associated with both an increased population of *Veillonella* and *Actinomyces* and decreased *Bacteroides* and *Butyricicoccus* compared to C1D1. Baseline stool microbiome composition was also evaluated to predict weight stability throughout treatment. In patient stool samples (n = 8) at C1D1, greater abundance of *Veillonella* (p = 0.0006) and reduced *Bifidobacterium* (p = 2.62E-5) were linked to greater weight stability. Microbiome alpha-diversity was also characterized using Shannon and Chao1 indices, where stable weight was related to reduced species richness (Chao1, p = 0.0194) but not evenness (Shannon, p = 0.1716). C1D1 patient stool samples were then analyzed and compared to OS (n = 16). Although no significant differences in global microbiome composition were noted between OS < 180 days and OS > 180 days, *Parasutterella*, *Tyzzerella*, *Phascolarctobacterium*, and *Lachnoclostridium* were identified as more prevalent in OS > 180 days despite their relatively low abundance. **Conclusions:** We are among the first evaluate stool bacteria changes over treatment course in PDAC pts. While *Veillonella* was associated with weight stability in a cohort of advanced PDAC pts all receiving enteral feeding, several genera were found in abundance in pts with prolonged OS, though this needs further validation. The potential impact of the gut microbiome and enteral feeding on weight stability is provocative given that cachexia is a hallmark of PDAC and an effective strategy to mitigate this process would be transformative. Research Sponsor: CTSI grant (UL1TR001881).

Circulating cell free tumor DNA detection as a prognostic tool in advanced pancreatic cancer. *First Author: Gehan Botrus, Mayo Clinic Arizona, Phoenix, AZ*

Background: Circulating cell-free tumor DNA (ctDNA) genomic profiling is an emerging tool for pancreatic cancer. The impact of detected genomic alterations in tumor response to systemic treatments and outcomes is under investigation. **Methods:** Patients with advanced pancreatic cancer and ctDNA collected at time of initial diagnosis were retrospectively evaluated. Results of ctDNA analysis were correlated with patients' demographics, systemic treatment response, progression-free survival (PFS) and overall survival (OS). **Results:** A total of 104 patients were included in the analysis. The mean age was 70.5 years (SD: 8.3), 50% were male, 37% with locally advanced disease and 63% with metastatic disease. Somatic alterations were detected in 84.6 % of the patients, no genetic alterations were detected in 15.4%, and were associated more with locally advanced pancreatic cancer as opposed to metastatic, p = 0.025. 60.6 % of the cohort had $\geq$ 2 genomic alterations detected. 28% were treated with FOLFIRINOX and 63% with gemcitabine plus nab-paclitaxel as first-line systemic treatment. Patients with any detectable genomic alterations when compared to patients with no detectable variant had worse median PFS (6.2 versus 15.3 months, p = 0.005) and patients with $\geq$ 2 detectable genomic alterations had worse median PFS (5.6 versus 11.0 months, p $<$ 0.001) and worse median OS (11.5 versus 24.2 months, p = 0.001). KRAS was detected in 62.5% of the patients and was associated with PD to systemic treatments (80.4% vs 19.6%, p = 0.006), worse median PFS (5.8 versus 13.0 months, p $<$ 0.001) and worse median OS (11.5 versus 26.3 months, p = 0.002). TP53 was detected in 60% of patients and was associated with worse median PFS (5.9 versus 10.9 months, p = 0.02) and worse median OS (13.5 versus 24.2 months, p = 0.001). CCND2 was detected in 14% of the patients and was associated with worse median PFS (3.6 versus 8.2 months, p = 0.004). **Conclusions:** Our study showed that initial detection of ctDNA may identify different genomic alterations that help predict disease outcomes, confirmation of these findings in larger studies are warranted. Research Sponsor: None.

Body composition measurements and overall survival in patients with resectable pancreatic adenocarcinoma receiving neoadjuvant chemotherapy: Analysis from SWOG S1505. *First Author: Davendra Sohal, University of Cincinnati, Cincinnati, OH*

Background: Sarcopenia and sarcopenic obesity have been associated with overall survival (OS) in patients (pts) with borderline resectable and advanced pancreatic ductal adenocarcinoma (PDA), but little is known about the effect of body composition on OS in pts with resectable PDA. We examined the relationship between skeletal muscle and adipose tissue measurements on baseline computed tomography (CT) and OS of pts with resectable PDA in a secondary analysis of SWOG S1505 (NCT02562716). **Methods:** SWOG S1505 enrolled pts with resectable PDA who were randomized to receive neoadjuvant FOLFIRINOX or gemcitabine-nab paclitaxel, followed by surgical resection. Baseline axial CT images at the L3 level were analyzed with externally validated software and measurements were recorded for skeletal muscle area (SMA), density (SMD) and index (SMI); visceral adipose tissue area (VATA) and density (VATD); and subcutaneous adipose tissue area (SATA) and density (SATD). Sarcopenia was defined as SMI $<$ 52 cm2/m2 for men and $<$ 39 cm2/m2 for women; sarcopenic obesity was defined as sarcopenia and a body mass index (BMI) $>$30 kg/m2. The relationships between CT metrics and OS were analyzed using Cox regression models, with 95% CI. Statistical significance was defined as p $<$ 0.05. **Results:** Of 98 pts with available baseline abdominal CT, 8 were excluded for scan quality, resulting in 90 evaluable cases: 51 men (57%), 39 women (43%); mean age, 63.2 years, SD 8.5; mean BMI, 29.3 kg/m2, SD 6.4; 80 (89%) White, 6 (7%) Black, and 4 (4%) unknown. Sarcopenia was present in 32 (36%) and sarcopenic obesity in 10 (11%) patients. Univariable analyses for the variables of interest indicated VATA (HR 1.24; 0.97-1.60; p = 0.09) and SMD (HR 0.75; 0.57-0.98; p = 0.04) were associated with OS. Analyses adjusted for sex, race, age, BMI, performance score, contrast use, sarcopenia, and sarcopenic obesity showed VATA was associated with OS (HR 1.58; 1.0-2.51; p = 0.05). No significant difference in median OS was observed between pts with vs. without sarcopenia (OS 23.6 [19.3-NA] vs. 27.9 months [18.6-NA], respectively). Pts with vs. without sarcopenic obesity had lower median OS: 18.6 (14.7-NA) vs. 25.1 (10.5-46.0) months, respectively, but this difference was not statistically significant (HR 1.90, 95%CI 0.81-4.47, p = 0.14). **Conclusions:** This is one of the first studies to systematically evaluate body composition parameters in a prospective trial of patients with resectable PDA who received neoadjuvant chemotherapy. We found that visceral fat (VATA) is a prognostic marker in this population, but that sarcopenia may not be predictive in early PDA. Further studies to define the impact of longitudinal changes in body composition on individual outcomes may provide greater precision in predicting OS for subsets of pts with pancreatic cancer. Clinical trial information: NCT02562716. Research Sponsor: U.S. National Institutes of Health.

The fear of cancer progression and recurrence in patients with pancreatic cancer. *First Author: Esther N. Pijnappel, Amsterdam UMC Location AMC, Amsterdam, Netherlands*

Background: Patients with pancreatic cancer run a considerable risk of disease progression or, after resection, disease recurrence, ultimately leading to death. Therefore, it is plausible that pancreatic cancer patients experience fear of cancer recurrence or progression (FOP). The aim of this study was to compare FOP in patients with pancreatic cancer treated with surgery, palliative systemic treatment or best supportive care (BSC), and examine the association between quality of life (QoL) and FOP and between FOP and overall survival (OS), respectively. **Methods:** This prospective multicenter cohort study included patients diagnosed with pancreatic cancer between 2015 and 2018, who participated in the Dutch Pancreatic Cancer Project (PACAP). Data on FOP (worry of cancer progression scale [WOPS]) and QoL (EORTC QLQ-C30 summary scale score), were obtained from the PACAP database. Data regarding patient and tumor characteristics were derived from the nationwide Netherlands Cancer Registry. The association between QoL and WOPS was assessed with logistic regression analysis. OS was evaluated using Kaplan Meier curves with log-rank test and multivariable Cox proportional hazard analyses. **Results:** In total, 315 patients were included, of whom 111 patients underwent surgery, 138 received palliative systemic treatment, and 66 BSC. WOPS scores tended to decrease and stabilize over time in all subgroups. Patients who underwent surgery had significantly lower WOPS scores (i.e. less FOP) at initial diagnosis compared to patients in the palliative systemic treatment and BSC group (p = 0.004). Higher QoL scores were independently associated with a lower probability of high WOPS scores in patients receiving BSC only (OR 0.95, P = 0.006). Baseline WOPS score was not independently associated with OS. **Conclusions:** Pancreatic cancer patients reported FOP at diagnosis, which decreased and stabilized over time. Given the distress that FOP evokes, FOP should be explicitly addressed by health care providers when guiding pancreatic cancer patients through their treatment trajectory, especially those receiving palliative treatment or BSC. Research Sponsor: None.

Local and systemic recurrence following total neoadjuvant therapy (TNT) and resection for borderline resectable and locally advanced pancreatic adenocarcinoma: Long-term follow up from two phase II studies. *First Author: Grace E. Ryan, Massachusetts General Hospital, Boston, MA*

Background: With the advent of FOLFIRINOX, the management of pancreatic cancer has undergone a profound change. There has been a shift to TNT with FOLFIRINOX followed by radiation and an attempt at surgical resection. Recent trials of TNT have demonstrated an ability to resect locally advanced (LA) and borderline resectable disease. There is a lack of prospective data demonstrating local and systemic recurrence rates after TNT. **Methods:** Two previously reported prospective clinical trials (Murphy JE, et al, JAMA Oncol 2018, 2019) of total neoadjuvant therapy were conducted between 2012 and 2018 for borderline and LA disease (NCT01591733, NCT01821729). Patients received FOLFIRINOX for 8 cycles. Upon restaging, patients with resolution of vascular involvement received short-course chemoradiotherapy (5 Gy x 5 with protons or 3 Gy x 10 w photons) with capecitabine (N=34). Patients with persistent vascular involvement received long-course chemoradiotherapy with capecitabine (N=56). All patients were considered for resection after TNT except for those patients with metastatic or unresectable disease. **Results:** 97 eligible patients were enrolled and started treatment on the borderline resectable (n = 48) and locally advanced (n= 49) study. 90 patients completed therapy. 80 patients were taken to the operating room. 61 patients had R0 resection and 5 patients had R1 resection. The table shows the distribution of local recurrences, local recurrences and metastatic disease, and metastatic disease alone. With a median follow-up of 5.2 years (range: 2.4-6.0), of the 61 R0 patients, 22 patients remained alive and free of disease, 7 patients had a local recurrence, 4 patients had locoregional and metastatic recurrence, and 24 patients had a metastatic recurrence. 3 patients who underwent R0 resection died of unrelated causes. Median survival for patients undergoing R0 resection is 43.8 months. **Conclusions:** Total neoadjuvant therapy for locally advanced and borderline resectable pancreatic cancer is potentially curable and may change the pattern of spread. Research Sponsor: None.

A phase 2 study of cyclophosphamide (CY), GVAX, pembrolizumab (Pembro), and stereotactic body radiation (SBRT) in patients (pts) with locally advanced pancreas cancer (LAPC). *First Author: Valerie Lee, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins, Baltimore, MD*

Background: Management of locally advanced pancreas cancer (LAPC) standardly involves chemotherapy with consolidative radiation and surgery in selected pts. Checkpoint inhibitors have shown limited benefit alone in pancreas cancer but may be primed by radiation and GM-CSF secreting allogeneic pancreatic cancer vaccine (GVAX). We present data from a phase 2 study for LAPC pts who have not developed metastases after standard of care chemotherapy treated with combination cyclophosphamide (CY), GVAX, pembrolizumab (pembro), and stereotactic body radiation therapy (SBRT). **Methods:** This is a single-arm, single institution, open-label study for pts with LAPC at diagnosis (as per NCCN guidelines, arterial involvement $>$ 180°, or unreconstructible SMV/PV) who remained without metastatic disease after 4-8 28-day cycles FOLFIRINOX or gemcitabine/abraxane based therapy. Pts received CY (200mg/m2 IV) and pembro (200mg IV) on day 1, followed by GVAX (6 intradermal inj) on day 2 q3 wk x 2 cycles, with cycle 2 initiating concurrently with 5 days SBRT. Pts were restaged 4-6 weeks after SBRT, and if non-metastatic, pts underwent surgical resection, irreversible electroporation (IRE), or biopsy (if not undergoing surgical resection). Pts received two cycles of chemotherapy, and if metastasis free, received q3 wk CY/pembro/GVAX x 6 cycles with restaging scans q3 mos. In 5/2017, the protocol was addended to include an extended phase with q3 wk pembro x 9 cycles and q6 mo CY/GVAX x 4. Primary endpoint was distant metastasis free survival (DMFS) defined as C1D1 to distant metastases or death. **Results:** From Jul 2016-Jan 2021, 58 pts with LAPC were enrolled at the Johns Hopkins Hospital, 54 completed 2 cycles CY/pembro/GVAX and SBRT and were evaluable for response (2 dropouts due to thrombocytopenia, 2 due to irAE (DKA and hepatitis)), median followup was 15.8 mos. Demographics: median age 66 (range 42-84), 53% male, 84% White, 12% African American. At first restaging (N = 54), 8 (15%) had metastatic disease, 9 (17%) were unresectable, 37 (69%) were eligible for surgical resection. 35 pts proceeded to the OR (1 died of cholangitis prior to surgery and 1 declined surgery), 24 had tumors resected (44% of evaluable pts, 10 (42%) had grade 1 (marked) pathologic response), 1 IRE, 2 were unresectable, 8 were metastatic. Common related AEs were vaccine site reactions; grade 3 irAE included 1 case each of dermatitis, colitis, DKA, nephritis, and pneumonitis. DMFS was 9.7 mos [95% CI 6.3-19.3 mos]. **Conclusions:** We present data from a ph II study of 54 pts w LAPC treated w CY/GVAX/pembro and SBRT. Primary endpoint of DMFS $>$ 13.6 mos not reached, however 44% of pts underwent surgical resection of whom 42% had grade 1 path response rate. Additional correlative studies are underway. Clinical trial information: NCT02648282. Research Sponsor: Gaitway, Pharmaceutical/Biotech Company.

Predictive value of germline *ATM* mutations in the CCTG PA.7 trial: Gemcitabine (GEM) and nab-paclitaxel (Nab-P) versus GEM, nab-P, durvalumab (D) and tremelimumab (T) as first-line therapy in metastatic pancreatic ductal adenocarcinoma (mPDAC). *First Author: Daniel John Renouf, BC Cancer Agency, Vancouver, BC, Canada*

Background: PA.7 evaluated whether combining PD-L1 and CTLA-4 inhibition with GEM and Nab-P increases efficacy. A previous analysis of the PA.7 data demonstrated high plasma based TMB (≥9 mut/Mb) was associated with improved OS in the Gem, Nab-P, D+T arm. DNA repair pathway aberrations beyond mismatch repair have been associated with potential immune sensitivity. We assessed the predictive value of germline *ATM* mutations in the PA.7 trial. **Methods:** This randomized phase II study (ClinicalTrials.gov NCT02879318) assessed the efficacy and safety of GEM, Nab-P, D, and T (arm A) vs. GEM and Nab-P (arm B) in patients (pts) with mPDAC (n = 180). The primary endpoint was overall survival (OS). Pre-treatment plasma was sequenced with the Predicine ATLAS next generation assay (600 gene, 2.4 Mb panel). 2-sided alpha set at 0.1. **Results:** 180 pts were randomized (119 to arm A and 61 to arm B) There was no significant difference in OS (9.8 months in arm A vs. 8.8 months in arm B, p-value 0.72) or PFS (5.5 months and 5.4 months respectively, HR 0.98, p-value 0.91). Plasma analysis was performed on 174/180 pts with available samples. 16/174 (9.2%) pts had germline *ATM* mutations, 12 in arm A and 4 in arm B. GEM, Nab-P, D+T was associated with improved OS in patients with *ATM* mutations (HR 0.10, 90% CI 0.03-0.37; median OS 13.9 months vs. 4.9 months) while no activity was seen in pts with *ATM* Wild Type (HR 0.99, 90% CI 0.73-1.33; median OS 9.79 months vs. 10.2 months); interaction p = 0.014. Germline *ATM* mutation status was independent of plasma TMB levels (Wilcoxon p = 0.76). **Conclusions:** Germline *ATM* mutation appeared predictive of benefit from the addition of dual immune checkpoint inhibitors (D and T) to Gem and Nab-P, with a significant interaction p-value. In addition to previous data from this trial regarding the predictive value of high plasma TMB (≥9 mut/Mb), this data further supports that there may be independent subgroups of PDAC, beyond MSI-H, that may benefit from immunotherapy, and trials evaluating immunotherapy in subgroups of PDAC with these profiles are warranted. Clinical trial information: NCT02879318. Research Sponsor: Canadian Cancer Trials Group (CCTG), Pharmaceutical/Biotech Company.

Impact of KRAS alterations in pancreatic ductal adenocarcinoma (PDAC). *First Author: Maahum Mehdi, Medical College of Wisconsin, Wauwatosa, WI*

Background: The genomic alterations which characterize PDAC holds great promise for novel therapeutic interventions. Constitutive signaling via mutated *KRAS* is considered the signature pathognomonic alteration in PDAC, less than 10% of patients (pts) have tumors which are *KRAS* wild type (WT). We retrospectively reviewed our institutional genomic database to characterize PDAC pts with *KRAS* WT tumors. **Methods:** We reviewed electronic medical records of PDAC pts who underwent comprehensive genomic profiling (CPG) utilizing Foundation One CDx (50.6%) or TEMPUS (49.4%) between 2015-2020. Demographic and disease characteristics were compared between cohorts using Wilcoxon rank-sum test or chi-square tests. Left truncation at the time of CGP was used to account for the time of entry into the study cohort. Kaplan-Meier method was used for survival curve estimation, and log-rank test was used for between-group comparison. Cox regression was used to adjust for confounders. **Results:** We identified 235 patients: median age at diagnosis was 65 years and 52% were male. Clinical stages at diagnosis were localized (resectable/borderline resectable), locally advanced, or metastatic in 105 (44.7%), 61 (26.0%), and 69 (29.4%) patients, respectively. *KRAS* status was mutated in 212 (90%) patients: the most common alterations being G12D (48%), G12V (28%) and G12R (14%). *KRAS* WT status was noted in 23 (9.8%) pts, actionable genomic alterations in this subgroup are summarized in the table. Baseline demographic and treatment characteristics were similar between patients with *KRAS* mutated and WT tumors. Of the 23 patients with *KRAS* WT tumors, 16 (69.6%) completed all planned curative intent therapy compared to 121 (57.3%) of the 212 *KRAS* mutated pts (p=0.26). Median Overall Survival of patients with *KRAS* mutated tumors was 18.6 months compared to 44.1 months for WT pts (p=0.03). Adjusting for stage, WT vs. mutated status was associated with a 62% decreased hazard of death (HR 0.38 [0.18-0.83]; p=0.016). **Conclusions:** Patients with *KRAS* WT PDAC appear to have a distinct biology compared to those with *KRAS* mutations, meriting exploration in larger data sets. Further, comprehensive whole genome or transcriptomic characterization of *KRAS* WT tumors is necessary to identify putative driver alterations as well as actionable therapeutic targets. Research Sponsor: None.

Genomic characteristics of KRAS WT.[1]

Most frequent pathologic genomic alterations[2]	N (%)	Strongly actionable alterations	N (%)	Potentially actionable alterations	N (%)
Total	16 (70)	Total	4 (17)	Total	9 (40)
TP53 mutation	7 (30)	BRAF V600E mutation	1 (0.4)	ARID1A mutation	5 (22)
ARID1A mutation	5 (22)	EGFR Exon 19 deletion	1 (0.4)	CHEK2 mutation	2 (9)
CDKN2A mutation/deletion	3 (13)	STK11 mutation	1 (0.4)	ATM mutation	1 (0.4)
SMAD4 mutation	3 (13)	RET fusion	1 (0.4)	BRAF G469S	1 (0.4)

Impact of the COVID-19 pandemic on care delivery and outcomes for patients with metastatic pancreatic ductal adenocarcinoma (mPDAC). *First Author: Ravi Kumar Paluri, Wake Forest Baptist Health, Winston-Salem, NC*

Background: The coronavirus disease 2019 (COVID-19) pandemic has caused abrupt changes to the US health system and disruption in cancer care delivery. Little has been reported on the impact of COVID-19 on patients with mPDAC and the care delivery. Our study aimed to characterize the impact of COVID-19 on healthcare utilization and outcomes for patients with mPDAC in the US in the community oncology setting. **Methods:** We performed a retrospective cohort study of adult patients diagnosed with mPDAC between March – September 2019 and March – September 2020 using the nationwide Flatiron Health EHR database, comprising data from over 280 (largely community based) cancer clinics. Patients were stratified into two cohorts based on the year of diagnosis (2019 vs. 2020). Clinical characteristics were summarized including age at metastatic diagnosis, stage at initial diagnosis, and ECOG performance score (PS). Overall survival (OS) from metastatic diagnosis was estimated using Kaplan-Meier methods. A sensitivity analysis limiting the follow-up time to November of each year was conducted. **Results:** Overall, 1,719 patients were included in the study (2019: n = 923, 2020: n = 796); both cohorts had similar demographic compositions in terms of age and sex (2019: median age = 70 (IQR: 62 – 76), 52.2% male; 2020: median age = 70 [IQR: 62 – 76], 53.5% male). In 2020, the number of newly diagnosed mPDAC patients decreased by 13.8% compared to 2019. A slightly higher proportion of patients were initially diagnosed with stage IV disease in 2020 (69.7%) vs 2019 (62.3%). A similar proportion of patients with ECOG PS 0-1 was observed between the two cohorts (2019: 48.5%; 2020: 47.9%). The number of visits recorded within the first 90 days after metastatic diagnosis was similar between the two cohorts (2019: median 8 [IQR: 3 – 14]; 2020: median 9 [IQR: 4 – 14]). For both cohorts, the proportion of patients who received 1L treatment was similar (2019: 75.8%; 2020: 76.5%), and the most common 1L treatment regimen was gemcitabine plus nab-paclitaxel (2019: 37.6%; 2020: 40.9%). Of the 1L treated populations, 37.6% of patients diagnosed in 2019 received second line (2L) compared to 17.9% of the 2020 cohort; 16.9% of 1L treated patients in 2019 received 2L in the sensitivity analysis. Patients diagnosed in 2020 had a significantly lower median OS of 6.1 months (95% CI: 5.4 – 6.9) compared to patients diagnosed in 2019: 8.4 months (7.5 – 9.0) ($p < 0.001$). **Conclusions:** During the COVID-19 pandemic era, the diagnoses of de novo mPDAC appears to have been impacted, with a higher number of patients diagnosed with advanced stage at presentation. Our analysis suggests that while patients diagnosed in 2020 received a similar level of care as those in 2019, their survival outcomes were adversely affected. Further research is necessary to characterize the impact of the COVID-19 pandemic on cancer care and outcomes. Research Sponsor: Ipsen.

Efficacy and safety of KN046 plus nab-paclitaxel/gemcitabine as first-line treatment for unresectable locally advanced or metastatic pancreatic ductal adenocarcinoma (PDAC). *First Author: Gang Jin, Changhai Hospital of Shanghai, Shanghai, China*

Background: Pancreatic ductal adenocarcinoma PDAC is one of the most lethal malignancies worldwide and is characterized by extremely poor prognosis. Nab-paclitaxel plus gemcitabine has been recommended by international guidelines for first-line treatment of advanced PDAC but chemoresistance is difficult to avoid. Combination of immune checkpoint inhibitors (ICIs) and chemotherapy has demonstrated substantial promise for the treatment of several advanced malignancies. A few recent studies have begun to explore the effect of ICIs monotherapy or co in advanced PDAC with few meaningful results. KN046, a novel recombinant humanized bispecific antibody, can simultaneously block PD-1/PD-L1 and CTLA-4 pathways and restore T-cell immune response to tumor. The purpose of this study is to evaluate the efficacy and safety of KN046 plus nab-paclitaxel/gemcitabine as first-line treatment for unresectable locally advanced or metastatic PDAC. **Methods:** This ongoing phase II trial in China enrolled pts with histologically or cytologically confirmed unresectable locally advanced or metastatic PDAC who have ECOG PS of 0-1 and never received systemic anti-tumor therapy for advanced or metastatic diseases. KN046 (5mpk, Q2W) plus nab-paclitaxel (125mg/m^2, D1, 8, 15, Q4W) and gemcitabine (1000mg/m^2, D1, 8, 15, Q4W) were administered 4-6 cycles followed by KN046 (5mpk) maintenance therapy every 2 weeks. Tumour response was assessed according to RECIST 1.1 every 8 weeks. The primary endpoint is investigator-assessed ORR. Secondary endpoints are DCR, DOR, TTP, PFS, OS and safety. **Results:** As of December 15, 2020, 17 pts were enrolled, median (range) age was 56 (36-75) years, 9 pts ECOG 1, and 7 pts had liver metastases. Median KN046 exposure time was 9.5 wks. 9 pts were included in the efficacy analysis and 17 pts in the safety analysis. In best overall response assessment, there were 55.6% PR (5/9) and 33.3% SD (3/9). ORR was 55.6% (95% CI: 21.2~86.3), and DCR was 88.9% (95% CI: 51.8~99.7). The overall incidence of KN046 related treatment-emergent adverse events was 64.7%, with 29.4% were grade 3 TRAE. The most common KN046 related treatment-emergent adverse events (≥10%) were alanine aminotransferase increased (n = 5, 29.4%), nausea (n = 3, 17.6%), rash (n = 3, 17.6%), aspartate aminotransferase increased (n = 2, 11.8%), diarrhoea (n = 2, 11.8%), hyperphosphataemia (n = 2, 11.8%), pyrexia (n = 2, 11.8%), vomiting (n = 2, 11.8%). **Conclusions:** Combining KN046 with nab-paclitaxel and gemcitabine as first-line treatment for unresectable locally advanced or metastatic PDAC patients is safe and feasible, and lays the foundation for subsequent clinical trials. Clinical trial information: NCT04324307. Research Sponsor: Jiangsu Alphamab Biopharmaceuticals Co., Ltd.

A phase II trial combining tumor-targeting *TP53* gene therapy with gemcitabine/nab-paclitaxel as a second-line treatment for metastatic pancreatic cancer. *First Author: Chris Poki Leung, SynerGene Therapeutics, Inc., Potomac, MD*

Background: Nearly all stage IV pancreatic adenocarcinoma (PAC) patients progress after first-line treatment, and second-line options are limited. SGT-53 is an investigational product for tumor-targeted *TP53* gene therapy that has completed phase Ia/Ib trials [Senser et al (2013), Mol Ther 21:1096; Pirollo et al (2016) Mol Ther 24:1697]. **Methods:** Here we provide an interim analysis of a Phase II trial (SGT53-02-1; NCT02340117) combining SGT-53 with gemcitabine/nab-paclitaxel (GEM/ABX). Eligible were first-line patients or those who had progressed after FOLFIRINOX (FFX) and/or gemcitabine-based therapy (second-line). In a 7-week treatment cycle, SGT-53 (3.6 mg DNA) was given once or twice weekly with GEM/ABX (1000 mg/m^2/wk and 125 mg/m^2/wk, respectively, for 3 of 4 weeks). Progression-free survival (PFS) and objective response rate (ORR) are primary endpoints.Overall survival (OS) and PFS are estimated by Kaplan-Meier analysis. **Results:** Of all evaluable patients (n=20), best response in 7 patients was determined to be partial response (PR) and 13 had stable disease (SD); none had progressive disease. In the second-line patients (n=11) there were 5 PR and 6 SD after 9 had failed FFX treatment, 3 had failed gemcitabine-based treatment and 1 had failed both. For patients with elevated CA19-9, SGT-53 + GEM/ABX resulted in marked reductions in the tumor marker. Published data for patients with PAC after therapy failure [Mita et al (2019) J Clin Med 8: 761; Portal et al (2015) Br J Cancer 113:989; Wang-Gillam et al (2016) Lancet 387:545] are shown for comparison. Notably, mPFS in our second-line patients was 7.4 months versus 3.1 months for the approved second-line therapy [Wang-Gillam et al (2016)]. This improvement in PFS exceeds the benchmark proposed to predict a clinically meaningful Phase III trial [Rahib et al (2016) Lancet Oncol 2:1209]. **Conclusions:** Our data suggest a clinically meaningful benefit of adding SGT-53 to GEM/ABX particularly for second-line PAC patients, most of whom had failed prior FFX treatment. Clinical trial information: NCT02340117. Research Sponsor: SynerGene Therapeutics, Inc.

Genetic and immune divergence in pancreatic cancer lesions at the time of metastatic relapse compared to primary tumor. *First Author: Bereket Gebregziabher, Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA*

Background: Relapse of pancreatic ductal adenocarcinoma (PDA) is common even after complete resection and adjuvant therapy. Compared to the resected tumor, the biological characteristics of metastatic tumors at the time of first relapse are poorly understood. **Methods:** Whole-exome sequencing (WES) (250x) and bulk RNA sequencing were performed on samples from 30 patients with PDA. Paired primary tumor samples were obtained after R0 or R1 resection, and metastatic tumor samples were obtained by biopsy at the time of first relapse. 74.1% of patients had received adjuvant chemotherapy and radiation therapy, 7.4% had received adjuvant chemotherapy only, and 3.7% had received adjuvant radiation therapy only. Most common metastatic sites were liver and lung. The cohort was 60% male with a median age at diagnosis of 64 years. The vast majority of patients had stage IIA or IIB disease at diagnosis. Median disease-free survival was 481 days. Analysis used Freebayes (somatic variant calling), Kallisto (transcript quantification), Danaher et al. (cell type deconvolution), and antigen.garnish (neoantigen prediction). **Results:** High-quality WES and/or RNA sequencing were available for 27/30 patients. Among these were 16 pairs of primary and metastatic samples for WES and 15 paired samples for RNA sequencing. Median tumor purity was 32% (primary) and 42% (metastatic). KRAS mutations were present in 43/48 evaluable samples, with conserved KRAS mutations in 14/16 primary-metastatic pairs. Tumors were otherwise highly variable, with 13/16 patients developing oncogenic mutations in metastatic tumors that were undetected in primary tumors (BRCA1 [3/16], AKT3 [3/16], TP53 [2/16], ROS1 [2/16]). Overall, primary and metastatic tumors had similar tumor mutation burden and neoantigen production rate. However, neoantigens were highly variable at the peptide and gene level, with conservation rates of 2.73% and 11.57%, respectively, across primary-metastatic pairs. PDA transcriptomic subtype also differed across primary-metastatic pairs in all cases. Furthermore, metastatic tumors contained lower immune suppressive signal by transcripts and deconvolution (CTLA4: p = 0.0012, FOXP3: p = 0.0026, PDCD11: p = 0.012, regulatory T cells: p = 0.012), while myeloid cells were higher (CD33: p = 0.0067). **Conclusions:** With the exception of KRAS, metastatic PDA tumors at relapse contain new oncogenes, distinct neoantigens, and lower immune-suppressive signal compared to primary PDA tumors. These data suggest a potential clinical utility for tumor biopsies at the time of first metastatic relapse and caution against clinical decisions for relapsed, metastatic patients based solely on sequencing of the originally resected tumor. Research Sponsor: U.S. National Institutes of Health.

Identification of pancreatic adenocarcinoma molecular subtypes on histology slides using deep learning models. *First Author: Charlie Saillard, OWKIN, Paris, France*

Background: Pancreatic adenocarcinoma (PAC) is predicted to be the second cause of death by cancer in 2030 and its prognosis has seen little improvement in the last decades. PAC is a very heterogeneous tumor with preeminent stroma and multiple histological aspects. Omic studies confirmed its molecular heterogeneity, possibly one of the main factors explaining the failure of most clinical trials. Two and three transcriptomic subtypes of tumor cells and stroma respectively, were described with major prognostic and predictive implications. The tumor subtypes, Basal-like and Classical, have been shown by several groups to be predictive of the response to first line chemotherapy. As of today, these subtypes can only be defined by RNA profiling which is limited by the quantity and quality of the samples (formalin fixation and low cellularity) as well as by the analytical delay that may restrict its application in routine care. In addition, tumors may harbor a mixture of several subtypes limiting their interpretation using bulk transcriptomic approaches and thereby their clinical use. Here, we propose a multistep approach using deep learning models to predict tumor components and their molecular subtypes on routine histological preparations. **Methods:** 728 whole-slide digitized histological slides corresponding to 350 consecutive resected PAC from four centers with clinical and transcriptomic data were assembled and used as a discovery set. PAC from TCGA (n = 134) was used as a validation set. Tumor regions from slides of the discovery set were annotated to train a multistep deep learning model that first recognizes tumor tissue and then predicts tumor and stroma cells molecular subtypes assessed by the published PurIST algorithm. **Results:** The tumor detection model was very efficient (AUC = 0.98 in the TCGA validation cohort). In the discovery set, the Basal-like/Classical classification performance of the model by cross validation was 0.79 (AUC) and reached 0.86 when restricted to samples with a high-confidence RNA-defined molecular subtype.Subtypes defined by the model were independently associated with overall survival in multivariate analysis (HR = 2.56 [1.87 - 3.49], pval $<$ 0.001), and association was higher relatively to PurIST RNA subtypes (HR = 1.60 [1.17 - 2.19] pval $<$ 0.001). In the validation cohort, the model had an overall AUC of 0.82, and 0.89 in the subset of subtype-pure tumors. In addition to demonstrating the value of histology-based deep learning models for tumor subtyping in PAC, these results also show the limit of molecular-based subtyping in highly heterogeneous samples. **Conclusions:** This study provides the first PAC subtyping tool usable worldwide in clinical practice, finally opening the possibility of patient molecular stratification in routine care and clinical trials. Research Sponsor: Owkin, Other Foundation.

Impact of KRAS mutational status on outcomes in patients with pancreatic cancer (PDAC). *First Author: Lucy Xiaolu Ma, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: KRAS mutations (m) (KRASm) are present in over 90% of pancreatic adenocarcinomas (PDAC) with a predominance of G12 substitutions. KRAS wildtype (WT) PDAC relies on alternate oncogenic drivers, and the prognostic impact of these remains unknown. We evaluated alterations in WT PDAC and explored the impact of specific KRASm and WT status on survival. **Methods:** WGS and RNAseq were performed on 570 patients (pts) ascertained through our translational research program from 2012-2021, of which 443 were included for overall survival (OS) analyses. This included 176 pts with resected and 267 pts with advanced PDAC enrolled on the COMPASS trial (NCT02750657). The latter cohort underwent biopsies prior to treatment with first line gemcitabine-nab-paclitaxel or mFOLFIRINOX as per physician choice. The Kaplan-Meier and Cox proportional hazards methods were used to estimate OS. **Results:** KRAS WT PDAC (n = 52) represented 9% of pts, and these cases trended to be younger than pts with KRASm (median age 61 vs 65 years p = 0.1). In resected cases, the most common alterations in WT PDAC (n = 23) included GNASm (n = 6) and BRAFm/fusions (n = 5). In advanced WT PDAC (n = 27), alterations in BRAF (n = 11) and ERBB2/3/4 (n = 6) were most prevalent. Oncogenic fusions (NTRK, NRG1, BRAF/RAF, ROS1, others) were identified in 9 pts. The BRAF in-frame deletion p.486_491del represented the most common single variant in WT PDAC, with organoid profiling revealing sensitivity to both 3rd generation BRAF inhibitors and MEK inhibition. In resected PDAC, multivariable analyses documented higher stage (p = 0.043), lack of adjuvant chemotherapy (p < 0.001), and the KRAS G12D variant (p = 0.004) as poor prognostic variables. In advanced disease, neither WT PDAC nor KRAS specific alleles had an impact on prognosis (median OS WT = 8.5 mths, G12D = 8.2, G12V = 10.0, G12R = 12.0, others = 9.2, p = 0.73); the basal-like RNA subtype conferred inferior OS (p < 0.001). A targeted therapeutic approach following first line chemotherapy was undertaken in 10% of pts with advanced PDAC: MMRd (n = 1), homologous recombination deficiency (HRD) (n = 19), KRASG12C (n = 1), CDK4/6 amplification (n = 3), ERBB family alterations (n = 2), BRAF variants (n = 2). OS in this group was superior (14.7 vs 8.8 mths, p = 0.04), mainly driven by HRD-PDAC where KRASm were present in 89%. **Conclusions:** In our dataset, KRAS G12D is associated with inferior OS in resected PDAC, however KRAS mutational status was not prognostic in advanced disease. This suggests that improved OS in the WT PDAC population can only be achieved if there is accelerated access to targeted drugs for pts. Research Sponsor: This study was conducted with the support of the Ontario Institute for Cancer Research (PanCuRx Translational Research Initiative) through funding provided by the Government of Ontario, the Wallace McCain Centre for Pancreatic Cancer supported by the Prin.

TCOG T5217 trial: A phase II randomized study of SLOG versus modified FOLFIRINOX as the first-line treatment in locally advanced or metastatic pancreatic ductal adenocarcinoma. *First Author: Nai-Jung Chiang, National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan*

Background: The triplet regimen of S-1, leucovorin, oxaliplatin and gemcitabine (SLOG) has shown promising efficacy for metastatic pancreatic ductal adenocarcinoma (PDAC) in our previous study. Current multicenter randomized, phase II study compared the efficacy and safety of SLOG versus modified FOLFIRINOX (mFOLFIRINOX) in patients with advanced/metastatic PDAC. **Methods:** Patients with chemonave, histologically confirmed advanced/metastatic PDAC, were randomly assigned to either SLOG (gemcitabine 800 mg/m^2, fixed-rate infusion and oxaliplatin 85 mg/m^2 on day 1, plus daily 40/50/60 mg of S-1 based on BSA and 30 mg of oral leucovorin, twice daily, on days 1-7, every 2 weeks) or mFOLFIRINOX (oxaliplatin 85 mg/m^2, irinotecan 150 mg/m^2 and leucovorin 400 mg/m^2 on day 1 plus 5-FU 2400 mg/m^2 for 46 hrs, every 2 weeks). Patients were stratified according to disease extent, ECOG PS and primary tumor location. The primary endpoint was 6-month progression-free survival (PFS) rate. The secondary endpoints were objective response rate (ORR), disease control rate (DCR), PFS, and overall survival (OS) and safety profile. Tumor response was assessed by CT/MRI every 8 weeks according to RECIST v1.1. As an exploratory trial, 130 (65 per arm) patients were estimated to detect a two-sided 15% difference in 6-month PFS (60% in SLOG and 45% in mFOLFIRINOX) with a significant level of $\alpha = 0.1$ and $\beta = 0.25$. **Results:** Between March 2018 and October 2019, 130 patients were accrued. One patient who was assigned to mFOLFIRINOX arm didn't receive assigned treatment. Of them, 62.3% were male, 45.4% were ECOG PS0, 81.5% had metastatic diseases, and 16.9% had prior surgery. The 6-month PFS rate was 55.4% in SLOG arm (n = 65) and 50% in mFOLFIRINOX arm (n = 64) (p = 0.850). The ORR and DCR in the SLOG and the mFOLFIRINOX arms were 40% versus 26.6% (p = 0.135) and 76.2% versus 71.9% (p = 0.550), respectively. The median PFS was 7.5 months in SLOG arm and 6.5 months in mFOLFIRINOX arm (p = 0.395); while the median OS was 12.9 months in SLOG arm and 12.1 months in mFOLFIRINOX arm (p = 0.88). Ten patients underwent conversion surgery, of whom 7 had SLOG and 3 had mFOLFIRINOX. The incidence of grade 3/4 neutropenia was significantly higher in mFOLFIRINOX arm (53.2% vs. 16.9% in SLOG arm, p < 0.0001). **Conclusions:** SLOG could achieve comparable but numerically better ORR, and median PFS and OS as compared to mFOLFIRINOX in patients of advanced PDAC. SLOG can be an alternative first-line regimen for advanced PDAC patients. Clinical trial information: NCT03443492. Research Sponsor: National Health Research Institutes, Pharmaceutical/Biotech Company.

Treatment with pembrolizumab in combination with the oncolytic virus pelareorep promotes anti-tumor immunity in patients with advanced pancreatic adenocarcinoma. *First Author: Devalingam Mahalingam, Northwestern University, Chicago, IL*

Background: Pelareorep is an intravenously delivered oncolytic reovirus that can induce a T-cell-inflamed phenotype in pancreatic ductal adenocarcinoma (PDAC). In prior studies, tumor tissue analysis from patients treated with pelareorep shows pelareorep replication, increased T cell infiltration, and upregulation of PD-L1. We hypothesized that pelareorep in combination with pembrolizumab in patients with PDAC would lead to improved responses and anti-tumor immunological changes within peripheral blood and tumor biopsies in responding patients. **Methods:** PDAC patients who progressed after first-line treatment received pelareorep at a dose of $4.5x10^{10}$ $TCID_{50}$ IV on Days 1, 2, 3 & 8 of Cycle (C) 1, and Days 1 & 8 with C2 onwards. Pembrolizumab was administered on Day 1 of each 21-day cycle at 200 mg IV. The primary objective was overall response rate by RECIST v 1.1 criteria. Secondary objectives included evaluating immunological changes within tumor tissue and peripheral blood, performed by multi-plex immunohistochemistry and spectral flow cytometry (Cytek), respectively. **Results:** Thirteen patients were enrolled. Disease control was achieved in 33% of the 12 efficacy-evaluable patients. One patient achieved a partial response (PR). Three additional patients achieved stable disease (SD). On-treatment tumor biopsies, collected during C1, showed pelareorep replication, increased infiltration of CD8 + T cells and PD-L1+ cells, and decreased expression of VDAC1, a mitochondrial gatekeeper for tumor promotion, relative to archival tissue. Reduced infiltration of Foxp3+ regulatory T cells (Treg) was observed in patients showing tumor response. Peripheral blood was collected at day 1 of each cycle and on C1 day 8. Relative to pretreatment samples, the number of CD8+ effector memory T cells and B cells tend to increase while the number of Treg cells declined in C2 onwards in patients with tumor response. Furthermore, these patients had increased expression of the mitochondrial protein TOMM20 in CD8+ T cells and decreased expression of PD-1 and the H3K27me3 epigenetic mark in Treg. Treatment was well tolerated with most treatment-related adverse events, including flu-like symptoms, being grade 1 or 2. **Conclusions:** The combination of pelareorep and pembrolizumab showed a manageable safety profile and modest efficacy in an unselected PDAC population. Additional correlation analyses between treatment efficacy and immunological changes will be presented. The anti-tumor activity of pelareorep and checkpoint blockade therapy is being evaluated further in additional ongoing studies. Clinical trial information: NCT03723915. Research Sponsor: Oncolytics and Merck.

Association of total neoadjuvant therapy with major pathologic response and survival in localized pancreatic cancer: A multi-institutional analysis of 504 patients. *First Author: Jashodeep Datta, University of Miami Miller School of Medicine, Miami, FL*

Background: Despite increased utilization of neoadjuvant therapy for pancreatic cancer (PC), a substantial proportion of patients never receive adjuvant therapy. We examined if total neoadjuvant therapy (TNT) would facilitate delivery of all prescribed (≥6 months) non-surgical therapy (NST: chemotherapy ± radiation) to improve oncologic outcomes. **Methods:** Patients receiving neoadjuvant FOLFIRINOX or gemcitabine/nab-paclitaxel ±radiation followed by pancreatectomy at 7 centers were reviewed. Patients receiving TNT (≥6 months NST *pre*-resection) were compared to those receiving < 6 months (< TNT). Primary outcomes were major (complete/near-complete) pathologic response (MPR) and overall survival (OS). **Results:** Of 504 patients, 105 (21%) were selected for TNT. TNT and < TNT patients had similar performance status and rates of borderline resectable/locally advanced disease (82% vs. 80%). TNT patients were significantly more likely to receive ≥6 months NST (100% vs. 31%; p < 0.001) vs. < TNT. While selection of chemotherapy regimen (FOLFIRINOX or gemcitabine/nab-paclitaxel) did not differ between TNT and < TNT cohorts, TNT patients were more likely to receive neoadjuvant radiation (44% vs. 25%, p < 0.001). Rates of vascular resection, postoperative complications, and mortality were similar between groups. TNT was associated with decreased rates of lymphovascular/perineural invasion (p = 0.002) and nodal positivity (p = 0.001), and increased rates of MPR (41% vs. 23%; p = 0.001) and pathologic complete response (13% vs. 6%; p = 0.02). TNT was associated with improved OS compared with < TNT (median 38 vs. 30 months; p = 0.039). Both MPR (median 38 [MPR] vs. 28 [limited response] months; p = 0.002) and ≥6 months NST (TNT or peri-operative) (median 38 [≥6m] vs. 26 [< 6m] months; p = 0.001) were associated with improved OS. Addition of radiation was not associated with MPR or OS. **Conclusions:** The TNT approach allows more patients with localized PC to receive ≥6 months NST and is associated with improved rates of MPR and OS. TNT should be considered for all patients with operable PC when possible. Research Sponsor: None.

Prognostic and predictive factors in patients treated with ramucirumab (RAM) with advanced hepatocellular carcinoma (aHCC) and elevated alpha-fetoprotein (AFP): Results from two phase III trials. *First Author: Josep M. Llovet, Mount Sinai Liver Cancer Program, Division of Liver Diseases, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Elevated AFP in patients with aHCC is a poor prognostic factor with distinct molecular features, including high vascular endothelial growth factor (VEGF) signalling and increased angiogenesis. RAM, a human IgG1 monoclonal antibody, VEGF receptor 2 (VEGFR2) inhibitor, demonstrated improved survival vs placebo among patients with elevated AFP in the REACH-2 trial and is accepted as a standard of care for management of aHCC. We analyzed prognostic factors in patients with AFP ≥400 ng/mL and predictors of clinical benefit to RAM in an individual participant data (IPD) meta-analysis of the REACH and REACH-2 Phase III trials. **Methods:** Patients with aHCC, Child-Pugh A, ECOG performance status (PS) ≤1, and prior sorafenib were randomized (REACH 1:1; REACH-2 2:1) to RAM 8 mg/kg or Placebo Q2W. Meta-analysis was conducted in patients with AFP ≥400 ng/mL (n = 542). Univariate (UV) and multivariate (MV) analyses were performed using a Cox proportional hazard regression model. MV used the cut-off p-value < 0.1 from UV, irrespective of treatment arm. Overall survival (OS) was evaluated by Kaplan-Meier estimator and Cox models. To define predictors of RAM benefit, treatment-by-covariate interactions terms were evaluated. **Results:** In terms of prognosis assessed by MV analysis in patients with AFP ≥400 ng/mL, 6 variables among demographic and baseline disease characteristics were associated with poor OS in the RAM cohort (ECOG PS 1, AFP > 1000 ng/mL, Child-Pugh > A5, Extrahepatic site > 1, neutrophil-to-lymphocyte ratio > 3.2 and aspartate aminotransferase > 57 U/L) with an additional 3 factors identified within the whole cohort (macrovascular invasion presence, etiology HCV vs. Other and alkaline phosphatase ≥146). RAM benefit was present across all subgroups, including patients with very aggressive HCCs (AFP > 4000 ng/mL; HR: 0.64; 95% CI: 0.49-0.84) and those with nonalcoholic steatohepatitis /alcohol related aHCC (HR: 0.56; 95% CI: 0.40-0.79). Of note, two treatment-emergent (TE) events were the only factors that were significantly associated with improved RAM-related survival: TE-hypertension (p interaction = 0.0392) and TE-ascites (p interaction = 0.0001). However, these results should be interpreted with caution given that TE events are factors only observed after randomization. **Conclusions:** Several poor prognostic factors for OS were identified in patients with aHCC and elevated AFP. RAM provided an OS benefit irrespective of baseline prognostic covariates, with greater benefit observed in patients with aggressive HCC and those who experienced TE-hypertension or TE-ascites. Clinical trial information: NCT01140347; NCT02435433. Research Sponsor: Eli Lilly and Company.

Prognostic impact of pSTAT3 on overall survival (OS) in gastrointestinal (GI) cancers: Data from 3 phase 3, randomized controlled trials (RCTs). *First Author: Emily Brooks, Sumitomo Dainippon Pharma Oncology, Inc., Cambridge, MA*

Background: Retrospective studies of phosphorylated STAT3 (pSTAT3, a regulator of gene expression) in cancer-lineage cells have suggested it is a biomarker of poor prognosis. We analyzed data from 3 phase 3 RCTs (BRIGHTER [T1; NCT02178956], CO.23 [T2; NCT01830621], CanStem111P [T3; NCT02993731]) to evaluate the prognostic impact of pSTAT3 on OS in GI cancer patients (pts). **Methods**: pSTAT3 was evaluated in archival tumor tissue from pts with gastric or gastroesophageal junction adenocarcinoma (T1), colorectal cancer (T2), or pancreatic cancer (T3) who received standard of care in the control arms (CTL) of their respective trials. pSTAT3 positive (+) or negative (−) status was determined by detecting pSTAT3 in both tumor and tumor microenvironment (TME) cells in a laboratory-developed immunohistochemistry (IHC) assay (T1; T2), later developed into the investigational pSTAT3 IHC D3A7 assay (Agilent Technologies, Inc.) (T3). The positivity cutoff requires a sample have both a TME score of 2 and ≥5% of tumor cells staining positively for pSTAT3. Pre-analytical variables (eg, specimen collection, handling, and processing), tumor indication, and slight differences in the assays used for each study may contribute to relative differences in evaluable rates between studies. In an exploratory analysis, OS was compared in pSTAT3+ vs pSTAT3− pts via an unstratified log-rank test. **Results**: In each study, intent-to-treat pts with evaluable pSTAT3 results were considered pSTAT3-evaluable. This abstract includes pSTAT3-evaluable pts randomized to the CTL arms (T1: n/N=248/357, 69.5%; T2: n/N=110/144, 76.4%; T3: n/N=243/569, 42.7%). Baseline characteristics are presented in the table. Median (m) OS was shorter in pts with pSTAT3+ tumors across all studies (T1 hazard ratio [HR]=1.32 [95% confidence interval (CI): 1.00, 1.74]; T2 HR=2.40 [1.50, 3.83]; T3 HR=1.08 [0.77, 1.50]). **Conclusions**: In pSTAT3-evaluable populations from 3 RCTs across GI cancers, CTL pts with pSTAT3+ (vs pSTAT3−) tumors had shorter mOS. These results suggest that pSTAT3 positivity may be a biomarker of poor clinical outcome. Clinical trial information: NCT02178956; NCT01830621; NCT02993731. Research Sponsor: Sumitomo Dainippon Pharma Oncology, Inc.

Phase II study of pembrolizumab-based therapy in previously treated extrapulmonary poorly differentiated neuroendocrine carcinomas: Results of Part B (pembrolizumab + chemotherapy). *First Author: Jennifer A. Chan, Dana-Farber Cancer Institute, Boston, MA*

Background: The efficacy of immune checkpoint inhibitor (CPI) therapy has not been established in extrapulmonary poorly differentiated neuroendocrine carcinomas (EP-PDNECs). In small cell lung cancer, CPI therapy is approved for use in the first-line and salvage settings. We investigated the efficacy and safety of pembrolizumab (PEM)-based therapy in biomarker-unselected patients (pts) with EP-PDNECs. PEM alone (Part A, N=14) was inactive (ASCO GI 2019; Abstr#363). We now report the results of Part B (PEM plus chemotherapy). **Methods:** We conducted an open label, multicenter, phase 2 study of PEM-based therapy in pts with EP-PDNECs, excluding Merkel cell carcinoma and well differentiated grade 3 neuroendocrine tumors (NET), with disease progression on first-line systemic therapy. In Part B of this trial, patients were treated with PEM 200 mg IV every 3 week cycle plus dealers' choice chemotherapy (chemo): weekly irinotecan (IRI, 125 mg/m2 day 1,8 of every 21 day cycle) or weekly paclitaxel (PAC, 80 mg/m2). After PEM/IRI safety lead-in (N=6), 16 additional pts (total N=22) were enrolled. This was based on a primary endpoint of objective response rate (ORR) by RECIST 1.1 and a plan to test H_a ORR 31% vs H_0 ORR 10% with 80% power at a type I error rate of 0.05. Secondary endpoints include safety, overall survival (OS), and progression-free survival (PFS). Serial blood samples and baseline tumor biopsies were required in all pts. **Results:** Preliminary data from Part B are available. Of 22 pts enrolled, male/female 15/7; median age 57 years (range 34-75); ECOG PS 0/1: 10/12; 6 large cell, 8 small cell, 8 NOS. Primary sites of disease: GI 73%, GYN 5%, unknown 23%. Ki67 index (available for 18 pts) median 68% (range 30 to >95%). Chemo choice: 17 IRI (77%) and 5 PAC (23%). PEM/IRI was safe based on lead-in. Median number of cycles of therapy administered was 3 (range 0-13). Treatment-related Gr 3 or 4 AE occurred in 7 (32%) of 22 pts overall: 4 (18%) had at least one Gr 3 AE attributed to PEM (1 pt each with pain, ALT increase, or nausea; 2 with fatigue); 7 (32%) had at least one Gr 3/4 AE attributed to chemo (2 with fatigue, 2 with neutropenia; 1 each with pain, ALT increase, hyponatremia, diarrhea, nausea, and/or acute kidney injury). No grade 5 AE. ORR was 9%: PR in 2 pts (9%), SD 3 pts (14%), PD 13 pts (60%); 4 pts (18%) unevaluable (off study before first scheduled scan). Median PFS 2 mo. At last follow-up, 5 pts (23%) were alive with 1 pt still on treatment. Median OS 4 mo. Of 21 pts off treatment, 76% off for PD, 10% off for AE, 14% off for withdrawal of consent/other therapy. **Conclusions:** PEM + chemotherapy was not effective in this pretreated, biomarker-unselected population of EP-PDNECs arising in different organs. Biomarker studies are planned (Parts A/B). Clinical trial information: NCT03136055. Research Sponsor: Merck.

TPS4149 **Poster Session**

Preventive HIPEC in combination with perioperative FLOT versus FLOT alone for resectable diffuse type gastric and gastroesophageal junction type II/III adenocarcinoma: The phase III PREVENT trial of the AIO /CAOGI /ACO. *First Author: Thorsten Oliver Goetze, University Cancer Center Frankfurt, Institut für Klinisch-Onkologische Forschung and Institut für Klinische Krebsforschung IKF GmbH am Krankenhaus Nordwest, Frankfurt, Germany*

Background: The main reason for treatment failure after curative surgical resection of gastric cancer is intra-abdominal spread, with 40- 50% peritoneal seeding as primary localization of recurrence. Peritoneal relapse is seen in 60-70% of tumors of diffuse type, compared to only 20-30% of intestinal type. Hyperthermic IntraPEritoneal Chemoperfusion (HIPEC) is an increasingly used therapy method for patients with peritoneal metastases. The preventive use of HIPEC could represent an elegant approach for patients (pts) before macroscopic peritoneal seeding, since patients with operable disease are fit and may have potential risk of microscopic involvement, thus having a theoretical chance of cure with HIPEC even without the need for cytoreduction. No results from a PCRT from the Western hemisphere have yet been published. **Methods:** This is a multicenter, randomized, controlled, open-label study including a total of 200 pts with localized and locally advanced diffuse and mixed type (Laurens`s classification) adenocarcinoma of the stomach and Type II/III GEJ (i.e. ≥cT3 any N or any T N positive). All enrolled pts will have received 3-6 pre-operative cycles of biweekly FLOT (Docetaxel 50 mg/m^2; Oxaliplatin 85 mg/m^2; Leucovorin 200 mg/m^2; 5-FU 2600 mg/m^2, q2wk). Pts will be randomized 1:1 to receive surgery only and postoperative FLOT (Arm A- Control arm) or surgery + intraoperative HIPEC (cisplatin 75mg/m2 solution administered at a temperature of 42°C for 90 minutes) and postoperative FLOT (Arm B- experimental arm). Surgery is carried out as gastrectomy or transhiatal extended gastrectomy. Primary endpoint is PFS/DFS, major secondary endpoints are OS, R0 resection rate, perioperative morbidity/mortality including VAS pain score and quality of life as assessed by EORTC QLQ C30 questionnaire. The trial starts with a safety run-in phase. After 20 patients had curatively intended resection in Arm B, an interim safety analysis is performed assessing feasibility, safety, and tolerability in Arm B. First patient was randomized on 18JAN2021. Currently one patient is recruited. EudraCT: 2017-003832-35; ClinicalTrials.gov ID: NCT04447352. Clinical trial information: NCT04447352. Research Sponsor: Deutsche Krebshilfe.

TPS4150 **Poster Session**

AdvanTIG-203: A randomized phase 2 study comparing anti-TIGIT ociperlimab plus tislelizumab versus tislelizumab plus placebo as second-line treatment in patients with advanced or recurrent esophageal squamous cell carcinoma (ESCC) expressing programmed death-ligand 1 (PD-L1). *First Author: Rui-hua Xu, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, China*

Background: The programmed death-1 (PD-1)/PD-L1 pathway plays an important role in tumor induced immunosuppression. PD-L1 overexpression is observed in approximately 30–60% of esophageal cancers and is associated with poor prognosis. Anti-PD-1 agents demonstrate moderate efficacy in PD-L1-positive esophageal cancer in terms of response rate and overall survival, however, long-term outcomes remain poor due to primary and secondary resistance driven by tumor immune escape. The T-cell immunoglobulin and immunoreceptor tyrosine-based inhibition motif domain (TIGIT) is upregulated on T-cells and natural killer cells in multiple solid tumors, which can inhibit anticancer immune responses. Ociperlimab (BGB-A1217) is a novel, humanized, monoclonal antibody that binds TIGIT with high specificity and affinity, blocking the interaction with its ligands on tumor cells. Preclinical and clinical studies suggest that dual targeting with anti-TIGIT and anti-PD-1 antibodies produces synergistic immune cell activation and enhanced antitumor activity. **Methods:** AdvanTIG-203 is a phase 2, global, randomized, double-blind, placebo-controlled study (NCT04732494) of patients with unresectable, locally advanced, recurrent or metastatic ESCC, who progressed on or after 1st line systemic therapy and whose tumors express PD-L1 (visually estimated combined positive score $\geq$10%). After stratification by Eastern Cooperative Oncology Group performance status (0 or 1), number of metastatic sites ($\leq$1 or $\geq$2) and region (Asian or non-Asian), 280 patients will be randomized (1:1) to either ociperlimab 900 mg intravenous (IV) plus tislelizumab 200 mg IV every 3 weeks (Q3W), or tislelizumab plus placebo Q3W, until disease progression (per RECIST v1.1), unacceptable toxicity, death or withdrawal of consent. Co-primary endpoints are investigator-assessed overall response rate (ORR) and overall survival (OS) in the intention-to-treat population. A sample size of 280 patients was estimated to provide approximately 94.8% power to detect a 20% difference in ORR at a one-sided significance level of 0.025. With 198 deaths, the study was estimated to provide approximately 86% power to detect a hazard ratio of 0.65 for OS. Secondary endpoints are ORR by independent review, progression-free survival, duration of response, disease control rate, and clinical benefit rate per investigator and independent assessment, cancer-specific health-related quality of life (HRQoL), and safety. Exploratory endpoints include but are not limited to expression of TIGIT, CD226, CD155, CD112, and PD-L1, pharmacokinetics, immunogenicity, and generic HRQoL measures. Clinical trial information: NCT04732494. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Jessica Jones, PhD, of Ashfield MedComms, an Ashfield Health company, and funded by BeiGene, Ltd.

MATTERHORN: Efficacy and safety of neoadjuvant-adjuvant durvalumab and FLOT chemotherapy in resectable gastric and gastroesophageal junction cancer—A randomized, double-blind, placebo-controlled, phase 3 study. *First Author: Yelena Y. Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Gastric and gastroesophageal junction cancers (GC, GEJC) are the fifth most common cancer types and the third leading cause of cancer-related deaths globally (Globocan 2020). Standard of care for resectable GC/GEJC includes neoadjuvant-adjuvant FLOT chemotherapy (5-fluorouracil + leucovorin + oxaliplatin + docetaxel) combined with surgery and lymph node dissection for some regions of the world. While treatment advances have improved survival, the 5-year recurrence rate remains high and 5-year overall survival (OS) is poor for patients with resectable disease. Evidence suggests cytotoxic chemotherapy can promote antitumor immunity, thus the combination of immune checkpoint inhibitors, such as durvalumab (an anti–PD-L1 antibody), with cytotoxic chemotherapy may result in increased efficacy (Yu et al. *Cancer Lett.* 2019; Li et al. *Mol Cancer.* 2021). MATTERHORN (NCT04592913) is a phase 3, multicenter study evaluating the efficacy and safety of neoadjuvant-adjuvant durvalumab or placebo with FLOT followed by adjuvant durvalumab or placebo in patients with resectable GC/GEJC. **Methods:** Approximately 900 adult patients will be randomized 1:1 to Arm A or Arm B for 2 neoadjuvant and 2 adjuvant cycles (single cycle defined as durvalumab or placebo every 4 weeks [Q4W] + FLOT [Q2W $\times$ 2]); followed by durvalumab or placebo Q4W for 10 cycles. Eligible patients must have histologically confirmed, resectable, stage II or higher GC or GEJC not treated with anticancer therapy, ECOG performance status 0 or 1, and adequate organ function. Complete surgical resection of the primary tumor must be achievable. A tumor tissue sample will be taken at screening or $<$3 months prior to enrollment. Key exclusion criteria are any prior immune-mediated therapy, peritoneal dissemination or distant metastasis, (adeno)squamous cell carcinoma, or gastrointestinal stromal tumor. The primary endpoint is event-free survival (EFS) assessed by blinded independent central radiology review (BICR) and/or local pathology testing. Secondary endpoints include OS and pathological complete response rate (pCR). Safety and tolerability will be evaluated by adverse events, vital signs, laboratory parameters, and electrocardiogram. Enrollment is ongoing. Funding: AstraZeneca. Clinical trial information: NCT04592913. Research Sponsor: AstraZeneca.

TPS4152 **Poster Session**

Phase II trial of docetaxel and ramucirumab combination therapy as second-line treatment in patients with metastatic or advanced gastric cancer (HGCSG1903). *First Author: Rika Saito, Division of Cancer Center, Hokkaido University Hospital, Sapporo, Japan*

Background: Paclitaxel and ramucirumab combination therapy had become a standard regimen in the second-line treatment of advanced gastric cancer, since RAINBOW trial showed paclitaxel and ramucirumab combination therapy increased overall survival compared with paclitaxel monotherapy. However, the incidence of neuropathy in paclitaxel and ramucirumab combination therapy has been reported 70.6% and 38.3% in Japanese and western patients, and the toxicity sometimes disturbs treatment continuation. Whereas docetaxel monotherapy used to be one of standard second-line treatment of advanced gastric cancer as well as paclitaxel monotherapy because the phase III trial, COUGAR-2 showed clinical benefit of docetaxel monotherapy. In addition, the combination therapy of docetaxel and ramucirumab was reported to cause neuropathy at an incidence of 21.3% in patients with lung cancer. Based on these results, we hypothesized that the combination therapy of docetaxel and ramucirumab for patients with gastric cancer could be as effective as the paclitaxel and ramucirumab combination therapy and could reduce the incidence of neuropathy. Therefore, we planned to develop new combination chemotherapy with docetaxel and ramucirumab for advanced gastric cancer. **Methods:** To evaluate efficacy and safety of docetaxel and ramucirumab combination therapy, HGCSG1903 study started as a multicenter, non-randomized, single arm, prospective, phase II study in November 2020. The patients with metastatic gastric adenocarcinoma that were refractory or intolerant to initial chemotherapy are eligible. Docetaxel and ramucirumab combination therapy is administered as follows; an intravenous infusion of docetaxel at 60 mg/m^2 on day 1, an intravenous infusion of ramucirumab at 8 mg/kg on day 1 and day 15 of each 4-week cycle is performed. The therapy is repeated until disease progression, unacceptable toxicity, or patient refusal. The primary endpoint is response rate, and the secondary endpoints are overall survival, progression-free survival, safety, and dose intensity for each drug. The response rate is calculated based on the RECIST version 1.1 criteria. Adverse events are evaluated using the CTCAE v5.0 criteria. A hypothesis test of binary probability was performed, with condition that threshold of response rate was set to 10.7% of docetaxel monotherapy in phase III trial and the expected response rate was set to 27.9% of paclitaxel and ramucirumab combination therapy in RAINBOW trial. A minimum number of cases that achieved a detection power of 80% at a one-sided significance level of 5% was calculated to be 32 cases. In anticipation of dropouts, the total number of registration cases was set to 35. Sixteen institutions are participated, and the registration period is 2 years. This study is registered with Japan Registry of Clinical Trials (jRCTs011200010). Clinical trial information: jRCTs011200010. Research Sponsor: Nipro Corporation.

TPS4153 **Poster Session**

Biomarker-oriented study of durvalumab in combination with olaparib and paclitaxel in gastric cancer: A phase 2 trial-in-progress. *First Author: Tae Yong Kim, Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea*

Background: Olaparib (PARP inhibitor) leads to DNA damage and cell death. In phase III study (GOLD), olaparib plus paclitaxel did not improve overall survival (OS) compared with paclitaxel in second-line gastric cancer (GC) patients with statistical significance, even though there was absolute increase of OS (Lancet Oncol 2017). This highlights the importance of biomarker-based patient selection. The changes of tumor microenvironment by paclitaxel/olaparib have not been explored. Besides DNA damage, olaparib induces positive or negative immune modulation by recruiting T cells, promoting type I interferon and upregulating PD-L1, which suggests anti-PD (L1) inhibitor plus olaparib could enhance anti-tumor immunity. Combination of Anti-PD-1 agents with chemotherapy showed a good clinical efficacy in first-line of GC compared with chemotherapy alone (Checkmate 649). Based on these findings, the combination of paclitaxel/olaparib/anti-PD(L1) 1 inhibitor, with different mode of actions, might enhance antitumor activity. This is phase II study of paclitaxel/olaparib/durvalumab combination in second-line GC patients, to find out immune modulation effects by paclitaxel/olaparib combination, and to see the efficacy, safety, optimal biomarkers for this combination. **Methods:** All patients with histologically confirmed unresectable GC have failed to prior one chemotherapy and measurable lesion. Prior exposure to anti-PD(L1)1, PARP inhibitor is excluded. At 1st cycle, paclitaxel (80 mg/m^2) on D1, 8 and 15 and olaparib (150 mg bid) on D1-28 is administered. Pre-treatment biopsy and after first cycle biopsy is done. From second cycle, durvalumab 1500 mg on D1 every 4 weeks is added. At the time of disease progression, tumor biopsy is mandatory. Blood samples for biomarkers should be obtained every cycles. Response evaluation is performed after first 3 cycles and repeated every 2 cycles. Primary endpoint is the disease control rate (the percentage of patients who have achieved complete or partial remission, stable disease based on RECIST v1). Key secondary endpoints are overall response rate, progression-free survival, OS, quality of life and safety. Clinical trial information: NCT03579784. Research Sponsor: AstraZeneca.

TPS4154 **Poster Session**

TGF-β and PD-L1 inhibition combined with definitive chemoradiotherapy in esophageal squamous cell carcinoma: A phase II clinical trial (NCT04595149). *First Author: Linde M. Veen, Department of Medical Oncology, Amsterdam University Medical Centers, location VUMC, Amsterdam, Netherlands*

Background: Esophageal cancer is the 6th leading cause of mortality worldwide, with an overall 5-year survival rate of 10%. This is in part due to more than 50% of patients presenting with irresectable or metastatic disease. With the introduction of definitive chemoradiation, 3-year survival rates of patients with irresectable tumors have risen to up to 40% (Hulshof et al., ASCO GI Oral Presentation, 2020). However, treatment still fails in the majority of patients due to locoregional recurrences or development of metastatic disease. Recently, it has been shown that addition of TGF-β inhibition to chemoradiation may improve treatment efficacy (Steins et al., Int J Cancer, 2019). Additionally, PD-L1 inhibition has emerged as a relevant therapeutic strategy in specific patient subgroups, such as squamous cell carcinoma (Kato et al., The Lancet Oncology, 2019). In this phase II study, we will investigate the feasibility of addition of bintrafusp alfa, a bifunctional fusion protein blocking TGF-β and PD-L1, to definitive chemoradiation in patients with esophageal squamous cell carcinoma. **Methods:** To assess feasibility, 52 patients will receive definitive chemoradiation combined with three doses of bintrafusp alfa at week 1, 4 and 7 (Table). Feasibility is defined as ≥80% of patients completing 2 cycles of bintrafusp alfa and will be tested with a one-sample test for a binomial proportion, comparing the observed percentage to the fixed reference value of unfeasibility (62%). Secondary endpoints are toxicity, progression-free survival, overall survival and quality of life. Additionally, exploratory endpoints include development of biomarkers to predict treatment response. Eligible for inclusion are patients with surgically irresectable (T1-4a N+ M0) squamous cell carcinoma of the esophagus or gastro-esophageal junction, or patients with resectable tumors refraining from radical surgery. Patients with M1 disease solely on the basis of supraclavicular metastasis are eligible. Patients with locoregional recurrences are eligible, provided that full dose of radiation can be safely delivered. Currently, 2 of planned 52 patients have been enrolled. Clinical trial information: NCT04595149. Research Sponsor: Health Holland.

TPS4155 **Poster Session**

MONEO: A phase II study of avelumab (Av) plus FLOT in the peri-operative treatment for patients (pts) with resectable gastric or gastroesophageal junction cancer (GC). *First Author: Maria Alsina, Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background: GC represents a worldwide problem; radical surgery remaining the gold standard of curative treatment. In the West, even with peri-operative chemotherapy, 5-year survival rate is approximately 40%. GC is a heterogeneous disease, well characterized by different molecular classifications, all having in common the role of the immune system and a T-cell inflamed phenotype across all subtypes. The anti-PD-L1 Av antibody has demonstrated efficacy in GC with response rates of around 10% in the refractory setting. The addition of other immune checkpoint inhibitors to chemotherapy have demonstrated efficacy in the metastatic setting. The combination of Av to perioperative chemotherapy may increase pathological responses by a synergistic effect, and then improving the survival (OS). **Methods:** The MONEO is an open-label, non-randomized, multicentric, phase II study that explores the combination of Av plus peri-operative FLOT (docetaxel, oxaliplatin, fluorouracil/leucovorin) in resectable GC pts. EudraCT 2019-000782-21; ClinicalTrials NCT03979131. Main inclusion criteria require pts with histologically proven GC, stage Ib (T1N1 only) - IIIC (7th AJCC Ed), available paraffin block from diagnosis and surgery, evaluable disease (RECIST 1.1) amenable to radical surgery. Significant comorbidities and active autoimmune diseases are excluded. Treatment consists of surgery with 4 peri-operatory cycles of FLOT + Av, followed by Av up to one year. The primary objective is the pathological complete response (pCR) rate, compared to historical data. Secondary objectives include OS, disease-free survival, R0 resection rate, tolerability and biomarker analysis. Key point is the comprehensive biomarker analysis from tissue and blood samples (pathological immune response, TCR clonality, immune contexture characterization, immunodynamic monitoring). Statistics for an estimated 33% pCR (historical 16%), 82% power, 0.1 one-side type I error. 37 pts will be recruited from 10 Spanish centers. The sponsor is Vall d'Hebron Institute of Oncology (VHIO), principal investigators Dr. Melero and Dr. Alsina. In compliance with the Helsinki Declaration. At a data cut-off day of 5th of February 2021, 38 patients have been enrolled, 27 of them have had the surgery. Although the difficulties during the COVID19 pandemia, only two patients had been withdrawn from the study. Clinical trial information: NCT03979131. Research Sponsor: Merck.

TPS4156 **Poster Session**

EORTC 1707 VESTIGE: Adjuvant immunotherapy in patients with resected gastric cancer following preoperative chemotherapy with high risk for recurrence (ypN+ and/or R1)—An open-label randomized controlled phase II study. *First Author: Elizabeth Catherine Smyth, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: Gastroesophageal adenocarcinoma (GEA) patients with metastatic lymph nodes (ypN+) or a microscopically incomplete surgical resection (R1) following neoadjuvant chemotherapy are at high risk of disease recurrence. Current practice is to continue with the same perioperative chemotherapy used prior to surgery, despite these suboptimal outcomes. Adjuvant immunotherapy with nivolumab has shown efficacy in poor risk GEA patients following chemoradiotherapy and surgery in the CheckMate 577 trial, and nivolumab and ipilimumab have demonstrated activity in advanced GEA. We hypothesise that high risk (ypN+ and/or R1) post resection GEA patients who are treated with nivolumab and ipilimumab will have better disease free survival than patients who continue with standard post-operative chemotherapy. **Methods:** VESTIGE is an ongoing, international, open label randomized phase II study designed to evaluate the efficacy of adjuvant nivolumab plus ipilimumab versus standard post-operative chemotherapy in high risk (ypN+ and/or R1) post resection GEA patients. Eligible patients (n=240) will be randomised 1:1 to receive post-operative adjuvant chemotherapy (identical regimen as pre-operatively) or nivolumab 3mg/kg IV q2w plus ipilimumab 1mg/kg IV q6w x 1 year. Key inclusion criteria include ypN + and/or R1 status following neoadjuvant chemotherapy plus surgery and an adequate pre-specified surgical resection. The primary endpoint of the study is disease free survival, with secondary endpoints of overall survival, safety, toxicity and quality of life. Since start of recruitment in August 2019, the trial has recruited 85 of 240 patients at 18 sites in the Czech Republic, France, Germany, Israel, Italy, Norway, Poland, Spain, and United Kingdom. The VESTIGE translational research programme includes collection of pre-treatment biopsies, post-chemotherapy resection specimens and serial liquid biopsy on treatment to explore biomarkers predictive of immune checkpoint blockade efficacy. Clinical trial information: NCT03443856. Research Sponsor: Bristol-Meyers Squibb.

TPS4157 **Poster Session**

A phase II study of short course FOLFOX chemotherapy with either nivolumab (Nivo) or Nivo plus radiation in the first line treatment of metastatic or unresectable gastroesophageal (GEA) cancers. *First Author: Rutika Mehta, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: GEA remains incurable and novel therapies are needed. Studies have shown that cytotoxic chemotherapy can enhance antigenicity of tumors, leading to the recent practice changing studies that demonstrate checkpoint inhibition therapy combined with chemotherapy in PD-L1 overexpressing patients significantly improves patient survival (Keynote-590 and Checkmate-649). But long-term use can also subsequently dampen the immune response. Moreover, the stop-and-go strategy with chemotherapy can maintain patient survival while minimizing chemotherapy related side effects when compared to the traditional strategy of continuous chemotherapy. These observations prompted the inception of this trial with the hypothesis that a short course of FOFLOX therapy combined with immunotherapy will likely have similar activity to that of continuing FOFLOX until disease progression when combined with immunotherapy. We also will examine the hypothesis that low dose radiotherapy can further augment immunotherapy efficacy. **Methods:** This is a multicenter, randomized phase II study examining Nivo alone vs radiation therapy (RT) with Nivo in subjects who did not have disease progression with 3 months of FOLFOX + Nivo. Subjects with advanced unresectable or metastatic GEA cancer are eligible. All subjects will receive FOLFOX + Nivo therapy. Subjects who demonstrate at least stable disease, on their first imaging assessment at 2 months will receive 1 additional month of FOLFOX + Nivo, and then will be randomly assigned at a 1:1 ratio to receive either Nivo alone or Nivo + RT. After 4 mos of therapy, patients who remain on study will receive Nivo Q4WKly. The primary endpoint is to demonstrate that the addition of fractionated radiation to immunotherapy is associated with an improvement in the 12-month progression-free survival (PFS) proportion from 25% (i.e., historical control estimate; Nivo alone; Arm A) to approximately 50% (i.e., with the fractional radiation and Nivo; Arm B). A key secondary aim is to demonstrate that short course FOLFOX of 3 months + Nivo is similar in efficacy to continuing FOLFOX until disease progression. Another secondary aim of this study is to demonstrate safety of the combination of fractionated RT + Nivo. Target sample size is 74 patients. The study is now open at six sites across the United States. Clinical trial information: NCT04021108. Research Sponsor: Bristol Meyers Squibb.

TPS4158 **Poster Session**

A multicenter, randomized phase 1b/2 study of gemcitabine and cisplatin with or without CPI-613 as first-line therapy for patients with advanced unresectable biliary tract cancer (BilT-04). *First Author: Vaibhav Sahai, University of Michigan, Ann Arbor, MI*

Background: Patients (pts) with advanced biliary tract cancers (BTC) have poor prognosis despite systemic chemotherapy. Gemcitabine and cisplatin is a standard first-line systemic therapy with an overall response rate (ORR) of 26% and a median overall survival of 11.7 months. This investigator-initiated, multi-institutional phase 1b/2 trial is designed to investigate the role of gemcitabine, cisplatin and CPI-613 in pts with advanced BTC. CPI-613 is a stable intermediate of a lipoate analog that inhibits pyruvate dehydrogenase and a-ketoglutarate dehydrogenase enzymes of the tricarboxylic (TCA) cycle preferentially within the mitochondria of cancer cells. **Methods:** Key eligibility criteria include histologically confirmed, metastatic or unresectable BTC (intra- or extra-hepatic and gallbladder) without prior systemic treatment, measurable disease per RECIST v1.1, and ECOG PS 0-1. Primary objective of the phase 1b portion (n = 20 pts; TiTE-CRM methodology) is to determine the recommended phase 2 dose of the combination, and for the phase 2 portion, ORR (n = 48-58 pts; 2:1 randomization). Assuming a null hypothesis ORR of 25% and an alternative hypothesis of 43%, this ongoing trial has at least 80% power with a one-sided alpha of 0.05 to identify treatment efficacy of the study arm. Secondary objectives include evaluation of progression-free survival, overall survival, and safety in this patient population. Exploratory objectives include identification of molecular markers of response and resistance in tumor samples and serially collected blood (pre-, on-, and post-therapy), including whole exome/transcriptomic analysis, and immunohistochemical staining (PDK, PDH, KGDH, SOD2 and CD79a). Gemcitabine 1000 mg/m^2, cisplatin 25 mg/m^2 with or without CPI-613 (dose levels: 500 mg/m^2, 1000 mg/m^2, 1500 mg/m^2, and 2000 mg/m^2) will be given IV on days 1 and 8 every 21 days. In the absence of disease progression, pts may continue therapy for up to 2 years. Total accrual goal is 68-78 evaluable pts. To date, 5 of planned 20 pts enrolled on the phase 1b portion are without dose limiting toxicity. Clinical trial information: NCT04203160. Research Sponsor: Rafael Pharmaceuticals, University of Michigan.

TPS4159 **Poster Session**

The IMMULAB trial: A phase II trial of immunotherapy with pembrolizumab in combination with local ablation for patients with early stage hepatocellular carcinoma (HCC). *First Author: Arndt Vogel, Hannover Medical School, Hannover, Germany*

Background: The investigator-initiated IMMULAB study investigates the clinical activity of peri-interventional treatment with the anti-PD1 antibody pembrolizumab in HCC patients who are candidates for local ablation via either radiofrequency ablation (RFA), microwave ablation (MWA) or brachytherapy, or - as recommended for tumor larger than 3 cm – by combination with TACE. Patients with extrahepatic disease are excluded. Local ablation is known to induce tumor destruction with subsequent antigen release resulting in host adaptive immune responses. However, tumors could quickly overcome the immune responses by upregulating PD-L1/PD-1 expression and inhibiting the function of CD8$^+$ and CD4$^+$ T cells. Thus, combination of local ablation with an anti-PD1 antibody might display interesting effects by activating immune cells and disabling immune inhibitory mechanisms at the same time. **Methods:** This is a prospective investigator initiated single-arm multicenter phase II trial investigating immunotherapy with the PD-1 inhibitor pembrolizumab in combination with local ablation in early stage hepatocellular carcinoma (HCC). Patients with a child-pugh classification score $\leq$ 6, including high risk candidates for local ablation (defined as patients having $\leq$ 5 tumor nodules with diameters $\leq$ 7cm [longest axis] each OR patients with vascular infiltration) receive 200mg pembrolizumab i.v. q3w for 2 cycles. Thereafter, radiologic imaging is followed by local ablation on day 1 of cycle 3. Further pembrolizumab (200mg) is applied 2 days after ablation and thereafter every 3 weeks (q3w) for a total treatment duration of up to 12 months. It is planned to enroll 30 pts. Primary efficacy endpoint is the overall response rate (RECIST 1.1) after 2 cycles of pembrolizumab and before performing local ablation aiming in the conversion / downstaging of borderline candidates by pre-interventional treatment with pembrolizumab. Overall recruitment has started; currently (Feb 2021) 18 of 30 planned patients have been enrolled. Clinical trial information: NCT03753659. Research Sponsor: MSD.

TPS4160 **Poster Session**

Camrelizumab plus apatinib combined with TACE and cryoablation in the first-line treatment of advanced hepatocellular carcinoma. *First Author: Wenge Xing, Department of Interventional Therapy, Tianjin Medical University Cancer Institute and Hospital, Key Laboratory of Cancer Prevention and Therapy, National Clinical Research Center for Cancer, Tianjin, China*

Background: Hepatocellular carcinoma (HCC) is a common cancer in the world, a leading cause of cancer-related death, and especially in China. Most of the HCC patients are diagnosed at an advanced stage and require a multidisciplinary approach. The IMbrave 50 trial has reported the successful efficacy of atezolizumab and bevacizumab combination therapy in advanced hepatocellular carcinoma, which indicate the potential efficacy of combination of immunotherapy and antiangiogenesis therapy in HCC patients. In some studies, the combinatorial approaches with immunotherapy and liver directed therapies such as transarterial chemoembolization (TACE), radiofrequency ablation (RFA), microwave ablation (MWA), and cryoablation are explored. Most combined interventional therapies reveal their enormous advantages as compared with any single therapeutic regimen alone, which may result from the immunologic enhancement effect of the multimodel therapy. In this study, we evaluated the efficacy and safety of combined therapy with camrelizumab plus apatinib mesylate and TACE plus cryoablation in patients with advanced HCC. **Methods:** This study was an open-label, single-arm, single centre, phase 2 trial in patients who were diagnosed with advanced HCC. Patients who meet the following criterias will be enrolled: (1) 18 - 75 years old; (2) Child-Pugh classification A or B($\leq$7);(3) Barcelona Clinic Liver Cancer stage B or C, or China liver cancer staging (CNLC) stage IIb~IIIa; (4) Eastern Cooperative Oncology Group Performance Status (ECOG PS) score of 0–1; (5) no history of previous systematic treatment; (6) expected life expectancy of more than 12 weeks; (7) adequate organs function. The key exclusion criteria were history of active autoimmune disease, or concurrent medical use of immunosuppressive medications or immunosuppressive doses of systemic corticosteroids. Eligible patients received camrelizumab 200 mg intravenously every 2 weeks and apatinib 250 mg orally once per day continuously in a treatment cycle of 4 weeks, treatment continued until 1 year or development of unacceptable toxicity or progression of disease. TACE was administrated at the first treatment cycles on day 1or 2, the chemotherapy regimens included 100-150mg oxaliplatin, 750-1000mg fluorouracil, or 30-50 mg lobaplatin, raltitrexed 2-4mg, and epirubicin 40-80 mg. Two or three weeks after the TACE, percutaneous cryoablation was performed under CT guidance. TACE and cryoablation was given as combination therapy and the periods were assessed by the investigator. The primary endpoint is objective response rate (complete or partial response according to mRECIST) and Progression-Free-Survival (Time ranges from random to the first occurrence of disease progression or death from any cause). This trial is registered with Chinese Clinical Trials Registry, ChiCTR2100043044, and is ongoing. Clinical trial information: ChiCTR2100043044. Research Sponsor: None.

TPS4161 **Poster Session**

A phase II trial of trastuzumab plus modified-FOLFOX for gemcitabine/cisplatin refractory HER2-positive biliary tract cancer (BTC): Multi-institutional study of the Korean Cancer Study Group (KCSG-HB19-14). *First Author: Choong-kun Lee, Yonsei Cancer Center, Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea*

Background: Biliary tract cancer (BTC), one of the most fatal cancers with limited treatment options, is generally rare in most high-income countries, but is relatively prevalent in South Korea. Recent genomic profilings have provided druggable molecular targets including HER2 amplification, which accounts for about 15% of total BTC patients. Trastuzumab is a humanized monoclonal antibody against HER2 with known efficacy in patients with HER2-positive breast and gastric cancer, and has not been tested prospectively in patients with HER2-positive BTC. The modified-FOLFOX regimen is currently being tested as a second-line therapy of BTC in phase III ABC-06 trial. This phase II study is investigating the combination of trastuzumab and modified-FOLFOX as second- or third-line treatment in HER2-postivie BTC. **Methods**: This study (KCSG-HB19-14; NCT04722133) is a phase II, multi-institutional, single arm trial to evaluate the efficacy and safety of trastuzumab plus modified-FOLFOX in gemcitabine/cisplatin refractory patients with HER2-positive BTC. The main inclusion criteria are HER2-positive (defined as IHC3+, or IHC2+/ISH+; ISH+ defined as HER2/CEP17 $\geq$2.0, or ERBB2 gene copy number $\geq$ 6.0 by NGS) BTC (intrahepatic cholangiocarcinoma, extrahepatic cholangiocarcinoma, gallbladder cancer and ampulla of vater cancer) patients who progressed on gemcitabine/cisplatin containing chemotherapy (one or two previous cytotoxic chemotherapy lines permitted), ECOG 0 or 1, and adequate organ function. Patients receive trastuzumab-pkrb 4mg/kg (after 6mg/kg load) D1, oxaliplatin 85mg/m^2 D1, leucovorin 200mg/m^2 D1, 5-FU 400mg/m^2 bolus D1, and 5-FU 2400mg/m^2 infusion D1-2 every 2 weeks until unacceptable toxicities or disease progression. The study has a Simon's two-stage design, with objective response rate (ORR) per RECIST v1.1 as primary endpoint. Secondary endpoints included progression-free survival, disease control rate, overall survival, safety, quality of life and correlative biomarker exploration. Additional patients were to be recruited if pre-specified thresholds for ORR are met at the first stage. The study will enroll up to 34 patients and is currently recruiting at eight sites in South Korea. As of February 2021, 16 patients have been enrolled. The pre-specified activity goal for the first stage of accrual was met; second stage accrual began in February 2021. Clinical trial information: NCT04722133. Research Sponsor: Boryung Pharmaceutical, Celltrion, Korean Cancer Study Group.

TPS4162 **Poster Session**

REPLACEMENT trial in progress: Combination therapy with atezolizumab plus bevacizumab for TACE unsuitable patients with beyond up-to-seven criteria in intermediate stage hepatocellular carcinoma: A phase II study. *First Author: Kazuomi Ueshima, Kindai University Faculty of Medicine, Osakasayama, Japan*

Background: Transarterial chemoembolization (TACE) had been developed as a standard of care in patients with intermediate-stage HCC at a time when systemic therapy was not available. This stage includes a certain TACE-unsuitable subpopulation, such as beyond up-to-seven criteria. Recently, the American Association for the Study of Liver Diseases and Asia-Pacific Primary Liver Cancer Expert Meeting have recommended systemic therapy for those patients to achieve overall survival (OS) beyond 2 years without impaired liver function in their consensus guideline. However, there is not enough data on systemic therapy for this population. Atezolizumab (Atezo), anti-PD-L1 antibody, plus Bevacizumab (Bev), anti-VEGF antibody, combination therapy has been shown to significantly improve OS, progression-free survival (PFS), and overall response rate (ORR) against sorafenib, which is a standard of care in unresectable HCC according to a phase III randomized controlled trial, IMbrave150. Therefore, we investigate the efficacy and safety of Atezo+Bev combination therapy in patients with HCC beyond up-to-seven criteria in this trial. **Methods:** REPLACEMENT trial is a multicenter, single-arm phase II study of Atezo+Bev combination therapy. Key eligibility criteria are age ≥20 years, ECOG performance status 0-1, Child-Pugh A, no vascular invasion, no extrahepatic metastasis, beyond up-to-seven criteria, and patients who have received neither systemic therapy nor TACE. Patients will be administrated Atezo 1200 mg/body + Bev 15 mg/kg once every 3 weeks. The primary endpoint is PFS per modified RECIST (mRECIST). The secondary endpoints include PFS, ORR, duration of response (DOR) per mRECIST; PFS, ORR, DOR per RECIST ver.1.1; OS and safety including change of liver function based on albumin-bilirubin (ALBI) score until disease progression. A total of 60 events are necessary to investigate the hypothesis that a target point estimation of PFS rate at 6 months (null population: 55%, alternative population: 73%). The estimated sample size is, therefore, 70 patients. In addition, the results of the Atezo+Bev therapy in this arm will be compared with those in approximately 600 TACE treated consecutive patients with intermediate-stage HCC, using the propensity score matching method, as an exploratory analysis of a possible replacement of TACE by the Atezo +Bev therapy. Patients' enrollment had already started in December 2020, and 12 patients were enrolled as of 16th February '21. Clinical trial information: jRCTs071200051. Research Sponsor: Chugai pharmaceuticals.

TPS4163 **Poster Session**

CaboRISE: A phase II study evaluating reduced starting dose and dose escalation of cabozantinib as second-line therapy for advanced HCC in patients with compensated liver cirrhosis. *First Author: Jorg Trojan, University Hospital, Johann Wolfgang Goethe-University Frankfurt, Frankfurt, Germany*

Background: The multi-targeted tyrosine kinase inhibitor cabozantinib is approved for the treatment of advanced hepatocellular carcinoma (HCC) in adults, who have previously been treated with sorafenib. In the pivotal phase 3 CELESTIAL trial a significant improvement for OS and PFS was shown for cabozantinib in comparison to placebo treated patients (Abou-Alfa GK et al. N Engl J Med 2018; 379:54-63). However, in 62% of patients a dose reduction of cabozantinib was necessary and the median average daily dose was 35.8 mg. The discontinuation rate due to treatment-related adverse events (TRAEs) was 16% and grade 3-4 TRAEs occurred in 68% of patients. For HCC patients treated with sorafenib in first-line, a reduced starting dose of 200 mg BID was not inferior in terms of OS but showed a trend toward a decreased rate of sorafenib discontinuation(Reiss KA et al. J Clin Oncol 2017; 35:3575-3581). The aim of the CaboRISE trial is to study the effect of a reduced starting dose of cabozantinib on tolerability, safety, and efficacy. **Methods:** The CaboRISE trial is an open-label, single arm, multicenter phase II trial, including patients with advanced stage hepatocellular carcinoma (HCC) with compensated liver cirrhosis (Child-Pugh A) in second line treatment, after first line treatment with sorafenib or lenvatinib. Forty evaluable patients will be enrolled in the study to receive a reduced starting dose of 40 mg cabozantinib once-daily for 4 weeks and subsequent dose escalation to 60 mg cabozantinib once-daily to be maintained until disease progression or intolerable toxicities. The objective of the trial is to assess the tolerability of a reduced starting dose of cabozantinib, in order to reduce the treatment discontinuation rates due to treatment-related adverse events below 10%. Primary endpoint is the treatment discontinuation rate due to TRAEs. Secondary endpoints are overall survival, progression free survival at 10 weeks, objective response rate, time on treatment, treatment exposure, toxicity, and quality of life. Study start of the CaboRISE trial was in October 2020. By February 2021, 7 centers across Germany have been initiated and a total of 4 out of 40 planned patients have been enrolled. The study is currently ongoing. This study is financially supported by Ipsen. ClinicalTrials.gov: NCT04522908 EudraCT: 2020-000775-20. Clinical trial information: NCT04522908. Research Sponsor: IPSEN Pharma GmbH.

TPS4164 **Poster Session**

Phase III study of NUC-1031 + cisplatin versus gemcitabine + cisplatin for first-line treatment of patients with advanced biliary tract cancer (NuTide:121). *First Author: Jennifer J. Knox, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: Biliary tract cancer (BTC) is an aggressive disease with a poor prognosis. Gemcitabine + cisplatin (GemCis) is the accepted global standard of care (SoC), however key cancer resistance mechanisms associated with the transport, activation and breakdown of gemcitabine are known to limit its clinical activity across a range of tumor types, including BTC. NUC-1031 is a phosphoramidate transformation of gemcitabine designed to overcome these key resistance mechanisms and generate much higher levels of the active anti-cancer metabolite, dFdCTP, in cells. Promising efficacy has been observed with single-agent NUC-1031 in a phase I study in advanced solid tumors and in the phase Ib ABC-08 study of NUC-1031 + cisplatin for first-line treatment of advanced BTC. Of 21 patients enrolled in 2 dose cohorts (NUC-1031 625 mg/m^2 or 725 mg/m^2 + cisplatin 25 mg/m^2 on Days 1 and 8 of 21-day cycle), 16 were considered to be efficacy evaluable. In this population, 1 patient had a CR and 6 patients had PRs, resulting in an ORR of 44% (7/16). This compares favorably to the 26% ORR reported for the SoC regimen. In addition, 6 patients had SD, resulting in a DCR of 81% (13/16). The combination was well tolerated with no unexpected AEs or DLTs. The recommended dose of NUC-1031 with cisplatin was 725 mg/m^2. The tolerability profile, together with encouraging efficacy led to initiation of a global registrational study. **Methods:** NuTide:121 is a phase III, open-label, randomized study of NUC-1031 + cisplatin vs GemCis for first-line treatment of advanced BTC. Patients ≥18 years with histologically- or cytologically-confirmed BTC (including cholangiocarcinoma, gallbladder, or ampullary cancer), who have had no prior systemic chemotherapy for locally advanced/metastatic disease, are eligible. A total of 828 patients are being randomized (1:1) to either 725 mg/m^2 NUC-1031 or 1000 mg/m^2 gemcitabine, both with 25 mg/m^2 cisplatin, administered on Days 1 and 8 of 21-day cycles. Primary endpoints are OS and ORR. Secondary endpoints include PFS, safety, PK and patient-reported quality of life. In addition to the final analysis, three interim analyses are planned. The study has passed an initial safety analysis, with no protocol changes required. NuTide:121 is being conducted at approximately 130 sites across North America, Europe and Asia Pacific. Clinical trial information: NCT04163900. Research Sponsor: NuCana.

TPS4165 **Poster Session**

First-in-human study of highly selective FGFR2 inhibitor, RLY-4008, in patients with intrahepatic cholangiocarcinoma and other advanced solid tumors. *First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Oncogenic activation of FGFR2 via genomic rearrangement, gene amplification, or point mutation in advanced solid tumors provides the opportunity for rapid clinical development of highly selective FGFR2 inhibitors using a precision oncology approach to deliver clinical benefit to genomically-defined patient (pt) populations. Unfortunately, this opportunity remains largely unrealized as current, non-selective small molecule inhibitors (pan-FGFRi) suffer from off-isoform toxicity (FGFR1-hyperphosphatemia; FGFR4-diarrhea) and on-target acquired resistance leading to only modest efficacy primarily limited to FGFR2-fusion+ intrahepatic cholangiocarcinoma (ICC). RLY-4008 is a novel, oral FGFR2 inhibitor designed to overcome the limitations of pan-FGFRi by potently and selectively targeting primary oncogenic FGFR2 alterations and acquired resistance mutations. We initiated a first-in-human (FIH) precision oncology study of RLY-4008 in advanced solid tumor pts with FGFR2 alterations with primary objectives to define the maximum tolerated dose/recommended phase 2 dose (MTD/RP2D) and adverse event (AE) profile of RLY-4008 and key secondary objectives to assess FGFR2 genotype in blood and tumor tissue, pharmacokinetics (PK), and anti-tumor activity. **Methods:** This is a global, multi-center, FIH dose escalation/expansion study of RLY-4008 (NCT04526106) in adult pts who have unresectable or metastatic solid tumors with FGFR2 alteration per local assessment, ECOG performance status 0-2, measurable or evaluable disease per RECIST 1.1, and who are refractory, intolerant, or declined standard therapy including pan-FGFRi. FGFR2 alteration will be confirmed retrospectively by central laboratory assessment. For the dose escalation (N~50), RLY-4008 is administered QD/BID on a continuous schedule with 4-week cycles according to a Bayesian Optimal Interval design that allows accelerated dose titration, additional accrual to dose levels declared tolerable, and exploration of alternative schedules if warranted. The MTD is determined via logistic regression of the dose limiting toxicity rate across all dose levels and an RP2D less than the MTD may be considered based on observed AEs, PK, and anti-tumor activity. Following dose escalation, the dose expansion (N~75) will treat pts with RLY-4008 at the MTD/RP2D and includes 5 groups with any prior therapy (except group 2): 1. FGFR2 fusion+ ICC pts; 2. FGFR2 fusion+ ICC pts with no prior FGFRi; 3. FGFR2 fusion+ pts with other solid tumors; 4. FGFR2-mutation + solid tumor pts and 5. FGFR2-amplified solid tumor pts. The primary endpoints are MTD/RP2D and AE profile; key secondary endpoints are FGFR2 genotype in blood and tumor tissue, PK parameters; overall response rate, and duration of response per RECIST 1.1. US enrollment began SEP2020 and Europe/Asia start-up is underway. Clinical trial information: NCT04526106. Research Sponsor: Relay Therapeutics.

TPS4166 **Poster Session**

DNA-damage response-umbrella study of the combination of ceralasertib and olaparib, or ceralasertib and durvalumab in advanced biliary tract cancer: A phase 2 trial-in-progress. *First Author: Jee Sun Yoon, Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea*

Background: Ceralasertib (AZD6738) is a selective ATR inhibitor that causes stalled replication forks to collapse, leading to accumulation of double-strand DNA breaks, which is expected to have synergistic anti-tumor effects with immune checkpoint inhibitors (ICI) or PARP inhibitors. First, accumulation of DNA damage by ceralasertib induces tumor cell death, leads to the release of tumor-specific antigen, changing the tumor microenvironment to promote antigen presentation and enhances the anti-tumor effect of ICI. Second, by simultaneously inhibiting two DNA-damage response (DDR) pathways downstream of PARP and ATR, cancer cells are unable to repair damaged DNA, leading to cell death. Ceralasertib has demonstrated promising anti-tumor activity and manageable toxicity in combination with durvalumab or olaparib in solid tumors in a phase 1 study (NCT02264678). In preclinical studies, ceralasertib has shown potent anti-tumor effects in biliary tract cancer (BTC) as a monotherapy and in combination with chemotherapy (Nam, et al, 2019). **Methods:** This is an open-label, phase 2 umbrella study assessing the efficacy of ceralasertib in combination with durvalumab or olaparib in patients with advanced BTC. Eligible patients have histologically confirmed BTC (including intrahepatic or extrahepatic cholangiocarcinoma, gallbladder cancer, or ampullary cancer), have failed at least one chemotherapy and have ECOG performance status of 0-1. Patients who have received prior ICI, ATR or PARP inhibitor are excluded. Each cycle consists of 4 weeks. In ceralasertib /durvalumab cohort, 37 patients will receive durvalumab 1.5g on day 1 and ceralasertib 240mg twice daily on days 15-28. In ceralasertib /olaparib cohort, 37 patients receive ceralasertib 160mg once daily on days 1-7 and olaparib 300mg twice daily on days 1-28. The primary endpoint is disease control rate, with key secondary endpoints including overall response rate, progression-free survival, overall survival, and safety. Tissue and blood samples are being collected for translational biomarker studies. Clinical trial information: NCT04298021. Research Sponsor: None.

TPS4167 **Poster Session**

Assessing safety and activity of cabozantinib combined with lanreotide in gastroenteropancreatic (GEP) and thoracic neuroendocrine tumors (NETs): The phase II LOLA trial. *First Author: Francesca Corti, Medical Oncology Department, ENETS Center of Excellence, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Well-differentiated (WD) NETs are a group of rare neoplasms with limited therapeutic options. New combinations of somatostatin analogs (SSAs) and investigational drugs are warranted to improve clinical outcomes. Cabozantinib (CAB) is an orally administered inhibitor of multiple tyrosine kinases, including c-MET and Vascular Endothelial Growth Factor Receptor 2 (VEGFR2), with a pivotal role in NET pathogenesis. The biological rationale of the synergistic effects of CAB plus SSAs lies in the concomitant modulation of the RAS/MAPK and PI3K/Akt/mTOR pathways both at the level of cancer cells and tumor stroma, leading to enhanced anti-proliferative and anti-angiogenic effects. CAB exhibited encouraging activity in a recent phase II trial of patients with progressive carcinoids and pancreatic (p)NETs (Chan JA et al. *JCO* 2017; 35:4_suppl, 228-228). The LOLA trial is the first prospective phase II study aiming to assess the safety and activity of CAB in combination with lanreotide (LAN) in WD NETs of GEP, thoracic and of unknown origin. Clinical trial information: NCT04427787. **Methods:** This is a multicenter, open-label, double-cohort, non comparative, non-randomized, three-stage phase II trial. Eligible patients have to meet the following inclusion criteria: diagnosis of advanced or metastatic, progressive, non-functioning WD thoracic NETs, GEP-NETs or NETs of unknown origin with Ki67 $\geq$10%; positive 68Ga-PET uptake or somatostatin receptor 2 immunohistochemical (IHC) stain; maximum 1 prior systemic regimen for metastatic disease. Two cohorts will be considered: pNETs and carcinoids. In the stage I, the primary objective is to find the optimal dose of CAB in combination with LAN and to evaluate the safety of the combination (defined as the percentage of patients experiencing grade 3-5 toxicities according to NCI-CTCAE v5.0). Starting dose of CAB is 60 mg/day continuously, plus LAN 120 mg every 28 days. In stage II and III, co-primary endpoints are safety and overall response rate (ORR) according to RECIST v1.1. The useful antitumor activity to be detected is fixed in ORR $>$ 20%. Secondary endpoints are progression-free survival and overall survival. Exploratory objectives include the assessment of IHC expression of c-MET, AXL and VEGFR2, with the aim to identify predictive or prognostic tissue biomarkers. Enrolment started in July 2020, with an expected trial duration of 42 months comprehensive of accrual, treatment and follow-up. Considering a drop out rate of 5%, the maximum number of enrolled patients will be 69. Supported by a solid rationale, the trial has the potential to generate milestone data about the synergistic effects of CAB plus LAN in a group of NET patients with relatively aggressive disease and limited therapeutic options, for whom optimal treatment sequencing is not yet defined. Clinical trial information: NCT04427787. Research Sponsor: Ipsen.

TPS4168 **Poster Session**

Biologically optimized schedule of gemcitabine and nab-paclitaxel regimen in metastatic pancreatic adenocarcinoma. *First Author: Laith I. Abushahin, Ohio State University, Comprehensive Cancer Center, Columbus, OH*

Background: Metastatic pancreatic adenocarcinoma has a poor prognosis, and improvements in therapy have been challenging. Alongside efforts in developing novel agents, there is a need to optimize and maximize the benefit of currently approved drugs. Gemcitabine + nab-paclitaxel is a frequently used regimen for pancreatic adenocarcinoma. Nab-paclitaxel is albumin–bound chemotherapy; hence the role of albumin uptake is critical for its effect. Caveolae are small membrane invaginations essential for transendothelial albumin uptake. Cav-1 is the principal structural component of caveolae. Williams and colleagues have published a series of preclinical studies demonstrating that tumor cell-specific Cav-1 expression directly correlates with albumin and albumin-bound chemotherapy uptake and subsequent apoptotic response in tumor cells. In vitro studies showed that exposure of pancreatic cancer cells to Gemcitabine resulted in up-regulation of Cav-1 peaking 48 hours after gemcitabine exposure. This Cav-1 up-regulation correlated with increased temporal albumin cellular uptake. In addition, Williams and colleagues noted that exposure of pancreatic cancer cell lines to Gemcitabine resulted in a time–specific re-entry of cells into the G2/M phase (nab-paclitaxel cytotoxicity phase) between 48-60 hours after gemcitabine treatment. Collectively this data suggest that infusing nab-paclitaxel after 48 hours of gemcitabine infusion would be optimal for both increased uptake as well as increased susceptible tumor cells. We had previously shown this effect on multiple cell lines as well as mouse models. **Methods:** This is a phase II trial; patients will receive a standard of care chemotherapy regimen consisting of FDA-approved Gemcitabine + nab-paclitaxel with modification of the schedule to deliver nab-paclitaxel 48 hours (2 days) after gemcitabine infusions. The primary endpoint is ORR, with a null hypothesis of 20% vs. a target of 35%. Employing a 2-stage design (minimax) and assuming 80% power and a 0.05 significance level, a total of 53 patients will be required. In the first stage, if at least 7/31 patients respond to therapy, an additional 22 patients will be added for a total of 53 patients. The study will be terminated early if $\leq$ six patients respond in the first stage. Observation of response in at least 16/53 patients would be required to warrant further investigation of this infusion schedule of combination therapy. The secondary endpoints include the safety of the regimen schedule, Relative dose intensity, disease control rate, PFS, and OS. The trial opened to enrollment in June 2020 and is accepting patients. Clinical trial information: NCT04115163. Research Sponsor: The Ohio State University Comprehensive Cancer Center.

TPS4169 **Poster Session**

Camrelizumab combined with ablation and chemotherapy for pancreatic cancer with liver metastases: A single-arm, phase II, prospective clinical study. *First Author: Zhiwei Li, The Affiliated Tumor Hospital of Harbin Medical University, Harbin, China*

Background: Pancreatic cancer represents one of the most aggressive tumors and the majority of patients receive a diagnosis of metastatic disease, mainly in the liver, leading to poor prognosis and survival. Currently, chemotherapy has been the treatment of choice for fit patients with pancreatic cancer liver metastases (PCLM), reaching a median survival of about 5 to 7 months. In addition, local ablation of the metastatic tumors, by increasing neoantigen exposure and transforming the immune microenvironment to reduce the progression of liver metastases, might increase the survival benefit of patients. Camrelizumab, an anti-PD-1 monoclonal antibody, has obtained preliminary results in metastatic pancreatic cancer. Therefore, this study aims to explore the effectiveness and safety of camrelizumab combined with ablation and chemotherapy in the treatment of PCLM. **Methods:** In this single-arm, prospective, phase II study, 34 patients with histological or cytological diagnosis of PCLM, ECOG performance score of 0-1, no prior chemotherapy or the interval of adjuvant chemotherapy $\geq$6 months, plan to be enrolled. The enrolled patients first received ablation surgery of liver metastases, then chemotherapy (the standard regimen for advanced pancreatic cancer, determined by the investigator) combined with camrelizumab (200 mg, iv, q3w) is administered 1 week after ablation. If the patient has multiple metastatic tumors, the ablation needs to be performed in stages. The treatment regimens will continue until the disease progression, unacceptable toxicity or withdrawal of consent. The primary endpoint is 6-month progress-free survival (6-month PFS) rate (per RECIST v1.1 by researcher). Secondary endpoints are objective response rate, disease control rate, progression-free survival, overall survival and safety. On the basis of a threshold 6-month PFS rate of 25%, targeting an expected 6-month PFS rate of 44% and assuming 18 months follow-up, 80% power and a one-sided $\alpha = 0.05$, this design requires 34 evaluable patients to be accrued over 2 years. Clinical trial information: NCT04420130. Research Sponsor: None.

TPS4170 **Poster Session**

A phase II, open-label pilot study evaluating the safety and activity of liposomal irinotecan (Nal-IRI) in combination with 5-FU and oxaliplatin (NALIRIFOX) in preoperative treatment of pancreatic adenocarcinoma (NEO-Nal-IRI study) (NCT03483038). *First Author: Sherise C. Rogers, University of Florida/UF Health Cancer Center, Gainesville, FL*

Background: Neoadjuvant treatment for potentially curable pancreatic cancer (PDAC) is increasing in acceptability, but a standard regimen has yet to be established. Multiple studies have demonstrated feasibility and effectiveness of the FOLFIRINOX (5-fluorouracil, leucovorin, oxaliplatin and irinotecan) regimen in the perioperative setting. However, FOLFIRINOX often requires dose modifications, delays and growth factor support due to excessive toxicity which can complicate care delivery when given neoadjuvantly. Liposomal irinotecan injection (Nal-IRI) is FDA approved with a well-tolerated safety profile in relapsed, refractory metastatic PDAC. The current study aims to substitute Nal-IRI for traditional irinotecan in the standard FOLFIRINOX regimen (NALIRIFOX) and to demonstrate safe and effective neoadjuvant delivery. **Methods:** This phase 2, open-label, multicenter single-arm study focuses on patients (pts) with operable PDAC without metastatic disease. Other key eligibility criteria include age ≥18 years, resectability confirmed by multiD GI tumor board (resectable vs. borderline), adequate cardiac, renal, hepatic function and ECOG performance status of 0 to 1. Pts receive NALIRIFOX regimen as per the table every 2 weeks for four months followed by disease reassessment. Pts who remain surgical candidates will undergo surgical resection within 4 to 8 weeks following last dose of therapy. The primary endpoint is to assess safety and feasibility of regimen in perioperative setting. Secondary endpoints include R0 resection rate, clinical, biochemical and radiological response rate and patient-reported quality of life during treatment as measured by the NCI validated FACT-G scale. Enrollment continues to a maximum of 28 evaluable pts to demonstrate a reduction in historical 30 day postoperative complication rate. NCT03483038. NALIRIFOX regimen components given intravenously (IV) every 14 days. Clinical trial information: NCT03483038. Research Sponsor: Ipsen, University of Florida Health Cancer Center.

TPS4171 **Poster Session**

Total neoadjuvant FOLFIRINOX or gemcitabine-based chemoradiotherapy and adjuvant gemcitabine for resectable and borderline resectable pancreatic cancer (PREOPANC-2): A nationwide multicenter randomized controlled trial. *First Author: Quisette Janssen, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Neoadjuvant therapy has several potential advantages over upfront surgery in patients with localized pancreatic cancer; more patients receive systemic treatment, fewer patients undergo futile surgery, and R0 resection rates are higher, thereby possibly improving overall survival (OS). Two recent randomized trials (including the Dutch PREOPANC trial) have suggested benefit of neoadjuvant chemoradiotherapy over upfront surgery, both including gemcitabine-based chemoradiotherapy regimens. Potentially, the multi-agent FOLFIRINOX regimen (5-fluorouracil with leucovorin, irinotecan, and oxaliplatin) may further improve outcomes in the neoadjuvant setting for localized pancreatic cancer, but randomized studies are needed. The PREOPANC-2 trial investigates whether total neoadjuvant FOLFIRINOX improves OS compared with neoadjuvant gemcitabine-based chemoradiotherapy and adjuvant gemcitabine (i.e. the intervention arm of the PREOPANC trial) in patients with resectable or borderline resectable pancreatic cancer. **Methods:** This nationwide multicenter phase III randomized controlled trial includes patients with pathologically confirmed resectable and borderline resectable pancreatic cancer with a WHO performance score of 0 or 1. Resectable pancreatic cancer is defined as no arterial and ≤90 degrees venous involvement; borderline resectable pancreatic cancer is defined as ≤90 degrees arterial and ≤270 degrees venous involvement without occlusion. Patients receive 8 cycles of neoadjuvant FOLFIRINOX chemotherapy followed by surgery without adjuvant treatment (arm A), or 3 cycles of neoadjuvant gemcitabine with hypofractionated radiotherapy (36 Gy in 15 fractions) added during the second cycle, followed by surgery and 4 cycles of adjuvant gemcitabine (arm B). The primary endpoint is OS by intention-to-treat. Secondary endpoints include progression-free survival, quality of life, resection rate, and R0 resection rate. To detect a hazard ratio of 0.70 with 80% power, 252 events are needed. The number of events is expected to be reached after inclusion of 368 eligible patients, assuming an accrual period of 3 years and 1.5 years follow-up. Between June 2018 and January 2021, 375 patients were enrolled in 20 centers in the Netherlands and accrual is complete. Final analyses are expected at the end of 2022. Netherlands Trial Register: NL7094. Clinical trial information: NL7094. Research Sponsor: Dutch Cancer Society and ZonMW.

TPS4172 **Poster Session**

Australasian Gastro-Intestinal Trials Group (AGITG) MASTERPLAN: Randomized phase II study of modified neoadjuvant FOLFIRINOX alone or in combination with stereotactic radiotherapy (SBRT) for patients with high-risk and locally advanced pancreatic cancer. *First Author: Andrew Oar, Gold Coast University Hospital, Southport, Australia*

Background: Eighty per cent of patients with non-metastatic pancreatic cancer have high-risk, borderline resectable (BRPC) or locally advanced pancreas cancer (LAPC), conferring a 5-year overall survival of only 12%. MASTERPLAN evaluates the safety and activity of stereotactic body radiotherapy (SBRT) added to neoadjuvant chemotherapy in these patient cohorts. **Methods:** MASTERPLAN is an investigator-initiated prospective multi-centre randomized phase II trial. Inclusion criteria include histologically confirmed high-risk, BRPC or LAPC. High risk is defined as tumour > 4cm, extrapancreatic extension or node positive. Randomisation is 2:1 to chemotherapy + SBRT (investigational arm) or chemotherapy (control arm) by minimisation with stratification by operability (potentially operable - high risk; BRPC versus inoperable – LAPC; medically inoperable), planned chemotherapy and institution. Both treatment arms receive 6 x 2 weekly cycles of modified FOLFIRINOX (mFOLFIRINOX). Gemcitabine and *nab*-paclitaxel is permitted if mFOLFIRINOX is unsuitable. The investigational arm receives SBRT (40Gy in 5 fractions) with real time quality assurance. Resectability will be evaluated following initial chemotherapy +/- SBRT. Adjuvant chemotherapy is 6 cycles (12 weeks) of mFOLFIRINOX, or the same duration of gemcitabine and capecitabine (GEMCAP) if neoadjuvant gemcitabine/*nab*-paclitaxel given. SBRT adverse events (AEs) will be recorded until study cessation. The primary endpoint is 12-month locoregional control. Secondary endpoints: safety, surgical morbidity and mortality, radiological response rate, progression free survival, pathological response rate, surgical resection rate, R0 resection rate, quality of life, deterioration free survival and overall survival. Biospecimens are collected for translational research for potential prognostic/predictive biomarkers of clinical endpoints and include serial tumour tissue collection from patients undergoing fiducial marker insertion and/or surgery, biopsy at disease progression, serial blood collection and serial buccal and faecal sample collection. An interim analysis will review locoregional failure, distant metastasis and rate of death on the first 40 patients after completion of 12 months follow up. The sample size is 120 patients (80 intervention:40 control), balanced for BRPC/LAPC (60 in each cohort). The minimum follow up is 12 months. The first site opened in October 2019 and 10 patients have been recruited from five sites at 17 Feb 2021. Overall 15 sites in Australia and New Zealand are planned to open to recruitment. Australian Clinical Trials Registry Number: ACTRN12619000409178. Clinical trial information: ACTRN12619000409178. Research Sponsor: Medical Research Future Fund (MRFF).

TPS4173 **Poster Session**

Phase II study of the anti-TGF-β1 monoclonal antibody (mAb) NIS793 with and without the PD-1 inhibitor spartalizumab in combination with nab-paclitaxel/gemcitabine (NG) versus NG alone in patients (pts) with first-line metastatic pancreatic ductal adenocarcinoma (mPDAC). *First Author: Peter Grell, Masaryk Memorial Cancer Institute, Brno, Czech Republic*

Background: Overall survival remains low for pts with mPDAC despite approved therapies, highlighting the need for further innovative treatment options. Intra-tumoral fibrosis that characterizes PDAC has been associated with a state of immune exclusion and may constitute a mechanical obstacle to the penetration of chemotherapy into the tumor as well as contribute to the lack of efficacy of immunotherapy. TGF-β plays a key role in regulating the tumor microenvironment and emerging evidence points to TGF-β as a pivotal activator of cancer-associated fibroblasts, leading to the development of fibrotic networks. Preclinical data in murine models have shown that TGF-β blockade augmented the benefit of both NG and anti-PD-1 therapy, leading to tumor regression. These data provide the rationale for combining TGF-β-targeting agents with immunotherapy and chemotherapy. NIS793 is a human IgG2 mAb that binds to TGF-β. This study investigates NIS793 with and without spartalizumab combined with NG in treatment nave mPDAC. **Methods:** This is a phase II open-label, randomized, multicenter study (NCT04390763) beginning with a safety run-in period followed by randomization. Eligible pts are adults with previously untreated mPDAC and an ECOG performance status ≤1. Pts are excluded if they have a tumor histology other than adenocarcinoma or microsatellite instability-high tumor. The safety run-in data will be analyzed after ≥6 pts have received NIS793 (intravenously [IV] 2100 mg Q2W) + spartalizumab (IV 400 mg Q4W) + nab-paclitaxel (IV 125 mg/m^2 on Days 1, 8 and 15) + gemcitabine (IV 1000 mg/m^2 on Days 1, 8 and 15) for 1 cycle (28 days) to assess the safety and tolerability of the combination and confirm the dose for the randomized part. Pts will be randomized 1:1:1 to NIS793 + spartalizumab + NG (n=50) or NIS793 + NG (n=50) or NG (n=50). Treatment will continue until unacceptable toxicity, disease progression, discontinuation by investigator's or pt's choice, or withdrawal of consent. The primary objective is to evaluate the progression-free survival of NIS793 + NG ± spartalizumab versus NG alone. Secondary objectives include safety and tolerability, antitumor activity, overall survival, change in CD8 and PD-L1 status, and characterization of immunogenicity and pharmacokinetics. Efficacy will be assessed locally per RECIST v1.1 and iRECIST at screening, every 8 weeks for 1 year and then every 12 weeks until disease progression. Blood and tumor samples will be taken at baseline and during study treatment for pharmacokinetic, immunogenicity and biomarker assessments. This study is ongoing and will enroll pts from 30 sites across 15 countries. The first pt was treated on October 22, 2020. Clinical trial information: NCT04390763. Research Sponsor: Novartis.

TPS4174 **Poster Session**

Trial in progress: Open-label, randomized, comparative phase 2/3 study of combination immunotherapy plus standard-of-care chemotherapy and SBRT versus standard-of-care chemotherapy for the treatment of locally advanced or metastatic pancreatic cancer. *First Author: Tara Elisabeth Seery, Chan Soon Shiong Institute for Medicine, El Segundo, CA*

Background: Pancreatic cancer will claim an estimated 47,050 lives in the USA in 2020, with an expected 5 year survival of 10%. Thus there is an urgent need for novel treatment options in this disease. We hypothesize that effective response against pancreatic cancer requires a coordinated approach that orchestrates both the innate and adaptive immune system. We further hypothesize that by orchestrating the activation of the entire immune system, we could accomplish immunogenic cell death with durable responses in this disease. We describe a novel combination immunotherapy protocol of low-dose chemoradiation, cytokine-induced NK and T cell activation via N-803 (an IL-15 cytokine fusion protein), and off-the-shelf PDL1-targeted high-affinity NK cell (PDL1 t-haNK) infusion. **Methods:** The ongoing QUILT 88 phase II/III, multi-center, three-cohort, open-label, US study (NCT04390399) to evaluate the comparative efficacy and overall safety of standard-of-care chemotherapy versus standard-of-care chemotherapy in combination with aldoxorubicin HCl, N-803, and PD-L1 t-haNK in subjects with locally advanced or metastatic pancreatic cancer. Each treatment setting (ie, first line maintenance, second line, or third line or greater) will be evaluated independently as a separate cohort. Subjects with locally advanced or metastatic pancreatic cancer who have received at least 16 weeks of treatment with gemcitabine plus nab-paclitaxel, and have had either a partial response (PR), CR, or stable disease (SD), will be enrolled into Cohort A to receive first-line maintenance therapy. Subjects who have disease progression on or after receiving first-line treatment with gemcitabine plus nab-paclitaxel or another first-line chemotherapy regimen (eg, FOLFIRINOX), or who have discontinued first-line treatment (eg, due to toxicity or intolerance) will be enrolled into Cohort B to receive second-line therapy randomized to irinotecan-liposome/5FU/LV versus experimental arm. Subjects who have disease progression after receiving at least 2 lines of therapy for pancreatic cancer, will be enrolled into Cohort C to receive third-line or greater treatment. Primary endpoints by cohort are: A) PFS per RECIST V1., B & C) OS. The secondary endpoints include overall response rate, DoR, DCR, OS(cohort A) and QoL by patient-reported outcomes. Clinical trial information: NCT04390399. Research Sponsor: ImmunityBio.

TPS4175 **Poster Session**

GRECO-2: A randomized, phase 2 study of stereotactic body radiation therapy (SBRT) in combination with GC4711 in the treatment of unresectable or borderline resectable nonmetastatic pancreatic cancer (PC). *First Author: Sarah E. Hoffe, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: While systemic treatment of PC has improved, rates of surgical resection - considered optimum treatment - remain low. Patients with un-resectable or borderline PC still have poor outcomes, with both toxicity and disease progression during induction chemotherapy limiting the number eligible for surgery. SBRT practice to enhance margin negative resection or to provide local control, if inoperable after neoadjuvant therapy, has shifted to higher dose delivery (Mellon 2015, Colbert 2018), but timing and appropriate patient selection are under constant debate. SBRT delivery over 50Gy exhibits superior cell killing compared to conventionally fractionated RT but carries potential GI toxicity risk (Zhong 2017). GC4711 is a selective superoxide dismutase mimetic that converts superoxide to hydrogen peroxide. As radiation response modifiers, dismutase mimetics have the potential to increase tumor control without compromising radiation safety (Sishc, AACR 2019). GC4711 consistently augmented tumor control by SBRT in PC experimental xenograft mouse models. In a pilot phase 1/2 trial (GC4419-101), subjects with locally advanced PC were randomized to receive SBRT plus either the selective dismutase mimetic GC4419 or placebo. This pilot trial has demonstrated acceptable safety with SBRT (5×10-11Gy), as well as apparent improvements in survival, surgical resection, locoregional control, and time to distant metastases. Altogether, these data support the hypothesis that GC4711 may improve tumor outcomes and the benefit-risk ratio of 5-fraction SBRT delivering 50Gy by improving efficacy without increasing GI-toxicity. **Methods:** GRECO-2 is a phase 2, multicenter, randomized, double-blind, placebo-controlled study to determine the effect on overall survival of adding GC4711 to SBRT following 4 months of chemotherapy in subjects with un-resectable or borderline non-metastatic PC. Approximately 160 subjects will be enrolled at over 20 sites to receive GC4711 100 mg or placebo IV given as IV infusion over 15 min, prior to each of 5 SBRT fractions of 10Gy). Subjects judged operable will be explored within 8 weeks after SBRT. All subjects will complete 2 additional months of adjuvant chemotherapy. Primary end point is overall survival and secondary endpoints address resection rates, local and distant disease progression, and safety, while exploratory studies include ctDNA, tumor exome/transcriptome sequencing, and immune profiling, patient-reported symptoms (PRO-CTCAE), CA19.9 normalization, and radiomics. Colbert L, Rebueno N, Moningi S et al Advances in Radiation Oncology (2018) 3, 693-700 Mellon EA, Hoffe SE, Springett GM, et al Acta Oncologica, 2015;54:7 Zhong J, Patel K, Switchenko J, et al. Cancer. 2017 Sep 15;123(18):3486-3493. Sishc BJ, Saha D, Story MD. AACR PADC 2019 C52. Clinical trial information: NCT04698915. Research Sponsor: Galera Therapeutics.

TPS4176 **Poster Session**

A phase II open-label study of cpi-613 in combination with modified (m) FOLFIRINOX in patients with locally advanced pancreatic cancer. *First Author: David Lawrence Bajor, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: For patients with locally advanced pancreatic cancer, neoadjuvant trials are the preferred strategy. The goals of neoadjuvant treatment are to diminish the size of the primary tumor to allow for safe surgical resection and to limit the chance of developing metastatic disease. mFOLFIRINOX is the gold-standard for treatment in the adjuvant setting and an acceptable regimen in the neoadjuvant setting with many ongoing neoadjuvant trials using it as a chemotherapeutic backbone. CPI-613 (devimistat) is a small-molecule inhibitor of pyruvate dehydrogenase and alpha-ketogluterate dehydrogenase that has been studied in combination with mFOLFIRINOX in a phase I trial of patients with metastatic pancreas cancer and shown to be safe at the proposed phase II dose. **Methods:** This is a single-center, single-arm phase II trial for patients with locally advanced pancreatic cancer; defined as either borderline resectable or unresectable according to NCCN guidelines and interpreted by the primary investigator. Patients with metastatic disease are excluded. Patients will receive treatment with CPI-613 and mFOLFIRINOX per the table below. The primary endpoint is overall survival. Secondary endpoints are progression free survival and resection rate. At the time of submission this study has completed initial accrual with 37 patients enrolled. Clinical trial information: NCT03699319. Research Sponsor: Rafael Pharmaceuticals Inc.

Drug	Dose	Days given of 14 day cycle
Devimistat/CPI-613	500 mg/m2	Days 1,3
5-Fluorouracil	400 mg/m2 as bolus	Day 1
Leucovorin	400 mg/m2	Day 1
Oxaliplatin	65 mg/m2	Day 1
Irinotecan	140 mg/m2	Day 1
5-Fluorouracil	2400 mg/m2 as continuous infusion	Day 1-3

4500 **Oral Abstract Session**

Pembrolizumab (pembro) plus axitinib (axi) versus sunitinib as first-line therapy for advanced clear cell renal cell carcinoma (ccRCC): Results from 42-month follow-up of KEYNOTE-426. *First Author: Brian I. Rini, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: In the first interim analysis of the randomized, multicenter, open-label, phase 3 KEYNOTE-426 study (NCT02853331), treatment with pembro + axi significantly improved OS, PFS, and ORR vs sunitinib monotherapy in treatment-naive advanced ccRCC. Extended follow-up (median, 30.6 mo) continued to demonstrate the superior efficacy of pembro + axi vs sunitinib monotherapy in this patient population. Here, we present the results of the prespecified final analysis with 42.8-mo median follow-up. **Methods:** Treatment-naive patients (pts) with advanced ccRCC, KPS ≥70%, and measurable disease (RECIST v1.1) were randomly assigned 1:1 to receive pembro 200 mg IV Q3W for up to 35 doses + axi 5 mg orally BID or sunitinib 50 mg orally QD on a 4-wk on/2-wk off schedule until progression, intolerable toxicity, or withdrawal. Randomization was stratified by IMDC risk (favorable vs intermediate vs poor) and geographic region (North America vs Western Europe vs Rest of World). Dual primary endpoints were OS and PFS. Secondary endpoints were ORR, DOR, and safety. The protocol-specified final analysis was based on a target of 404 OS events. No formal hypothesis testing was performed because all efficacy endpoints were met previously at the first interim analysis; nominal *P* values are reported. **Results:** Overall, 861 pts were randomly assigned to receive pembro + axi (n=432) or sunitinib (n=429). Median duration of follow-up, defined as time from randomization to the database cutoff date, was 42.8 mo (range, 35.6-50.6). At data cutoff, 418 pts had died: 193 (44.7%) of 432 pts in the pembro + axi arm vs 225 (52.4%) of 429 pts in the sunitinib arm. Compared with sunitinib, pembro + axi improved OS (median: 45.7 vs 40.1 mo; HR, 0.73 [95% CI, 0.60-0.88]; $P<0.001$) and PFS (median: 15.7 vs 11.1 mo; HR, 0.68 [95% CI, 0.58-0.80]; $P<0.0001$). The 42-mo OS rate was 57.5% with pembro + axi vs 48.5% with sunitinib; the 42-mo PFS rate was 25.1% with pembro + axi vs 10.6% with sunitinib. For pembro + axi vs sunitinib, ORR was 60.4% vs 39.6% ($P<0.0001$); CR rate was 10.0% vs 3.5%; median DOR was 23.6 mo (range 1.4+ to 43.4+) vs 15.3 mo (range, 2.3-42.8+). Subsequent anticancer therapy was administered to 47.2% of pts in pembro + axi arm vs 65.5% of pts in sunitinib arm. Although a similar proportion of pts in each arm received VEGF/VEGFR inhibitors, only 10.2% of pts in the pembro + axi arm received subsequent treatment with a PD-1/L1 inhibitor compared to 48.7% of pts in the sunitinib arm. No new safety signals were observed. **Conclusions:** With a median follow-up of 42.8 mo, this is the longest follow-up of an anti-PD–1/L1 immunotherapy combined with a VEGF/VEGFR inhibitor for first-line RCC. These results show that pembro + axi continues to demonstrate superior efficacy over sunitinib with respect to OS, PFS, and ORR, with no new safety signals. Clinical trial information: NCT02853331. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4501 **Oral Abstract Session**

CANTATA: Primary analysis of a global, randomized, placebo (Pbo)-controlled, double-blind trial of telaglenastat (CB-839) + cabozantinib versus Pbo + cabozantinib in advanced/metastatic renal cell carcinoma (mRCC) patients (pts) who progressed on immune checkpoint inhibitor (ICI) or anti-angiogenic therapies. *First Author: Nizar M. Tannir, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Dysregulated metabolism is a hallmark of RCC, driven by overexpression of glutaminase (GLS), a key enzyme of glutamine metabolism. Telaglenastat (Tela) is an investigational, first-in-class, selective, oral GLS inhibitor that blocks glutamine utilization and critical downstream pathways. Preclinically, Tela synergized w/ cabozantinib (Cabo), a VEGFR2/MET/AXL inhibitor, against RCC tumors. In a Ph 1 study cohort, Tela+Cabo showed encouraging safety/efficacy as 2L+ therapy for mRCC. This trial compared Tela+Cabo vs Pbo+Cabo in previously treated pts w/ clear-cell mRCC (NCT03428217). **Methods:** Eligible pts had 1-2 prior lines of systemic therapy for mRCC, including ≥1 anti-angiogenic therapy or nivolumab + ipilimumab (nivo/ipi), KPS ≥70%, measurable disease (RECIST 1.1), no prior Cabo or other MET inhibitor. Pts were randomized 1:1 to receive Cabo (60 mg PO QD) with either Tela (800 mg PO BID) or Pbo, until disease progression/unacceptable toxicity, and were stratified by prior PD-(L)1 inhibitor therapy (Y/N) and IMDC prognostic risk group. Primary endpoint was progression-free survival (PFS; RECIST 1.1) by blinded independent radiology review. The study was designed to detect a PFS hazard ratio (HR) of 0.69 w/ alpha 0.05 and 85% power. Data cutoff date: August 31, 2020. **Results:** 444 pts were randomized (221 Tela+Cabo; 223 Pbo+Cabo). Baseline characteristics were balanced between arms. Median follow-up was 11.7 mo; 276 pts received prior ICI, including 128 w/ prior nivo/ipi. Median PFS (mPFS) was 9.2 mo for Tela+Cabo vs 9.3 mo for Pbo+Cabo (HR = 0.94; 95% CI: 0.74, 1.21; stratified log-rank P= 0.65) with overall response rates (ORR; confirmed) of 31% with Tela+Cabo vs 28% Pbo+Cabo, respectively. Overall survival was not mature at data cutoff. In a prespecified subgroup analysis in pts w/ prior ICI, mPFS was numerically longer w/ Tela+Cabo than Pbo+Cabo (11.1 vs 9.2 mo, respectively; unstratified HR = 0.77; 95% CI: 0.56, 1.06). In the Pbo+Cabo arm, mPFS was 9.2 mo for pts w/ prior ICI exposure and 9.5 mo for pts without, and ORR was 32% and 20%, respectively; if ICI included nivo/ipi, ORR was 37%. Rates of adverse events (AEs) were similar between arms.Grade 3-4 AEs occurred in 71% of Tela+Cabo pts and 79% of Pbo+Cabo pts and included hypertension (17% vs 18%) and diarrhea (15% vs 13%). Cabo was discontinued due to AEs in 10% of Tela+Cabo pts and 15% of Pbo+-Cabo pts. **Conclusions:** The addition of Tela did not improve the efficacy of Cabo in mRCC in this study. Tela+Cabo was well tolerated with AEs consistent with known risks of both agents. The study provides valuable insight on efficacy outcomes of a contemporary population of pts w/ mRCC who receive Cabo in the 2/3L setting. Clinical trial information: NCT03428217. Research Sponsor: Calithera Biosciences, Inc.

4502 **Oral Abstract Session**

Health-related quality-of-life (HRQoL) analysis from the phase 3 CLEAR trial of lenvatinib (LEN) plus pembrolizumab (PEMBRO) or everolimus (EVE) versus sunitinib (SUN) for patients (pts) with advanced renal cell carcinoma (aRCC). *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: LEN + PEMBRO improved PFS, OS and ORR vs SUN in the first-line treatment of pts with aRCC; LEN + EVE improved PFS and ORR vs SUN (Motzer R et al. *NEJM.* 2021). We report results of a secondary objective of the CLEAR trial comparing the impact of LEN + PEMBRO or EVE vs SUN, on HRQoL. **Methods:** Pts (N=1069) were randomized (1:1:1) to receive LEN 20 mg PO QD + PEMBRO 200 mg IV Q3W; LEN 18 mg + EVE 5 mg PO QD; or SUN 50 mg PO QD (4 wks on/2 wks off). HRQoL was assessed per FKSI-DRS, EORTC QLQ-C30, and EuroQoL EQ-5D-3L, at baseline, on day 1 of subsequent 3 wk cycles starting with cycle 2, and at the off-treatment visit. HRQoL analyses (unless otherwise noted) were based on data from randomized pts with any HRQoL data who received ≥1 dose of study treatment. No adjustments for multiple testing or estimation were used; *P*-values and CIs are nominal and descriptive. **Results:** For comparisons of LEN + PEMBRO vs SUN, overall changes from baseline at mean follow-up (wk 46) favored LEN + PEMBRO with significant differences between treatments for physical functioning (least squares mean difference [LS MD] [95% CI]: 3.0 [0.5, 5.5]) and fatigue (−2.8 [−5.5, −0.1]), dyspnea (−2.8 [−5.3, −0.3]), and constipation (−2.2 [−4.2, −0.2]). LS MD of the FKSI-DRS total score was 0.2 (−0.4, 0.7). For comparisons of LEN + EVE vs SUN, overall changes from baseline at wk 46 favored SUN with significant differences in overall HRQoL (−2.8 [−5.1, −0.5] assessed by the EORTC QLQ-C30 GHS/QoL scale) and pain (2.8 [0.1, 5.5]), appetite loss (4.2 [1.3, 7.1]), and diarrhea (5.3 [2.6, 7.9]). LS MD of the FKSI-DRS total score was −0.4 (−1.0, 0.2). 14 of 18 scales for both LEN + PEMBRO and LEN + EVE vs SUN had no significant differences in LS MD comparisons. The LEN + PEMBRO arm is favored over SUN for the median time to first deterioration (TTD) for physical functioning, dyspnea, appetite loss and EQ-5D VAS (Table). 15 of 19 scales for both LEN + PEMBRO and LEN + EVE vs SUN had no significant differences in TTD comparisons. **Conclusions:** Compared with SUN, pts in LEN + PEMBRO group had similar or better symptoms and HRQoL. Clinical trial information: NCT02811861. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Time to first deterioration.

	Median TTD, wks			HR (95% CI)	
Scale	LEN + PEMBRO	LEN + EVE	SUN	LEN + PEMBRO vs SUN	LEN + EVE vs SUN

*Statistically significant log-rank difference of distribution of TTD ($P<0.05$) vs SUN.

4503 **Oral Abstract Session**

Phase 2 trial of gemcitabine, cisplatin, plus nivolumab with selective bladder sparing in patients with muscle- invasive bladder cancer (MIBC): HCRN GU 16-257. *First Author: Matt D. Galsky, Division of Hematology and Medical Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Transurethral resection of bladder tumor (TURBT) plus systemic therapy has been known for decades to achieve durable bladder-intact survival in a subset of patients with MIBC but efforts to advance this paradigm have been complicated by (a) lack of prospective studies exclusively testing cisplatin-based neoadjuvant chemotherapy, (b) lack of rigorous methods to define clinical complete response (cCR) and its association with long term outcomes and (c) limited understanding of the role of "salvage" cystectomy. **Methods:** Eligible patients were cisplatin-eligible with cT2-T4aN0M0 urothelial bladder cancer. Patients received 4 cycles of gemcitabine, cisplatin, plus nivolumab followed by clinical restaging including urine cytology, MRI/CT of the bladder, cystoscopy and bladder/prostatic urethral biopsies. Patients achieving a cCR (normal cytology, imaging, and cT0/Ta) were eligible to proceed without cystectomy and receive nivolumab q2 weeks x 8 followed by surveillance; otherwise, patients underwent cystectomy. Coprimary endpoints included (1) cCR rate and (2) ability of cCR to predict 2-year metastasis-free survival (MFS). The key secondary endpoint was the impact of genomic alterations in baseline TURBT (TMB, ERCC2, FANCC, RB1, ATM) on performance of cCR for predicting MFS. The cCR rate coprimary endpoint, and interim analysis of 1-year outcomes, are reported. **Results:** Between 8/2018-11/2020, 76 patients were enrolled at 7 sites (male 79%, median age 69; cT2 = 56% , cT3 = 32% , cT4 = 12%) and 64 (84%) have completed post-cycle 4 restaging; 31/64 achieved a cCR (48%; 95% CI 36%, 61%). The median follow-up of cCR patients is 13.7 months (range, 2.5-24 months). One cCR patient opted for immediate cystectomy (pTaN0M0). Outcomes for the entire cohort are summarized in the table below. Local recurrence has occurred in 8/31 cCR patients and 6 underwent cystectomy (pT0N0 = 1, pTaN0 = 1, pTisN0 =1, pT2N0 = 2, pT4N1 = 1). TMB ≥ 10 mut/Mb (p=0.02) or mutant ERCC2 (p=0.02) were associated with cCR or pT0. **Conclusions:** TURBT + gemcitabine, cisplatin, plus nivolumab achieves stringently defined cCR in a large subset of patients with MIBC. 1-year bladder intact survival is possible though the durability of responses, and role of genomic biomarkers in management algorithms, requires longer follow-up. Clinical trial information: NCT03558087. Research Sponsor: BMS, Other Foundation.

% at 1 year	Group	N	Estimate	95% CI
Alive	Overall	76	92.4%	80.9%, 97.1%
	cCR	31	100%	NA
	Non-cCR	33	87.7%	66.2%, 95.8%
Alive, bladder intact	cCR	31	81.2%	60.4%, 91.7%
	Non-cCR	33	11%	2.9%, 25%
Alive, metastasis free	cCR	31	100%	NA

Alive, local recurrence free	cCR	31	78%	54.6%, 90.3%

4504 **Oral Abstract Session**

Pembrolizumab (pembro) in combination with gemcitabine (Gem) and concurrent hypofractionated radiation therapy (RT) as bladder sparing treatment for muscle-invasive urothelial cancer of the bladder (MIBC): A multicenter phase 2 trial. *First Author: Arjun Vasant Balar, Perlmutter Cancer Center at NYU Langone Health, New York, NY*

Background: Trimodality bladder preservation therapy (TMT) is a standard treatment option for clinically localized MIBC with curative intent. Pembro has shown activity in MIBC in the neoadjuvant setting and may combine well with TMT to improve outcomes. This trial evaluated the safety and efficacy of pembro added to TMT in MIBC. **Methods:** This multicenter phase 2 trial included pts with cT2 – T4aNOM0 MIBC who declined or were ineligible for cystectomy (RC), ECOG PS 0/1, eGFR > 30 cc/min, and no contraindications to pelvic RT or pembro. No perioperative chemotx for MIBC was permitted. Pts received pembro 200 mg x 1 followed 2-3 weeks by maximal TURBT and then whole bladder RT (52 Gy/20 fx; IMRT preferred) with twice wkly gem 27 mg/m2 and pembro Q3 wks x 3 treatments. 12 wks post-RT, CT/MR AP, TUR of tumor bed and cytology were performed to document response. Up to 6 pts were enrolled to a safety cohort (SC) followed by 48 pts in efficacy cohort (EC). The primary endpt is 2-yr bladder-intact disease-free survival (BIDFS: first of MIBC or regional nodal recurrence, distant metastases, or death) assessed by serial cysto/cytology and CT/MRI. EC had 85% power to detect a 20% absolute improvement in 2-yr BIDFS rate over 60% historical rate (RTOG Pooled analysis; Mak JCO 2014). Key secondary endpts were safety, 12 wks CR rate, metastases-free survival and overall survival. Tumor tissue was collected at study entry, maximal TURBT and post-treatment TUR of tumor bed with serial PBMCs for correlative analyses. **Results:** From 5/2016 to 10/2020, 54 pts (6 SC, 48 EC; 72% M) enrolled at 5 centers; Median age 67 (65-89) for SC and 74 (51-97) for EC. C-stage (74% cT2, 22% cT3, and 4% cT4). 39 (72%) declined RC. All 6 pts in SC and 42/48 (88%) of EC pts completed all study therapy; 1/48 (2%), 2/48 (4%), and 4/48 (8%) discontinued RT/Gem, Gem or Pembro, respectively, most often due to toxicity. As of 1/2021 (median F/U 40.9 mos (38.6-50.8) SC and 11.7 mos (0.6 – 32.2) EC), no recurrences in SC, and 12/48 EC pts had any recurrence (6 NMIBC, 0 MIBC, 2 regional and 4 distant). The estimated 1 yr BIDFS rate is 77% (95% CI: 0.60-0.87). 12 wks CR rate was 100% in SC and 83% for EC (1 PR, 3 NR, 1 Progression, 11 NE; 2 still on active study). In the EC, 35% of pts had a Gr ≥3 TEAE (Gr 3 events included UTI 8%, diarrhea 4%, colitis 4%, bladder pain/obstruction 4%, neutropenia 2%, thrombocytopenia 2%). Notable Pembro Gr ≥3 TRAE included 3 pts (6%) Gr 3 GI toxicity and 1 pt Gr 4 colonic perforation. 1 patient died due to fungemia, unrelated to study therapy. **Conclusions:** Pembro added to hypofractionated RT and twice weekly gem was well-tolerated with promising efficacy in this early analysis. Pembro-related toxicity was consistent with prior monotherapy trials. Selected correlative analyses from serially collected blood and tissue specimens will be presented. Clinical trial information: NCT02621151. Research Sponsor: Merck, U.S. National Institutes of Health.

4505 **Oral Abstract Session**

Phase II trial of durvalumab plus tremelimumab with concurrent radiotherapy (RT) in patients (pts) with localized muscle invasive bladder cancer (MIBC) treated with a selective bladder preservation approach: IMMUNOPRESERVE-SOGUG trial. *First Author: Xavier Garcia del Muro, Medical Oncology. Institut Català d'Oncologia (ICO) L'Hospitalet del Llobregat, Barcelona, Spain*

Background: Bladder-preserving combined-modality therapies constitute an alternative to radical cystectomy for selected pts with MIBC. In preclinical studies, combination of radiation and dual checkpoint blockade appears to activate non-redundant immune mechanisms, potentiating antitumor activity. The purpose of the present study is to explore feasibility, toxicity and activity of this approach in MIBC. **Methods:** Pts with localized MIBC in clinical stages T2-4a N0 M0, ECOG 0-1, without contraindications to immunotherapy, who either wished for bladder preservation or were ineligible for cystectomy, were included in this phase II study. Treatment consisted of initial transurethral resection (TUR) of the tumor, followed by durvalumab 1,500 mg i.v. plus tremelimumab 75 mg i.v., every 4 weeks for 3 doses. Normofractionated external-beam RT was started 2 weeks later, at doses of 46 Gy to minor pelvis and 64-66 Gy to bladder. Pts with either residual or relapsed MIBC were offered salvage cystectomy. The primary endpoint was complete response (CR) defined as absence of MIBC at post-treatment tumor site biopsy. A 2-stage sequential design was used (CR rate P0=5, P1=0.7, α=0.10, β=0.20) requiring at least 6 CR in the first 12 pts to expand to a second cohort of 20 pts. **Results:** From 1/2019 to 8/2020, 32 pts were enrolled at 6 centers. Median age was 71 years (49-91). PS was 0 in 24 pts,1 in 8. 25 were males. Clinical stage was T2 in 28 pts, T3 in 3 and T4a in 1. All pts received at least two immunotherapy cycles. The median dose of RT administered was 64 Gy (60-65). CR at post-treatment biopsy was documented in 26 (81%) pts, 2 pts had residual MIBC and 4 pts were not evaluated due to rejection (1), clinical impairment (1), death from COVID 19 (1) and a suspected treatment-related death from peritonitis (1). After a median follow up of 6.1 months (2.5 - 20.1), 2 pts underwent salvage cystectomy because of MIBC and T1 relapses, respectively. The estimated 6-months rates for disease-free survival (DFS) with bladder intact, DFS and overall survival were 76% (95%CI, 61%-95%), 80% (95%CI, 66%-98%) and 93% (95%CI, 85%-100%), respectively. A total of 31 (97%) pts experienced adverse events related to RT and/or immunotherapy, with diarrhea (41%) and urinary disorders (37.5%) as the most frequent. Grade 3 or 4 adverse events related to therapy were reported in 31% pts, being the most frequent gastrointestinal toxicity (12.5%), acute kidney failure (6%) and hepatitis (6%). **Conclusions:** A combined-modality approach including durvalumab + tremelimumab with concurrent RT is feasible and safe, showing high efficacy in terms of response and eliciting bladder preservation in a large number of pts. Further research on this approach as an alternative to cystectomy is warranted. Clinical trial information: NCT03702179. Research Sponsor: AstraZeneca, Spanish Oncology Genitourinary Group (SOGUG).

4507 **Oral Abstract Session**

A randomized phase II study comparing cisplatin and gemcitabine with or without berzosertib in patients with advanced urothelial carcinoma. *First Author: Sumanta K. Pal, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Cisplatin with gemcitabine (CG) remains the standard upfront chemotherapy regimen for metastatic urothelial cancer (mUC). Preclinical synergy was noted between cisplatin and berzosertib, a selective ATR inhibitor. The current study sought to determine if the combination of berzosertib and CG could improve clinical outcomes in mUC. **Methods:** An open-label, randomized study was conducted across 23 centers in the United States through the Experimental Therapeutics Clinical Trials Network of the National Cancer Institute. Key eligibility criteria included confirmed mUC, no prior cytotoxic therapy for metastatic disease, ≥ 12 months since perioperative therapy and eligibility for cisplatin based on standard criteria. Patients (pts) were randomized to receive either CG alone (control arm) or CG plus berzosertib (experimental arm). In the control arm, 70 mg/m^2 of cisplatin was given on day 1 and gemcitabine at 1000 mg/m^2 on days 1 and 8 of a 21-day cycle. In the experimental arm, 60 mg/m^2 of cisplatin was given on day 1, gemcitabine at 875 mg/m^2 on days 1 and 8 and berzosertib at 90 mg/m^2 on days 2 and 9 of a 21-day cycle. The primary endpoint of the study was progression-free survival (PFS), with secondary endpoints including response rate (RR), overall survival (OS) and toxicity. **Results:** A total of 87 pts (median age 67; M:F 68:19) were randomized; 41 pts received CG alone while 46 received CG with berzosertib. Visceral metastases were present in 49% of pts and 52%, 45% and 3% of pts were Bajorin risk 0, 1 and 2, respectively. Median PFS was 8.0 months for both arms (Bajorin risk adjusted hazard ratio [HR] 1.22, 95% confidence interval [CI] 0.72-2.08). RR was 54%(4 CR, 21 PR) in the CG with berzosertib arm and 63% (4 CR, 22 PR) in CG alone arm (P = 0.66). Median OS was shorter with CG with berzosertib as compared to CG alone (14.4 versus 19.8 months; Bajorin risk adjusted HR 1.42, 95%CI 0.76-2.68). Notably higher rates of grade 3/4 thrombocytopenia (59% vs 39%) and neutropenia (37% vs 27%) were observed with CG plus berzosertib compared to CG alone. Higher rates of toxicity-related discontinuation were seen in the experimental arm (24% vs 15%), and the median cumulative cisplatin dose in the experimental arm was 250 mg/m^2, as compared to 370 mg/m^2 in the control arm (P < 0.001). **Conclusions:** No improvement in PFS was observed with the addition of berzosertib to CG, and a trend towards inferior survival was observed. These results suggest caution in reducing the starting dose of cytotoxic therapy to accommodate addition of a myelosuppressive agent, as in the experimental arm of this study. Clinical trial information: NCT02567409. Research Sponsor: U.S. National Institutes of Health.

4508 **Oral Abstract Session**

First-line pembrolizumab (pembro) in cisplatin-ineligible patients with advanced urothelial cancer (UC): Response and survival results up to five years from the KEYNOTE-052 phase 2 study. *First Author: Peter H. O'Donnell, The University of Chicago, Chicago, IL*

Background: Pembro was approvedfor cisplatin-ineligible patients with untreated advanced UC based on initial results of the phase 2 KEYNOTE-052 study (NCT02335424), which showed an ORR of 29%. Updated results after up to 5 years of follow-up are presented. **Methods:** KEYNOTE-052 is a single-arm, multi-site, open-label trial. Patients had advanced or metastatic UC, were cisplatin ineligible (criteria: ECOG PS 2, CrCl ≥30 to ~60 mL/min, grade ≥2 peripheral neuropathy/hearing loss, NYHA class III heart failure), and had not previously received chemotherapy for advanced/metastatic disease. Patients received pembro 200 mg IV Q3W until progression, unacceptable toxicity, withdrawal, or 24 mo of therapy, whichever occurred first. PD-L1 status was determined by combined positive score (CPS, number of PD-L1–staining cells [tumor cells, lymphocytes, macrophages] divided by the total number of viable tumor cells, multiplied by 100); PD-L1–positive was CPS ≥10. The primary end point was confirmed ORR (RECIST v1.1, independent central review). Key secondary end points were duration of response (DOR), OS, and safety. **Results:** Among 370 enrolled patients, median age was 74 y, 315 (85.1%) had visceral disease, and 43 (11.6%) completed 24 mo of therapy. Median time from enrollment to data cutoff (Sep 26, 2020) was 56.3 mo (range, 51.2-65.3) for all patients and 56.0 mo (range, 51.4-65.2) for the 110 patients (29.7%) with CPS ≥10. Confirmed ORR for all patients was 28.9% (95% CI, 24.3-33.8); complete response, 9.5% (n=35); partial response, 19.5% (n=72). Median DOR was 33.4 mo (range, 1.4+ to 60.7+); 44.8% and 39.4% of patients had DOR ≥36 and ≥48 mo, (Kaplan-Meier estimates). Median OS was 11.3 mo (95% CI, 9.7-13.1); 24- and 36-mo OS rates were 31.5% and 22.1%. Patients with CPS ≥10 had better outcomes than patients with CPS <10 (Table). Treatment-related adverse events (AEs) occurred in 67.3% of patients; 21.1% of treatment-related AEs were grade ≥3, including 1 death (myositis). **Conclusions:** After up to 5 y of follow-up, pembro continued to elicit clinically meaningful, durable antitumor activity in cisplatin-ineligible patients with advanced UC. These effects were more pronounced in patients with CPS ≥10. Clinical trial information: NCT02335424. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Nivolumab plus cabozantinib in patients with non-clear cell renal cell carcinoma: Results of a phase 2 trial. *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cabozantinib plus nivolumab (CaboNivo) improved objective response rate (ORR), progression-free survival (PFS), and overall survival (OS) over sunitinib in a phase 3 trial for metastatic clear cell renal cell carcinoma (RCC). (Choueiri, abstract 6960, ESMO 2020) We report the results of a phase 2 trial of CaboNivo in patients (pts) with non-clear cell RCC. **Methods:** Pts had advanced non-clear cell RCC, 0 or 1 prior systemic therapies excluding prior immune checkpoint inhibitors, and measurable disease by RECIST. Cabo 40 mg/day plus Nivo 240 mg every 2 weeks or 480 mg every 4 weeks was given across two cohorts. Cohort 1: papillary, unclassified, or translocation associated RCC; Cohort 2: chromophobe RCC. The primary endpoint was ORR by RECIST; secondary endpoints included PFS, OS, and safety. Cohort 1 was a single stage design that met its primary endpoint and was expanded to produce more precise estimates of ORR. Cohort 2 was a Simon two-stage design that closed early for lack of efficacy. Correlative analyses by next generation sequencing were performed and to be presented. **Results:** A total of 40 pts were treated in Cohort 1, and 7 pts were treated in Cohort 2 (data cutoff: Jan 20, 2021). Median follow up time was 13.1 months (range 2.2 – 28.6). In Cohort 1, 26 (65%) pts were previously untreated, and 14 (35%) pts had 1 prior line: 10 (25%) received prior VEGF-targeted therapy and 8 (20%) received prior mTOR-targeted therapy. ORR for Cohort 1 was 48% (95% CI 31.5–63.9; Table). Median PFS was 12.5 months (95% CI 6.3–16.4) and median OS was 28 months (95% CI 16.3–NE). No responses were seen among 7 patients in Cohort 2 with chromophobe histology (Table). Grade 3/4 treatment emergent adverse events were consistent with that reported in the phase 3 trial; Grade 3/4 AST and ALT were 9% and 15%, respectively. Cabozantinib and nivolumab were discontinued due to toxicity in 17% and 19% of pts, respectively. **Conclusions:** CaboNivo had an acceptable safety profile and showed promising efficacy in metastatic non-clear cell RCC pts with papillary, unclassified, or translocation associated histologies whereas activity in patients with chromophobe RCC was limited. Clinical trial information: NCT03635892. Research Sponsor: Exelixis, BMS.

4510 Poster Discussion Session; Discussed in Poster Discussion Session

Phase II study of nivolumab and salvage nivolumab + ipilimumab in treatment-naïve patients (pts) with advanced non-clear cell renal cell carcinoma (nccRCC) (HCRN GU16-260-Cohort B). *First Author: Michael B. Atkins, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: The HCRN GU16-260 trial reported on the efficacy and toxicity of nivo monotherapy in treatment naïve clear cell RCC (Cohort A) and the efficacy of nivo/ipi salvage therapy in pts with tumors resistant to initial nivo monotherapy (Atkins JCO 2020.38.15_suppl.5006). Limited information is available on the effects of such an approach in pts with advanced nccRCC. **Methods:** Eligible pts with treatment-naïve nccRCC received nivo 240mg IV q2 wk x 6 doses followed by 360mg IV q3 wk x 4 doses followed by 480 mg q4 wk until progressive disease (PD), toxicity, or completion of 96 wks of treatment (Part A). Pts with PD prior to or stable disease (SD) at 48 wks (pSD) were potentially eligible to receive salvage nivo (3mg/kg) /ipi (1 mg/kg) q3 wk x 4 doses followed by q4 wk nivo maintenance for up to 48 wks (Part B). All pts were required to submit tissue from a metastatic lesion obtained within 12 months (mo) prior to study entry and prior to enrolling on Part B for correlative studies. **Results:** 35 pts with nccRCC were enrolled between 5/2017 and 12/2019 at 12 participating HCRN sites. Median age 63 (range 35-84 years); 89% male. IMDC favorable 8 (23%), intermediate 18 (51%) and poor risk 9 (26%). Of the 35 pts 19 (54%) had papillary, 6 (17%) chromophobe and 10 (29%) unclassified histology. RECIST defined ORR was 5 of 35 (14.3%) [CR 2 (5.7%), PR 3 (8.6%)], SD 16 (45.7%), PD 14 (40.0%). Immune-related ORR was 8 of 35 (22.9%). RECIST ORR by histology was: papillary - 1/19 (5%); chromophobe - 1/6 (17%); unclassified - 3/10 (30%). 9 pts (26%) had tumors with sarcomatoid features with 3 (33%) (2 unclassified, 1 papillary) responding. Median PFS was 4.0 (2.7, 4.3) mo. 21 pts remain alive. None of the responders have progressed or died. 28 pts (25 PD, 3 pSD) were potentially eligible for salvage nivo/ipi (Part B), but 12 did not enroll due to symptomatic PD (2), grade 3-4 toxicity on nivo (3), or other including no biopsy tissue (7). In the 16 Part B pts, best response to nivo/ipi was: PR (1, 6%) – (unclassified/non-sarcomatoid); SD (7, 44%); PD (8, 50%). Grade 3 Treatment-related adverse events (TrAEs) were seen in 7/35 (20%) on nivo. Grade 3-5 TrAEs were seen in 7/16 (44%) on nivo/ipi with 1 pt experiencing sudden death. Correlative studies including PD-L1 status, WES and RNAseq are pending. **Conclusions:** Nivo monotherapy has limited activity in treatment naïve nccRCC with most responses (4 of 5) seen in pts with sarcomatoid and/or unclassified tumors. Toxicity is consistent with prior nivo studies. Salvage treatment with nivo/ipi was provided in 16 of 28 (57%) pts with PD/pSD on nivo monotherapy, with 1 response observed. Clinical trial information: NCT03117309. Research Sponsor: Bristol Meyers Squibb, Other Government Agency.

4511 Poster Discussion Session; Discussed in Poster Discussion Session

Clinical activity of durvalumab and savolitinib in MET-driven, metastatic papillary renal cancer. *First Author: Cristina Suarez Rodriguez, Vall d' Hebron University Hospital, Barcelona, Spain*

Background: Savolitinib is a potent and selective MET inhibitor with activity in MET-driven papillary renal cancer (PRC). Durvalumab is a PD-L1 inhibitor which has been tested in combination with savolitinib in metastatic PRC with response rates of 29% (12/41). Here we describe the efficacy of this combination in MET-driven metastatic PRC. **Methods:** This single arm phase I/II trial explored durvalumab (1500mg Q4W) and savolitinib (600mg OD) together in metastatic PRC, with a 4wk savolitinib run in. Biomarker analysis results were compared with responses to treatment as planned in the protocol. The analysis presented here focuses on those patients with MET DNA alterations (central analysis:chromosome 7 gain/MET or HGF amplification/MET kinase domain mutations). Confirmed response rate (RR) (RECIST v1.1), progression-free survival (PFS), tolerability (CTCAE v4.03) and overall survival (OS) were analysed. **Results:** 42 patients were enrolled in the metastatic papillary cohort, of which 41 patients received treatment. The median follow up was 26.8 months. The confirmed RR was 29% (12/41) and median PFS was 4.9 months (95% CI 2.5-10.0). 14/41 (34%) of these patients had MET-driven disease. 71% (10/14) of MET-driven patients had not previously received systemic therapy and 7% (1/14) were PD-L1 positive. IMDC good, intermediate, and poor risk disease occurred in 36% (5/14), 57% (8/14), and 7% (1/14) of MET-driven patients respectively. Confirmed RR in MET-driven patients was 57% (8/14) with duration of response at 9.4 months (95% CI 3.9-Not reached [NR]). Median PFS and OS in MET-driven patients were 10.5 months (95% CI 2.9-15.7) and 27.4 months (95% CI 7.3-NR) respectively. No new safety signals were seen. **Conclusions:** The combination of savolitinib and durvalumab has clinical activity in MET-driven PRC. A randomised phase III study is planned based upon these data. Clinical trial information: NCT02819596. Research Sponsor: AstraZeneca.

Vorolanib, everolimus, and the combination in patients with pretreated metastatic renal cell carcinoma (CONCEPT study): A randomized, phase 3, double-blind, multicenter trial. *First Author: Xinan Sheng, Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: The combination of agents targeting both VEGF- and mTOR-mediated pathways has been investigated in renal cell carcinoma (RCC). We conducted the CONCEPT study to assess vorolanib, everolimus, or their combination as second-line treatment in Chinese patients (pts) with metastatic RCC. **Methods:** Pts with cytologically or histologically confirmed RCC who had disease progression after one prior VEGFR-TKI were eligible for participation in the study. They will be randomized by 1:1:1 ratio to receive matching placebo plus vorolanib or everolimus, or the combination. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), objective response rate (ORR), and safety. **Results:** Between November 2016 and June 2019, 399 pts (133 pts in each group) were enrolled. At the data cutoff (October 23, 2020), the median PFS in combination group was significantly longer than that in single-agent everolimus group (10.0 months [95% CI, 8.2-10.4] vs. 6.4 months [95% CI, 4.7-8.3]; HR = 0.70 [95% CI, 0.52-0.94]; P = 0.0171), while the median PFS was similar between single-agent vorolanib group and single-agent everolimus group (6.4 months [95% CI, 4.6-8.3] vs. 6.4 months [95% CI, 4.7-8.3]; HR = 0.94 [95% CI, 0.69-1.24]; P = 0.6856). An objective response was achieved by 33 (24.8%) of 133 pts allocated vorolanib plus everolimus compared with 11 (8.3%) of 133 who received single-agent everolimus and 14 (10.5%) of 133 pts assigned single-agent vorolanib. OS was immature with no significant difference between pts assigned vorolanib plus everolimus (30.4 months [95% CI, 16.5-NE]) and those allocated single-agent everolimus (25.4 months [95% CI 19.4-NE]) or single-agent vorolanib (30.5 months [95% CI, 22.8-NE]). Treatment-related adverse event (TRAE) occurred in 132 (99%) of 133 pts with vorolanib plus everolimus, 127 (96%) of 133 pts with single-agent vorolanib and 131 (99%) of 133 pts with single-agent everolimus, respectively. Grade 3 or higher TRAEs occurred in fewer patients who received single-agent vorolanib (52 [39%]) than in those who received single-agent everolimus (71 [53%]) or vorolanib plus everolimus (96 [72%]). Safety profiles of both agents were consistent with previous studies. **Conclusions:** This is the first phase 3 study of combination of mTOR- and VEGF-targeted agents in second-line treatments. Vorolanib plus everolimus showed a PFS benefit for patients with metastatic RCC who have progressed after one previous VEGF-targeted therapy with a safe tolerance profile. Clinical trial information: NCT03095040. Research Sponsor: Betta pharmaceuticals.

4513 Poster Discussion Session; Discussed in Poster Discussion Session

First results of a randomized phase IB study comparing nivolumab/ipilimumab with or without CBM-588 in patients with metastatic renal cell carcinoma. *First Author: Luis A Meza, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Recent evidence suggests that the gut microbiome is a potent mediator of immune checkpoint inhibitor (ICI) activity in metastatic renal cell carcinoma (mRCC), with both specific bacterial species and cumulative microbial diversity driving response (Routy *et al* Science 2018; Salgia *et al* Eur Urol 2020). We examined whether the butyrate-producing bacterium *Clostridium butyricum*, the key constituent of CBM-588, could modulate the gut microbiome in patients (pts) with mRCC receiving nivolumab/ipilimumab (N/I) and secondarily improve clinical outcome. **Methods:** An open-label, randomized study was conducted, with key eligibility criteria including confirmed clear cell and/or sarcomatoid mRCC, intermediate/poor risk by IMDC criteria and no systemic therapy for metastatic disease. Patients were randomized 2:1 to receive either N/I+CBM-588 or N/I alone. N/I was dosed at 3 mg/kg and 1 mg/kg IV every 3 weeks for 12 weeks, followed by N at 480 mg IV every 4 weeks. CBM-588 was dosed orally at 80 mg bid. Stool was collected for bacteriomic profiling at baseline and 12 weeks. Metagenomic sequencing was employed using previously published methods (Dizman *et al* Cancer Med 2020). The primary endpoint of the study was change in *Bifidobacterium* spp. from baseline to week 12. Secondary endpoints included change in microbial diversity and clinical outcomes including response rate (RR) and progression-free survival (PFS). **Results:** 30 pts were randomized between April 2019 and Nov 2020; 1 pt was excluded after genomic sequencing clarified a diagnosis of sarcoma. Among 29 evaluable patients (21:8 M:F), median age was 66, 10 pts (34%) had sarcomatoid features and 24 pts (83%) were intermediate risk . Metagenomic sequencing of paired stool specimens showed an 8-fold increase in *B. bifidum* and a 6-fold increase in *B. adolescentis* in pts receiving N/I+CBM-588 from baseline to week 12. *C. butyricum* was detected only in pts receiving CBM-588. Pathogenic species (e.g., *Escherichia. coli* and *Klebsiella* spp.) were more prevalent in pts not receiving CBM-588. RR was significantly higher among pts receiving N/I+CBM-588 vs N/I alone (59% vs 11%; P = 0.024). Median PFS was also prolonged with the addition of CBM-588 to N/I (NR vs 11 weeks; $P < 0.001$). No significant difference in grade 3/4 toxicities were observed between study arms. **Conclusions:** This is the first randomized, prospective study to suggest enhancement of ICI response with a live bacterial product. The observed clinical impact is corroborated by biologic findings supporting gut modulation by CBM-588. Clinical trial information: NCT03829111. Research Sponsor: None.

4514 Poster Discussion Session; Discussed in Poster Discussion Session

Outcomes of patients who progressed while receiving avelumab + axitinib (A + Ax) and received subsequent treatment (Tx) in JAVELIN Renal 101. *First Author: Laurence Albiges, Department of Cancer Medicine, Gustave Roussy Cancer Campus, University of Paris Sud, Boston, MA*

Background: There are limited data on the outcomes of patients receiving second-line (2L) therapy following immunotherapies plus tyrosine-kinase inhibitors in the first-line (1L). We describe the outcomes of patients with advanced renal cell carcinoma (aRCC) who had received 1L A + Ax in the phase 3 JAVELIN Renal 101 trial and went on to receive subsequent Tx. **Methods:** At the cutoff date for the third interim analysis (April 28, 2020), patients who received 1L A + Ax (n = 442) and received any subsequent lines of Tx were assessed. We report the overall survival (OS), progression-free survival on next-line systemic therapy (PFS2) per type of Tx, and duration of 2L Tx. **Results:** Anticancer drug therapies were received by 204/442 patients following A + Ax Tx. Of patients who received a follow-up anticancer drug Tx, 163/204 received a single agent (SA), and 41/204 received a combination Tx (CT) regimen. The most common 2L SA was cabozantinib (60/163), and the most frequent 2L CT was everolimus + lenvatinib (12/41). OS, PFS2, and duration of treatment (DOT) for the various subgroups are summarized in the table below. Analyses on additional subgroups will also be presented. **Conclusions:** In patients with aRCC who received 2L CT following 1L treatment with A + Ax, long-term OS and PFS2 were observed. Clinical trial information: NCT02684006. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

	2L SA (n = 163)	2L SA cabozantinib (n = 60)	2L combination (n = 41)
18-mo OS (95% CI), %	75.8 (68.4, 81.7)	68.3 (55.0-78.5)	85.3 (70.2-93.1)
36-mo OS (95% CI), %	44.1 (35.9, 52.0)	36.9 (24.2-49.7)	63.4 (45.7-76.6)
mOS (95% CI), mo	30.4 (24.7, NE)	26.2 (21.3, 34.1)	NE (30.4 to NE)
18-mo PFS2 (95% CI), %	56.2 (48.0, 63.6)	52.6 (39.2-64.4)	65.9 (49.3-78.2)
mPFS2 (95% CI), mo	20.4 (17.6, 23.0)	18.2 (14.7-22.6)	24.1 (17.7 to NE)
mDOT (95% CI), mo	11.1 (8.4, NE)	19.1 (7.3 to NE)	12.9 (7.4 to NE)

4515 Poster Discussion Session; Discussed in Poster Discussion Session

Safety and efficacy outcomes with nivolumab plus ipilimumab in patients with advanced renal cell carcinoma and brain metastases: results from the CheckMate 920 trial. *First Author: Hamid Emamekhoo, University of Wisconsin School of Medicine and Public Health, Madison, WI*

Background: Combination therapy with nivolumab plus ipilimumab (NIVO+IPI) has demonstrated long-term efficacy and tolerability in patients with previously untreated advanced renal cell carcinoma (aRCC). Previous phase 3 clinical trials of patients with advanced or metastatic cancers have mostly excluded patients with brain metastases. CheckMate 920 is an ongoing, phase 3b/4 clinical trial of NIVO+IPI treatment in patients with aRCC with a high unmet medical need. We present updated safety and efficacy results for the cohort of patients with aRCC of any histology and brain metastases from CheckMate 920 (NCT02982954). **Methods:** Patients with previously untreated advanced/metastatic aRCC of any histology, with asymptomatic brain metastases (not currently receiving corticosteroids or radiation), and Karnofsky performance status $\geq$ 70% were assigned to treatment with NIVO 3 mg/kg + IPI 1 mg/kg every 3 weeks $\times$ 4 doses followed by NIVO 480 mg every 4 weeks for $\leq$ 2 years or until disease progression/unacceptable toxicity. The primary endpoint was incidence of grade $\geq$ 3 immune-mediated adverse events (imAEs) within 100 days of last dose of study drug. Key secondary endpoints included progression-free survival (PFS) and objective response rate (ORR) by RECIST v1.1 (both per investigator). Exploratory endpoints included overall survival (OS). **Results:** Of 28 treated patients with brain metastases, 85.7% were men; median (range) age was 60 (38–87) years, and 14.3% had sarcomatoid features. With 24.5 months minimum follow-up of the 28 patients enrolled, median duration of therapy (range) was 3.4 (0.0–23.3) months for NIVO and 2.1 (0.0–3.3) months for IPI. No grade 5 imAEs occurred. Grade 3–4 imAEs by category were diarrhea/colitis (7.1%), hypophysitis (3.6%), rash (3.6%), hepatitis (3.6%), and diabetes mellitus (3.6%). Of the 25 patients who were evaluable for ORR, the ORR was 32.0% (95% CI, 14.9–53.5). No patients achieved complete response, 8 achieved partial response, and 10 patients had stable disease. Median time to response (range) was 2.8 (2.4–3.0) months. Median duration (range) of response was 24.0 (3.9–not estimable [NE]) months; 4 of 8 responders remain without reported progression. Of 28 patients, 7 (25%) had intracranial progression. Median PFS (n = 28) was 9.0 (95% CI, 2.9–12.0) months. Median OS (n = 28) was still not reached (95% CI, 14.1 months–NE). **Conclusions:** In patients with previously untreated aRCC and brain metastases, a population with high unmet medical need that is often underrepresented in clinical trials, the approved treatment regimen of NIVO+IPI followed by NIVO for aRCC showed no new safety signals and continues to show encouraging antitumor activity with longer follow-up. Clinical trial information: NCT02982954. Research Sponsor: Bristol Myers Squibb.

4516 Poster Discussion Session; Discussed in Poster Discussion Session

Survival benefit of nephrectomy prior to immunotherapy-based combinations in patients with metastatic renal cell carcinoma: An FDA pooled analysis. *First Author: Jaleh Fallah, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Immunotherapy-based combination therapies (IO-X) are standard of care for metastatic RCC (mRCC) in the frontline setting. Limited data is available on the role of cytoreductive nephrectomy prior to IO-X in patients (pts) with mRCC (Bakouny, et al. GU ASCO 2020). We assessed the correlation between nephrectomy prior to IO-X and overall survival (OS) in pts with de novo mRCC. **Methods:** We pooled data from trials submitted for FDA review of a checkpoint inhibitor combination as first-line treatment for pts with mRCC. We only included trials with available data for stage at initial diagnosis (dx) to identify pts with stage IV disease at initial dx and to exclude those with nephrectomy in the non-metastatic setting. Kaplan-Meier method was used to estimate median OS in pts with de novo mRCC with and without nephrectomy prior to IO-X. **Results:** Five trials met inclusion criteria, all of which evaluated IO in combination with a kinase inhibitor. Data for stage at initial dx was available in 1708 pts who received IO-X. The majority of pts were male (72%) and White (80%). Among the 849 pts (50%) with stage IV RCC at initial dx, 523 pts (62%) had nephrectomy prior to IO-X. All pts had clear cell histology; Sarcomatoid differentiation was present in tumor pathology of 25% and 10% of pts with and without prior nephrectomy, respectively. Proportion of pts with favorable, intermediate and poor risk disease was 10%, 70% and 20%, respectively. OS appeared better in those with stage IV disease at dx who had prior nephrectomy compared to pts without nephrectomy (Hazard ratio (HR) = 0.53, 95% CI: 0.42, 0.68), even after adjusting for age and prognostic risk group (HR = 0.59, 95% CI: 0.46, 0.75) (see table). **Conclusions:** In this retrospective exploratory analysis, nephrectomy prior to IO-X in pts with new dx of stage IV RCC appeared to be associated with improved OS, even when controlling for age and prognostic risk group. The decision for nephrectomy is affected by factors such as medical comorbidities which could not be completely controlled. Results should be considered hypothesis generating. Research Sponsor: None.

Pts with stage IV RCC at initial dx (N = 849)	Prior Nephrectomy (N = 523)	No Prior Nephrectomy (N = 326)	HR (95% CI)
Age, mean (SD)	59.8 (9.3)	62.3 (10.3)	
Months from diagnosis to randomization, median (IQR)	3.4 (1.9 , 8.0)	1.5 (1.0 , 2.5)	
Death events N (%)	139/523 (27%)	134/326 (41%)	
Favorable risk	9/44 (20%)	10/37 (27%)	0.69 (0.28 , 1.72)
Intermediate risk	93/397 (23%)	80/200 (40%)	0.47 (0.35 , 0.64)
Poor risk	37/82 (45%)	44/87 (51%)	0.84 (0.54 , 1.30)
Median OS (unadjusted HR)	NR (31.8 , NR)	24.5 (19.6 , NR)	0.53 (0.42 , 0.68)
Median OS (HR adjusted for age and prognostic risk group)	NR (31.8 , NR)	25.2 (19.8 , NR)	0.59 (0.46 , 0.75)

4517 Poster Discussion Session; Discussed in Poster Discussion Session

Neoadjuvant atezolizumab (A) with gemcitabine and cisplatin (GC) in patients (pts) with muscle-invasive bladder cancer (MIBC): A multicenter, single-arm, phase 2 trial. *First Author: Samuel Aaron Funt, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neoadjuvant GC is standard for pts with MIBC and can result in pathologic downstaging to non-MIBC (< pT2N0) at radical cystectomy (RC), which correlates with improved survival. Based on the known activity of A in metastatic BC (mBC), we tested the combination of GC+A as neoadjuvant therapy for MIBC in a phase II trial (NCT02989584). **Methods:** Eligible pts with MIBC (cT2-T4aN0M0) received a single dose of A (1200 mg IV) and, two weeks later, began C (as either 70mg/m2 IV on D1 or 35 mg/m2 on D1,D8), G (1000 mg/m2 on D1,D8), and A (1200 mg IV on D8) every 21 days for 4 cycles followed by RC. Pts were also able to receive one additional dose of A 3 weeks after the last dose of A and prior to RC. The primary endpoint was proportion of pts with < pT2N0. Pts were considered not evaluable for the primary endpoint if they received less than 2 cycles due to withdrawal of consent or unrelated adverse events (AEs). Secondary endpoints included the proportion of pts with pT0N0, recurrence-free survival (RFS), and safety. We prespecified null and alternate < pT2N0 rates of 35% and 55%, respectively, with the null being rejected if at least 19 of 39 pts achieved < pT2N0. Pretreatment tumors underwent centralized PD-L1 staining (SP142; positive if ≥5% of immune cells). **Results:** Between Feb 2018 and May 2020, 44 pts were enrolled from five institutions. Five pts were not evaluable (withdrawal of consent before C3, n = 4; unrelated AEs during C1, n = 1). Of the 39 evaluable pts (cT2N0 79%, cT3N0 18%, cT4N0 3%), 1 pt refused surgery and was considered a non-responder. The primary endpoint was met, with 27 of 39 pts (69%) < pT2N0 at RC, including 15 (38%) pT0N0. All pts achieving < pT2N0 are alive and disease free. The median RFS was not reached with a median follow-up of 16.7 months (range: 7.7-33.2). The median time from last dose of chemotherapy to RC was 7.8 weeks (range 5.1 – 17). The most common grade 3-4 treatment related AEs were due to chemotherapy and were neutropenia (36%), lymphopenia (16%), and anemia (11%). Possible grade 3-4 immune related AEs included 2 pts with asymptomatic grade 3 pancreatic enzyme elevation, 1 pt with grade 3 pancreatitis, and 1 pt with hepatitis requiring steroids. Only 4 of 39 (10%) pts had PD-L1 positive tumors, which is low compared to mBC (25% positive; Powles et al. Lancet 2017) and MIBC (40% positive; Powles et al. Nature Med 2019) cohorts also tested with the SP142 clone. All 4 pts with PD-L1 positive tumors achieved < pT2N0. Twelve of 12 (100%) non-responding pts were PD-L1 negative and 23 of 27 (85%) responding pts were PD-L1 negative (p = 0.3). **Conclusions:** Neoadjuvant GC+A is an effective and safe regimen for the treatment of pts with MIBC. The PD-L1 positivity rate was low compared with other studies and was not predictive of pathologic downstaging. Additional interrogation of the genomic and host immune factors mediating response and resistance to GC+A is ongoing. Clinical trial information: NCT02989584. Research Sponsor: Genentech/Roche, Conquer Cancer Foundation of the American Society of Clinical Oncology.

4518 Poster Discussion Session; Discussed in Poster Discussion Session

PrE0807: A phase Ib feasibility trial of neoadjuvant nivolumab (N) without or with lirilumab (L) in cisplatin-ineligible patients (pts) with muscle-invasive bladder cancer (MIBC). *First Author: Petros Grivas, University of Washington, Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA*

Background: Neoadjuvant cisplatin-based chemotherapy (CT) prior to radical cystectomy (RC) improves overall survival (OS) in MIBC, but about half of pts are cisplatin-unfit or refuse it. Neoadjuvant immune checkpoint inhibitors can induce high pathologic complete response rate (ypT0N0). The combination of anti-PD-1 (N) and anti-KIR (L) is hypothesized to be safe and have significant activity based on the complementary and possibly synergistic roles in regulating adaptive and innate immune response in MIBC. **Methods:** This is a phase Ib multi-institutional trial in pts with localized MIBC treated with 2 neoadjuvant doses (4 weeks apart) of N alone (480 mg) in cohort 1 or N (480 mg) + L (240 mg) in cohort 2 prior to RC without adjuvant therapy (NCT03532451). Cohorts were enrolled sequentially and were not randomized. Key eligibility criteria included stage cT2-4aN0-1M0, ≥20% tumor content at TURBT and cisplatin-ineligibility (Galsky criteria) or refusal. Primary endpoint was safety manifested as rate of ≥G3 treatment related adverse events (TRAE) assessed in each cohort with CTCAE v5.0. Key secondary endpoints included the % of pts who had RC > 6 weeks after last neoadjuvant dose due to TRAE, CD8+ T cell density at RC, ypT0N0 and < ypT2N0 rates, CD8+ T cell density change between TURBT and RC, recurrence-free survival (RFS) and biomarkers in tumor tissue, blood and urine. **Results:** Among 43 pts enrolled (13 cohort 1, 30 cohort 2), median age was 75 (51-89), 67% were men, all had PS ECOG 0-1. Pts were cisplatin-ineligible due to impaired renal function (47%) and hearing loss (37%), while 14 % refused cisplatin. At baseline, 37 pts had cT2 stage, 2 had cN1 and 3 cNx. In cohort 1 and 2, 13 and 29 pts, respectively, completed intended neoadjuvant treatment, and 41/43 underwent RC (12/13 cohort 1, 29/30 cohort 2). One pt progressed to metastatic disease prior to RC (cohort 1) and 1 withdrew consent prior to being treated (cohort 2). Additionally, 1 patient was found to have cervical cancer at RC. Median time from last neoadjuvant dose to RC was 27 (95%CI: 24-29) days. There was no RC delayed > 6 weeks from treatment completion due to TRAE. G3 TRAEs occurred in 0% with N and 6.7% (90%CI 1.2-19.5%) in N+L (1: arthralgia, 1: gout, 2: hip pain) that all resolved. No G4/5 TRAEs occurred. Of 40 pts with MIBC and RC, ypT0N0 rates for N and N+L were 8% and 18%, while < ypT2N0 rates were 17% and 29%, respectively. Data on RFS and OS, and biomarker data were not yet mature. **Conclusions:** Neoadjuvant N alone and N+L combination prior to RC were safe, feasible and well tolerated in cisplatin-ineligible pts with MIBC, but ypT0N0 rates were unexpectedly low, especially with N alone. Two phase 3 trials (NCT03661320; NCT04209114) are evaluating the peri-operative role of N + chemotherapy +/- Linrodostat in cisplatin-fit and N +/- Bempeg in cisplatin unfit patients and are also assessing biomarkers. Clinical trial information: NCT03532451. Research Sponsor: Bristol Myers Squibb.

4519 Oral Abstract Session

Inducible T-cell co-stimulatory (ICOS) receptor agonist, feladilimab (fela), alone and in combination (combo) with pembrolizumab (P): Results from INDUCE-1 urothelial carcinoma (UC) expansion cohorts (ECs). *First Author: Arjun Vasant Balar, Perlmutter Cancer Center at NYU Langone Health, New York, NY*

Background: INDUCE-1 is a first-in-human trial evaluating fela, an IgG4 ICOS agonist non-T-cell depleting mAb, as monotherapy (mono) and in combo with P. ECs include tumor types, such as UC, with high ICOS expression and immunotherapy-favorable features. Fela induced IFNγ, increased PD-1/L1 expression, and enhanced antitumor activity in combo with PD-1 blockade nonclinically. We report preliminary efficacy, safety, and biomarker data of fela ± P in INDUCE-1 UC ECs. **Methods:** Eligible patients (pts) had recurrent/metastatic (R/M) UC of the upper or lower urinary tract, ≤6 prior systemic therapy lines in the advanced setting, measurable disease, and no active autoimmune disease. Pts received 0.3 or 1 mg/kg fela (mono EC; anti-PD-1/L1–experienced [exp] pts) or 0.3 mg/kg fela + 200 mg P (combo EC; anti-PD-1/L1–naïve pts) every 3 wks, up to 35 cycles until disease progression or unacceptable toxicity. Disease was assessed every 9 wks through wk 54, then every 12 wks. Archival and/or fresh biopsy tumor tissue was collected for biomarker analyses and safety assessed. **Results:** By Nov 6 2020, 13 anti-PD-1/L1–exp and 32 anti-PD-1/L1–naïve pts were evaluable in the mono and combo ECs, respectively. In the mono EC, median age was 69 yrs (range: 47–82), 92% of pts were male, and 85% received ≥2 prior therapy lines in the metastatic setting. In the combo EC, median age was 70 yrs (range: 42–84), 75% of pts were male, and 72% received ≥1 prior therapy line in the metastatic setting. In the mono EC, median duration of follow-up (mDoF) was 10.6 mo (range: 1.1–22.8); overall response rate (ORR) was 8% (1 partial response [PR]; 95% CI: 0.2, 36.0) with a duration of response (DoR) of 6.1 mo; disease control rate (DCR [response or stable disease for ≥9 wks]) was 23% (95% CI: 5.0, 53.8), and median overall survival (mOS) was 14.5 mo (95% CI: 2.8, NR), with 74% of pts alive at 6 mo. In the combo EC, mDoF was 9.6 mo (range: 0.9–28.3); ORR was 22% (7 PRs; 95% CI: 9.3, 40.0) with a median DoR of 8.3 months (range: 3.5–23.3+); DCR was 63% (95% CI: 43.7, 78.9), and mOS was 10.7 mo (95% CI: 5.2, 18.1), with 64% of pts alive at 6 mo. Grade ≥3 treatment-related AEs were reported for 0% and 9% of pts in the mono (N = 16) and combo (N = 44) safety populations, respectively. PD-L1 expression and ICOS-specific biomarkers are being evaluated, with promising trends observed in enrichment of clinical activity in preliminary analyses. **Conclusions:** Fela is the first ICOS agonist with reported single-agent activity in anti-PD-1/L1–exp relapsed/refractory UC. Fela + P in combo shows promising clinical activity and manageable safety in PD-1/L1–naïve R/M UC. Further study is warranted. Updated data to be presented. 4520 Poster Discussion Session; Discussed in Poster Discussion Session

Avelumab first-line (1L) maintenance for advanced urothelial carcinoma (UC): Analysis of clinical and genomic subgroups from the JAVELIN Bladder 100 trial. *First Author: Thomas Powles, Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, St Bartholomew's Hospital, London, United Kingdom*

Background: In the phase 3 JAVELIN Bladder 100 trial, avelumab 1L maintenance + best supportive care (BSC) significantly prolonged overall survival (OS) vs BSC alone in patients (pts) with advanced UC that had not progressed on 1L platinum-based chemotherapy (HR, 0.69 [95% CI: 0.56, 0.86; 1-sided *P*= 0.0005]). We report post hoc analyses in previously unreported clinical and genomic subgroups. **Methods:** In JAVELIN Bladder 100 (NCT02603432), eligible pts had unresectable locally advanced or metastatic UC without progression after 4-6 cycles of 1L gemcitabine + cisplatin or carboplatin, and were randomized to receive avelumab + BSC (n = 350) or BSC alone (n = 350). The primary endpoint was OS, in all randomized pts and pts with PD-L1+ tumors (Ventana SP263 assay). In this exploratory analysis, we analyzed OS in disease stage and site subgroups, in pts with PD-L1+ tumors who received 1L gemcitabine + carboplatin, and in genomic subtypes (RNAseq whole-transcriptome profiling of tumor tissue) defined using data from The Cancer Genome Atlas (TCGA 2017). Interaction tests were not performed. **Results:** Prolonged OS was observed in the avelumab + BSC arm vs the BSC alone arm in pts with upper or lower tract tumors, metastatic or locally advanced (LA) and unresectable disease (prior to chemotherapy), and lymph node-only disease post-chemotherapy (Table). OS was also prolonged with avelumab + BSC in pts in PD-L1+ tumors who had received 1L gemcitabine + carboplatin, consistent with findings in the overall population. In genomic subtypes, the OS benefit for avelumab + BSC was apparent across TCGA subtypes except luminal. **Conclusions:** An OS benefit was seen for avelumab 1L maintenance + BSC vs BSC alone across subgroups of interest. Results are consistent with previously reported findings, further supporting avelumab 1L maintenance as a standard of care for pts with advanced UC that has not progressed with 1L platinum-containing chemotherapy. Clinical trial information: NCT02603432. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

Safety and efficacy of rogaratinib in combination with atezolizumab in cisplatin-ineligible patients (pts) with locally advanced or metastatic urothelial cancer (UC) and *FGFR* mRNA overexpression in the phase Ib/II FORT-2 study. *First Author: Jonathan E. Rosenberg, Department of Medicine, Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Rogaratinib (R) is a novel pan-FGFR inhibitor that showed promising efficacy and safety in a Phase I trial in pts with advanced solid tumors, including UC, with *FGFR1-3* mRNA overexpression. The Phase Ib/II FORT-2 study (NCT03473756) of R plus atezolizumab (A) in pts with first-line cisplatin-ineligible, *FGFR*-positive, advanced/metastatic UC previously identified a maximum tolerated dose of R 600 mg twice daily (BID) plus A (1200 mg every 3 weeks). We report updated safety, efficacy, and the recommended Phase II dose (RP2D) for combination therapy from the Phase Ib study. **Methods:** Pts with cisplatin-ineligible, locally advanced/metastatic UC with *FGFR1/3* mRNA overexpression detected by RNA *in situ* hybridization of archival tissue (RNAscope) received oral R 600 mg BID plus A 1200 mg on day 1 of a 21-day cycle. Archival tissue was examined for programmed cell-death ligand 1 (PD-L1) protein expression levels, *FGFR3*-activating mutations via a targeted Illumina NGS panel, and *FGFR* fusions via an Archer fusion plex assay. Primary objectives were safety, tolerability, and determination of the RP2D. **Results:** 26 pts (enrolled May 25, 2018 to Nov 25, 2020) were treated; 89% were male, median age was 76 years (range 47-85), 58% had an ECOG performance status of 1, and 77% displayed low or absent (negative or non-detectable) PD-L1 expression (combined positive score $< 10\%$). Common treatment-emergent adverse events (TEAEs) included diarrhea (n = 17, 65%; 1 grade [G] 3), hyperphosphatemia (n = 15, 58%; all G1 or 2), and nausea (n = 11, 42%; 1 G3). The most common G3/4 TEAEs were elevated lipase without pancreatitis (n = 5, 19%), elevated amylase (n = 3, 12%), and rash and syncope (n = 2, 8% each). TEAEs led to interruption/reduction/discontinuation of R in 69%/46%/19% of pts. R-related unique TEAEs were hyperphosphatemia in 15 pts (58%) and retinal pigment epithelium detachment in 1 pt (4%). G5 events occurred in 3 pts (12%), unrelated to treatment. 13 of 24 evaluable pts (54%) had an objective response (OR) per RECIST v1.1. The disease control rate was 83%, including 3 pts (13%) with a complete response (CR), 10 (42%) with a partial response (PR), and 7 (29%) with stable disease. Median duration of response was not reached. OR rate was 56% (2 CRs and 7 PRs) in the 16 pts with tumors having low/negative PD-L1 protein and *FGFR3* mRNA overexpression without mutation. The RP2D for R+A was 600 mg BID. **Conclusions:** First-line treatment with the RP2D of R+A achieved favorable clinical efficacy and tolerability in pts with cisplatin-ineligible, metastatic UC characterized by high *FGFR1/3* mRNA expression and generally low/negative PD-L1 expression. Encouraging efficacy was observed regardless of PD-L1 expression or *FGFR3* mutation status, warranting future investigation. Clinical trial information: NCT03473756. Research Sponsor: Funding: Bayer AG. Writing support: Complete HealthVizion.

Phase I/II study to evaluate the efficacy of TAS0313, a cancer peptide vaccine, combined with pembrolizumab for locally advanced or metastatic urothelial carcinoma. *First Author: Ryuji Matsumoto, Department of Renal and Genitourinary Surgery, Hokkaido University, Sapporo, Japan*

Background: TAS0313 is a cancer vaccine cocktail comprising three long peptides with a total of 12 cytotoxic T lymphocyte epitope peptides. We performed a multicenter phase I/II study including patient (pts) with urothelial carcinoma (UC) treated using TAS0313 combined with pembrolizumab. **Methods:** The enrolled pts with a histologically or cytologically confirmed diagnosis of urothelial carcinoma had at least one of the following HLA types: HLA-A*02:01, -A*02:06, -A*02:07, -A*11:01, -A*24:02, -A*31:01, or -A*33:03. For cohort C1, eligible pts were those who received platinum-based chemotherapy and were naïve to immune checkpoint inhibitors (ICI). For cohort C2, eligible pts were those who progressed onto treatment with pembrolizumab. TAS0313 (9 mg) was subcutaneously administered on days 1, 8, and 15 of cycles 1 and 2 and day 1 of cycle 3 or later in 21-day cycles, while pembrolizumab (200 mg) was intravenously administered on day 1 of cycle 1 or later in 21-day cycles until disease progression or unacceptable toxicity occurred. Tumor response was evaluated using the RECIST v1.1 criteria. The TAS0313 target antigen-specific immunoglobulin G (IgG) was analyzed before and after treatment. The primary objective was to evaluate efficacy, while the secondary objective was to evaluate the safety and tolerability of the combination therapy. **Results:** As of 10th September 2020, 46 pts with a median age of 71.0 and 65.5 years, in cohort C1 (n = 36) and cohort C2 (n = 10), respectively, have been treated with the combination therapy. For cohorts C1 and C2, the median follow-up duration was 6.47 and 6.95 months, while the median treatment duration was 4.86 and 2.56 months, respectively. In cohort C1, the overall response rate and disease control rate (DCR) were 33.3% (16.7% complete response, 16.7% partial response) and 66.7% (33.3% stable disease), respectively. The median progression-free survival was 5.0 months, median overall survival (OS) was not yet reached, and 1-year OS rate was 74.3%. The best overall response in cohort C2 was stable disease in 5/10 pts, resulting in a DCR of 50.0%. Increase in IgG level was detected after treatment in both the cohorts. The most common adverse drug reactions (ADRs) of TAS0313 and/or pembrolizumab were grade 1–2 injection site reactions and pyrexia. There were no grade 3–5 ADRs with an incidence of $\geq$10%. **Conclusions:** This study confirmed the tolerability, safety, and immune response of TAS0313 combined with pembrolizumab in cohorts C1 and C2. We observed promising efficacy in pts with ICI-naïve UC in cohort C1; however, in pts with pembrolizumab-refractory UC in cohort C2, limited efficacy was seen. Therefore, a large-scale randomized study is needed to clarify the benefits of TAS0313 combined with ICI in ICI-naïve pts. Clinical trial information: 183824. Research Sponsor: Taiho Pharmaceutical Co., Ltd.

Circulating tumor cell-driven use of neoadjuvant chemotherapy in patients with muscle-invasive bladder cancer. *First Author: Nick Beije, Department of Medical Oncology, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, Netherlands*

Background: International guidelines for the treatment of non-metastatic muscle-invasive bladder cancer (MIBC) recommend neoadjuvant chemotherapy (NAC), which, however, is underutilized in practice. We hypothesized that the absence of circulating tumour cells (CTCs), an established prognostic marker in MIBC, may identify patients with such a favourable prognosis that NAC may be withheld. **Methods:** The *CirGuidance* study included adults with clinical stage T2-T4aN0-N1M0 muscle-invasive urothelial carcinoma of the bladder who were fit to undergo radical cystectomy. CTCs were enumerated using the CellSearch system. CTC-negative patients (no CTCs detectable) underwent radical surgery without NAC; CTC-positive patients ($\geq$1 detectable CTCs) were advised to receive NAC followed by radical surgery, but NAC could be withheld at the discretion of the treating physician. The primary endpoint was the two-year overall survival (OS) in the CTC-negative group, analysed in the intention-to-treat population. The prespecified criterion for trial success was a two-year OS of minimally 75% (95% confidence interval (CI) ±5%) in the CTC-negative group. **Results:** Of 315 patients screened for eligibility, 273 were enrolled in the study. The median age was 69 years; the median follow-up was 36 months. The two-year OS in the CTC-negative group was 69.5% (n = 203; 95% CI 62.6%-75.5%); in the CTC-positive group it was 58.2% (n = 70; 95% CI 45.5%-68.9%). CTC-positive patients had a higher rate of cancer-related mortality (hazard ratio (HR) 1.61, 95% CI 1.05-2.45, p = 0.03) and disease relapse (HR 1.87, 95% CI 1.28-2.73, p = 0.001) than CTC-negative patients. Explorative analyses suggested that CTC-positive patients who had received NAC (n = 22) survived longer than CTC-positive patients who had not (n = 48), with a two-year OS of 74.8% (95%CI 49.5%-88.8%) versus 52.0% (95% CI 37.2%-65.0%), respectively. **Conclusions:** The two-year OS in the CTC-negative group did not meet the prespecified criterion for trial success. However, given the trial population's advanced age and high rate of non-cancer related mortality, the benefit of NAC is likely to be limited in CTC-negative MIBC patients. CTC enumeration at the moment of diagnosis could aid in the decision to prescribe neoadjuvant chemotherapy for a muscle-invasive bladder cancer patient as a criterion in addition to clinical characteristics. Clinical trial information: NL3954. Research Sponsor: Erasmus MC Grants & Cancer Genomics Netherlands.

Enfortumab vedotin in cisplatin-ineligible patients with locally advanced or metastatic urothelial cancer who received prior PD-1/PD-L1 inhibitors: An updated analysis of EV-201 Cohort 2. *First Author: Bradley Alexander McGregor, Dana-Farber Cancer Institute, Boston, MA*

Background: Cisplatin (cis)-ineligible, platinum-naive patients (pts) with locally advanced or metastatic urothelial carcinoma (la/mUC) who progress on/after anti-PD-1/L1 treatment (tx) have a poor prognosis and few tx options. Enfortumab vedotin (EV), a Nectin-4-directed antibody-drug conjugate, demonstrated overall survival (OS) benefit in pts with la/mUC who previously received anti-PD-1/L1 tx and platinum-containing chemotherapy (EV-301). EV-201 (NCT03219333) is a pivotal, single-arm, 2-cohort (C) study. C2 enrolled cis-ineligible pts with prior anti PD-1/L1 tx and no prior platinum for la/mUC. Results of the C2 primary analysis were previously presented. In this updated analysis, with 3 additional mo of follow-up (f/u), all responders were followed for $\geq$6 mo after onset of response. **Methods:** Pts received 1.25 mg/kg EV on Days 1, 8, and 15 of each 28-day cycle. The primary endpoint was confirmed objective response rate (ORR) per RECIST 1.1 by blinded independent central review (BICR). Secondary endpoints were duration of response (DOR), progression-free survival (PFS), OS, and safety. **Results:** 91 pts were enrolled and 89 treated in C2. Median (m) age was 75 y (range: 49-90). Pts were cis-ineligible at baseline, primarily due to CrCl < 60 mL/min (78%). Primary tumor site was upper tract in 43%, and 79% had visceral mets, including 24% with liver mets. As of 04 Dec 2020 (data cut-off), m f/u was 16.0 mo and m tx duration was 6.0 mo (range: 0.3-24.6). Confirmed ORR per BICR was 51% (95% confidence interval [CI] 39.8-61.3), including 22% complete response (CR) among treated pts. mDOR was 13.8 mo (95% CI 6.4-not reached). mPFS and mOS were 6.7 mo (95% CI 5.0-8.3) and 16.1 mo (95% CI 11.3-24.1), respectively. All-grade and grade (G) $\geq$3 tx-related adverse events (TRAEs) were reported in 97% and 55% of pts, respectively. Most common all-grade TRAEs were alopecia (51%), peripheral sensory neuropathy (49%), and fatigue (34%). For TRAEs $\geq$G3, each preferred term occurred in $< 10\%$ pts. TRAEs of interest included skin reactions (61% all grade, 17% $\geq$G3), peripheral neuropathy (56% all grade, 8% $\geq$G3), and hyperglycemia (10% all grade, 6% $\geq$G3). Four deaths were previously reported as tx related by investigators: 3 events $\leq$30 d of first EV dose (acute kidney injury, metabolic acidosis, multiple organ dysfunction syndrome) and 1 $>$ 30 d of last EV dose (pneumonitis). **Conclusions:** Efficacy and safety in this updated analysis of EV-201 C2 are consistent with the primary analysis. The majority of platinum-naive, cis-ineligible la/mUC pts who progressed on/after anti-PD-1/L1 tx responded to EV, with 22% achieving CR and mDOR exceeding a year. PFS and OS continue to be encouraging in this elderly population, with no new safety signals. These data show the potential for EV as a non-platinum option for cis-ineligible pts following anti-PD-1/L1 tx. Clinical trial information: NCT03219333. Research Sponsor: Astellas Pharma Global Development, Inc. and Seagen Inc.

Avelumab first-line (1L) maintenance plus best supportive care (BSC) versus BSC alone for advanced urothelial carcinoma (UC): Analysis of time to end of next-line therapy in JAVELIN Bladder 100. *First Author: Petros Grivas, University of Washington, Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA*

Background: Avelumab 1L maintenance is approved in various countries for patients (pts) with advanced UC that has not progressed with 1L platinum-based chemotherapy based on significantly prolonged overall survival (OS) seen with avelumab + BSC vs BSC alone in the phase 3 JAVELIN Bladder 100 trial. OS was prolonged despite the more frequent use of subsequent anticancer therapy in the BSC alone arm (42.3% in the avelumab + BSC arm vs 61.7% in the BSC alone arm), most commonly with immune checkpoint inhibitors (6.3% vs 43.7%, respectively). To further characterize the efficacy benefits of avelumab 1L maintenance, we report a post hoc analysis of the time to end of next-line therapy (for any reason) in the randomized trial population. **Methods:** In JAVELIN Bladder 100 (NCT02603432), eligible pts had unresectable locally advanced or metastatic UC without disease progression with 4 to 6 cycles of 1L gemcitabine + either cisplatin or carboplatin. The primary endpoint was OS from randomization, assessed in 2 populations: all pts and pts with PD-L1+ tumors (Ventana SP263). In this exploratory analysis, time from randomization until end of next-line treatment received after first progression (due to death or discontinuation) was assessed. **Results:** A total of 700 pts were randomized 1:1 to avelumab 1L maintenance + BSC or BSC alone. Among all randomized pts, time to end of next-line therapy was prolonged in the avelumab + BSC arm vs the BSC alone arm (Table). Time to end of next-line therapy was also longer in the avelumab + BSC arm vs the BSC alone arm in pts with PD-L1+ tumors (n = 358) or PD-L1− tumors (n = 270). **Conclusions:** Pts who received avelumab 1L maintenance + BSC had prolonged time to end of next-line treatment compared with those who received BSC alone, irrespective of PD-L1 status. These data provide further evidence of the efficacy of a maintenance approach with avelumab in pts with advanced UC that has not progressed with 1L platinum-based chemotherapy. Clinical trial information: NCT02603432. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

	Patients, n		Median time to end of next-line therapy (95% CI), months		
	Avelumab + BSC	BSC alone	Avelumab + BSC	BSC alone	Hazard ratio (95% CI)
All randomized pts	350	350	14.8 (12.0, 17.0)	9.2 (8.0, 11.5)	0.67 (0.545, 0.815)
Pts with PD-L1+ tumors	189	169	18.1 (12.5, 19.2)	9.0 (7.9, 12.5)	0.61 (0.451, 0.818)
Pts with PD-L1− tumors	139	131	11.9 (9.1, 15.4)	9.3 (7.6, 12.8)	0.76 (0.560, 1.035)

4526 **Poster Session**

Large cell neuroendocrine carcinoma of the urothelial tract (LNEC): The MSKCC experience. *First Author: Brendan John Guercio, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: LNEC is a rare, poorly characterized entity morphologically resembling small cell NEC of the urothelial tract (SNEC). **Methods:** Pure and partial LNEC and SNEC cases were identified by histopathologic re-review; clinical outcomes were compared. A subset was sequenced with MSK-IMPACT (279-505 genes). **Results:** Between 1992-2020, 43 patients (pts) with LNEC were identified (42 bladder, 1 upper tract); 19 (44%) had concomitant SNEC. LNEC cases were compared to 192 SNEC without LNEC (SNEC-only) (Table 1). Compared to SNEC-only pts, LNEC pts experienced longer overall survival (OS), adjusting for age and M0 vs M1 (median OS not reached vs 22.4 months [mos]; HR 0.34, 95% CI 0.16-0.74, p = .006). Neoadjuvant chemo (NAC) use increased over time. Pathologic response rate (<ypT2N0) after NAC was 25% for LNEC and 50% for SNEC-only (p = .13); the ypTONO rate was 25% for LNEC and 40% for SNEC-only (p = .52). Perioperative chemo did not improve OS compared to surgery alone in LNEC, adjusting for age and concurrent SNEC (HR 1.46, 95% CI 0.12-17.5, p = .76), but was associated with longer OS among SNEC-only pts (n = 98; HR 0.39, 95% CI 0.22-0.69, p = .001). Two M1 LNEC pts received immunotherapy (IO) in the first-line: 1 atezolizumab, 1 atezolizumab + chemo. Both remained free of progression on IO at a follow-up of 20 and 12 mos, respectively. Of 18 sequenced LNEC tumors, 89% had *TERT* promoter alterations (alts), similar to 85% seen in 52 SNEC tumors. All LNEC tumors had alts of *TP53* or *RB1*, and 10 (56%) had both. Median tumor mutational burden (TMB) was 14 (IQR 8-38) in LNEC and 30 (IQR 15-55) in SNEC. Epigenetic modifiers were altered in 78% LNEC and 79% SNEC. Two LNEC pts had *ERCC2* alts and received platinum chemo; both were alive at last follow-up from NEC diagnosis of 30.7-39.1 mos. **Conclusions:** LNEC pts experienced longer OS compared to pts with SNEC-only in this cohort, but did not appear more chemo-sensitive. Genomic profiles of LNEC and SNEC-only tumors were similar; *TERT* promoter mutations suggest a potential urothelial precursor. Further investigation of IO for LNEC is warranted. Research Sponsor: U.S. National Institutes of Health.

LNEC (includes LNEC with concurrent SNEC) vs SNEC-only cases.

Characteristics	LNEC (n = 43)	SNEC-only (n = 192)
Age, median (range)	69 (44-84)	68 (38-94)
% Male	74%	81%
% M0 at diagnosis	81%	74%
NAC (14 LNEC, 62 SNEC-only)	Platinum + etoposide (64%) Platinum + gemcitabine (29%) MVAC (7%)	Platinum + etoposide (81%) Platinum + gemcitabine (10%) MVAC (5%) Other chemo/unknown (5%)
Other treatments (tx) for M0 pts (20 LNEC, 72 SNEC-only)	Surgery alone (30%) Surgery + adjuvant chemo (10%) RT ± chemo (35%) Chemo only (5%) Other/unknown (20%)	Surgery alone (32%) Surgery + adjuvant chemo (18%) RT ± chemo (18%) Chemo only (19%) Other/unknown (13%)
First-line tx for M1 pts (8 LNEC, 46 SNEC-only)	Platinum + etoposide (50%) Platinum + taxane (13%) IO + chemo (13%) IO alone (13%) No systemic tx (13%)	Platinum + etoposide (70%) Platinum + taxane (2%) MVAC (2%) Other chemo (17%) No systemic tx (9%)

Avelumab first-line (1L) maintenance for advanced urothelial carcinoma (UC) in the JAVELIN Bladder 100 trial: Subgroup analysis by duration of treatment-free interval (TFI) from end of chemotherapy to start of maintenance. *First Author: Srikala S. Sridhar, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: The phase 3 JAVELIN Bladder 100 trial, which enrolled patients (pts) with advanced UC that had not progressed with 1L platinum-containing chemotherapy, showed that maintenance therapy with avelumab + best supportive care (BSC) significantly prolonged overall survival (OS) compared with BSC alone (hazard ratio [HR], 0.69 [95% CI: 0.56, 0.86; 1-sided P= 0.0005]). However, the optimal timing for starting avelumab after completing 1L chemotherapy is unknown. In this post hoc analysis, we report efficacy by duration of the TFI from completion of 1L chemotherapy. **Methods:** In the JAVELIN Bladder 100 trial (NCT02603432), eligible pts had unresectable locally advanced or metastatic UC without disease progression following 4 to 6 cycles of 1L platinum-containing chemotherapy. Pts were randomized to receive avelumab + BSC (n = 350) or BSC alone (n = 350) after a TFI of 4 to 10 weeks from the last dose of chemotherapy. In this exploratory analysis, subgroups with a TFI of 4 to < 6 weeks (< 42 days), 6 to < 8 weeks (42 to < 56 days), or 8 to 10 weeks (≥56 days) were evaluated. **Results:** In the avelumab + BSC and BSC alone arms, the TFI was 4 to < 6 weeks in 143 and 158 pts, 6 to < 8 weeks in 109 and 80 pts, and 8 to 10 weeks in 98 and 110 pts, respectively. Baseline characteristics in these subgroups were generally well balanced between arms. For both arms combined, however, the TFI 4 to < 6 weeks subgroup vs the other 2 subgroups included more pts with visceral metastases (57.8% vs 54.0% and 50.0%), an objective response with 1L chemotherapy (76.4% vs 69.3% and 68.3%), and an ECOG performance status of 1 (44.5% vs 33.3% and 35.6%). OS was prolonged with avelumab + BSC vs BSC alone in all subgroups; the HR was 0.76 (95% CI: 0.546, 1.059) in the TFI 4 to < 6 weeks subgroup (median OS, 19.9 months [95% CI: 16.3, 25.3] vs 13.5 months [95% CI: 11.7, 17.4]), 0.64 (95% CI: 0.404, 1.021) in the TFI 6 to < 8 weeks subgroup (median OS, 26.1 months [95% CI: 19.9, not estimable] vs 21.0 months [95% CI: 10.7, not estimable]), and 0.70 (95% CI: 0.468, 1.035) in the TFI 8 to 10 weeks subgroup (median OS, 20.1 months [95% CI: 13.8, not estimable] vs 14.1 months [95% CI: 11.7, 19.6]). **Conclusions:** In patients with advanced UC that had not progressed with 1L platinum-containing chemotherapy, avelumab 1L maintenance prolonged OS irrespective of the TFI assessed in this study (4-10 weeks), supporting this new treatment strategy as a standard of care. Differences in duration of TFI were likely related to individual patient- and disease-specific characteristics or logistics and did not impact the OS benefit observed with avelumab 1L maintenance. Clinical trial information: NCT02603432. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

Study EV-103: Update on durability results and long term outcome of enfortumab vedotin + pembrolizumab in first line locally advanced or metastatic urothelial carcinoma (la/mUC). *First Author: Terence W. Friedlander, University of California San Francisco Medical Center, San Francisco, CA*

Background: Significant unmet need remains for people with cisplatin-ineligible (cis-ineligible) locally advanced or metastatic urothelial carcinoma (la/mUC). In the first-line (1L) setting, carboplatin-based regimens have demonstrated poor tolerability, modest objective response rate (ORR) and limited durability. PD-1/PD-L1 inhibitors demonstrate durable responses; however, only a minority of pts achieve a response (ORR 24-29%). Enfortumab vedotin (EV) is an antibody-drug conjugate (ADC) delivering the microtubule-disrupting agent monomethyl auristatin E (MMAE) to targeted tumor cells expressing Nectin-4. EV has shown an overall survival benefit versus chemotherapy in previously treated la/mUC. Preclinical studies show that ADCs utilizing MMAE can induce immunogenic cell death and may enhance antitumor immunity. Clinical data suggests the combination of EV + pembrolizumab (P) may have the potential to induce greater antitumor activity compared to either agent alone. Preliminary data on EV + P was previously presented, and the FDA granted breakthrough therapy designation to EV + P for the treatment of pts with 1L cis-ineligible la/mUC in Feb 2020. Here we report updated data with 24.9 months median follow-up. **Methods:** This multi-cohort EV-103 study (NCT03288545) evaluates the safety/activity of EV + P (Dose Escalation/Cohort A). This report highlights 1L cis-ineligible pts treated with 3-week cycles of EV 1.25 mg/kg (Days 1, 8) and P (Day 1). Endpoints include safety/tolerability, investigator response per RECIST v1.1, DOR, PFS, and OS. **Results:** As of 13 Oct 2020, the median follow-up for the 45 1L la/mUC pts (median age 69 yrs [51-90]) was 24.9 months. The median number cycles of EV + P was 9 (range 1-34). The most common treatment-related adverse events were peripheral sensory neuropathy (56%, 4% ≥G3), fatigue (51%, 11% ≥G3), and alopecia (49%). There was one death reported as possibly related to study treatment (multiple organ dysfunction syndrome) per investigator assessment. Confirmed ORR is 73.3% (95% CI: 58.1, 85.4) including 17.8% CR and an ORR of 57.1% (8/14) in pts with liver metastasis. The median DOR was 25.6 months (95% CI: 8.3, -). Fifty-three percent of the responders had DOR at 24 months. Additionally, the DCR is 93.3%, the median PFS is 12.3 months (95% CI: 8.0, -), and the median OS is not reached. The OS rate at 24 months is 56.3% (95% CI: 39.8, 69.9). **Conclusions:** EV + P, a platinum-free option, continues to demonstrate promising activity with a durable response profile in 1L cis-ineligible pts with la/mUC. The safety profile is manageable and stable over time with no new safety signals. Cohort K of EV-103 in cis-ineligible pts with la/mUC is actively randomizing pts to EV monotherapy or EV + P to evaluate the contribution of each agent. Clinical trial information: NCT03288545. Research Sponsor: Astellas and Seagen Inc.

Effect of Bacillus Calmette-Guerin (BCG) exposure on severity of COVID-19 infection: A COVID-19 and Cancer Consortium (CCC19) study. *First Author: Andrew Lachlan Schmidt, Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Oncology patients experience more severe disease outcomes from COVID-19 infection than the general population. BCG is a live bovine tuberculosis bacillus with immunotherapeutic effects in urothelial cancers; it is also used as vaccination against *Mycobacterium tuberculosis* in parts of the world. As BCG vaccination has been associated with broad protection against viral pathogens, BCG exposure through vaccination or intravesical therapy may modulate host immunity and reduce the severity of COVID-19 infection. We report the effect of BCG exposure on COVID-19 severity in oncology patients from the CCC19 registry. **Methods:** The CCC19 registry (NCT04354701) was used to identify patients with prior BCG exposure. Cohort A received intravesical treatment for bladder carcinoma, and cohort B received prior BCG vaccination. Each cohort was matched 3:1 to non-BCG-exposed controls by age, sex, race, primary cancer type, cancer status, ECOG performance status (PS) and calendar time of COVID-19 infection. The primary endpoint was COVID-19 severity reported on an ordinal scale (uncomplicated, hospitalized, admitted to ICU +/- ventilated, died within 30 days) of patients exposed to prior BCG compared to matched non-exposed controls. 2-sided Wilcoxon rank-sum tests were used. **Results:** As of 6-Feb-2021 we included 124 patients with BCG exposure, 68 patients with bladder carcinoma who had received intravesical BCG (Cohort A), and 64 cancer patients with prior BCG vaccination (Cohort B). Median age was 76 years, IQR 69-83 (Cohort A) and 67 years, IQR 62-74 (Cohort B). Bladder cancer pts were predominately male (78%) vs 55% for Cohort B. Patients with PS 2+ were uncommon, 18% in Cohort A and 16% in Cohort B. COVID-19 illness severity was no different in patients exposed to prior intravesicular BCG (p=0.87). COVID-19 illness severity was no different in patients exposed to prior intradermal BCG vaccination (p=0.60). **Conclusions:** Despite this being the largest such cohort reported to date, we failed to demonstrate an association of prior BCG exposure with modulation of severity of COVID-19 illness. Prospective trials evaluating the protective effect of BCG vaccination are ongoing and will add further insight into the effect of BCG on COVID-19 illness. Research Sponsor: P30 CA068485.

COVID-19 severity and relationship to BCG exposure.

Fibroblast growth factor receptor alteration (*FGFRa*) status and progression outcomes of patients with advanced or metastatic urothelial cancer (mUC). *First Author: Sarah Fleming, Janssen Research & Development, LLC, Raritan, NJ*

Background: *FGFRa* appear in approximately 15% of cases of mUC. Data on whether *FGFRa* in mUC have a prognostic impact or predictive benefit for particular treatments have been limited by small sample sizes. The objective of this study was to evaluate the association between tumor *FGFRa* and clinical outcomes of patients with advanced UC or mUC regardless of therapy type and status. **Methods:** A convenience sample of oncologists and urologists across the United States provided patient level data on 400 patients with stage IIIb or IV UC via a standardized questionnaire over a 1-month period (August 17, 2020 – September 20, 2020). Study design enriched for *FGFRa* by requiring physicians to provide ≥1 *FGFRa* patient record. The questionnaire included physician characteristics, patient demographic information, FGFR status, therapy given, response, and clinical and radiographic measures of progression. Patient records were eligible for inclusion if they were identified and treated during July 1, 2017, to June 30, 2019. Cox proportional hazards models were used to estimate adjusted risk of disease progression by FGFR status. **Results:** A total of 104 physicians (58.7% medical oncologists, 31.7% hematologic oncologists, and 9.6% urologic oncologists) contributed 414 patient records Overall, 73.9% of the patients were male and the average age was 64.5 years (SD ±10.6). Median follow-up was 15 months. Of the 414 patients, 218 (52.7%) had *FGFRa* and 196 (47.3%) had FGFR wild-type (*FGFRwt*) mUC. Of the 218 patients with *FGFRa*, 47.2% were treated with front-line chemo, 27.5% with a programmed death-ligand 1 inhibitor (PD-L1), 11.5% with chemo + PD-L1, and 13.8% with other treatments. Of the 196 *FGFRwt* patients , 63.2% were treated with front-line chemo, 21.9% with PD-L1, 12.2% with chemo + PD-L1, and 2.6% with other treatments. There was no difference in response or progression status for those receiving front-line chemo (HR, 1.15; 95% CI, 0.86-1.55). Among 97 patients (55 *FGFRa* and 42 *FGFRwt*) who received PD-L1 alone as front-line therapy, those who had *FGFRa* had an adjusted risk of progression 2 times higher than their *FGFRwt* counterparts (HR, 2.12; 95% CI, 1.13-4.00). **Conclusions:** Patients with *FGFRa* mUC progressed earlier than *FGFRwt* patients treated with front-line PDL-1 inhibitors; however, there was no difference in progression in patients treated with chemo based upon FGFR status. This real-world study using a survey design efficiently generated a relatively large *FGFRa* dataset, mitigating a core limitation of other studies assessing the patient population with *FGFRa*. Further work is warranted to validate these results and determine the optimal strategy for treating the patient with *FGFRa* mUC. Gene expression profiling of *FGFRa* mUC samples from clinical trials will help determine the potential impact of subtype or other features that may associate with benefit from therapy. Research Sponsor: Janssen Research & Development, LLC.

Safety evaluation of combined PD-1+CTLA4 inhibition concurrently to chemoradiotherapy (CRT) in localized muscle invasive bladder carcinoma (MIBC). *First Author: Ben-Max de Ruiter, Amsterdam UMC, University of Amsterdam, Department of Urology, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Neoadjuvant nivolumab (nivo) + ipilimumab (ipi) prior to radical cystectomy showed efficacy in localized MIBC. The safety of PD-1 and PDL-1+CTLA4 inhibition concurrent with CRT in localized MIBC has not been assessed. We present the first clinical trial data on concurrent 3 doses of q4w nivo 480mg (cohort1) and concurrent 4 doses of q3w nivo 3mg/kg + ipi 1kg/mg (nivo3+ipi1, cohort2) in combination with Mitomycin C/Capecitabin (MMC/Cape) CRT. **Methods:** We report the first 2 cohorts of a phase 1b, EC approved, study with nivo only or nivo3+ipi1 added to MMC/Cape CRT. CRT consists of MMC i.v. on day 1 with Cape 750mg/m2 on days of radiotherapy. Radiotherapy schedule comprises a 20x2Gy whole bladder irradiation with a simultaneous tumorboost of 20x0.75Gy. Patients with MIBC, T2-4N0-1, ECOG performance status <2 were included. A dose escalation scheme, with a staggered enrollment is used. The first 10 patients received nivo 480mg on week 1, 5, 9. Cohort2 of 10 patients received nivo3+ ipi1 at week 1, 4, 7 and 10. Relevant severe Adverse Events (AEs) were registered as Dose Limiting Toxicity (DLT) when they occurred within 6 weeks after start of treatment. Clinical efficacy is evaluated by cystoscopy and CT at week 12 and 24. **Results:** Both cohorts enrolled 10 patients. Median age was 68 [IQR 61-75] and 70 [IQR 66-75] years in cohort1 and 2, respectively. In cohort1 no patients experienced DLT. No dose reductions were applied. In cohort2, 2 patients experienced DLT, 1 trombocytopenia (grade 4) and 1 asystole (grade 5). 50% of patients did not receive all 4 q3w nivo3+ipi1 infusions, due to AEs. Table 1 reports an overview of AEs. In cohort2 6 SAE's occurred in 3 patients. Median follow up is 71 [IQR 59-86] and 30 weeks [IQR 12-45] in cohort1 and 2, respectively. 1year OS and DFS is 100% in cohort1. **Conclusions:** Concurrent 3 doses nivo 480mg q4w added to MMC/Cape based CRT is feasible with a favorable toxicity profile and shows promising efficacy in MIBC patients. An escalated regimen with 4 doses nivo 3mg/kg + ipi 1mg/kg q3w concurrent to CRT shows acceptable toxicity. Cohort3 with ipi 3mg/kg and nivo 1mg/kg is enrolling. Clinical trial information: NCT03844256. Research Sponsor: Cure for Cancer Foundation & Dutch Cancer Society.

Pembrolizumab (pembro) versus investigator's choice of paclitaxel, docetaxel, or vinflunine in recurrent, advanced urothelial cancer (UC): 5-year follow-up from the phase 3 KEYNOTE-045 trial. *First Author: Joaquim Bellmunt, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA*

Background: Pembro was approved for the treatment of locally advanced or metastatic UC that progressed during or after a platinum-containing regimen, based on the phase 3 KEYNOTE-045 (NCT02256436) trial that showed significantly improved OS with use of pembro. Updated results are presented from KEYNOTE-045 after >5 y of follow-up since the last patient (pt) was randomized. **Methods:** KEYNOTE-045 is a randomized, multisite, open-label, phase 3 trial. Pts with histologically or cytologically confirmed UC, progression after platinum-containing chemo, ECOG PS 0-2, measurable disease per RECIST v1.1, and ≤2 prior lines of systemic therapy were eligible. Pts were randomly assigned 1:1 to receive pembro 200 mg Q3W or investigator's choice of paclitaxel 175 mg/m^2 Q3W, docetaxel 75 mg/m^2 Q3W, or vinflunine 320 mg/m^2 Q3W. Primary end points are PFS (RECIST v1.1, blinded central review) and OS. ORR and duration of response (DOR) were key secondary end points. **Results:** As of Oct 1, 2020, among 542 enrolled pts, median time from randomization to data cutoff was 62.9 mo (range 58.6-70.9). 9.4% and 0% of pts in the pembro and chemo arms, respectively, completed 2 years of therapy. Median OS was longer for pembro vs chemo (10.1 vs 7.2 mo; HR, 0.71 [95% CI, 0.59-0.86]) overall and in pts with CPS ≥10 (8.0 vs 4.9 mo; HR, 0.59 [95% CI, 0.40-0.86]). For pts with CR or PR, median OS was not reached and 16.4 (95% CI, 11.3-25.1) mo in the pembro and chemo arms, respectively (Table). OS rates at 48 mo were 16.7% for pembro and 10.1% for chemo; 60-mo OS rates were 14.9% and 8.7%, respectively. OS benefit with pembro vs chemo continued regardless of age, ECOG PS, prior therapy, liver metastases, baseline hemoglobin, time from last chemo, histology, risk factors, and chemo choice. Median DOR for responders was longer for pembro vs chemo (29.7 mo [1.6+ to 60.5+] vs 4.4 mo [1.4+ to 63.1+]), and a greater proportion of responses lasted ≥48 mo (40.9% vs 28.3%, Kaplan-Meier) and ≥60 mo (32.8% vs 28.3%). ORR was higher for pembro vs chemo (21.9% vs 11.0%; difference 10.8% [95% CI, 4.6-17.0]). Fewer pts given pembro vs chemo experienced a treatment-related AE of any grade (62.0% vs 90.6%) or grade ≥3 (16.9% vs 50.2%). **Conclusions:** After 5 y, pembro maintained clinically meaningful OS benefit vs chemo in pts with locally advanced or metastatic UC that progressed during or after platinum-based chemo. Pts who responded to pembro experienced a durable response (median >2 y). Clinical trial information: NCT02256436. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Stool microbiota profiling of patients with muscle invasive bladder cancer receiving neoadjuvant pembrolizumab. *First Author: Filippo Pederzoli, Vita-Salute San Raffaele University, Milan, Italy*

Background: Immune checkpoint inhibitors (ICIs) showed efficacy in metastatic urothelial carcinoma (UC) and promising activity in muscle-invasive and non-muscle invasive UC of the bladder. Recent studies revealed the immunomodulatory effect of the gut microbiota on ICIs efficacy across several malignancies, identifying microbial "signatures" associated with response to therapy and effective antitumoral T-cell activity. In our study, we aimed to study the stool microbiota in patients undergoing neoadjuvant immunotherapy (IO) for muscle-invasive UC. **Methods:** Pre-IO stools were available for analysis from 42 patients enrolled in the PURE-01 trial (NCT02736266), testing 3x200mg flat-dose pembrolizumab every 21 days before radical cystectomy (RC). All samples were collected using Stool Nucleic Acid Collection and Preservation Tubes (Norgen) and extracted using the Stool DNA Isolation Kit (Norgen), according to the manufacturer's protocol. 16s sequencing was performed using standardized protocols at the internal facility, using mock communities and DNA standards (ZymoBIOMICS) to control for extraction and sequencing contaminations. A QIIME-based bioinformatic pipeline was used for microbiome analyses. Complete response (CR) to neoadjuvant IO was defined as ypT0N0 at pathologic examination on radical cystectomy specimens, while partial response (PR) was defined as < ypT2N0. Concomitant antibiotic therapy (ABT) was defined as any ATB between 30 days prior to the first pembrolizumab dose and the planned RC. **Results:** In our study sample, 23 patients responded to IO (21 CR + 2 PR). Overall median age was 68.5 years. Among responders, 20 (87%) patients had a smoking history (vs. 15 (79%) in non-responders) and 4 (17%) underwent concomitant ABT (vs. 6 (32%) in non-responders). Alpha-diversity assessed by richness (ACE index) was higher in responders vs. non-responders ($p = 0.05$), while no significant diversity was found. Beta-diversity did not show clear clustering of responders vs. non-responders. LEfSe identified 16 bacterial taxa with a linear discriminant analysis (LDA) score ≥2.5 that were differently enriched between responders and non-responders. Among them, we identified the genus *Sutterella* enriched in responders ($p = 0.02$), while the species *Ruminococcus bromii* was enriched in non-responders ($p = 0.02$). **Conclusions:** Our analyses showed an association between response to neoadjuvant-IO and microbiome composition in an intention-to-cure population with muscle invasive UC. We found bacterial taxa specifically enriched in responders or non-responders using pre-therapy stool specimens. The identified taxa may be tested in future studies as potential indicators of therapy outcomes, alone or in combination with other IO biomarkers. These results may also inspire new strategies of gut microbiota modulation to promote response in immunotherapy-refractory patients. Research Sponsor: None.

RC48-ADC combined with toripalimab, an anti-PD-1 monoclonal antibody (Ab), in patients with locally advanced or metastatic urothelial carcinoma (UC): Preliminary results of a phase Ib/II study. *First Author: Li Zhou, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: RC48-ADC is a novel humanized anti-HER2 antibody-drug conjugate (ADC), which showed promising data in HER2-positive and even negative patients (pts). Anti-PD-1 Abs have durable antitumor effect for mUC especially in PD-L1 positive patients. The combination may have synergistic antitumor effect. This phase 1b/II study evaluated the safety and activity of RC48-ADC combined with toripalimab in mUC. **Methods:** In dose-escalation cohort, pts received 1.5 or 2 mg/kg RC48-ADC + 3mg/kg toripalimab with the traditional 3+3 escalation design. In expansion cohort, patients received the recommended dose of RC48-ADC + toripalimab every 2 weeks. The primary endpoints were safety/tolerability and recommended RC48-ADC dose; secondary endpoints included pharmacokinetics, ORR per RECIST 1.1, PFS, and OS stratified by HER2 and PD-L1 expression. HER2 positivity was determined by IHC and in situ hybridization (ISH). PD-L1 expression was tested with IHC 22C3 pharmDx assay. **Results:** As of 8 Jan 2021 (data cutoff), 14 mUC pts (9 males, median age 66 y [52-76]) were enrolled. Most pts were systemic treatment naïve (57%) in the locally advanced or metastatic setting. The primary site was in upper tract UC in 50%; 50% had visceral metastases (mets), including 36% with liver mets; HER2 expression was positive (IHC 3+ or 2+ ISH+) in 28%, and 43% PD-L1 CPS≥10. A total of 36 pts is anticipated to be enrolled by Apr 2021. No dose limiting toxicity was reported and the recommended dose for RC48-ADC was 2mg/kg. At data cutoff, 10/14 patients were evaluable for response, with 8 PR, 1 SD (tumor shrinking), and 1 PD. The objective response rate (ORR) was 80%, and disease control rate (DCR) was 90%. All responsive patients have durable efficacy and are still on treatment. Follow-up continues for PFS and OS. Most common treatment-related AEs were grade 1-2, including aminotransferase level increased (7/14, 50%), weight loss (6/14, 43%), alopecia (6/14, 43%), asthenia (4/14, 29%), anemia (3/14, 21%), leukopenia (21%), peripheral sensory neuropathy (21%), hypothyroidism (21%), blood triglycerides increased (21%), and creatine phosphokinase increase (21%). One pt had G3 intestinal obstruction attributed to study drug and went back to treatment after recovery. **Conclusions:** RC48-ADC in combination with toripalimab had a good tolerance and promising anti-tumor activity in pts with mUC. Further evaluation of safety and efficacy is ongoing. Clinical trial information: NCT04264936. Research Sponsor: Remegen.

Influence of first-line chemotherapy regimen on survival outcomes of patients with advanced urothelial carcinoma who receive second-line immunotherapy. *First Author: Benjamin Miron, Fox Chase Cancer Center, Philadelphia, PA*

Background: Treatment of advanced urothelial carcinoma (mUC) has improved following approvals of PD-1/PD-L1 inhibitors. Platinum chemotherapy remains the standard-of-care in the first-line (1L). Cisplatin (Cis) regimens are accepted to be superior to carboplatin (Carbo) regimens for patients (pts) who are Cis-eligible. We sought to evaluate if differences in efficacy of 1L Cis vs. Carbo have meaningful impact on overall survival (OS) in the era of second-line (2L) immunotherapy (IO). **Methods:** We conducted a retrospective, observational cohort study to compare OS for pts treated with 1L Cis or Carbo combined with gemcitabine (Gem) followed by 2L IO using patient-level data from the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database. Pts included were diagnosed with mUC between 9/1/2015 and 9/15/2020. 2L IO was defined as single-agent atezolizumab, avelumab, durvalumab, nivolumab, or pembrolizumab. OS was calculated from start of 1L and 2L therapy and compared using Kaplan-Meier curves. Time to 2L IO was calculated from start of 1L to start of IO. Adjusted OS was calculated using multivariable Cox regression models, adjusting for age, gender, race, ECOG performance status, primary site, prior cystectomy, smoking status, and year of diagnosis. **Results:** A total of 1882 pts were included, 924 (49.1%) received Gem/Cis and 958 (50.9%) received Gem/Carbo in 1L. A similar percentage of pts did not receive any 2L therapy following Gem/Cis (46.4%) or Gem/Carbo (46.0%). Our analysis focused on the 780 pts (41.4%) who received 2L IO—381 after Gem/Cis and 399 after Gem/Carbo. Median follow-up time for the group was 35 months (mo). Pts in the Gem/Cis cohort were younger, had better performance status and lower incidence of upper tract disease (Table). OS from start of 1L therapy was numerically longer in pts who received Gem/Cis compared to Gem/Carbo on unadjusted (median 18.0 v 16.2 mo, $p = 0.06$) and adjusted analyses (HR = 0.83, 95% CI 0.69-1.00, $p = 0.055$) but neither result was statistically significant. Time to 2L IO was longer for pts receiving Gem/Cis (6.5 mo) vs Gem/Carbo (5.5 mo, $p = 0.008$). Survival time on 2L IO did not differ significantly by 1L regimen (Gem/Cis 8.0 mo vs Gem/Carbo 8.2 mo $p = 0.36$). **Conclusions:** Real world data suggests that in pts with mUC who are able to receive second-line IO, the choice of first-line platinum chemotherapy may not provide a distinguishable OS benefit. Despite methodologic limitations of this data, a greater focus in discussions with patients on toxicity associated with cisplatin vs carboplatin may be warranted. Research Sponsor: None.

Use of neoadjuvant chemotherapy in elderly patients with muscle invasive bladder cancer: A population-based study, 2006 to 2017. *First Author: Natasza Posielski, Virginia Mason Medical Center, Seattle, WA*

Background: Current guidelines recommend neoadjuvant chemotherapy (NAC) prior to radical cystectomy (RC) for muscle invasive bladder cancer (MIBC). NAC has been shown to confer a survival benefit across all ages. Yet, many elderly patients are not offered NAC due to concern regarding physiologic reserve and postoperative complications. Our objective was to evaluate age-based disparity in treatment and outcomes of MIBC. **Methods:** Using the National Cancer Database, we identified patients with MIBC from 2006-2017. First, use of different treatments, RC, RC and adjuvant chemotherapy, RC with NAC ("optimal treatment"), chemo-radiation, and no treatment, was compared between age groups. A second analysis was performed in the cohort of elderly patients, ≥70, undergoing cystectomy. Propensity weighting was used to compare peri-operative and mortality outcomes in those who received NAC vs. no NAC. **Results:** In 70,911 patients with non-metastatic MIBC, use of RC with NAC was lower in patients ≥70, 7.2 vs. 20.9%, $p<0.001$ (Table). Patients receiving RC with NAC were younger, had private insurance, higher high school completion rate and median income, shorter distance to hospital, lower CCI, diagnosis in recent years, and higher stage disease. NAC use was also associated with pelvic lymph node dissection (OR 4.55, $p<0.001$). In patients ≥70 undergoing RC, NAC was associated with shorter length of stay (LOS) (8.5 vs 9.6 days, $p<0.001$), decreased 30-day readmission (8.6 vs 10.6%, $p=0.003$), lower 30- and 90-day mortality (1.9 vs 3.6%, $p=0.01$ and 4.9 vs 7.7%, $p=0.004$, respectively), and better overall survival (OS) (43.8% vs. 37.5%, $p<0.001$). Multivariate logistic regression found NAC as an independent predictor of shorter LOS, lower 30-and 90-day mortality, and improved OS. **Conclusions:** Despite increased omission of NAC in patients ≥70, NAC is not associated with worse peri-operative outcomes or mortality in elderly patients. Advanced age in properly selected patients should not preclude offering NAC prior to radical cystectomy. Research Sponsor: None.

Response and outcomes to immune checkpoint inhibitors (ICI) in advanced urothelial cancer (aUC) based on prior intravesical BCG. *First Author: Rafee Talukder, University of Washington, Seattle , WA*

Background: Little is known regarding response and outcomes to ICI for patients (pts) with aUC who were previously treated with BCG for non-muscle invasive bladder cancer. We hypothesized that prior intravesical BCG would not be associated with changes in objective response or survival in pts with aUC treated with ICI. **Methods:** We performed a retrospective cohort study across 25 institutions. Demographic, intravesical BCG history, treatment and outcomes data were collected for pts with aUC who received ICI. Pts with aUC treated with ICIs were included, pts with pure non-UC, those treated with combination or on clinical trials, pts with multiple ICI treatment lines and those with upper tract UC were excluded. Pts were stratified to prior exposure versus no exposure to BCG. We compared overall response rate (ORR) using logistic regression; and progression-free survival (PFS) and overall survival (OS) using Kaplan-Meier and Cox proportional hazards. All analyses were performed in the overall population and further stratified by treatment line (first-line [1L] vs salvage [2+L]) and multivariable models. The stratified analysis was also adjusted for an internally developed risk score for 1L and Bellmunt risk score for 2+L; $p<0.05$ was significant. **Results:** 1026 aUC pts treated with ICI were identified; 614 pts, 617 pts, and 641 pts were included in ORR, OS and PFS analyses, respectively. Overall, mean age at CPI initiation was 70, 76% were men, 70% were current or former smokers, 75% White, 29% with mixed histology, and 24% had prior exposure to BCG. ORR to ICI in pts with or without prior exposure to BCG was similar, 27% and 28% respectively (OR=0.93 [95% CI 0.61-1.42], p=0.73). Median OS (mOS) for pts with vs without prior BCG exposure was 9 vs 10 mo (HR=1.13 [95% CI 0.88-1.44], p=0.35). Median PFS (mPFS) was 4 months (mo) in both groups (HR=1.02 [95% CI 0.82-1.27], p=0.83). ORR, PFS and OS analyses stratified by ICI treatment line (1L vs 2+L) are listed in the table. **Conclusions:** In this multi-institutional retrospective analysis, prior intravesical BCG was not associated with objective response or survival in pts with aUC treated with ICI. Limitations of this study include retrospective nature, lack of randomization and possible confounding, but it does provide important preliminary data that selection for ICI treatment should not be impacted by prior exposure to BCG. Further clinical and molecular biomarker exploration is needed to refine patient selection for ICI in aUC. Research Sponsor: None.

Real-world treatment patterns and clinical outcomes among patients with metastatic urothelial carcinoma. *First Author: Daniel M. Geynisman, Fox Chase Cancer Center, Department of Hematology and Oncology, Philadelphia, PA*

Background: Knowledge of large-scale real-world treatment patterns and clinical outcomes in patients (pts) with metastatic urothelial carcinoma (mUC) is limited. We conducted this study to address the lack of knowledge and identify unmet needs in pts with mUC in real-world clinical practice. **Methods:** The US nationwide Flatiron Health electronic health records–derived, de-identified database, comprised of 280 oncology practices across the US, was utilized to conduct a retrospective cohort analysis of pts diagnosed with mUC between Jan 1, 2011, and Aug 31, 2020. Baseline pt characteristics were assessed descriptively, and treatment patterns were classified by cisplatin (CIS) eligibility. Kaplan–Meier methods were used to evaluate overall survival (OS) and progression-free survival (PFS). In a subgroup analysis of cisplatin-ineligible (CIS-inelig) pts, a multivariable model adjusting for baseline covariates was used to assess survival outcomes. **Results:** Of 8183 pts with mUC, median age was 73.0 years at diagnosis. Primary tumor sites were bladder (78.5%), upper tract (20.6%), and urethra (0.9%). Median (range) follow-up from mUC diagnosis was 9.7 (0.2-116.6) months. Of 5855 (71.6%) pts who received first-line (1L) systemic therapy, 1764 (30.1%) were CIS eligible (CIS-elig), 2293 (39.2%) were CIS-inelig, and 616 (10.5%) did not receive CIS despite qualifying ECOG PS (0–1) and renal function; CIS eligibility was unknown in 1182 (20.2%). Among all 1L pts, 4380 (74.8%) received chemotherapy and 1410 (24.1%) received immunotherapy (IO); of the IO users, 1345 (95.4%) received monotherapy. Among CIS-elig pts, CIS plus gemcitabine (GC) and methotrexate, vinblastine, doxorubicin, CIS (MVAC) accounted for 1562 (88.5%) of 1L therapy. Among CIS-inelig pts, carboplatin plus gemcitabine (GCa; 36.1%), pembrolizumab (pembro) monotherapy (18.5%), and atezolizumab (atezo) monotherapy (15.1%) were the most common 1L therapies. Across CIS eligibility groups, the most common second-line therapies included pembro, atezo, and GCa; the most common third-line therapies included atezo, pemetrexed, paclitaxel, and GCa. Median OS (95% CI) was longer in pts who received $\geq$ 1 line of systemic therapy (14.5 [14.0–15.2] months) than in those who did not receive therapy (6.8 [6.2–7.3] months). Median (95% CI) OS and PFS were also longer in CIS-elig pts (OS, 19.7 [18.2–21.4] months; PFS, 11.5 [10.8–12.1] months) than in CIS-inelig pts (OS, 11.4 [10.8–12.0] months; PFS, 7.0 [6.7–7.4] months), irrespective of receiving treatment. In a subgroup analysis of CIS-inelig pts, 1L IO monotherapy was associated with worse OS than 1L chemotherapy (HR, 1.26; 95% CI, 1.13–1.40, $P < 0.0001$). **Conclusions:** This study of > 8000 mUC pts, of whom almost 30% never received systemic therapy, demonstrates real-world treatment patterns in mUC and highlights the substantial unmet need in this population, in particular for CIS-inelig pts. Research Sponsor: None.

Quality of life, functioning, and symptoms in patients with previously treated locally advanced or metastatic urothelial carcinoma from EV-301: A randomized phase 3 trial of enfortumab vedotin versus chemotherapy. *First Author: Ronac Mamtani, University of Pennsylvania, Philadelphia, PA*

Background: In EV-301, a randomized, open-label phase 3 study (NCT03474107), enfortumab vedotin (EV), a Nectin-4–directed therapy, significantly prolonged median overall survival by ~3.9 months and reduced the risk of death by 30% compared with standard chemotherapy (SC; docetaxel, paclitaxel, or vinflunine) in patients with previously treated locally advanced/metastatic urothelial carcinoma. Understanding patient perspectives and experiences is important to further contextualize the benefits/risks of EV. Here, we report key prespecified quality-of-life (QoL) endpoints, a secondary objective of EV-301. **Methods:** Patients completed the validated European Organization for Research and Treatment of Cancer Core Quality of Life Questionnaire Core 30 (QLQ-C30) at baseline, on Day 1 of each week for the first 12 weeks, and then every 12 weeks until discontinuation. The QLQ-C30 assessed functional domains, symptom scales/items, financial impact, and overall health/QoL. Descriptive statistics were used to summarize instrument compliance rates and scores; mixed model repeated measures were used to evaluate changes from baseline over time. Logistic regressions were conducted to assess confirmed improvement rates, defined as clinically meaningful improvement (predefined per domain) over two subsequent visits. **Results:** Of the 608 randomized patients (EV, n = 301; SC, n = 307), 77.3% were male, median age was 68 (range: 30-88), and 30.9% had liver metastasis. Questionnaire compliance rates at baseline were ~90% in both groups; during the study, average rates were 70.2% (EV) and 66.9% (SC). Baseline QLQ-C30 scores were similar between groups. At Week 12, scores on the global health status (GHS) scale were similar between groups (EV: -2.8, SC: -5.0; P= .2429), but SC was associated with numerically greater deterioration and more variability in QoL over the first 12 weeks. Patients receiving EV had significant reduction in pain symptoms (EV: -5.62, SC: +0.11; adjusted difference: -5.73, $P< .05$), but significant worsening of appetite loss (EV: +8.55, SC: +1.26; adjusted difference: 7.29, $P< .05$) compared with SC. Other symptom scores were not significantly different between groups. Higher proportions of patients on EV vs SC had significant confirmed improvements across all functioning domains (role, physical, emotional, social, cognitive), GHS, and several symptom scales (pain, fatigue, dyspnea, constipation). The greatest difference in improvement was reported for pain (EV: 51.6%, SC: 28.8%; OR = 2.76[1.81, 4.22]). **Conclusions:** Compared with SC, patients receiving EV had numerically less deterioration and variability in QoL during the first 12 weeks of treatment. More patients in the EV group had improvements over SC in 10 of 15 QLQ-C30 domains; improvement in pain showed the largest benefit. Clinical trial information: NCT03474107. Research Sponsor: Astellas Pharma, Inc, Pharmaceutical/Biotech Company.

Impact of recurrence on health-related quality of life in patients at high risk of recurrence after radical surgery for muscle-invasive urothelial carcinoma (MIUC): Results from the phase 3 CheckMate 274 trial. *First Author: Matt D. Galsky, Division of Hematology and Medical Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Patients (pts) undergoing radical surgery for MIUC face a high risk of disease recurrence. Recurrence is associated with worse survival, but its effect on health-related quality of life (HRQoL) is unclear. This post hoc analysis assessed the impact of recurrence on HRQoL using data from the phase 3 CheckMate 274 trial. **Methods:** Pts who had undergone radical surgery for high-risk MIUC ($\leq$ 120 days previously) were randomized 1:1 to nivolumab 240 mg Q2W or placebo for $\leq$ 1 year. HRQoL was assessed using the EORTC QLQ-C30 and EQ-5D-3L every 4–6 weeks during treatment; 35 and 115 days after the last dose; and every 3 months after that until the end of the study (EQ-5D-3L only). The analysis included pts with a valid HRQoL assessment at baseline and at $\geq$1 post-baseline visits. Confirmed deterioration in HRQoL was defined as worsening exceeding an a priori points threshold (± 10 for the EORTC QLQ-C30 domains, –7 for the EQ-5D visual analogue scale [VAS]) at $\geq$ 2 consecutive visits. Recurrence was classified as local only or distant (with or without local recurrence). The effect of recurrence on HRQoL deterioration was assessed by Cox proportional hazards regression with recurrence as a time-dependent covariate. The models controlled for treatment arm and baseline HRQoL score, and were stratified by PD-L1 expression, pathologic nodal status, and use of neoadjuvant cisplatin-based chemotherapy. **Results:** The analysis included 645 pts for EORTC QLQ-C30, of whom 71 (11%) had local recurrence only and 136 (21%) had distant recurrence during the HRQoL assessment period; and 648 pts for EQ-5D-3L. with recurrence had a significantly higher risk of confirmed deterioration in all HRQoL domains than those without recurrence (see table). However, hazard ratios were consistently greater for distant recurrence than for local recurrence across all HRQoL domains. For local recurrence only, a higher risk of confirmed deterioration in HRQoL compared to no recurrence was observed only for global health status/QoL. **Conclusions:** Recurrence, particularly distant recurrence, had a significant, negative impact on HRQoL. This suggests that treatment delaying recurrence after radical surgery for high-risk MIUC may prevent or delay HRQoL deterioration in these pts. Clinical trial information: NCT02632409. Research Sponsor: Bristol Myers Squibb.

Adjusted hazard ratios (95% confidence interval) for recurrence vs. no recurrence.

Phase II trial of atezolizumab in BCG-unresponsive non-muscle invasive bladder cancer: SWOG S1605 (NCT #02844816). *First Author: Peter C. Black, Vancouver Prostate Centre, University of British Columbia, Vancouver, BC, Canada*

Background: Radical cystectomy (RC) is the standard of care for patients with BCG-unresponsive high risk non-muscle invasive bladder cancer (NMIBC), but many patients are unfit for surgery or elect bladder preservation. This trial was designed to evaluate the activity of atezolizumab in BCG-unresponsive high risk NMIBC. **Methods:** This single arm phase II registration trial testing systemic atezolizumab (1200 mg IV) every 3 weeks for one year aimed to enroll 135 (70 CIS and 65 non-CIS) eligible patients with histologically proven BCG-unresponsive high risk NMIBC who were unfit for or declined RC. Here we report the 18 month results for all eligible patients who received at least one protocol treatment. The co-primary endpoints were pathological complete response (CR) rate at 6 months in patients with CIS (reported at ASCO 2020), and event-free survival (EFS) in all patients at 18 months using Kaplan-Meier methods (KM), conditional on a positive CIS response rate. A sample size of 135 evaluable patients provided 93% statistical power for detecting a 30% 18-month EFS rate versus 20% using a one-sided alpha = 0.05. EFS in the subset with Ta/T1 disease and duration of response in CIS patients were secondary endpoints. **Results:** 172 patients were enrolled, 166 received at least one dose of atezolizumab and are included in the safety analysis, and, of those, 128 were eligible and included in the efficacy analysis. As previously reported, 20 (27%) out of 74 patients with CIS attained a pathologic CR at 6 months. The KM estimate of 12 month (actual 11.9 mo) duration of response after 6 month CR for CIS patients was 54% (95% CI 30%, 78%) and the median duration of response was 16.5 months. The KM EFS rate at 18 months in 74 patients with CIS was 17% (90% CI 9%, 25%). The 18 month KM EFS rate in the overall population of 128 patients with Ta, T1 and CIS was 29% (90% CI 22%, 36%). The 18 month actuarial EFS rate in 54 patients with Ta/T1 disease was 45% (90% CI 34, 57%). Any possibly or probably treatment-related adverse event (TRAE) was observed in 142 out of 166 (86%) patients who received any atezolizumab regardless of eligibilty. The most frequent TRAEs were fatigue 72 (43%), diarrhea 34 (20%), and anemia 38 (23%). Grade 3-5 TRAEs occurred in 28 (17%) patients, including rash in 4 (2%), hyponatremia in 4 (2%), hypertension in 3 (2%) and elevated liver function tests in 3 (2%). There were two treatment-related deaths (sepsis and respiratory failure due to myasthenia gravis). **Conclusions:** The observed response of atezolizumab at 6 and 18 months in patients with BCG-unresponsive CIS suggests that this could be a valuable treatment to address a critical unmet need in this patient population. The 18 month EFS in patients with Ta/T1 disease suggests activity in this patient subset. This trial provided no new safety concerns. Funding: NIH/NCI grants: CA180888, CA180819, CA180820, CA180821, CA180863 and in part by Genentech. Clinical trial information: NCT02844816. Genomic predictors of response to PD-1 axis inhibitors in metastatic urothelial cancer (mUC) patients using machine learning analysis of tissue comprehensive genomic profiling (CGP). *First Author: Raquel Reisinger, University of Utah School of Medicine, Salt Lake City, UT*

Background: Immune check point inhibitors (ICI), specifically PD-1 axis inhibitors, are an established treatment for mUC patients (pts), though molecular markers of response are not well-established. Probabilistic Graphical Models (PGMs) are artificial intelligence (AI) algorithms that capture multivariate, multi-level dependencies in complex patterns in large datasets while retaining human interpretability. We hypothesize that machine learning analysis can reveal biomarkers of response to ICI beyond Tumor Mutational Burden (TMB) and PD-L1 expression. **Methods:** Pts with mUC receiving systemic therapy and available tumor CGP were included in the analysis. CGP was performed by a CLIA validated NGS panel (Foundation Medicine). 17 clinically relevant variables were included in the analyses. Multilevel molecular and clinical interdependencies between ICI response were assessed using a Bayesian network (BN) machine learning approach. To account for high computational cost of the BN dependence structure discovery, variables were selected based on primary and secondary dependencies to ICI Objective Response Rate (ORR) via Hill Climbing Algorithm. Genes selected for analysis included those present in $>$ 5% of the cohort. All variants of unknown significance were removed. Kaplan-Meyer (KM) survival analysis was also performed. **Results:** 174 pts were eligible and included: median age was 67 (33 – 86), 54.6% were smokers, 27.6% male, 14.4% had upper tract disease at diagnosis and 77 pts were treated with an approved ICI. Results from BN analysis revealed strong positive interdependencies between ICI ORR and TMB $\geq$ 10 or mutated *PIK3CA* gene. KM analysis was in agreement with BN results, a low TMB ($<$ 10 muts/MB) and wild-type PIK3CA were predictive of poor PFS (Table). PGMs will be presented at the meeting. **Conclusions:** BN and KM survival analysis supported TMB $\geq$ 10 as a biomarker of improved outcomes to ICI. Moreover, these results reveal mutated PIK3CA as a novel biomarker of improved outcomes to ICI. Study has limitations as expected in a retrospective analysis. These hypothesis-generating data require external validation. Research Sponsor: U.S. National Institutes of Health.

Biomarker	RR of ICI ORR[1] (± Std Dev)
High TMB (≥10 Muts/MB)	1.31 (0.22)
PIK3CA (mutant)	1.61 (0.25)
PFS HR (95% CI), p-value	
TMB (< 10 vs ≥10 Muts/MB)	2.411 (1.244 - 4.672), p < 0.01
PIK3CA (wild-type vs mutant)	2.223 (1.160 - 4.260), p < 0.02

[1]Relative risk of codependency of biomarker and ICI ORR compared to biomarker alone.

Survival outcomes in patients receiving immune checkpoint inhibitor (ICI) for metastatic small cell urothelial cancer (SCUC). *First Author: Omar Alhalabi, Beaumont Health, Royal Oak, TX*

Background: The prognosis in patients with metastatic SCUC (mSCUC) remains poor with median survival around 1 year with systemic chemotherapy. We aimed to investigate the impact of ICI on survival of patients with mSCUC. **Methods:** Patients who received systemic therapy at MD Anderson Cancer Center (MDACC) for de novo or metachronous mSCUC after completing local management. within 12 months of neoadjuvant or adjuvant chemotherapy were included in this cohort, with overall survival (OS) calculated from the time of receipt of initial chemotherapy. Hazard ratios (HR) and 95% confidence intervals (95% CI) were calculated using logrank test. **Results:** 102 patients with mSCUC received systemic therapy at MDACC between April 2006 and June 2020. Median age was 66 (range 24 – 86 years), male to female ratio was 5. Bladder was the primary site in 85 (83%), 45 (44%) had prior cystectomy and 9 (9%) had prior nephroureterectomy. Histologies included 51 (50%) with predominant small cell (SC) features, 28 (27%) with focal SC features, 20 (20%) with pure SC, and 3 (3%) mixed with large cell component. Thirty-nine (38%) received ICI during their disease course: 29 (28%) following front-line chemotherapy (15 of whom within 12 months of neoadjuvant/adjuvant platinum therapy), 5 (5%) combined with front-line chemotherapy, and 5 (5%) received ICI front-line (two of whom were able to receive second-line chemotherapy). ICI agents used included anti-PD-1 (n=19), anti-PD-L1 (n=12), anti-PD-1/anti-CTLA-4 (n=5), anti-PD-1/anti-TIM3 (n=1), anti-PD-1/anti-STAT3 (n=1), anti-PD-L1/PARPi (n=1). Those who received ICI at any time had an improved median OS compared to those treated with chemotherapy alone (20.1 vs 12 months), [HR=0.45, 95% CI 0.27-0.72, p=0.003]. When we limited the analysis to those with de novo mSCUC (n=36), those who received ICI at any time (n=13) had an improved median OS compared to those treated with chemotherapy alone (n=23) (not reached vs 9.41 months), [HR=0.28, 95% CI 0.12-0.68, p=0.03]. Among patients who received ICI (n=39), median OS in those with liver metastases (n=11) was numerically shorter than those without (n=28) (13.1 vs 21.6 months), [HR=1.83, 0.59-5.7, p=0.21]. **Conclusions:** ICI improves OS for patients with mSCUC. Although clinical trials remain difficult in these rare variants, further prospective studies are indicated to confirm this finding. Research Sponsor: None.

Phase I/II trial of pembrolizumab and cabozantinib in the treatment of metastatic renal cell carcinoma (mRCC). *First Author: Elizabeth R Kessler, University of Colorado Cancer Center, Anschutz Medical Campus, Aurora, CO*

Background: Checkpoint inhibitors (CPI) and vascular endothelial growth factor receptor inhibitors (VEGFi) are standard treatments for patients (pts) with mRCC. This phase I/II study evaluated the safety and efficacy of the novel combination of pembrolizumab (pembro) and cabozantinib (cabo). The phase I dose escalation data was presented at ASCO GU 2019. We now report the objective response rate (ORR), progression free survival (PFS), overall survival (OS), and toxicity of patients in the phase II dose expansion. **Methods:** Eligible pts had metastatic clear cell (ccRCC) or non-clear cell (nccRCC) histology, normal organ function, ECOG 0-1, and no prior exposure to pembro or cabo. Pts could be treatment-naïve or have received prior CPI and/or VEGFi. Pts were dosed at the recommended phase 2 dose of pembro 200 mg IV Q3W in combination with cabo 60 mg PO QD. Scans were obtained every 9 weeks. Treatment beyond progression, in the setting of continued clinical benefit, was allowed. The primary endpoint was ORR. Simon's two-stage design was implemented to test the null hypothesis that ORR $\leq$ 0.20 versus the alternative that ORR $\geq$ 0.50. **Results:** Forty pts were enrolled, of which 34 pts (85%) had ccRCC and 6 pts (15%) had nccRCC. This was first-line treatment for 15 pts (38%) and second- and subsequent-line therapy for 25 pts (62%). IDMC risk category was favorable in 15%, intermediate in 72.5%, and poor in 12.5% of pts. Prior therapies included VEGFi in 17 pts (43%), CPI in 17 pts (43%), and 9 pts (23%) had both prior VEGFi and CPI in combination or sequentially. At a median follow up of 17.8 months (mo), the ORR was 60% (95% CI 0.458-1.00), clinical benefit rate (CBR) was 92.5% (95% CI 0.817-1.00), median time to response was 4.2 mo; median duration of response was 8.4 mo. Three of six nccRCC pts achieved partial response. Median PFS was 10.4 mo (95% CI 6.3 mo-NR). Median OS was not reached. Twelve patients remain on treatment. The most common grade 1 and 2 (G1/2) treatment-related AEs were diarrhea (53%), fatigue (49%), weight loss (47%), nausea (43%), and dysgeusia (43%). Twenty-five patients (47%) experienced a treatment-related G3 AE and there were no G4 related AEs. Thirteen pts experienced serious adverse events, 8 of which were related to treatment: G3 transaminitis and hypoglycemia were attributed to the combination; G3 pancreatitis, nephritis, and pneumonitis attributed to pembro; G3 pulmonary embolus, confusion due to reversible posterior leukoencephalopathy (RPLS), and stroke attributed to cabo. There was one treatment-related death in the pt with RPLS, possibly related to cabo. **Conclusions:** This study of the combination of pembrolizumab 200mg and cabozantinib 60mg met the primary endpoint of ORR. Benefit was seen in first- and subsequent-line therapy. The safety profile was manageable. This combination warrants further confirmation in a randomized controlled trial. Clinical trial information: NCT03149822. Research Sponsor: Merck.

Health care disparities and barriers to palliative care among metastatic renal cell carcinoma patients: An NCDB analysis. *First Author: Janvi Wadiwala, Houston Healthcare, Perry, GA*

Background: Palliative care improves quality of life for both patients and caregivers but may be underutilized due to socioeconomic barriers to access. An NCDB analysis was performed to analyze the effect of socioeconomics on palliative care receipt among patients with metastatic renal cell carcinoma. **Methods:** A retrospective hospital-based analysis was performed using the National Cancer Database to identify variables that significantly affect receipt of palliative care among patients diagnosed with metastatic renal cell carcinoma diagnosed between 2004 and 2016. Sub-cohort analysis was also performed among patients with the most severe disease. Multivariate binominal logistic regression was performed to determine the association of underlying socioeconomics with receipt of palliative care. The odds of receiving palliative care based on socioeconomic factors was reported as odds ratios (OR) with 95% CI. **Results:** There were 50405 patients meeting inclusion criteria with 40448 (80.2%) undergoing no palliation and 9957 (19.8%) undergoing palliative care. Both Black and Spanish/Hispanic patients had decreased odds of receiving palliative care (OR, 0.816, 95% CI, 0.753 to 0.885 and OR, 0.599, 95% CI, 0.540 to 0.665, respectively). Increasing age, papillary histology, increasing income, and increasing distance were also significantly associated with decreased odds of receiving palliation while treatment at an integrated network cancer program or comprehensive community cancer program and higher educational attainment were associated with increased odds of receiving palliative care. Similar findings were demonstrated among patients with the most severe disease. Limitations include the retrospective design and potential underlying selection biases of this study. **Conclusions:** Significant associations between receipt of palliative care and socioeconomic factors exist among patients with metastatic renal cell carcinoma. In this study among patients with metastatic renal cancer, we found associations between socioeconomics and palliative care access including age, race, Spanish/Hispanic origin, income, education, and other factors. Research Sponsor: None.

TIVO-3: Durability of response and updated overall survival of tivozanib versus sorafenib in metastatic renal cell carcinoma (mRCC). *First Author: Elena Verzoni, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: Tivozanib is a potent and highly selective VEGF receptor (R) tyrosine kinase inhibitor in clinical development for mRCC. **Methods:** The TIVO-3 study enrolled subjects with mRCC who failed 2 or 3 prior systemic regimens, one of which included a VEGFR TKI, stratified by IMDC risk category and type of prior therapy (two TKIs; TKI plus checkpoint; TKI + other) then randomized 1:1 to T or sorafenib. Tivozanib demonstrated PFS and ORR advantages over sorafenib. Here we report long term durability of response based on investigator assessment and updated overall survival. **Results:** There were 41 responders (23%) to tivozanib and 20 responders (11%) to sorafenib. The median duration of response (mDoR) was 20.3 months (95% CI: 9.8, 29.9) and 9.0 months (95% CI: 3.7, 16.6) for tivozanib and sorafenib, respectively. With prolonged follow up there were 270 deaths; the HR for overall survival favored tivozanib at 0.91 (95% CI: 0.716, 1.165). Clinical trial information: NCT02627963. **Conclusions:** Tivozanib treatment in third and fourth line mRCC results in longer PFS, higher objective response rate and more durable responses compared to sorafenib. There is no difference in overall survival. Research Sponsor: AVEO Oncology.

Treatment	N	Objective Response	Ongoing Response	mDoR in Months (95% CI)	HR (95% CI)
Sorafenib	175	20 (11%)	3	9.0 (3.7, 16.6)	0.55 (0.30, 1.00)
Tivozanib	175	41 (23%)	13	20.3 (9.8, 29.9)

Integrating peripheral biomarker analyses from JAVELIN Renal 101: Avelumab + axitinib (A + Ax) versus sunitinib (S) in advanced renal cell carcinoma (aRCC). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, The Lank Center for Genitourinary Oncology, Boston, MA*

Background: In the phase 3 JAVELIN Renal 101 trial (NCT02684006), treatment-naive patients (pts) with aRCC demonstrated prolonged progression-free survival (PFS) and a higher objective response rate with A + Ax vs S. We report the association of blood-based biomarkers with differential responses to treatment. **Methods:** Biomarkers in pretreatment (pre-tx) and on-treatment (on-tx) blood samples from 886 enrolled pts were correlated with clinical outcomes and molecular profiling data from corresponding tumor samples. Analyses include blood counts of unique populations, T-cell receptor sequencing, circulating cytokines, and serum proteomics by mass spectrometry MALDI-TOF. **Results:** At baseline, higher pre-tx monocyte counts were associated with shorter PFS in the A + Ax arm (Table). In the S arm, higher pre-tx levels of multiple T-cell–related metrics, including the percent of productively rearranged peripheral T cells, were associated with longer PFS but had no association in the A + Ax arm (Table). Higher pre-tx neutrophil counts were associated with shorter PFS in both arms, but neutrophil-to-lymphocyte ratio (NLR) was only associated with PFS for the S arm (Table). On-therapy biomarkers showed differential post-tx changes in T-cell numbers and clones at C2D1. Tx-specific differences were also seen in non–T-cell populations such as monocytes and neutrophils at multiple time points through C3D1. Serum levels of pre- and on-tx VEGF, CRP, and several interleukins showed differential associations with PFS (eg, higher pre-tx VEGF was associated with shorter PFS in only the S arm) (Table). Specific genomic alterations in tumor tissues were associated with differences in several pre- and on-tx angiokines & cytokines. **Conclusions:** Response to treatment with first-line A + Ax or S was associated with immune fitness and tx-specific immunomodulation. We identified peripheral biomarkers in pts with aRCC associated with the presence of impactful genomic alterations and differential clinical outcomes. Clinical trial information: NCT02684006. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

Association of C-reactive protein (CRP) with efficacy of avelumab + axitinib (A + Ax) in advanced renal cell carcinoma (aRCC): Long-term follow-up results from JAVELIN Renal 101. *First Author: Yoshihiko Tomita, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*

Background: CRP is an important prognostic and predictive factor in patients with aRCC receiving various therapies, such as cytokines and tyrosine kinase inhibitors. In this extended follow-up to the phase 3 JAVELIN Renal 101 trial (NCT02684006), we report the association of CRP levels at baseline (BL) and early after treatment with the efficacy of A + Ax or sunitinib (S). **Methods:** CRP levels were assessed at screening and day 1 of each 6-week cycle. Patients were categorized into CRP normal (BL CRP $<$ 10 mg/L), normalized (BL CRP $\geq$10 mg/L and $\geq$1 CRP value decreased to $<$ 10 mg/L during 6 weeks of treatment), and non-normalized (CRP $\geq$10 mg/L at BL and during 6 weeks of treatment) groups. Multivariate analysis of BL characteristics, including CRP for efficacy, was also conducted. Progression-free survival (PFS) and best overall response per independent central review (RECIST 1.1) from the second interim analysis (IA2) of overall survival (OS) and OS from the third interim analysis (IA3) were assessed. **Results:** Minimum duration of follow-up for IA2 and IA3 were 13 and 28 months, respectively. The table shows objective response rate (ORR), PFS, and OS by CRP group. Efficacy outcomes in the normal and normalized groups were favorable compared with the non-normalized group with both A + Ax and S. In the A + Ax arm, the complete response rate was 11.8% (normalized group), 3.8% (normal group), and 0.9% (non-normalized group). With A + Ax, the PFS in the normalized group was longer than in the normal group, but this was not observed with S. In each CRP group, all efficacy outcomes were favorable with A + Ax vs S. In the multivariate analysis, normalized or non-normalized CRP was an independent predictive factor of ORR or OS with A + Ax. **Conclusions:** Normal and normalized CRP levels were associated with improved A + Ax efficacy. A + Ax demonstrated favorable efficacy across CRP groups. OS in this study was immature; follow-up for the final analysis is ongoing. Further research in defining predictive value of CRP is warranted. Clinical trial information: NCT02684006. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

Association between neutrophil-to-eosinophil ratio (NER) and efficacy outcomes in the JAVELIN Renal 101 study. *First Author: Matthew D Tucker, Vanderbilt University Medical Center, Nashville, TN*

Background: Baseline NER has been reported to be associated with outcomes of immuno-oncology based combination treatment in advanced renal cell carcinoma (aRCC). We report outcomes by baseline NER of patients with aRCC in the JAVELIN Renal 101 trial who received avelumab + axitinib (A + Ax) or sunitinib (S). **Methods:** We calculated the median NER (mNER) for patients in the A + Ax and the S arms at the data cutoff (April 20, 2020) for the 3rd interim analysis (IA3). Progression-free survival (PFS), overall survival (OS), and objective response (OR) by NER are reported. Multivariate Cox regression analyses of PFS and OS were also conducted. **Results:** At the IA3 cutoff date, the mNERs for the A + Ax arm (n = 383) and S arm (n = 396) were 29.2 and 27.0, respectively. OR, PFS and OS for both arms are summarized in the table below. Better observed treatment outcomes in OR (63.9% vs 55.2%) and median PFS (15.5 vs, 11.1 months) were observed for patients with a NER $<$ median vs. NER $\geq$ median in the A + Ax arm, while there were not major differences in outcome based on NER in the S arm. The stratified hazard ratio (HR) for PFS in patients with a NER $<$ median compared with those with a NER $\geq$ median in the A + Ax arm was 0.81 (95% CI, 0.630-1.035) and 0.93 (95% CI, 0.728-1.181) in the S arm. Patients with a NER $<$ median had improved OS compared with those with a NER $\geq$ median in the A + Ax arm (stratified HR, 0.67; 95% CI, 0.481-0.940) and the S arm (stratified HR, 0.57; 95% CI, 0.424-0.779). Multivariate analysis showed that a low NER was associated with longer PFS and OS by treating baseline NER as either a continuous variable or a binary variable (dichotomized by median). **Conclusions:** Baseline NER may be predictive of OR and PFS in aRCC patients treated with A + Ax, and prognostic for overall survival regardless of therapy. Clinical trial information: NCT02684006. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

Camrelizumab plus famitinib for advanced renal cell carcinoma or unresectable urothelial carcinoma: Updated results from a phase II trial. *First Author: Yuan-Yuan Qu, Department of Urology Surgery, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Considering the synergistic/additive effect of PD-1 blockade and angiogenesis inhibition, we conducted an open-label, multi-center phase II study of camrelizumab (an anti-PD-1 antibody) plus famitinib (a TKI against VEGFR-2, PDGFR, c-kit, and FGFR) in pts with heavily treated advanced renal cell carcinoma (RCC) and unresectable urothelial carcinoma (UC). **Methods:** Based on an adaptive two-stage design, 22 pts were enrolled in the RCC and UC cohort, respectively, at stage 1; if there were $\geq$7 responders of the 22 pts, enrollment would be extend to 33 at stage 2. Pts received famitinib 20 mg orally QD plus camrelizumab 200 mg IV Q3W. Primary endpoint was ORR per RECIST v1.1. Preliminary data at stage 1 were reported at ASCO 2020 annual meeting (#5085). More than 7 pts in each cohort had CR/PR during stage 1; enrollment of stage 2 had been completed, and the data are firstly reported here. **Results:** 74 pts (38 advanced RCC and 36 unresectable UC) were enrolled from Jan 23, 2019 to Dec 14, 2020. In RCC cohort, 65.8% of pts had received $\geq$1 prior VEGFR inhibitors. In UC cohort, all pts had progressed on or relapsed after a platinum-containing chemotherapy. As of Jan 10, 2021, median time from enrollment to data cutoff was 18.8 mos (range, 8.5-22.7) for RCC cohort and 7.0 mos (range, 0.9-23.6) for UC cohort. In RCC cohort, ORR was 63.2% (95% CI, 46.0-78.2; 24 PRs), DCR was 89.5% (95% CI, 75.9-95.8), median DOR was not reached (range 2-19+ mos), mPFS was not reached, and 12-mo OS rate was 88.0%. Most pts (92.1%) had reduction in target lesions, and median reduction was 47% from baseline. ORR was 84.6% (95% CI, 57.8-97.3; 11/13) for untreated RCC pts and 52.0% (95% CI, 31.3-72.2; 13/25) for pre-treated pts; DCR was 100% (95% CI, 77.2-100.0) and 84.0% (95% CI, 65.3-93.6), mPFS was not reached and 13.4 mos (95% CI: 4.1-21.0), respectively. In UC cohort, of the 33 pts with post-baseline efficacy evaluation, ORR was 33.3% (95% CI, 19.8-50.4; 1 CR, 10 PRs), DCR was 60.6% (95% CI, 43.7-75.3), median DOR was not reached (range 1.0+-16.7+ mos), mPFS was 6.4 mos (95% CI, 2.1-11.8), and mOS was not reached. ORR trended to be higher for bladder cancer (43.8%, 7/16) than upper tract urothelial carcinoma (25.0%, 4/16). Treatment-related AEs (TRAEs) occurred in 97.3% of 74 pts. Grade 3 or 4 TRAEs occurred in 63.5% of pts, mainly hypertension (23.4%), decreased platelet count (21.3%), proteinuria (17.0%), anemia (14.9%), and palmar-plantar erythrodysesthesia syndrome (14.9%). 1 pt died of TRAE (multiple organ dysfunction syndrome). **Conclusions:** Camrelizumab plus famitinib showed potent anti-tumor activity in pts with advanced RCC and UC with no new safety concerns. Additionally, promising ORR and durable DOR were observed in pts with heavily-treated RCC. These results support further investigation in these settings. Clinical trial information: NCT03827837. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

4551 **Poster Session**

Real-world outcomes in patients with metastatic clear cell renal cell carcinoma receiving front-line axitinib plus pembrolizumab versus ipilimumab plus nivolumab. *First Author: Kevin Zarrabi, Fox Chase Cancer Center, Philadelphia, PA*

Background: Front-line treatment for patients (pts) with metastatic clear cell renal cell carcinoma (mRCC) has undergone rapid advances in the last five years. This evolution has led to uncertainty about the optimal first line combination regimen. Herein, we compare real-world outcomes in pts treated with either axitinib/pembrolizumab (A/P) or ipilimumab/nivolumab (I/N) reported by International Metastatic RCC Database Consortium (IMDC) score. **Methods:** The nationwide Flatiron Health electronic health records-derived database was used to select pts diagnosed with mRCC and treated with front-line A/P or I/N from 2018-2020. The primary endpoints were overall-survival (OS) and real-world progression free survival (rwPFS). The survival analyses were adjusted using propensity score-based Inverse Probability of Treatment weighting, providing balance on age, gender, insurance, race, IMDC, practice type, and nephrectomy. Survival was assessed from beginning of therapy, and survival by treatment groups was compared using weighted and unweighted Kaplan-Meier curves with log-rank tests and weighted Cox proportional hazards regressions. Disease characteristics between the treatment groups were compared using chi-square and T-tests. **Results:** 821 pts received frontline A/P (n=259) or I/N (n= 562). Demographics and clinical parameters were similar between the two cohorts. Median age was 66 years, 73% were male, and 54.9% had a nephrectomy. 459 pts had all IMDC criteria factors available, 242 pts had missing factors but enough to define as intermediate/poor risk, 120 pts had unknown IMDC risk. Adjusted median OS was not statistically different: mOS for A/P was not reached (NR) while I/N was 22 mo (95% CI, 19.8-NR; p=0.40). Twelve-month survival was 68.5% for A/P treated pts and 65.8% for I/N treated pts (P=0.41). Twelve-month rwPFS was 41.4% for A/P treated pts and 39.7% for I/N treated pts (P=0.14). No statistical difference in survival was seen within IMDC risk strata (see table). **Conclusions:** In this retrospective, real-world study of pts treated with front-line A/P or I/N, 12-month survival was not statistically different irrespective of IMDC risk. Longer follow-up will be necessary to discern any significant differences. Research Sponsor: None.

Adjusted 12-month survival.

IMDC Score	A/P n=259	I/N n=562	p-value
Favorable (n=69)	93.2%	72.5%	0.31
Intermediate/Poor (n=632)	64.6%	56.1%	0.61
Int.	73.9%	65.9%	0.29
Poor	52.1%	51.9%	0.80
Unknown (n=120)	76.4%	76.7%	0.61
Full cohort (n=821)	68.5%	65.8%	0.41

The impact of antibiotic (Ab) exposure on clinical outcomes in patients with metastatic renal cell carcinoma (mRCC) treated with immune checkpoint inhibitors (ICI) or VEGF targeted therapy (VEGF-TT). *First Author: Matthew Scott Ernst, Tom Baker Cancer Center, University of Calgary, Calgary, AB, Canada*

Background: Retrospective studies have shown an association between Ab exposure and inferior clinical outcomes in patients receiving ICI across various tumor types, including mRCC. However, it is unclear whether Ab exposure has a unique interaction with ICI or is an independent prognostic marker, regardless of treatment. We sought to examine Ab exposure and its association with clinical outcomes in patients with mRCC treated with ICI compared to VEGF-TT. **Methods:** We identified patients treated with ICI (anti-PD-L1 alone or in combination with VEGF or CTLA4 inhibitor) or VEGF-TT alone in first to fourth line settings from 2009-2020 across 3 academic centers in North America. Ab exposure was defined as administration of Ab within 60 days prior to initiation of systemic therapy. Outcomes of interest were response rate (RR), time to treatment failure (TTF) and overall survival (OS). Multivariable Cox regression was performed to control for imbalances in International mRCC Database Consortium (IMDC) risk factors, histology, and treatment line. **Results:** We identified 748 patients. Among the ICI (n=427) and VEGF-TT (n=321) cohorts, 13% vs 15% (p=0.47) had Ab exposure and 57% vs 48% (p=0.046) were treated in the first line setting. The proportion of favorable, intermediate, and poor risk disease by IMDC criteria differed between Ab exposed and unexposed patients in the ICI (14% vs 18%, 47% vs 62%, 39% vs 21% p=0.03) and VEGF-TT (7% vs 13%, 43% vs 60%, 50% vs 27%, p=0.01) cohorts. RR, TTF and OS results are displayed in Table 1. Multivariable analysis did not show a significant independent association between Ab exposure and OS in both the ICI (HR 1.13, p=0.62) and VEGF-TT (HR 1.32, p=0.16) cohorts. Treatment modality (ICI vs VEGF-TT) did not modify the effect of Ab exposure on OS (p=0.84). **Conclusions:** Ab exposure was associated with higher IMDC risk scores in both the ICI and VEGF-TT cohorts as well as inferior OS on univariable analysis. After adjusting for IMDC risk factors, histology and treatment line, we were unable to find an independent association between Ab exposure and OS in multivariable analysis for either cohort. Research Sponsor: None.

	ICI Cohort			VEGF-TT Cohort		
	Ab	No Ab	P-value	Ab	No Ab	P-value

Nivolumab plus cabozantinib (N+C) versus sunitinib (S) for advanced renal cell carcinoma (aRCC): Outcomes by baseline disease characteristics in the phase 3 CheckMate 9ER trial. *First Author: Andrea B. Apolo, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: First-line N+C significantly improved progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) vs S in aRCC patients (pts) in the phase 3 CheckMate 9ER trial, leading to FDA approval of N+C in this setting. A deeper understanding of how baseline disease characteristics may impact clinical outcomes with N+C vs S may inform clinical decision making. **Methods:** Pts with clear cell aRCC were randomized to N 240 mg IV Q2W + C 40 mg PO QD vs S 50 mg PO QD (4 weeks of 6-week cycles). In this post hoc exploratory analysis, PFS, OS, and ORR were evaluated across pt subgroups defined by baseline IMDC risk status, organ sites of metastases (mets), number of organs with any lesions, or target lesion size. Consistent with primary/secondary efficacy endpoints in ITT pts, PFS and ORR were evaluated per RECIST v1.1 by blinded independent central review in subgroups. **Results:** Median follow-up in ITT pts was 23.5 months. PFS, OS, and ORR (including complete response [CR]) outcomes are summarized in the table across subgroups: IMDC risk (favorable [FAV], intermediate [I], poor [P]); number of organs with ≥ 1 target/nontarget lesion (T/NT; 1 and ≥ 2); sum of diameters of target lesions (sDTL; < and ≥ median [72.1 mm]), and in pts with liver, bone, or lung mets. The PFS HR favored N+C vs S and median (m) PFS was longer with N+C vs S across all subgroups. The OS HR also favored N+C vs S across most subgroups. ORR ranged from 38%–66% (N+C) vs 10%–44% (S) across subgroups, and CR benefits were seen with N+C in most subgroups. Additional outcomes including landmark OS and response details in subgroups will be reported. **Conclusions:** Consistent with outcomes in ITT pts, efficacy benefits with N+C vs S were observed regardless of IMDC risk status, organ site of mets, or extent of tumor burden at baseline. These results support N+C as a new first-line treatment option for pts with aRCC. Clinical trial information: NCT03141177. Research Sponsor: Bristol Myers Squibb.

Outcomes of first-line (1L) ipilimumab and nivolumab (IPI-NIVO) and subsequent therapy in metastatic renal cell carcinoma (mRCC): Results from the International mRCC Database Consortium (IMDC). *First Author: Chun Loo Gan, Tom Baker Cancer Center, University of Calgary, Calgary, AB, Canada*

Background: IPI NIVO is approved for 1L treatment of IMDC intermediate/poor risk mRCC based on the CHECKMATE 214 trial. Herein, we report the clinical effectiveness of 1L IPI NIVO and second line (2L) therapy in the real-world setting. **Methods:** Using the IMDC dataset, patients (pts) treated with 1L IPI NIVO were identified. The outcomes of interest were 1L and 2L overall response rate (ORR), treatment duration (TD), time to next treatment (TTNT), and overall survival (OS). **Results:** 706 pts were included: 9% (57/614), 58% (354/614), and 33% (203/614) were IMDC favorable (fav), intermediate (int), and poor risk, respectively. Median age was 61 years. The majority of pts were males (71%), had clear cell histology (85%), and underwent nephrectomy (61%). 36%, 19%, and 8% of patients had bone, liver, and brain metastases, respectively. The 12-month OS for pts with IMDC fav, int, and poor risk disease was 92%, 79%, and 56%, respectively (p<0.01). The corresponding estimates for 24 months were 80%, 69%, and 38% (p<0.01). Pts who responded (39%) were more likely to have better IMDC risk category (p=0.02), received nephrectomy (p=0.04), normal neutrophil count (p<0.01), and clear cell histology (p=0.01). Pts with progressive disease as best response (27%) were more likely to have not received nephrectomy (p<0.01), worse IMDC risk category (p=0.02), bone metastases (p=0.01), liver metastases (p=0.04), and non-clear cell histology (p=0.01). Of the 66% (466/706) of pts who discontinued 1L IPI NIVO, 51% (236/466) received 2L therapy: sunitinib (40%), cabozantinib (25%), pazopanib (18%), axitinib (8%), and others (9%). The ORR, median TD, and median OS for those who received either sunitinib, cabozantinib, pazopanib or axitinib was 16%, 4.5 months (mo) (95% CI 3.7-5.6), and 14.5 mo (95% CI 10.9-25.9), respectively. 33% (129/386) of pts discontinued IPI NIVO due to irAEs. **Conclusions:** Our study benchmarks the real-world experience of 1L IPI NIVO in mRCC. IMDC criteria is prognostic for clinical outcome. Tyrosine kinase inhibitors have clinical activity post IPI NIVO. Research Sponsor: None.

1L IPI NIVO Clinical Outcome	All IMDC risk category				IMDC Int/Poor		
	Overall	Fav*	Int	Poor	All	Clear Cell histology	Non clear cell
ORR %, (n/n)	39% (201/518) P=0.02	45% (23/51)	43% (129/303)	30% (49/164)	38% (170/467)	43% (151/352)	30% (14/46)
Median TD (mo) (95% CI)	5.0 (4.0-6.4) P=0.03	6.9 (4.3-13.6)	6.4 (4.3-7.9)	3.0 (2.5-5.4)	5.0 (3.9-6.6)	6.2 (4.6-7.9)	4.2 (2.6-8.5)
Median TTNT (mo) (95% CI)	11.3 (9.6-13.9) P<0.01	24.0 (10.9-NR)	12.9 (9.9-17.9)	7.5 (5.4-9.8)	10.5 (9.1-12.6)	11.3 (9.4-15.4)	9.3 (4.1-NR)
Median OS (mo) (95% CI)	41.4 (27.6-53.4) P<0.01	47.8 (40.8-NR)	48.0 (35.1-NR)	14.0 (11.2-22.1)	40.2 (25.7-NR)	48.1 (35.1-NR)	17.6 (7.9-NR)

*Interpret with caution as the use of IPI NIVO in IMDC fav was highly selected in the real-world.
NR= not reached.

4555 **Poster Session**

Phase 2 study of belzutifan (MK-6482), an oral hypoxia-inducible factor 2α (HIF-2α) inhibitor, for Von Hippel-Lindau (VHL) disease-associated clear cell renal cell carcinoma (ccRCC). *First Author: Ramaprasad Srinivasan, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Inactivation of *VHL* leads to aberrant stabilization and accumulation of HIF-2α, which drives tumor growth. Patients (pts) with VHL disease are at risk for ccRCC, pancreatic neuroendocrine tumors (pNETs), and hemangioblastomas. Repeated surgeries are often needed to control ccRCC and other VHL disease manifestations. Prior results of this ongoing open-label phase 2 study (NCT03401788) showed activity with belzutifan in VHL disease. Updated results are presented. **Methods:** Adults with germline *VHL* alterations, measurable and localized/nonmetastatic ccRCC, no prior systemic anticancer therapy, and ECOG PS 0 or 1 received belzutifan 120 mg once daily until progression, intolerable toxicity, or decision to withdraw. The primary end point is ORR of VHL-associated ccRCC tumors per RECIST v1.1 by independent review committee (IRC). Secondary end points include DOR, time to response (TTR), PFS, and safety. **Results:** As of June 1, 2020, 61 pts enrolled. Most pts (82%) had ECOG PS 0, and the median number of prior tumor reduction procedures (eg, partial nephrectomy, craniotomy, radiation therapy) per pt was 5 (range, 0-15). Lesions outside the kidney (non-RCC tumors) evaluable by IRC included pNETs (33%) and CNS hemangioblastomas (82%). Median follow-up was 69 wk (range, 18-105), median duration of treatment was 68 wk (range, 8-105), and 56 pts (92%) remain on therapy. There were 22 confirmed responses (ORR, 36% [95% CI, 24-49]) and 7 (11%) unconfirmed responses (documented at 1 time point, to be confirmed at subsequent time point); all were PRs. In pts with confirmed PR, median DOR was not reached (range, 12+ to 62+ wk), median TTR was 31 wk (range, 12-61), and 56 pts (92%) had some reduction in the sum of all target lesion diameters. PFS rate at 52 wk was 98% (95% CI, 89-100). For non-RCC tumors, ORR was 80% (16/20; 1 CR) in pNETs and 32% (16/50; 1 CR) in CNS hemangioblastomas. Of 16 pts with evaluable retinal hemangioblastomas at baseline, 11 (69%) showed improvement per IRC. In those 16 pts, 29 eyes were monitored for retinal hemangioblastomas: 16 eyes (55%) showed improvement, 12 (41%) were stable, and no evaluation was available for 1 eye (3%). All 61 pts (100%) had at least one AE. The most common all-cause AE was anemia (90%), which is considered an on-target toxicity. Treatment-related AEs (TRAE) were reported by 60 pts (98%), and 8 pts (13%) had a grade 3 TRAE. No pts had grade 4/5 TRAEs. One pt discontinued treatment because of a TRAE (grade 1 dizziness). **Conclusions:** Belzutifan demonstrates clinical benefit and has a favorable safety profile in patients with VHL disease–associated ccRCC, pNETs, and hemangioblastomas. Clinical trial information: NCT03401788. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Randomized phase Ib study to evaluate safety, pharmacokinetics and therapeutic activity of simlukafusp α in combination with atezolizumab ± bevacizumab in patients with unresectable advanced/ metastatic renal cell carcinoma (RCC) (NCT03063762). *First Author: Jose Luis Perez-Gracia, Department of Medical Oncology, Clinica Universidad de Navarra, Pamplona, Spain*

Background: Simlukafusp α ([SIM], FAP-IL2v) is a novel IL-2v immunocytokine engineered to preferentially activate effector CD8 T and NK cells, but not regulatory T cells (Tregs), due to abolished binding to Interleukin-2 receptor α (IL-2Rα) and retained affinity to IL-2Rβγ. High affinity binding of SIM to fibroblast activation protein (FAP), expressed on cancer-associated fibroblasts, mediates its accumulation in malignant lesions. **Methods:** The Dose-Escalation (DE) consisted of: Arm A: SIM 5-25 mg weekly for 4 weeks, and every 2 weeks (Q2W) thereafter in combination with atezolizumab [ATZ] 840mg Q2W; and Arm B: same as Arm A + bevacizumab [BEV] 10 mg/kg Q2W. Patients (pts) not previously treated were evaluated in the Extension Part: Arm C (n=3): SIM + ATZ every 3 weeks (Q3W); or Arm D (n=25): SIM + ATZ + BEV ("triplet") Q3W. Primary objectives were: finding the recommended dose of SIM and assessment of objective response rate (ORR) by RECIST v1.1. **Results:** We enrolled 69 pts with unresectable advanced/ metastatic clear-cell and/or sarcomatoid RCC. Median age of patients was 57 years (range: 35-78). The recommended dose for extension of SIM was 10 mg. Median treatment duration in days in each arm were: A: 106 (range: 1-877); B: 324 (8-940); C: 659 (71-768); D: 437 (1-682). Twenty-five pts are evaluable for therapeutic activity in Arm A [ORR: 24% (6 PR; 90% CI 12.95, 40.12)]; 15 in Arm B [46.7% (1 CR, 6PR; 90% CI 27.67, 66.68)]; 3 in Arm C [33.3% (1PR; 90% CI 7.83, 74.65)]; and 23 in Arm D [47.8% (2 CR, 9 PR; 90% CI 35.74, 68.15)]. Twelve patients are ongoing on study treatment. Treatment related grade 3 and 4 adverse events (AE) occurred respectively in 69.7% and 9.1% patients. The most common serious AEs were pyrexia (10.6 %) and infusion-related reactions (9.1%). 65.2% Of the patients reported at least one AE of elevations in liver transaminases/GGT/ alkaline phosphatase/bilirubin. Drug-related AEs led to dose modification/interruption in 37.9 % of the pts, and treatment discontinuation in 3% of the patients. SIM led to preferential expansion and activation of NK and CD8 T cells (but not Tregs) in peripheral blood and augmented tumor infiltration and tumor inflammation. Intriguingly responses were observed not only in pts with PD-L1 positive or inflamed tumors, but also in pts with PD-L1 negative tumors (n=13) or poorly infiltrated tumors classified as immune deserts (n=2). **Conclusions:** The combination of SIM with ATZ ± BEV was feasible with an acceptable safety profile. Clinical activity was more favorable for the triplet among the study Arms, but comparable to the ATZ + BEV combination in the IMmotion151 (Rini B, et al 2019). Observed pharmacodynamic findings were consistent with the expected effects. Clinical trial information: NCT03063762. Research Sponsor: Roche.

Treatment outcomes in renal cell carcinoma patients with metastases to the pancreas and other sites. *First Author: Cassandra Duarte, University of Colorado Denver, Denver, CO*

Background: Metastatic RCC (mRCC) involving the pancreas is distinct from RCC involving other metastatic sites and is characterized by an indolent clinical course, heightened angiogenesis, and an inflamed stroma (PMID: 32271170). We previously reported on outcomes of RCC patients (pts) with pancreatic oligometastasis (ASCO GU 2020). We now report on outcomes in pts with mRCC involving the pancreas in conjunction with other metastases (mets). **Methods:** We conducted a retrospective, multi-institutional study of mRCC pts with mets to the pancreas and other sites. Data on pt demographics, tumor characteristics, systemic therapy, and outcomes were collected. Pts were classified based on treatment category: immunotherapy (IO) or vascular endothelial growth factor/receptor inhibitors (VEGFI). Outcomes measured included objective response rates (ORR), time-on-treatment (TOT), and overall survival (OS). **Results:** The analysis included 229 pts from 9 institutions, diagnosed between 1985-2020. Of these, 211 (92%) had clear-cell histology; 131 (57%) had nephrectomy; 41 (18%) had local pancreas-directed therapy; 111 (48%) had synchronous presentation of disease in the pancreas and other sites at time of mets. IMDC risk was favorable in 33%, intermediate in 41%, poor in 11%, and unknown in 15% pts. Median lines of therapy was 2 (range 0-9). Of 219 pts who received first-line (1L) therapy, 151 (69%) had VEGFI therapy, 41 (19%) had IO, and 18 (8%) had VEGFI/IO combination (Table). The IO group included 21 pts on checkpoint inhibitor (CPI), 16 pts on HD-IL2, 4 pts on other IO. 1L ORR was 39.7% for VEGFI (95% CI 31.8-48.0) and 31.7% for IO (95% CI 18.1-48.1) and was not statistically significant (NS, OR 1.4, 95% CI 0.65-3.23, p = 0.371). Median TOT for 1L therapy was 11.6m for VEGFI and 6.5m for IO (p = 0.0106). With a median follow-up of 51.5m, the median OS (mOS) for all pts from time of metastatic disease was 7.7 years (y) (95% CI 6.3-10.3). The mOS for pts who received 1L VEGFI was 7.6y (95% CI 5.5-9.5) and was not reached (NR) for those who got 1L IO (95%CI 6.5-NR); this difference was significant with an unadjusted p-value of 0.029. The pair-wise comparison between mOS of the 1L CPI subgroup compared to that of the 1L VEGFI group was significant (p = 0.0148). **Conclusions:** Consistent with the literature, mRCC pts with involvement of the pancreas in this study have prolonged OS compared to historical OS for the standard mRCC population. Additionally, our findings suggest that the choice of first-line therapy may impact outcomes. Additional analyses will be presented. Research Sponsor: None.

First-Line therapy.

	N=219	ORR %	Median TOT, months [IQR]	Median OS, years (95% CI)

Programmed death ligand-1 (PD-L1) expression in patients (pts) with metastatic renal cell carcinoma (mRCC) treated with nivolumab (NIVO) in combination with stereotactic body radiotherapy (SBRT) in NIVES study. *First Author: Cristina Masini, Medical Oncology Unit, Clinical Cancer Centre, AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy*

Background: The NIVES study represents the first prospective trial with NIVO in combination with SBRT in pre-treated mRCC patients . This study did not meet the primary endpoint in terms of objective response rate (ORR) as previously reported. However this combination showed a faster time to treatment response, a long progression free survival and median duration of response without increasing toxicities. Here we have tested with an exploratory analysis the correlation between PD-L1 expression and clinical outcomes in pts treated with NIVO plus SBRT. **Methods:** PD-L1 expression was assessed in archival collected tumour samples in our central laboratory using 4 commercial kits for immunoistochemical (ICH) analysis (clone 22C3 pharm DX Dako Agilent, 28.8 Abcam and SP142 and SP263 Ventana Medical System). A tumor cell was considered positive if any membranous staining was found regardless of the intensity. In particular the immunostaining was scored 0 when all tumor cells were unstained (PD-L1-negative), 1+ when $<$ 1% positive tumor cells were counted, 2+ when the percentage was between 1% and 50%,3+ when the number of stained cells was more than 50%. ORR and overall survival (OS) were correlated with PD-L1 staining. **Results:** Formalin-fixed paraffin-embedded (FFPE) specimens were obtained from 44 of 69 pts enrolled in the NIVES study. Twenty-two pts of 44 (50%) were considered PD-L1-negative using all the 4 commercial kits for ICH analysis, while 14 of 44 pts (31,8%) were defined PD-L1 weakly positive (positive tumor cells $<$ 1% at least in one kit for ICH). Eight of 44 pts (18.1%) were defined PD-L1 strong positive when at least one kit for ICH scored 2+ or 3+. About the correlation between ORR and PDL1 staining in the 42 pts (2/44 pts are not evaluable for ORR), ORR was 18.2% (95% CI, 5.2% to 40.3%) in the PD-L1-negative group vs 20% (95% CI, 5.7% to 43.7%) in weakly/strongly PD-L1 positive (p = 1.00). Among the 44 pts in the intention-to-treat population with available PD-L1 status, median OS was not significantly different between pts with PD-L1 negative (20.56 months, 95% CI, 7.16 to NR) and PD-L1 positive (18.33 months, 95% CI, 6.83 to NR) (p = 0.56). **Conclusions:** For the first time four commercial kits for ICH analysis were used to test PD-L1 expression in pretreated mRCC pts. Data from these small sample size seem to confirm that PD-L1 in pre-treated mRCC cancer is not a predictive biomarker for selecting pts to receive NIVO-based treatment. Clinical trial information: NCT03469713. Research Sponsor: GOIRC, Pharmaceutical/Biotech Company.

An FDA-pooled analysis of frontline combination treatment benefits by risk groups in metastatic renal cell carcinoma (mRCC). *First Author: Daniel Lee, Natl Cancer Inst, Germantown, MD*

Background: The International Metastatic RCC Database Consortium (IMDC) risk model was developed for prognosis of patients with mRCC treated with vascular endothelial growth factor (VEGF)-targeted monotherapy in the first-line setting. Efficacy in trials of anti-VEGF therapy has been generally consistent across risk groups, including for overall survival (OS). For trials of immunotherapy combinations, the small numbers of OS events for the favorable risk group in each trial limited reliable conclusions; however, there was a suggestion of possible differential effects on OS between favorable risk and other risk groups. **Methods:** We pooled individual patient data (n=3447) from four phase III randomized trials of combinations of immunotherapy + immunotherapy (n=1) or immunotherapy + anti-VEGF therapy (n=3) submitted to the US Food and Drug Administration in support of marketing applications. All trials calculated IMDC risk group for each patient and used a control arm of sunitinib. We combined intermediate and poor prognostic groups (“intermediate/poor”) and compared their OS to that of the favorable risk group using Kaplan-Meier and Cox Proportional Hazards methods. **Results:** In this pooled analysis, treatment with combination immune checkpoint therapy did not demonstrate an improvement in OS compared to sunitinib in the favorable risk group (HR 0.953; 95% CI: 0.72, 1.27). An improvement in OS was observed in the intermediate/poor risk group (HR 0.696; 95% CI: 0.62, 0.78). **Conclusions:** Our analysis of OS in patients treated with immunotherapy combinations compared to sunitinib suggests possible differential benefit in the favorable risk compared to the intermediate/poor risk group. These results are not conclusive and considered exploratory due to the relative immaturity of OS in the favorable risk group. Follow-up for survival continues in each study to allow for more definitive results. Research Sponsor: FDA.

Analysis of the CLEAR study in patients (pts) with advanced renal cell carcinoma (RCC): Depth of response and efficacy for selected subgroups in the lenvatinib (LEN) + pembrolizumab (PEMBRO) and sunitinib (SUN) treatment arms. *First Author: Viktor Grünwald, University Hospital Essen, Essen, Germany*

Background: In the multicenter, open-label, randomized, phase 3 CLEAR study, LEN + PEMBRO had significant PFS and OS benefits, and improved ORR vs SUN in first-line advanced RCC. Herein, we explore efficacy according to selected subgroups and the association between pts’ depth of response and OS. **Methods:** Pts in the CLEAR study were randomly assigned 1:1:1 to 1 of 3 treatment arms: LEN 20 mg orally QD + PEMBRO 200 mg IV Q3W; LEN 18 mg + everolimus 5 mg orally QD; or SUN 50 mg orally QD (4 weeks on/2 weeks off). We report PFS, OS, and ORR based on IMDC risk group (favorable and intermediate/poor) and presence of a target kidney lesion at baseline (post hoc analysis). Post hoc 6-month landmark analyses assessed the association between tumor shrinkage and OS. Pts who were alive at 6 months were grouped based on maximum tumor shrinkage from baseline or confirmed complete response (CR) up to 6 months. Tumor assessments were performed by independent review committee per RECIST v1.1. Odds ratios were calculated using the Cochran-Mantel-Haenszel method; HRs were based on stratified Cox proportional hazards model. **Results:** Among 1069 pts randomized in the CLEAR study, 355 were assigned to LEN + PEMBRO and 357 to SUN. Median follow-up was 27 months for the LEN + PEMBRO group and 26 months for the SUN group. PFS favored LEN + PEMBRO (median 22.1 months, n=243) vs SUN (median 5.9 months, n=229) in the IMDC-intermediate/poor subgroup (HR 0.36 [95% CI 0.28-0.47]); and in the IMDC-favorable subgroup (median 28.1 months, n=110 vs median 12.9 months, n=124; HR 0.41 [95% CI 0.28-0.62]). OS favored LEN + PEMBRO vs SUN in the IMDC-intermediate/poor subgroup (HR 0.58 [95% CI 0.42-0.80]); few events were observed in the IMDC-favorable subgroup thus, it was inadequate to evaluate OS. ORR favored LEN + PEMBRO vs SUN in the IMDC-intermediate/poor subgroup (72.4% vs 28.8%; odds ratio 6.60 [95% CI 4.39-9.90]) and the IMDC-favorable subgroup (68.2% vs 50.8%; odds ratio 2.00 [95% CI 1.17-3.42]). In pts with target kidney lesions, PFS, OS, and ORR were improved with LEN+PEMBRO vs SUN (table). The 6-month landmark analysis in the LEN + PEMBRO group showed that the OS rate at 24 months was 100% (95% CI not estimable [NE]-NE) for pts with confirmed CR per RECIST v1.1 and 91.7% (95% CI 53.9-98.8) both for pts with $>$75% to $<$100% target-lesion reduction and pts with 100% target-lesion reduction. **Conclusions:** In pts with target kidney lesions, LEN + PEMBRO conferred survival benefits vs SUN similar to benefits observed in the overall population. Overall, pts treated with LEN + PEMBRO who had greater than 75% reduction in target lesions had similar OS rates to pts with CR. Clinical trial information: NCT02811861. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Cabozantinib (C) exposure-response (ER) analysis for the phase 3 CheckMate 9ER (CM 9ER) trial of nivolumab plus cabozantinib (N+C) versus sunitinib (S) in first-line advanced renal cell carcinoma (1L aRCC). *First Author: Amishi Yogesh Shah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In the phase 3 CM 9ER trial (NCT03141177), N+C significantly improved progression-free survival (PFS; HR 0.51, 95% CI 0.41–0.64; p < 0.0001), overall survival (OS; HR 0.60, 98.89% CI 0.40–0.89; p = 0.0010), and objective response rate (p < 0.0001) vs S in 1L aRCC (Choueiri, 2020). N+C was generally well tolerated with low rates of treatment-related discontinuations, indicating successful adverse event (AE) management with dose modification to maintain tolerability. Here the impact of C exposure on efficacy and safety outcomes in CM 9ER was evaluated using ER analysis. **Methods:** Patients (pts, N = 320) with previously untreated aRCC received C 40 mg QD in combination with N 240 mg Q2W; dose reductions of C to 20 mg QD or 20 mg Q2D were allowed to manage AEs. Time-to-event Cox proportional hazard ER models were developed to characterize the relationship between predicted C exposure or apparent clearance (CL/F) and specified endpoints, including PFS, dose modification, and select AEs (palmar-plantar erythrodysesthesia [PPE; Gr ≥1], diarrhea [Gr ≥3], hypertension [Gr ≥3], fatigue/asthenia [Gr ≥3], and ALT/AST elevation [Gr ≥3]). C exposure was defined as the overall average concentration from time zero to the time of event or censoring (CAVG) and estimated by population pharmacokinetic modeling for a typical patient. ER analysis for OS was not done due to the low number of events at the database lock date (March 30, 2020). **Results:** In the ER analysis of PFS, predicted C exposure at 40-mg and 20-mg QD doses was not significantly associated with the rate of progression or death (HR 1.00, 95% CI 0.78–1.27, for 20-mg vs 40-mg dose). In the ER analysis of AEs, lower predicted C exposure was significantly associated with lower rates of PPE (HR 0.63, 95% CI 0.50–0.78, for 20-mg vs 40-mg dose) and diarrhea (HR 0.48, 95% CI 0.29–0.80) but was not significantly associated with the rates of hypertension, fatigue/asthenia, or ALT/AST elevation. Higher predicted C CL/F was associated with a lower rate of C dose modification; however, this association was not statistically significant (HR 0.80, 95% CI 0.57–1.12, for CL/F 3.2 vs 1.2 L/hr). **Conclusions:** In ER models of pts with 1L aRCC treated with the combination of N+C, C exposure was not significantly associated with PFS; however, higher C exposure was associated with higher rates of PPE and diarrhea. ER modeling predicts that a starting dose of 40 mg QD C in combination with N with appropriate dose modifications to manage C AEs will not adversely affect the efficacy of the combination in 1L aRCC. Clinical trial information: NCT03141177. Research Sponsor: BMS/Exelixis.

Post hoc analysis of the CLEAR study in advanced renal cell carcinoma (RCC): Effect of subsequent therapy on survival outcomes in the lenvatinib (LEN) + everolimus (EVE) versus sunitinib (SUN) treatment arms. *First Author: Thomas E. Hutson, Texas Oncology, Dallas, TX*

Background: The multicenter, open-label, randomized, phase 3 CLEAR study showed that LEN + EVE had a significant PFS benefit (HR 0.65, 95% CI 0.53-0.80, *P*<0.001) and improved objective response rate (relative risk 1.48, 95% CI 1.26-1.74) vs SUN in the first-line treatment of patients (pts) with advanced RCC. The difference in overall survival (OS) for LEN + EVE vs SUN was not statistically significant (HR 1.15, 95% CI 0.88-1.50) (Motzer R et al. *NEJM*. 2021). Post hoc subgroup analyses were performed to assess the impact of subsequent therapy on OS. **Methods:** Pts in the CLEAR study were randomly assigned (1:1:1) to 1 of 3 treatment arms, including LEN 18 mg + EVE 5 mg once daily (QD) and SUN 50 mg QD (4 weeks on then 2 weeks off). These post hoc analyses examined OS by subsequent systemic anticancer medication in the LEN + EVE and SUN arms. Hazard ratios (HR; LEN + EVE vs SUN) were based on stratified (geographic region and MSKCC prognostic risk groups) Cox proportional hazards model. **Results:** Among 1069 pts with advanced RCC randomized in the CLEAR study, 714 pts were randomly assigned to the LEN + EVE and SUN arms (N=357/each). The median duration of survival follow-up was 27 months in the LEN + EVE arm and 26 months in the SUN arm. Given the shorter median duration of study treatment with SUN (7.8 months) vs LEN + EVE (11.0 months), more pts in the SUN arm received subsequent anticancer therapy during survival follow-up (LEN + EVE, n=167; SUN, n=206). Among pts who received subsequent therapy, pts in the LEN + EVE arm had a longer median time from randomization to initiation of subsequent therapy vs those in the SUN arm (8.0 vs 6.6 months, respectively). OS for the overall population, for pts with no subsequent anticancer therapy, and for pts with no subsequent immunotherapy is shown in the table. In the US population subgroup (LEN + EVE, n=62; SUN, n=61) of the CLEAR study, in which a similar number of pts received subsequent systemic anticancer therapies in the LEN + EVE vs SUN arms (62.9% vs 65.6%, respectively), OS was comparable among the 2 arms (HR 0.95, 95% CI 0.51-1.76). Overall, the safety profile was consistent with the known safety profiles of LEN + EVE and SUN. In both arms, most treatment-emergent deaths were due to progressive disease; there were few treatment-related deaths (<1%, per arm) and no clustering of events. **Conclusions:** In the CLEAR study, LEN + EVE met the primary endpoint of a significant benefit in PFS vs SUN. The results of these exploratory analyses suggest that subsequent systemic anticancer therapy affected the OS outcome results for LEN + EVE vs SUN in the CLEAR study. Clinical trial information: NCT02811861. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Association of baseline neutrophil-to-eosinophil ratio (NER) and neutrophil-to-lymphocyte ratio (NLR) with response to combination immunotherapy (IO) with ipilimumab plus nivolumab (ipi/nivo) in patients with metastatic renal cell carcinoma (mRCC). *First Author: Matthew D Tucker, Vanderbilt University Medical Center, Nashville, TN*

Background: Previous reports have shown that the baseline neutrophil-to-lymphocyte ratio (NLR) is associated with prognosis in patients with mRCC. However, NLR has not been shown to reliably predict for response to IO. Retrospective analyses in metastatic melanoma and mRCC have shown an association of eosinophilia with improved outcomes to single agent immunotherapy. We sought to evaluate and compare the baseline NLR and NER with response to ipi/nivo in patients with mRCC. **Methods:** A retrospective review of patients with mRCC treated at the Vanderbilt-Ingram Cancer Center or Duke Cancer Institute with ipi/nivo was performed. Patients with clear cell histology and a baseline complete blood count with differential were included. Patients previously treated with IO were excluded. Patients were separated into groups (above and below the median) based on baseline median NER and baseline median NLR. Analyses of progression free survival (PFS) and overall survival (OS) were conducted using the log rank test. The odds ratio (OR) for objective response rate (ORR) was analyzed using Fisher's exact test. **Results:** 111 patients met inclusion criteria. The median age was 60, 77% of patients were male, 68% had prior nephrectomy, 74% were naïve to systemic therapy, and 84% were IMDC intermediate/poor risk. The median NER was 25.0 and median NLR was 3.4. Patients with < median baseline NER had significant improvement in PFS, OS, and ORR (see table). Patients with < median baseline NLR had significant improvement in OS but not in PFS or ORR. **Conclusions:** Baseline NER was associated with improved outcomes with ipi/nivo. While both NER and NLR were associated with improved OS, only NER was additionally associated with both improved PFS and ORR. With multiple first-line treatment options for mRCC, baseline NER may serve as an early non-invasive predictor for response to ipi/nivo. Research Sponsor: None.

Phase II trial of stereotactic ablative radiation (SAbR) for oligoprogressive kidney cancer. *First Author: Raquibul Hannan, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Metastatic renal cell carcinoma (mRCC) patients on systemic therapy may experience oligoprogression. SAbR has been demonstrated to be safe and is associated with high local control rates in mRCC. In this prospective phase II single arm trial, we investigated SAbR to control oligoprogressive mRCC. **Methods:** Patients with mRCC who demonstrated response to systemic therapy with subsequent radiographic evidence of three or fewer sites of progression were treated with SAbR to all progressive sites. Systemic therapy was held during SAbR at the discretion of the treating oncologist. Follow-up included radiographic imaging at three-month intervals. Sequential SAbR for continued oligoprogression was allowed. The primary objective was extension of ongoing systemic therapy by >6 months in 40% of the patients. Progression was defined by any of these 3 criteria: (1) local failure at a radiated site; (2) progression ineligible for additional SAbR (>3 sites) or involving >30% of metastasis; or (3) progression as clinically determined by treating physicians. An exact binomial test was used to test the probability of postponing systemic therapy. Secondary endpoints focused on overall survival (OS), local control (LC) rates, toxicity, and health-related quality of life (QOL). **Results:** The trial completed accrual with enrollment of 20 patients who received SAbR to a total of 36 sites. At enrollment four, twelve, three, and one patients were on first, second, third, and fourth line of systemic therapy, respectively. Eleven were on immunotherapy and nine on a tyrosine-kinase inhibitor. Three patients required repeat SAbR to a new site for sequential disease control. At a median follow-up of 8.3 months (interquartile range 3.9 – 15.1), SAbR extended the duration of the ongoing systemic therapy by >6 months in 12 out of 17 patients (70.6%, 95% CI: 48.9%-92.3%). Thirteen out of 20 patients progressed with a median PFS of 8.7 months (95% CI: 3.2-12.4). Five patients died and the OS did not reach the median. LC was 36/36 (100%). Treatment related grade 1 and grade 2 toxicity was experienced by three and one patient, respectively; no grade 3 toxicities were reported. When compared to baseline, no significant decline in QOL was detected. **Conclusions:** SAbR extended PFS of ongoing systemic by >6 months in oligoprogressive patients with mRCC. SAbR was safe and did not adversely affect QOL. These data support further evaluation of SAbR for oligoproressive mRCC in a prospective randomized setting. Clinical trial information: NCT03696277. Research Sponsor: UT Southwestern Medical Center Department of Radiation Oncology.

Ipilimumab + nivolumab in people with rare variant renal cell carcinoma refractory to nivolumab alone: Part 2 of UNISON (ANZUP 1602) nivolumab then ipilimumab + nivolumab in advanced non-clear cell renal cell carcinoma. *First Author: Craig Gedye, Calvary Mater Newcastle, Waratah, NSW, Australia*

Background: Immunotherapy targeting PD1 is active across many cancers, but many people are failed by PD1 inhibition alone. UNISON (ANZUP 1602/ NCT03177239) has previously reported the activity and outcomes of nivolumab monotherapy in people with nccRCC (OTRR 17%, PFS6 45%; part 1), and here we report the outcomes of combining ipilimumab (I) and nivolumab (N), in people whose cancers are refractory to N alone (part 2). **Methods:** Participants (pts) with advanced nccRCC with good performance status (ECOG 0/1), were initially enrolled and took N alone. 41 pts refractory to N were offered the combination I (1mg/kg) + N (3mg/kg) every 3 weeks for up to 4 doses. Pts with disease control after N, or N + I could continue N for up to 1 year. UNISON was powered to distinguish a clinically relevant improvement in objective tumour response rate (OTRR) from 15% to 30% in people taking I+N in part 2. **Results:** 85 pts were enrolled and received N. 41 pts were refractory to N, were well enough to take I+N, and had a representative spectrum of nccRCC histologies (n=41; papillary 44%, chromophobe 20%, Xp11 translocation 12%, RCC unclassified 7%, other 17%). The median time on treatment was 2.1 months, the median number of doses was 3; median follow up at the time of reporting was 20.3 months. The OTRR of I+N in pts refractory to N was 10% with 1 complete and 3 partial responses. Stable disease was experienced by 36% of pts and disease progression by 52%. The disease control rate at 6 months was 45% (95% CI: 34%, 56%). The median PFS was 2.6 months (95% CI: 2.2, 3.8). The 6 month progression-free survival (PFS) was 25% (95% CI: 13-39). Only 14% of patients were free of progression at 12 months. The safety of I+N appeared similar to previous reports. 68% of pts experienced serious adverse events, 34% treatment related SAE. One pt died from refractory pneumonitis. 11 pts (27%) experienced treatment delays or permanent treatment discontinuation. **Conclusions:** The primary endpoint of the study was not met. A minority of pts with nccRCC refractory to nivolumab derive benefit from combination I+N but many pts remain refractory to immunotherapy. No new safety issues were identified. More effective therapeutic options are needed for people with rare variant renal cell carcinoma. Clinical trial information: NCT03177239. Research Sponsor: Bristol Myers Squibb, Other Government Agency, Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP).

Survival trends of men and women with metastatic clear cell renal cell carcinoma. *First Author: Claud Grigg, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Clear cell renal cell carcinoma (ccRCC) is nearly twice as common in men as in women, and women with non-metastatic RCC have a better prognosis than men. The etiology for these disparities is not known, though sex-specific differences in risk factor prevalence and tumor biology have been reported. The differential impact of systemic therapies, including tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICIs), on prognosis in women and men with metastatic ccRCC is not defined. **Methods:** Clinicopathologic features and survival of patients with clinical stage IV ccRCC were obtained from the National Cancer Database (NCDB). Patients were grouped by date of metastatic diagnosis into three eras that correspond to major advances in systemic therapy: 2004-2005 (pre-TKI), 2006-2014 (TKI), and 2015-2016 (ICI). Uni- and multi-variable chi-square, logistic regression, and survival analyses were used for comparisons. Survival differences were assessed using Kaplan-Meier curves. **Results:** 15,025 male and 7,100 female patients with metastatic ccRCC were identified. Demographic features were similar between cohorts though females were slightly older (median 64.8 vs 62.7 mo, $p < 0.0001$), more likely to be black (6.5% vs 6.0%, $p = 0.0119$) or receiving Medicare benefits (46.4% vs 39.9%, $p < 0.0001$). In the combined cohort, median overall survival (OS) was higher in patients diagnosed in the ICI vs TKI (23.0 vs 16.5 mo) and pre-TKI eras (14.4 mo, log-rank $p < 0.0001$). Compared with men of the same age groups, OS was inferior for women age 50-64 yr (median 18.4 vs 21.1mo, $p = 0.0084$) and $>$ 64 yr (15.3 vs 12.6mo, $p = 0.0001$), but not $<$ 50 yr (20.3 vs 21.7mo, $p = 0.6290$). In the ICI era, median OS improved by a lesser absolute but similar relative amount for women compared to men (+5.6mo [+39%] and +7.2mo [+41%]), respectively). After controlling for age, race, Charlson-Deyo score, initial treatment modality, and insurance and socioeconomic status, women remained at increased risk of death in both the ICI era (HR 1.12 [95% CI 1.04-1.22], $p = 0.004$) and the TKI era (HR 1.08 [1.04-1.12], $p < 0.001$). **Conclusions:** Women with metastatic ccRCC have a worse prognosis than men which is not explained by demographic differences. This disparity is observed in both the TKI and ICI eras. This finding contrasts with previous studies suggesting women with localized RCC have a favorable prognosis compared with men. Further investigation into the sex-specific biology of metastatic ccRCC is warranted. Research Sponsor: None.

Temporal characteristics of treatment-emergent adverse events and dose modifications with tivozanib and sorafenib in the phase 3 TIVO-3 study of relapsed or refractory mRCC. *First Author: Sumanta K. Pal, Department of Medical Oncology & Therapeutics, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: The randomized phase 3 TIVO-3 study met the primary endpoint of improved PFS with tivozanib (TIVO) vs sorafenib (SOR) in patients with relapsed/refractory mRCC with fewer dose reductions, interruptions and discontinuations despite a longer time on therapy. Greater insight into temporal characteristics of treatment-emergent adverse events (TEAEs) may enable proactive supportive care strategies and improve patient experience. **Methods:** Updated safety from the previously reported TIVO-3 study with a data cutoff August 15, 2019, was analyzed by treatment arm for time-to-onset (TTO, days [d]) of the most commonly reported TEAEs, and TTO of first dose reduction, interruption, and discontinuation occurring with TIVO and SOR. Duration of TEAE (median d and IQ range), and rate of dose reduction, interruption, or discontinuation due to the TEAE was calculated for each arm. **Results:** Patients in the safety analysis randomly assigned to TIVO (n = 173) or SOR (n = 170) received 11.9 and 6.7 cycles, or 336 and 192 mean days of treatment exposure, respectively. Incidence of any Gr, Gr >3, and TTO of any Gr TEAE of special interest occurring with >20% frequency in either arm is shown in Table 1. While TIVO was associated with less Gr>3 diarrhea, rash and PPE and more HTN than SOR, there were few differences in the TTO or duration of these TEAEs. Overall, dose reductions, interruptions, and discontinuations due to TEAEs were less frequent with TIVO than SOR, and TTO of first dose reduction (85 vs 45 d), interruption (81 vs 50 d), and discontinuation (114 vs 49 d) was longer for TIVO than SOR. Among those experiencing the same TEAE in either arm, resulting dose modifications were less frequent with TIVO than SOR. **Conclusions:** TIVO-3 demonstrated improved PFS with TIVO compared to SOR in mRCC, with longer duration of TIVO exposure, but fewer all Gr and Gr >3 TEAEs. Temporal characteristics of TEAEs were similar, but time to dose modifications was longer with TIVO than SOR. Among those with the same TEAEs, unmodified treatment was continued more often with TIVO than SOR. Clinical trial information: NCT02627963. Research Sponsor: AVEO Oncology.

Immune checkpoint inhibitors (ICI) in advanced sarcomatoid renal cell carcinoma (sRCC): A multicenter study. *First Author: Dharmesh Gopalakrishnan, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Advanced sRCC is an aggressive disease with limited responsiveness to chemotherapy and VEGF-targeted therapies. Subgroup analyses from randomized trials showed improved outcomes with ICI, though sample sizes were relatively small. **Methods:** We conducted a multi-institutional retrospective analysis of consecutive patients (pts) who had RCC with any sarcomatoid component and received systemic therapy for advanced disease. The pts were classified into ICI^+ and ICI^- groups (gp) based on whether they had received ICI in any treatment line. Overall survival (OS) was measured from the initiation of first systemic therapy. Time to ICI failure (TIF) was defined as the interval from initiation of ICI to subsequent therapy or death. Survival distributions were estimated using the Kaplan-Meier method. Association between covariates and survival was analyzed using multivariate Cox regression. Two-tailed $P < 0.05$ was considered statistically significant. **Results:** 203 pts from 6 US academic cancer centers met the inclusion criteria – 155 in ICI^+ gp and 48 in ICI^- gp. Overall, 137 (67%) pts were male and 181 (89%) were white; median age at mRCC diagnosis was 59.7 (IQR 52.4-67.7) years; 129 (63%) pts presented *de novo* with distant metastases, 154 (76%) had clear cell (CC) histology, and 182 (90%) had intermediate/poor risk by IMDC criteria. ICI^+ had a higher proportion of purely CC tumors (81% vs 64%, $P = .02$); other demographic and clinical features were similar between the two gps. After a median follow-up of 48.1 (95% CI 40.7-55.5) months (mos), median OS and response rates were significantly higher in the ICI^+ gp (Table). OS benefit, compared to ICI^-, was maintained in pts who received ICI in ≥ second line (39.6 vs 7.6 mos, HR 0.33, 95% CI 0.22-0.51, log-rank $P < .001$). TIF was comparable between pts treated with ICI upfront vs in ≥ second line (6.0 vs 5.3 mos, HR 1.27, 95% CI 0.87-1.85, $P = .21$). On multivariate analysis, ICI^- (HR 2.50, 95% CI 1.61-3.88, $P < .001$), non-CC histology (HR 3.14, 95% CI 1.98-5.00, $P < .001$) and sarcomatoid component ≥20% (HR 1.92, 95% CI 1.28-2.90, $P = .002$) were predictive of all-cause mortality. Among pts with non-CC or mixed histology (n=45), ICI^+ had higher OS (18.0 vs 5.5 mos, HR 0.20, 95% CI 0.09-0.44, $P < .001$) and ORR (44% vs 12%, $P = .03$), compared to ICI^-. **Conclusions:** Treatment with ICI led to markedly higher survival and response rates in advanced sRCC. OS benefit was maintained with ICI in the second line and beyond. Significant benefit was also noted among pts with non-CC or mixed histology sRCC. Research Sponsor: None.

A phase 2 single-arm study of cabozantinib in patients with advanced or unresectable renal cell carcinoma pretreated with one immune checkpoint inhibitor: The BREAKPOINT trial (MeetUro trial 03-NCT03463681). *First Author: Giuseppe Procopio, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: For many years, vascular endothelial growth factor (VEGF)-targeted therapy (tp) has been a milestone for metastatic renal cell carcinoma (mRCC). Recently, first line tp based on anti-PD-1/PD-L1 immune-checkpoint inhibitors (ICIs) plus tyrosine-kinase-inhibitors (IO-TKI) and anti-PD-1 plus anti-CTLA-4 combos (IO-IO) significantly improved survival of mRCC patients (pts). Prospective data are lacking to determine the efficacy of anti-VEGF tp after IO-IO or IO-TKI. Cabozantinib (Cabo) showed to prolong survival in mRCC pts pre-treated with TKIs and to target kinases involved in immune-escape. So, it may represent an ideal agent to be used sequentially after ICIs. **Methods:** This is an open label, single arm, multicenter, phase II study evaluating efficacy and safety of Cabo in mRCC pts who received an anti-PD-1/PD-L1-based adjuvant (adj) or first line tp. Cabo 60 mg/daily was administered until progressive disease (PD) or unacceptable toxicity. Primary endpoint was progression free survival (PFS) by Brookmeyer-Crowley test, secondary endpoints were overall survival (OS), objective response rate (ORR) and safety. Exploratory endopoints were to investigate tissue PD-L1 expression, to assess the modulating activity of Cabo on local and systemic tumor immunity and to explore bone formation and reabsorption markers. **Results:** From July 2018, 49 pts were enrolled and 48 were included in the analysis. Median age was 62.5 years (range: 30-78), 63% of pts were male. At baseline, 26% of pts had a good Heng risk score, 47% intermediate and 28% a poor risk, while in 2% of pts the class of risk was undetermined. 74% of pts received an IO-IO combo as first line tp, 17% IO-TKI, 9% pts an adj IO monotherapy. Pts received a median of 10 cycles of Cabo (range 5-17 cycles). 25 pts (53%) are still on tp, 1 patient discontinued Cabo for AEs, 13 pts for radiological PD, 6 pts discontinued for clinical PD or death, while 2 pts for reasons other than AEs or PD. Among evaluable cases, 17 pts (43%) achieved a partial response and 15 pts (37%) stable disease. Complete responses were not observed. At a median (m) follow-up of 8.0 months (mo) (4.4-13.5 mo), 71% of pts were alive and mPFS was 9.3 mo (95% CI 7.1-29.0 mo). Grade (G) 3-4 adverse events (AEs) occurred in 34% of pts, including more frequently serum bilirubin increase, hypertension, calcium and sodium serum levels alterations and oral mucositis. G1-2 were observed in 61% of pts, including in most of cases diarrhoea, nausea, oral mucositis, disgeusia, hand-foot syndrome, fatigue and hypothyroidism. Due to AEs, transitory withholding of Cabo was observed in 53.5% of pts and for 23 pts (48%) dose reductions were needed. **Conclusions:** So far, Cabo tp after IO-IO or IO-TKI showed promising results and was well tolerated. Longer follow-up is needed for final OS and exploratory endpoints results. Clinical trial information: NCT03463681. Research Sponsor: Ipsen.

Plasma exosome microRNA-155 expression in patients with metastatic renal cell carcinoma treated with immune checkpoint inhibitors: A potential biomarker of response to systemic therapy. *First Author: Maryam Soleimani, BC Cancer, Vancouver, BC, Canada*

Background: The search for a reliable predictive biomarker of response to immune checkpoint-based therapy (ICBT) remains a critically unmet need in the management of metastatic renal cell carcinoma (mRCC). We sought to evaluate the biomarker potential of plasma exosome microRNAs (miRNAs) implicated in RCC and in augmentation of the tumour microenvironment (TME) for such a role. **Methods:** Eleven miRNAs that are over-expressed in RCC and/or immune-associated were evaluated in 40 patients with mRCC (prior to initiating ICBT) and in 30 healthy volunteers. Exosomes were extracted from 500 uL of plasma and were used for miRNAs extraction. MiRNAs expression was evaluated by RT-PCR. Cycle threshold values were normalized to miR-30-3b, and the relative quantity of the expression (RQ) was compared to those of healthy volunteers and calculated using the $2^{\Delta\Delta Ct}$ method. Mann-Whitney U test was used to evaluate the expression of miRNAs between mRCC pts and healthy volunteers according to best response to first line ICBT between responders (n = 27) v non-responders (n = 13). The cut-off value of significant expression was established by Youden's index. Responders were defined as those patients experiencing complete response, partial response or stable disease and non-responders were those who experienced progressive disease. **Results:** The most common first line ICBT was nivolumab + ipilimumab (n = 32), followed by pembrolizumab + axitinib (n = 5), and avelumab + axitinib (n = 3). A significantly higher expression of miRNA-1233 (median 1.85 v 0.81 p = 0.008) and miRNA-155 [miR-155] (3.69 v 0.21 p = 0.006) were found in patients compared to healthy volunteers. Higher miR-155 expression was associated with higher Fuhrman grade (p = 0.002). There was no association with other clinical prognostic factors. MiR-155 was expressed at a significantly lower level in responders than in non-responders (median 0.61 v 35.29, p = 0.042). Response rate amongst patients with low and high expression of miR-155 (RQ $\leq$ 2.5) was statistically different (p = 0.042) and 84.2% of the pts with low miR-155 expression responded to the treatment. **Conclusions:** Lower expression of miR-155 was associated with response to ICBT in patients with mRCC. Functionally, miR-155 is involved in regulation and modulation of the TME. These results underscore the need for further work in this area to elucidate the role of this and other miRNAs as biomarkers of response in mRCC. Research Sponsor: GUMOC Bayer Research Grant Program jointly established by the Genitourinary Medical Oncologists of Canada (GUMOC) and Bayer Canada.

A phase 2 prospective trial of cabozantinib as first-line treatment for metastatic collecting ducts renal cell carcinoma: The BONSAI trial (Meeturo 2) clinical trial information—NCT03354884. *First Author: Giuseppe Procopio, Fondazione Istituto Nazionale Tumori Oncologia Medica Genitourinaria, Milan, Italy*

Background: Metastatic collecting ducts carcinoma (mCDC) is a rare disease with bad prognosis and no standard treatments. Due to its rarity, mCDC is biologically poorly characterized and under-represented in prospective randomized trials. We recently identified two different molecular subtypes of mCDC based on relative expression levels of angiogenesis, metabolic and immune-related genes. **Methods: :** This prospective, monocentric, phase II trial evaluated cabozantinib (cabo) 60 mg orally once daily until progression or unacceptable toxicity in untreated mCDC patients (pts). Primary endpoint was objective response rate (ORR) as the proportion of pts with best overall response of confirmed complete (CR) or partial responses (PR) per RECIST 1.1. Secondary endpoints were progression-free survival (PFS), overall survival and safety profile. Exploratory objectives were: to identify somatic mutations by targeted NGS-based sequencing; to define molecular subtypes, signatures and transcript fusions genes by RNA sequencing; to monitor circulating immune cells and study the immunological context of tumor cells. A central pathological review was mandatory. The study was based on a Simon's two stage optimal design: at least 2 responses in 9 pts in the first stage were needed to proceed to the second stage where at least 6 responses in 14 additional pts were needed to prove activity of cabo. **Results:** From January 2018 to November 2020, 25 pts were enrolled, of whom 23 started treatment. Median age was 66 years, 19 pts were male. 19 (83%) pts received a previous nephrectomy. 9 pts presented with only one metastatic site, 8 pts with two, while the remaining part with multiple sites. The most common metastatic sites were lymphnodes and bone (15 and 13 pts respectively), followed by lung and liver (10 and 4 pts respectively). Median follow up was 8 months. As best overall response, 6 pts presented a stable disease (26%),1 pt achieved a confimed CR and 7 a PR for an ORR of 35%. Median PFS was 6 months. Treatment was feasible and well tolerated. All pts reported at least one grade (G) 1-2 adverse event (AE): the most common were fatigue (43%), hypotiroidism (28%), stomatitis (28%), anorexia (26%), Hand-Foot Syndrome (13%), hypertension (17%), and diarrhea (13%). 5 pts reported G3 AEs (2 thromboembolic events, 2 arterial hypertension, 1 fatigue), while no G4-5 AEs were reported. 17% of pts required dose reduction. DNA sequencing on CDC showed to be feasible, finding 256 mutations in 119 genes (missens mutations the majority). Altered genes, molecular subtypes and signatures will be associated to different outcomes and responses to cabo. **Conclusions:** The study met its primary endpoint showing promising efficacy and acceptable tolerability of cabo in mCDC pts. Mature results according to mutational profiles and gene signatures will be presented. Clinical trial information: NCT03354884. Research Sponsor: IPSEN PHARMA.

Characterization of the tumor immune microenvironment in clear cell renal cell carcinoma (ccRCC): Prognostic value and therapeutic implications of an M0-macrophage enriched subtype. *First Author: Mark Farha, University of Michigan Medical School, Ann Arbor, MI*

Background: Metastatic clear cell renal cell carcinoma (ccRCC) has a 5-year survival of 12%, but the number of approved immune checkpoint blockade (ICB) agents is growing, necessitating the need to better identify responders. The composition and role of the tumor immune microenvironment (TIME) has yet to be comprehensively characterized in ccRCC. Here, we leveraged a genomic data driven approach to characterize TIME subtypes in ccRCC. **Methods:** Whole transcriptome data from patients with local and metastatic disease in the Cancer Genome Atlas KIRC (TCGA-KIRC) project was utilized (n = 537). CIBERSORT was used for immune cell deconvolution, and unsupervised hierarchical clustering divided the cohort based on similar immune profiles. Progression free (PFS) and overall (OS) survival of each cluster was analyzed, and Gene Set Enrichment analysis was performed among clusters. The tumor immune dysfunction and exclusion (TIDE) tool, which uses a genomic signature validated on immunotherapy treated melanoma patients to model tumor immune evasion, was then used to predict response to ICB in the TCGA-KIRC clusters. **Results:** There was a distinct $M0^{hi}$ cluster identified which demonstrated a higher proportion of patients with stage III/IV disease, decreased PFS and OS (Table). Additionally, the $M0^{hi}$ cluster was characterized by lower PD-L1 expression (ANOVA, p = 0.0045) and an enrichment of epithelial to mesenchymal transition (EMT) hallmark genes [Enrichment Score = 0.64, p = 0.001]. The $M0^{hi}$ cluster also showed a higher degree of T-Cell Exclusion (ANOVA, $p = 2.2x10^{-16}$), predominance of Cancer Associated Fibroblasts (CAFs; ANOVA, $p = 2.2x10^{-16}$) and Myeloid Derived Suppressor Cells (MDSCs; ANOVA, $p = 4.1x10^{-10}$). The $M0^{hi}$ cluster had the lowest predicted response to immunotherapy using the TIDE tool (Table). **Conclusions:** Comprehensive characterization of the TCGA-KIRC cohort led to identification of a distinct cluster of ccRCC defined molecularly by decreased PD-L1 and increased EMT gene expression and cellularly by enrichment of M0 macrophages, CAFs, MDSCs, and an exclusion of T Cells. Patients within this cluster exhibited aggressive disease and poor predicted response to ICB. These findings warrant further validation to identify appropriate therapeutic approaches for this ccRCC subgroup. Research Sponsor: None.

Dynamic changes of the immune infiltrate after neoadjuvant avelumab/axitinib in patients (pts) with localized renal cell carcinoma (RCC) who are at high risk of relapse after nephrectomy (NeoAvAx). *First Author: Axel Bex, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Antibodies targeting PD-1/PD-L1 combined with vascular endothelial growth factor (VEGF) inhibitors are a front-line standard of care for metastatic RCC. Neoadjuvant use of these combinations is associated with tumor downsizing, but dynamic effects on key immune biomarkers are uncertain. We report early dynamic changes in the tumour immune environment after neoadjuvant treatment with avelumab/axitinib. **Methods:** Neoavax is an open label, single arm, phase II trial, investigating 12 weeks of neoadjuvant avelumab/axitinib prior to nephrectomy in patients with high-risk non-metastatic clear-cell (cc) RCC (cT1b-4N0-1M0). Partial primary tumour response (RECIST 1.1) occurring in ≥25% is the primary endpoint. Biomarker analysis on sequential tissue is an exploratory endpoint. Expression of PD-L1 (SP263), CD8+, CD8-granzyme-B (CD8/GZMB)+, Foxp3+ cells, CD8/CD39+ and major histocompatibility complex class I (MHC-I) were compared on paired samples (pre-treatment biopsy and nephrectomy) (NCT03341845). **Results:** Paired, sequential tissue from the first 24 patients was analysed for immune biomarker expression. Of these patients, 70% were ≥pT3a, 30% pN1, 58% had ISUP/WHO grade ≥3 with 8% sarcomatoid features. Compared to pre-treatment biopsy there was a significant increase in PD-L1 ($p = 0.0002$) and CD8+ expression ($p = 0.0003$) after therapy, whereas changes in CD8/GZMB+, MHC-I and CD8/CD39+ were not significant. Furthermore, neoadjuvant avelumab/axitinib therapy was associated with a significant decrease in Foxp3+ cells ($p = 0.009$). **Conclusions:** 12 weeks of neoadjuvant axitinib/avelumab treatment in ccRCC leads to significant dynamic changes in the tumour microenvironment for CD8+, PD-L1 and Foxp3+ expression. High baseline Foxp3+ infiltration is associated with an unfavorable outcome in the majority of solid tumours. The significant on-treatment decrease in Foxp3+ may account for the positive interaction seen between VEGF targeted therapy and immune checkpoint inhibitors in mRCC. If these cells represent regulatory T cells (Tregs), activated CD4 T cells or fragile Tregs remains to be determined. Clinical trial information: NCT03341845. Research Sponsor: Pfizer.

Efficacy of avelumab + axitinib (A + Ax) versus sunitinib (S) by IMDC risk group in advanced renal cell carcinoma (aRCC): Extended follow-up results from JAVELIN Renal 101. *First Author: John B. A. G. Haanen, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: In the phase 3 JAVELIN Renal 101 trial (NCT02684006), treatment-naive patients with aRCC receiving A + Ax showed improved progression-free survival (PFS) and objective response rate (ORR) across International Metastatic RCC Database Consortium (IMDC) risk groups (favorable [F], intermediate [I], and poor [P]) compared with patients receiving S. Here we report updated efficacy results for A + Ax vs S by IMDC risk groups from the third interim analysis. **Methods:** Patients were randomized 1:1 to receive either A (10 mg/kg intravenously every 2 weeks) plus Ax (5 mg orally twice daily) or S (50 mg orally once daily) for 4 weeks (6-week cycle). Patients were categorized per IMDC risk group into F, I, and P subgroups, and outcomes were assessed for F, I, P, and I + P. Overall survival (OS) and PFS, ORR, complete response (CR), and duration of response (DoR) per investigator assessment (RECIST v1.1) were assessed. **Results:** The study enrolled 886 patients with aRCC. At data cutoff (Apr 2020), median (95% CI) follow-up for OS in the A + Ax was NR (42.2-NE) vs 37.8 (31.4-NE) months with S. The Table shows OS, PFS, ORR, CR, and DOR by IMDC risk group. A + Ax generally showed improved efficacy compared with S across IMDC groups. **Conclusions:** Consistent with previously reported results from prior interim analyses, extended follow-up confirms the efficacy benefits of A + Ax vs S across IMDC risk groups in patients with aRCC. Patients continue to be followed up for the final OS analysis. Clinical trial information: NCT02684006. Research Sponsor: Funded by Pfizer as part of an alliance between Merck KGaA, Darmstadt, Germany and Pfizer.

Association with immune checkpoint inhibitor efficacy of a 27-gene classifier in renal cell cancer. *First Author: Robert Seitz, Oncocyte Inc, Nashville, TN*

Background: The 27-gene immuno-oncology (IO) signature that incorporates expression from activated inflammatory cells, cancer associated fibroblasts, and tumor cells to produce a binary classifier has been shown to be associated with efficacy to immune checkpoint inhibitors (ICIs) in breast, lung, and bladder cancers. Here we created clustered heat maps using data from The Cancer Genome Atlas (TCGA) to confirm the classifier function and diagnostic threshold in renal cell carcinoma (RCC), then applied the predefined algorithm to RNAseq data from a community RCC cohort treated with ICI therapy. **Methods:** Previously, we described the selection of 939 genes from the TCGA breast and lung datasets that comprise mesenchymal (M), mesenchymal stem-like (MSL), and immunodulatory (IM) gene expression patterns centered upon the twenty-seven genes selected for the IO score (AACR, 2021). We created an expression dataset using these genes in clear cell (n = 403) and papillary (n = 203) RCC and used k-means clustering to organize the genes and cases (k=3). We assessed the 27-gene classification of cases by utilizing area under the curve for phenotypic classification and determining the sensitivity and specificity of the previously established threshold compared to optimal accuracy for quantitating the fraction of cases enriched into the IM+ cluster (likely sensitive to ICIs) as opposed to the M or MSL clusters (likely insensitive). Finally, the IO score was evaluated in a small multi-institutional RNAseq dataset of forty-three RCC patients treated with an ICI for which there was definitive one-year progression free survival (PFS) data. **Results:** The 27-gene IO signature applied to the TCGA sample data had an AUC of 90.3 for stratification of cases into IM+ as opposed to M and MSL clusters while the established threshold for likely sensitive enriched 90% of cases into the appropriate IM cluster as opposed 28% into the M and MSL. Efficacy was defined by PFS. Given this result, the 27-gene IO signature was applied with the predefined threshold to the forty-three ICI treated patients. Patients who had a IO+ score by the 27-gene signature had significantly better one-year PFS compared to patients with a negative IO score (hazard ratio = 0.235, 95% CI = 0.069 - 0.803, $p < 0.01$). Median PFS was 5.2 months for patients classified as IO score negative versus 8.6 months for those classified as IO score+. **Conclusions:** The 27-gene IO signature has been validated across multiple tumor types and here in RCC to classify the tumor immune microenvironment without changing the algorithm or threshold. Results demonstrate that the 27-gene classifier has a strong correlation with efficacy of ICI therapy in RCC. This is the fourth tumor type in which the same algorithm has been validated as a predictor of ICI efficacy. These data support this assay as a strong pan-cancer immune system classifier worthy of further prospective study for ICI therapy. Research Sponsor: Oncocyte Inc.

Efficacy of nivolumab/ipilimumab in patients with initial or late progression with nivolumab: Updated analysis of a tailored approach in advanced renal cell carcinoma (TITAN-RCC). *First Author: Marc-Oliver Grimm, Department of Urology, Universitaetsklinikum Jena, Jena, Germany*

Background: TITAN-RCC uses a tailored immunotherapy approach in renal cell carcinoma (RCC), starting with nivolumab (nivo) induction followed by nivo + ipilimumab (ipi) as immunotherapeutic "boost" in non-responders. Patients with initial partial or complete response (PR/CR) continued with nivo maintenance but received later "boosts" for progressive disease (PD). Here we report updated results focusing on the efficacy of nivo+ipi in patients with initial PD vs. initial responders with later PD. **Methods:** Patients with IMDC intermediate and poor risk advanced clear cell RCC were recruited between OCT 2016 and DEC 2018. Patients started with nivo 240 mg Q2W induction. Patients with early significant PD (week 8) or non-responders at week 16 received 2-4 nivo+ipi "boost" cycles. Responders (PR/CR) to nivo monotherapy continued with maintenance but could receive nivo+ipi for later PD. The primary endpoint is confirmed investigator assessed objective response rate (ORR) per RECIST in first line (1L) and second line (2L). Secondary endpoints included activity of nivo monotherapy, remission rate with nivo+ipi "boost", safety and overall survival (OS). **Results:** 109 1L and 98 2L (after TKI) patients were analyzed for efficacy. Median age was 65 years (range 20-87). 71 % were intermediate and 25 % poor risk. Confirmed ORR with nivo monotherapy was 28 % for 1L and 17 % for 2L. After a median follow-up of 12.8 months best overall response after nivo induction ± nivo+ipi was 36 % in 1L and 30 % in 2L. Of all patients, 38 received nivo+ipi for stable disease (SD) up to week 16, with 1 (3 %), 4 (11 %) and 26 (68 %) achieving CR, PR and SD, respectively. 28 patients in 1L and 43 in 2L were boosted with nivo+ipi for initial PD. Of these, 3 (11 %) and 8 (29 %) achieved PR and SD, respectively, in 1L, whereas 3 (7.0 %) achieved CR, 6 (14 %) PR and 13 (30 %) SD in 2L. 16 and 10 patients received "boosts" later than week 16 for PD during nivo maintenance in 1L and 2L, respectively. Thereof, 3 (19 %) achieved PR and 5 (31 %) SD in 1L, whereas 2 (20 %) achieved PR and 3 (30 %) SD in 2L. Progression-free survival was 6.3 months (95 % CI 3.7 – 10.1) and 3.7 months (95 % CI 2.0 - 4.5) in 1L and 2L, respectively. OS was 27.2 months (95 % CI 19.9 – not estimable (NE)) in 1L and 20.2 months (95 % CI 15.6 – NE) in 2L. Treatment-related adverse events will be presented. **Conclusions:** Our tailored approach with nivo+ipi "boosts" results in improved response rates compared to nivo monotherapy. Our updated analysis suggests that almost half of the patients receiving "boosts" for PD improve to either PR/CR (18 %) or SD (30 %), irrespective of initial or later progression with nivo. Clinical trial information: NCT02917772. Research Sponsor: Bristol-Myers Squibb.

Retrospective study for the characterization of COVID-19 in renal cancer (COVID-REN) patients treated with antiangiogenics or immunotherapy and outcome comparison with non-infected cases. *First Author: Jesus Garcia Donas, Hospital Universitario Madrid Sanchinarro, Madrid, Spain*

Background: Cancer is recognized as a major risk factor for severe COVID19. However little is known about the impact of oncologic treatments in the evolution of the disease. On the other hand, the influence of SARS-CoV2 in cancer response remains to be established. We aim to determine both aspects in renal cancer patients receiving different therapeutic options. **Methods:** We designed a retrospective case-control study to compare the outcome of patients with advanced renal cancer who developed COVID19 under antiangiogenic treatment (cohort A [ChA]) vs immunotherapy (alone or in combination: cohort B [ChB]) vs matched controls (cohort C [ChC]). Controls were renal cancer patients who were not infected during the period of study. One control per case was selected regarding age, gender, kidney cancer histology and type of treatment. **Results:** From May 20 to Feb 21, 80 patients were recruited. We present the first 55 patients included (15 ChA, 16 ChB and 20 ChC, 4 patients were screening failure) from 13 centers in Spain. Median age was 62 (range 25 to 88) overall and 62 (range 44 to 88) in Ch A, 64,5 (range 42 to 83) in ChB and 61 (range 41 to 77) in ChC. 38 patients were male and 13 were female. Overall 45 cases were clear cell carcinoma (13 ChA, 14 ChB and 18 ChC), 4 papillary (1 ChA, 2 ChB and 1 ChC), 1 chromophobe (ChA) and 1 unclassified (ChC). Median number of prior lines of treatment was 2 (range 1 to 6) overall, (1 [range 1 to 4] in ChA, 2 [range 1 to 4] in ChB and 2 [range 1 to 6] in ChC). 25 patients required treatment interruptions (8 in ChA [32%], 14 in ChB [56%] and 3 [12%] in ChC). 9 patients were hospitalized (4 in Ch A, 5 in ChB and none in ChC) for a median of 10 days (range 4 to 16) overall (7 [range 4 to 14] in ChA and 12 [range 5 to 16] in ChB). No patient required ICU admission. Best tumor response was complete or partial (CR+PR) in 25 patients (5 [20%] in ChA, 9 [36%] in ChB and 11 [44%] in ChC). Clinical benefit (CR+PR+stable disease) was observed in 38 patients (11 [28,9%] in ChA, 10 [26,3%] in ChB and 17 [44,7%] in ChC). One patient in ChB died (due to COVID19). Updated results will be presented. **Conclusions:** Patients with renal cancer who developed COVID19 held treatment more frequently and presented lower clinical benefit rates than non infected cases. Patients receiving immunotherapy required more frequent dose interruptions and longer hospitalizations than cases on antiangiogenics. These results point to an impact of SARS-CoV2 in renal cancer outcome. Therapies administered to treat renal cancer, could play a role in the evolution of COVID19. Research Sponsor: unrestricted grant from Pfizer.

Efficacy outcomes of nivolumab + cabozantinib versus pembrolizumab + axitinib in patients with advanced renal cell carcinoma (aRCC): Matching-adjusted indirect comparison (MAIC). *First Author: Bradley Alexander McGregor, Dana-Farber Cancer Institute, Boston, MA*

Background: Nivolumab in combination with cabozantinib (N+C) has demonstrated significantly improved progression-free survival (PFS), objective response rate (ORR), and overall survival (OS), compared with sunitinib as a first-line (1L) treatment for aRCC in the phase 3 CheckMate (CM) 9ER trial. As there are no head-to-head trials comparing N+C with pembrolizumab in combination with axitinib (P+A), this study compared the efficacy of N+C with P+A as 1L treatment in aRCC. **Methods:** An MAIC was conducted using individual patient data on N+C (N = 323) from the CM 9ER trial (median follow-up: 23.5 months) and published data on P+A (N = 432) from the KEYNOTE (KN)-426 trialof P+A (median follow-up: 30.6 months). Individual patients within the CM 9ER trial population were reweighted to match the key patient characteristics published in KN-426 trial, including age, gender, previous nephrectomy, International Metastatic RCC Database Consortium risk score, and sites of metastasis. After weighting, hazards ratios (HR) of PFS, duration of response (DoR), and OS comparing N+C vs. P+A were estimated using weighted Cox proportional hazards models, and ORR was compared using a weighted Wald test. All comparisons were conducted using the corresponding sunitinib arms as an anchor. **Results:** After weighting, patient characteristics in the CM 9ER trial were comparable to those in the KN-426 trial. In the weighted population, N+C had a median PFS of 19.3 months (95% CI: 15.2, 22.4) compared to a median PFS of 15.7 months (95% CI: 13.7, 20.6) for P+A. Using sunitinib as an anchor arm, N+C was associated with a 30% reduction in risk of progression or death compared to P+A, (HR: 0.70, 95% CI: 0.53, 0.93; $P = 0.015$; table). In addition, N+C was associated with numerically, although not statistically, higher improvement in ORR vs sunitinib (difference: 8.4%, 95% CI: -1.7%, 18.4%; $P = 0.105$) and improved DoR (HR: 0.79; 95% CI: 0.47, 1.31; $P = 0.359$). Similar OS outcomes were observed for N+C and P+A (HR: 0.99; 95% CI: 0.67, 1.44; $P = 0.940$). **Conclusions:** After adjusting for cross-trial differences, N+C had a more favorable efficacy profile compared to P+A, including statistically significant PFS benefits, numerically improved ORR and DoR, and similar OS. Research Sponsor: BMS.

Post-weighting efficacy comparison for N+C vs. P+A using anchor-based MAIC.

	N+C vs. sunitinib (CheckMate 9ER)	P+A vs. sunitinib (KEYNOTE-426)	N+C vs. P+A (anchor-based comparison)

Patient-reported experience of diagnosis, management, and burden of renal cell carcinomas: Results from the 2020 Global Patient Survey from 41 countries. *First Author: Rachel H. Giles, International Kidney Cancer Coalition, Duivendrecht, Netherlands*

Background: The sustained increased global prevalence of kidney cancer (renal cell carcinoma, RCC) has increased the burden to health systems, and most of all, to individual patients and their families. Although individual national surveys have been held, no conclusions could be drawn about country-level variation in patient experience or best practice. Here, we report on the second biennial Global Patient Survey on the diagnosis, management, and burden of RCC. Conducted by the International Kidney Cancer Coalition (IKCC) and involving its Affiliate Organizations worldwide, the survey aims to improve collective understanding and to contribute toward the reduction of the burden of kidney cancer around the world. **Methods:** A 35-question survey on the diagnosis, management, and burden of RCC was designed by a multi-country steering committee of patient leaders to identify geographic variations in 6 key dimensions: patient education, experience and awareness, access to care and clinical trials, best practices, quality of life, and unmet psychosocial needs. The survey was distributed in 13 languages to patients with kidney cancer and their caregivers, through IKCC's 46 Affiliate Organisations and social media. It was completed online or in paper form between 29 Oct 2020 and 5 Jan 2021. **Results:** 2,012 (1,586 patients, 417 carers, 9 undisclosed) responses were recorded from 41 countries in 13 languages. Survey results were analyzed using cross-tabulations by an independent third-party organization. The full global report will be publicly available, as well as 7 individual country reports where at least 100 responses were received. 52% lacked understanding of subtype at diagnosis. 42% reported that the likelihood of surviving their cancer beyond 5 years was not explained. 51% reported that they were involved as much as they wanted to be in developing their treatment plan. 41% indicated that "No one" discussed cancer clinical trials with them. 31% were invited to take part in a clinical trial. 56% experienced barriers to their treatment. 45% self-reported that they were insufficiently physically active; 15% were completely sedentary. 50% indicated that they 'very often' or 'always' experienced disease-related anxiety. 55% indicated that they 'very often' or 'always' experienced a fear of recurrence. 52% reported having talked to their doctor/healthcare professional about their concerns. **Conclusions:** The IKCC and its global affiliates will use these results to ensure that patient and caregiver voices are heard and acted upon, with ultimate incorporation of these findings by much broader communities into care pathways, clinical practice, or health technology assessments. Furthermore, individual countries can use their reports to advance understanding of patient experiences and to drive improvements in providing care locally. Research Sponsor: International Kidney Cancer Coalition.

Outcomes with novel combinations in non-clear cell renal cell carcinoma(nccRCC): ORACLE study. *First Author: Deepak Kilari, Medical College of Wisconsin, Milwaukee, WI*

Background: Despite advances in the treatment of clear cell RCC, there is a paucity of data to guide management of nccRCC due to the heterogeneity and rarity of these tumors. The clinical activity of new combination therapies (including immunotherapy (IO), anti-vascular endothelial growth factor inhibitors (VEGF), and mammalian target of rapamycin (mTOR) inhibitors) in metastatic nccRCC is not known. **Methods:** In this multicenter retrospective analysis, we explored the efficacy of combination systemic therapies in patients with nccRCC. Baseline and follow-up demographic, clinical, treatment, and radiographic data were collected. The primary endpoint was objective response rate (ORR) assessed by investigator review. Secondary endpoints include progression- free survival (PFS), disease control rate (DCR), median duration of response (DOR), overall survival (OS), and biomarker correlates. **Results:** Among 66 included patients, median age was 59 yr; 60% were male and 62% white. Histologies included papillary (38%), chromophobe (17%), unclassified (24%), translocation (12%), and other (9 %). Sarcomatoid and/or rhabdoid differentiation was present in 18%, 70% had prior nephrectomy, 86% were IMDC intermediate/poor risk, 29% and 32% had liver and bone metastasis respectively. 67% received combination treatment in the first line. Comparison of outcomes based on treatment regimen is shown in the table. **Conclusions:** Antitumor activity was observed with novel combinations in nccRCC which warrants further prospective studies. Response rates and survival with combination therapy in this dataset remain inferior to rates seen in clear cell RCC. Research Sponsor: None.

	IO/VEGF	IO/IO	VEGF/mTOR
n	19	40	7
ORR(%)	21	19	0
DCR(%)	69	46	72
Median PFS (mo.) 1st line	16.8	13.6	2.1

Disease-free survival as a predictor of overall survival in localized renal cell carcinoma (RCC) following first nephrectomy. *First Author: Naomi B. Haas, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Intermediate endpoints (e.g., disease free survival [DFS]) have gained traction lately as potential surrogates for OS in oncology as they require shorter follow up to show clinical benefit. Given the high post-nephrectomy survival in patients (pts) with localized RCC, evidence on if DFS can be used as a predictor of OS in the disease is warranted. We assessed the association between DFS and OS in pts with newly diagnosed, completely resected, intermediate-high (pT2N0 high grade, pT3N0) or high-risk (pT4N0, pTanyN1) RCC post-nephrectomy. **Methods:** This retrospective observational study used the SEER-Medicare database (2007–2016). DFS was defined as time from initial nephrectomy date to first recurrence (diagnosis of metastatic disease, additional surgery, starting systemic treatment for advanced RCC) or death, whichever occurred first. OS from time of recurrence in pts with recurrence were compared with OS from comparable time point in pts without, using Kaplan-Meier analyses and adjusted Cox models. OS was also compared between pts with and without recurrence by landmark time points at 1, 2, 3, 4 and 5 years (yrs) post-nephrectomy; hazard ratios (HRs) between the two cohorts were estimated using adjusted Cox models. Correlation between DFS and OS was assessed using the Kendall's τ rank correlation. Monthly healthcare costs were compared between the two cohorts using generalized linear model. **Results:** 643 post-nephrectomy RCC pts (269 with recurrence vs 374 without) met the inclusion criteria (Median follow-up: 23 months). The mean age was 75.5 yrs, 61% male, and 86% white. The median post-nephrectomy OS and DFS was 8.61 and 4.44 yrs, respectively. Pts with and without recurrence had comparable baseline characteristics. Pts with recurrence had significantly shorter OS than those without [median: 2.53 yrs vs not reached; adjusted HR (95% confidence interval [CI]): 6.00 (4.24–8.48)]. Pts with recurrence by each landmark time point had significantly shorter OS than those without [1 yr post-nephrectomy median OS: 2.35 vs 9.66 yrs, and the OS 1, 3, and 5 after the 1 yr landmark was 69.9 vs 96.5%, 41.8 vs 83.8%, and 37.0 vs 70.1%, respectively; all Ps (log-rank test) < 0.001]. Cox models indicated that pts with recurrence by each landmark time point had 2.6–3.5 times increased risk of death compared with those without. Kendall's τ rank correlation model demonstrated a statistically significant correlation between DFS and OS (Kendall's $\tau = 0.70$; 95% CI: 0.65–0.74; $P < 0.001$). Pts with recurrence had $4,924 and $1,387 higher adjusted all-cause medical costs and pharmacy costs per month ($P < 0.001$). **Conclusions:** Post-nephrectomy recurrence is associated with significantly shorter OS among pts with intermediate-high or high-risk RCC, resulting in a strong positive association between DFS and OS in the population. Higher healthcare cost was also seen among pts with recurrence. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Role of cytoreductive nephrectomy (CN) in metastatic renal cell carcinoma (mRCC). *First Author: Pooja Ghatalia, Fox Chase Cancer Center, Philadelphia, PA*

Background: The role of CN in mRCC was challenged by the results of the CARMENA trial in the targeted therapy (TT) era. We sought to evaluate the role of both upfront and deferred CN in pts receiving modern IO-based and TT regimens. **Methods:** Pts with synchronous mRCC who received systemic therapy (tx) for mRCC after 2011 were included from the de-identified nationwide Flatiron Health database. We evaluated 3 groups: systemic tx alone, systemic-> CN, and CN-> systemic tx. Overall survival (OS) was calculated from the time of initiation of first therapy – systemic or CN. Patient characteristics were compared using chi-squared tests or t-test. Weighted Kaplan-Meier curves, log-rank tests, and Cox proportional hazards regressions with time-varying covariates were used to assess the effect of tx on survival. Adjustment was conducted via inverse probability of treatment weighing based on the generalized propensity score, estimated via Bayesian Additive Regression Trees. Covariates in the model were age, gender, race, insurance at mRCC diagnosis, and IMDC risk group. **Results:** Of 1719 pts with mRCC, 972 (56.5%) received systemic tx alone, 605 (35.1%) received CN-> systemic tx, and 142 (8.2%) received systemic->CN. 310 pts received IO or IO/IO, 123 pts received IO+TT and 1152 pts received only TT. The median follow-up was 37.1 months. In adjusted analyses using propensity score weighting and time-varying covariates, CN-> systemic was significantly associated with improved OS compared with systemic tx alone (Table). When stratifying groups by type of systemic treatment (IO and TT), there was improvement of OS in the CN groups compared to systemic tx alone, although we lacked power to reach statistical significance. Among CN-treated patients, the order of systemic tx relative to CN did not change OS (hazard ratio [HR] = 1.00, 95% CI 0.76-1.32, p=0.96). **Conclusions:** Using a national, EHR-based cohort, which includes a large number of IO treated pts, our findings support an oncologic role for CN in select mRCC pts. The timing of CN, for pts who were able to receive both systemic therapy and CN, may not affect overall outcome. The associated improvement in survival of CN is seen in pts receiving IO and TKI based systemic tx. Research Sponsor: None.

Adjusted median OS from weighted Kaplan-Meier curves and HR from weighted time-varying Cox model.

Effect of high-dose corticosteroid use on efficacy of immune checkpoint inhibitors in patients with renal cell carcinoma (RCC). *First Author: Chris Labaki, Dana Farber Cancer Institute - (Individuals), Boston, MA*

Background: The use of High-Dose Corticosteroids (HDC) has been linked to poor outcomes in patients with lung cancer treated with immune checkpoint inhibitors (ICIs) (Ricciuti B, JCO, 2019). There is no data on the effect of HDC on renal cell carcinoma patients (RCC) treated with immunotherapy. We hypothesized that HDC use would be associated with worse outcomes in RCC patients receiving ICIs. **Methods:** This study evaluated a retrospective cohort of patients with RCC at Dana-Farber Cancer Institute in Boston, MA. Clinical information including demographics, IMDC risk score, RCC histology, steroid administration, ICI regimen, line of therapy, time to treatment failure (TTF) and overall survival (OS) were collected. Patients were divided into those receiving HDC (prednisone $\geq$10 mg or equivalent for $\geq$ 1 week, HDC group) or not receiving HDC (No-HDC group). HDC administration was evaluated in relation to TTF and OS in a univariate analysis (Log-rank test) and a multivariate analysis (Cox regression). **Results:** 190 patients with RCC receiving ICIs were included, with a median age of 59 years. HDC were administered to 56 patients and 134 patients received no (N= 116) or only low-dose (N=18) steroids. In the HDC group, 40 patients received steroids for immune-related adverse events, 8 for other cancer-related indications, and 8 for non-oncological indications. There was no difference in TTF between the HDC and No-HDC groups (12-mo TTF rate: 34.8 vs. 32.3%, respectively; log-rank p=0.65). Similarly, there was no difference in OS between the HDC and No-HDC groups (36-mo OS rate: 56.7 vs. 62.4%, respectively; log-rank p=0.97). After adjusting for IMDC risk group, RCC histology, ICI regimen type, and line of therapy, TTF and OS did not differ in the HDC group as compared to No-HDC group (HR=1.14 [95%CI: 0.80-1.62], p=0.44 and HR=1.17 [95%CI: 0.65-2.11], p=0.59, respectively). **Conclusions:** In this retrospective study of patients with RCC treated with ICIs, administration of high-dose corticosteroids was not associated with worse outcomes. Research Sponsor: None.

Clinical characteristics, 12-mo TTF and 36-mo OS rates in study groups.

An open-label, single-arm, multicenter, phase II study of RC48-ADC to evaluate the efficacy and safety of subjects with HER2 overexpressing locally advanced or metastatic urothelial cancer (RC48-C009). *First Author: Xinan Sheng, Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: There is still urgent medical needs in the patients with locally advanced or metastatic urothelial cancer (mUC) post to the failure of at least one line chemotherapy. RC48-ADC, a novel humanized anti-HER2 antibody-drug conjugate (ADC), has proved its efficacy in these patients (RC48-C005, NCT03507166), most of whom had received gemcitabine and platinum. Taking into consideration that taxane is another possible active agent for mUC, this study aims to further evaluate the efficacy of RC48-ADC in HER2 overexpressing mUC post to the failure of platinum, gemcitabine and taxane. **Methods:** This study was an open-label, multicenter, single-arm, non-randomized phase II study. Eligibility criteria included: histologically confirmed UC, HER2 overexpressing (IHC 2+ or 3+), ECOG PS 0-1, failed platinum, gemcitabine and taxane. The patients received RC48-ADC treatment alone (2 mg/kg IV infusion, q2w) until disease progression, unacceptable toxicity, withdrawal, death or study termination. The primary endpoint was objective response rate (ORR) assessed by blinded independent review committee (BIRC) according to RECIST v1.1. Progress-free survival (PFS), duration of response (DOR), overall survival (OS), and safety was also assessed. **Results:** Patient enrollment for this study started in December 2018 and completed in September 2020. A total of 64 patients were enrolled, with a median age of 62.5 years. At baseline, most patients (82.8%) had visceral metastasis. Fifty-five patients (85.9%) had received $\geq$ 2 lines treatment and 19 (29.7%) patients had prior immune checkpoint inhibitor (CPI) therapy. As of Nov 30, 2020, the confirmed ORR assessed by BIRC was 46.9% (95% CI: 34.3%, 59.8%) and the median DOR was 8.3 months (95% CI: 4.3, NE), the median PFS was 4.3 months (95% CI: 4.0, 6.8). The median OS was 14.8 months (95% CI: 8.7, 21.1). The ORR was 60.0% (15/25) in patients with HER2 IHC3+ or FISH test positive, 45.3% (24/53) in patients with visceral metastasis, 42.1% (8/19) in patients post to CPI therapy. The ORR was 55.6% (5/9), 50.0% (21/20) and 30.8% (4/13), in patients who had received 1 line, 2 lines and $\geq$ 3 lines treatment, respectively. Most commonly reported TRAEs were leukopenia (45.3%), AST increase (43.8%), neutropenia (42.2%), hypoesthesia (42.2%), ALT increase (37.5%) and fatigue (35.9%); Most commonly reported $\geq$ grade 3 TRAEs were neutropenia (9.4%) and hypoesthesia (6.3%) **Conclusions:** In patients with HER2 overexpressing (IHC 2+ or 3+) mUC who had failed platinum, gemcitabine and taxane, and the great majority of whom had received $\geq$2 prior lines treatment, RC48-ADC has demonstrated consistently excellent efficacy and benefit-risk profile compared with the RC48-C005 study which enrolled patients with mUC who had received $\geq$1 line prior chemotherapy. Clinical trial information: NCT03809013. Research Sponsor: remegen.

4585 **Poster Session**

Circulating tumor DNA (ctDNA) in patients with advanced adrenocortical carcinoma. *First Author: Bassel Nazha, Emory University Department of Hematology and Medical Oncology, Atlanta, GA*

Background: Adrenocortical Carcinoma (ACC) is a rare and aggressive malignancy with poor prognosis and limited treatments in the advanced setting. Molecular pathways with tumor suppressor genes (e.g. TP53, CDKN2A) and oncogenes (e.g. CTNNB1 and RAS) are implicated in oncogenesis. To our knowledge, the genomic landscape of ctDNA alterations for ACC has not been described in a large cohort. We report plasma-based ctDNA alterations in patients with advanced ACC. **Methods:** We retrospectively evaluated genomic data from 102 patients with ACC who had ctDNA testing between 12/2016 – 10/2020 using Guardant360 (Guardant Health, CA). ctDNA analysis interrogated single nucleotide variants (SNV), fusions, indels and copy number variations (CNV) of up to 83 genes. We evaluated the frequency of genomic alterations, the landscape of co-occurring mutations, and pathogenic or likely pathogenic alterations with potential targeted therapies. The prevalence of alterations identified in ctDNA were compared to those detected in tissue using a publicly available database (cBioPortal). **Results:** The median age was 54 years (range 24-81), and 55% of patients were male. Among the entire cohort, 84 pts (82.4%) had ≥1 somatic alteration detected. Mutations were most frequently detected in TP53 (52%), EGFR (23%), CTNNB1 (18%), MET (18%), and ATM (14%). The frequencies detected in ctDNA were similar to the results detected in tissue. Pathogenic and/or likely pathogenic mutations in therapeutically relevant alterations were observed in 36 patients (35%), including EGFR, BRAF, MET, CDKN2A, and CDK4/6 (Table 1). The most frequently co-occurring mutations were EGFR + TP53 (14%), EGFR + MET (11%), BRAF + MET (10%). **Conclusions:** Blood-based ctDNA profiling in advanced ACC provided comprehensive genomic data in most patients, with a similar profile to tumor tissue analyses. Over one third of patients had actionable mutations with approved therapies in other cancers. This approach might inform the development of personalized treatment options for this aggressive malignancy. Research Sponsor: None.

	ACC patients with mutations in the rapeutically relevant alterations	
Gene	N	%
EGFR	10	11.9%
BRAF	9	10.7%
MET	9	10.7%
CDKN2A	7	8.3%
NF1	7	8.3%
CDK4	7	8.3%
CDK6	6	7.1%
GNAS	6	7.1%
FGFR 1 or FGFR2	5	6.0%
ATM	4	4.8%

TPS4586 **Poster Session**

A phase 3, multicenter, randomized study evaluating the efficacy of TAR-200 in combination with cetrelimab versus concurrent chemoradiotherapy in participants with muscle-invasive urothelial carcinoma of the bladder. *First Author: Stephen B. Williams, University of Texas Medical Branch (UTMB), Galveston, TX*

Background: The standard of care for patients with muscle-invasive bladder cancer (MIBC) consists of neoadjuvant chemotherapy and radical cystectomy (RC) or chemoradiotherapy (CRT). However, RC is associated with potential morbidity or mortality from the procedure. TAR-200 is an intravesical drug-delivery system designed for the local continuous release of gemcitabine within the bladder. Cetrelimab is an investigational immunoglobulin G4 anti–programmed cell death protein-1 antibody. In patients with MIBC, this clinical trial will evaluate whether combination treatment with intravesical TAR-200 and systemic cetrelimab will result in enhanced local and systemic antitumor activity versus concurrent CRT. **Methods:** SunRISe-2 (NCT04658862) is a prospective, multicenter, open-label, randomized phase 3 study evaluating the efficacy and safety of intravesical TAR-200 plus systemic cetrelimab versus CRT in participants with MIBC. Eligible participants are aged ^{3}18 years with an ECOG performance status of 0, 1, or 2, and histologically proven, cT2-T4a, N0, M0 urothelial carcinoma of the bladder diagnosed within 90 days of the randomization date, and who refuse or are ineligible for RC. Approximately 550 participants will be randomized in a 1:1 ratio and with stratification by 2 factors: transurethral resection of bladder tumor screening results (visibly complete vs incomplete) and screening tumor stage (T0 vs Ta/T1/Tis vs T2-T4a). Participants in Arm 1 will receive intravesical TAR-200 every 3 weeks for the first 18 weeks on study; and, beginning at week 24, every 12 weeks through study year 3. Cetrelimab will be dosed every 3 weeks until month 18. Participants in Arm 2 will receive standard of care CRT (with either cisplatin or gemcitabine, for up to 6 weeks). A primary disease assessment will be performed at week 18 to evaluate treatment response in both arms. Subsequent assessments (axial imaging and cystoscopy) will occur at week 24 and every 12 weeks thereafter through study year 2, and then every 24 weeks through study year 5. The primary endpoint is bladder intact event-free survival. Key secondary endpoints include metastasis-free survival, overall survival, overall response rate (at week 18), and safety and tolerability. Other/exploratory end points include assessments of cancer-specific survival, time to symptomatic progression, pharmacokinetics, immunogenicity, health-related quality of life, healthcare resource utilization, and biomarkers. Participants are being enrolled at approximately 272 study sites worldwide. The study opened for enrollment in December 2020. Clinical trial information: NCT04658862. Research Sponsor: Janssen Research & Development, LLC.

TPS4587 **Poster Session**

KEYNOTE-B15/EV-304: Randomized phase 3 study of perioperative enfortumab vedotin plus pembrolizumab versus chemotherapy in cisplatin-eligible patients with muscle-invasive bladder cancer (MIBC). *First Author: Christopher J. Hoimes, Duke University, Durham, NC*

Background: Standard of care for MIBC is neoadjuvant cisplatin-based chemotherapy followed by radical cystectomy and pelvic lymph node dissection (RC+PLND); however, in time, patients experience disease recurrence or progression. Enfortumab vedotin (EV) is a Nectin-4–directed antibody–drug conjugate comprising a fully human, monoclonal antibody and the microtubule-disrupting agent monomethyl auristatin E. The KEYNOTE-869/EV-103 phase 1/2 study (NCT03288545) showed that the PD-1 inhibitor pembrolizumab + EV had encouraging antitumor activity and acceptable safety as first-line treatment for cisplatin-ineligible patients with metastatic urothelial cancer (Rosenberg JE et al. J Clin Oncol. 2020;38[15 suppl]:5044). Based on these data, investigating EV + pembrolizumab in an earlier setting such as MIBC and in a perioperative fashion is appropriate. KEYNOTE-B15/EV-304 (NCT04700124) is a randomized, open-label, phase 3 study to evaluate the efficacy and safety of perioperative EV + pembrolizumab versus neoadjuvant chemotherapy using gemcitabine/cisplatin in cisplatin-eligible patients with MIBC. **Methods:** Patients must have histologically confirmed urothelial cancer/MIBC (clinical stage T2-T4aN0M0 or T1-T4aN1M0) with predominant (≥50%) urothelial histology, have nonmetastatic disease (≥N2 disease and/or M1 excluded) confirmed by blinded independent central review (BICR), have ECOG PS 0 or 1, and not have previously received systemic therapy for MIBC. Approximately 784 patients will be randomly assigned 1:1 to receive either 4 cycles of neoadjuvant EV + pembrolizumab followed by 5 cycles of adjuvant EV + 13 cycles of adjuvant pembrolizumab after RC+PLND or 4 cycles of neoadjuvant cisplatin-based chemotherapy followed by observation after RC+PLND. Neoadjuvant and adjuvant pembrolizumab 200 mg + EV 1.25 mg/kg will be administered intravenously every 3 weeks (Q3W), and neoadjuvant chemotherapy will consist of gemcitabine 1000 mg/m^2 + cisplatin 70 mg/m^2 Q3W. Randomization will be stratified by centrally determined (pathology or imaging) initial T and N stage (T2N0 or T3/T4aN0 or T1-T4aN1), PD-L1 combined positive score (CPS ≥10 or CPS < 10), and geographic region (United States or Europe or most of world). Imaging (CT or MRI) will be performed ≤6 weeks before cystectomy and 6 weeks after cystectomy. After postcystectomy imaging, additional imaging will be performed Q12W up to the end of year 2 (week 96) and at discontinuation. In year 3 and beyond, imaging will be performed Q24W. Primary end points are pathological complete response and event-free survival by BICR. Secondary end points are overall survival, disease-free survival, pathological downstaging, and safety and tolerability. Clinical trial information: NCT04700124. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Consolidative radiotherapy for metastatic urothelial bladder cancer patients without progression and with no more than three residual metastatic lesions following first line systemic therapy: A prospective randomized comparative phase II trial (BLAD RAD01/GETUG-AFU V07). *First Author: Jonathan Khalifa, Institut Claudius Regaud/IUCT-Oncopole, Toulouse, France*

Background: Consolidative local treatment of the primary tumor in the treatment of metastatic malignancies has shown promising results in several types of tumors, mostly relying on the seed-and-soil theory. Furthermore, the local treatment of the residual metastases following systemic treatment is a promising approach, in part due to the high incidence of progression at prior sites of disease in patients who had initially responded to chemotherapy. To date, no prospective data exists on such consolidative approach in metastatic urothelial bladder cancer (mUBC). The phase II trial BLAD-RAD01 GETUG-AFU V07 was designed to investigate the role of local consolidative radiotherapy in patients with limited mUBC and without progression following the initial phase of first-line systemic therapy. **Methods:** This is a phase II, multicenter, randomized open-label and comparative study. Patients with mUBC (excluding brain and liver metastases), without progression following standard first-line systemic therapy according to RECIST v1.1, and with no more than 3 residual metastatic lesions on 18FDG-PET scanner and/or contrast-enhanced CT-scanner are eligible for the study. After the completion of systemic treatment, an estimated 130 patients will be randomized in a 1:1 ratio between consolidative local treatment (pelvic radiotherapy +/- previous transurethral resection of bladder tumor, associated with stereotactic body radiotherapy (SBRT) to the residual metastases) plus standard of care (arm B) and standard of care only (arm A). Stratification is performed based upon: the center, the ECOG performance status, the administration of immunotherapy or not, the number of residual metastatic lesions and the imaging modality for assessment of the number of residual lesions. To date, standard of care for this population is maintenance treatment with avelumab. Radiotherapy regimens consist in conventionally fractionated (64Gy in 32 fractions) or hypofractionated (55Gy in 20 fractions) irradiation of the bladder, optional pelvic nodes irradiation, and 3 to 5 fractions of 6 to 18 Gy in SBRT for metastases, depending on the location. The main objective is to detect an increase in 20-month overall survival rate following chemotherapy from 50% (based upon the JAVELIN 100 trial) to 66%; this corresponds to a hazard ratio of 0.6. A total of 83 events are necessary for 85% power to detect this difference if it is true using a one-sided logrank test at the 10% of significance. Target difference, type I and II error rates are relaxed and compatibles with recommendations for comparative phase II trials. Key secondary endpoints are progression free survival, safety and quality of life. To date, one patient has been enrolled and eight centers are open for accrual. Clinical trial information: NCT04428554. Research Sponsor: PHRC-K 2019 (programme hospitalier de recherche clinique national en cancérologie).

TPS4589 **Poster Session**

AUREA study: Atezolizumab (Atezo) combined with split-dose gemcitabine plus cisplatin (s-GC) in locally advanced or metastatic urothelial cancer (LA/mUC): A SOGUG study. *First Author: Alfonso Gomez De Liano Lista, Medical Oncology Department, Complejo Hospitalario Universitario Insular-Materno Infantil, Las Palmas, Spain*

Background: First-line cisplatin-based chemotherapy (70 mg/m^2) is the standard of care for LA/mUC patients (pts). However, about 50% will be ineligible for Cisplatin according to Galsky's criteria. Moreover, a significant proportion of cisplatin-fit pts will receive carboplatin based on physician criteria. s-GC represents a feasible alternative in such situations, and could improve response rate compared to carboplatin regimens. Atezo is a programmed death-ligand 1 (PD-L1) inhibitor that is approved as first line treatment for cisplatin-ineligible LA/mUC pts with PD-L1 expression ≥5% (Ventana SP142). We present the study design of a phase II single arm trial of Atezo +s-GC in previously untreated pts with LA/mUC (NCT04602078). **Methods:** This single arm, open-label, multicenter study evaluates the efficacy and safety of Atezo +s-GC in previously untreated pts with LA/mUC. 66 pts will be enrolled and receive s-GC x 6 cycles (Cisplatin 35mg/m2 + Gemcitabine 1000mg/m2 on days 1 and 8 Q3W) and Atezo (1200 mg IV Q3W), followed by Atezo (1200 mg IV Q3W) until disease progression, toxicity or absence of clinical benefit. Eligibility criteria include histologically confirmed unresectable LA/mUC, measurable disease per RECIST 1.1 and adequate organ and marrow. Pts must be unfit for full cisplatin dose based on: age > 70 years, PS ECOG 0-2, creatinine Clearance >30 and <60 mL/min per Cockroft-Gault formula or by 24-hour urine collection. Other reasons for cisplatin ineligibility as considered by investigator, including those uncovered by Galsky's criteria, will be allowed, prior discussion with PI. Exclusion criteria include prior systemic therapy for LA/mUC (adjuvant/neoadjuvant allowed if finished > 12 months prior to inclusion), prior autoimmune disease and uncontrolled significant illnesses. The primary endpoint is ORR per RECIST 1.1 assessed by investigator; the secondary endpoints are DoR, OS, PFS and safety. Biomarker analysis, including PD-L1 expression and microbiome relationship, will be an exploratory objective. The first two patients were enrolled in February 2021. Clinical trial information: NCT04602078. Research Sponsor: Roche, Spanish Oncology Genito Urinary Group (SOGUG).

TPS4590 **Poster Session**

EA8185: Phase 2 study of bladder-sparing chemoradiation (chemoRT) with durvalumab in clinical stage III, node positive urothelial carcinoma (INSPIRE)—An ECOG-ACRIN and NRG Collaboration. *First Author: Monika Joshi, Penn State Cancer Institute, Hershey, PA*

Background: Patients [pts] withlymph node positive (LN+), non-metastatic bladder cancer (BC) have a better prognosis than those with metastatic (M1) disease. However, this population is under-represented in advanced bladder trials and ineligible for bladder-sparing trials. Therefore, there have been no larger prospective trials establishing the standard of care in LN+ BC. Given the promise of immunotherapy in advanced BC and potential synergy between immunotherapy and radiation, INSPIRE was designed to determine the role of concurrent and adjuvant durvalumab (durva) in this patient population when treated with induction chemotherapy (IC) followed by concurrent chemoRT. **Methods:** This is a randomized phase II study that is enrolling BC pts with stage III [N1-2 M0], pure or mixed urothelial cancer. Pts must have received ≥3 cycles of IC [either before or after registration, prior to randomization] without progression. LN+ is defined as radiologically LN ≥1.0 cm in short axis, with or without biopsy prior to IC. As long as pts do not progress on induction chemotherapy, they will be randomized to chemoRT+/- durva using 5 stratification factors (Simon Pocock minimization method) a) IC prior vs. post registration b) cisplatin vs non-cisplatin regimen during RT c) LN size d) response to IC e) extent of TURBT. Pts on the chemoRT+durva arm will get chemotherapy per physician choice + IMRT + 3 x doses of Q3wk durva for 6.5-8 wks, whereas those on the control arm will get chemoRT alone. The primary end point is clinical complete response [CR], defined as no radiologically measurable disease in the LNs and negative cystoscopy and bladder biopsy 8-10 weeks post-chemoRT +/- durva. Pts on the chemoRT + durva arm who have a CR or clinical benefit (> T0 and ≤T2 in bladder per cystoscopy, biopsy + CR/PR/SD in LN by imaging) will get adjuvant Q4wk durva for 9 doses, while those on the chemoRT arm will undergo observation. Secondary end points include OS, PFS, bladder-intact event-free survival, rate of toxicity and salvage cystectomy. This study is designed to detect an improvement of 25% in clinical CR between both arms (37.5% to 62.5%). A total accrual of 114 pts (in order to enroll 92 evaluable pts) will provide 81% power to detect this difference using a Fisher's exact test (assuming 10% drop out + anticipating that 20% chemotherapy-naïve pts will progress post IC). We are banking blood and primary tumor tissue pre- and post-chemoRT in both groups. The study was activated in August 2020 and accrual is ongoing. INSPIRE is the first prospective study designed for only LN+ BC and will define both short-term and long-term outcomes for bladder sparing in this patient population and has the potential to define a new treatment strategy for stage III BC. Clinical trial information: NCT04216290. Research Sponsor: U.S. National Institutes of Health.

TPS4591 **Poster Session**

A phase 2 study of cabozantinib in combination with atezolizumab as neoadjuvant treatment for muscle-invasive bladder cancer (HCRN GU18-343) ABATE study. *First Author: Deepak Kilari, Medical College of Wisconsin, Milwaukee, WI*

Background: ABACUS and PURE-01 trials demonstrated the activity of single agent atezolizumab and pembrolizumab respectively as neoadjuvant therapy for muscle invasive urothelial carcinoma (MIUC). However, downstaging to non-muscle invasive disease was noted in only 50 percent of patients. Resistance to programmed death (PD)- 1/L-1 antibodies is likely to include factors such as impaired dendritic cell maturation/function, infiltration of T-Regs and myeloid derived suppressor cells, impaired T-cell priming and T-cell trafficking in tumors. Cabozantinib is a tyrosine kinase inhibitor which targets MET, AXL, MER, Tyro3 and VEGFR2. Cabozantinib has a unique immunomodulatory profile and has demonstrated clinical activity as monotherapy and in combination with PD-1/L1 antibodies in various solid tumors including UC, renal cell cancer, castrate- resistant prostate cancer, and non-small cell lung cancer. We hypothesize that the combination of cabozantinib and atezolizumab as neoadjuvant therapy for MIUC would improve rates of pathologic downstaging compared to single-agent checkpoint inhibitors. **Methods:** ABATE(NCT04289779) is an open-label, single arm, multi-center study to assess the efficacy and safety of cabozantinib with atezolizumab as neoadjuvant therapy for cT2-T4aN0/xM0 MIUC. An estimated 38 patients will be enrolled and receive cabozantinib 40 mg PO daily with atezolizumab 1200mg every 3 weeks for a total duration of 9 weeks followed by radical cystectomy. Adults (≥18 years) with resectable UC who are either cisplatin-ineligible or decline cisplatin are eligible. Patients are required to have an ECOG PS of 0-2 and provide tumor tissue for PD-L1 analysis. UC should be predominant component (≥ 50%). Previous systemic anticancer therapies for MIUC are not permitted. CT/MRI will be performed before investigational therapy and cystectomy. Primary endpoint is pathologic response rate defined as the absence of residual muscle-invasive cancer in the surgical specimen (< pT2). Secondary endpoints are safety and toxicity, pathologic complete response rate and event-free survival. Exploratory end points include patient-reported outcomes and outcome associations with biomarkers. Accrual began May 2020. Clinical trial information: NCT04289779. Research Sponsor: Exelixis and Genentech.

TPS4592 **Poster Session**

Cabozantinib (C) in combination with nivolumab (N) and ipilimumab (I) (CaNI) for advanced renal cell carcinoma with variant histology (aRCCVH). *First Author: Bradley Alexander McGregor, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite advances in therapy of clear cell renal cell carcinoma, outcomes for patients with aRCCVH remain poor and these patients have typically been excluded from pivotal phase III studies. COSMIC-313 (NCT03937219) exploring C/N/I vs N/I excludes those with aRCCVH. Given responses seen with C as well as N/I in aRCCVH, there is reason to explore this triplet combination in this population. **Methods:** NCT04413123 is single arm phase 2 trial multi-institutional study involving Dana-Farber Cancer Institute, Beth Israel Deaconess Medical Center, Winship Cancer Institute, Karmanos Cancer Center, University of California in San Diego and University of Texas Southwestern. The primary objective is to assess the objective response rate (ORR) by investigator-assessed Response Evaluation Criteria in Solid Tumors (RECIST) Version 1.1 of C in combination with N/I in aRCCVH. Key secondary endpoints are progression-free survival (PFS), overall survival (OS) and toxicity by Common Terminology Criteria for Adverse Events (CTCAE) version 5. Mandatory pretreatment biopsy (unless medically infeasible) is required for correlative analysis to define the composition and transcriptional states of tumor and immune cells within the aRCCVH microenvironment in addition to determining the number and state of tumor-infiltrating T cell clones in aRCCVH and relation to response. Any variant histology is allowed, including clear-cell RCC with over 80% sarcomatoid features. Patients may be treatment naïve or received prior therapy including up to one anti-vascular endothelial growth factor agent not including C; prior therapy with immune checkpoint inhibitors is exclusionary. All International Metastatic RCC Database Consortium risk classifications are allowed; patients should have adequate organ function with performance status 0-1. C will be administered at a starting dose of 40 mg daily. N will be dosed at 3 mg/kg with I 1 mg/kg every 3 weeks followed by maintenance N 480 mg IV every 4 weeks and will be continued until progressive disease or unacceptable toxicity. C can be reduced to. 20 mg daily or 20 mg every other day as needed for toxicity. Dose reductions of N or I are not permitted but delays up to 12 weeks are allowed; N may be continued without I if toxicity can be directly attributed to I. Radiographic imaging is performed at baseline with first scheduled assessment at 12 weeks then every 8 weeks thereafter. A one-stage design is employed to enroll 40 eligible patients, which provides 93% power at 1-sided alpha of 0.09 to distinguish an ORR of 40% versus 20%. 12 or more responses are required to deem treatment promising. Seven of the planned 40 patients have been enrolled as of 2/1/2021. Clinical trial information: NCT04413123. Research Sponsor: Exelixis, Pharmaceutical/Biotech Company.

TPS4593 **Poster Session**

A randomized trial of radium-223 (Ra-223) dichloride and cabozantinib in patients (pts) with advanced renal cell carcinoma (RCC) with bone metastases (RADICAL/Alliance A031801). *First Author: Rana R. McKay, University of California San Diego, Moores Cancer Center, La Jolla, CA*

Background: Bone metastases are prevalent in approximately 30% of pts with advanced RCC. Pts with bone metastases have a worse prognosis compared to pts without bone metastases and are at risk of symptomatic skeletal events (SSEs). Cabozantinib, a multitargeted inhibitor of multiple kinases, including vascular endothelial growth factor (VEGF) receptor and MET, has improved survival in pts with metastatic RCC and has enhanced activity in bone. Ra-223, an alpha-emitting radioisotope with natural bone-seeking proclivity, has been shown to prolong survival in men with castration-resistant prostate cancer. We previously conducted a pilot study of Ra-223 with VEGF inhibition and demonstrated safety and declines in markers of bone formation and resorption with the combination (McKay et al, CCR 2018). Given that decreasing rates of SSEs and improving outcomes for pts with RCC with bone metastases are unmet needs in pts with RCC, we designed a randomized phase 2 study through the National Clinical Trials Network (NCTN) investigating cabozantinib with or without Ra-223 in patients with RCC with bone metastases. **Methods:** This is an open-label multicenter study. Eligible pts have metastatic RCC of any histology with ≥2 metastatic bone lesions untreated with prior radiation therapy and no more than 2 prior lines of systemic therapy. Pts with non-clear cell RCC are eligible and will be capped at 20% of the total accrual goal. Pts must have a Karnofsky performance status of ≥60%, have symptomatic bone pain defined as a prior SSE or need of analgesics, and be on osteoclast-targeted therapy unless otherwise contraindicated. Pts are randomized 1:1 to cabozantinib with (Arm A) or without (Arm B) Ra-223. Starting dose of cabozantinib for Arm A is 40 mg by mouth daily to be escalated to 60 mg daily after cycle 1 (1 cycle = 28 days) if no persistent grade 2 or grade ≥3 toxicity. Ra-223 is administered at a fixed dose of 1.49 microcurie/kg IV every 28 days x 6 doses. The primary endpoint is SSE-free survival. Secondary endpoints include safety, progression-free survival, overall survival, quality of life measures, and correlative analyses including liquid biopsy studies and tumor tissue analysis. The study has 90% power to detect an improvement in 6-month SSE-free survival rate from 65% to 78% with one-sided $\alpha = 0.025$ significance. To ensure 191 evaluable patients, target accrual is 210 pts. This design includes a safety run-in and an interim analysis for futility when 50% of the expected number of events (72 SSE events) have been observed. Final data analysis will occur when 143 events have been observed. The study was activated in December 2019 and accrual is currently ongoing throughout the NCTN. Clinical trial information: NCT04071223. Research Sponsor: U10CA180821, U10CA180882, U24CA196171, https://acknowledgments.alliancefound.org. U10CA180820 and UG1CA233302 (ECOG-ACRIN).

TPS4594 **Poster Session**

A phase 1b/2 umbrella study of investigational immune and targeted combination therapies as first-line therapy for patients with advanced renal cell carcinoma (RCC). *First Author: Elizabeth R. Plimack, Fox Chase Cancer Center, Philadelphia, PA*

Background: For advanced clear cell RCC (ccRCC), first-line treatment with PD-1/PD-L1 inhibitors in combination with CTLA-4 inhibitors or VEGF TKIs are established treatment options. However, patients eventually experience progression; therefore, more effective therapies are needed. This umbrella platform study is an open-label, rolling-arm, multicenter, phase 1b/2 trial with an adaptive design that will evaluate the safety and efficacy of experimental combinations of investigational agents in advanced ccRCC based on their mechanisms of action and toxicity profile. Substudy 03A (NCT04626479) will evaluate treatment combinations as first-line therapy for patients with advanced ccRCC. Given promising results of the phase 1b/2 KEYNOTE-146 (NCT02501096) and phase 3 KEYNOTE-581/CLEAR (NCT02811861) studies, pembrolizumab (400 mg IV Q6W) + lenvatinib (20 mg orally QD) will be used as the reference arm. **Methods:** Patients must be aged ≥18 years with histologically confirmed ccRCC, measurable disease per RECIST v1.1, and KPS score ≥70 and must have not received prior systemic therapy for advanced RCC (neoadjuvant therapy is acceptable if completed ≥12 mo before randomization). The study will comprise a safety lead-in phase for experimental combinations with investigational agents without an established recommended phase 2 dose (RP2D) and an efficacy phase. Patients will be randomly assigned 2:1 to an experimental arm or a reference arm. Each experimental arm will contain approximately 80 patients. During the efficacy phase, if more than 1 experimental arm is open for enrollment, patients in the reference arm can be shared. Treatments in the experimental arms are composed of the following: MK-1308A (coformulation of quavonlimab [MK-1308] 25 mg + pembrolizumab 400 mg IV Q6W) + lenvatinib (20 mg orally QD), MK-4280A (coformulation of MK-4280 800 mg + pembrolizumab 200 mg IV Q3W) + lenvatinib (20 mg orally QD), and pembrolizumab (400 mg Q6W IV) + belzutifan (MK-6482, 120 mg orally QD) + lenvatinib (20 mg orally QD). Treatment with pembrolizumab (including coformulations with MK-1308 and MK-4280) will continue up to 2 years, whereas treatment with lenvatinib and belzutifan will continue until disease progression, unacceptable toxicity, or withdrawal of consent. Patients will be stratified by IMDC risk group (favorable vs intermediate/poor). Tumor imaging will occur 12 weeks after randomization, then Q6W until week 54, and Q12W thereafter. Coprimary end points are safety and tolerability, establishing the RP2D during the safety lead-in phase (if applicable) and objective response rate per RECIST v1.1 by blinded independent central review (BICR) during the efficacy phase. Secondary end points during the efficacy phase are duration of response, progression-free survival and clinical benefit rate per RECIST v1.1 (BICR), and overall survival. Clinical trial information: NCT04626479. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA, and Eisai Inc., Woodcliff Lake, NJ, USA.

TPS4595 **Poster Session**

KEYNOTE-B61: Open-label phase 2 study of pembrolizumab in combination with lenvatinib as first-line treatment for non-clear cell renal cell carcinoma (nccRCC). *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Most RCCs contain clear cell histology; the remainder of cases are summarized as nccRCC. nccRCC is a heterogeneous group of tumors and, with advanced metastases, survival is uniformly worse than with clear cell RCC (ccRCC) because of the aggressiveness of these cancers and a lack of effective systemic treatment options. Because data are limited for patients with nccRCC, the role of various agents in the treatment of nccRCC is poorly defined and there is no standard of care; treatment guidelines recommend clinical trials as preferred strategy. Inhibition of the PD-1/PD-L1 pathway is an effective treatment option for nccRCC, and pembrolizumab monotherapy has shown efficacy with an acceptable safety profile as first-line treatment. The VEGF TKI lenvatinib has also shown efficacy with a tolerable safety profile as combination therapy with everolimus for nccRCC. Also, in the phase 3 KEYNOTE-581 study (NCT02811861), the combination of lenvatinib + pembrolizumab as first-line therapy showed antitumor activity in patients with metastatic ccRCC, suggesting this combination might be an excellent therapeutic option for nccRCC. The phase 2, open-label, single-arm, KEYNOTE-B61 study (NCT04704219) is being conducted to evaluate pembrolizumab in combination with lenvatinib as first-line treatment for nccRCC. **Methods:** Patients with centrally confirmed nccRCC, locally advanced/metastatic measurable disease per RECIST v1.1 per blinded independent central review (BICR), no prior systemic therapy for nccRCC, and KPS score ≥70 will be enrolled. Approximately 152 patients will receive pembrolizumab 400 mg every 6 weeks and lenvatinib 20 mg once daily. Pembrolizumab treatment will continue for up to approximately 2 years or until a discontinuation criterion is met (disease progression, unacceptable toxicity, or withdrawal of consent); lenvatinib treatment can continue beyond 2 years or until one of the same discontinuation criterion is met. Participants who discontinue one of the treatments can continue to receive the other treatment as monotherapy. A second-course treatment phase is available for patients who meet specific criteria. CT/MRI will be performed at 12 weeks from the start of treatment, every 6 weeks until week 54, and every 12 weeks thereafter. Adverse events will be monitored throughout the study and graded using CTCAE, version 5.0, guidelines. The primary end point is objective response rate based on RECIST v1.1 per BICR. Secondary efficacy end points for this study are clinical benefit rate, disease control rate, duration of response, progression-free survival, overall survival, and safety. Tertiary/exploratory end points are biomarker analysis and association with clinical response/disease etiopathogenesis. Clinical trial information: NCT04704219. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA, and Eisai Inc., Woodcliff Lake, NJ, USA.

TPS4596 **Poster Session**

PROSPER: Phase III RandOmized Study Comparing PERioperative nivolumab versus observation in patients with renal cell carcinoma (RCC) undergoing nephrectomy (ECOG-ACRIN EA8143). *First Author: Mohamad E. Allaf, James Buchanan Brady Urological Institute, Dept. of Urology, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: There is no standard adjuvant systemic therapy that increases overall survival (OS) over surgery alone for non-metastatic RCC. Anti-PD-1 nivolumab (nivo) improves OS in metastatic RCC and is well tolerated. In mouse models, priming the immune system prior to surgery with anti-PD-1 results in superior OS compared to adjuvant dosing. Remarkable pathologic responses have been seen with neoadjuvant PD-1 in multiple ph 2 studies in bladder, lung and breast cancers. Phase 2 neoadjuvant RCC trials of nivo show preliminary feasibility and safety with no surgical delays. PROSPER RCC seeks to improve clinical outcomes by priming the immune system with neoadjuvant nivo prior to nephrectomy followed by continued immune system engagement with adjuvant blockade in patients (pts) with high risk RCC compared to standard of care surgery alone. **Methods:** This global, unblinded, phase 3 National Clinical Trials Network study is accruing pts with clinical stage ≥T2 or $T_{any}N+$ RCC of any histology planned for radical or partial nephrectomy. Select oligometastatic disease is permitted if the pt can be rendered 'no evidence of disease' within 12 weeks of nephrectomy (≤3 metastases; no brain, bone or liver). In the investigational arm, nivo is administered 480mg IV q4 weeks with 1 dose prior to surgery followed by 9 adjuvant doses. The control arm is nephrectomy followed by standard of care surveillance. There is no placebo. Baseline tumor biopsy is required only in the nivo arm but encouraged in both. Randomized pts are stratified by clinical T stage, node positivity, and M stage. 805 pts provide 84.2% power to detect a 14.4% absolute benefit in recurrence-free survival at 5 years assuming the ASSURE historical control of ~56% to 70% (HR = 0.70). The study is powered to evaluate a significant increase in OS (HR 0.67). Critical perioperative therapy considerations such as safety, feasibility, and quality of life metrics are integrated. PROSPER RCC embeds a wealth of translational studies to examine the contribution of the baseline immune milieu and neoadjuvant priming with anti-PD-1 on clinical outcomes. As of February 10, 2021, 704 patients have been enrolled (N = 805). Clinical trial information: NCT03055013. Research Sponsor: U.S. National Institutes of Health, Bristol Myers Squibb.

TPS4597 **Poster Session**

A randomized phase II study of nivolumab plus ipilimumab versus standard of care in previously untreated and advanced non-clear cell renal cell carcinoma (SUNIFORECAST). *First Author: Marit Ahrens, Medical Clinic II, University Hospital, Frankfurt Am Main, Germany*

Background: Non-clear cell renal cell carcinomas (nccRCC) account for approximately 25% of RCC patients (pts.). Data on treatment strategies for this heterogenous group of RCC are still limited, since most clinical trials focus on clear-cell RCC (ccRCC) histology. Recently combination therapies with immune checkpoint inhibitors (IO, avelumab or pembrolizumab) and tyrosinekinaseinhibitors (TKI) (axitinib) have been approved for treatment in RCC in all International Metastatic RCC Database Consortium (IMDC) risk groups. Additionally nivolumab and ipilimumab (IO/IO) has been approved for treatment in intermediate and high risk pts. showing a significant improvement in overall response rate (ORR), progression free (PFS), and overall survival (OS) compared to sunitinib. Moreover retrospective analysis in nccRCC pts. have shown promising results for IO-based therapies as well in these entities. **Methods:** In this prospective randomized phase-II multicenter European trial adults with advanced or metastatic nccRCC without prior systemic therapy are eligible. Other key inclusion criteria include: available tumor tissue, Karnofsky >70% and measurable disease per RECIST 1.1. All histological diagnoses are reviewed by a central pathologist. The study plans to randomize ~306 pts. stratified for papillary or non-papillary non-clear cell histology and by the IMDC risk score. Pts. will be randomized 1:1 to either i) nivolumab 3mg/kg intravenously (IV) plus Ipilimumab 1mg/kg IV every 3 weeks for 4 doses followed by nivolumab fixed dose 240mg IV every 2 weeks or fixed dose 480mg IV every 4 weeks or ii) standard of care therapy according to the approved schedule. Treatment will be discontinued in case of unacceptable toxicity or withdrawal of informed consent. Pts may continue treatment beyond progression, if clinical benefit is achieved and treatment is well tolerated. Primary endpoint is the OS rate at 12 months. Secondary endpoints include OS rate at 6 and 18 months, median OS, PFS, ORR and quality of life. The trial is in progress and 214 patients (132 pts with papillary, 76 pts with non-papillary histology) have been enrolled until now. Clinical trial information: NCT03075423. Research Sponsor: Bristol-Myers Squibb.

TPS4598 **Poster Session**

Cyto-KIK: A phase II trial of cytoreductive surgery in kidney cancer plus immunotherapy (nivolumab) and targeted kinase inhibition (cabozantinib). *First Author: Karie Runcie, Columbia University Medical Center, New York, NY*

Background: Despite recent therapeutic advancements in metastatic renal cell carcinoma (mRCC), only 5-10% of patients will achieve a complete response (CR) to therapy. Cytoreductive nephrectomy removes a large portion of the tumor which may be a source of immunosuppression driven by tumor cell-intrinsic factors in the tumor microenvironment. A pre-clinical orthotopic mouse model of aggressive metastatic triple negative breast cancer showed that neoadjuvant anti-PD-1 checkpoint inhibition generated enhanced and sustained antitumor immune responses with improved survival compared to adjuvant therapy (Liu J et al. *Cancer Discov.* 2016:1382). Clinical validation of improved outcomes with neoadjuvant compared to adjuvant immune checkpoint inhibitors has been demonstrated in trials for patients with non-small cell lung cancer, advanced melanoma, and recurrent glioblastoma (Forde, P.M., et al. *N Engl J Med.* 2018:1976; Amaria, R.N., et al *Nat Med.* 2018:1649; Cloughesy T.F., et al. *Nat Med* 2019:477). Recent data from a phase III trial in subjects with untreated mRCC, demonstrated the superiority of combination cabozantinib and nivolumab over sunitinib and established a new standard of care for mRCC (Choueiri T.K., et al. *Annals of Onc*, 2020;31 (suppl; abstr 6960). We hypothesize that if tumor specific immune responses to immunotherapy are greatest prior to nephrectomy, then treatment with nivolumab (nivo) and cabozantinib (cabo) prior to cytoreductive nephrectomy will lead to maximal peripheral and intra-tumoral specific immune responses and higher rates of CR during the course of treatment. **Methods:** This is an open label phase II, multicenter clinical trial of combination nivo and cabo prior to cytoreductive nephrectomy in patients with mRCC (NCT04322955). 48 treatment- naïve subjects with radiological or histological diagnosis of mRCC will be enrolled with the primary endpoint of CR rate according to RECIST version 1.1. Subjects will receive cabo (40mg) daily and nivo (480mg) every 4 weeks for 12 weeks prior to nephrectomy and a 3+3 design will be used to evaluate the safety of the interval (21 or 14 days) between the discontinuation of cabo and nephrectomy. Post-operatively, subjects will resume treatment with cabo and nivo until evidence of disease progression. Secondary endpoints include median size reduction of the primary tumor, response rate, PFS, OS, and surgical outcomes using the Clavien-Dindo classification system. Tissue based assays will quantify treatment related changes in the renal tumor microenvironment through polychromatic immunofluorescence, single cell RNA sequencing of the biopsy and nephrectomy specimen, and multiplex assessment of circulating serum cytokines. Dynamic contrast-enhanced MRI will be performed in a subset of subjects to assess radiologic correlates of response. The study is currently open to enrollment. Clinical trial information: NCT04322955. Research Sponsor: Exelixis, Bristol-Myers Squibb.

TPS4599 **Poster Session**

A phase I study of bintrafusp alfa (M7824) and NHS-IL12 (M9241) alone and in combination with stereotactic body radiation therapy (SBRT) in adults with metastatic non-prostate genitourinary malignancies. *First Author: Scot Anthony Niglio, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: The majority of non- prostate genitourinary (GU) cancers are lethal when metastatic and rare GU cancers have limited treatment options. Bintrafusp alfa is a bifunctional fusion protein composed of human TGF-β receptor II, which sequesters or "traps" all three TGF-β isoforms and a monoclonal PD-L1 antibody. NHS-IL12 is an immunocytokine composed of two IL-12 heterodimers, each fused to the H-chain of the NHS76 antibody. The NHS76 IgG1 antibody has affinity for both single- and double-stranded DNA (dsDNA) allowing for targeted delivery of pro-inflammatory cytokine, IL-12, to necrotic portions of tumor with DNA exposure to promote local immunomodulation. Preclinical data suggest synergy between these two agents. There is also evidence suggesting that stereotactic body radiation therapy (SBRT) can promote anti-tumor immune responses both locally and systemically while also synergizing with immune checkpoint inhibitors. Therefore, the combination of Bintrafusp alfa, NHS-IL12 and radiation is a potential strategy for metastatic non-prostate GU tumors. **Methods:** This is an open label, non-randomized, three-stage phase I trial of bintrafusp alfa and NHS-IL12 or bintrafusp alfa and NHS-IL12 in combination with either sequential or concurrent SBRT. Bintrafusp alfa (IV 1200 mg q2w) and SBRT (8 Gy x 3 fractions) are planned with a deescalating NHS-IL12 (subQ q4w) dose schedule. The accrual ceiling has been set at 66 patients. The trial will enroll patients with a pathologically confirmed diagnosis of metastatic non-prostate genitourinary cancer with an ECOG $\leq$ 2 (KPS $\geq$60%). Participants may have had prior cancer immunotherapy but excluding prior treatment with bintrafusp alfa and/or NHS-IL12. 9 patients will receive treatment in cycles consisting of 4 weeks. The primary objective is to determine the safety and highest tolerated doses with acceptable toxicity (recommended phase II dose) of bintrafusp alfa and NHS-IL12 alone or in combination with SBRT administered sequentially or concurrently in patients with metastatic non-prostate genitourinary cancers. Secondary objectives are objective response rate (ORR), progression free survival (PFS) and overall survival (OS). Exploratory objectives are to determine peripheral immune modulation and the status of the immune microenvironment using cytokine analysis, circulating tumor cells, multiplex immunohistochemistry, T-cell receptor sequencing, and RNA-sequencing. The study is open and enrolling. Clinical trial information: NCT04235777. Research Sponsor: U.S. National Institutes of Health.

5000 **Oral Abstract Session**

A phase 3 trial with a 2x2 factorial design of abiraterone acetate plus prednisone and/or local radiotherapy in men with *de novo* metastatic castration-sensitive prostate cancer (mCSPC): First results of PEACE-1. *First Author: Karim Fizazi, Institut Gustave Roussy, University of Paris-Saclay, Villejuif, France*

Background: Historically, androgen deprivation therapy (ADT) was the standard of care (SOC) for men with mCSPC. Since 2015, combining ADT with either docetaxel, novel hormonal therapies, or radiotherapy to the primary tumor (RXT) (for those with low burden metastases) was shown to improve overall survival (OS) and thus has become the new SOC. It is unknown whether combining these new treatments on top of ADT further increments outcomes. **Methods:** Men with *de novo* mCSPC were randomized to SOC, SOC + abiraterone acetate-prednisone (abiraterone), SOC + RXT, or SOC + abiraterone + RXT. SOC was initially ADT alone, then from Oct 2015 onwards the use of docetaxel was authorized as part of SOC (at the investigator's discretion until 2017, then, following the publication of the LATITUDE and STAMPEDE trials, accrual was restricted to men receiving ADT+docetaxel). The trial has two co-primary endpoints of radiographic progression-free survival (rPFS) and OS with type I error of 0.1% and 4.9%, respectively. The required number of rPFS events to achieve 80% power has been reached for the abiraterone question (not yet for the RXT question). The interaction between abiraterone and RXT was first tested using a Cox model adjusted for stratification factors (performance status, type of castration, metastatic burden, and when applicable, docetaxel). A hierarchical testing was used to test the effect of abiraterone: overall population, then ADT+docetaxel population. Results: From Nov 2013 to Dec 2018, 1173 men were enrolled (SOC was ADT+docetaxel in 710 pts and ADT alone in 463 pts), median age 67y (IQR: 60-72), high volume 57%, low volume 43%. The median follow-up is 3.5y. No interaction was detected between the effect of abiraterone and that of RXT ($p = 0.64$), allowing to pool abiraterone arms for comparisons. rPFS was significantly improved in the abiraterone arm in the overall population (HR: 0.54 (0.46-0.64), $p < 0.0001$; medians: 2.2 vs 4.5 years) and in the ADT+docetaxel population: (HR: 0.50 (0.40-0.62), $p < 0.0001$; medians: 2.0 vs 4.5 years). bPFS (PFS including PSA progression as an event) also significantly favored abiraterone in the overall population (HR: 0.40 (0.35-0.47), $p < 0.0001$; medians: 1.5 vs 3.8 years) and in the ADT+docetaxel population (HR: 0.38 (0.31-0.47), $p < 0.0001$; medians: 1.5 vs 3.2 years). OS is maturing. Grade 3-4 adverse events reported in > 5% of pts within the first 6 months in the ADT+docetaxel population included neutropenic fever (4.5% vs 5.4%), liver toxicity (19.7% vs 13%), and hypertension (12.2% vs 8.6%) in the abiraterone and control arms, respectively. Conclusion: Adding abiraterone to ADT + docetaxel significantly improves rPFS in men with *de novo* metastatic prostate cancer, with about 2.5 years of absolute benefit in medians, and no meaningful additional short-term toxicity. Clinical trial information: NCT01957436. Research Sponsor: PHRC, Pharmaceutical/Biotech Company.

5001 **Oral Abstract Session**

SWOG S1216: A phase III randomized trial comparing androgen deprivation therapy (ADT) plus TAK-700 with ADT plus bicalutamide in patients (pts) with newly diagnosed metastatic hormone-sensitive prostate cancer (mHSPC) (NCT01809691). *First Author: Neeraj Agarwal, University of Utah, Salt Lake City, UT*

Background: Tak is an oral selective nonsteroidal 17, 20-lyase inhibitor that blocks the synthesis of gonadal and adrenal androgens. We evaluated the clinical benefit of Tak with ADT in pts with newly diagnosed mHSPC. **Methods:** Pts with mHSPC with a Zubrod performance status (PS) of 0-2 and a PSA of ≥ 2 ng/ml were randomized 1:1 to ADT+Tak (300 mg twice daily) or ADT+Bic (50 mg daily). Stratification factors included PS (0-1 vs ≥2), extent of disease (minimal vs extensive), and receipt of ADT prior to registration (yes vs no). The primary endpoint was overall survival (OS). Secondary endpoints were progression free survival (PFS; based on PSA, imaging or clinical progression), PSA at 7 months (≤0.2 vs $0.2 <$ PSA; ≤-4 vs. > 4 ng/ml) and adverse event (AE) profile. With 2.75 yrs to accrue 1,186 eligible pts and 3 additional yrs of follow-up, we would have 90% power to determine a 33% improvement in OS from 54 to 72 mos (1-sided $\alpha = 0.025$). A final analysis was pre-specified after 523 deaths using a 1-sided $\alpha = 0.022$ to account for interim analyses. **Results:** Between 3/2013 and 7/2017, 1,313 pts were randomized and 1,279 were included in the intention-to-treat (ITT) analysis (32 pts were ineligible and 2 pts withdrew consent). Median age was 68 yrs and 10% of subjects were Black. Median PSA was 30 ng/mL (range 2-6710) and 49% of pts had extensive disease. After a median follow-up of 4.9 yrs, PFS and PSA response were significantly improved with Tak over Bic but no significant improvement in OS was observed (Table). More grade 3/4 AEs occurred in Tak vs. Bic arms (43% vs. 14%), and included hypertension (20% vs. 5%) and fatigue (5% vs. 2%). Five pts in Tak and 1 pt in the Bic arm had grade 5 AE. **Conclusions:** Despite clinically meaningful improvement in various outcome measures with Tak+ADT over Bic+ADT in this representative population of mHSPC, the improvement in OS did not meet the pre-specified criteria for statistical significance. The median OS of 70 mos in the control arm (standard ADT) was higher than that reported in contemporary phase 3 trials in this setting, and 16 mos higher than originally estimated. This trial sets a new landmark for survival estimates when pts with mHSPC have access to multiple approved subsequent life-prolonging therapies. Funding: NIH/NCI/NCTN grants U10CA180888, U10CA180819, U10CA180820; U10CA180821; and in part by Millennium Pharmaceuticals, Inc. (Takeda Pharmaceutical Company LTD) Clinical trial information: NCT01809691. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Decreased fracture rate by mandating bone protecting agents in the EORTC 1333/PEACEIII trial combining Ra223 with enzalutamide versus enzalutamide alone: An updated safety analysis. *First Author: Silke Gillessen, Kantonsspital St. Gallen, St. Gallen, Switzerland*

Background: The randomized phase III EORTC-1333-GUCG (NCT02194842) trial compares enzalutamide vs. a combination of Radium 223 and enzalutamide in asymptomatic or mildly symptomatic metastatic castration resistant prostate cancer (mCRPC) patients. The premature unblinding of ERA223 (NCT02043678) in Nov 2017 due to a significant increase in the rate of fractures in the combination of abiraterone and Ra223 arm led to the implementation of the mandatory use of bone protecting agents (BPA) in the EORTC-1333-GUCG trial. Skeletal fractures, pathological or not, are a frequent and underestimated adverse event of systemic treatment of advanced prostate cancer. Whether this mandated use of BPA (zoledronic acid or denosumab) would mitigate the risk of fractures in this patient population was unclear. An early safety analysis (Tombal, ASCO, 2019) suggested that the risk of fractures was well controlled in both arms when patients receive BPA. We present here an updated analysis of fracture incidence with longer follow-up. **Methods:** As of 28/01/2021, a total of 253 patients (134 after making BPA mandatory) were randomized between enzalutamide/Ra223 and enzalutamide. The fracture rate was estimated with the cumulative incidence method in the safety population of 237 (122 after making BPA mandatory) treated patients. Death in absence of fracture was analyzed as competing risk and censoring was applied at last follow-up. **Results:** Overall, 69.5% of enzalutamide/Ra223 patients (95.2% after making BPA mandatory) and 73.1% of enzalutamide patients (95% after making BPA mandatory) received BPA on treatment: 13.6% in the enzalutamide/Ra223 arm and 21.8% in the enzalutamide arm did not use BPA at registration, but started during protocol treatment and 55.9% and 51.3% respectively, received BPA since entry. At 36.7 months median follow-up in patients without BPA and 23.1 months median follow-up in patients receiving BPA, a total of 39 patients reported a fracture. Among them, 30 patients (20 in enzalutamide/Ra223 arm) did not receive BPA and 9 (4 in the enzalutamide/Ra223 arm) received BPA (see table). **Conclusions:** The updated safety analysis confirms the early fracture rate results. In the absence of BPA, the risk of fracture is increased when RA223 is added to enzalutamide. Strikingly, in both arms, the risk remains almost abolished by a preventive continuous administration of BPA, thus stressing the importance of complying to international recommendations in terms of giving BPA to mCRPC patients. This study is sponsored by EORTC and supported by Bayer and Astellas. Clinical trial information: NCT02194842. Research Sponsor: Bayer-Astellas.

Ancestral characterization of the genomic landscape, comprehensive genomic profiling utilization, and treatment patterns may inform disparities in advanced prostate cancer: A large-scale analysis. *First Author: Smruthy Sivakumar, Foundation Medicine, Inc., Cambridge, MA*

Background: Prostate cancer (PCa) incidence, mortality, and outcomes vary widely across race/ethnicity. The underlying drivers of these differences are multifactorial, including systemic barriers that lead to wide variation in access to care including genomic and precision medicine. Men of African ancestry (AFR) are particularly underrepresented in genomic and precision medicine studies. Therefore, we sought to comprehensively assess patterns of gene alterations, comprehensive genomic profiling (CGP) utilization, and treatment patterns in a large, diverse advanced PCa cohort. **Methods:** 11,741 PCa patients with CGP, as part of routine clinical care (Foundation Medicine Inc., FMI) were evaluated for their genomic landscape. Predominant ancestry was inferred using a SNP-based approach (Connelly et al, AACR 2018). Independently, the US-based de-identified Flatiron Health (FH)-FMI clinico-genomic database (CGDB) of 897 evaluable PCa patients was also queried. Clinical characteristics and treatment selections were described for patients who received metastatic or castrate-resistant diagnosis between 1/2011 and 6/2020. **Results:** The FMI cohort included 1,422 (12%) men of AFR and 9,244 (79%) men of European ancestry (EUR). Median age was lower in AFR compared with EUR men (64 vs. 67, $p < 0.001$). *TP53* and *PTEN* alterations and *TMPRSS2-ERG* rearrangements occurred less frequently in AFR than EUR men (35% vs. 43%, 21% vs. 33%, 15% vs. 33% respectively, $p < 0.05$). In contrast, alterations in *SPOP* (11.9% vs. 7.3%), *CDK12* (10.0% vs. 5.2%), *CCND1* (6.0% vs. 3.8%), *KMT2D* (7.7% vs. 5.1%), *HGF* (4.1% vs. 2.5%), and *MYC* (13.4% vs. 10.6%) were enriched in the AFR cohort ($p < 0.05$). Alteration frequency in *BRCA1/2*, *AR*, DNA damage response pathway genes, and actionable genes with therapy implications, were similar across ancestry. Of note, *BRAF* alterations were slightly enriched in AFR (5.0% vs. 3.2%, $p < 0.05$). In the CGDB cohort (79 AFR, 762 EUR), AFR men received a median of 2 lines of therapy prior to CGP, compared to 1 line for EUR men. Notably, the proportion of patients receiving immunotherapy and PARPi was similar across ancestry, however AFR men were less likely to receive clinical study drug compared with EUR men (11% vs 30%, $p < 0.001$), even among men with actionable alterations (1% vs 6%, $p < 0.001$). **Conclusions:** To our knowledge, this study encompasses the largest cohort, particularly of AFR men in a genomic study, that defines CGP utilization, the genomic landscape and therapeutic implications of CGP in PCa across ancestry. Overall, there were largely similar rates of actionable gene alterations across ancestry. Notably, AFR men were less likely to receive CGP earlier in their treatment course, and less likely to be treated on clinical trials, which could impact the genomic landscape, outcomes, and ultimately disparities. Association of increased intensity of prostate-specific antigen screening in younger African American men with improved prostate cancer outcomes. *First Author: Edmund M. Qiao, Department of Radiation Medicine and Applied Sciences, University of California San Diego, La Jolla, CA*

Background: African-American (AA) men are substantially more likely to present with lethal prostate cancer (PCa) at younger ages than non-Hispanic White men. Despite this disparity, AA men are poorly represented in the prostate-specific antigen (PSA) screening studies on which evidence-based PCa screening guidelines are based. This limits proper PSA screening guidance for AA men, especially for those younger than 55. We examined associations of PSA screening intensity with disease severity at diagnosis and prostate cancer-specific mortality (PCSM) in AA men $<$ 55 years of age. **Methods:** The earliest recommended age to begin discussion of PSA screening is 40 years. We identified AA men aged 40-55 years, diagnosed with PCa from 2004 to 2017 within the Veterans Health Administration. PSA screening was identified using procedural codes. Screening intensity was defined as percentage of years screened within the pre-diagnostic observation period. This included up to 5 years prior to diagnosis. Multivariable logistic regression assessed the influence of PSA screening intensity on metastatic disease at diagnosis. Lead-time correction using published screening-dependent lead times was performed. PCSM was evaluated using Fine-Gray regression and non-cancer death as a competing event. Additional analysis was performed stratifying PSA screening into 'High' and 'Low' groups centered on the mean. **Results:** The cohort included 4,654 AA men at a mean age of 51.8 years with mean PSA screening rate of 53.2%. The pre-diagnostic observation period ranged from 1 to 5 years (median = 5 years). Median follow-up was 7 years. At diagnosis, there was a higher prevalence of Gleason sum $\geq$ 8 (Grade Group $\geq$ 4) and metastatic disease in the 'Low' group compared with the 'High' group ([Gleason sum $\geq$ 8 (Grade Group $\geq$ 4)]: 18.6% vs. 14.4%, $p < 0.01$; Metastatic disease at diagnosis: 3.7% vs. 1.4%, $p < 0.01$). Increased PSA screening intensity was associated with significantly reduced odds of metastatic disease at diagnosis (odds ratio: 0.61, 95% confidence interval (CI) = [0.47-0.81], $p < 0.01$) and decreased risk of PCSM (sub-distribution hazard ratio: 0.75, 95% CI = [0.59-0.95], p = 0.02). **Conclusions:** In this large national cohort of AA men aged 40 to 55 years, PSA screening increased intensity was associated with decreased risk of lethal disease and metastases at time of diagnosis and decreased PCSM. These data support the hypothesis that PSA screening and early prostate cancer detection may improve outcomes in younger AA men. Research Sponsor: U.S. National Institutes of Health.

A prospective validation of the genomic classifier to define high-metastasis risk in a subset of African American men with early localized prostate cancer: VanDAAM study. *First Author: Kosj Yamoah, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Risk stratification of prostate cancer (PC) using routine clinical variables remains suboptimal as they do not account for underlying tumor biology. The genomic classifier provides information on underlying biology and independently predicts an individual patient's risk of metastasis. Although the performance of the genomic classifier has been tested across different cohorts primarily comprised of White men, its validation as an optimal genomic risk classifier for African American men (AAM) is thus far lacking in a prospective trial. We report the initial results on the prospective validation of the genomic classifier in a matched cohort of AAM and non-AAM (NAAM). **Methods:** This was a multisite, prospective validation trial of the genomic classifier i.e. Decipher score in AAM. Participants were recruited on a 1:1 enrollment ratio of AAM to NAAM diagnosed with low-intermediate risk PC. Patient on active surveillance were ineligible. NAAM were matched to AAM on PSA, age, biopsy Gleason score, clinical stage, and percent positive biopsy cores. Diagnostic biopsy specimens were processed at a CLIA certified laboratory and Decipher score was assessed using whole transcriptome profiling platform. Total target accrual was 250 men treated for low-intermediate PC over three years. Statistical analyses include categorical comparison of race dependent risk group migration between NCCN risk group and genomic classifier. Relative risk of metastasis was estimated using negative binomial model. **Results:** Final analytical cohort included 207 evaluable cases (AAM = 102 and NAAM = 107) with comprehensive genomic information. Risk of metastasis was determined based on pretreatment biopsy Decipher score, and patients were classified as low, favorable-, and unfavorable intermediate risk. Despite achieving a robustly matched clinical cohort, we observed significant genomic heterogeneity between AAM and NAAM across NCCN risk groups. In a comparative analysis, 49% of low-favorable intermediate risk AAM harbored high genomic risk tumors as compared to only 10% NAAM, p = 0.02. Similarly, using the modified clinico-genomic risk classifier (cGC), comprised of both Decipher score and clinical variables, AAM experienced an extreme deviation of risk status (difference [δ] between cGC and NCCN $\geq$ 2) as compared to NAAM (26.8% vs 8.1%, p = 0.03). In a binomial model, low-favorable NCCN risk AAM were 3.9 times more likely to be reclassified as high genomic risk for distant metastasis compared to NAAM (RR = 3.99, 95% CI, 1.15 – 13.86, p = 0.02). **Conclusions:** Clinical NCCN risk classification is an inadequate surrogate of tumor biology and offers suboptimal risk stratification for AAM with PC. Integration of patient specific genomic classifier into standard of care will improve accuracy in disease risk classification and treatment recommendations for AAM. Clinical trial information: NCT02723734. Research Sponsor: U.S. National Institutes of Health.

Testicular cancer in the cisplatin era: Causes of death and mortality rates in a population-based cohort. *First Author: Ragnhild Hellesnes, Department of Oncology, University Hospital of North Norway, Tromso, Norway*

Background: Previous studies have reported an increased risk of premature mortality in testicular cancer (TC) survivors, probably associated with previous platinum-based chemotherapy (PBCT) or radiotherapy (RT). However, complete data regarding PBCT cycles are lacking in available literature. Using complete TC treatment data, this population-based cohort study aimed to investigate non-TC mortality in relation to TC treatment. **Methods:** Overall, 5,707 men diagnosed with TC 1980-2009 were included, identified from the Cancer Registry of Norway. Clinical parameters and treatment data were abstracted from medical records and linked with the Norwegian Cause of Death Registry. Causes of death were classified by the European Shortlist. Standardized mortality ratios (SMRs) were calculated to compare the cause-specific mortality in the cohort to an age-matched general population. Age-adjusted hazard ratios (HRs) were estimated to evaluate the impact of number of PBCT cycles on non-TC mortality. **Results:** During a median follow-up of 18.7 years, 665 (12%) men were registered with non-TC death. The overall excess non-TC mortality was 23% (SMR 1.23, 95% CI 1.14-1.33) compared with the general population, with increased risks after PBCT (SMR 1.23, 95% CI 1.06-1.42) and RT (SMR 1.28, 95% CI 1.15-1.43), but not after surgery (SMR 0.95, 95% CI 0.79-1.14). SMRs increased significantly with increasing follow-up time $\geq$10 years, and the overall risk of non-TC death reached a maximum after $\geq$30 years follow-up (SMR 1.64, 95% CI 1.31-2.06). The most important cause of death was non-TC second cancer with an overall SMR of 1.53 (95% CI 1.35-1.73). Increased risks appeared after PBCT (SMR 1.43, 95% CI 1.12-1.83) and RT (SMR 1.59, 95% CI 1.34-1.89). Treatment with PBCT was associated with significantly 1.69-6.78-fold increased SMRs for cancers of the oral cavity/pharynx, esophagus, lung, bladder, and leukemia. After RT, significantly 3.02-4.91-fold increased SMRs emerged for cancers of the oral cavity/pharynx, stomach, liver, pancreas and bladder. Non-cancer mortality was also increased by 15% (SMR 1.15, 95% CI 1.04-1.27), and excesses appeared after PBCT (1.23, 95% CI 1.03-1.47) and RT (SMR 1.17, 95% CI 1.01-1.34). Importantly, we report excess suicides after PBCT (SMR 1.65, 95% CI 1.01-2.69). Long-term overall cardiovascular mortality was not increased in the study cohort nor according to treatment modality. Compared with surgery, the overall non-TC mortality was increased after 4 (HR 1.41, 95% CI 1.00-1.98) and $>$4 (HR 2.03, 95% CI 1.24-3.33) PBCT cycles after $>$10 years of follow-up. **Conclusions:** TC treatment with PBCT or RT is associated with significantly increased long-term non-TC mortality, with non-TC second cancer being the most important cause of death. Significantly elevated risks for non-TC mortality emerged after $\geq$4 PBCT cycles after $>$10 years of follow-up. Research Sponsor: Helse Nord (HNF1582-21).

Late relapse of germ cell tumors: Detection and treatment outcomes. *First Author: Noah Hunter Richardson, Indiana University Department of Medicine, Indianapolis, IN*

Background: Late relapse (LR) of germ cell tumors (GCT) is defined as relapsed disease $>$ 2 years from initial treatment. LR remains a challenge both for optimal screening methods and treatment. We report the method of detection, treatments received, and outcomes in patients with LR GCT. **Methods:** The prospectively maintained Indiana University testicular cancer database was queried identifying 2712 pts with GCT treated at Indiana University from January 2000 to January 2019. Method of detection of LR was recorded along with site, treatment received, chemo-naive vs chemo-exposed LR, and survival outcomes. **Results:** 90 pts with LR were identified. Median age at LR was 35.2 yr (range, 19.2-56.8). Primary tumor site was testis in 88 (98%), retroperitoneum in 1 (1%), and mediastinum in 1 (1%). Chemo-exposed accounted for 42 (47%) and chemo-naïve for 48 (53%) of cases. Table compares clinical characteristics and survival outcomes of chemo-exposed vs. chemo-naïve late relapse. 62% of chemo-exposed LR were diagnosed with elevated AFP. For the 42 chemo-exposed LR pts, 2-yr PFS based on treatment: surgery vs. chemo vs surgery+chemo was 48% vs 10% vs 45% (p = 0.105). For the 48 chemo-naïve LR pts, 2-yr PFS based on treatment: surgery vs. chemo vs. surgery+chemo was 100% vs 74% vs 37% (p = 0.004). Next generation sequencing was available for 9 patients. No actionable findings were found. Tumor mutational burden was low in all patients where genomic testing was available. **Conclusions:** Most pts with chemo-exposed LR will be diagnosed with an elevated AFP. GCT pts require lifetime follow-up with annual physical exam and tumor markers. Surgical resection, when feasible, remains our preferred treatment for chemo-exposed LR as chemotherapy alone offers only brief responses. Pts with chemo-naïve LR have more chemo-sensitive biology. Research Sponsor: None.

The CADMUS trial: A paired cohort, blinded study comparing multiparametric ultrasound targeted biopsies with multiparametric MRI targeted biopsies in the detection of clinically significant prostate cancer. *First Author: Alistair Grey, University College London, London, United Kingdom*

Background: Multiparametric MRI (mpMRI) of the prostate followed by targeted biopsy is recommended in men at risk of prostate cancer. Dissemination of this pathway may be limited by cost, variable scan and reporting quality, and contraindicated in the presence of metallic implants and claustrophobia. Multi-parametric ultrasound (mpUSS) is a point of care test with low cost that combines b-mode, colour Doppler, elastography and contrast enhancement. CADMUS compared the diagnostic performance of mpUSS to mpMRI. **Methods:** CADMUS recruited 370 patients from seven sites to a prospective, multicentre, paired-cohort trial (ISRCTN 38541912). Ethics committee approval was obtained. Patients underwent both mpUSS and mpMRI independently, each with a positive test defined as a Likert score of >3. Those with either a positive mpUSS or mpMRI, or both, were advised to undergo targeted biopsies. Reporting of each scan was carried out blind to the other and prior to biopsy; patients advised for biopsy were blinded to which test was positive. The order of mpUSS and mpMRI targeting was randomised. Primary outcomes were proportion of positive tests and detection of clinically significant cancer (csPCa) defined as Gleason >4+3 of any length and/or maximum cancer core length of >6mm of any grade [PROMIS definition1]. **Results:** 306 completed both mpUSS and mpMRI. Agreement in lesion detection between mpUSS and mpMRI was 73.2% (kappa 0.06, p = 0.14). 257 with positive results on mpUSS, mpMRI or both had targeted biopsies. Agreement on detection of csPCa was 91.1% (expected 59.8%, kappa 0.78, $p < 0.01$) . Overall, mpUSS detected 4.3% fewer csPCa than mpMRI (95% CI = [-8.3%, -1.5%]; p = 0.042 [Bonferroni correction]). mpUSS detected 7.2% (6/83) csPCa missed by mpMRI; mpMRI detected 20.5% (17/83) csPCa that mpUSS missed. At a less stringent definition of significant cancer, Gleason grade >3+4 of any length (definition 3), agreement was 89.1% (expected 55.6%, kappa 0.75, $p < 0.01$) mpUSS detected 5.4% fewer definition 3 cancers than mpMRI overall. mpUSS detected 7% (7/99) definition 3 cancers that mpMRI missed; mpMRI detected 21% (21/99) definition 3 cancers that mpUSS missed. **Conclusions:** The CADMUS trial shows mpUSS has a diagnostic performance approaching that of mpMRI and significant cancer detection is improved by the use of both scans over mpMRI alone. Clinical trial information: 38541912. Research Sponsor: JP Moulton Charitable Foundation, Prostate Cancer UK, UCLH and Barts Charitable Trustees.

MRI and targeted biopsies compared to transperineal mapping biopsies for targeted ablation in recurrent prostate cancer after radiotherapy: Primary outcomes of the FORECAST trial. *First Author: Taimur T. Shah, Imperial College London, London, United Kingdom*

Background: Radiotherapy is a common and effective treatment for localised prostate cancer. However, recurrence of cancer can occur in 10-15% of men in the following 5 years. Most patients with recurrence are managed using hormonal therapy with associated systemic side-effects and subsequent development of castrate resistance. Salvage prostatectomy confers a high risk of urine incontinence and rectal injury. Accurately localising and ablating only areas of recurrence within the prostate might be effective with fewer side-effects. The FOcal RECurrent Assessment and Salvage Treatment (FORECAST) trial assessed this diagnostic and treatment pathway for men with radiorecurrent cancer (NCT01883128). **Methods:** We first compared the accuracy of multiparametric MRI (mp-MRI) and MRI-targeted biopsy in identifying areas of recurrent cancer to a transperineal template prostate mapping (TTPM) biopsy (Apr/2014-Jan/2018) in 181 patients from 6 UK centres. We then assessed the functional and cancer control outcomes of focally ablating areas of intraprostatic recurrence in 93 patients with localised or metastatic cancer (using cryotherapy or HIFU). Primary outcomes were sensitivity of mpMRI and MRI-targeted biopsies and urinary continence after focal ablation. A key secondary outcome was progression free survival (PFS) defined as no new metastases or hormone use (localised group only), or chemotherapy or further local treatment. **Results:** Of 181 men with suspicion of recurrence following radiotherapy, restaging whole-body imaging (Choline PET and Bone Scan) showed localised disease in 128 (71%), nodal disease only in 13 (7%) and 38 (21%) metastatic. The sensitivity of MRI-targeted biopsy was 92% (95%CI 83-97%). Specificity, and positive and negative predictive values, were 75% (95%CI 45-92%), 94% (95%CI 86-98%) and 65% (95%CI 38-86%). 4/72 (6%) cancers were missed on TTPM biopsies alone and 6/72 (8%) were missed on MRI-targeted biopsies alone. Overall sensitivity of mpMRI was 81% (95%CI 73-88%) using Likert score 4-5 to denote a positive test. Specificity, and positive and negative predictive values, were 88% (95%CI 73-98%), 96% (95%CI 90-99%) and 57% (95%CI 42-70%). In the 93 men undergoing focal ablation, urinary continence was preserved in 78/93 (84%); 5/93 (5%) had a CTCAE grade 3+ adverse events. There were no rectal injuries. With a median follow-up of 27.8 [SD 1.3] months, PFS was 66% [54-75] at 24-months. Metastases-free survival in the 73 men with localised disease was 80% [95%CI 68–88] at 24-months. There were no cancer specific deaths. **Conclusions:** Prostate mpMRI and MRI-targeted biopsies can accurately detect and localise recurrent prostate cancer following radiotherapy. Focal ablation to areas of intra-prostatic recurrence preserves continence in the majority of men with good cancer control. Clinical trial information: NCT01883128. Research Sponsor: Funded by Pelican Cancer Foundation, National Institute of Health and Research and the Medical Research Council [UK].

Validation of the decipher genomic classifier (GC) in SAKK 09/10: A phase III randomized trial of dose-escalated salvage radiotherapy (SRT) after radical prostatectomy (RP). *First Author: Alan Dal Pra, Miller School of Medicine, University of Miami, Miami, FL*

Background: GC has been shown to independently prognosticate outcomes in prostate cancer. Herein, we validate the GC in a European randomized phase III trial of dose escalated SRT after RP. **Methods:** SAKK 09/10 (NCT01272050) randomized 350 patients with biochemical recurrence after RP to 64Gy vs 70Gy. No patients received androgen deprivation therapy (ADT) or pelvic nodal radiotherapy. A pre-specified statistical plan was developed to assess the impact of the GC on clinical outcomes. RP samples were centrally reviewed for the highest-grade tumor and those passing quality control (QC) were run on a clinical-grade whole-transcriptome assay to obtain the GC score (0 to 1; < 0.45, 0.45-0.6, > 0.6 for low-, intermediate-, and high, respectively). The primary aim of this study was to validate the GC for the prediction of freedom from biochemical progression (FFBP) using Cox multivariable analysis (MVA) adjusting for age, T-category, Gleason score, persistent PSA after RP, PSA at randomization, and randomization arm. The secondary aims were to evaluate the association of GC with clinical progression-free survival (CPFS) and use of salvage ADT. **Results:** Of 233 patients with tissue available, 226 passed QC and were included for analysis. The final GC cohort was a representative sample of the overall cohort, with a median follow-up of 6.3 years (IQR 6.0-7.2). GC score (continuous per 0.1 unit, score 0-1) was independently associated with FFBP (HR 1.14 [95% CI 1.03-1.25], p = 0.009). Higher GC scores were independently associated with CPFS, use of salvage ADT, and rapid biochemical failure (< 18 months after SRT). High- vs. low/intermediate-GC showed a HR of 2.22 ([95% CI 1.37-3.58], p = 0.001) for FFBP, 2.29 ([95% CI 1.32-3.98], p = 0.003) for CPFS, and 2.99 ([95% CI 1.50-5.95], p = 0.002) for use of salvage ADT. Patients with high-GC had 5-year FFBP of 45% [95% CI 32-59] vs 71% [95% CI 64-78] in low-intermediate GC. Similar estimates for GC risk groups were observed in the 64Gy vs 70Gy in GC high (5-year FFBP of 51% [95% CI 32-70] vs 39% [95% CI 20-59]) and in low-intermediate GC (75% [95% CI 65-84] vs 69% [95% CI 59-78]). **Conclusions:** This study represents the first contemporary randomized controlled trial in patients with recurrent prostate cancer treated with early SRT without ADT that has validated the prognostic utility of the GC. Independent of standard clinicopathologic variables and radiotherapy dose, patients with a high-GC were more than twice as likely than a lower GC score to experience biochemical and clinical progression and receive salvage ADT. This data confirms the clinical value of Decipher GC for tailoring treatment in the postoperative salvage setting. Research Sponsor: Decipher Biosciences.

Radiation and androgen deprivation therapy with or without docetaxel in the management of non-metastatic unfavorable-risk prostate cancer: A prospective randomized trial. *First Author: Anthony Victor D'Amico, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA*

Background: For men with unfavorable-risk non-metastatic (M0) prostate cancer (PC) the addition of docetaxel to radical prostatectomy (RP) or radiation therapy (RT) and androgen deprivation therapy (ADT) has been studied in 6 randomized controlled trials with negative or inconclusive results. Specifically, an overall survival (OS) benefit with a non-significant reduction in PC-specific mortality (PCSM) has been observed in two of the 6 studieswhere > 80% of the patients had high-grade PC. A plausible hypothesis for the OS benefit and a non-significant reduction in PCSM is that docetaxel reduces PCSM in the small subset of men with low prostate-specific antigen (PSA)-producing, high-grade PC that may be resistant to conventional ADT while also reducing non-PCSM by reducing death from RT-induced cancers. Given that docetaxel even at low doses (i.e. 20 mg/m^2) is a potent radiosensitizer,it is plausible that it can sterilize cells that survive RT-induced damage and later develop into RT-induced cancers. Therefore, while docetaxel is not recommended when managing men with unfavorable-risk prostate cancer given inconclusive results from prior randomized trials, unstudied benefits may exist. **Methods:** This multicenter international randomized phase 3 trial (National Clinical Trial # 00116142) assigned 350 men with T1c-4N0M0 unfavorable-risk PC to receive ADT+RT and Docetaxel (60 mg/m^2 q3 weeks for 3 cycles before RT and 20 mg/m^2 weekly during RT) versus ADT+RT (1:1 ratio). Collection of data at each follow-up visit on second cancer incidence and survival status was recorded. We evaluated the treatment effect of adding docetaxel to ADT+RT on the primary endpoint of OS and the incidence of RT-induced cancers and explored whether the treatment effect impacted OS differed differently within PSA subgroups (< 4, > 20 versus 4-20 ng/mL) using the interaction test for heterogeneity adjusted for age and known PC prognostic factors. **Results:** After a median follow-up of 10.2 years, 89 men died (25.43%); of these 42 from PC (47.19%). While OS was not significantly increased on the docetaxel arm [restricted mean survival time over 10-years was 9.11 versus 8.82 years with a difference of 0.29 (95% CI: -0.19, 0.76) years (p = 0.22)], significantly fewer RT-induced cancers were observed [10-year estimates: 0.61% versus 4.90%: age-adjusted HR of 0.13: 95% CI: 0.02, 0.97; p = 0.046]. For men with a PSA < 4 ng/mL versus 4-20 ng/mL the treatment effect of adding docetaxel to ADT+RT on OS differed significantly [Adjusted HR: 0.27, 1.51; $p_{interaction}$ = 0.047] due to less PCSM on the docetaxel arm [0/13 (0.00%) versus 4/14 (28.57%)] among men with PSA < 4 ng/mL. **Conclusions:** Adding docetaxel to ADT+RT did not prolong OS in men with unfavorable-risk PC, but decreased RT-induced cancer incidence, and may prolong OS in the subgroup of men with a PSA < 4 ng/mL by reducing PCSM. Clinical trial information: NCT00116142. Research Sponsor: Sanofi-Aventis and Astra-Zeneca.

Interim results of aasur: A single arm, multi-center phase 2 trial of apalutamide (A) + abiraterone acetate + prednisone (AA+P) + leuprolide with stereotactic ultra-hypofractionated radiation (UHRT) in very high risk (VHR), node negative (N0) prostate cancer (PCa).

First Author: Sean Matthew McBride, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Standard of care in VHR PCa is radiation therapy (RT) with 18-36 months (mos) of androgen-deprivation therapy (ADT). With this regimen, chronic ADT toxicity is significant and biochemical recurrence (BCR) frequent. We sought to improve tumor control and minimize toxicity with intensified short course ADT with dual androgen receptor signaling inhibitors (ARSI) and UHRT. **Methods:** 64 patients (pts) with VHR, N0 PCa were enrolled from 4 centers. VHR PCa was defined as Gleason score (GS) 9-10, >4 cores of GS 8 disease, or 2 high-risk features (including rT3/T4 disease). Treatment (tx) involved 6 mos of A, AA+P, and leuprolide with prostate/seminal vesicle-directed RT (7.5-8 Gy x 5 fractions). The primary endpoint was BCR defined as nadir PSA + 2ng/mL. Biochemical recurrence-free survival (bRFS) is reported herein. Our hypothesized reduction in BCR from 25% to 10% at 3 years (yrs) required 53 pts to provide a power of 0.84 and an alpha of 0.03. Undetectable PSA was defined as <0.10 ng/mL. Non-castrate testosterone (T) was a post-tx value >150 ng/mL. All analyses were intention-to-treat. Toxicity and health-related quality of life measures were evaluated using CTCAEv4.0 and the EPIC-26 questionnaire. **Results:** Baseline characteristics are summarized in the Table; 63 of 64 pts completed protocol tx. Median time to nadir PSA from tx start was 2 mos (range, 1-9); 63 of 64 pts (98.4%) achieved an undetectable nadir PSA. Median time to post-tx, non-castrate T was 6.5 mos (range, 2.5-25.5). Median follow-up (f/u) for pts without BCR was 30 mos (range, 15-44). Seven pts had BCR; 2-yr bRFS was 95.0% (95% CI, 89.7-100); 3-yr bRFS was 89.7% (95 CI, 81.0-99.3). For the 57 pts without BCR, 56 (98.2%) had T > 150ng/mL at last f/u; median PSA at last f/u was 0.10 ng/mL (IQR, <0.10-0.30); of these, 40 (70.2%) pts had PSAs ≤ 0.20 ng/mL with 24 (42.1%) undetectable. Fifteen pts experienced transient Grade 3 toxicities: 12 (18.8%) with hypertension and 3 with rash (4.7%). EPIC-26 scores for a subset of pts (n=21) at baseline and 12 mos showed no significant decline in urinary or bowel domains; declines in sexual (-11.9) and hormone (-5.7) domains met significance. **Conclusions:** Compared to historic controls with the long course ADT, AASUR demonstrated impressive 3-yr bRFS, rapid T recovery, and limited toxicities; the safety profile of this regimen was consistent with the known AE profile of the ARSI and RT. This regimen warrants further, randomized evaluation. Funded by Janssen Pharmaceuticals. Managed by the Prostate Cancer Clinical Trials Consortium. Clinical trial information: NCT02772588. Research Sponsor: Janssen Pharmaceuticals.

Results of an ongoing phase 1/2a dose escalation study of HPN424, a tri-specific half-life extended PSMA-targeting T-cell engager, in patients with metastatic castration-resistant prostate cancer (mCRPC).

First Author: Johann S. De Bono, The Institute of Cancer Research and Royal Marsden Hospital, London, United Kingdom

Background: HPN424 is a prostate-specific membrane antigen (PSMA)-targeting T cell engager designed to redirect T cells to kill PSMA-expressing prostate cancer cells; engineered with three binding domains: anti-PSMA for tumor cell engagement, anti-albumin for half-life extension and anti-CD3 for T cell engagement. HPN424 is optimized for small size and increased stability compared to other bispecific platforms. **Methods:** This Ph1/2a study is evaluating HPN424 in mCRPC patients (pts) who have received > 2 prior systemic therapies. Primary endpoints are safety, tolerability and determination of MTD/RP2D. Secondary objectives are pharmacokinetics (PK), pharmacodynamics, immunogenicity and preliminary anti-tumor activity. HPN424 is administered IV once weekly. Tumor assessments include PSA, CT and bone scans every 9-weeks. **Results:** As of 2/8/21, 80 pts were dosed in 15 cohorts with target doses ranging from 1.3 to 160ng/kg fixed dose, and up to 300ng/kg with step dosing to the target dose after initial priming dose. Pts had received a median of 6 prior systemic regimens, 75% received prior chemotherapy for mCRPC. Median age was 70 (43 – 91). Most common grade > 3 TEAEs were AST increase (18%), anemia (11%) and ALT increase (11%). DLTs include CRS G3 (n = 3), elevated lipase G3 (n = 1) and seizure G3 (n = 1). These events did not limit escalation, MTD has not been reached and escalation continues. All grade CRS occurred in 63% of pts, 4% grade 3 per ASTCT and no Grade 4/5 CRS. CRS G3 events occurred after first administration of target dose (n = 2 fixed dose, n = 1 step dose). Transaminase elevation occurred predominantly during Cycle 1, was transient and had no clinical sequelae. Disease progression was the primary reason for drug discontinuation; 2 pts (3%) discontinued due to TRAE. Reduction in circulating tumor cells (CTC) was seen in 32 of 56 pts (57%) with measurable CTC at baseline. Fifteen of 62 pts (24%) with > 24 weeks follow-up remained on treatment ≥ 24 weeks. Thirteen of 63 pts (21%) with post-baseline levels had PSA declines from baseline, including 3 PSA50, 2 PSA30 responses. In chemo-naïve pts, 5 of 15 (33%) showed PSA declines post-baseline. In the highest fixed dose cohort (160ng/kg) tested to-date, 3 of 7 evaluable pts had PSA declines from baseline and 1 had a confirmed partial response per RECIST. **Conclusions:** HPN424, a novel half-life extended PSMA-targeting T cell engager, was well tolerated when administered once weekly. AEs were transient, manageable and consistent with class of agent. Grade 3 CRS was observed in 4% of patients, occurring with first administration of target dose. Evidence of antitumor activity included PSA and CTC reductions and treatment duration > 24 weeks in 15/62 pts. Encouraging signals were seen at the highest fixed dose cohort including a confirmed RECIST partial response. NCT03577028 Clinical trial information: NCT03577028. COMBAT-CRPC: Concurrent administration of bipolar androgen therapy (BAT) and nivolumab in men with metastatic castration-resistant prostate cancer (mCRPC).

First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD

Background: During BAT, intramuscular (IM) testosterone (T) is administered, which results in rapid cycling of serum T levels from supraphysiologic to near-castrate in men with metastatic castration resistant prostate cancer (mCRPC). We previously observed anecdotal clinical responses to immune checkpoint blockade (ICB) in mCRPC patients (pts) previously treated with BAT and hypothesized that that a BAT/ICB combination would be synergistic. Here we report a prospective phase 2 study of men with mCRPC treated with BAT in combination with nivolumab. **Methods:** This was a multi-center, single arm, open label phase 2 trial (NCT03554317) of men with mCRPC who received T cypionate 400mg IM (BAT) every 28 days and nivolumab 480mg IV every 28 days. LHRH agonist treatment was continued. All pts received BAT as single agent therapy for a 12-week lead-in prior to the addition of nivolumab. Eligible pts were those with asymptomatic mCRPC who had soft tissue disease amenable to biopsy and progressed on at least one prior novel AR targeted therapy. Up to one line of chemotherapy was allowed for the treatment of mCRPC disease. The primary endpoint was confirmed PSA_{50} response rate. Key secondary endpoints included safety, objective response rate (ORR), and radiographic progression-free survival (rPFS). The trial was designed to detect a 20% absolute increase in PSA_{50} response rate from the null of 25%. **Results:** 45 pts were enrolled on study and treated. The confirmed PSA_{50} response rate was 40.0% (N=18/45, 95% CI: 26-56%, P=0.02 against the 25% null hypothesis). For pts with measureable disease, the ORR was 23.8% (N=10/42). Median rPFS on BAT and nivolumab was estimated at 5.7 months (95% CI: 4.9-7.8 months). 11.1% (N=5/45) of pts were free from radiographic progression for 11 or more months. One patient achieved a complete radiographic response, which is ongoing (>13 months). The majority of adverse events (AE) were Grade <2. The most common AEs were edema (20%), nausea (20%), and back pain (13%). Immune related AE (irAE) were generally mild (Grade <2) with N=2 Grade 3 irAE observed (pericarditis, lipase elevation). Serial biopsies were obtained on trial for translational studies. **Conclusions:** BAT plus nivolumab was well tolerated without concerning safety signals. The combination met the pre-specified primary endpoint of confirmed PSA_{50} response in a heavily treated population. Durable responses were observed in a subset of pts. Biomarker analysis is ongoing to identify a molecular signature predictive of response. Clinical trial information: NCT03554317. Research Sponsor: Bristol-Myers Squibb, Other Foundation.

Phase I study of ^{225}Ac-J591 for men with metastatic castration-resistant prostate cancer (mCRPC).

First Author: Scott T. Tagawa, Weill Cornell Medicine, New York, NY

Background: Antibodies and small molecule ligands target PSMA with different kinetics and biodistribution, with certain sites of PSMA expression such as salivary/lacrimal glands, kidneys, and small bowel less accessible to large antibodies. Alpha emitters such as ^{225}Ac have high potency, but short range. We report dose-escalation plus expansion cohort results of a first in human study of ^{225}Ac-J591. **Methods:** Men with progressive mCRPC following at least 1 potent AR-pathway inhibitor (ARPI, e.g. abi/enza) and chemo (or unfit/refuse chemo) without limit of # prior therapies (including Ra-223 or prior ^{177}Lu-PSMA) provided adequate organ function were eligible. Baseline ^{68}Ga-PSMA11 PET was performed, but not used for eligibility. Dose-escalation was in single-subjects x4 followed by 3+3 with a single infusion of ^{225}Ac-J591 (13.3 KBq/kg with planned escalation up to 93.3 KBq/kg). Dose-limiting toxicity (DLT) was defined as attributable grade (Gr) 4 heme toxicity or Gr 3/4 non-heme tox. Imaging, genomic, patient-reported outcomes (PRO), and immune correlates embedded. **Results:** 32 men were treated with a single dose of ^{225}Ac-J591 on 7 dose levels with expansion at the highest dose level (n = 16). Median age 69.5 (range 52-89), PSA 149.1 (4.8-7168.4); 75% with >2 prior ARPI, 62.5% chemo, 28% Ra-223, 43.7% ^{177}Lu-PSMA. One (3.1%) CALGB (Halabi) good prognostic risk, 8 (25%) intermediate, and 23 (71.9%) poor risk. While PSMA uptake was not a prerequisite for treatment, of 28 with pre-treatment PSMA PET, none had tumor SUVmax < liver, 5 (17.8%) with tumor SUVmax 1-2.5x liver, 2 (7.2%) with tumor SUVmax 2.5-5x liver, and 21 (75%) with tumor SUVmax > 5x liver SUVmean. 1 of 6 in cohort 6 (80 KBq/kg) had DLT (Gr 4 anemia and platelets) with 0 of 6 at the highest dose level (93.3 KBq/Kg) and this dose was expanded. High Gr AEs were restricted to hematologic: In addition to DLT, 4 (12.5%) Gr 3 platelets and 2 (6.2%) with Gr 3 neutropenia. Non-heme AE's were restricted to Gr 1/2 and included: 10 (31.2%) fatigue, 5 (15.6%) pain flare, 14 (43.7%) nausea, 8 (25%) with Gr 1 xerostomia (of which 5 received prior ^{177}Lu-PSMA), 12 (37.5%) AST elevation. Despite prior treatment including ^{177}Lu-PSMA and no selection for PSMA expression, 22 (68.7%) with any PSA decline, 12 (37.5%) with > 50% PSA decline. Of 21 with paired baseline and 12-wk CTC counts, 12 declined (5 converting from unfavorable to favorable and 5 converting detectable to 0), 5 remained 0, 4 increased. In the subset with PRO data, pain scores by BPI-SF tended to improve by wk 12. Following a single dose of ^{225}Ac-J591, median PFS 7.2 months [95% CI 4.6-NR], median OS 10.9 months [7.6-21.1]. **Conclusions:** PSMA-targeted alpha-emitter ^{225}Ac utilizing intact antibody J591 is tolerable with early evidence of clinical activity. Based upon these results, a follow up study [NCT04506567] testing multiple and fractionated dosing of ^{225}Ac-J591 is underway. Clinical trial information: NCT03276572. Hearing loss after cisplatin-based chemotherapy: Patient-reported outcomes versus audiometric assessments. *First Author: Shirin Ardeshirrouhanifard, Indiana University School of Medicine, Indianapolis, IN*

Background: Although pure-tone audiometry is the gold standard to evaluate hearing loss (HL), patient-reported outcomes are practically more time and cost effective. However, no data exist on factors associated with discrepancies between patient-reported and audiometrically-defined HL in adult-onset cancer survivors after cisplatin-based chemotherapy (CBCT); and few comprehensive assessments of factors associated with audiometrically-defined HL have been conducted. **Methods:** A total of 1,410 testicular cancer survivors (TCS) ≥6 months post-CBCT completed comprehensive audiometric assessments (0.25-12 kHz) and detailed questionnaires of sociodemographic, clinical, and health behaviors. Audiometrically-defined HL severity was defined using American Speech-Language-Hearing Association (ASHA) criteria. Multivariable multinomial logistic regression identified factors associated with discrepancies (overestimation and underestimation vs. concordance), between patient-reported and audiometrically-defined HL and multivariable ordinal logistic regression evaluated factors associated with the HL severity. **Results:** Overall, 34.8% of TCS self-reported HL, while 77.8% had audiometrically-defined HL. Among TCS without tinnitus, those with audiometrically-defined HL at only extended high frequencies (EHFs) (10-12 kHz) (17.8%) or at both EHFs and standard frequencies (0.25-8 kHz) (23.4%) were significantly more likely to self-report HL than those with no audiometrically-defined HL (8.1%) (OR = 2.48; 95%CI, 1.31-4.68 and OR = 3.49; 95%CL,1.89-6.44, respectively). Older age (OR = 1.09; $P<$ 0.0001), absence of prior noise exposure (OR = 1.40; $P=$ 0.02), and mixed/conductive HL (OR = 2.01; $P=$ 0.0007) were associated with greater underestimation of audiometrically-defined HL severity. Hearing aid use (OR = 0.18; $P=$ 0.003) and higher education ($P=$ 0.004) were associated with less underestimation of audiometrically-defined HL severity, while tinnitus was associated with greater overestimation ($P<$ 0.0001). Older age (OR = 1.13; $P<$ 0.0001), cumulative cisplatin dose ($>$ 300 mg/m^2, OR = 1.47; $P=$ 0.0001), and hypertension (OR = 1.80; $P=$ 0.0007) were associated with greater ASHA-defined HL severity, whereas post-graduate education (OR = 0.58; $P=$ 0.005) was associated with less severe HL. **Conclusions:** Discrepancies between patient-reported and audiometrically-defined HL after CBCT are associated with several factors including age, education, tinnitus, prior noise exposure, use of hearing aids, and conductive HL. Understanding these factors will help clinicians to better interpret self-reported HL as a surrogate for audiometric assessments. For survivors who self-report HL, but have normal audiometric findings at standard frequencies, referral to an audiologist for additional testing and inclusion of EHFs in audiometric assessments, should be considered. Research Sponsor: U.S. National Institutes of Health.

5017 **Poster Discussion Session**

Immunity to childhood vaccines following high dose chemotherapy (HDCT) and autologous stem cell transplantation (ASCT) for germ cell tumors (GCT) with comparison to Hodgkin lymphoma (HL). *First Author: Darren R. Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HDCT/ASCT represents a curative salvage treatment for patients with GCT but is rarely used for other solid tumors. Patients undergoing HDCT/ASCT for hematologic neoplasms require revaccination for their childhood immunizations. Whether this is necessary in patients with GCT is unknown. **Methods:** In this prospective longitudinal study, patients with GCT undergoing HDCT-ASCT from 11/2010 to 5/2018 had serologies for Measles, Mumps, Rubella, Diphtheria, Tetanus, Polio, and Varicella Zoster measured before HDCT and at 3, 6, and in a subset, 12+ months after the last HDCT with results at these timepoints compared using descriptive statistics. In addition, titer levels at ≥6 months post-transplant were matched 1:1 for age and gender with HL patients who underwent HDCT/ASCT during the same time period. Immunity was compared between cohorts using the Cochran-Mantel-Haenszel test. **Results:** Of 80 patients with GCT (median age 30, 84% nonseminoma), 91% received 3 sequential transplants and 68 had repeat titers at ≥6 months. Immunity at baseline was >95% for Diphtheria, Tetanus and Polio and 89% for Varicella Zoster but lower for Measles (74%), Mumps (85%), and Rubella (83%) (Table). Compared to baseline, proportional immunity for all infections was similar at 3, 6, and 12 months post-transplant in the GCT population (≥6 months shown in Table). Matching resulted in 58 GCT-HL pairs. One-year immunity was numerically lower for most infections in the HL vs. GCT patients and significantly decreased for Measles and Rubella (Table). **Conclusions:** To our knowledge, this is the first study to assess vaccine titers following HDCT/ASCT for GCT. We demonstrate that HDCT/ASCT does not result in loss of immunity to childhood vaccines and that GCT patients retain protective titers more frequently than those with HL. However, 15-31% of GCT patients lack MMR immunity at baseline and at 1-year post-ASCT. Therefore, we recommend checking MMR titers at 1-year post-ASCT with revaccination of those lacking immunity. Titer evaluation and revaccination is not necessary for other childhood immunizations. Research Sponsor: Craig D. Tifford Fund and the The Louise B. Blackman Foundation.

Proportion of patients with immunity to childhood vaccines.

Surveillance after complete response in patients with metastatic non-seminomatous germ-cell tumor (NSGCT). *First Author: Jennifer King, Indiana University School of Medicine, Indianapolis, IN*

Background: The optimal management of patients (pts) with complete response (CR) after first-line chemotherapy remains unsettled with guidelines recommending either surveillance or retroperitoneal LN dissection (RPLND). We present long-term outcomes from a large dataset of pts managed with surveillance after achieving CR to first-line chemotherapy. **Methods:** The prospectively maintained Indiana University testicular cancer database was queried for pts with metastatic NSGCT treated between 1990-2017 who achieved a CR after first-line chemotherapy. CR was defined as normalization of tumor markers (AFP+hCG) and no residual mass > 1cm. Kaplan-Meier methods were used to analyze progression-free survival (PFS) and overall survival (OS). **Results:** 388 pts met eligibility and were included in this analysis. Median age at diagnosis was 28.4 (range, 13-61.5). Primary site was testis in 385 pts (99%). Primary tumor predominant histology was embryonal ca (241), mixed (61), seminoma (31), yolk sac tumor (20), choriocarcinoma (10), and teratoma (14). 126 pts (32.5%) had teratoma in the primary tumor. Metastasis sites were retroperitoneum (295), mediastinal LN (15), pulmonary (149), liver (15), bone (7), and brain (6). IGCCCG risk was good in 325, intermediate in 25, and poor in 32 pts. Pre-chemotherapy retroperitoneal LN size was available in 232 pts: < 3cm in 170 and ≥3cm in 62. Median pre-chemo AFP was 10.7 (1-31,000) and hCG was 16.5 (0-595,930). First-line chemo was BEPx3 in 274, BEPx4 in 30, other regimens in 82 pts. With a median follow-up of 3.9 yrs, 34 pts (8.8%) progressed. At most recent follow-up, 363 (93.6%) pts were alive with no evidence of disease and 10 pts (2.6%) died of their disease. The estimated 2-yr PFS was 90.1% (95% CI: 86.2-93%) and 2-yr OS was 97.8% (95% CI: 95.2-99%). The estimated 2-yr PFS by IGCCCG risk category was 90.4% for good vs 90.4% for intermediate vs 86.5% for poor risk (p = 0.23), and the estimated 2-yr OS was 98.6% for good vs 95.5% for intermediate vs 92.9% for poor risk disease respectively (p = 0.002). For the 34 pts who progressed on surveillance, 16 (4%) progressed in the retroperitoneum only. 3 pts had malignant transformation of teratoma to PNET, adenocarcinoma, or other elements. 11 of progressed pts were treated with surgery, 12 were treated with salvage chemo, and 11 were treated with surgery+chemo. At most recent follow up, 21 of progressed pts had NED, 10 had died of disease, and 3 were lost to follow up. **Conclusions:** Pts with metastatic NSGCT who achieve CR after first-line chemotherapy can be safely observed with surveillance. Most pts who relapse can be salvaged with surgery and/or chemotherapy. Research Sponsor: None.

5019 **Poster Discussion Session**

Effect of pretreatment central adiposity on the cardiometabolic risk of male germ cell tumor survivors after cisplatin-based chemotherapy. *First Author: Andreas Georg Wibmer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Preferential fat accumulation in the visceral compartment (i.e. central adiposity) increases cardiovascular risk in the general population independent of body mass index (BMI). We investigated how body fat distribution modulates the cardiometabolic risk of male germ cell tumor (GCT) survivors after cisplatin-based chemotherapy. **Methods:** For 456 patients in The Platinum Study enrolled at Memorial Sloan Kettering Cancer Center, visceral (VAT) and subcutaneous (SAT) adipose tissue compartments were quantified on pre-chemotherapy computed tomography (CT) scans (median time between CT and chemotherapy: 13 days, range: 0-56). The VAT/SAT ratio was calculated as a quantitative indicator of central adiposity. Endpoints were (I) post-chemotherapy cardiovascular risk as per the office-based Framingham risk calculator, and (II) incidence of post-chemotherapy cardiometabolic disease defined as need for new anti-hypertensive drugs, or lipid-lowering drugs, or medication used to treat diabetes. Changes in fat distribution after chemotherapy were analyzed in a subgroup with post-chemotherapy CTs (n = 108; median interval from chemotherapy start: 18 months, range: 7-185). Linear regression with interaction terms (endpoint 1, subgroup analysis) and Cox proportional hazard regression (endpoint 2) were applied. **Results:** For all 456 patients, median age at chemotherapy initiation was 31 years and median follow-up was 27 months (range: 7, 207). At baseline (pre-chemotherapy), the median BMI was 26.2 kg/m^2, and 102 patients (22.4%) had a BMI of ≥30 kg/m^2. The median VAT/SAT ratio at baseline CT was 0.49, and positively associated with higher post-chemotherapy Framingham risk scores after adjustment for age, BMI, and blood pressure measurements at chemotherapy start, as well as post-therapy follow-up time (adjusted β-estimate: 1.36, 95% CI: 1.15, 1.59, p < 0.001). A higher VAT/SAT ratio also inferred a higher likelihood of new onset cardiometabolic disease in patients with BMI ≥30 kg/m^2 (age-adjusted HR: 3.11, 95%CI: 1.01, 9.62, p = 0.048), but not in those with BMI < 30 kg/m^2. In the subgroup analysis, we observed a significant increase of BMI after chemotherapy (mean: +1.1 kg/m2, 95% CI: +0.58, +1.54; p < 0.001). Changes in BMI were positively associated with changes of the VAT/SAT ratio (β-estimate: 3.0, 95% CI: 2.23, 4.04; p < 0.001), meaning that weight gain occurred preferentially in the VAT compartment, while weight loss tended to be paralleled by an improved body fat distribution. **Conclusions:** In male GCT patients, central adiposity at baseline increases cardiometabolic risk after cisplatin-based chemotherapy, particularly for obese individuals. Quantification of an individual's body fat distribution on pre-chemotherapy CT could potentially help to identify high risk individuals who may benefit from intensified risk-modulating interventions. Research Sponsor: None.

Concordance of DNA damage repair (DDR) gene mutations in paired primary and metastatic prostate cancer (PC) samples. *First Author: Michael Thomas Schweizer, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Mutations in DDR genes represent actionable alterations that can be used to guide precision medicine strategies in men with advanced PC. However, acquisition of contemporary tissue samples for advanced molecular testing can be a barrier to deploying precision medicine approaches. We hypothesized that most DDR alterations represent early truncal events in PC and that archival primary tissue would faithfully reflect mutations found in cell-free circulating tumor (ctDNA) and/or metastatic tissue. **Methods:** Patients were included in this study if a DDR pathway mutation was detected in metastatic tissue or ctDNA and primary tissue sequencing was available for comparison. Sequencing data from three cohorts were analyzed: 1) FoundationOne, 2) University of Washington (UW-OncoPlex or SU2C/PCF International Dream Team sequencing pipelines) and 3) University of Washington rapid autopsy series. Only pathogenic somatic mutations were included and we required ≥30 days between primary tumor tissue and ctDNA/tumor tissue acquisition. Clonal hematopoiesis of indeterminant potential (CHIP) and germline events were adjudicated by an expert molecular pathologist and excluded. Variants detected only in plasma were considered likely to be CHIP or low subclones if the variant fraction was <1% and/or >5-fold less than the estimate tumor content in plasma. **Results:** Paired primary and ctDNA/metastatic samples were sequenced from 72 individuals with known DDR alterations. After excluding ctDNA cases where only CHIP (N=13) and/or germline events (N=7) were observed, 51 subjects remained and were included in the final analysis. The median time from acquisition of primary tissue to acquisition of ctDNA or tumor tissue was 52 mos (range: 1 – 193 mos). Concordance in DDR genes across samples was 86% (95% CI: 74-93%). Rates of concordance between metastatic-primary and ctDNA-primary pairs were similar when CHIP cases were excluded (87% and 85%, respectively). *BRCA2* reversion mutations associated with resistance to PARP inhibitors and platinum chemotherapy were detected in ctDNA from two subjects. **Conclusions:** These data provide evidence that primary prostate tissue accurately reflect the mutational status of actionable DDR genes in men with metastatic PC, supporting the hypothesis that DDR alterations are early truncal events. After excluding likely CHIP events, ctDNA profiling accurately captured these truncal DDR mutations, while also detecting reversion alterations that may suggest potential resistance mechanisms. Research Sponsor: None.

Summary of DDR gene alterations in paired primary PC and ctDNA/metastatic tissue. Only gene alterations identified in ≥2 subjects are presented. Note: Several patients had alterations in more than one gene.

Gene	Number of mutations (N)	Concordance (%)
CDK12	17	16 (94%)
BRCA2	16	13 (81%)
ATM	9	8 (89%)
PALB2	2	2 (100%)
FANCA	2	2 (100%)
ATR	2	1 (50%)
	Total	48 (86%)

Copy number profiles of primary tumors for risk stratification of advanced prostate cancer: A biomarker study embedded in the multicenter STAMPEDE trial. *First Author: Emily Grist, University College London Cancer Institute, London, United Kingdom*

Background: Men with advanced hormone-sensitive prostate cancer (HSPC) starting long term androgen deprivation therapy (ADT) follow a highly variable clinical course. Treatment intensification with docetaxel or AR targeted therapies improves outcomes but there is a risk of overtreatment, especially in non-metastatic (M0) or metastatic (M1) low volume disease. We established a framework for biomarker evaluation in the STAMPEDE trial. We aimed to evaluate the feasibility and clinical utility of assessing the burden of copy number (CN) aberrations in newly diagnosed advanced HSPC. We hypothesised that increased percentage genome altered (PGA) would associate with higher disease burden and worse prognosis. **Methods:** We implemented a scalable strategy using low coverage whole genome sequencing (lpWGS) of formalin fixed paraffin embedded (FFPE) diagnostic core biopsies from STAMPEDE participants randomised to the standard of care ADT arm, between 2005 and 2016. Tissue was retrieved from 136 trial sites. 315 cases were randomly selected, aiming for a biomarker population of 300, anticipating an assay failure rate ~5%. We defined 40% as the minimum histopathologically determined tumor cellularity (TC) for inclusion. We performed a survival analysis investigating PGA at diagnosis as a continuous measure with fractional polynomial specification in Cox models adjusting for disease burden, Gleason grade, pre-ADT PSA (log-transformed), age at randomisation and TC. We pre-specified that all hypothesis tests required evidence at the 5% significance level to consider rejecting the null hypothesis. **Results:** We successfully CN profiled 300/315 cases. There were no significantly different baseline clinico-pathological features between the full trial comparison n = 3106 and final biomarker population n = 300, 290/300 cases were *de novo* presentations. PGA in the core with highest Gleason grade and TC was median 18% (range 0%-75%; n = 300). PGA was significantly higher in M1 (n = 169) compared to M0 (n = 131) cases (median: 21% vs 14%; p = 0.00006). 284/300 were subclassified by disease burden into M0 node negative and node positive, and M1 low and high volume. PGA was significantly associated with increased disease burden (p = 0.00002). Increased PGA was significantly and non-linearly associated with an increased hazard of failure-free survival (p = 0.004), progression-free survival (p = 0.002), metastatic progression-free survival (p = 0.003), overall survival (p = 0.045) and prostate cancer-specific survival (p = 0.011). **Conclusions:** Evaluation of the burden of CN aberrations in archival, poor quality FFPE diagnostic tissue from men randomised in the STAMPEDE trial is feasible using lpWGS and has potential clinical utility to identify better prognosis advanced HSPC patients, who may not require treatment intensification. Research Sponsor: Prostate Cancer UK, Other Foundation.

Characterization of findings on prostate cancer tumor sequencing that should prompt consideration for germline testing. *First Author: Hong Truong, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor sequencing is increasingly used for therapeutic selection in men with advanced prostate cancer (PC). If tumor-only sequencing is performed without matched germline, identified mutations could be of somatic or germline origin. Germline mutations could confer additional risk for other cancers to the patient and at-risk family members. The objective of this study is to determine the overall and gene-specific probability of pathogenic/likely pathogenic germline mutations based on tumor-only sequencing. **Methods:** We investigated mutations found in a cohort of men with PC who underwent targeted next generation sequencing of PC tumor and matched peripheral blood using the MSK-IMPACT assay between 01/2015 and 01/2020. A germline probability for each gene was determined by dividing the number of germline mutations by the total number of somatic and germline mutations. Cancer susceptibility genes commonly sequenced on tumor-based tests for PC were assessed, including *ATM*, *BRCA1/2*, *BRIP1*, *CHEK2*, *HOXB13*, *MLH1*, *MSH2*, *MSH6*, *NBN*, *PALB2*, *PMS2* (henceforth referred to as PC genes). **Results:** A total of 1883 men with PC were included, with median age of diagnosis of 62.0 ± 8.8 years. 84% had high risk PC, 52% had metastasis, 38% had family history of PC. A total of 364 (19%) men had at least one mutation (either somatic or germline) in PC genes. Overall, 189 (10%) men had at least one germline mutation that would not have been reported as germline without matched normal. The average germline probability of PC genes was 40% (range: 0% in *MLH1* to 83% in *CHEK2*). The number of total mutations, germline mutations, and germline probability of genes found in > 0.5% of the study cohort are summarized in Table. All these genes are moderate/high penetrance autosomal dominant genes with established guidelines for cascade testing, enhanced cancer screening, or potential risk-reducing surgery. **Conclusions:** In this study, an average of 40% of mutations found in cancer susceptibility genes on PC tumor sequencing were germline mutations. Men undergoing tumor-only sequencing should be counseled on the possibility of uncovering a germline mutation. In addition to *BRCA1/2*, mutations in certain genes, such as *CHEK2* and *PALB2*, have a high probability of being germline and should prompt referral for genetic counseling and germline testing. Research Sponsor: U.S. National Institutes of Health.

Genes	Total mutations (n, %)	Germline mutations (n, %)	Germline probability (%)
BRCA2	158, 8.4	74, 3.9	47
ATM	77, 4.1	24, 1.3	31
CHEK2	58, 3.1	48, 2.5	83
MSH2	34, 1.8	7, 0.4	21
MSH6	26, 1.4	4, 0.2	15
BRCA1	20, 1.1	11, 0.6	55
PALB2	16, 0.9	11, 0.6	69

PSMA-targeted imaging with ^{18}F-DCFPyL-PET/CT in patients (pts) withbiochemically recurrent prostate cancer (PCa): A phase 3 study (CONDOR)—A subanalysis of correct localization rate (CLR) and positive predictive value (PPV) by standard of truth. *First Author: Frederic Pouliot, Cancer Research Center, Centre Hospitalier Universitaire (CHU) de Québec-Université Laval, Québec City, QC, Canada*

Background: PSMA-targeted PET/CT is superior to conventional imaging modalities to localize biochemically recurrent (BCR) PCa after local therapy, particularly in pts with low PSA (< 2 ng/mL). However, few studies have reported PSMA-targeted PET/CT accuracy compared to a pre-specified rigorous standard of truth (SOT) including histopathology, correlative imaging or treatment response in this population. Here, we report the CLR and PPV of PSMA-targeted ^{18}F-DCFPyLPET/ CT, for each of the pre-defined SOT criteria for the CONDOR prospective phase 3 study. **Methods:** The study enrolled men with rising PSA after definitive therapy and negative or equivocal standard of care imaging (e.g., CT/MRI, bone scintigraphy, F-18 fluciclovine). A single 9 mCi (333 MBq) ± 20% dose of ^{18}F-DCFPyL was injected, followed by PET/CT 1-2 hours later. Pts with positive ^{18}F-DCFPyL-PET/CT scans based on local interpretation were scheduled for follow up within 60 days to verify suspected lesion(s) using a composite SOT. The primary endpoint was CLR defined as PPV with the requirement of anatomic lesion co-localization between ^{18}F-DCFPyL-PET/CT and the SOT. The SOT consisted of, in descending priority: 1) histopathology, 2) subsequent correlative imaging findings determined by twocentral readers, or 3) post-radiation PSA response. The trial was successful if the lower bound of the 95% confidence interval for CLR exceeded 20% for at least two of three independent, blinded central ^{18}F-DCFPyL-PET/CT reviewers. **Results:** 208 men (median PSA 0.8 ng/mL) underwent ^{18}F-DCFPyL-PET/CT and the study achieved its primary endpoint: CLR was between 84.8% to 87.0% (lower bound of 95% CI: 77.8%-80.4%) among the three ^{18}F-DCFPyL-PET/CT readers, against the composite SOT. The performance of ^{18}F-DCFPyL-PET/CT by CLR (≥1 lesion co-localized) and PPV (≥1 lesion confirmed) was maintained through all 3 SOT categories. Histopathology (N = 31): 78.6-82.8% and 92.9-93.3% for CLR and PPV, respectively; correlative imaging (N = 100): 86.1-88.6% and 87.0-89.5% for CLR and PPV, respectively; and PSA response (N = 1): 100% for both CLR and PPV. Further analyses of the correlative imaging results showed CLR remained high across the different modalities used a) ^{18}F-fluciclovine-PET/CT (N = 71): (86.8-90.9%); b) MRI (N = 23): (80.0-86.7%); and c) CT (n = 6): (80.0-100%). **Conclusions:** PSMA-targeted ^{18}F-DCFPyL-PET/CT detected and localized metastatic lesions with high CLR and PPV regardless of which criterion defined CLR that was used, in men with BCR who had negative or equivocal baseline imaging. Clinicaltrials.gov: NCT03739684 Clinical trial information: NCT03739684. Research Sponsor: Progenics Pharmaceuticals, Inc.

Evaluation of PSA progression after initiation of enzalutamide or abiraterone: Real-world data on metastatic castration-resistant prostate cancer (mCRPC). *First Author: Fernando López-Campos, Radiation Oncology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: PSA value is widely used for the monitoring of treatment outcome in mCRPC in the clinical real-world setting. Early PSA changes are not considered in the definition of PSAProg due to the potential for spurious "flare" reactions. We aimed to evaluate the significance of an early PSA increase in mCRPC patients (pts) treated with enzalutamide or abiraterone (Enz/Abi). **Methods:** We retrospectively evaluated Enz/Abi-treated mCRPC pts from 11 hospitals between 2011-2020. Early PSAProg was defined as a 25% increase in PSA from baseline at 4 (PSAProg4) or 8 (PSAProg8) weeks after treatment initiation. PSA progression at 12 weeks (PSAProg12) was confirmed by a second reading. Uni- and multivariable (MV) Cox regression models were conducted to explore the association of PSAProg and overall survival (OS) in chemotherapy naïve patients treated with Abi or Enz. Interaction tests were conducted to explore differences in the impact of PSA progression on OS in Abi or Enz-treated pts. **Results:** We analyzed 511 chemotherapy-naïve mCRPC pts treated with Abi (N=391; 76.5%) or Enz (N=120; 23.5%). Median follow-up: 30.2 months. OS was longer in Enz-treated pts (38.1 vs 29m; HR 1.4; p=0.027). 59 (15.1%), 70 (17.9%) and 48 (12.3%) of Abi-treated and 9 (7.5%), 11 (9.2%) and 10 (8.3%) of Enz-treated pts experienced PSAProg4, PSAProg8 and PSAProg12, respectively, although differences were not statistically significant. PSAProg was associated with worse OS at all 3 timepoints only in Abi-treated pts. In Enz-treated pts, PSAProg4 had a large impact on OS, not observed in PSAProg8 or PSAProg12. We observed no significant interaction between agent (Enz/Abi) and PSA progression (Table). **Conclusions:** PSA progression at 4 weeks after Enz/Abi is significantly associated with shorter OS and may help identify pts not benefitting from Abi/Enz before clinical or radiographic progression. PSA pattern progression and its association with OS might differ depending on the drug used (Enz/Abi). Prospective validation studies are needed. Research Sponsor: None.

Association between PSA prog and OS in abi- and enz-treated pts.

		Abiraterone		Enzalutamide		Interaction test
		OS	HR (p-val)	OS	HR (p-val)	
PSAProg4	Yes	25.9 m	1.47 (p=0.018)	15.2 m	3.57 (p=0.004)	p=0.103
	No	30.4 m		41.7 m		
PSAProg8	Yes	22.9 m	1.69 (p<0.001)	17 m	2.14 (p=0.06)	p=0.624
	No	31.1 m		38.1 m

Factors associated with use of medications for anxiety and depression in testicular cancer survivors after cisplatin-based chemotherapy. *First Author: Shirin Ardeshirrouhanifard, Indiana University School of Medicine, Indianapolis, IN*

Background: Cancer survivors are at increased risk of anxiety and depression that can affect health-related quality of life. There is no study to date that has examined the characteristics of testicular cancer survivors (TCS) taking medications for anxiety or depression since pharmacological interventions are typically reserved for more severe cases of these disorders. In this study, we aimed to examine sociodemographic factors, cisplatin-related adverse health outcomes (AHOs), and cumulative burden of morbidity (CBM_{Pt}) scores associated with medication use for anxiety and/or depression in TCS. **Methods:** A total of 1,802 TCS who completed CBCT ≥12 months previously completed validated questionnaires regarding sociodemographic features and cisplatin-related AHOs (hearing impairment, tinnitus, peripheral sensory neuropathy (PSN), kidney disease). Patients were recognized as users of medications for anxiety and/or depression if they used pharmacological classes of these medications and also indicated that the reason for use was for anxiety or depression. Individual AHOs were graded 0-to-4 based on severity according to NCI Common Terminology Criteria for Adverse Events version 4.03. A CBM_{Pt} score encompassed the number and severity of cisplatin-related AHOs. Multivariable logistic regression models assessed the relationship of individual AHOs and CBM_{Pt} with medication use for anxiety and/or depression. **Results:** A total of 151 TCS (8.4%) used medications for anxiety and/or depression. Any grade of HL, tinnitus, PSN, and kidney disease were reported by 37.9%, 39.5%, 55.2%, and 2.4% of 1,802 participants, respectively. No cisplatin-related AHO were reported by 511 (28.4%) participants, whereas 622 (34.5%), 334 (18.5%), 287 (15.9%), and 48 (2.7%), respectively, had very low, low, medium, and high CBM_{Pt} scores. Higher CBM_{Pt} scores were significantly associated with greater medication use for anxiety and/or depression (CBM_{Pt} scores of low (OR = 2.96, 95%CI, 1.67-5.24), medium (OR = 3.47, 95%CI, 1.95-6.18), and high (OR = 3.18, 95%CI, 1.22-8.3). A multivariable model including individual AHOs indicated that tinnitus (P= 0.0009), PSN (P= 0.02), and having health insurance (OR = 2.15, 95%CI, 1.01-4.56) were associated with significantly greater use of these medications; whereas being employed (OR = 0.39, 95%CI, 0.23-0.66) and vigorous physical activity (OR = 0.63, 95%CI,0.44-0.89) were associated with significantly diminished use. **Conclusions:** We found that TCS with higher CBM_{Pt} scores had a higher probability of using medications for anxiety and/or depression and conversely, those who were employed and physically active tended to have reduced use. These findings deserve further investigation in longitudinal studies. In the interim, healthcare providers should be aware of these associations in formulating survivorship care plans. Research Sponsor: U.S. National Institutes of Health.

Adjuvant chemotherapy with CAV/IE for malignant transformation of teratoma to primitive neuroectodermal tumor (PNET): An institutional analysis from Indiana University. *First Author: Cynthia Wei, Indiana University School of Medicine, Indianapolis, IN*

Background: Malignant transformation of teratoma to PNET has an aggressive disease biology and generally poor outcomes when metastasis occurs. The optimal management of patients (pts) with PNET who have complete surgical extirpation is unknown. Most pts who are monitored with surveillance will relapse. We report results from pts with metastatic PNET who had complete surgical resection to NED status followed by adjuvant chemotherapy, most commonly cyclophosphamide + doxorubicin + vincristine alternating with ifosfamide + etoposide (CAV/IE) for 4 cycles. **Methods:** We reviewed records for pts with histologically confirmed malignant transformation of teratoma at Indiana University from 1990 to 2020. We identified 13 pts with PNET who underwent resection of metastatic disease to NED status followed by treatment with adjuvant chemotherapy, most commonly CAV/IE comprising of cyclophosphamide (1200 mg/m2), doxorubicin (75 mg/m2), and vincristine (2 mg/m2) alternating with ifosfamide (1.8 g/m2) plus etoposide (100 mg/m2). Treatment was delivered every 3 weeks for 4 cycles or until unacceptable toxicity. **Results:** Thirteen pts with metastatic PNET resected to NED status and received adjuvant chemotherapy were identified. Median age at diagnosis was 29 (range, 20 to 55). Primary tumor site was testis in 11 pts, retroperitoneum in 1 pt, and mediastinum in 1 pt. Metastasis site was retroperitoneal lymph nodes in 11 pts, mediastinal lymph nodes in 1 pt, and local mediastinal recurrence in 1 pt. After resection to NED status, all 13 pts were treated with adjuvant chemotherapy: 11 pts were treated with CAV/IE and 2 received etoposide-ifosfamide-cisplatin (VIP) x 2. Among the 11 pts who received CAV/IE: 3 pts received $<$ 4 cycles due to toxicity and 8 completed 4 cycles. With a median follow-up of 16.3 months, 3 of 13 pts relapsed (23%) and 10 of 13 remained continuously disease free (77%). Of those who relapsed, median time to relapse was 9.3 months, 2 remained alive with disease at follow up and one patient died of disease progression. **Conclusions:** Adjuvant CAV/IE improves the outcomes of pts with malignant transformation of teratoma to PNET and who had resection of metastasis to NED status. Most pts who received adjuvant therapy remain continuously disease-free in comparison to historically high relapse rates in pts with resected PNET monitored with surveillance. Research Sponsor: None.

Clinical utility of FDG PET-CT in stage 1 and advanced testicular seminoma. *First Author: Ciara Conduit, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Testicular seminoma is highly curable; however, treatments can cause long-term morbidity in survivors. Following chemotherapy for advanced seminoma, positron emission tomography with 2-[18F]fluoro-2-deoxy-D-glucose together with computerised tomography (PET-CT) can identify patients with residual masses who do not need additional treatment. Its role in detecting recurrence during active surveillance, particularly in patients with small indeterminate masses, is unknown. We assessed the clinical utility of PET-CT in testicular seminoma undergoing active surveillance for stage 1 disease and following curative-intent treatment for advanced disease. **Methods:** An institutional database was interrogated to identify patients with testicular seminoma who underwent PET-CT between 2000-2020. Demographic, clinicopathological, PET-CT findings and outcome data were retrieved. The positive predictive value (PPV) of PET-CT for correctly identifying disease recurrence was calculated, with disease recurrence (true positive) defined as progressive radiological change, response to treatment or histological confirmation. Negative predictive value (NPV) was calculated for correctly identifying non-recurrence (true negative) at 24-months post PET-CT. **Results:** We identified 193 PET-CT in 181 stage 1 patients. Of these, 18 (10%) PET-CT were positive, with all correctly diagnosing recurrence, PPV 100%. Of the 138 negative PET-CT with at least 24 months follow up, 5 recurrences developed, NPV 96%. In the subset of PET-CT conducted for suspicion of recurrence in stage 1 patients (n = 71: abnormal imaging n = 65, elevated markers n = 4, other clinical suspicion n = 2), 16 (23%) PET-CT were positive, with all correctly diagnosing recurrence, PPV 100%. In this subset, the NPV is 93% at 24 months (3 recurrences in 44 negative PET-CT). We also identified 154 PET-CT in 77 post-treatment, advanced stage patients. Of these, 69 (45%) PET-CT were positive, with 51 correctly diagnosing recurrence, PPV 74%. Of the 66 negative PET-CT with at least 24 months follow up, 5 recurrences developed, NPV 92%. In the subset of PET-CT performed for suspicion of recurrence following treatment for advanced disease (n = 61: abnormal imaging n = 49, elevated markers n = 5, other clinical suspicion n = 7), 41 (67%) PET-CT were positive, with 36 correctly diagnosing recurrence, PPV 88%. In this subset, the NPV is 94% at 24 months (1 recurrence in 17 negative PET-CT). **Conclusions:** At our centre, PET-CT has a very high PPV for recurrence, particularly in stage 1 disease, and a very high NPV for non-recurrence in all disease settings. In the subset of PET-CT performed for suspicion of recurrence, PPV is $>$ 88% and NPV is $>$ 93%. The role of PET-CT should be considered in patients with suspicion of recurrence where it may prevent over-treatment in up to 70% patients in stage 1 or 30% in advanced disease. Research Sponsor: None.

Efficacy of TIP (paclitaxel, ifosfamide and cisplatin) as salvage chemotherapy for relapsed germ cell cancer patients stratified by the modified International Prognostic Factors Study Group (IPFSG) score: The Northern Ireland (NI) Experience. *First Author: Adam Uprichard, Belfast City Hospital, Belfast, United Kingdom*

Background: Salvage therapy for relapsed or refractory germ cell tumours (GCTs) after first-line treatment (1LT) failure remain controversial. The ongoing TIGER trial aims to compare conventional-dose chemotherapy (CDCT) using TIP with high-dose chemotherapy (HDCT) and to validate a modified version of the IPFSG stratification system as a secondary objective. We retrospectively analysed data from patients treated with TIP at our institution and stratified by the modified IPFSG (mIPFSG) groupings, correlating this with clinical outcomes. **Methods:** Data from all GCT patients who received TIP in NI between 2005 and 2014 was collected. Patients were scored using known IPFSG factors including progression-free interval (0-1), metastasis site (0-3), response to 1LT (0-2), primary tumour site (0-3), HCG (0-1), AFP (0-2), and histology (-1 to 0), and categorised into the modified strata. Descriptive and inferential statistics using SPSS compared survival measure outcomes and the favourable response rate (FRR) i.e the proportion of patients achieving either a complete response or partial response with normal serum tumour markers, according to mIPFSG group. **Results:** Thirty patients were identified, all of whom received 4 cycles of TIP. The median age was 37 years (range 17-57), 28 patients were non-seminoma histology with 2 patients seminoma. The cohort comprised predominantly of patients with more adverse mIPFSG features and the FRR of the group was 30%, with a median progression-free survival (PFS) of 9 months and 2-year overall survival (OS) of 50%. Clinical outcomes differed by mIPFSG score as shown below. **Conclusions:** Our study shows TIP efficacy comparable to published data, and to our knowledge is the first to show correlation between clinical outcomes with the regimen and the new mIPFSG model. The differences in outcomes to CDCT using TIP across risk groups in real world practice shows potential for a stratified approach to patient selection for salvage therapy, as is under investigation by the TIGER study. Research Sponsor: None.

mIPFSG point score	FRR	2-year OS

Outcomes of patients with germ cell tumors diagnosed with stage I disease who subsequently received high dose chemotherapy (HDCT) with peripheral stem cell transplant (PBSCT) following failure of initial therapy for metastatic disease: The Indiana University experience. *First Author: Stephen B Benzinger, Indiana University School of Medicine, Indianapolis, IN*

Background: Pts with stage I testicular germ cell tumors (GCT) have a 15-year DFS of 99%. However, 1% are not cured, despite orchiectomy and systemic therapy at relapse. Predictive variables for relapse in this small population have not been identified. **Methods:** Pts undergoing HDCT with PBSCT as salvage therapy for relapsed GCT after an initial diagnosis of stage I disease managed with orchiectomy and surveillance were evaluated from a database at Indiana University. Patient demographics, disease characteristics, adherence to standard surveillance guidelines for stage I disease, prognostic variables, treatment received in the first-line setting, pattern of relapse, and outcomes were analyzed. **Results:** From 1/92 to 10/19, 71 pts (34 seminoma, 37 NSGCT) initially diagnosed with stage I GCT managed with orchiectomy and surveillance but subsequently relapsed and eventually required HDCT with PBSCT were identified. Median f/u time was 5.1 years (range, 1.1-18.8). Median age was 34.1. First-line chemo consisted of BEP or EP in most pts. Risk category at relapse: good/intermediate/poor (52/8/11). Pattern of initial relapse included 22 (seminoma n=13, NSGCT n=9) with RPLN only. Relapse and death after HDCT occurred in 2 of these 22 pts. Strict adherence to standard surveillance guidelines was observed in 62/71 pts. Relapse and/or death after HDCT occurred in 3 of 9 with inadequate surveillance follow-up. At a minimum of 1 yr follow-up, 54 of 71 (76%) remain alive, including 47 (66%) who have no evidence of disease (NED). **Conclusions:** Most patients in this series progressed despite appropriate surveillance and first-line chemotherapy. Pattern of relapse was also not indicative of further progression in most patients. Further investigation should evaluate disease biology that puts patients with potentially easily curable disease at risk of multiple relapses. Research Sponsor: None.

Very late recurrence in germ cell tumor of the testis: Lessons and implications. *First Author: Joseph A Moore, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Up to 30% of patients with germ cell tumor of the testis (TGCT) develop recurrent disease after initial treatment. The majority of recurrences occur in the first 2 years after treatment. Very late recurrence (LR), i.e. > 5 years after initial presentation, occurs in about 1% of patients with TGCT and is associated with poor prognosis. Current guideline does not require follow-up after 5 years to detect LR, except in those presenting with metastatic NSGCT. **Methods:** We retrospectively reviewed the records of patients from the Genitourinary Medical Oncology clinic at the M. D. Anderson Cancer Center, who developed recurrent disease > 5 years after their initial diagnosis of TGCT. Specifically, we examined the pathology and location of their primary and recurrent tumors, treatments rendered (e.g., surgery, radiotherapy, chemotherapy), and overall survival after LR. Overall survival from the time of LR was estimated using Kaplan-Meier estimates and compared for patient subgroups with log rank tests. Fisher's exact test was used to compare proportions in patient subgroups. **Results:** We identified 25 patients who developed LR between July 2007 and August 2020. Age at time of LR: median 46 years (range, 29-61); time of late LR: median 16.1 years (range, 6.8-33.1 years) after diagnosis. Stage at time of diagnosis: I – 5, II-IIIA – 13, IIIB-C – 7. Pathology of primary: nonseminoma with yolk sac tumor or teratoma – 15, nonseminoma without yolk sac tumor or teratoma – 1, not available – 9. Pathology of LR: somatic transformation to carcinoma – 9, somatic transformation to sarcoma – 2, nonseminoma with yolk sac tumor or teratoma – 10, nonseminoma without yolk sac tumor or teratoma – 2, not available – 2. Overall, 5 patients (20%) had LR in retroperitoneum alone, 6 patients (24%) had non-retroperitoneal nodal or pulmonary metastases, and 14 patients (56%) had non-pulmonary visceral metastases. Nine patients (36%) are deceased, ten patients (40%) are alive without evidence of disease (NED), and 6 patients are alive with disease (24%). With a median follow-up of 42 months, 68% of patients are alive 3 years after LR. Patients with prior post-chemotherapy consolidation surgery have longer survival, 80% vs. 53% at 3 years, respectively (p = 0.01). Additionally, at their last follow-up 9/12 vs. 1/13 patients were NED with vs. without prior post-chemotherapy consolidation surgery, respectively (p = 0.001). **Conclusions:** Patients with LR > 5 years after initial presentation tend to harbor nonseminoma (with yolk sac tumor and or teratoma). Among these patients, a majority who did not undergo surgery to remove residual disease after chemotherapy developed somatic transformation and succumbed to their LR. Further investigation into rates of LR among all patients may be warranted given the poor survival after LR. Research Sponsor: None.

First-in-human study of TAS3681, an oral androgen receptor (AR) antagonist with AR and AR splice variant (AR-SV) downregulation activity, in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) refractory to abiraterone (ABI) and/or enzalutamide (ENZ) and chemotherapy (CT). *First Author: Johann S. De Bono, Institute of Cancer Research and Royal Marsden NHS Foundation Trust, Sutton, Surrey, United Kingdom*

Background: Second-generation AR signaling inhibitors have improved outcomes from mCRPC; drug resistance, however, invariably evolves with AR overexpression, AR mutation, or AR-SVs and continued AR signaling. TAS3681 is an oral and selective AR antagonist with AR and AR-SV down-regulation and has antitumor efficacy in AR-SV+, ENZ-resistant CRPC models. We report the dose escalation part of the first-in-human trial of TAS3681 in pts with mCRPC (NCT02566772). **Methods:** mCRPC pts with progressing disease after ABI and/or ENZ, and ≥1 additional CT, received TAS3681 in a 3+3 dose escalation design; QD or BID tablets were given in 28-day cycles; BID dosing at ≤600 mg was introduced to increase daily exposure while limiting C_{max}. Primary endpoints: incidence of dose limiting toxicities (DLTs) and adverse events (AEs); other endpoints: pharmacokinetics (PK), and antitumor activity per Prostate Cancer Clinical Trials Working Group 3 (PCWG3). **Results:** As of January 22, 2021, 56 pts in 10 cohorts were dosed (QD: 25, 50, 100, 200, 400, 600, 800, and 1000 mg; and BID: 300 and 400 mg). Median age was 66 (56–79) yrs; pts had a median of 6 prior lines of systemic therapy. Of 41 pts evaluable for DLTs, 3 had confirmed DLTs: 1/10 DLT evaluable pts at 600 mg QD (QT prolongation >480 ms) and 2/3 DLT evaluable pts at 400 mg BID (1 pt with QT prolongation >480 ms, 1 pt with G3 hypertension). The most common treatment-related AEs (TRAEs) were: nausea (32 pts, 57.1%), hyperbilirubinemia (21 pts, 37.5%), fatigue (18 pts, 32.1%), vomiting (17 pts, 30.4%) and diarrhea (16 pts, 28.6%); AEs of QT prolongation were seen in 11 pts (19.6%). TRAEs ≥G3 were reported in 12 pts (21.4%). TAS3681 exposure increased dose-dependently up to 600 mg QD and then plateaued. Steady state was reached by Day 8 and accumulation ratios of AUC were approximately 2 to 6 times. Confirmed PSA declines of >50% from baseline were seen in the 600 mg QD (2 pts) and 300 mg BID cohorts (1 pt). Antitumor activity was observed; tumor response rate was 23.1% in the 600 mg QD cohort (3 confirmed partial responses (cPRs) in 13 dosed pts), 22.2% in the 300 mg BID cohort (1 cPR and 1 unconfirmed complete response in 9 dosed pts), and 14.3% in the 400 mg BID cohort (cPR in 1/7 dosed pts). Responses occurred after 2–4 cycles of treatment. The longest duration of response (DoR) to date is 16.2 mo. The 5 pts with cPR had DoR >6 mo with the exception of 1 pt who had a short follow-up period. 300 mg BID was found to be the best tolerated dose with antitumor activity. **Conclusions:** The recommended phase 2 dose is 300 mg BID. TAS3681 has a manageable safety profile and has antitumor activity against heavily pretreated, multi-drug resistant mCRPC. The study expansion phase is enrolling pts who have progressed on ABI or ENZ +/- taxane CT. Clinical trial information: NCT02566772. Research Sponsor: Taiho.

Survival of veterans treated with enzalutamide and abiraterone in advanced prostate cancer. *First Author: Martin W. Schoen, Saint Louis University School of Medicine, St. Louis, MO*

Background: Abiraterone (AA) and enzalutamide (ENZ) are two second generation antiandrogens used to treat advanced prostate cancer, but no large head-to-head trials have been performed. These oral therapies are commonly used in older patients with medical comorbidities who are not candidates for chemotherapy or clinical trials and have different mechanisms of action, adverse events, and drug interactions. To understand survival of patients with prostate cancer, we studied United States veterans treated prior to approval of AA and ENZ for metastatic hormone sensitive prostate cancer when both drugs had approval for metastatic castration resistant prostate cancer. **Methods:** We identified patients treated with AA or ENZ between 9/10/2014 and 6/3/2017 in the Veterans Health Administration and followed them to April 2020. Age, Elixhauser comorbidity score, treatment with androgen deprivation therapy (ADT) and docetaxel were collected. Cox proportional hazards modeling was used to assess the association between first oral treatment (AA or ENZ) and overall survival, while adjusting for covariates. **Results:** Of 5895 patients, 2562 (43.5%) were initially treated with ENZ, 3333 (56.5%) with AA, and 3040 (51.6%) received only one of the two drugs during the study period. Patients initially treated with ENZ compared to AA were older (mean 75.9 vs. 75.0 years, $p = 0.001$), had higher mean comorbidity score (6.2 vs. 5.9, $p < 0.001$), and were less likely to receive both ENZ and AA (45.2% vs. 51.0%, $p < 0.001$) or docetaxel (24.1% vs. 28.4%, $p < 0.001$). Patients who received only AA or ENZ and never received docetaxel were older (mean 78.3 vs. 73.2 years, $p < 0.001$) with higher mean comorbidity scores (6.4 vs. 5.7, $p < 0.001$). In the entire cohort, initial treatment with ENZ was associated with longer median survival (24.1 vs. 22.2 months, $p = 0.003$). After adjusting for age and comorbidities, ENZ was associated with a decreased risk of death compared to AA (HR 0.87, 95% CI 0.82-0.92). In 3317 patients who received two or more therapies (ENZ, AA, docetaxel) there was no difference in median survival between initial treatment with ENZ or AA (28.0 vs. 27.9 months). In 2578 patients (43.7%) who never received docetaxel and either ENZ or AA only, median survival was longer in patients treated with ENZ (18.9 vs. 13.6 months, $p < 0.001$) and was associated with decreased mortality when adjusting for age and comorbidities (HR 0.73, 95% CI 0.67-0.80). **Conclusions:** In the overall cohort, initial treatment with ENZ was associated with increased survival compared to AA. Patients who received only ENZ or AA and never received docetaxel had the largest benefit from ENZ, a difference of 5.3 months median survival. Efforts should be made to improve therapy selection for patients with prostate cancer, especially older patients with comorbidities. Research Sponsor: Saint Louis Veterans Affairs Medical Center.

A methodology for the extraction and analysis of real-world radiographic and electronic medical record data to reconstruct treatment arms of historical prostate cancer clinical trials. *First Author: William David Lindsay, Oncora Medical, Inc., Philadelphia, PA*

Background: Real-world evidence (RWE), including synthetic comparator arms created from historical real-world data (RWD), has the potential to support the safety and efficacy evaluation of new medical products. However, many available RWD sources lack the details necessary to reliably identify patients comparable to clinical trial cohorts or to assess essential oncologic efficacy endpoints. This project demonstrates the ability to extract and analyze RWD to identify patients matching eligibility criteria to four historical clinical trials in metastatic castration-resistant prostate cancer (mCRPC), and calculate outcome measures. **Methods:** A total of 5,741 patients treated for prostate cancer at multiple institutions (2010-2020) were analyzed in two cohorts using data extracted from the EMR, Tumor Registry, Oncology Information System, and Picture Archiving and Communication System. Of 3,486 patients with prostate cancer in Cohort 1, 422 mCRPC patients were identified: those treated with ADT who achieved castration-level testosterone (< 50 ng/dL), had evidence of metastatic disease, and exhibited rising PSA (PCWG2). These patients were further matched to four historical clinical trial treatment arms (COU-AA-301: 49, COU-AA-302: 143, AFFIRM: 30, PREVAIL: 79), based on prior chemotherapy and receipt of Abiraterone or Enzalutamide. Overall survival (OS) and time to skeletal related events (SRE) (pathological fracture, spinal compression, surgery to bone, and radiotherapy to bone) were calculated based on diagnosis and procedure codes using the Kaplan-Meier (KM) Estimator. Of 2,255 patients with prostate cancer in Cohort 2, 101 patients received Abiraterone or Enzalutamide and 59 patients had sufficient baseline and follow-up imaging to be scored. Radiographic progression-free survival (rPFS) was calculated from the start of treatment to the time of progression (RECIST 1.1) or loss to follow-up using the KM estimator. **Results:** In Cohort 1, median OS was 37.7 months (95% CI: 31.5-NR), and median time to SRE was 17.9 months (13.5-22.6). Median OS per patient cohort matched to historical trial treatment arm was COU-AA-301: 23.7 months (10.7-NR), COU-AA-302: 45.9 months (34.9-NR), AFFIRM: 35.3 months (6.34-NR), PREVAIL: 41.5 months (21.9-NR). In Cohort 2, median rPFS was 37.2 months (13.3-NR). **Conclusions:** The methodology employed in this analysis not only successfully identified a cohort of RWD patients similar to clinical trial-defined patients, but also curated sufficiently reliable data to calculate essential endpoints (e.g., rPFS). At scale, this methodology can be used to generate RWE, including synthetic comparator arms to support clinical trials with radiographic endpoints. Research Sponsor: Tmunity Therapeutics.

A phase 2 study of berzosertib (M6620) in combination with carboplatin compared with docetaxel in combination with carboplatin in metastatic castration-resistant prostate cancer. *First Author: Atish Dipankar Choudhury, Dana-Farber Cancer Institute, Boston, MA*

Background: Alterations in DNA damage repair (DDR) genes are common in metastatic castration-resistant prostate cancer (mCRPC), and are implicated in responses to carboplatin [carbo], PARP inhibitors and immunotherapeutics. Inhibitors of the ATR kinase, which is involved in the DDR response, have been demonstrated to have synergistic activity with platinum compounds in preclinical models. We therefore conducted a phase 2 study of the ATR inhibitor berzosertib [berzo]+carbo vs. docetaxel [doce]+carbo in mCRPC. **Methods:** Patients (pts) previously treated with at least one secondary hormonal therapy and taxane underwent mandatory pre-treatment biopsy and were randomized 1:1 to receive Arm A (doce 60 mg/m2 day 1 + carbo AUC 4 day 1) or Arm B (berzo 90 mg/m2 days 2,9 + carbo AUC 5 day 1) every 21 days. Pts randomized to Arm A who were not candidates for doce received carbo AUC 5 monotherapy. Stratification factors were 1) prior PARP inhibitor (yes vs. no) and 2) evaluable disease by RECIST 1.1 (yes vs. no). Pts on Arm A crossed over to Arm B (berzo+carbo) at the earlier of PSA or radiographic progression. The primary endpoint was overall response rate (ORR; PSA reduction by $\geq$ 50% or radiographic response by RECIST 1.1). Secondary endpoints included time to PSA progression, radiographic PFS (rPFS), PFS by PCWG3 criteria, and adverse events (AEs) in each arm. Planned enrollment was 136 pts (for 130 to be treated), with interim analysis for futility after 65 pts were treated. **Results:** 73 pts were randomized between 6/2019 and 7/2020; 34 pts were treated on Arm A (26 carbo+doce; 8 carbo alone) and 31 on Arm B. Median number of prior systemic therapies (excluding ADT, 5α-reductase inhibitors, 1st generation antiandrogens) was 4 (range 2-8). Median treatment duration was 3 cycles, and 4 pts in each arm discontinued for AEs. Grade 3 or higher treatment-related AEs (TrAE) were seen in 13(38%) pts in Arm A and 21(68%) in Arm B. Pts in Arm B had greater frequency of grade 3-4 thrombocytopenia (8[26%] vs. 3[9%]). 1 pt in Arm B had grade 5 sepsis attributed to study treatment. ORR was 15% in Arm A (5/34; 5/26[19%] in pts who received carbo+doce) and 0% in Arm B (0/31). 14 pts in Arm A crossed over, with no subsequent responses seen. Median rPFS was 2.1(95% CI:2.0,3.2) mo in Arm A and 2.4(1.9,4.2) mo in Arm B. At planned interim analysis, trial enrollment and crossover to Arm B were halted due to futility. **Conclusions:** Carbo+berzo led to fewer overall responses and a higher rate of grade 3 or higher TrAEs compared to carbo+doce. All responses seen were in pts who received carbo+doce despite requirement for prior progression on taxane, suggesting that this combination is favored over carbo+berzo or carbo monotherapy in a heavily pre-treated biomarker-unselected population. Extensive genetic and molecular studies for DDR assessment from tissue and cfDNA are in progress. Clinical trial information: NCT03517969. Research Sponsor: U.S. National Institutes of Health.

Cortisol as biomarker for CYP17 inhibition in mCRPC patients treated with abiraterone acetate. *First Author: Maaike Bruin, The Netherlands Cancer Institute–Antoni van Leeuwenhoek, Amsterdam, Netherlands*

Background: Abiraterone acetate is an effective metastatic castration resistant prostate cancer (mCRPC) treatment, however, there is a high variability in response. It inhibits CYP17, thereby preventing the production of androgens. Abiraterone trough concentrations (C_{min}) > 8.4 ng/mL have been associated with an increased progression free survival (PFS) (Eur J Cancer. 2017;72:54-61; Prostate Cancer Prostatic Dis. 2020;23(2):244-251). However, plasma levels do not directly provide information on the level of CYP17 inhibition. Ideally, testosterone levels should be measured, but these levels are below the detection limit of available assays. The synthesis of cortisol is also inhibited by abiraterone via CYP17 inhibition and might therefore be a biomarker for CYP17 inhibition. The objective of this study was to investigate if cortisol levels are related to abiraterone levels and to clinical response. **Methods:** An observational study was performed in mCRPC patients treated with abiraterone acetate. At the outpatient clinic, plasma samples were collected for pharmacokinetic (PK) monitoring at each hospital visit. Reference populations of healthy volunteers and mCRPC patients using enzalutamide were included to investigate the influence of mCRPC and abiraterone treatment on the circadian rhythm of cortisol. Abiraterone and cortisol levels were measured using validated liquid chromatography-mass spectrometry (LC-MS/MS) assays. Clinical (prostate specific antigen (PSA) independent) PFS and PSA response were evaluated. **Results:** In total, 117 mCRPC patients using abiraterone acetate, 100 mCRPC patients using enzalutamide and 12 healthy volunteers were included. A clear circadian rhythm of cortisol was described in healthy volunteers and unaffected in mCRPC patients using enzalutamide. Contrarily, a circadian rhythm of cortisol could not be identified in mCRPC patients using abiraterone acetate, due to continuous suppression throughout the day. Patients with an abiraterone $C_{min} > 8.4$ ng/mL (n = 77) had a median cortisol concentration of 1.03 ng/mL vs. 2.59 ng/mL in patients with an abiraterone $C_{min} \leq 8.4$ ng/mL (n = 40) ($p = 0.020$). The median cortisol concentration in PSA responders (n = 63) was 1.02 ng/mL vs. 2.59 ng/mL for PSA non responders (n = 54) ($p = 0.037$). Patients in the highest cortisol tertile (> 3.03 ng/mL) had a median PFS of 3.7 months (n = 39) vs. 13.8 months in patients with cortisol levels ≤ 3.03 ng/mL (n = 78) ($p = 0.007$). The median PFS was 16.3 months in patients with an abiraterone $C_{min} > 8.4$ ng/mL and cortisol concentration < 3.03 ng/ml vs. 5.3 months in patients with an abiraterone $C_{min} > 8.4$ ng/mL and cortisol concentration > 3.03 ng/ml ($p = 0.02$). **Conclusions:** This study demonstrates that cortisol levels are of additional value to abiraterone concentrations as a marker for abiraterone acetate efficacy. This might help be helpful to assess efficacy of abiraterone treatment. Research Sponsor: None.

Biomarker analysis of phase (Ph) IB trial of radium-223 (Rad) and niraparib (Nira) in patients (Pts) with metastatic castrate-resistant prostate cancer (mCRPC) (NiraRad). *First Author: Eddy Shih-Hsin Yang, University of Alabama at Birmingham, Birmingham, AL*

Background: Rad is an alpha particle emitter that causes DNA double strand breaks and has been FDA-approved for use in mCRPC pts with bone metastases. PARP-1 activity critically supports androgen receptor (AR) activity in mCRPC and potentiates AR-dependent DNA damage response pathways that promote prostate cancer cell survival. Nira is a potent and selective PARP-1/2 inhibitor that has shown single agent clinical activity in mCRPC. We previously reported the safety of targeting the PARP-1/AR axis with Nira in combination with Rad. Herein we describe the results of an exploratory biomarker analysis. **Methods:** The primary objective of NiraRad is to determine the optimum Ph II dose of Nira plus Rad (55 kBq/kg of body weight IV every 4 weeks (wks) x 6) in pts with and without prior chemotherapy (docetaxel). Pts were enrolled to one of three dose levels of Nira (100, 200, or 300 mg PO daily). All cohorts were combined for exploratory biomarker analysis using Nanostring PanCancer Driver and Immune Pathways panels and the nSolver Advanced analysis module was performed on blood obtained from 23 pts at baseline, cycle (C) 1 day (D) 15, and C3D15. A favorable response was defined as any PSA reduction at week 12 or treatment (tx) duration $>$ 18 wks, the median time on tx in the cohort of pts analyzed. A threshold of $>$ 2 fold (X) differentially expressed genes was used. **Results:** Of the 23 pts with biomarker data, 7 (30%) experienced PSA reductions and 11 (48%) received tx for $>$ 18 wks, 6 of which also had PSA reductions. Exploratory analysis revealed that the PI3K/Ras, MAPK, and transcriptional misregulation pathways were differentially regulated in pts who had favorable responses. The top downregulated gene, PAX5, which has been shown to promote prostate cancer growth, was decreased at C1D15 (2.7X, $p < 0.01$) and C3D15 (4.8X, $p < 0.001$) in pts with tx duration $>$ 18 wks and at baseline in pts who had PSA reductions (3.1X, $p < 0.05$). Immune pathways analysis suggested downregulation of immunosuppressive B-cell (plasma cell) and upregulation of NK and T cell pathways in pts with tx duration $>$ 18 wks. **Conclusions:** Previously Nira and Rad have been shown to have acceptable tolerability in mCRPC pts. This exploratory analysis suggests potential response biomarkers that warrant further investigation. Managed by: the Prostate Cancer Clinical Trials Consortium; Funded by: Janssen Pharmaceuticals and Bayer Healthcare Pharmaceuticals, Inc. Clinical trial information: NCT03076203. Research Sponsor: Janssen Scientific Affairs, LLC, Pharmaceutical/Biotech Company.

5037 **Poster Session**

Analysis of two poor prognosis subgroups in ACIS evaluating apalutamide + abiraterone acetate plus prednisone (APA + AAP) versus placebo (PBO) + AAP in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Fred Saad, Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada*

Background: In the double-blind PBO-controlled ACIS study, investigator-assessed radiographic progression-free survival (rPFS) was significantly improved with APA + AAP vs PBO + AAP in chemo-naive mCRPC, with no significant new safety signals (Rathkopf ASCO GU 2021). Among prespecified subgroups, efficacy and safety were explored in two difficult to treat subgroups: pts with visceral disease (VD; liver, lung, and/or adrenal gland metastasis) or age $\geq$ 75 y. **Methods:** Pts with mCRPC with ongoing ADT and no prior life-prolonging treatment were randomized 1:1 to APA (240 mg QD) + AA (1000 mg QD) + P (5 mg BID) or PBO + AAP. Stratified: presence or absence of VD, ECOG PS 0 or 1, geographic region. Primary end point: rPFS (randomization to radiographic progression or death); secondary end points: overall survival (OS), time to initiation of cytotoxic chemotherapy, time to chronic opioid use, time to pain progression, safety. **Results:** 982 pts enrolled. 14.6% had VD and 35.9% were $\geq$ 75 y. Median rPFS, OS, and time to pain progression favored APA + AAP vs AAP (HR $<$ 1) in both subgroups (Table). For pts $\geq$ 75 y, rPFS and OS were $\geq$ 7 mo longer with APA + AAP. Overall, treatment-emergent adverse events (TEAEs) were similar (all $>$ 94%) in pts with VD, $\geq$ 75 y, and overall safety population; hypertension was more frequent with APA + AAP vs AAP mainly in pts $\geq$ 75 y (31.7% vs 17.6%). Grade 3/4 TEAEs (APA + AAP vs AAP): VD, 60.8%, n = 74 vs 48.5%, n = 68; $\geq$ 75 y, 71.5%, n = 186 vs 68.5%, n = 165; overall, 63.3%, n = 490 vs 56.2%, n = 489. TEAEs leading to discontinuation: VD, 17.6% vs 5.9%; $\geq$ 75 y, 26.3% vs 20.6%; overall, 16.9% vs 12.5%. TEAEs leading to death: VD, 6.8% vs 5.9%; $\geq$ 75 y, 5.4% vs 13.9%; overall, 3.5% vs 7.6%. **Conclusions:** In this analysis of two difficult to treat subgroups, addition of APA to AAP favored rPFS and OS. Safety, while generally consistent with the overall population, showed higher hypertension rate in $\geq$ 75 y and TEAEs leading to discontinuation in VD. Clinical trial information: NCT02257736. Research Sponsor: Janssen Research & Development.

Complementary detection of genomic alterations in metastatic castration-resistant prostate cancer (mCRPC) from CheckMate 9KD through analyses of tumor tissue and plasma DNA. *First Author: Mark Sausen, Bristol Myers Squibb, Princeton, NJ*

Background: Accurate analysis of the genomic alteration landscape within tissue- and plasma-derived tumor DNA using next-generation sequencing (NGS) may provide insights into specific patient populations that benefit from different therapies. The interchangeable use of tissue- and plasma-based assessments may benefit patients when tissue availability is limited, a common occurrence in individuals with mCRPC. To understand the potential sources of technical and biological variability in this setting, we performed comprehensive comparative analyses across 3 NGS platforms, using samples from patients enrolled in CheckMate 9KD, a phase 2 study of nivolumab combined with docetaxel, rucaparib, or enzalutamide for patients with confirmed mCRPC (NCT03338790). **Methods:** We performed retrospective integrated analyses of sequence and structural alterations identified through comprehensive genomic profiling (CGP) of DNA obtained from formalin-fixed, paraffin-embedded tissue specimens and cell-free DNA obtained from plasma. Tissue-based analysis was performed using the FoundationOne assay (F1, 395 genes), while the FoundationACT (FACT, 70 genes) and GuardantOMNI (OMNI, 500 genes) assays were used for plasma-based analysis. Analysis was performed on samples from 103 patients for which datasets from all 3 assays were available. Inter-platform analysis considered variants with $\geq$ 0.50% variant allele fraction and common to the shared pairwise targeted regions, while excluding synonymous variants. **Results:** Through broad profiling of DNA obtained from tissue and plasma, we uncovered previously identified recurrent alteration of *AR*, *TP53*, *PTEN*, and *TMPRSS2* fusion with ETS genes. Additionally, we found that 42% (F1), 45% (FACT), and 34% (OMNI) of patients harbored a combination of germline and somatic mutations in homologous recombination repair pathway genes. Across all samples, median tumor mutational burden was 3.5 mutations per megabase (mut/Mb) by F1 and 8.6 mut/Mb by OMNI. Inter-platform variant analyses demonstrated concordance of 52% for F1 vs FACT, 40% for F1 vs OMNI, and 75% for FACT vs OMNI. **Conclusions:** Overall, these data demonstrate the value of integrated tissue and liquid biopsy profiling in mCRPC. Both technical and biological sources of variation, including panel size, mutation detection algorithms, variant annotation and reporting, analytical performance, circulating tumor DNA levels, and tumor heterogeneity, may be captured differently by tissue- and plasma-based techniques, accounting for the discordance in reported results. Clinical trial information: NCT03338790. Research Sponsor: Bristol Myers Squibb.

5039 **Poster Session**

ARC-6: A phase 1b/2, open-label, randomized platform study to evaluate efficacy and safety of etrumadenant (AB928)-based treatment combinations in patients with metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Sumit Kumar Subudhi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Standard-of-care (SOC) chemotherapy may contribute to immunosuppression by elevating intratumoral levels of adenosine, activating the A_{2a} and A_{2b} receptors on immune cells. Extracellular adenosine is primarily produced by the enzyme CD73; in prostate cancer, additional adenosine is also produced by the highly expressed protein, prostatic acid phosphatase (PAP). Etrumadenant (etruma) is an orally bioavailable, small-molecule, selective dual adenosine receptor antagonist and has been well tolerated in dose escalation studies as monotherapy or combined with chemo/immunotherapy. Adenosine axis inhibition combined with SOC regimens and/or immunotherapy may have a synergistic effect on the induction of sustained antitumor immunity against mCRPC. Initial results from the etruma + zimberelimab (zim; antiPD-1 mAb) + docetaxel (doc) arm are presented herein. **Methods:** ARC-6 (NCT04381832) is an ongoing, phase 1b/2, open-label, multicohort platform study to evaluate efficacy and safety of etruma combination therapy. All eligible patients (pts) have mCRPC that has progressed on androgen deprivation therapy and are checkpoint inhibitor-naive; additionally, for this arm, pts must be androgen signaling inhibitor (ASI)-experienced and taxane-naive. Study pts receive 150 mg etruma orally once daily + 360 mg zim IV every 3 weeks + SOC doc (EZD). The primary objectives are to evaluate safety and antitumor activity (prostate-specific antigen [PSA], radiographic, and composite response rates) of EZD. PSA levels are assessed every 3 weeks, and radiographic scans are performed every 12 weeks. PSA response-evaluable pts have baseline (BL) + $\geq$2 consecutive post-BL PSA assessments; radiographic response-evaluable pts have RECIST measurable or non-measurable disease per BL imaging + $\geq$1 post-BL radiographic assessment. **Results:** As of 22Jan2021, 17 pts have received EZD in phase 1b; 14 are PSA response-evaluable and 8 are radiographic response-evaluable. 15 (88%) pts reported treatment emergent adverse events (TEAEs); the most common ($>$ 30%) were lymphocyte count decreased and neutrophil count decreased (7 pts each; 41%), and hyponatremia and alopecia (6 pts each; 35%). Grade $\geq$3 treatment-related TEAEs were reported by 9 pts (53%). As of 22Jan2021, 16 pts were continuing treatment; median time on EZD for all pts was 9.9 weeks (0.127.4+ weeks). In response-evaluable pts, PSA response rate was 36% (5/14), radiographic response rate was 38% (3/8; 1 CR), and the composite response rate was 43% (6/14). **Conclusions:** Phase 1b results indicate that EZD treatment in pts with mCRPC had a manageable safety profile and was associated with clinical benefit. Having met phase 2 advancement criteria, randomized pt enrollment to EZD vs. doc is ongoing. Clinical trial information: NCT04381832. Research Sponsor: Arcus Biosciences, Inc.

Differential responses to taxanes and PARP inhibitors (PARPi) in *ATM*- versus *BRCA2*-mutated metastatic castrate-resistant prostate cancer (mCRPC) patients (pts).

First Author: Christopher T Su, University of Michigan Rogel Cancer Center, Ann Arbor, MI

Background: PARPi have shown promise in mCRPC pts with mutations in DNA repair, but *ATM*- and *BRCA2*-altered pts may respond differently to PARPi. We hypothesized that differences may also exist for taxane therapy, aiding in treatment sequencing decisions. **Methods:** mCRPC pts (N = 137) with deleterious *ATM* or *BRCA2* mutations who received taxanes, PARPi, or both were identified from 8 US academic centers. Demographic, treatment, and survival data were collected. Kaplan-Meier analyses were performed for time-to-treatment-discontinuation (TTD), as well as overall survival (OS), from time of first taxane or PARPi therapy. Cox hazard ratio (HR) regression analyses were performed, adjusting for Gleason sum (≤7 vs. 8-10). For OS, receipt of subsequent therapies following first taxane or PARPi was also included as a covariate. **Results:** 50 *ATM*- and 87 *BRCA2*-mutated pts were identified. 40/50 (80%) of *ATM*-mutated pts received taxane only or taxane prior to PARPi, while 10/50 (20%) received PARPi only or PARPi prior to taxane. *ATM*-mutated pts showed a trend towards longer TTD when taxane was given first vs PARPi given first (P = 0.08, adjusted HR for taxane treatment 0.50 [95% CI: 0.24–1.08]). Considering all pts who received taxane first, *ATM*-mutated pts had longer TTD than *BRCA2*-mutated pts who received taxane first (*P*= 0.04, adjusted HR for *ATM* 0.61 [CI: 0.37–0.99]). Among *ATM*-mutated pts, OS was longer in those receiving taxane first (*P*= 0.06, adjusted HR for taxane treatment 0.33 [CI: 0.10–1.05]). Among *BRCA2*-mutated pts, 43/87 (49%) received taxane first and 44/87 (51%) received PARPi first. *BRCA2*-mutated pts had longer TTD when PARPi was given first vs taxane given first (*P*< 0.0001, adjusted HR for PARPi treatment 0.32 [CI: 0.19–0.56]). Considering all pts who received PARPi first, *BRCA2*-mutated pts also had longer TTD than *ATM*-mutated pts who received PARPi first (*P*= 0.0031, adjusted HR for *BRCA2* 0.29 [CI: 0.12–0.66]). There was no significant OS difference in *BRCA2*-mutated pts regarding which treatment was given first (*P*= 0.63, adjusted HR for PARPi treatment 1.18 [CI: 0.59–2.35]). **Conclusions:** Our data in *ATM*- and *BRCA2*-mutated mCRPC pts suggests a trend towards improved clinical outcomes when taxanes are used prior to PARPi in *ATM*-mutated pts, while the reverse sequence appears to be better for *BRCA2*-mutated pts. Research Sponsor: U.S. National Institutes of Health.

	Taxane given first	PARPi given first	Adjusted Cox p
Median duration of therapy in *ATM*-mutated pts (95% CI)	126 days (105-165) N = 40	87 days (17-222) N = 9	0.08
Median overall survival in *ATM*-mutated pts from time of first taxane or PARPi therapy	509 days (319-987) N = 25	279 days (18-not reached) N = 5	0.06
Median duration of therapy in *BRCA2*-mutated pts	122 days (84-136) N = 43	224 days (111-335) N = 33	< 0.0001
Median overall survival in *BRCA2*-mutated pts from time of first taxane or PARPi therapy	545 days (394-828) N = 32	453 days (343-632) N = 15	0.63

Molecular, immunologic, and clinicodemographic landscape of MYC-amplified (MYCamp) advanced prostate cancer (PCa).

First Author: Brandon Arvin Virgil Mahal, University of Miami, Miami, FL

Background: The *MYC* oncogene is one of the most commonly amplified genes in PCa, contributes to androgen independent growth, and is potentially targetable. We sought to define the molecular, immunologic, and clinicodemographic landscape of *MYC*amp in advanced PCa to better understand progression and establish rationale for personalized treatments and combinations. **Methods:** Hybrid capture-based comprehensive genomic profiling (CGP) was performed on tumor samples from predominantly advanced PCa samples. *MYC*amp was defined as copy number (CN) ≥6. PD-L1 IHC was performed using Dako 22C3. A subset of patients (pts) with advanced PCa were selected from the Flatiron Health- Foundation Medicine (FM) clinicogenomic database (CGDB), a nationwide de-identified EHR-derived clinical DB linked to FM CGP data for pts treated from 01/2011-12/2020. The de-identified data originated from approximately 280 US cancer clinics (~800 sites of care). **Results:** The genomic profiles of 12,528 tissue samples from unique PCa pts (including hormone sensitive and castrate resistant) were evaluated. *MYC*amp was detected in 10.6%, with a median *MYC* CN of 8. Median age was 67 years (67 for *MYC*wt versus 68 for *MYC*amp). *MYC*amp occurred at a higher frequency in men with African (N = 190/1,473, 12.9%) versus European (N = 996/9,796, 10.2%) ancestry (P = 0.002), was more frequent in metastatic biopsy sites vs primary (15.7% vs 6.2%, P < 0.001), and was most common in liver mets (20.2%). *MYC*amp CN > 15 was enriched for PD-L1 positivity (26.1%) compared with *MYC*wt (9.8%) or *MYC*amp CN 6-15 (11.5%) (CN > 15 vs wt P = 0.025). In pts with *MYC*amp vs *MYC*wt PCa *AR*, *RAD21*, *PTEN*, *CCND1*, *ZNF703*, *FGF19*, *FGFR1*, and *FGF3* each had significantly higher rates of CN changes (all p < 0.001); *TP53* mutation was also more common with *MYC*amp (47.5% vs 39.7%, P < 0.001). *MYC*amp tumors were less likely to harbor microsatellite instability vs *MYC*wt (0.8% vs 2.4%, P < 0.001) and had higher tumor mutational burden (median 2.6 vs 1.7 mut/Mb, P < 0.001). In liquid samples with evidence of circulating tumor DNA (compositive tumor fraction [cTF] > 0) from PCa pts *MYC*amp was detected in 2.0% (28/1,402), and in 4.5% (20/445) with cTF > 20%. Among evaluable PCa pts in the CGDB, (67 *MYC*amp and 658 *MYC*wt) *MYC*amp did not significantly impact treatment decisions, with the majority receiving novel hormone therapies (35.8% *MYC*amp vs. 31.5% *MYC*wt) or chemotherapy containing regimens (37.3% *MYC*amp vs. 27.7% *MYC*wt) as first therapy after CGP report. **Conclusions:** Herein, we report the largest analysis to date of molecular, immunologic, and clinicodemographic features of *MYC*amp advanced PCa. These findings suggest that *MYC*amp defines a biologically distinct subset of PCa pts for whom personalized combination treatments utilizing targeted and/or immunotherapies may be effective. Independent cohorts are needed to validate these findings. Research Sponsor: Foundation Medicine.

Pembrolizumab plus enzalutamide for enzalutamide-resistant metastatic castration-resistant prostate cancer (mCRPC): Updated analyses after one additional year of follow-up from cohorts 4 and 5 of the KEYNOTE-199 study.

First Author: Julie N Graff, OHSU Knight Cancer Institute, Portland, OR

Background: KEYNOTE-199 (NCT02787005) is a multicohort phase 2 study to evaluate pembrolizumab (pembro) in mCRPC. A previous analysis of patients with RECIST-measurable (cohort 4 [C4]) or bone-predominant nonmeasurable (cohort 5 [C5]) disease who were chemotherapy-naive and had progression while on enzalutamide (enza) found that pembro + enza showed antitumor activity and manageable safety. Long-term outcomes are of interest with immunotherapy; hence, updated efficacy and safety data after an additional 1 year of follow-up are presented. **Methods:** Pts were eligible if they had resistance to enza after prior response. Prior treatment with abiraterone was allowed. Pts received pembro 200 mg Q3W for up to 35 cycles + enza QD until progression, unacceptable toxicity, or withdrawal. Primary end point was ORR per RECIST v1.1 by blinded independent central review (BICR) in C4. Secondary end points were DOR (C4), and DCR, rPFS, OS and safety (both cohorts). **Results:** 126 pts (C4, 81; C5, 45) were treated. Median age was 72 years (range 43-92), 32.5% had visceral disease and 87.3% previously received ≥6 mo of enzalutamide; 121 pts (96.0%) discontinued, most because of progressive disease. Median (range) time from enrollment to data cutoff was 31.7 mo (23.1-37.1) in C4 and 35.5 mo (22.9-37.3) in C5. In C4, confirmed ORR was 12.3% (95% CI 6.1-21.5) (2 CRs, 8 PRs); median (range) DOR was 8.1 mo (2.5+ to 15.2), and 62.5% had a response ≥6 mo (Kaplan-Meier estimate). Additional efficacy analyses are outlined in the table. A total of 27.2% and 28.9% of pts in C4 and C5, respectively, experienced grade ≥3 treatment-related adverse events. Two pts in C4 died of immune-related AEs (Miller Fisher syndrome and myasthenia gravis). Incidence of any-grade (34.1%) and grade 3 or 4 (5.6%) rash, regardless of relatedness to treatment, was higher than previously reported for individual agents but manageable with standard-of-care treatments; 2 pts discontinued because of rash. **Conclusions:** After an additional 1 year of follow-up, pembro + enza continued to show antitumor activity and a manageable safety profile in pts with mCRPC who became resistant to enza. The treatment combination is being further evaluated in the ongoing phase 3 KEYNOTE-641 trial (NCT03834493). Clinical trial information: NCT02787005. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

A phase (Ph) 1b/2 study of ribociclib (R) in combination with docetaxel (D) plus prednisone (P) in metastatic castration-resistant prostate cancer (mCRPC).

First Author: Ivan de Kouchkovsky, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: The survival benefit of D in mCRPC is modest. CDK4/6 inhibitors such as R have shown synergistic activity with taxanes in pre-clinical cancer models. We sought to determine the safety and efficacy of R + D + P in mCRPC patients (pts). **Methods:** This was a Ph 1b/2 multicenter, open-label single arm trial of mCRPC pts with progression (PD) on ≥ 1 prior androgen receptor signaling inhibitor (ARSi) who had not previously received D for mCRPC (NCT02494921). Pts were treated with escalating doses of R in combination with D + P for 6-9 cycles, followed by single agent maintenance R until radiographic or clinical PD. The Ph 2 primary endpoint was 6-month (mo) radiographic progression-free survival (rPFS) rate by PCWG2 criteria, with a target rate of 55% and null hypothesis of 35%. Ph 2 pts underwent baseline circulating tumor cell (CTC) enumeration and genome sequencing (Epic Sciences). Cox proportional hazard model and log-rank test were used to test for associations between rPFS and CTC burden and copy number (CN) variants, respectively. **Results:** 43 pts were enrolled from 11/2015 to 6/2019. Median age was 68 (range 55-84). 20.9% of pts had visceral metastases. 33 (77%) had PD on prior abiraterone, 27 (63%) on enzalutamide, and 17 (40%) on both. In Ph 1b, 19 pts were enrolled. In the first cohort (D 75 mg/m^2 day [d] 1, R 200 mg/d d2-14 of every 21d cycle), 2 pts experienced DLTs (febrile neutropenia [FN] and grade 4 neutropenia). With an alternative dosing schema of D 60 mg/m^2 on d1, and R daily on d1-4 and 8-15 of cycle, with daily G-CSF support on d5-7, the MTD was not reached and D 60 mg/m^2 + R 400 mg/d was chosen as the recommended Ph 2 dose (RP2D). In total, 30 pts were treated at RP2D; median number of D cycles was 8.5 and 60% went on to receive maintenance R. The Ph 2 primary endpoint was met with a 6-mo rPFS rate of 65% (95% CI 50-85%). Median rPFS was 8.0 mos (95% CI 4.1-10.0). PSA response rate (RR) defined as ≥50% reduction was 27.6% (95% CI 12.7-47.2%) and objective RR was 30.8% (95% CI 9.1-61.4%). Among pts treated at RP2D, the most common grade ≥3 treatment-related adverse events were neutropenia (n= 11, 36.7%), lymphocytopenia (n=3, 10%); no cases of FN were observed. Baseline CTC burden was associated with an increased risk of radiographic PD or death (HR 1.038, 95% CI 1.001-1.074, p = 0.038). Pts harboring CTCs without MYC (4/11 pts) or CDK6 CN gain (7/11 pts) had prolonged rPFS compared to those with gene amplification (median rPFS 10.76 vs 4.11 mos, p = 0.03, and 7.01 vs 1.92 mos, p = 0.053, respectively). **Conclusions:** The combination of R + D was well tolerated and showed promising activity in mCRPC pts who had progressed on an ARSi. The Ph 2 study met its primary endpoint, with an encouraging 6-mo rPFS rate of 65%. Lack of MYC or CDK6 amplification on CTC sequencing was associated with longer rPFS. Funding: Novartis Pharmaceuticals, PCF YIA. Managed by the PCCTC. Clinical trial information: NCT02494921. Research Sponsor: Novartis, Other Foundation, Other Government Agency.

CheckMate 9KD cohort A1 final analysis: Nivolumab (NIVO) + rucaparib for post-chemotherapy (CT) metastatic castration-resistant prostate cancer (mCRPC). *First Author: Russell Kent Pachynski, Washington University School of Medicine, St. Louis, MO*

Background: CheckMate 9KD is a phase 2 trial of NIVO (anti-PD-1) combined with either rucaparib, docetaxel, or enzalutamide for mCRPC. PARP inhibitors, like rucaparib, increase cellular DNA damage, particularly in tumors with DNA repair defects, leading to genomic instability and cell death. This DNA damage promotes immune priming and adaptive PD-L1 upregulation. Consequently, dual PD-(L)1 and PARP inhibition is a plausible therapeutic strategy for mCRPC. We report final results for cohort A1 (NIVO + rucaparib for post-CT mCRPC) of CheckMate 9KD. **Methods:** Cohort A1 enrolled patients (pts) with post-CT mCRPC (1–2 prior taxane regimens), ongoing ADT, ≤ 2 prior novel hormonal therapies (abiraterone, enzalutamide, etc) for mCRPC, and no prior PARP inhibitor treatment. Pts received NIVO 480 mg Q4W + rucaparib 600 mg BID until disease progression/unacceptable toxicity (NIVO dosing limited to 2 yrs). Coprimary endpoints: objective response rate (ORR) per PCWG3 criteria and prostate-specific antigen response rate (PSA-RR; ≥ 50% PSA reduction) in all treated pts and pts with homologous recombination deficiency positive (HRD+) tumors, determined before enrollment. Secondary endpoints included radiographic progression-free survival (rPFS), overall survival (OS), and safety. **Results:** Of 88 treated pts, median age 66 yrs (range, 46–85), 34.1% had visceral metastases and 65.9% had measurable disease. Median follow-up was 11.9 mo. Pts had a median of 4.5 NIVO doses and 3.8 mo of rucaparib. The table summarizes primary and key secondary efficacy results, and shows better outcomes for HRD+ vs HRD–/not evaluable (NE) tumors. In pts with *BRCA2* mutations, confirmed ORR was 37.5% (3/8 pts) and confirmed PSA-RR was 45.5% (5/11 pts). Any-grade treatment-related AEs (TRAEs) occurred in 93.2% of pts, most commonly nausea (40.9%) and fatigue (33.0%). Grade ≥ 3 TRAEs occurred in 54.5% of pts, most commonly anemia (20.5%) and neutropenia (10.2%). TRAEs led to discontinuation in 27.3% of pts. One pt had a stroke, considered related to rucaparib by the investigator, after 28 days on rucaparib and 2 NIVO doses and died 2 months later due to post-thrombolysis hematoma. **Conclusions:** NIVO + rucaparib is active in pts with HRD+ post-CT mCRPC, although the trial design and short follow-up limit assessment of benefits of the combination vs individual components. Pts with HRD– tumors did not appear to benefit from either drug. No new safety signals were observed with NIVO + rucaparib. Additional biomarker analyses are ongoing. Clinical trial information: NCT03338790. Research Sponsor: Bristol Myers Squibb.

The impact of prior radiation therapy on outcome in a phase 2 trial combining sipuleucel-T (SipT) and ipilimumab (Ipi) in patients (pts) with metastatic castration resistant prostate cancer (mCRPC). *First Author: Li Zhang, University of California San Francisco, San Francisco, CA*

Background: SipT is an FDA-approved autologous cellular immunotherapy targeting Prostatic Acid Phosphatase (PAP) that improves survival in patients with mCRPC. Combining immunotherapies could provide opportunities to enhance efficacy. We performed a randomized phase II trial adding CTLA-4 blockade with Ipi following SipT treatment and assessed whether timing of this sequence could modify immune and/or clinical responses to this treatment. **Methods:** Fifty chemotherapy-naïve mCRPC pts were randomized to receive ipi (4 doses of 3mg/kg every 3 weeks) either immediately (n = 24) or 3 weeks (n = 26) following completion of sipT. Blood was collected at various time points of the study. Immune-related adverse events (irAE) were recorded. The primary endpoint was to determine the proportion of pts who achieved an antibody titer of ^{3}1:400 to PA2024, the targeting cassette in SipT and/or PAP. Clinical response was defined as ^{3}30% reduction in serum prostate specific antigen (PSA) compared to pre-treatment levels. Radiographic progression-free survival (rPFS) and overall survival (OS) were defined as from the date of randomization to the date of radiographic progression and the date of death, respectively, or last follow-up date. Luminex assays for anti-PAP and anti-PA2024 specific serum IgG and ELISpot for IFN-g production against PAP and PA2024 were used to assess antigen-specific B and T cells responses, respectively. Modulation of circulating immune cells was evaluated by CyTOF. **Results:** SipT + Ipi did not induce any unexpected irAEs. The timing of Ipi did not significantly alter the rates of clinical response, rPFS, OS, toxicity, nor antigen-specific B and T cell responses. Clinical responses were observed in 6 of 50 (12%) pts and were often durable (median 140 days, range 55-689 days). Pts experiencing irAEs were more likely to have a PSA response (P = 0.001). The median rPFS was 5.7 months (mos). The median OS was 31.9 mos. This treatment induced antibody and T cell immune responses irrespective of treatment arm. Single cell assessment bt CyTOF demonstrated that treatment induced CD4 and CD8 T cell activation that was more pronounced with the immediate schedule. Lower frequencies of CTLA-4 positive circulating T cells were associated with better clinical outcomes even at baseline. Lower frequencies of CTLA-4 positive T cells was associated with prior radiation therapy. Prior radiation treatment was associated with improved rPFS (6.5 vs. 3.9 mos, P = 0.004). **Conclusions:** These findings suggest that pre-existing immunity may help dictate responsiveness to Ipi and SipT combination immunotherapy in mCRPC pts. Prior radiation therapy seems to leave not only a lasting impression on the T cell compartment, but also can associate with improved clinical outcomes with subsequent immunotherapy. Clinical trial information: NCT01804465. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company, Prostate Cancer Foundation.

ODENZA: A French prospective, randomized, open-label, multicenter, cross-over phase II trial of preference between darolutamide and enzalutamide in men with asymptomatic or mildly symptomatic metastatic castrate-resistant prostate cancer (CRPC). *First Author: Emeline Colomba, Cancer Medicine Department, Gustave roussy Paris Saclay University, Villejuif, France*

Background: Darolutamide (Daro) and enzamutamide (Enza) are both next generation androgen receptor inhibitors with demonstrated activity in men with CRPC. Although both agents are associated with survival improvement, their toxicity profiles are different. To help decipher whether this may impact on patient preference, we designed the ODENZA trial. **Methods:** ODENZA is a prospective, randomized, open-label, multicenter, cross-over, phase II trial of preference between Daro and Enza in men with asymptomatic or mildly symptomatic metastatic CRPC. Patients were randomized 1/1 to receive Daro 1200 mg/d for 12 weeks followed by Enza 160 mg/d for 12 weeks (Daro-Enza arm) or the reverse sequence (Enza-Daro arm). In both arms, the second treatment was given in absence of evidence of cancer progression at week 12. The primary endpoint was patient preference between the two drugs, as assessed by a questionnaire at week 24. The Prescott's test was used to determine treatment preference in patients fullfilling pre planned criteria (exposure to both treatments, no progression at week 12, and completion of the preference questionnaire). A p-value greater than 0.05 indicates that there is no difference in preference between treatments. Stratification factors were performance status and prior taxane for mCSPC. After week 24, patients went on to an extension period during which they received the chosen treatment until progression or toxicity. The main secondary objectives included reasons for preference, response at week 12, cognitive assessment, and toxicity. **Results:** Overall 249 pts were randomized, median age 72y (68; 79), ECOG PS 0 (56%), prior taxanes (22%). Two hundred pts fulfilled the pre-planned criteria for evaluation of the preference primary endpoint : 97 (48.5% [41.3;55.7]), 80 (40.0% [33.0;47.0]), and 23 (11.5% [6.8;16.2]) chose Daro, Enza, and had no preference, respectively (unilateral p-value of 0.92). After preference assessment, 186 patients entered the extension period: 103 (55.4%) and 83 (44.6%) received Daro and Enza respectively. The most common factors influencing patient preference all numerically favored Daro over Enza, without significant differences were: less fatigue (44% vs 29%), ease of taking the medication (37% vs 31%), better quality of life (36% vs 28%), ability to be more active (26% vs 15%), ability to concentrate (22% vs 15%) and less falls (6% vs 3%). A PSA50 response was achieved in 76.2% and 83.9% at week 12 with Daro and Enza respectively (p = 0.13). Fatigue was the most frequently reported all grade adverse event at week 12, in 21% and 36% with Daro and Enza, respectively. **Conclusions:** More patients with early mCRPC preferred Daro over Enza, although the difference did not reach significance, with fatigue as the key influencing factor. Clinical trial information: NCT03314324. Research Sponsor: ODENZA.

5047 **Poster Session**

Talazoparib (TALA), an oral poly (ADP-ribose) polymerase (PARP) inhibitor for men with metastatic castration-resistant prostate cancer (mCRPC) and DNA damage response (DDR) alterations: Detailed safety analyses from TALAPRO-1 trial. *First Author: Niven Mehra, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: PARP inhibitors have recently been approved for the treatment of mCRPC. In this Phase 2 study, we explore the safety profile of TALA in men with mCRPC with the aim of understanding how patients (pts) with adverse events (AEs) were managed during the trial. **Methods:** TALAPRO-1 (NCT03148795) is a single-arm, open-label, phase 2 study of TALA in pts with progressive mCRPC, measurable soft tissue disease, and DDRm likely to sensitize to PARPi (*ATM, ATR, BRCA1/2, CHEK2, FANCA, MLH1, MRE11A, NBN, PALB2, RAD51C*), who received ≥1 taxane-based chemotherapy and progressed on ≥1 novel hormonal therapy (enzalutamide/abiraterone). The primary objective was confirmed objective response by central independent review; the assessment of safety included AEs, incidence of dose modifications and of permanent treatment discontinuation due to AEs, and clinical laboratory tests. **Results:** In the TALA-treated population (1 mg/daily; n=127), 95.3% (121/127) experienced all-causality AEs. The most common (≥15%) hematologic AEs were anemia (any grade, 48.8%; G3, 30.7% [no G4 events]), thrombocytopenia (all grade, 18.9%; G3/4, 8.7%), and neutropenia (all grade, 16.5%, G3, 7.9% [no G4]). Median time from first dose of TALA to onset of first episode of G≥3 anemia, neutropenia, and thrombocytopenia was 56, 48, and 17 days, respectively. G3 anemia lasted a median of 7 days, G3 neutropenia lasted a median of 12 days, G3 and G4 thrombocytopenia lasted a median of 8 and 11 days, respectively. Hematologic AEs typically occurred during the first 4–5 months of TALA treatment and were managed by dose modifications and supportive care. 34.6% of pts received a blood transfusion product, and most transfusions occurred when hemoglobin was between 7.0–10.0 g/dL. Overlapping G3/4 hematologic AEs were infrequent on TALA (anemia + neutropenia 4.7%; anemia + thrombocytopenia 5.5%; neutropenia + thrombocytopenia 1.6%). In pts who had anemia, 12.6% also had fatigue; in those with thrombocytopenia, 4.7% had a subsequent bleeding event; in those with neutropenia, 1.6% had an overlapping infection. The most common non-hematologic AEs (≥15%) were nausea (any grade, 33.1%; G3/4, 2.4%), decreased appetite (any grade, 28.3%; G3/4, 3.1%), and asthenia/fatigue (any grade, 23.6%/19.7%; G3/4, 3.9%/1.6%). In the treated population, dose reduction of TALA due to all-causality AE occurred in 33 pts (26.0%). Treatment discontinuation due to all-causality AEs was low and occurred in 15 pts (11.8%); the most frequent (≥2 pts) AEs leading to discontinuation of TALA were back pain and platelet count decrease (each, 1.6% [2/127 pts]). There were no treatment-related deaths. **Conclusions:** A manageable safety profile and durable antitumor effects were observed with TALA in men with heavily pretreated mCRPC in this phase 2 study. Clinical trial information: NCT03148795. Research Sponsor: Pfizer.

Association of plasma tumor DNA (ptDNA) with increased risk of venous thromboembolism (VTE) in metastatic castration resistant prostate cancer patients (mCRPC). *First Author: Vincenza Conteduca, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRCCS, Italy, Meldola, MA, Italy*

Background: Cancer is a risk factor for VTE. In mCRPC, ptDNA is an independent predictor of outcome (*Romanel, Sci Transl Med 2015; Conteduca, Br J Cancer 2020*). We firstly aimed to investigate the association between ptDNA and VTE in mCRPC men treated with androgen receptor signaling inhibitors (ARSI) **Methods:** This prospective biomarker study included mCRPC patients treated with abiraterone and enzalutamide from April 2013 to December 2018. We excluded patients with a previous VTE history and/or ongoing anticoagulation. Targeted next-generation sequencing was performed to determine ptDNA fraction from pre-treatment plasma samples. Assessment of VTE risk based on survival analysis was performed using cumulative incidence function and estimating sub-distributional hazard ratio (SHR) **Results:** Median age of 180 enrolled patients was 74 years (range 42-90). Of these, 60 (33.3%) were chemotherapy-naive. At a median follow-up of 58 months (range 0.5-111.0), 21 patients experienced VTE (venous thrombosis and/or pulmonary embolism) with a cumulative incidence of VTE at 12 months of 17.1% (95% CI 10.3-23.9). Before starting ARSI, ptDNA fraction above median value of 0.175, presence of visceral metastasis (mets), prior chemotherapy and serum lactate dehydrogenase (LDH) were significantly associated with higher incidence of VTE compared with patients with no thrombosis (12-month estimate, 18.6 *vs* 3.5%, P=0.0003; 44.4 *vs* 14.8%, P=0.015; 24.7 *vs* 4.5%, P=0.006; and 30.0 *vs* 13.5%, P=0.050, respectively). In the multivariate analysis (Table) including baseline ptDNA level, visceral, liver and lung mets, number of lesions, LDH, high ptDNA fraction was the only independent factor associated with the risk of thrombosis (HR 5.78, 95% confidence interval [CI] 1.63-20.44, P=0.006). All these patients received anticoagulant therapy for VTE. No ARSI discontinuation and VTE-related death were reported, and no significant difference in progression-free/overall survival was observed in mCRPC patients with and without VTE. **Conclusions:** These results suggest that baseline ptDNA fraction in mCRPC patients treated with ARSI is associated with increased risk of VTE. These patients may be followed up more closely for the risk of VTE and the need for a primary thromboprophylaxis should be taken into account in mCRPC with elevated ptDNA concentration. Validation of these findings in larger multicenter trials is warranted. Research Sponsor: None.

Multivariable analysis of risk factors associated with VTE events.

	SHR (95% CI)	p
ptDNA fraction (high *vs* low)	5.78 (1.63-20.44)	0.006

Circulating tumor DNA fraction (ctDNA%) to independently predict for clinical outcomes in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Corinne Maurice-Dror, BC Cancer, Vancouver, BC, Canada*

Background: CtDNA% (the tumour-derived proportion of cell-free DNA (cfDNA)) is abundant in >60% of mCRPC pts and associates with adverse clinical prognostic factors. However, prognostic associations have not been comprehensively tested across clinical contexts. We evaluated the utility of ctDNA% as an independent prognostic biomarker in patients with mCRPC prior to first-line (1L) therapy. **Methods:** 410 treatment-naïve mCRPC pts had blood samples drawn prior to 1L therapy and followed prospectively for outcomes. Plasma cfDNA was subjected to deep targeted sequencing and ctDNA% was calculated using validated methods (Annala, *Cancer Discov*, 2018). Overall survival (OS), PSA progression free survival (PSA PFS) and PSA declines ≥50% from baseline (PSA50 response rate (RR)) were stratified by ctDNA% and compared using Kaplan--Meier and Cox proportional hazards analysis. **Results:** Median age was 73 yrs. (range 45-98), the majority of pts had ECOG PS 0-1 (78%) and 9.5% had liver metastases at baseline. The most common 1L therapy employed was androgen receptor pathway inhibitors (90%). Median follow-up was 21 mo. (range 1-75) and median ctDNA% was 4.9% (range: 0-89%). Stratifying patients into high ctDNA (>30%) and Low ctDNA (≤2%) groups showed stronger association with OS and PSA PFS than grouping by median (Table). In a univariate comparison to pts with low ctDNA (≤2%), pts with high ctDNA% (>30%) had significantly shorter median PSA PFS, median OS and a lower PSA50 RR (Table). In a multivariable adjustment for clinical prognostic factors and cfDNA concentration, high ctDNA% remained strongly associated with OS (HR= 3.3, 95%CI: 2.1-5.3, p<0.001) and PSA PFS (HR: 3.7, 95%CI: 2.4-5.9, p<0.001). Although ctDNA% and total cfDNA concentration were correlated (R^2=0.55), association with OS was stronger for ctDNA% than cfDNA concentration (stratified at median; HR: 2.9 (2.3-3.7), p<0.001 vs HR: 2.1 (1.7-2.6), p<0.001). **Conclusions:** In a large cohort of treatment-naïve mCRPC pts, ctDNA% prior to 1L treatment provided strong prognostic information independent of known clinical factors. These data further demonstrate the multipronged clinical utility of ctDNA-based profiling for actionable genomic alterations. Research Sponsor: BC Cancer Foundation, Other Foundation.

Outcomes.

	ctDNA ≤2% (n =169)	ctDNA >30% (n = 89)	ctDNA ≤ median (n = 208)	ctDNA > median (n = 202)

An open-label, pharmacokinetic study to determine the bioavailability, safety and tolerability of single dose oral docetaxel in metastatic prostate cancer (mPC) patients treated with IV docetaxel. *First Author: Christopher G. C. A. Jackson, Dunedin Hospital, Dunedin, New Zealand*

Background: Docetaxel has poor oral bioavailability in part due to extrusion by intestinal p-glycoprotein. To improve IV solubility, it is fomulated with the nonionic surfactant polysorbate 80, requiring steroid premedication to manage hypersensitivity type reactions. Oral administration has the potential to improve tolerability, reduce day-stay utilization and improve patient convenience and allows investigation of alternative dosing schedules. Oradoxel is a new combination of oral docetaxel capsules plus the novel gut-selective P-glycoprotein inhibitor encequidar (HM30181A). **Methods:** Patients with mPC receiving IV docetaxel were enrolled in 3 cohorts with a dose escalation schedule of Oradoxel 75 mg/m^2 in Cohort 1, 150 mg/m^2 in Cohort 2, 300mg/m^2 in Cohort 3. Oradoxel was given 3 weeks before or after IV docetaxel treatment. Intensive PK samples were taken on days 1-5 for Oradoxel and days 1-4 for IV docetaxel. Dose limiting toxicity (DLT) or serious adverse events (SAE) were assessed per CTCAE v4.03. **Results:** 3 evaluable patients in each Cohort were studied. No DLT, MTD, or drug-related SAE were observed. PK parameters of Oradoxel vs IV docetaxel are summarized in the table below. Mean absolute bioavailability of Oradoxel was 15.9% (range 8-25%). PK became non linear at 300mg/m^2. **Conclusions:** Oradoxel was well tolerated. Based on the results of this and related studies, Oradoxel 300mg/m^2 in divided doses is being further evaluated in phase 2 studies. Clinical trial information: 12616000983404. Research Sponsor: Athenex.

Indirect treatment comparison of the efficacy of olaparib 300 mg tablets BID and cabazitaxel 25 mg/m^2 every 3 weeks plus daily prednisolone and granulocyte colony-stimulating factor in the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Tim Reason, Estima Scientific, London, United Kingdom*

Background: In PROfound, olaparib demonstrated improved radiological PFS (rPFS) and overall survival (OS) versus new hormonal agent (NHA) in patients with homologous recombination repair mutated (HRRm) mCRPC that had progressed on prior NHA. This efficacy was observed across prespecified subgroups including patients treated with prior taxane therapy and for whom intravenous cabazitaxel is an alternative treatment option. The relative efficacy of olaparib versus cabazitaxel has not been assessed in head-to-head studies. An indirect treatment comparison (ITC) was performed to simulate the comparative efficacy of olaparib and cabazitaxel in patients with HRRm mCRPC after prior taxane and NHA. **Methods:** Fixed-effects frequentist ITCs were conducted using efficacy data from the prior taxane subgroup of PROfound (NCT02987543) and published data from the Phase IV CARD study of cabazitaxel versus NHA after prior NHA and taxane treatment (NCT02485691). Baseline variables feasible for comparison across studies were assessed for effect modification. Efficacy analyses were performed on the hazard ratios (HR) of rPFS by independent central review and OS. The OS analysis was performed using the final PROfound OS results, which included switching from NHA to olaparib after progression, and using results that were adjusted for switching. In the absence of biomarker subgroup data, the efficacy results of the overall population in CARD were assumed generalizable to the HRRm biomarker population of PROfound, such that mutation status is not a modifier of relative treatment effect for cabazitaxel versus NHA. Results were presented for the comparison of olaparib with cabazitaxel in the BRCA1-/BRCA2-mutated (BRCAm) and BRCAm/ATM populations. **Results:** The ITC HR for rPFS was 0.36 (95% confidence interval 0.20–0.64) in BRCAm and 0.51 (0.31–0.84) for the BRCAm/ATM population. Without adjustment for switching in PROfound, the ITC HRs for OS in the BRCAm population and BRCAm/ATM population were 0.99 (0.55–1.78) and 0.88 (0.52–1.47), respectively; after switch adjustment, the OS HRs were 0.47 (0.12–1.79) and 0.44 (0.17–1.10), respectively. **Conclusions:** The ITC results suggest that olaparib is associated with significantly improved rPFS versus cabazitaxel in the treatment of BRCAm and BRCAm/ATM patients who have progressed on taxane and NHA therapy. After removing the effect of switching from NHA to olaparib in PROfound, olaparib appears associated with a non-significant OS improvement versus cabazitaxel in both populations. The results require confirmation in comparative studies. Analysis limitations include uncertainty over the efficacy of cabazitaxel versus NHA in HRRm mCRPC patients, and heterogeneity in prior taxane and NHA therapy. Clinical trial information: NCT02987543. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

A phase II study evaluating the efficacy of enzalutamide and the role of ARv7 in metastatic castration-resistant prostate cancer (mCRPC) patients (pts) with visceral disease. *First Author: Pierangela Sepe, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Enzalutamide is a second-generation androgen receptor inhibitor that showed to prolong survival in different setting of prostate cancer. Visceral metastases, occurring in 10–30% of mCRPC pts, have been associated with poor outcomes. Given the poor prognosis, trial investigating hormone therapies often excluded men with visceral disease, especially in the pre-docetaxel setting. To date, there are no prospective studies designed ad hoc to test hormone therapies in this subgroup of pts. **Methods:** In this open label phase II multicentre study mCRPC pts with visceral metastases were treated with enzalutamide 160 mg orally once daily as first or second line after docetaxel until progressive disease or unacceptable toxicity. Pts were eligible if they had documented measurable metastatic visceral disease (according to RECIST 1.1 criteria), including lesions in lung or liver or extraregional lymphnodes. Pts must have PSA progression or radiographic progression (according to PCWG2). Primary endpoint was to determine the clinical benefit, as measured by 3-months (mo) disease control rate (DCR) defined as the proportion of pts with best overall response of confirmed complete (CR) or partial responses (PR) or stable disease as per RECIST 1.1 at mo 3. Secondary endpoints were safety, quality of life (assessed by EQ-5D-5L e FACT-P questionnaire), pain assessment (by BPI-SF questionnaire). Exploratory objectives were to assess the association between ARv7 splicing variants (in CTCs samples) and treatment response/resistance. For CTC and ARv7 detection, we used the Adna test Prostate Cancer Panel. **Results:** From March 2017 through January 2021, 68 pts were enrolled at 6 Italian centres. One pt never started treatment because of withdrawal of consent. Median age was 70 years (IQR 65- 78). All pts presented with visceral disease at baseline: 27, 6, 55 pts presented with lung, liver and lymphnodes lesions, respectively. 26 pts presented with only one metastatic site, 22 pts with two, while the remaining part with multiple sites. 15 pts received a previous treatment with docetaxel in the mCRPC phase. The median follow-up was 10 mo. The median time on treatment was 8 mo. At mo 3, 24 pts presented a stable disease, 1 pt achieved a confirmed CR and 20 pts a PR for a 3 mo-DCR of 67% (45/67). Discontinuations due to adverse-events, disease-related death, or disease progression occurred in 6%, 7%, and 40% of pts, respectively. So far, only 26 patients were evaluated for baseline CTC and ARv7. Interestingly, 75% of patients experiencing a progression at month 3 were classified as ARv7 positive at baseline. **Conclusions:** The study met its primary endpoint showing enzalutamide is an active treatment option for men with mCRPC and visceral disease in both pre or post-docetaxel setting. CTCs status combined with ARv7 detection could be useful to personalize treatments. Clinical trial information: NCT03103724. Research Sponsor: Astellas.

Immunogenic priming with ^{177}Lu-PSMA-617 plus pembrolizumab in metastatic castration resistant prostate cancer (mCRPC): A phase 1b study. *First Author: Rahul Raj Aggarwal, University of California, San Francisco, San Francisco, CA*

Background: Immune checkpoint inhibitors have limited single agent activity in microsatellite-stable mCRPC. ^{177}Lu-PSMA-617 (Lu) is a PSMA-targeting radioligand therapy that has demonstrated promising anti-tumor activity. We sought to determine whether a single dose of Lu can induce an immunogenic priming effect to improve outcomes of men with mCRPC subsequently treated with pembrolizumab (P). **Methods:** We undertook a phase 1b, single arm trial enrolling chemotherapy-naïve mCRPC patients (pts) with progression (PD) on at least one prior androgen signaling inhibitor (NCT03805594). Pts were required to have $\geq$ 3 PSMA-avid lesions on ^{68}Ga-PSMA-11 PET and measurable disease by RECIST 1.1 criteria. No genomic selection was undertaken. Pts were enrolled sequentially on one of three schedules: A) Single dose of Lu (7.4 GBq) followed by initiation of P (200 mg IV q 3 weeks) 28 days later; B) Lu x 1 dose given concomitantly with first P administration; C) Lu x 1 dose given on C2D1 following initiation of P on C1D1. Pts were treated with P until confirmed radiographic or clinical PD. The primary endpoint was safety; key secondary endpoints included PSA response, objective response rate by RECIST 1.1 criteria (ORR), median duration of response (DOR), and radiographic progression-free survival (rPFS). **Results:** 18 pts were enrolled, 6 per schedule. The median age was 64 (range 51 – 80) and 44% of pts had visceral metastases. The median baseline number of PSMA-avid metastatic lesions was 20 (range 6 – 50+). Six pts (33%) had progressed on prior abiraterone, 4 (22%) on enzalutamide, and 8 (44%) on both. There were no dose-limiting toxicities and one Grade $\geq$ 3 treatment-related adverse event (AE) (inflammatory arthritis, schedule B). There were no grade $\geq$ 3 hematologic AEs. The ORR was 8/18 (44%) and median DOR has not been reached (range 1.9+ – 15.9+ months). Four pts (2 on schedule A, 1 on schedule B, 1 on schedule C) with durable partial responses remain on study treatment for 5.4+, 8.9+, 9.2+, and 17.8+ months, respectively. The median rPFS was 6.5 months (95% CI: 2.5 – 9.8). PSA30, PSA50, and PSA90 response rates were 44%, 28%, and 17%, respectively. Fourteen pts (78%), including all durable responders, had somatic genomic data available. One (7%) harbored a DNA repair mutation (*BRCA1*, non-responder), none were MSI-high, and all carried low tumor mutational burden ($\leq$ 5 mutations/MB). Single cell sequencing of the immune microenvironment from paired metastatic tumor biopsies is underway. **Conclusions:** ^{177}Lu-PSMA-617 as a priming dose followed by pembrolizumab was well tolerated and leads to durable responses in a subset of mCRPC without high mutational burden or microsatellite instability, suggesting a possible immunogenic priming effect of radioligand therapy. Further evaluation of the combination is ongoing in a phase 2 study. Clinical trial information: NCT03805594. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Philanthropic gift - Gene and Ethel Daly.

Using real-world outcomes to evaluate the predictive power of tissue-assessed genomic biomarkers for taxane versus novel hormonal therapy (NHT) outcomes in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Ryon Graf, Foundation Medicine, Cambridge, MA*

Background: No established genomic biomarkers exist for guiding treatment decisions between novel hormonal therapy (NHT) vs taxane chemotherapy in mCRPC. However, specific alterations in *AR* have been associated to decreased responsiveness to NHT in this setting. Leveraging routine comprehensive genomic profiling (CGP) testing of mCRPC tissue samples, we hypothesized that patients (pts) with *AR* amplification (*AR*amp) would have better outcomes on taxanes over NHT. **Methods:** Pts were selected from Flatiron Health (FH)-Foundation Medicine (FMI) clinico-genomic database (CGDB), a nationwide deidentified electronic health record database linked to CGP. Data originated from approximately 280 US cancer clinics (~800 sites). CGP results (including analysis of *AR* and 15 other genomic biomarkers) were obtained from mCRPC tumor tissue collected up to 180 days before or 30 days after initiation of new systemic therapy between 1/1/11 - 6/30/20, and linked to PSA response, time to next therapy (TTNT) and overall survival (OS). Multivariable treatment interaction models were adjusted for drug assignment imbalances (line of therapy, prior NHT or taxane use, PSA, alkaline phosphatase, hemoglobin, albumin, years to CRPC, biopsy site) using inverse probability of treatment weighting via propensity scores. **Results:** Among 5754 evaluable mCRPC lines of therapy, 180 receiving NHT and 179 receiving taxanes met inclusion criteria, 359 total from 308 unique patients. Pts with *AR*amp vs no *AR*amp on NHT had worse PSA response (median +57.3% vs. -31.4%, p = 0.002), TTNT (HR: 2.03, p $<$ 0.001), and OS (HR: 2.28, p $<$ 0.001), but had no difference in outcomes on taxanes. Multivariable interaction Cox models found *AR*amp independently associated to better TTNT on taxanes vs. NHT (HR: 0.48, p = 0.010), similar to pts with *RB1* alterations (HR: 0.46, p = 0.027). Consistent treatment interactions were seen with OS for *AR*amp (HR: 0.53, p = 0.025) and *RB1* (HR: 0.32, p = 0.024). While *CDK12* was not predictive, it independently associated with worse OS overall (HR: 2.25, p = 0.0011). In the 55 pts who received NHT followed by taxane immediately after, *AR*amp pre-NHT was associated with better TTNT on the subsequent taxane than on the initial NHT (HR: 0.40, p = 0.028). Of these, 33 had PSA responses evaluable, and *AR*amp pre-NHT was significantly associated with better PSA decline on the subsequent taxane, despite disadvantage of first progressing on NHT (OR: 10.9, p = 0.021). **Conclusions:** Genomic biomarkers routinely identified with CGP such as *AR*amp may aid in identifying mCRPC pts who are to obtain greater benefit from taxane chemotherapy instead of NHT. Prospective efforts are needed to further validate the utility of CGP for assisting treatment decisions for mCRPC patients. Research Sponsor: Foundation Medicine.

Long-term adverse events (AE) in patients with metastatic castration-resistant prostate cancer (mCRPC) receiving prostate-specific membrane antigen (PSMA)-based targeted radionuclide therapy (TRT). *First Author: Michael Sun, Weill Cornell Medicine, New York, NY*

Background: PSMA-TRT is a promising investigational treatment for patients with mCRPC. Expected short-term toxicities associated with PSMA-TRT include dose-dependent myelosuppression and xerostomia. However, there is a lack of information regarding long-term effects of PSMA-TRT on marrow, renal, and liver function. Additionally, potential organ dose limits for radiation are derived from studies of external beam radiation, which may not be applicable to TRT. **Methods:** Men treated on prospective clinical trials of PSMA-TRT, from 2003 through 2020 with at least six months of follow-up were included. Variables included treatment, co-morbidities, baseline and most recent renal, liver, and marrow function, along with respective short-term ($<$ 6 months) and long-term toxicities. AEs were graded using CTCAE version 5 and attribution was assessed with most recent clinical follow up. Multivariable logistic regression was used to control for type of TRT, comorbidities, and subsequent therapies. **Results:** 71 (59.7%) patients who received 177Lu-J591, 30 (25.2%) 177Lu-PSMA-617, 11 (9.2%) 225Ac-J591, and 7 (5.9%) 90Y-J591 were included, with median follow up 18 months (range 6-133). Long-term (most recent) laboratory values and AEs are summarized in the table. A majority of AEs were attributed to alternate etiologies. 5 of 14 cases of grade (Gr) $\geq$2 creatinine increase, 3 of 36 cases of Gr $\geq$2 platelets, 2 of 14 cases of Gr $\geq$2 bilirubin, 1 of 15 cases of Gr $\geq$2 AST increase, and 1 of 5 cases of Gr $\geq$2 ALT increase were deemed possibly related to PSMA-TRT. Only two Gr $\geq$3 AEs were attributed to possibly being related to PSMA-TRT: one case of Gr 4 creatinine elevation and one case of Gr 3 ALT elevation. On multivariable analysis, alpha-TRT was associated with hepatic AEs (OR 4.38, p = 0.047), and there was a trend towards higher Charlson Comorbidity scores associating with hematologic AEs (OR 1.27, p = 0.095). **Conclusions:** This is the largest analysis to-date of long-term AEs in patients who have received PSMA-TRT. Long-term effects on renal, liver, and marrow function are infrequent. Research Sponsor: Weill Cornell Medicine, Other Foundation, Other Government Agency, U.S. National Institutes of Health.

VERU-111, an oral cytoskeleton disruptor, to treat men with metastatic castration-resistant prostate cancer (mCRPC) who failed an androgen receptor targeting agent. *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: VERU-111 is an oral cytoskeletal disruptor that disrupts microtubules supporting the cytoskeleton and has no affinity for multidrug resistance proteins. A phase 1b/2 clinical study has been conducted to establish the maximum tolerated dose (MTD) and evaluate the preliminary efficacy in men with mCRPC also resistant to androgen receptor targeting agents. **Methods:** In the phase 1b component of the study, a 3+3 design with escalating oral dosing of 4.5 mg to 81 mg (7 days on drug/14 days off per 21-day cycle) was utilized. The schedule was also expanded to continuous dosing/cycle. The phase 2 portion utilized 63 mg daily dosing to evaluate efficacy in approximately 40 taxane-naïve men with mCRPC that have failed at least one androgen receptor targeting agent. **Results:** In the phase 1b portion of the study, 30 taxane-naïve men with mCRPC and a median age of 76 (61-92) were enrolled. 8 had received prior enzalutamide, 12 abiraterone and 10 both. 8 men had bone mets, 5 lymph node, 5 mixed and 1 had soft tissue metastases at study entry. The MTD of VERU-111 is 72mg (3/11 men had grade 3 diarrhea) and the recommended phase 2 dose is 63mg. Grade 3 diarrhea was not observed at doses $\leq$ 63mg per day and the most common non-dose limiting AEs were mild to moderate nausea, vomiting, diarrhea, and fatigue, with no observed neurotoxicity or neutropenia. Efficacy was assessed by PSA and bone/CT scans. In men treated for $\geq$ 4 continuous 21-day cycles, 6/10 (60%) had PSA declines, 4(40%) men had $\geq$ 30% declines and 2(20%) $\geq$ 50% declines compared to their 21-day cycle baseline PSA. Median PFS is currently 12 months (6-23+ months) with 3 patients continuing on study, 2 of which have been on study for approximately 2 years. In patients receiving at least a single dose of $\geq$ 63 mg daily (n=19), objective tumor responses were seen in 3 men (16%). The median rPFS in these patients is currently 12.4 months. In the phase 2 portion of the study, 55% of the patients had bone only metastases, 11% had nodal only, 32% had mixed bone and nodal disease and 3% had visceral disease at study entry. 6/32 (19%) were previously treated with abiraterone alone, 12/32 (38%) with enzalutamide alone, and 14/32 (44%) had abiraterone in combination with enzalutamide, proxalutamide or apalutamide. The phase 2 portion of the study is ongoing and objective tumor responses have been observed including a CR and PRs and PSA decreases >50%. Patients have been on study as long as 9 months. **Conclusions:** This phase 1b/2 clinical trial, demonstrates that oral daily dosing of VERU-111 has a favorable safety profile and that chronic dosing is feasible. The recommended phase 2 dose of 63mg daily has significant durable antitumor activity. These data support a potential prominent role of VERU 111 for the treatment of men with mCRPC who previously failed an androgen receptor targeting agent and prior to the administration of intravenous chemotherapy. Clinical trial information: NCT03752099. Research Sponsor: Veru Inc.

Radiographic progression-free survival as a surrogate endpoint of overall survival in men with metastatic castrate-resistant prostate cancer. *First Author: Susan Halabi, Duke University Medical Center, Durham, NC*

Background: Radiographic progression-free survival (rPFS) is commonly used as a co-primary endpoint in randomized clinical trials in men with metastatic castrate-resistant prostate cancer (mCRPC). However, rPFS has not been established as a valid surrogate endpoint of overall survival (OS) in men with mCRPC. Here, we hypothesized that rPFS is a reliable surrogate for OS in mCRPC. We also explored whether PFS is a valid surrogate endpoint of OS at the aggregate trial level. **Methods:** We performed a systematic search of the literature encompassing the period January 2004-December 2020 using PubMed and clinical trials.gov to identify completed phase III trials in mCRPC post-docetaxel. Eligible trials had to be randomized phase III therapeutic trials that reported OS, PFS or rPFS. OS was measured from the date of random assignment to date of death from any cause or date of last follow-up. rPFS was defined as the time from random assignment to date of disease progression on CT and/or Tc bone scan per trial definition or death from any cause, whichever occurred first. PFS included PSA progression as a component of the composite endpoint. Trial level surrogacy was evaluated by fitting linear regression on the treatment effect of rPFS (or PFS) and OS (in other words, the weighted linear regression of the log(hazard ratio) of OS on the log(hazard ratio) of rPFS). It was pre-specified that rPFS would be considered a valid surrogate for OS if R^2 was 0·7 or higher. **Results:** We identified 33 in men with mCRPC post docetaxel approval. We assessed the association between PFS and OS in 29,456 patients from 30 trials. Overall, a moderate correlation was observed at the trial level between OS and PFS (R^2 = 0.46, 95 %CI = 0.20-0.68) in these trials. In 18 trials with 16,818 mCRPC patients where rPFS was considered as a key endpoint, a moderate correlation between the treatment effects on rPFS and OS was observed at the trial level (R^2= 0.65, 95% CI = 0.23-0.87). **Conclusions:** This meta-analysis demonstrates moderate correlation between treatment effects of rPFS and OS in patients with mCRPC. However, rPFS did not meet the pre-specified surrogacy threshold of 0.7. Clinical trial information: several. Research Sponsor: None.

Differences in the tumor genomic landscape between African Americans (AA) and Caucasians (CA) advanced prostate cancer (aPC) patients (pts) by comprehensive genomic profiling (CGP) of cell-free DNA (cfDNA). *First Author: Pedro C. Barata, Tulane Cancer Center, New Orleans, LA*

Background: Emerging data suggest differences in the tumor genomic profile of AA compared with CA men with aPC. We hypothesized that there will be significant differences in the tumor genomic landscape between AA and Ca pts as detected by cfDNA CGP. **Methods:** Pts with aPC and available cfDNA CGP by the Guardant (G360) 73 gene panel were included. In addition, G360 74 gene panel was used to identify CDK12 mutation (not detected in 73 gene panel) in an independent cohort of aPC pts. Barnard's test was used to evaluate the association between genetic mutation and gene. Genomic landscape was also compared by a Bayesian Network (BN) machine learning approach. **Results:** A total of 552 pts (125 AA, 427 CA) tested by G360 73 gene panel were included. Multiple genomic aberrations were enriched in AA patients (Table). In the independent cohort of 261 aPC patients (AA=106 pts, CA=155 pts) tested by G360 74 gene panel, *CDK12* mutation was significant enriched in AA pts. (9.4% vs. 1.9%, p=0.006). Machine learning analysis supported these results, and will be presented at the meeting. **Conclusions:** These hypothesis generating data suggest significant differences in the tumor genomic profile between AA and CA pts with aPC. Identification of molecular drivers of tumor progression enriched in AA pts may allow development of tailored systemic therapy for these men, and decrease disparities in disease related outcomes. Data need external validation. PB,RR,MAB contributed equally to this work. Research Sponsor: None.

First results from a randomized phase II study of cabazitaxel (CBZ) versus an androgen receptor targeted agent (ARTA) in patients with poor-prognosis castration-resistant prostate cancer (mCRPC). *First Author: Kim van der Zande, Netherlands Cancer Insitute, Amsterdam, Netherlands*

Background: In the OSTRICh trial, poor-prognosis mCRPC patients were randomized between CBZ and ARTA, following progression on docetaxel (DOC) treatment. **Methods:** The OSTRICh trial is an open label, multicenter, phase IIb study. Patients with poor-prognosis mCRPC (visceral metastases AND/OR < 12 months responsive to androgen deprivation AND/OR progressing during or within 6 months after DOC completion), were randomized 1:1 between CBZ (25 mg/m^2 IV Q3W and prednisone 2 d 5 mg PO) and ARTA (daily abiraterone 1000 mg and prednisone 2 d 5 mg PO OR enzalutamide 160 mg PO). Life prolonging therapy between DOC and randomization was not allowed. Primary endpoint was to establish the Clinical Benefit Rate (no radiotherapy, no ECOG PS increase $\geq$2, no change of therapy AND no radiological progression) at 12 weeks (CBR) in the study arms, while formal comparison of the CBR was a secondary endpoint. A Fisher Exact test was used to assess differences in rates and a log rank test to assess differences in progression free and overall survival. All time to event endpoints were estimated with the Kaplan-Meier method and censored at last follow-up. **Results:** A total of 106 patients were randomized, 53 in each arm. Baseline median age was 70 (IQR 67-75) years and PSA 79.4 (IQR 29.0 - 160) ng/ml. ECOG PS score was 0/1 in 99 (93%) and 2 in 7 (7%) patients. Al patients fulfilled the criteria for poor-prognosis disease. Thirty-six (34%) patients received DOC in the metastatic hormone sensitive stage, while 41 (39%) previously received ARTA. Twenty-six of 43 evaluable patients in the CBZ arm had clinical benefit at 12 weeks (CBR: 60%, 95% CI: 44%-75%) and 20 of 39 (CBR: 51%, 95% CI: 35%-68%) in the ARTA arm (p = 0.50). At 12 weeks, 30 of 34 (88%, 95% CI: 73% - 97%) patients in the CBZ arm and 24 of 36 (67%, 95% CI: 49% - 81%) patients in the ARTA arm had no radiological progression (p = 0.046). After a median follow-up of 16.4 months (95% CI: 13.6–27.8), a serum PSA decrease $\geq$50% from baseline was established in 12 (23%, 95% CI: 12% - 36%) and 26 (49%, 95% CI: 35% - 63%)(p = 0.008) patients treated with CBZ and ARTA, respectively. Median radiological progression free survival (rPFS) was 6.0 months (95%CI: 4.11-14.5) in the CBZ arm and 5.8 months (95% CI: 5.22-10.2) months in the ARTA arm (p = 0.5), while median overall survival (OS) was 15.3 months (95%CI 9.49-22.4) and 13.8 months (95%CI 11.7-16.4) in CBZ and ARTA treated patients, respectively (p = 0.8). Grade $\geq$3 adverse events (AEs) occurred in 15 (29%) and 8 (15%) of patients treated with CBZ and ARTA, respectively. **Conclusions:** No significant difference in CBR was established between CBZ and ARTA treated patients. However, at 12 weeks significantly more CBZ treated patients had no radiological progression, while $\geq$50% PSA response rates were higher in ARTA treated patients. Clinical trial information: NCT03295565. Research Sponsor: Sanofi.

TROP-2 co-expression with androgen receptor splice variants as a new therapeutic target in prostate cancer. *First Author: Charlotte Stahlfeld, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: Tumor-associated calcium signal transducer 2 (TROP-2, *TACSTD2*) is a transmembrane glycoprotein that is highly expressed in many epithelial cancers. Overexpression of TROP-2 is postulated to mediate cancer cell growth, invasion, and is associated with more aggressive disease. TROP-2 has emerged as a therapeutic target for antibody-drug conjugates in clinical trials including sacituzumab govitecan and DS-1062. Here, we evaluated the expression of TROP-2 in tumor biopsies and circulating tumor cells (CTCs) in men with metastatic castration resistant prostate cancer (mCRPC) to evaluate TROP-2 as a clinically relevant target. **Methods:** RNA-seq data from the SU2C-PCF database and PROMOTE clinical trial (NCT#01953640) was assessed for *TACSTD2* and androgen receptor (AR) splice variant (*AR_V7/AR_V9*) expression. Prostate cancer ChIP-seq data was analyzed to identify binding of the AR to the TROP-2 promoter. EpCAM and TROP-2 captured CTCs were isolated from patients with mCRPC using the VERSA (Versatile Exclusion-based Rare Sample Analysis) platform and assessed for splice variant, neuroendocrine (NE), and AR-regulated gene signatures, in addition to CTC enumeration and TROP-2 protein expression. **Results:** TROP-2 expression was detectable in 90% of patients, in both bone and visceral metastatic biopsies (SUC2-PCF). Although TROP-2 low biopsies were infrequent (10%), 58% of these samples showed high levels of NE markers, as compared with 5% in all other patients. In the PROMOTE study, elevated TROP-2 gene expression was significantly higher in biopsies with high *AR_V7* expression than in those with low ($p = 0.04$) or negative ($p < .01$) *AR_V7* expression. ChIP-seq data demonstrated binding of AR at the TROP-2 promoter as well as at a potential enhancer site upstream, suggesting that TROP-2 expression can be regulated by AR activity. Splice variants and NE gene signatures were expressed in CTCs captured with both EpCAM and TROP-2, although markedly different gene expression profiles between EpCAM and TROP-2 CTCs were observed in a subset of patients with neuroendocrine prostate cancer. Detection of *AR_V7* from TROP-2 CTCs corresponded to shorter overall survival in 20 patients with mCRPC. TROP-2 protein expression was identified on EpCAM captured CTCs, although patients exhibited a wide degree of both intra- and inter-patient heterogeneity. **Conclusions:** Our findings demonstrate that TROP-2 is highly expressed in mCRPC, and is reduced in a subset of patient tumors expressing neuroendocrine markers. In the PROMOTE clinical trial with abiraterone acetate, TROP-2 AR variant expression correlated with increased TROP-2 expression. Binding of the AR to the TROP-2 promoter and potential enhancer was observed in prostate cancer cell lines and biopsies. These results indicate TROP-2 is a high value a biomarker and therapeutic target mCRPC. Research Sponsor: Prostate Cancer Foundation, Other Government Agency, U.S. National Institutes of Health.

The national impact of the COVID-19 pandemic on U.S. prostate cancer community care. *First Author: Matthew R. Cooperberg, University of California-San Francisco, San Francisco, CA*

Background: We used data from a specialty-wide, community-based urology registry to determine trends in outpatient prostate cancer (PCa) care during the COVID-19 pandemic. **Methods:** 3,165 (~ 25%) of US urology providers, representing 48 states and territories, participate in the American Urological Association Quality (AQUA) Registry, which collects data via automated extraction from electronic health record systems. We analyzed trends in PCa care delivery from 156 practices contributing data in 2019 and 2020. Risk stratification was based on prostate-specific antigen (PSA) at diagnosis, biopsy Gleason, and clinical T-stage, and we used a natural language processing algorithm to determine Gleason and T-stage from unstructured clinical notes. The primary outcome was mean weekly visit volume by PCa patients per practice (visits defined as all MD and mid-level visits, telehealth and face-to-face), and we compared each week in 2020 through week 44 (November 1) to the corresponding week in 2019. **Results:** There were 267,691 PCa patients in AQUA who received care between 2019 and 2020. From mid-March to early November, 2020 (week 10 – week 44) the magnitude of the decline and recovery varied by risk stratum, with the steepest drops for low-risk PCa (Table). For 2020, overall mean visits per day (averaged weekly) were similar to 2019 for the first 9 weeks (~25). Visits declined to week 14 (18.19; a 31% drop from 2019), recovered to 2019 levels by week 23, and declined steadily to 11.89 (a 58% drop from 2019) as of week 44, the cut off of this analysis. **Conclusions:** Access to care for men with PCa was sharply curtailed by the COVID-19 pandemic, and while the impact was less for men with high-risk disease compared to those with low-risk disease, visits even for high-risk individuals were down nearly one-third and continued to fall through November. This study provides real-world evidence on the magnitude of decline in PCa care across risk groups. The impact of this decline on cancer outcomes should be followed closely. Research Sponsor: Verana Health.

Genomic landscape of *MSH6*-mutated clinically advanced castrate-resistant prostate cancer (mCRPC). *First Author: Gennady Bratslavsky, SUNY Upstate University Hospital, Bethesda, MD*

Background: Loss-of-function genomic alterations (GAs) in *MSH6* have been associated with a unique subtype of hypermutated mCRPC that is often microsatellite stable (MSS) and may occur in either a sporadic or familial Lynch Syndrome-like clinical setting. **Methods:** 5,617 mCRPC cases were sequenced to evaluate all classes of GA using a hybrid capture-based FDA-approved comprehensive genomic profiling (CGP) assay. Tumor mutational burden (TMB) was determined on 0.8 Mb of sequenced DNA and microsatellite instability high (MSI-High) was determined on 95 loci. MSI-low status was not assessed. **Results:** 78 (1.4%) mCRPC were *MSH6*^{mut} (Table). *MSH6*^{mut} mCRPC included 73.1% short variant mutations, 23.1% biallelic deletions, 2.6% genomic rearrangements, and 1.3% multiple GAs/sample. Co-mutation of *MSH2* was found in 28% of *MSH6*^{mut} cases vs. 2% in *MSH6*^{wt} cases ($P < .0001$) and was most frequently caused by biallelic co-deletion of both genes (73% of co-mutated cases). MSI-High status was present in 46% of *MSH6*^{mut} mCRPC, which was significantly greater than the 2% seen in *MSH6*^{wt} cases ($P < .0001$). An MMR single nucleotide mutational signature was observed in 65% of *MSH6*^{mut} cases, compared to 3% *MSH6*^{wt} cases ($P < .0001$). Among *MSH6*^{mut} cases with neither MSI-High nor MMR mutational signature, 87% did not have biallelic loss of *MSH6* or any other MMR gene, confirming that monoallelic pathogenic mutations are insufficient to cause the MMR-D phenotype. For subjects whose variants could be classified, 45% (19/42) of pathogenic *MSH6* alleles were germline; of these, 58% (11/19) had neither MSI-High nor an MMR single nucleotide signature. *MSH6*^{mut} cases had fewer *TMPRSS2:ERG* fusions ($P = .01$), but harbored significantly higher frequencies of GAs in *AR* ($P = .0002$), *ATM* ($P = .04$), *PIK3CA* ($P = .0003$), *APC* ($P = .005$), *ERBB2* ($P = .001$), and *CDK6* ($p = .046$), likely at least partially attributable to the higher TMB in *MSH6*^{mut} cases ($P < .0001$). **Conclusions:** *MSH6*^{mut} mCRPC is a unique disease that often features a hypermutated genomic signature, although only 46% of cases exhibited MSI-high status. This complex phenotype highlights the potential utility of multiple rather than single biomarkers to understand tumor biology and determine patients who may benefit from immunotherapy. Association of ATM mutations in metastatic prostate cancer with differential genomic alteration profiles from homologous recombination deficient and proficient tumors. *First Author: Charles J. Ryan, Division of Hematology, Oncology and Transplantation, Department of Medicine, University of Minnesota, Minneapolis, MN*

Background: ATM mutations, one of a family of DNA repair defects prevalent in prostate cancer, have been included in a list of actionable mutations for PARP inhibitor (PARPi) therapeutic trials. Despite preclinical evidence, PARPi have shown minimal clinical activity in ATM mutant prostate cancer (ATMmPCa). The present analysis explores co-occurring genomic alterations that may drive outcomes of metastatic PCa (mPCa) patients with tumors harboring ATM mutations and provide clues for understanding therapy resistance and potential targets. **Methods:** This study included molecular profiling analysis of 1375 cases of mPCa. Tumors were analyzed using next-generation sequencing (NGS), whole transcriptome sequencing (WTS), and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ). dMMR/MSI-H status was determined by IHC, NGS, and fragment analysis and tumor mutational burden (TMB) was calculated based on somatic nonsynonymous missense mutations. We performed differential gene expression analysis of HR-associated transcripts such as ATR, PARP1-3, RAD50, RAD51A/B/C/D and RAD54. Significance was determined using the χ^2 test and Benjamini-Hochberg method. **Results:** Fifty-nine (4.2%) cases harbored pathogenic ATM mutations, 84 (6.2%) harbored BRCA2 mutations. 1018 tumors (74%) were deemed homologous recombination proficient (HRP) and 155 tumors (11.3%) were HR Deficient (HRD); harboring one or more mutation in HR-related genes excluding ATM and BRCA2. The mutation rate of TP53 was significantly lower in ATMmPCa (12.0%) compared to BRCA2mPCa (35%), HRD (35%) and HRP (46.6%) tumors. ATMmPCa showed higher rates of SMAD2 (3.7%/1%) and FLCN (5.2%/0.3%) alterations compared to HRP cases. PARP1 and RAD51D gene expression was reduced in ATMmPCa compared to HRP ($p < 0.05$) and BRCA2mPCa ($p < 0.05$) tumors, respectively. No differences in gene expression levels were detected for ATR, PARP2, PARP3, RAD50, and RAD54. Chromosomal segments demonstrating differential CNA in ATMmPCa vs HRP, HRD, or BRCA2mPCa included FGF19, FGF4, PTPN11, ALDH2, DAXX, BCL7A, CCND1, BMPR1A and MEF2B (Q-value < 0.05 determined by χ^2). The most common CNA in ATMmPCa was CCND1, present in approximately 13% (7/55) of cases. Compared to BRCA2mPCa and HRD cases, ATMmPCa cases are less likely to display markers of immunotherapy response such as dMMR/MSI-H or TMB ≥10 mutations/MB. **Conclusions:** ATMmPCa demonstrated several differences in co-occurring alterations compared to BRCA2mPCa, HRD and HRP mPCa. ATMmPCa tumors were less likely to harbor alterations in TP53 compared to BRCA2, HRD or HRP tumors. CNA in ATMmPCa occurred in 9 genes across distinct mPCa molecular subtypes and were enriched for those associated with the 11q13 amplicon harboring Cyclin D1. The FGF and PTPN11 related pathways are potentially targetable pathways in ATMmPC and may merit further study. Research Sponsor: None.

PSMA-PET/CT Registry for Recurrent Prostate Cancer (PREP): Initial findings from a single center. *First Author: Anil Kapoor, McMaster University Hamilton, Hamilton, ON, Canada*

Background: Several lesion-targeted therapies exist for locally recurrent or limited stage metastatic prostate cancer (PCa) post-radiotherapy (RT) and radical prostatectomy (RP). However, detection of disease sites is limited using conventional imaging (CI) including computed tomography (CT) and bone scan. Prostate specific membrane antigen (PSMA) targeting PET radiopharmaceuticals like [18F]DCFPyL may help detect disease not seen on CI. Our objective was to assess the ability of PSMA targeted PET/CT to detect sites of disease recurrence and impact on patient management. **Methods:** This multi-center prospective registry study included six Ontario centers. Eligible patients in 1 of 7 clinical cohorts (Table) were identified and approved by Cancer Care Ontario (CCO) to have restaging with PSMA targeted PET/CT. Referring physicians were asked to complete a form indicating whether a change in management strategy would occur based on the PET/CT results. At 6 months post-PET/CT, actual patient management will be confirmed via provincial registries. These interim results are from a single center. **Results:** 253 patients were enrolled and had a PSMA targeted PET/CT. At baseline, median age was 71 years (range 50-102 years) and median PSA was 2.7 ng/mL (range 0.04-134.0 ng/mL). The majority of patients (n=59; 23.3%) were in cohort 2 (biochemical failure post-RP). In patients with negative CI, PSMA targeted PET/CT detected disease sites in 68.5% (170/248), resulting in a change in management for 67.8% (137/202) overall and 72.1% and 64.3% post-RT and post-RP, respectively. **Conclusions:** PSMA targeted PET/CT detected occult lesions on CI in the majority of patients enrolled, leading to a high rate of change in management. Our institutional results are in keeping with preliminary results reported for the provincial cohort. Clinical trial information: NCT03718260. Research Sponsor: Cancer Care Ontario.

Change in management post- PSMA PET/CT and median (range) PSA by cohort allocation.

Cohort	N (%)	Change in management n (%)*	Median PSA ng/mL (range)
1. Post RP node + disease or persistently detectable PSA	4 (1.6)	2 (50%)	2.0 (.22-4.1)
2. BF post-RP	59 (23.3)	28 (47.5)	.27 (.11-9.7)
3. BF post-RP followed by adjuvant or salvage prostate bed RT	52 (20.6)	29 (55.8)	1.5 (.11-32.7)

Single-lesion PSMA protein expression and response to Lu-177 PSMA therapy in patients with castration-resistant prostate cancer. *First Author: Judith Stangl-Kremser, Department of Urology, Michigan Medicine, Ann Arbor, MI*

Background: The recent introduction of Lu-177 PSMA for the treatment of castration-resistant prostate cancer (CRPC) has been met with much excitement. Initial reports of clinical response are promising, despite known inter- and intra-patient molecular heterogeneity. In this study, we examined the utility of PSMA protein expression in metastatic tumor tissues as a predictor of lesion-specific response to Lu-177 PSMA therapy in men with CRPC. **Methods:** Between 2015-2020, 19 patients with metastases at multiple sites underwent metastatic lesion biopsy, Ga-68 PSMA PET imaging, and subsequent treatment with three cycles of Lu-177 PSMA. A monoclonal anti-PSMA antibody (EPITOMICS (USA), 1:50) was used to semi-quantitatively assess PSMA protein expression in the biopsy specimen. The histoscore (range 0-300) was derived from intensity and extent of the immunohistochemistry staining and was determined by experienced genitourinary pathologists. Imaging evaluation was performed according to the Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST) criteria. We assessed the association of the PSMA protein expression in metastatic tumor tissues and the lesion-specific response to Lu-177 PSMA therapy. **Results:** In 12 patients with biopsy specimens available for staining, PSMA expression correlated with enhancement (SUV_{max}) of the biopsy site on Ga-68 PSMA PET imaging ($r_s = 0.63$). Of the nine patients with repeat imaging after Lu-177 PSMA therapy, five (55.6%) had a lesion-specific response at the site of biopsy. PSMA expression on immunohistochemistry was unable to accurately predict lesion-specific response in univariable analysis (p = 0.81, 95% CI 94.6-76.6). Among the five men with a lesion-specific response, three (60%) experienced overall progression based on PERCIST. There was no association between lesion-specific response and overall progression (p = 0.64). **Conclusions:** In patients with multiple metastases, PSMA protein expression from a single site biopsy was not predictive of site-specific Lu-177 PSMA response based on PERCIST. Additional studies are necessary to further interrogate the clinical consequence of PSMA expression heterogeneity in metastatic sites as well as the mechanisms underpinning resistance to Lu-177 PSMA in patients with CRPC. Interim PSMA PET/CT for response evaluation during LuPSMA treatment in mCRPC (INTERIM PET): An explorative, multicenter study. *First Author: Andrei Gafita, Ahmanson Translational Theranostics Division, University of California, Los Angeles, CA*

Background: The aim of this analysis was to evaluate the prognostic value of interim PSMA PET/CT in men with metastatic castration-resistant prostate cancer (mCRPC) treated with ^{177}Lu-PSMA and to develop a novel framework for Response Evaluation Criteria In PSMA-imaging (RECIP). **Methods:** This was an explorative, multicenter, retrospective study; 124 men with mCRPC who underwent ^{177}Lu-PSMA treatment and received PSMA-PET/CT at baseline (bPET) and at interim after two cycles of treatment (iPET) met the eligibility criteria and were included in this analysis. The primary endpoint was overall survival (OS). Pairs of bPET and iPET were interpreted by three independent readers for appearance of new lesions. Whole-body tumor lesions were segmented using qPSMA software and total PSMA-positive tumor volume (PSMA-VOL) was obtained. Changes in PSMA-VOL on iPET relative to bPET were calculated. After being tested separately for associations with OS, appearance of new lesions and changes in PSMA-VOL were combined to develop RECIP. **Results:** The median OS was 13.5 months (95%CI, 11.6-15.4). Appearance of at least one new lesion on iPET was observed in 73 (59%) patients and was associated with poor OS (hazard ratio [HR] 2.23; 95%CI, 1.51-3.28; $P < .001$). Based on the current data, RECIP were defined as: partial response (PSMA-PR) as a decline ≥20% in PSMA-VOL and no appearance of new lesions; progressive disease (PSMA-PD) as an increase ≥20% in PSMA-VOL and appearance of new lesions; stable disease (PSMA-SD) was defined as any condition but not PSMA-PR or PSMA-PD. The OS of men with PSMA-PD (n = 41) was significantly worse compared to men with PSMA-SD (n = 47; HR 2.52; 95%CI, 1.61–3.93; $P < .001$) and PSMA-PR (n = 36; HR 4.16; 95%CI, 2.54–6.78; $P < .001$). PSMA-SD was associated with significantly worse OS compared to PSMA-PR (HR 1.65; 95%CI, 1.02–2.65; $P = .039$). The time dependent C-index of associations with OS for response according to RECIP was 0.68 (95%CI, 0.63-0.72). **Conclusions:** Interim staging using PSMA-PET/CT and response classification by RECIP is prognostic for survival of men with mCRPC treated with ^{177}Lu-PSMA. Validation of these findings in clinical trials is warranted. Research Sponsor: None.

Impact of androgen deprivation therapy on mortality of prostate cancer patients with COVID-19: A propensity score-based analysis. *First Author: Mateus Bringel Oliveira Duarte, Universidade Estadual de Campinas, Campinas, Brazil*

Background: Previous studies suggested that androgen deprivation therapy (ADT) may reduce severe acute respiratory syndrome coronavirus 2 (SARS-COV2) infectivity. However, it is unknown whether there is an association between ADT and a higher survival in prostate cancer patients with COVID-19. **Methods:** We performed a retrospective analysis of prostate cancer (PC) patients hospitalized to treat COVID-19 in Brazil's public health system. We compared patients with the active use of ADT versus those with non-active ADT, past use. We constructed propensity score models of patients in active versus non-active use of ADT. All variables were used to derive propensity score estimation, and for the outcome analysis we performed a multivariate backward elimination process to select variables to add to the propensity score model. **Results:** We analyzed 109 PC patients with COVID-19 that presented past or current use of ADT. In total, 52.8% of our patients were less than 75 years old, 44.0% (48/109) were in active ADT, and most were using a GnRH analog (73%, 35/48). Also, 63.3% of our cohort died from COVID-19. ADT active use were protective factor in our logistic regression model (OR 0.28, 95% CI 0.12–0.66, P = 0.0036). We noticed a significant imbalance in the propensity score of patients in active and those in non-active ADT. Then, when we performed a propensity score-based inverse weight double robust estimation model, we observed that ADT remained statistically associated with improved overall survival (average treatment effect [ATE] -0.26, 95% CI -0.45 to -0.08, P = 0.0058). **Conclusions:** The active use of ADT was associated with a reduced risk of death in patients with COVID-19. Health-related quality of life (HRQoL) and patient-reported outcomes at final analysis of the TITAN study of apalutamide (APA) versus placebo (PBO) in patients (pts) with metastatic castration-sensitive prostate cancer (mCSPC) receiving androgen deprivation therapy (ADT).

First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: The phase 3 TITAN study evaluated APA vs PBO in pts with mCSPC receiving ADT. At primary analysis with 22.7 mo median follow-up, APA significantly improved overall survival (OS) and radiographic progression-free survival vs PBO (Chi *NEJM* 2019) while preserving HRQoL (Agarwal *Lancet Oncol* 2019). The study was unblinded; pts on PBO were allowed to cross over to APA. At final analysis with 44 mo median follow-up, APA significantly improved OS vs PBO, reducing risk of death by 35% despite crossover (Chi ASCO GU 2021). We evaluated HRQoL and treatment bother at final analysis. **Methods:** mCSPC pts (N = 1052) were randomized 1:1 to APA (240 mg QD; n = 525) or PBO (n = 527). All pts received ADT. Patient-reported outcomes were assessed using Brief Pain Inventory-Short Form (BPI-SF) and Functional Assessment of Cancer Therapy-Prostate (FACT-P). BPI was completed for 7d consecutively (Days -6 to 1 of each 28-d cycle [C]) through end of treatment (EOT). FACT-P was completed at baseline (BL), C2-C7, then every other C through EOT. Mean scores were reported by treatment group and over time. Time to deterioration on BPI and FACT-P scores was calculated by Kaplan-Meier methods and compared between groups by fitting proportional hazards regression models. **Results:** Of eligible pts per C, > 62% completed BPI through C32 and > 50% completed FACT-P through C31. Pts were relatively asymptomatic with good BL HRQoL: on 0-10 worst pain severity scale (BPI), median scores were 1.1 (APA) and 1.0 (PBO); on 0-156 HRQoL scale (FACT-P total; higher score = better HRQoL), median scores were 113.0 (APA) and 113.3 (PBO). Low BL BPI scores remained stable over time in both groups. On average, favorable BL FACT-P scores did not notably worsen over time in APA or PBO groups. There were no significant differences between groups in median time to deterioration in any BPI or FACT-P scores (Table). At each C at least 86% (APA) and 85% (PBO) of pts were either "not at all" or "a little bit" bothered by side effects. At BL, 76% (APA) and 72% (PBO) had favorable energy levels (reporting lack of energy "not at all" or "a little bit"). Energy levels remained stable or improved at each C for > 78% (APA) and > 71% (PBO) of pts. **Conclusions:** In the final analysis of TITAN, survival benefit with addition of APA to ADT was achieved without significant patient-reported side effect burden or reduced HRQoL compared with PBO in pts with mCSPC. Clinical trial information: NCT02489318. Research Sponsor: Janssen Research & Development.

Median time to deterioration, months	APA	PBO	p Value
BPI worst pain	19.3	12.0	0.17
BPI pain interference[a]	NE	NE	0.32
FACT-P total	9.0	9.2	0.76
FACT-P physical wellbeing	5.6	11.0	0.62

Association of androgen receptor signature and *RB1*, *PTEN*, *TP53* gene expression with clinical outcome in metastatic hormone-sensitive prostate cancer treated with docetaxel and androgen deprivation therapy.

First Author: Laura Ferrer-Mileo, Department of Medical Oncology, Hospital Clínic of Barcelona, Barcelona, Spain

Background: Androgen deprivation therapy (ADT) with docetaxel or new antiandrogens has demonstrated a survival benefit in metastatic hormone-sensitive prostate cancer (mHSPC). However, treatment selection for individual patients (pts) remains a challenge. We propose that *TMPRSS2-ERG* and cell plasticity [neuroendocrine (NE), epithelial to mesenchymal transition (EMT)], immune-related, androgen receptor (AR) and tumor suppressor genes (TSG) (*RB1*, *PTEN* and *TP53*) expression signatures may predict clinical outcome in mHSPC pts treated with ADT+docetaxel. **Methods:** This is a multicenter retrospective biomarker study performed in mHSPC pts treated with ADT+-docetaxel. A customized panel of 184 genes was designed and tested in total mRNA from FFPE tumor samples by nCounter platform (Nanostring Technologies). Expression levels were correlated with castration resistance-free survival (CRPC-FS) (primary endpoint) and overall survival (OS) by Kaplan Meier and multivariate Cox modeling. A predictive modeling approach was performed with Bujar R package to develop a signature able to predict CRPC-FS. R (v.3.6.3) software was used for statistical analyses. **Results:** 136 pts were included, and 120 of them were eligible. Median age was 66.9 years (range 46.3-83.6). Gleason score was ≥ 8 in 80.8% of pts; 87.5% and 20.8% of pts had bone and visceral metastases, respectively. Median follow-up was 30.7 months (m) (range 5.5-70.6). 76 pts (63.3%) developed castration-resistant prostate cancer (CRPC). Median time to CRPC was 20 m (range 16.9-23.1) and median OS was not reached. High AR-signature expression independently correlated with longer CRPC-FS (HR 0.4, 95% CI 0.2-0.7, p = 0.003). Considering AR-signature individual gene expression, *ARV7* was independently associated with shorter CRPC-FS (HR 1.7, 95% CI 1.2-2.4, p = 0.003). Low expression of all TSG (*PTEN*, *RB1* and *TP53*) independently correlated with shorter CRPC-FS (HR 0.3, 95% CI 0.2-0.7, p = 0.003) and OS (HR 0.2, 95% CI 0.1-0.5, p < 0.001). Similarly, low expression of 2 out of the 3 TSG genes or only *RB1* plus *PTEN* were also independently associated with shorter CRPC-FS (HR 0.5, 95% CI 0.3-0.9, p = 0.015; HR 0.4, 95% CI 0.2-0.7, p = 0.003, respectively) and OS (HR 0.4, 95% CI 0.2-0.9, p = 0.027; HR 0.2, 95% CI 0.1-0.6, p = 0.001, respectively). *TMPRSS2-ERG* expression, NE, EMT and immune-related signatures were not associated with clinical outcome. Bujar analysis defined a 17-gene signature (including *ARV7*, *RB1*, *PTEN*, *BRCA2* and *ATM)* that was able to discriminate pts at different risk of developing early CRPC. **Conclusions:** High AR-signature expression correlates with a longer CRPC-FS while *ARV7* expression is associated with shorter CRPC-FS. Low expression of TSG is associated with an aggressive clinical evolution in mHSPC pts treated with ADT+taxanes. The efficacy of enzalutamide (ENZA) plus androgen deprivation therapy (ADT) on bone oligometastatic hormone-sensitive prostate cancer: A post hoc analysis of ARCHES.

First Author: Andrew J. Armstrong, Duke Cancer Institute Center for Prostate & Urologic Cancers, Duke University, Durham, NC

Background: In ARCHES (NCT02677896), ENZA + ADT reduced the risk of radiographic progression and improved secondary clinical outcomes in patients with metastatic hormone-sensitive prostate cancer (mHSPC) with variable patterns of disease spread over placebo (PBO) + ADT. This *post hoc* analysis aimed to evaluate the efficacy of ENZA + ADT in patients with bone oligometastatic mHSPC compared to polymetastatic mHSPC in ARCHES. **Methods:** Patients with mHSPC (n = 1150) were randomized 1:1 to ENZA (160 mg/day) + ADT or PBO + ADT, stratified by disease volume and prior docetaxel chemotherapy. This *post hoc* analysis included patients with bone metastases only, categorized as oligometastatic (1–≤5 metastases) or as polymetastatic (≥6 metastases) based on central review at screening. Efficacy outcomes were compared across treatment arms. **Results:** Of the ARCHES population with bone metastases (n = 512), the largest subgroup included patients with ≤5 metastases (ENZA + ADT, n = 160; PBO + ADT, n = 136). Baseline characteristics were generally comparable between treatment arms and across subgroups. When compared to PBO + ADT, ENZA + ADT improved rPFS and secondary endpoints in patients with ≤5 metastases (Table). Similar results were observed across other oligometastatic subgroups (1–≤4) as well as in polymetastatic disease (≥6). The safety profile of ENZA + ADT versus PBO + ADT was similar across subgroups and consistent with previous findings. **Conclusions:** This *post hoc* analysis demonstrates that ENZA + ADT provides clinical benefit across bone oligometastatic as well as polymetastatic mHSPC, supporting the utility of ENZA irrespective of metastatic burden in the ARCHES study. Clinical trial information: NCT02677896. Research Sponsor: This study was funded by Astellas Pharma Inc. and Pfizer Inc., the co-developers of enzalutamide. Medical writing and editorial assistance were provided by Folabomi Oladosu, PhD, and Jane Beck, MA, from Complete HealthVizion, funded by the study sponsors.

Real-world first-line (1L) treatment patterns in patients (pts) with metastatic castration-sensitive prostate cancer (mCSPC) in a U.S. health insurance database.

First Author: Umang Swami, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: Over the past 6 years, intensification of androgen deprivation therapy (ADT) with docetaxel (DOC) and novel hormonal therapies (NHT) [abiraterone, enzalutamide, and apalutamide], has been shown to improve survival outcomes in men with mCSPC. This study assessed the real-world utilization of effective combination therapies as 1L treatment in insured pts in the U.S. with mCSPC. **Methods:** This retrospective study used the Optum health insurance claims database, which includes pt claims data from both commercially insured and Medicare Advantage populations. Eligible pts were adult men with ≥1 claim with a metastatic International Classification of Diseases diagnostic code (first claim was index date) within 90 days (d) prior to, or any time after, a prostate cancer diagnosis between January 2014 and June 2019. Pts with evidence of systemic anticancer therapy during the 1-year pre-index baseline period were excluded, unless the first drug claim occurred within 90 d prior to the diagnosis of metastatic disease. The 1L treatments were identified as any treatment for mCSPC within 90 d pre-index, plus any other treatment received within 180 d of the first, and were grouped by regimen: ADT only; ADT + first-generation antiandrogens (AA); ADT + DOC; ADT + NHT; and ADT + NHT + DOC. **Results:** Of 4221 men with mCSPC, 2364 (56.0%) received ADT only; 892 (21.1%) ADT + AA; 577 (13.7%) ADT + NHT; 348 (8.2%) ADT + DOC; and 40 (0.9%) ADT + NHT + DOC. Pts who received ADT + DOC or ADT + DOC + NHT were generally younger than the other treatment groups (Table). By 2019, use of ADT only and ADT + AA had declined, while the use of ADT + NHT and ADT + NHT + DOC had increased (Table). However, in 2018 and 2019, the majority of men with mCSPC still received either ADT alone, or ADT + AA, including those with visceral metastases (Table). Survival analysis across treatment cohorts is ongoing. **Conclusions:** Despite level 1 evidence demonstrating improved survival with intensified treatment (ADT + DOC or NHT), this study shows its underutilization in pts with mCSPC. This is evident even in those with more aggressive disease (visceral metastases) as recently as 2019. These data highlight that a minority of pts with mCSPC received optimal life-prolonging therapies in a commercially insured and Medicare Advantage U.S. population. Further studies are needed to identify the reasons for this underutilization of intensified treatments. Research Sponsor: This study was funded by Astellas Pharma Inc. and Pfizer Inc., the co-developers of enzalutamide. Medical writing was provided by Bioscript and editorial assistance was provided by Complete HealthVizion, funded by the study sponsors.

Real-world utilization of advanced therapies and racial disparity among patients with metastatic castration-sensitive prostate cancer (mCSPC): A Medicare database analysis. *First Author: Stephen J. Freedland, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Several randomized controlled trials have shown that adding docetaxel or novel hormonal therapy (NHT) to androgen deprivation therapy (ADT) improves survival in mCSPC patients. This study aimed to evaluate the real-world utilization of advanced therapies over time and to provide data on utilization patterns among racial minorities that are often under-represented in clinical trials. **Methods:** This was a retrospective analysis of a Medicare database (Jan 2009-Dec 2018). Adult men with ≥1 claim for prostate cancer (PC) who initiated ADT (index date) within 90 days prior to or any time after a metastasis diagnosis were included. The first-line (1L) treatment was grouped by PC drugs prescribed within 30 days prior to and 120 days after the index date, in 4 categories: ADT alone, ADT + first-generation anti-androgen (AA; ≥90 days to avoid capturing AA for flare control), ADT + docetaxel, and ADT + NHT (abiraterone, apalutamide, and enzalutamide). The 1L treatment distributions were described over time and stratified by race. **Results:** A total of 35,195 patients with mCSPC were included in the study, with a mean (SD) age of 76.5 (7.9) years. 11.8% were Black, 5.3% Hispanic, and 78.5% White. 76.4% received ADT alone as 1L treatment, 14.3% ADT + AA, 4.8% ADT + docetaxel, and 4.5% ADT + NHT. While the proportion of patients treated with ADT alone and ADT + AA slowly decreased over time, the utilization of ADT + docetaxel increased since 2015 and the utilization of ADT + NHT increased since 2017 (Table). After the emergence of NHTs for treatment of mCSPC in 2017, treatment intensification with ADT + NHT was numerically lower for Black than White patients. Data from before 2017 also suggest a similar lower use of ADT + AA in Black patients (Table). Survival analysis across treatment cohorts and race are ongoing. **Conclusions:** In this large and nationally representative sample of mCSPC patients, less than one-third of patients received treatment intensification by 2018, possibly due to patient/disease characteristics, provider awareness or therapeutic inertia, or cost. Importantly, the data showed less frequent treatment intensification in Black vs White patients. Further study is required to elucidate underlying reasons for this disparity. Research Sponsor: Pfizer and Astellas Pharma.

Real-world treatment patterns among patients diagnosed with metastatic castration-sensitive prostate cancer (mCSPC) in community oncology settings. *First Author: Daniel J. George, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University, Durham, NC*

Background: Androgen deprivation therapy (ADT) served as standard of care for mCSPC for decades. Combining ADT with docetaxel (DOC) starting in 2015 or with novel hormonal therapies (NHT) starting in 2017 has demonstrated improved survival compared to ADT alone. This study examined the impact of new evidence on treatment selection for mCSPC patients in real-world oncology practice. **Methods:** Electronic medical record (EMR) data from a network of U.S.-based oncology practices in the ConcertAI Oncology Dataset were used to retrospectively evaluate treatment patterns in mCSPC patients who initiated first-line (1L) therapy between 2014–2019. We estimated the proportion of mCSPC patients receiving each 1L regimen, duration of therapy until initiation of next regimen, and trends in 1L regimen. Treatment patterns were studied in the overall population and by race/ethnicity. Anti-androgen (AA) use for <90 days was not included. **Results:** A total of 858 mCSPC patients were included (70% White, 16% Black, 3% Hispanic, and 11% other race/unknown). Median age at mCSPC diagnosis was 69 years, and 63% presented with *de novo* metastases. The most common mCSPC 1L regimens were ADT + older AA (26.3%, mainly bicalutamide), ADT monotherapy (20.5%), ADT + NHT ± AA (19.2%), and ADT + DOC ± AA (16.4%). The remaining 17.5% received a variety of other therapies, including AA monotherapy (5.9%) or NHT ± AA (5.5%). NHT included abiraterone, apalutamide, and enzalutamide. ADT + NHT ± AA treatment increased each year, while ADT + DOC ± AA treatment peaked in 2017 and then decreased (Table). By contrast, ADT + AA was the most common therapy in 2014 but declined every year. Median duration until initiation of a subsequent regimen was 14.3 months for ADT + NHT ± AA and 10.8 months for ADT + DOC ± AA. Differences in 1L treatment patterns across White and Black patients were not statistically significant in unadjusted analyses. **Conclusions:** Even in 2019, over half of mCSPC patients treated in real-world settings did not receive 1L therapy now known to significantly improve survival (ADT + NHT or ADT + DOC) over ADT alone. Those who did, received shorter durations of treatment than observed in registrational trials. However, we found no initial evidence of racial disparities in treatment. The disconnect between trial evidence and real-world practice could be due to patient/disease characteristics, cost/access issues, or provider awareness. A better understanding of these contributing factors is worthy of further study. Research Sponsor: Pfizer and Astellas Pharma.

Initiation of 1L treatment following mCSPC diagnosis (%).

mCSPC 1L regimen	Median duration to next regimen (months)	2014	2015	2016	2017	2018	2019
ADT + AA	14.3	42.6%	31.9%	31.7%	20.1%	19.8%	16.5%
ADT	8.9	20.4%	19.8%	22.0%	21.5%	15.8%	26.6%
ADT + NHT ± AA	14.3	10.2%	11.2%	14.6%	19.2%	27.7%	34.2%
ADT + DOC ± AA	10.8	8.3%	19.8%	14.6%	22.0%	17.0%	10.1%
Other treatment	n/a	18.5%	17.2%	17.1%	17.3%	19.8%	12.7%

Impact of age on efficacy and safety of relugolix: A subgroup analysis from the randomized, phase 3 hero study versus leuprolide in men with advanced prostate cancer. *First Author: Michael Cookson, University of Oklahoma Health Sciences Center, Stephenson Cancer Center, Oklahoma City, OK*

Background: In the phase 3 HERO study, the oral GnRH receptor antagonist relugolix demonstrated sustained testosterone suppression superior to that of leuprolide and a comparative 54% decrease in risk of major adverse cardiovascular events. Relugolix was recently approved for use in the US for the treatment of adult patients with advanced prostate cancer. Here, we further characterize the impact of age on the use of relugolix in advanced prostate cancer from the HERO study. **Methods:** The HERO study was a randomized, open-label, parallel group study evaluating relugolix in men with advanced prostate cancer. Overall, 934 men with advanced prostate cancer underwent 2:1 randomization to receive relugolix 120 mg orally once daily after a single loading dose of 360 mg or leuprolide 3-month injections for 48 weeks. Subgroups analyzed by age were <65 years or ≥65 years and ≤75 years or >75 years. Assessments analyzed included sustained testosterone suppression to castrate levels (<50 ng/dL) from day 29 through 48 weeks, early and profound (<20 ng/dL) castration rates, prostate-specific antigen (PSA) levels, and safety. Testosterone recovery (≥280 ng/dL) was evaluated in 184 patients who enrolled in the testosterone recovery substudy. **Results:** Of the 930 patients (relugolix:622;leuprolide:308) that received study drug in the HERO study, 173 (18.6%) were <65 years and 757 (81.4%) were ≥65 years of age, while 664 (71.4%) were ≤75 years and 266 (28.6%) were >75 years of age. Across all age subgroups, point estimates for sustained castration rates through 48 weeks for relugolix patients were consistent with the overall estimate of relugolix sustained castration rate observed in the overall population. Differences in sustained castrations rates at week 48 between relugolix and leuprolide groups were similar regardless of the age subgroup (table). The likelihood of testosterone recovery at 90 days after completion of treatment was higher in the relugolix group versus the leuprolide group in all age subgroups: <65 (79.1% vs 16.7%), ≥65 (48.6% vs 0%), ≤75 (60.0% vs 4.0%),and >75 years (40.7% vs 0%). No clinically relevant differences were noted in the incidence or types of adverse events within treatment groups in all the age subgroups analyzed. **Conclusions:** In this subgroup analysis of the HERO study, relugolix was effective regardless of age, and the benefit/risk profile remained favorable for relugolix compared with leuprolide, consistent with the overall population. Testosterone recovery was higher in the relugolix group than the leuprolide group for all age subgroups analyzed, with higher rates of recovery in younger versus older men. Clinical trial information: NCT03085095. Research Sponsor: Myovant Sciences GmbH, in collaboration with Pfizer, Inc.

Castration rates.

	Differences Between Relugolix and Leuprolide Groups
<65 years	6.8% (95% CI: -4.3%, 17.9%)
≥65 years	8.2% (95% CI: 4.2%, 12.2%)
≤75 years	6.3% (95% CI: 1.7%, 10.8%)
>75 years	12.1% (95% CI: 5.0%, 19.2%)

Proliferation index and survival in men with prostate cancer starting long-term androgen deprivation therapy in the STAMPEDE clinical trial. *First Author: Larissa Mendes, University College London Cancer Institute, London, United Kingdom*

Background: Treatment intensification with docetaxel or abiraterone improved survival for advanced prostate cancer starting androgen deprivation therapy (ADT) in the Systemic Therapy in Advancing or Metastatic Prostate Cancer: Evaluation of Drug Efficacy (STAMPEDE, NCT00268476) trial. However, survival and time-to-progression is highly variable on ADT, introducing the risk of unnecessary toxicity from additional treatments for some patients. Here we test the prognostic association of proliferation index using Ki67 scores in the control arm of the STAMPEDE population of high-risk localised (M0) and metastatic (M1) prostate cancer. **Methods:** Pre-ADT diagnostic needle biopsies were obtained from 517 men randomized in STAMPEDE arm A between 2006 and 2015. These were assessed for proliferation using an analytically optimised Ki67 immunohistochemistry assay. Ki67 was tested for associations with baseline clinico-pathological variables (Grade group, pre-ADT serum PSA and imaging metastatic burden) in univariable linear-regression models, and for associations with survival outcomes in multivariable Cox-regression models adjusted for these and additional confounding variables. Primary outcome measure was overall survival, secondary outcomes were prostate cancer-specific, failure-free, progression-free and metastatic progression-free survival. **Results:** Ki67 was available for 475 patients who received ADT only for at least 2 years ± radiotherapy. Of 202 M0, 74 were node positive. Of 273 M1, 116, 127 and 30 were respectively low, high and unknown radiological M1 volume. Ki67 score associated with higher Gleason ($p=7.15x10^{-11}$) and presence of extra-pelvic metastases ($p=1.41x10^{-8}$). Increasing Ki67 scores showed a strong linear association with poorer overall survival, with an estimated 2% increase in the hazard of death per percentage increase in the score (adjusted HR=1.02, 95% CI 1.01-1.02; $p=1.04x10^{-5}$). There was also strong evidence that Ki67 associated positively with all secondary outcomes, including prostate cancer-specific survival (adjusted $p=5.50x10^{-6}$) and metastatic progression-free survival (adjusted $p=3.50x10^{-9}$). **Conclusions:** Ki67 immunoscore is strongly prognostic in clinically advanced prostate cancer independent of Gleason score and the other clinicopathological variables tested in this study. Ki67 is a clinically scalable assay that could improve selection for treatment intensification and provide a tool for screening patients most likely to benefit from further molecular investigation. Correlation of baseline circulating tumor cells (CTC) and associated genomic profile with survival outcomes in patients (pts) with metastatic castration-sensitive prostate cancer (mCSPC) in a real-world cohort. *First Author: Umang Swami, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: We recently published, in the context of SWOG1216 trial in pts with mCSPC, that higher baseline CTC level were associated with inferior survival outcomes (Goldkorn. Agarwal, CCR, 2021). Here in, we validate these findings in a real world population of mCSPC and interrogate tumor genomic profile with respect to the CTC level. **Methods:** Eligibility criteria: new mCSPC receiving ADT without or with intensification (docetaxel or novel hormonal therapy) and enumeration of baseline CTCs by FDA cleared Cell Search CTC assay. Gene alterations were determined by comprehensive genomic profiling (CGP) of tumor tissue (Foundation Medicine). CTC counts were categorized as 0, 1-4 and ≥5/7.5 ml. Relationships between CTC counts and number (no.) of genes altered and individual gene alterations were assessed via Kruskal-Wallis and chi-squared tests, respectively. Relationships between progression-free survival (PFS), overall survival (OS) and individual mutations were assessed via log-rank tests. Relationships between CTC counts, PFS and OS were assessed by Cox proportional hazards models, both unadjusted and adjusted for multiple variables (Table). **Results:** Overall 103 pts were eligible. Median age: 67 yrs, Gleason score: 9, PSA at ADT initiation: 41 ng/mL. 67 (65%) pts had de-novo metastatic disease and 44 (43%) pts underwent ADT intensification therapy. Pts with greater CTC counts tended to have greater no. of altered genes (p=0.017), greater no. of total alterations (p=0.017) and higher rate of TP53 mutations (p=0.036). In univariate analyses (UVA) and multivariable analyses (MVA), both CTC counts and no. of genes altered were strongly associated with both PFS and OS (Table). CGP of tumors with respect to CTC counts will be presented in meeting. **Conclusions:** Herein, we validate our previous findings from SWOG1216 trial of association of higher CTC level with inferior survival outcomes in a real world mCSPC cohort. The CTC enriched population is associated with a distinct tumor genomic landscape, which may guide further drug development in this pt population at the highest risk of progression and/or death. Research Sponsor: None.

Diagnostic performance of Gallium-68 prostate-specific membrane antigen (PSMA) PET/CT imaging in early-relapsed prostate cancer: Phase 3, prospective, multicenter study (IAEA-PSMA study). *First Author: Juliano J Cerci, Quanta-Diagnóstico e Terapia, Curitiba, Brazil*

Background: Biochemical recurrence (BCR) is a clinical challenge in prostate cancer (PCa) patients with impact on defintion of subsequent therapies. The use of positron emission tomography (PET) with prostate-specific membrane antigen (PSMA) presents better accuracy than standard imaging practice. This phase3, prospective, multicentric, international study evaluates the diagnostic performance and clinical impact of PSMA-PET/CT in evaluating BCR in PCa. **Methods:** Patients with PCa who have undergone primary definitive treatment and with rising PSA were recruited in the study. Overall 17 centers from 15 countries (Azerbaijan, Brazil, Colombia, India, Israel, Italy, Jordan, Lebanon, Malaysia, Mexico, Pakistan, Poland, South Africa, Turkey, and Uruguay) were involved. Images and data were centrally reviewed; data were collected for PSMA site of findings, positivity rate, defined as the percentage of patients with a positive 68Ga-PSMA PET/CT taking into account the composite standard: pathology, correlative imaging, PSA response, with at least 6 mo. clinical follow-up, and impact on patient management by determining changes in the treating physician's documented clinical plans before and after 68Ga-PSMA PET/CT. **Results:** Were enrolled 1198 patients and presented final data from 1004 patients. 68Ga-PSMA PET/CT was positive in 654/1004 patients (65.1%); lesions were identified as: prostate/prostatic bed only in 13.7% cases; pelvic lymph nodes only 20.5%, and with any metastatic disease in 27.0%. There was a correlation between PSMA-PET/CT positivity and Gleason score ($p<0.001$): detection rate was 371/613 (60.5%) in patients with Gleason 7, 130/196 (66.3%) in Gleason 8, 140/180 (77.8%) in Gleason 9 and 13/15 (86.7%) in Gleason 10. There was also significant correlation between lesions identification and PSA values ($p<0.001$): detection rate was 21/41 (51.2%) for PSA <0.2, 84/188 (44.7%) for PSA between 0.2-0.5, 124/232 (53.4%) for PSA 0.5-1.0, 158/235 (67.2%) for PSA ≥1 and <2, 171/206 (83.0%) for PSA ≥2 and <4, and 96/102 (94,1%) in PSA 4 to 10. Also, treatment was modified based on PSMA results in 56.8% of patients. The 68Ga-PSMA PET/CT positivity was consistent and not statistically different among the countries. **Conclusions:** This is the largest multicenter trial on 68Ga-PSMA PET/CT detected local and metastatic recurrence in most men with BCR. 68Ga-PSMA PET/CT results changed the recommended treatment approaches in the majority of patients. This study confirms the reliability of PSMA PET in BC and the worldwide feasibility of such approach. Research Sponsor: International Atomic Energy Agency - IAEA.

Darolutamide (DARO) tolerability from extended follow up and treatment response in the phase 3 ARAMIS trial. *First Author: Karim Fizazi, Institut Gustave Roussy and University of Paris Saclay, Villejuif, France*

Background: Patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC) need therapy that prolongs survival with little added toxicity, thus preserving quality of life. The second-generation androgen receptor inhibitors (ARIs) including DARO, apalutamide, and enzalutamide offer durable survival in nmCRPC but differences exist in AE profiles (eg, fatigue, falls, fractures, rash, mental impairment, and hypertension) that can limit daily activities. These AEs may require dose modifications and limit pts' willingness to continue treatment, with an adverse impact on efficacy. DARO is a structurally distinct ARI that significantly extended metastasis-free survival and overall survival (OS) vs placebo (PBO) in ARAMIS (NCT02200614), with minimal AE risk. We report tolerability from extended follow-up and treatment response analyses from ARAMIS. **Methods:** Pts with nmCRPC (N=1509) were randomized 2:1 to DARO or PBO with androgen deprivation therapy. The ARAMIS trial was unblinded at the primary analysis, after which all pts could receive open-label (OL) DARO. Tolerability was assessed every 16 weeks. Pharmacodynamic modeling investigated the association between treatment response (maximum prostate-specific antigen [PSA] decline from baseline) and OS at 2 years using a Cox proportional hazards model. **Results:** As shown in the table, DARO remained well tolerated over the double-blind (DB) and OL periods: 98.8% of pts on DARO received the full planned dose and almost all pts with dose modifications were able to resume and re-establish the planned dose (DARO 89.6% vs PBO 89.7%). Discontinuation of DARO due to AEs increased slightly from the DB period (9.0%) to the DB+OL period (10.5%). Pharmacodynamic modeling showed that longer OS was positively associated with maximum PSA decline in DARO-treated pts. **Conclusions:** DARO remained well tolerated with extended treatment at the recommended dose of 600 mg twice daily. Almost all pts with nmCRPC were able to receive the full planned dose, increasing the likelihood of clinical benefit from effective disease control (PSA decline) and prolonged survival. Tolerability of different ARIs in the real world should be assessed. Clinical trial information: NCT02200614. Research Sponsor: Bayer AG, Pharmaceutical/Biotech Company.

A phase II randomized controlled trial of exercise on biochemical progression in men with prostate cancer on active surveillance. *First Author: Dong-Woo Kang, University of Alberta, Edmonton, AB, Canada*

Background: Men with prostate cancer (PCa) undergoing active surveillance (AS) are at increased risks of cardiovascular death and disease progression. Any intervention that can address these issues during AS would be highly beneficial. Clinical and preclinical studies have demonstrated the benefits of exercise to improve cardiovascular health in cancer patients and suggested the potential role of exercise in suppressing PCa progression in men with PCa undergoing AS. Therefore, the purpose of this study was to investigate the effects of exercise on cardiorespiratory fitness and biochemical progress of PCa in men with PCa on AS. **Methods:** The Exercise During Active Surveillance for Prostate Cancer (ERASE) Trial was a single-centre, two-armed, randomized controlled trial in Edmonton, Canada. 52 men with localized PCa who were undergoing AS were randomized to high-intensity interval training (HIIT; n = 26) or usual care (UC; n = 26). The HIIT group performed thrice-weekly, supervised, aerobic HIIT on a treadmill at 85-95% of peak cardiorespiratory fitness (VO_{2peak}) for 12 weeks. The primary outcome was VO_{2peak}, and the secondary and exploratory outcomes included biochemical progression of PCa (prostate-specific antigen [PSA]), PSA kinetics, and growth of prostate cancer cell line LNCaP. **Results:** 46/52 participants (88%) completed the postintervention VO_{2peak} assessment and adherence to HIIT was 96%. Compared to UC, HIIT significantly improved VO_{2peak} (adjusted between-group mean difference, 1.6 $ml \cdot kg^{-1} \cdot min^{-1}$; 95% confidence interval [CI], 0.3 to 2.9; p= 0.014). HIIT also significantly reduced PSA level (adjusted between-group mean difference, -1.1 ug/L; 95% CI, -2.1 to 0.0; p= 0.043) and PSA velocity (p= 0.040), and suppressed LNCaP cell growth (p =0.024). No significant differences were found in PSA doubling time (p= 0.10) and testosterone (p= 0.24). **Conclusions:** The ERASE Trial is the first randomized controlled trial to demonstrate the impact of HIIT exercise for improving physical fitness and inhibiting biochemical progression of PCa in men with localized PCa on AS. Our findings suggest that supervised aerobic HIIT may be a promising intervention in this clinical setting. Larger-scale randomized controlled trials are warranted to determine if improvements in physical fitness and PCa-related markers translate into improved long-term clinical outcomes in these men such as disease progression, receipt of radical treatments, posttreatment complications, and survival. Clinical trial information: NCT03203460. Research Sponsor: Canadian Institutes of Health Research (No. 389507), Other Foundation.

Active surveillance of postradical prostatectomy biochemical recurrence: Long-term assessment of outcomes. *First Author: Tom Edward Ahlering, University of California, Irvine, Orange, CA*

Background: Biochemical recurrence (BCR) following radical prostatectomy (RP) is an unreliable predictor of distant metastatic progression/prostate cancer death, resulting in potential complications & expenses of overtreatment. Little has been published on management decisions & outcomes of active surveillance (AS). We characterize our long term experience with AS following post-RP BCR without radiation/androgen deprivation therapy. **Methods:** From June 2002 - September 2019, 1865 men underwent RP. 406 experienced BCR; of these, 138 (34%) were observed without treatment intervention. BCR defined as PSA>0.2 ng/dl, x2. PSAs checked every 1-3 months and entered into a PSADT graph. Men were considered to be formally AS after 3+ years of increasing DT following RP. Men with decreasing DT were treated and censored. **Results:** The table depicts demographics of the AS patients; median follow-up was 7.3 years (IQR: 4.6-10.6) post-RP. Of patients on AS, average age was 63.7 +/- 7.2 years and 86%, 48%, 40%, 51% and 14% were GG 1 through 5, respectively. Current DT of AS patients averages 20 months, with 0% PCSM. Only 10% of patients with decreasing DT began treatment after average 4 years following BCR. **Conclusions:** Of 406 patients experiencing post-RP BCR, 34% of patients are effectively managed with AS, with 0% PCSM across all GG. Presently 69 (50%) AS men have been under observation for 7.3 to 18 years. This suggests that significant portion of patients display benign recurrence, characterized by increasing DT following BCR and can be managed safely with observation alone. Research Sponsor: None.

The somatic mutation landscape of germline *CHEK2*-altered prostate cancer. *First Author: Emily Nizialek, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: The intersection between germline and somatic genomics is an evolving field in which germline mutations may predispose to unique patterns of subsequent somatic mutations in cancer. Germline mutations in *CHEK2*, involved in cell cycle regulation and DNA damage response, are associated with an increased risk of prostate cancer (PCa), while somatic-only *CHEK2* alterations in PCa are rare. The association of germline *CHEK2* (g*CHEK2*)-altered PCa with somatic mutations is unknown, and may inform hypotheses about the etiology of these cancers. **Methods:** Germline DNA sequencing of 1,042 consecutive PCa patients (pts) from the public SignalDB database (www.signaldb.org) was analyzed for prevalence of pathogenic g*CHEK2* mutations and was compared to individuals from the general population estimated by the ExAC database (containing 53,105 germline exomes). A separate cohort of 33 PCa pts from Johns Hopkins (JH) with known g*CHEK2* mutations and available somatic tumor DNA sequencing (from primary prostatic tissue) was used to assess the association of g*CHEK2* mutations with somatic mutations in genes that are recurrently altered in PCa (*TP53*, *RB1*, *PTEN*, *ATM*, *BRCA1/2*, and *CDK12*); the prevalence of these somatic alterations was compared to those in 333 unselected PCa pts from the TCGA cohort. Somatic biallelic inactivation of *CHEK2* was analyzed in a subset of pts. After uncovering a potential link between g*CHEK2* and somatic *CDK12* mutations, we studied a cohort of 69 pts with somatic *CDK12* mutations where germline data were also available. **Results:** 28 of 1,042 (2.7%) PCa pts from SignalDB had a pathogenic g*CHEK2* mutation, compared to a population prevalence (in ExAC) of 1.4% (750 of 53,105) (RR 1.9, 95%CI 1.3–2.8, $P<$ 0.001). Strikingly, only 23.8% of pts from SignalDB with g*CHEK2* mutations had biallelic inactivation in the tumor. Furthermore, none of the 33 g*CHEK2* pts from the JH cohort had evidence of somatic LOH. There were no differences in mutation prevalences involving *TP53*, *RB1*, *PTEN*, *ATM*, and *BRCA1/2* between g*CHEK2*-altered and non-altered PCa pts. Unexpectedly, 5 of 33 (15%) g*CHEK2*-altered pts from the JH cohort had a somatic *CDK12* mutation, compared to only 3 of 333 *CDK12* mutations (1%) in unselected PCa pts from the TCGA cohort (RR 16.8, 95%CI 4.2–67, $P<$ 0.001). Conversely, 11 of 69 (16%) pts with a somatic *CDK12* mutation harbored a pathogenic g*CHEK2* mutation, compared to 28 of 1,042 (2.7%) unselected PCa pts from SignalDB (RR 5.9, 95%CI 3.1–11.4, $P<$ 0.001). **Conclusions:** Prostate cancers from g*CHEK2*-altered pts are infrequently characterized by biallelic *CHEK2* inactivation and may be enriched for somatic *CDK12* mutations, suggesting a unique mechanism of carcinogenesis that is different from g*BRCA2*-altered pts. Conversely, somatic *CDK12*-mutated cancers may be enriched for g*CHEK2* mutations. The co-occurrence of *CHEK2* and *CDK12* mutations suggests a synergistic role in promoting cancer growth. Research Sponsor: None.

TPS5085 **Poster Session**

The Courage study: A first-in-human phase 1 study of the CBP/p300 inhibitor FT-7051 in men with metastatic castration-resistant prostate cancer. *First Author: Andrew J. Armstrong, Duke Cancer Institute Center for Prostate & Urologic Cancers, Duke University, Durham, NC*

Background: Prostate cancer is the second leading cause of cancer-related death among men in the U.S., largely due to metastatic disease that progresses despite hormonal therapy (tx). The role for androgen receptor (AR) signaling in prostate cancer and hormone tx resistance is well-established. CBP/p300 are essential co-activators of AR-mediated transcription. FT-7051 is an oral, potent, and selective inhibitor of CBP/p300 with activity in preclinical models of prostate cancer including models resistant to currently used AR inhibitors like enzalutamide. The Courage Study (NCT04575766) is a first-in-human, multicenter, phase 1, open-label study examining the safety, pharmacokinetics (PK), preliminary anti-tumor activity, and pharmacodynamics (PD) of FT-7051 for the treatment of men with metastatic castration-resistant prostate cancer (mCRPC) who have progressed despite prior tx and have been treated with at least one approved androgen receptor pathway inhibitor. The study will enroll up to 45 men with mCRPC at ~8-15 US sites. **Methods:** The study employs a Bayesian optimal interval (BOIN) design with an accelerated titration. Patients (pts) will initially be enrolled in a dose level cohort size of 1 until a Grade 2 or higher toxicity occurs that is considered related to FT-7051 or the highest dose level is reached. Upon completion of the accelerated titration phase, subsequent cohorts will enroll 3-5 pts. *Treatment:* FT-7051 capsules will be administered on a 28 d cycle (21 d on / 7 d off) with Dose Levels -1 to 7 assigned per protocol using the BOIN design. *Key inclusion criteria*: Diagnosis of mCRPC with either adenocarcinoma or mixed histology AND rising PSA; previously failed at least one approved androgen receptor pathway inhibitor; ≥ 18 yrs of age; prior taxane chemotherapy permitted. *Key exclusion criteria*: Previous solid organ transplant, prior anticancer tx including prior tx with small molecules within 4 wks of first dose of study treatment, prior radiation tx within 4 wks prior to initiation of study treatment, prior androgen antagonist tx within 2 wks, prior radium-223 tx within 6 wks. *Endpoints*: Primary endpoints are to define the recommended phase 2 monotherapy dose of FT-7051 through assessments of DLTs, SAEs, clinically relevant AEs, and clinically relevant safety laboratory values. Key secondary endpoints include: PSA at 12 wks, time to PSA progression, time to radiographic progression, overall response rate, and plasma PK parameters. PD assessments of CBP/p300 inhibition in surrogate tissue, biomarker assessments in CTCs (AR, AR-v7), and peripheral blood are included. *Duration*: Pts will remain on study treatment until they are deemed to be no longer clinically benefiting (NLCB) by the treating Investigator or until unacceptable toxicity. Pt may be followed for survival for up to 24 months from last dose of study treatment. The first pt was dosed January 2021. Clinical trial information: NCT04575766. Research Sponsor: Forma Therapeutics, Inc.

TPS5086 **Poster Session**

CYCLONE 1: A phase 2 study of abemaciclib in patients with metastatic castration-resistant prostate cancer (mCRPC) previously treated with a novel hormonal agent and taxane-based chemotherapy. *First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: In cancer cells, the cyclin-dependent kinases 4 and 6 (CDK4 & 6)/retinoblastoma protein (Rb) pathway is commonly altered, resulting in uncontrolled cell cycle entry and proliferation. CDK4 & 6 inhibitors represent a major advance in the management of hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced or metastatic breast cancer (ABC or MBC, respectively). Abemaciclib is an oral selective inhibitor of CDK4 & 6 administered on a continuous dosing schedule, approved in combination with endocrine therapy for HR+, HER2- ABC or MBC. In addition, abemaciclib is also approved by the FDA as monotherapy for HR+, HER2- ABC or MBC following endocrine therapy and prior chemotherapy in the metastatic setting. Similar to the estrogen receptor signaling pathway in breast cancer cells, there is evidence that the androgen receptor axis activates CDK4 & 6 to sustain prostate cancer cell proliferation and survival. Preclinical studies in prostate cancer cell lines and xenograft models showed that abemaciclib exhibits single agent activity by inducing cell cycle arrest and tumor growth inhibition. Clinical activity of abemaciclib in combination with abiraterone and prednisone is investigated in a randomized phase 2 study in the first-line mCRPC setting (CYCLONE 2, NCT03706365). Despite recent advances, management of heavily pretreated mCRPC remains a major clinical challenge. Herein, we hypothesize that mCRPC patients whose disease progressed after novel hormonal agents (NHA) and taxane therapies may derive therapeutic benefit from single agent abemaciclib. **Methods:** CYCLONE 1 is a phase 2, single-arm, multicenter study to assess the safety and efficacy of abemaciclib monotherapy in 40 patients with mCRPC progressing after ≥1 NHA and 2 taxane regimens. Patients will be enrolled at time of prostate specific antigen (PSA) or radiographic progression per PCWG3 criteria and have at least 1 measurable lesion per RECIST 1.1. Metastatic tumor tissue (fresh biopsy or archival material <12 weeks) is required at baseline for biomarker analysis. Patients will receive abemaciclib 200 mg twice daily until unacceptable adverse events or disease progression. The primary objective is investigator-assessed objective response rate (ORR). Key secondary objectives include safety, radiographic progression-free survival, overall survival, PSA response rate, time to PSA progression, time to symptomatic progression, Ki-67 expression, patient-reported outcomes, and pharmacokinetics. Assuming an ORR of 15%, the study has over 73% power to observe a response rate of at least 12.5%. Accrual began in January 2021. Clinical trial information: NCT04408924. Research Sponsor: Eli Lilly and Company Ltd.

TPS5087 **Poster Session**

Study evaluating metastatic castrate resistant prostate cancer (mCRPC) treatment using ^{177}Lu-PNT2002 PSMA therapy after second-line hormonal treatment (SPLASH). *First Author: Kim N. Chi, BC Cancer Agency-Vancouver Centre, Vancouver, BC, Canada*

Background: Treatment options with minimal toxicity and novel mechanisms of action are urgently needed to improve clinical outcomes from mCRPC. Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) represents a new treatment for patients with PSMA-avid mCRPC. ^{177}Lu-PNT2002 (also known as [Lu-177]-PSMA-I&T) is a PSMA-targeting agent and studies have shown demonstrable promising initial data. This trial seeks to prospectively evaluate the efficacy of ^{177}Lu-PNT2002 for men with progressive mCRPC after androgen receptor axis-targeted (ARAT) therapy. **Methods:** This is a multi-center, open-label, phase III study. All patients must be at least 18 years of age, have documented progressive mCRPC at time of screening, high PSMA expression by PSMA PET/CT per blinded independent central review (BICR), chemotherapy naïve for CRPC and unfit or unwilling to receive chemotherapy. The study will commence with a 25-patient dosimetry lead-in. In the dosimetry phase, patients will receive up to four cycles of ^{177}Lu-PNT2002 at 6.8 GBq every 8 weeks. In the randomization phase, approximately 390 patients will be randomized in a 2:1 ratio to receive ^{177}Lu-PNT2002 (Arm A) versus enzalutamide or abiraterone (with prednisone or dexamethasone) (Arm B). Patients randomized to Arm B have an option to crossover to ^{177}Lu-PNT2002 treatment after BICR-assessed radiologic progression. The primary endpoint is Radiological progression-free survival (rPFS) assessed by BICR using Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 (soft tissue) and Prostate Cancer Working Group 3 (PCWG3) (bone) criteria. Key secondary endpoints include objective response rate, duration of response, PSA response, and overall survival. The study is powered at 90% to test the alternative hypothesis of a hazard ratio (HR) $\leq$ 0.66 at an α of 0.025. ClinicalTrials.gov identifier: NCT04647526. Clinical trial information: NCT04647526. Research Sponsor: POINT Biopharma Inc.

TPS5088 **Poster Session**

Safety and efficacy of AMG 160, a half-life extended BiTE immune therapy targeting prostate-specific membrane antigen (PSMA), and other therapies for metastatic castration-resistant prostate cancer (mCRPC). *First Author: Sumit Kumar Subudhi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Lesions in mCRPC are typically immunologically cold. AMG 160 binds to PSMA on cancer cells and CD3 on T cells, leading to T-cell infiltration, activation, expansion, and tumor cell killing. In a first-in-human study, AMG 160 has demonstrated a manageable safety profile with preliminary efficacy in heavily pretreated patients. Enzalutamide and abiraterone are novel hormonal therapies (NHTs) that improve survival in mCRPC and may enhance T-cell responses, but resistance occurs. Combination therapy with AMG 160 may help overcome hormonal therapy resistance and broaden use for earlier line mCRPC. Preclinical data have demonstrated enhanced activity when AMG 404, an anti-PD-1 that can overcome T-cell exhaustion, and AMG 160 are combined. The safety and efficacy of AMG 160 combinations will be evaluated. **Methods:** NCT04631601 will enroll ~100 men with histologically or cytologically confirmed adenocarcinoma of the prostate. The protocol consists of 3 subprotocols. Subprotocols A and B are phase 1b, multicenter, open-label studies; subprotocol C is a phase 1b/2 study. Therapeutic combinations include AMG 160 + enzalutamide (A), AMG 160 + abiraterone (B), and AMG 160 + AMG 404 vs AMG 404 monotherapy (C). Patients who received prior PSMA radionuclide therapy may be eligible. Patients must not have received prior PSMAxCD3 bispecific therapy, prior taxane treatment (unless approved by the sponsor) across subprotocols, and prior NHT specific to the subprotocol. In subprotocol C, patients must have progressive disease on an NHT to be eligible. Patients with CNS metastases, leptomeningeal disease, or active autoimmune disease will be excluded. AMG 160 will be administered intravenously (IV). Dexamethasone (or other corticosteroids) will be administered before AMG 160 administration in cycle 1 and possibly subsequent cycles. Enzalutamide or abiraterone will be administered per label. AMG 404 will be administered IV. Primary objectives are to evaluate safety and tolerability and determine the maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D) of AMG 160 combinations. Subprotocol C will also evaluate the preliminary antitumor activity of AMG 404 monotherapy. Secondary objectives are to assess preliminary antitumor activity and characterize pharmacokinetics. MTD/RP2D will be established in the dose-escalation phase, and the safety and tolerability of the MTD/RP2D will be confirmed in the expansion phase. Evaluation of preliminary antitumor activity will be based on RECIST 1.1 with Prostate Cancer Working Group 3 modifications, prostate-specific antigen (PSA) response, circulating tumor cell response, progression-free survival (radiographic, PSA, clinical), overall survival, and ^{68}Ga-PSMA-11 and ^{18}F-FDG PET/CT imaging. The study is currently recruiting patients. Clinical trial information: NCT04631601. Research Sponsor: Amgen Inc.

TPS5089 **Poster Session**

TALAPRO-2: A phase 3 randomized study of enzalutamide (ENZA) plus talazoparib (TALA) versus placebo in patients with new metastatic castration-resistant prostate cancer (mCRPC). *First Author: Neeraj Agarwal, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: TALA blocks poly(ADP-ribose) polymerase (PARP) activity and traps PARP on single-strand DNA breaks, preventing DNA damage repair (DDR) and causing death of cells with DDR alterations (eg, *BRCA1/2*).[a] TALA is approved in multiple countries as monotherapy for germline *BRCA1/2*-mutated human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer. Olaparib and rucaparib are PARP inhibitors approved for use in mCRPC. ENZA is an androgen receptor (AR) inhibitor and an established therapy for mCRPC. As PARP activity has been shown to support AR function, inhibition of PARP is expected to increase sensitivity to AR-directed therapies. In addition, AR blockade downregulates homologous recombination repair gene transcription, which induces a "*BRCA*ness" phenotype. A proof-of-concept study combining olaparib and abiraterone (abi) in pts with mCRPC demonstrated improved median radiographic progression-free survival (rPFS) vs placebo plus abi (13.8 vs 8.2 months) and a tolerable safety profile. Therefore, ENZA may be efficacious regardless of DDR alterations. TALAPRO-2 (NCT03395197) is a Phase 3, 2-part study evaluating the efficacy, safety, pharmacokinetics, and patient-reported outcomes (PROs) of TALA plus ENZA in pts with mCRPC with or without DDR alterations. **Methods:** Enrollment goal is 1037 patients (pts; 19 pts, part 1 dose-finding [completed]; 1018 pts, part 2 placebo-controlled [ongoing; accrual completed in unselected cohort]). Key eligibility criteria: age $\geq$18 years; asymptomatic/mildly symptomatic mCRPC; ECOG performance status $\leq$1; metastatic disease (no brain metastases); and no prior life-prolonging systemic therapy for nonmetastatic CRPC or mCRPC. Prior therapies (excluding novel AR inhibitors) in the castration-sensitive (CSPC) setting are allowed. ADT must continue throughout the study. The randomized double-blind portion (part 2) will evaluate safety, efficacy, and PROs of TALA (0.5 mg once daily [QD]) + ENZA (160 mg QD) vs placebo + ENZA (160 mg QD). Pts are stratified by prior novel hormonal therapy or docetaxel for CSPC or mCSPC (yes or no) and DDR alteration status (deficient vs nondeficient/unknown). The primary endpoint is rPFS, defined as time to progression in soft tissue per RECIST v.1.1 or in bone per PCWG3 criteria by independent central review or death. The key secondary endpoint is overall survival. Efficacy is assessed radiographically every 8 weeks up to Week 25 and every 8–12 weeks thereafter. rPFS will be compared between the two arms by a one-sided stratified log-rank test. Pt recruitment is ongoing at 223 sites in 26 countries, including 32 states across the US, and Europe, Israel, South America, South Africa, and Asia-Pacific region. [a]DDR alterations are defined as known/likely pathogenic variants or homozygous deletions. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc, Pharmaceutical/Biotech Company.

TPS5090 **Poster Session**

A phase 1/2a, open-label, multicenter study of intramuscular (IM) abiraterone decanoate (PRL-02) depot in patients with advanced prostate cancer (NCT04729114). *First Author: Tim Warneke, Propella Therapeutics, Inc., Pittsboro, NC*

Background: PRL-02 is a long-acting IM formulation of a lipophilic abiraterone prodrug being developed for the treatment of patients with metastatic castration-sensitive (mCSPC) and metastatic castration-resistant prostate cancer (mCRPC). In nonclinical models, PRL-02 has a longer effective half-life and duration of action compared to oral abiraterone acetate (AA), due to slow release of the prodrug into circulation. PRL-02 is expected to provide greater abiraterone bioavailability and less variability in pharmacokinetics than oral AA. Based upon results in non-human primate models, PRL-02 should provide efficacy (e.g., testosterone [T] suppression) comparable to oral AA, but with lower abiraterone peak plasma concentrations and overall exposures, potentially leading to a superior therapeutic index and safety profile. The current trial is a phase 1/2a, open-label, dose escalation and subsequent dose expansion study of PRL-02 in men with metastatic prostate cancer. Study Objectives: The primary objective of this study is to determine a recommended phase 2 dose (RP2D) of PRL-02 that provides adequate T suppression up to 84 days. The secondary objectives of this study include the evaluation of safety and tolerability, the pharmacokinetic profile following IM administration and the pharmacodynamic effects of PRL-02. **Methods:** The phase 1 portion (Dose Escalation) is a standard 3+3 design intended to identify a RP2D that adequately suppresses T up to 84 days. The phase 2a portion (Dose Expansion) will confirm the safety, tolerability and pharmacodynamic effects of the RP2D. Main inclusion criteria are orchiectomy or ongoing GnRH analogue therapy for at least 3 months and a screening T level $<$50 ng/dL but $>$2 ng/dL. Prior treatment with abiraterone (or any other CYP17 inhibitor) and current treatment with enzalutamide or any other AR blocking agents are excluded. Patients will undergo scheduled periodic assessments of T levels. Patients may remain on study unless their T is $>$1 ng/dL on two sequential determinations starting on Day 28 through Day 77 of the first dosing cycle. In phase 1, three patients will initially be enrolled at each dose. The starting dose is 180 mg (i.e., 1.0 mL of PRL-02) and dose escalation will proceed with a modified Fibonacci sequence. If none of the patients in a cohort experience a dose-limiting toxicity (DLT), the dose will be escalated in the next cohort of 3 patients. A DLT is defined as a drug-related Grade 3 or higher toxicity on the Common Terminology Criteria for Adverse Events v5.0, or meets drug-induced liver injury criteria, occurring during the first 28 days following the first dose. In phase 2a, 12 mCSPC and 12 mCRPC patients will be enrolled to receive up to 4 cycles of PRL-02 at the RP2D. The results of this phase 1/2a study will be presented at a future ASCO conference. Clinical trial information: NCT04729114. Research Sponsor: Propella Therapeutics.

TPS5091 **Poster Session**

A phase III trial of docetaxel versus docetaxel and radium-223 (Ra-223) in patients with metastatic castration-resistant prostate cancer (mCRPC): DORA. *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ra-223, a bone-targeted alpha therapy, prolongs survival in patients (pts) with symptomatic mCRPC to bone. Docetaxel targets microtubule trafficking improving survival in the mCRPC and metastatic hormone-sensitive settings. We hypothesized that simultaneously targeting the tumor and bone compartment yields superior outcomes than targeting either alone. We previously determined the dose and schedule of co-administering Ra-223 + docetaxel in a randomized phase I/IIa trial. The combination appeared to have improved declines in prostate specific antigen (PSA) and bone markers, delayed PSA progression, and was better tolerated (with adjusted dose/schedule) relative to standard docetaxel alone. We are now conducting a phase III study to determine the clinical benefit of the regimen. **Methods:** Randomization (1:1) of 738 men with mCRPC to docetaxel or docetaxel + Ra-223 is planned with a projected hazard ratio for treatment effect (15 vs 20 months median survival) of 0.75. Pts with ≥2 bone lesions and progression by Prostate Cancer Working Group 3 criteria are eligible. Other key inclusion criteria are an Eastern Cooperative Oncology Group performance status of 0–1 and normal organ function. Key exclusion criteria are: use of anticancer therapy ≤4 weeks (wks) before randomization and use of bone-seeking radiopharmaceuticals or chemotherapy in the castration-resistant setting, and bulky visceral metastases (≥3 lung and/or liver or a lesion ≥2 cm in the previous 8 wks). Subjects receive docetaxel 75 mg/m^2 IV q3w for 10 doses or docetaxel 60 mg/m^2 IV q3w for 10 doses + Ra-223 55 kBq/kg IV q6w for 6 doses. The primary endpoint is overall survival. Secondary and exploratory endpoints include: radiographic progression-free survival, symptomatic skeletal event-free survival, safety, markers of bone metabolism, alterations in circulating tumor cells and DNA, detection of androgen-receptor splice variant 7, changes in automated bone scan index (aBSI), and assessment of patient-reported outcome instruments (FACT-P, Brief Pain Inventory, Brief Fatigue Inventory). The study is open at 32 sites in the US and Netherlands and has 170 subjects enrolled. The study is sponsored by Memorial Sloan Kettering Cancer Center, and managed by the Prostate Cancer Clinical Trials Consortium. Clinical trial information: NCT03574571. Research Sponsor: Bayer Pharmaceuticals.

TPS5092 **Poster Session**

TNB585.001: A multicenter, phase 1, open-label, dose-escalation and expansion study of tnb-585, a bispecific T-cell engager targeting PSMA in subjects with metastatic castrate resistant prostate cancer. *First Author: Ben Buelow, TeneoBio, Inc., Menlo Park, CA*

Background: Prostate cancer (CaP) is the most common cancer in US men. Disseminated CaP invariably progresses to metastatic castrate-resistant prostate cancer (mCRPC). Current treatment options for mCRPC usually lead to therapeutic resistance, and novel therapies are urgently needed. PSMA is a prostate-specific antigen over-expressed on most mCRPC. Antibodies against PSMA have been used to create T-cell engaging bispecific Abs (TCEs) and chimeric antigen receptor T cells, but all such approaches to date induce frequent/severe cytokine release syndrome (CRS). We combined a high-affinity αPSMA moiety with a low-activating αCD3 binder to create TNB-585; in preclinical studies, TNB-585 showed equivalent anti-tumor efficacy but much reduced cytokine secretion compared to PSMA-targeted TCEs with a strongly activating αCD3 domain. TNB-585 also has a full length silenced Fc domain, conferring a 3-week half-life. A phase 1 study investigating the safety, pharmacokinetics (PK), anti-drug antibodies (ADA) and preliminary activity of TNB-585 in patients with mCRPC is ongoing and described. **Methods:** TNB585.001 (NCT04740034) is an open-label, multi-center study of TNB-585 in patients with mCRPC. The study is divided into escalation (Arm A, N=24) and expansion (Arm B, N=30) arms. Subjects who have received 2 or more prior lines of therapy are eligible. Prior exposure to PSMA-targeted therapy is permitted, as are well-controlled HBV, HCV, and HIV infection; subjects with secondary malignancies that do not interfere with the study may also be enrolled. Other key inclusion/exclusion criteria include EGFR of > 30ml/min and ECOG ≤ 2. TNB-585 is administered as an intravenous infusion every 3 weeks. Subjects must be admitted for 48 hours after their 1st dose; TNB-585 is given on an outpatient basis thereafter. Dose escalation is proceeding in Arm A via single patient cohorts until the onset of toxicity or activity; thereafter subjects enroll using a BOIN design. Arm B will start once the maximum tolerated dose (MTD) / recommended phase 2 dose (RP2D) has been selected. Subjects will be treated until progression or unacceptable toxicity. In Arm A, occurrence of dose limiting toxicities (DLTs) will drive identification of the MTD (or RP2D) based on the BOIN escalation and de-escalation boundaries (λe of 0.236 and a λd of 0.358). In Arm B accrual will be suspended if more than 33% of subjects experience a DLT event. Adverse events (AEs), laboratory profiles, and vital signs will be assessed throughout the study. AEs are graded according to the NCI CTCAE, version 5.0. The activity endpoints (per PCWG3/RECIST1.1) include overall response rate, PSA50, PSA30, CTC counts, progression free survival and overall survival. The relationship between PSMA expression (via PSMA-PET) and activity will be assessed. Clinical trial information: NCT04740034. Research Sponsor: Teneobio, Inc.

TPS5093 **Poster Session**

Radium-223 (Ra-223) versus novel antihormone therapy (NAH) for progressive metastatic castration-resistant prostate cancer (mCRPC) after 1 line of NAH: RADIANT, an international phase 4, randomized, open-label study. *First Author: Karim Fizazi, Institut Gustave Roussy and University of Paris Saclay, Villejuif, France*

Background: Men with mCRPC often receive sequential NAH (abiraterone and enzalutamide) despite reported cross-resistance, indicating a need for further life-prolonging options for progressive disease after prior NAH. Ra-223 is a targeted alpha therapy approved for mCRPC with symptomatic bone metastases based on the phase 3 ALSYMPCA study, in which it demonstrated significantly increased overall survival (OS), reduced symptomatic skeletal event (SSE) risk, improved quality of life, and reduced treatment-emergent adverse event rates vs placebo. As life-prolonging therapy is increasingly used in hormone-sensitive settings, this study has been designed to assess Ra-223 outcomes in patients with mCRPC that progressed after prior treatment with NAH and docetaxel for metastatic hormone-sensitive prostate cancer (mHSPC) or mCRPC. **Methods:** This study is conducted in accordance with the Declaration of Helsinki, international ethical and good clinical practice guidelines, and local laws and regulations, with institutional review board/ethics committee approval at each site and written informed consent from patients before participation. This trial is registered with EudraCT: 2019-000476-42. Participants must be ≥18 years old, with an Eastern Cooperative Oncology Group performance status of 0/1; they must have mCRPC that progressed on/after ≥3 months of NAH for mHSPC or mCRPC and ≥2 cycles of docetaxel unless they refused or were ineligible, with ≥2 bone metastases on bone scan, no visceral metastases, and a worst pain score ≥1 on the Brief Pain Inventory-Short Form. Patients are randomized 1:1 to Ra-223 or NAH: Ra-223 55 kBq/kg intravenously every 4 weeks for 6 cycles or until disease progression, death, or withdrawal of consent if earlier; or abiraterone 1000 mg + prednisone 10 mg daily (if prior enzalutamide) or enzalutamide 160 mg daily (if prior abiraterone) until disease progression, death, or withdrawal of consent. NAH dosing may be modified to manage adverse events. Patients must use luteinizing hormone-releasing hormone analogs, if not surgically castrated, and bone health agents (bisphosphonates or denosumab) throughout the study. The primary endpoint is OS. Secondary endpoints are time to first SSE, radiologic progression-free survival, time to pain progression, adverse events, fracture incidence, and time to deterioration in quality of life (FACT-P total score). Using a test with a two-sided alpha of 0.05, 90% power, and randomization ratio of 1:1, approximately 508 events are required to detect a 33% increase in OS with Ra-223 vs NAH, assuming a median OS of 10 months with NAH. The expected study duration is 55 months, with a target of 696 patients to be randomized. The first patient was enrolled on November 9, 2020; 5 patients have been randomized and 2 have started treatment to date. Clinical trial information: 2019-000476-42. Research Sponsor: Bayer AG.

TPS5094 **Poster Session**

Phase I study of CCW702, a bispecific small molecule-antibody conjugate targeting PSMA and CD3 in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: CCW702 is a novel bispecific antibody comprised of a small molecule imaging agent ligand (DUPA) with specificity for prostate specific membrane antigen (PSMA) conjugated to an anti-CD3 antibody via an unnatural amino acid. This format has the structure of an antibody drug conjugate with the activity of a CD3-engaging bispecific antibody. The design of CCW702 was leveraged to optimize the structure and function of T cell redirected cytotoxicity against PSMA-positive prostate cancer tumors in preclinical development. **Methods:** This is a first-in-human, open-label, multicenter phase 1 study evaluating the safety and tolerability of CCW702 when administered via subcutaneous (SC) injection in men with mCPRC. This study will be conducted in two parts: Part I, a dose escalation to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (R2PD); Part II, a dose expansion to determine efficacy at the R2PD. Safety, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity, and preliminary efficacy will be evaluated. Efficacy will be assessed by change in circulating tumor cells (CTC), PSA_{50} response rate, and objective tumor response by RECIST v1.1. Key biomarkers include characterization of CTC, T cell phenotyping in peripheral blood, chemokines and cytokines over time, and evaluation of available tumor biopsies by IHC. Key inclusion criteria include men age ≥ 18 years with histologically or cytologically confirmed adenocarcinoma who, in the metastatic setting, have progressed on at least one novel AR-targeted therapy. Up to 1 prior chemotherapy regimen is allowed. This study will enroll 20-30 patients in Part 1 and approximately 40 patients in Part 2. The study opened in December 2019 and is currently enrolling in the dose escalation phase. Clinical trial information: NCT04077021. Research Sponsor: Wellcome Trust.

TPS5095 **Poster Session**

Open label phase II trial of cabozantinib (cabo) in patients with metastatic castrate resistant prostate cancer (mCRPC) and known amplifications or activating mutations in gene targets who have received prior anti-androgen therapy. *First Author: Jones T. Nauseef, NewYork-Presbyterian Hospital/ Weill Cornell Medical Center, New York, NY*

Background: Despite a variety of therapy classes extending survival in mCRPC – and excepting select population eligible for PARP inhibitors – no molecularly selected drugs are FDA approved in mCRPC. Previously, cabo, an inhibitor of multiple tyrosine kinases (*e.g.* MET, VEGFRs 1-3, RET, KIT, TRKB, FLT-3, AXL, TIE-2), was evaluated in phase III trials (COMET-1, COMET-2) in mCRPC. Despite initial promising results, particularly in bone scan responses and rPFS benefit, further application of cabo in mCRPC was halted after improvement in OS was not observed. It is unclear why prolonged rPFS in COMET-1 (vs. prednisone) did not translate into improved OS. Previous failures may reflect inclusion of relatively cabo-insensitive tumors due to an unselected population with regard to presumed cabo activity. Given that mCRPC specimens from our precision medicine cohort have increased expression of target genes *MET* and *KIT*, and qualifying genomic alterations (amplifications, activating mutations) are reported in ~15% of a publicly-available mCRPC cohort, we developed this rationally-designed study. We predict a molecularly-defined mCRPC cohort will identify the population that most benefits from cabo therapy, as reflected by prolonged rPFS and OS, and more frequent PSA declines and CTC conversions. **Methods:** We have activated a phase II non-randomized, open label trial designed to evaluate treatment response and survival of patients with mCRPC who harbor evidence of increased signaling of the targets of cabo. Study population will have progressed on an ARSI; prior taxane therapy in castration-sensitive PC or CRPC (beyond 12 mos) will be eligible. Molecular eligibility: DNA (tumor or cfDNA) evidence of amplification or activating mutation in selected targets of cabo. Alternatively, IHC confirming high expression (2 or 3+) via CLIA-approved assay is allowed. Overexpression via RNAseq, validated by CLIA-approved IHC, is permitted. All patients will receive 40 mg/d of cabo, with dose-reductions allowed (to 20 mg/d, then 20 mg EOD). Repeat biopsy after 3 weeks on treatment is mandated. Primary endpoint is rPFS. Using median of 5.6 mos (COMET-1) to guide our H_0 (50% rPFS rate at 6 mo), the H_1 is $\geq$75% rPFS at 6 mo. Sample size (30) provides 90% power with one-sided alpha of 0.05 via chi-square test. Secondary endpoints include PSA decline by PCWG3, objective radiographic response proportion, OS, and CTC response rate. Exploratory studies will include serial evaluation of cfDNA (via PCF-SELECT); immune tumor microenvironment response via on-treatment biopsy and collection of plasma for circulating immune markers; and exploration of baseline and on-treatment tumor genomic alterations. This trial is multicentered via the Prostate Cancer Clinical Trials Consortium (PCCTC c20-254). Clinical trial information: NCT04631744. Research Sponsor: Exelixis, Conquer Cancer Foundation of the American Society of Clinical Oncology.

TPS5096 **Poster Session**

A phase I/II study of bintrafusp alfa and NHS-IL12 in combination with docetaxel in adults with metastatic castration sensitive (mCSPC) and castration-resistant prostate cancer (mCRPC). *First Author: Mohammad O. Atiq, National Cancer Institute, Bethesda, MD*

Background: Immune checkpoint inhibition is successful in a small subpopulation of men with prostate cancer. This could be related to barriers to immune response in the tumor microenvironment. Immunocytokines present an opportunity to specifically target the pleiotropic tumor microenvironment impacting immune cells beyond T-cells. NHS-IL12 is an immunocytokine that carries IL-12 (shown to impact natural killer and myeloid cells) and binds to necrotic tissue with exposed histones. Phase 1 studies have indicated immune and even PSA responses in prostate cancer to NHS-IL12 (Strauss J, CCR 2019). Preclinical data has demonstrated synergy with docetaxel, which is standard therapy in both mCSPC and mCRPC. Further synergy has been shown with a novel first-in-class bifunctional fusion protein (bintrafusp alfa) composed of the extracellular domain of human TGF-β receptor II (TGFβRII), which effectively functions to sequester or "trap" all three TGF-β isoforms (Lind H, JITC 2020), fused to a monoclonal antibody against PD-L1. This study will examine the potential of a novel combination of chemotherapy, checkpoint inhibition, and immunocytokines in metastatic prostate cancer. **Methods:** The study will evaluate safety of NHS-IL12 with docetaxel at escalating doses followed by the addition of bintrafusp alfa in all metastatic patients. Once safety of the combination is established, patients will enroll in 2 cohorts with either mCSPC or mCRPC. Eligible patients include mCSPC ($\leq$134 days of starting ADT) and mCRPC (must have been previously treated with abiraterone or enzalutamide), with good performance status (ECOG of $\leq$ 2). Patients with brain metastases or who are immunocompromised are excluded. For mCSPC, the primary endpoint will evaluate the increase in the proportion of patients who have a PSA less than 0.2 ng/mL 7 months after the start of ADT, which is based on the prognostic value of PSA less than 0.2 ng/mL at 7 months in mCSPC (Harshman L, JCO 2017). The secondary endpoint is biochemical and radiographic time to progression. The primary endpoint for the mCRPC patients will evaluate progression free survival with secondary endpoints examining the percentage of patients with a 50% PSA decline from baseline and radiographic response rates per RECIST. Exploratory analysis will analyze changes in immune cell subsets after treatment as well as immune status of the tumor microenvironment. Clinical trial information: NCT04633252. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS5097 **Poster Session**

Identifying androgen receptor (AR) and genomic characteristics that define populations of patients with mHSPC who benefit from early PARP inhibition therapy with talazoparib. *First Author: Saro Kasparian, City of Hope, Duarte, CA*

Background: A minority of men with mCRPC, those with DNA repair mutations, can benefit from PARP inhibitor therapy. In addition to DNA repair, PARP is used by cancer cells to interact with other cellular mechanisms including androgen receptors (AR). The next generation PARP inhibitor talazoparib can, in addition to inhibiting DNA repair, trap PARP, preventing it from carrying out its other functions. As progression in mHSPC is based on AR escape mechanisms, we predict that early exposure to PARP inhibition will delay progression. In addition, AR characteristics and function vary by ethnic populations. AR expression is inversely related with the number of polymorphic CAG repeats. As African American (AfrAm) men commonly have shorter CAG repeats in their AR, they may experience different response duration, but have been under-represented in clinical trials. Furthermore, CAG repeats may be associated with greater signaling through pathways such as wnt and Myc, which is associated with aggressive disease. Thus, studying intensified up-front therapy in a diverse prostate cancer population is a critical unmet need. **Methods:** 70 subjects will be treated with ADT + abiraterone + talazoparib. Outreach by our Division of Health Equities and accrual at community satellites located near diverse populations will be enlisted to accrue a target of 30% African American. Talazoparib will be dosed at 1mg daily (0.75 mg in renal insufficiency). LHRH and abiraterone formulations will be left to physician's choice. PSA and safety labs will be checked every 4 weeks for the first 12 weeks. Imaging will be performed every 12 weeks for the first year then every 24 weeks if PSA is decreasing, or 12 weeks if rising. Data safety monitoring for toxicity after every 10 subjects have been accrued. Diversity of accrual will be evaluated after 30 subjects are enrolled; amendments will be made if the diversity goal is not achieved. Tissue genomics and ctDNA will be measured at baseline; ctDNA will be repeated after 4 weeks and at castration resistance. Endpoints: Primary: PSA nadir at 7 months has been found to be associated with overall survival and is achieved by 55% of men with mHSPC with ADT + abiraterone. With 70 subjects there is 97% power to confirm improved nadir rate of 75%, and 83% power to determine a nadir rate $>$70%. Secondary endpoints include objective response by RECIST 1.1 for subjects with measurable disease. radiographic progression free survival. Correlative objectives include comparing outcomes in subsets of men with high vs low number of AR CAG repeats, men with genomic alterations, and the change in ctDNA alteration fractions from baseline to 4 weeks and at progression. Progress: The trial is open to accrual as of Feb 2021. Sponsor: Pfizer/ Prostate Cancer Foundation RFP Clinical trial information: NCT04734730. Research Sponsor: Pfizer.

TPS5098 **Poster Session**

Phase III study of local or systemic therapy INtensification DIrected by PET in prostate CAncer patients with post-prostaTEctomy biochemical recurrence (INDICATE): ECOG-ACRIN EA8191. *First Author: Neha Vapiwala, University of Pennsylvania, Philadelphia, PA*

Background: Radiation therapy (RT) to the prostate bed and pelvic nodes with short-term androgen deprivation therapy (STAD) is considered a standard of care (SOC) salvage therapy (ST) paradigm for prostate cancer (PC) patients (pts) with post-prostatectomy (RP) biochemical recurrence (BCR). Fluciclovine-PET/CT imaging is FDA-approved in this setting, with improved accuracy for detection of metastases not identified with conventional imaging (CIM). Given PET's greater sensitivity and specificity, its findings are increasingly but variably applied to justify modification or omission of SOC therapies without high-level evidence of clinical benefit. PET may help identify candidates for local or systemic treatment intensification of the otherwise non-tailored SOC approach. Improved systemic control and disease detection with molecular imaging have led to increasing use of focally ablative metastasis-directed RT, to delay or enhance systemic therapy through increased local control. There is also interest in earlier use of systemic therapy; apalutamide (Apa) is a nonsteroidal antiandrogen with established efficacy in improving overall and radiographic progression-free survival (PFS) for non-metastatic castration-resistant and metastatic castration-sensitive PC. This study will evaluate whether pts with PET-detected lesions benefit from such local or systemic treatment intensification approaches. **Methods:** PC pts with post-RP BCR (PSA$>$0.5ng/mL; $>$0.2ng/mL if within 12 mos of RP) and no metastases on CIM who are candidates for SOC ST (RT to prostate bed and pelvic nodes with STAD) are eligible. Prior to study registration, pts undergo SOC baseline PET (^{18}F-fluciclovine but PSMA radiotracers permitted pending commercial availability). Based on institutional clinical interpretation of the SOC PET, pts will be placed in Cohort 1 (PET-negative) or 2 (PET-positive for extra-pelvic metastases). Cohort 1 will be randomized to SOC ST +/- Apa for 6 months and Cohort 2 will be randomized to SOC ST and Apa +/- metastasis-directed RT to PET-positive lesions. The primary endpoint is PFS, defined as time from randomization to radiographic progression on CIM, symptomatic disease or death. Primary objectives are to evaluate whether addition of Apa to SOC ST and addition of metastasis-directed RT to SOC ST and Apa could prolong PFS in Cohorts 1 and 2, respectively. For Cohort 1, 480 pts will be randomized with 85% power to distinguish 5-year PFS rate of 90% (Apa arm) vs. 80% (SOC arm) using one-sided stratified log-rank test with type I error of 0.025. For Cohort 2, 324 pts will be randomized with 85% power to distinguish 5-year PFS rate of 76.5% in the experimental arm from 61.5% in the control arm. Secondary endpoints include overall and event-free survival, toxicity, and PET progression. Clinical trial information: NCT04423211. Research Sponsor: U.S. National Institutes of Health.

TPS5099 **Poster Session**

The fluciclovine (FACBC) PET/CT site-directed therapy of oligometastatic prostate cancer (Flu-BLAST-PC) trial. *First Author: Risa Liang Wong, University of Washington, Seattle, WA*

Background: Patients with biochemical recurrence (BCR) after local definitive therapy for prostate cancer (PC) represent the largest group of patients alive with PC in the United States. For patients with BCR after both radical prostatectomy and radiation, no further definitive treatment options currently exist as standard of care. FACBC PET/CT is a next-generation imaging modality approved in 2016 for suspected PC recurrence based on elevated PSA levels following prior treatment. FACBC PET/CT allows for earlier detection at lower PSA levels of oligometastatic PC in patients who would otherwise be considered as having micro-metastatic disease. FACBC PET/CT may provide potential targets for site-directed therapy; however, it is unknown whether this approach leads to improvement in clinically relevant outcomes. **Methods:** Flu-BLAST-PC (ClinicalTrials.gov Identifier: NCT0417543) is a prospective, interventional study enrolling men with PC and BCR who have previously undergone both radical prostatectomy and adjuvant or salvage radiation to the prostatic fossa, with PSA $\geq$0.5 to $<$ 10 ng/mL, PSA doubling time $>$ 3 to $<$ 18 months, and no radiographically detectable metastases by conventional CT and bone scan imaging. Enrolled patients undergo FACBC PET/CT imaging, and those with no PC metastases detected (Group 1) undergo observation with repeat FACBC PET/CT performed at PSA thresholds of $>$ 2 and $>$ 5 ng/mL, with eligibility for the trial ending at PSA $\geq$10 ng/mL if FACBC PET/CT remains negative. Those with 1-3 PC regions (defined as radiation fields) detected on FACBC PET/CT (Group 2) undergo site-directed therapy with surgery (e.g. lymphadenectomy) and/or radiation, as well as six months of systemic treatment with androgen deprivation therapy (ADT) and abiraterone acetate with prednisone. Patients with $\geq$4 PC regions detected on FACBC PET/CT (Group 3) undergo six months of ADT and abiraterone acetate with prednisone without any site-directed therapy. Patients initially in Group 1 who subsequently have PC metastases detected on repeat FACBC PET/CT imaging per protocol join Group 2 or Group 3 based on the number of PC regions involved. Given the long anticipated survival of patients with PC and BCR, the primary endpoint of the study is undetectable PSA ($<$ 0.2 ng/mL) rate in Group 2 at two years beyond study treatment, with secondary endpoints including the same outcome measure for Group 3, undetectable PSA rate two years after testosterone recovery from ADT in Groups 2 and 3, time to re-initiation of ADT, overall survival, and safety and tolerability. Assuming a null hypothesis of 15% undetectable PSA rate for patients with BCR two years after completing ADT and alternative hypothesis of improvement to 40% in Group 2, planned enrollment is 65 patients in Group 2. This will provide 90% power at the two-sided significance level of 0.05. Five patients have enrolled to date. Clinical trial information: NCT0417543. Research Sponsor: Institute for Prostate Cancer Research, Pharmaceutical/Biotech Company.

TPS5100 **Poster Session**

Phase 1b study of AMG 757, a half-life extended bispecific T-cell engager (HLE BiTEimmune-oncology therapy) targeting DLL3, in de novo or treatment emergent neuroendocrine prostate cancer (NEPC). *First Author: Rahul Raj Aggarwal, Univ of California San Francisco, S San Francisco, CA*

Background: NEPC is an aggressive cancer with poor prognosis. No standard treatment approach for NEPC exists and it remains an unmet need. NEPC is usually treatment-emergent, characterized by histological transformation from adenocarcinoma to a high-grade neuroendocrine tumor (NET), and may develop in 15%–20% of patients (pts) treated with standard prostate adenocarcinoma therapies, including novel hormonal therapies. The inhibitory Notch ligand, Delta-like ligand 3 (DLL3), is highly expressed on the surface of cancer cells, including NEPC cells, making it an attractive and a promising therapeutic target. AMG 757 is an HLE BiTE immuno-oncology therapy designed to redirect cytotoxic T cells to tumor cells by binding DLL3 on cancer cells and CD3 on T cells, resulting in T cell activation and expansion and T cell-dependent killing of tumor cells. AMG 757 showed in vitro activity in DLL3-expressing NETs, including NEPC. Preliminary results of an on-going first-in-human study suggest AMG 757 is safe and effective in pts with small cell lung cancer (NCT03319940), which prompted its study in NEPC. **Methods:** NCT04702737 is an open-label, phase 1b study evaluating AMG 757 infusion in pts with metastatic de novo or treatment-emergent NEPC, consisting of dose exploration and then dose expansion. Key eligibility criteria include adults ($\geq$18 y) with NEPC whose disease progressed/recurred after $\geq$1 treatment course including a platinum-based regimen for de novo NEPC or an androgen signaling inhibitor, measurable disease per modified RECIST 1.1 per Prostate Cancer Working Group 3 modifications, ECOG performance status $\leq$2, life expectancy $>$ 3 mo, adequate organ function, and no untreated/symptomatic brain metastases. Primary objectives are to evaluate safety and tolerability and determine the maximum tolerated dose or recommended phase 2 dose of AMG 757. Secondary objectives are to evaluate antitumor activity (ie, objective response, duration of response, progression-free survival, overall response) and characterize pharmacokinetics. The starting dose for dose exploration will be based on the dose deemed safe and tolerable in the ongoing trial of AMG 757 in SCLC. The study is open to enrollment. Clinical trial information: NCT04702737. Research Sponsor: Amgen Inc.

5500 **Oral Abstract Session**

Efficacy and safety results from neopembrov study, a randomized phase II trial of neoadjuvant chemotherapy (CT) with or without pembrolizumab (P) followed by interval debulking surgery and standard systemic therapy ± P for advanced high-grade serous carcinoma (HGSC): A GINECO study. *First Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard, University Claude Bernard, Lyon, France*

Background: To investigate whether adding Pembrolizumab (P) to neoadjuvant carboplatin-paclitaxel chemotherapy (CP) may increase the optimal debulking rate, assessed by Complete Resection Rate (CRR) after Interval Debulking Surgery (IDS) in patients (pts) with initially unresectable International Federation of Gynecology and Obstetrics (FIGO) stage IIIC/IV ovarian, tubal or peritoneal HGSC. **Methods**: Multicenter, open-label, non-comparative randomized phase II trial. Pts were randomized (2:1) to receive 4 cycles of CP ± P before IDS. After IDS, all patients received post-operative chemotherapy (2 to 4 cycles) and optional bevacizumab for 15 months in total ± P as maintenance therapy for up to 2 years. Randomization was stratified on center, FIGO stage, Bev planned after IDS and disease volume (<5cm/>5cm). Primary endpoint was the centrally reviewed CRR at IDS. 60 pts were planned in the CP+P arm (A'Hern's single-stage design P0=50%, P1=70%). Safety (particularly due to P addition), surgical morbidity, ORR, PFS and OS were secondary endpoints. **Results**: 91 pts were randomized from 02/18 to 04/19 with a median Peritoneal Cancer Index at 24 (range 7-39). 80 pts (88%) received Bev in combination with CP followed by bev ± P in maintenance. In the CP+P group (n=61), 58 (95%) pts had IDS and 78% achieved complete resection. The CRR in this group was 74%, statistically superior to the pre-defined hypothesis. In the CP group, CRR was 70% (29/30 pts underwent IDS). Complete resection after strictly 4 cycles of CP±P was obtained for 41 pts (71%) and 17 (58%) pts in CP+P and CP group, respectively (sensitivity analysis). For CP+P group, numerically higher ORRs were observed before IDS compared to CP group (76% vs 61%). Grade ≥3 adverse events (AE) occurred in 75% of the CP+P group and 67% in the CP group: mainly blood and lymphatic, gastrointestinal and vascular disorders. Postoperative AE (mainly infectious, vascular and gastrointestinal) occurred in 20% and 13% of the pts in CP+P and CP arm, respectively. No difference in the number of fatal events between the two arms: 2 in the experimental arm vs 1 in the control arm. Progression free survival rate at 18 months was 61% (95CI% [47-73]) and 57% (95CI% [37-72]) in CP+P and CP arm, respectively. **Conclusions:** P may be safely added to preoperative treatment in pts deemed non-optimally resectable. The primary objective was met with an improved CRR on CP+P arm. The CRR in the control group was higher than expected. Survival data and translational research including PDL1 status are ongoing to better define P as treatment option in this setting. Clinical trial information: 2016-004-163-39. Clinical trial information: NCT03275506. Research Sponsor: MSD, Fondation ARC.

5501 **Oral Abstract Session**

Optimal treatment duration of bevacizumab (BEV) combined with carboplatin and paclitaxel in patients (pts) with primary epithelial ovarian (EOC), fallopian tube (FTC) or peritoneal cancer (PPC): A multicenter open-label randomized 2-arm phase 3 ENGOT/GCIG trial of the AGO Study Group, GINECO, and NSGO (AGO-OVAR 17/BOOST, GINECO OV118, ENGOT Ov-15, NCT01462890). *First Author: Jacobus Pfisterer, AGO Study Group & Gynecologic Oncology Center, Kiel, Germany*

Background: GOG-0218 established the addition of BEV 15 mg/kg every 3 weeks (q3w) for 15 months to standard front-line chemotherapy for advanced ovarian cancer, but the optimal BEV duration remained unknown. We report primary results from a randomized phase 3 trial designed to address this question. **Methods:** Eligible pts with FIGO stage IIB–IV EOC, FTC, or PPC and ECOG PS ≤2 underwent primary cytoreductive surgery followed by 6 cycles of chemotherapy (paclitaxel 175 mg/m^2 + carboplatin AUC 5 q3w) and BEV (15 mg/kg q3w). Pts were randomized to receive BEV for either 15 months (standard arm BEV15) or 30 months (experimental arm BEV30), stratified by FIGO stage/residual tumor (stage IIB–IIIC/no residual tumor vs stage IIB–IIIC/residual tumor or stage IV). The primary endpoint was investigator-assessed progression-free survival (PFS) according to RECIST v1.1. Secondary endpoints were overall survival (OS), objective response rate, quality of life, safety, and tolerability. The trial was designed with 80.2% power to detect a hazard ratio (HR) of 0.66 favoring BEV30 (2-sided log-rank test, 5% significance level, 10% dropout rate) after 697 PFS events. The trial was funded by F. Hoffmann-La Roche Ltd., performed according to ENGOT model A. **Results:** From Nov 2011 to Aug 2013, 927 women (83% with EOC) from 161 centers were randomized. Baseline characteristics were balanced between arms; median age was 61 years, 96% had ECOG PS 0/1, 58% had no residual tumor, and 77% had high-grade serous histology. Serious adverse events of special interest for BEV occurred in 51/448 pts (11%) vs 61/442 pts (14%) receiving BEV15 vs BEV30, respectively: hypertension (2.7%/4.5%), thromboembolic event (2.2%/3.2%), fistula (3.1%/1.1%), gastrointestinal perforation (0.2%/0.9%), proteinuria (0.7%/1.4%), hemorrhage (0.2%/0.9%), and myocardial infarction (0%/1.1%). Efficacy is shown in the table. **Conclusions:** Longer treatment with BEV for up to 30 months improves neither PFS nor OS in pts with primary EOC, FTC, or PPC. Therefore BEV treatment duration of 15 months remains standard of care. Clinical trial information: NCT01462890. Research Sponsor: F. Hoffmann-La Roche Ltd., Basel, Switzerland.

Endpoint	BEV15 (n = 464)	BEV30 (n = 463)	p-value
PFS events, n (%)	333 (72)	340 (73)	
Median PFS, months (95% CI)	24.2 (22.2–26.5)	26.0 (23.7–29.7)	
PFS HR (95% CI)	0.99 (0.85–1.15)		p = 0.90
Restricted mean PFS (95% CI)*	39.5 (36.3–42.7)	39.3 (36.2–42.4)	p = 0.92
OS events, n (%)	257 (55)	275 (59)	
Median OS, months (95% CI)	54.3 (51.0–64.6)	60.0 (54.0–68.6)	
OS HR (95% CI)	1.04 (0.87–1.23)		p = 0.68

5502 **Oral Abstract Session**

Maintenance vigil immunotherapy in newly diagnosed advanced ovarian cancer: Efficacy assessment of homologous recombination proficient (HRP) patients in the phase IIb VITAL trial. *First Author: Rodney Paul Rocconi, University of South Alabama, Mobile, AL*

Background: In the VITAL (NCT02346747) trial, maintenance therapy with Vigil, an autologous tumor cell vaccine transfected with a DNA plasmid encoding GMCSF and bi-shRNA-furin for TGFβ expression control, following frontline platinum-based chemotherapy led to a recurrence-free survival (RFS) benefit in patients with advanced high-grade ovarian cancer (HR=0.69, 90% CI 0.44–1.07, p=0.078) and significantly in *BRCA*-wt patients (HR=0.51, 90% CI 0.30-0.88, p=0.020) (Rocconi et al. *Lancet Oncol.* 2020). Here we report post-hoc HR deficiency (HRD) subgroup analysis and identification of an additional molecular subgroup sensitive to Vigil therapy involving STRING analysis. **Methods:** This double-blind, placebo-controlled, Phase 2b study randomized 92 patients with newly diagnosed stage III/IV ovarian cancer with a complete clinical response (CR) to frontline surgery and chemotherapy. Patients received 1 x 10e7 cells/ml of Vigil or placebo intradermally once a month for up to 12 doses or disease progression. RFS was the primary endpoint assessed by blinded independent central review. HRD status was determined according to the Myriad Genetics myChoice CDx assay (HRD score < 42 for proficient). Using tumor annotated DNA polymorphism data, a protein-protein interaction network was constructed using the STRING database. Properties of this network including topological distance and the identification of hub genes were used to predict a target molecular population sensitive to Vigil. **Results:** In the per-protocol population (PP, n=91), 62 BRCA-wt patients were tested for HRD status. Forty-five patients were HR proficient (HRP) and 17 patients were HR deficient (HRD). No HRP patients in the Vigil group reported treatment related Grade 3 or higher adverse events. From the time of study randomization median RFS was improved with Vigil (n=25) in HRP patients compared to placebo (n=20) (Table 1). Similarly, overall survival (OS) benefit was observed in the Vigil group compared to placebo (Table 1). Improved RFS was demonstrated for a subset of patients with STRING predicted molecular profile. **Conclusions:** Vigil immunotherapy as frontline maintenance in Stage III/IV ovarian cancer is well tolerated and showed clinical benefit in both *BRCA*-wt and HRP molecular profile patients. Results suggest a unique molecular network that enhances sensitivity to Vigil therapy. Clinical trial information: NCT02346747. Research Sponsor: Gradalis, Inc.

5503 **Oral Abstract Session**

Phase 3, randomized, single-dose, open-label study to investigate the safety and efficacy of pafolacianine sodium injection (OTL38) for intraoperative imaging of folate receptor positive ovarian cancer. *First Author: Janos Laszlo Tanyi, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Pafolacianine sodium is under investigation as an adjunct to visual inspection and palpation by providing intra-operative imaging of folate receptor positive (FR+) ovarian cancer. Since complete resection (R0) is the strongest predictor of overall survival, methods to enhance detection of lesions are expected to benefit patient outcomes. **Methods:** For this phase 3, randomized, multicenter, single dose, open-label pivotal trial (NCT03180307), patients with ovarian cancer who were scheduled to undergo cytoreductive surgery were recruited from 11 sites in the US and Netherlands from March 2018 through April 2020. The study objectives were to confirm efficacy and safety of pafolacianine sodium (0.025 mg/kg i.v., ≥1 h prior to imaging) in combination with intraoperative near-infrared fluorescence (NIRF) imaging to detect additional lesions not detected by palpation and normal white light alone. **Results:** Pafolacianine sodium was administered to 150 total patients (safety analysis set); 109 patients comprised the full analysis set for efficacy analyses. Patients had primarily serous adenocarcinoma (n = 72; 68.6%) and advanced stage disease (n = 83; 76.1%). In 33% of patients (36 of 109), NIRF imaging with pafolacianine sodium identified additional lesions that were not planned for resection and were not detected by normal white light and palpation ($P < 0.001$, 95% CI [0.243, 0.427]). Among patients who underwent interval debulking surgery, the rate was higher, at 39.7% of patients (23 of 58; 95% CI [0.270, 0.534]). At the individual lesion level, the accuracy of pafolacianine sodium with NIRF to detect ovarian cancer is reflected by sensitivity of 83% (95% CI [73.9, 89.4]) and a false positive rate of 32.7% (95% CI [25.6, 40.7]). Investigators reported achieving complete resection (R0) in 62.4% (68 of 109) of patients. Drug-related adverse events (AEs) were reported by 30% of patients (45 out of 150). The most frequently reported drug-related AEs were nausea (18.0%), vomiting (5.3%), and abdominal pain (4.7%). Infusion reactions at the time of the procedure were mostly (96%) mild or moderate in severity; 89% resolved within 24 hours of onset. No drug-related serious AEs or deaths were reported. **Conclusions:** This phase 3 trial of pafolacianine sodium with NIRF imaging met its primary endpoint, intraoperatively identifying additional cancer not planned for resection in a statistically significant number of patients. Therefore, pafolacianine sodium may offer a novel real-time adjunct to current surgical imaging practice in ovarian cancer surgery. Clinical trial information: NCT03180307. Research Sponsor: On Target Laboratory.

Mirvetuximab soravtansine, a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC), in combination with bevacizumab in patients (pts) with platinum-agnostic ovarian cancer: Final analysis. *First Author: David M. O'Malley, The Ohio State University Wexner Medical Center and James Cancer Hospital, Columbus, OH*

Background: Mirvetuximab soravtansine (MIRV) is an ADC comprising a FRα-binding antibody, cleavable linker, and the maytansinoid DM4, a potent tubulin-targeting agent. As part of the Phase 1b FORWARD II trial (NCT02606305), the combination of MIRV with bevacizumab (BEV) was evaluated in pts with FRα-positive (medium/high expression; ≥50%/ ≥75% of cells with PS2+ staining intensity), platinum agnostic ovarian cancer, defined as pts with either platinum resistant (PROC) (recurrence within 6 months after last platinum dose) or platinum sensitive (PSOC)responded to the last platinum therapy and did not progress within 6 months) for whom a non-platinum based doublet would be appropriate. **Methods:** Pts received MIRV (6 mg/kg; adjusted ideal body weight) and BEV (15 mg/kg) on Day 1 of a 21-day cycle. Responses were assessed by investigator according to RECIST 1.1 and adverse events (AEs) evaluated by CTCAE v4.03. **Results:** In total, 60 pts received the combination, with a median age of 60 years, a median of 2 prior lines of systemic therapy (range 1-4) and a median follow-up of 17.5 months. The cohort included 32 pts (53%) with PROC disease and 28 (47%) with PSOC disease. Objective responses were seen in 28 of 60 pts for a confirmed overall response rate (ORR) of 47% (95% CI, 34, 60), median duration of response (mDOR) of 9.7 months (95% CI 6.7, 12.9), and median progression free survival (mPFS) of 8.3 months (95% CI 5.6, 10.6). In pts with high FRα expression (n=33), the confirmed ORR was 64% (95% CI 45, 80), mDOR of 11.8 months (95% CI 6.7, 13.7), and mPFS of 10.6 months (95% CI 8.3, 13.3); efficacy results in PROC and PSOC subsets of pts with high FRα expression are shown in the table below. The most common treatment related AEs (all grade, grade 3+) were diarrhea (68%, 2%), blurred vision (63%, 2%), fatigue (58%, 7%), and nausea (57%, 0%). The most common treatment related grade 3 and 4 AEs were neutropenia and hypertension, (12%, 3% and 13%, 0%, respectively); all other grade 3+ events occurred in ≤ 10% of pts. **Conclusions:** The combination of MIRV with BEV demonstrates impressive anti-tumor activity with durable responses and favorable tolerability in high FRα recurrent ovarian cancer. These results build on data previously reported for MIRV/BEV in PROC patients (*Gyn Oncology* O'Malley, et al 2020), suggesting that MIRV has the potential to be a preferred partner for BEV in patients with high FRα recurrent ovarian cancer regardless of platinum sensitivity. Clinical trial information: NCT02606305. Research Sponsor: ImmunoGen.

EFFORT: EFFicacy Of adavosertib in parp ResisTance: A randomized two-arm non-comparative phase II study of adavosertib with or without olaparib in women with PARP-resistant ovarian cancer. *First Author: Shannon Neville Westin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Wee1 phosphorylates and inhibits cyclin-dependent kinases 1 and 2 and is involved in regulation of the intra-S and G2/M cell cycle checkpoint arrest for premitotic DNA repair. The Wee1 inhibitor, adavosertib, has demonstrated activity alone and in combination with olaparib in PARP inhibitor (PARPi)-resistant preclinical models. We sought to evaluate efficacy of adavosertib (A) with or without olaparib (O) in a phase II noncomparative study of recurrent PARPi-resistant ovarian cancer. **Methods:** Women with recurrent ovarian, fallopian tube or primary peritoneal cancer with documented progressive disease on a PARPi were eligible. All patients (pts) had measurable disease and adequate end organ function. On the A arm, pts received A 300mg PO daily on days 1-5 and 8-12 of a 21-day cycle. On the A/O arm, pts received A 150mg PO BID on days 1-3 and 8-10 and O 200mg PO BID on days 1-21 of a 21-day cycle. Primary endpoint was objective response per RECIST 1.1 and was assessed every 2 cycles. Clinical benefit rate (CBR) was defined as proportion of pts with objective response or stable disease > 16 weeks. Progression free survival (PFS) was assessed using the Kaplan Meier method and calculated from date of treatment initiation to earliest date of progression, death, or last visit. **Results:** 116 pts were screened with 80 pts enrolled and randomized (A: n=39, A/O: n=41). Median age was 60 years (range 36-76) and the majority of pts had platinum resistant disease (64%) and high grade serous histology (98%). Pts received a median of 4 prior therapies (range 1-11) and 48% had germline or somatic *BRCA* mutations. There were 35 pts evaluable for response in each arm. Table demonstrates efficacy data. On the A arm, Grade 3/4 toxicities occurred in 51% of pts, most commonly neutropenia (13%), thrombocytopenia (10%), and diarrhea (8%). 28 (72%) pts required at least one dose interruption and 20 (51%) required dose reduction. On the A/O arm, Grade 3/4 toxicities occurred in 76% of pts, most commonly thrombocytopenia (20%), neutropenia (15%), diarrhea (12%), fatigue (12%), and anemia (10%). 36 (88%) of pts required at least one dose interruption, 29 (71%) required dose reduction, and 4 (10%) did not restart due to toxicity. **Conclusions:** A given alone and in combination with O demonstrated efficacy in pts with PARPi-resistant ovarian cancer. Although grade 3 and 4 toxicities were observed on both arms, these were generally manageable with supportive care, dose interruptions and dose reductions as needed. Additional translational analyses are ongoing to clarify which pts received clinical benefit. Clinical trial information: NCT03579316. Research Sponsor: AstraZeneca, U.S. National Institutes of Health.

Endpoint	A arm n=35	A/O arm n=35
ORR (90% CI)	23% (12–38)	29% (16–44)
Duration of response, months (95% CI)	5.5 (2.8–NE)	6.4 (2.8–14.6)
CBR (90% CI)	63% (48–76)	89% (76–96)
Median PFS, months (90%CI)	5.5 (3.9–6.9)	6.8 (4.3–8.3)

5506 **Oral Abstract Session**

Intensive versus minimalist follow-up in patients treated for endometrial cancer: A multicentric randomized controlled trial (The TOTEM study—NCT00916708). *First Author: Paolo Zola, Departement of surgical sciences University of Turin, Turin, Italy*

Background: Intensive follow-up in cancer patients, which absorbs a lot of health system resources and can be a source of increased stress for patients, are often proposed on the assumption that an early recognition of relapse will translate in better outcomes. In endometrial cancer few randomized controlled trials were conducted to assess the role of a reduced number of the scheduled visits and of different settings of the follow-up, but did not investigate the contribution of routine serum, cytological or imaging follow-up investigations in improving overall survival or quality of life. The TOTEM study was planned to compare an intensive (INT) vs minimalist (MIN) 5- year follow-up regimen in endometrial cancer patients in terms of overall survival (OS). **Methods:** Patients surgically treated for endometrial cancer, in complete clinical remission confirmed by imaging, FIGO stage I-IV, were stratified by center and in low (LoR) or high (HiR) risk of recurrence and then randomized to INT or MIN hospital-based follow-up regimens. The main study hypothesis was to demonstrate an improvement from 75% to 80% (expected hazard ratio, HR = 0.78) of the 5-year OS with the INT regimen. Secondary objectives were to compare relapse free survival (RFS), health-related quality of life (HRQL) assessed at baseline, at 6 and 12 months and then yearly (with the SF-12 Physical and Mental Health Summary Scale) and costs. **Results:** 1884 patients were randomized in 42 centers between 2008 and 2018, and 1847 patients were available for the final analysis (60% LoR). Compliance with the follow-up scheduled visits was 75.3%, similar between INT (74.7%) and MIN (75.9%) arms, whereas the mean number of recorded exams (laboratory or imaging) was markedly higher in the INT than in the MIN arms (9.7 vs 2.9, $p < 0.0001$). After a median follow-up of 66 months, the overall 5-year OS was 91.3%, 90.6% in the INT and 91.9% in the MIN arms, respectively (HR = 1.12, 95%CI 0.85-1.48, p = 0.429). Comparing the INT vs MIN arms, the 5-year OS were 94.1% and 96.8% (HR = 1.48, 0.92-2.37, p = 0.104) in the LoR and 85.3% and 84.7% (HR = 0.96, 0.68-1.36, p = 0.814) in the HiR group. No relevant differences emerged in RFS between INT and MIN regimens, (HR = 1.13, 0.87-1.48, p = 0.365). At the time of the relapse most women were asymptomatic (146/228, 64.0%), with a tendency of higher proportions in the INT than in the MIN arm, both in the LoR group (78.8% vs 61.1%, p = 0.070) and in the HiR one (64% vs 60%, p = 0.754). HRQL was available only for a subgroup of patients (50% at baseline) and did not differ between arms. **Conclusions:** Intensive follow-up in endometrial cancer treated patients showed a weak and uncertain advantage in detecting earlier asymptomatic relapses but did not improve OS, even in HiR patients, nor influenced HRQL. Frequent routine use of imaging and laboratory exams in these patients should be discouraged. Clinical trial information: NCT00916708. Research Sponsor: Rete Oncologica Piemonte e Valle d'Aosta.

5507 **Oral Abstract Session**

Victoria: A multicentric, randomized, open-label, phase I/II of mTOR inhibitor (VISTUSERTIB) combined with anastrozole in patients with hormone receptor-positive advanced/metastatic endometrial cancer—A CLIPP program INCA in collaboration with GINECO group. *First Author: Pierre-Etienne Heudel, Centre Léon Bérard, Lyon, France*

Background: Endometrial carcinoma is generally hormone dependent and aromatase inhibitors are used in routine practice before or after 1st line chemotherapy (CT) for HR positive patients. Deregulation of the Pi3K-Akt-mTOR signaling pathway is observed in many tumor types including endometroid carcinoma driven oncogenesis and hormonal resistance. Vistusertib (V) is a small-molecule ATP competitive inhibitor of both mTORC1 and mTORC2 complexes. **Methods:** Adult patients (pts) with recurrent oestrogen or progesterone (ER and/or PR) positive advanced/metastatic endometrial carcinoma, one previous line of chemotherapy (CT) allowed, with ECOG PS 0/1, were randomised (2:1, stratification according to prior CT line: 0 vs 1) to receive V (125 mg bid/2 days/week, orally) + Anastrozole (A, 1 mg/d, orally) or A alone. Treatments were given until progression, intolerable toxicity or patient willingness. Following a safety run in phase, a Simon's 2-stage design was employed to explore the 8-week progression free rate (PFR-8W) according to central review (p1: 60%, p0: 40%, type I error rate of 5%, power of 80%). At the end of Stage II, if ≥24/46 evaluable pts are progression free at 8w in Arm A+V, the combination will be considered of interest for further investigation. Overall response rate (ORR) by RECIST v1.1, safety and progression-free survival (PFS) were key secondary endpoints. **Results:** Out of 75 patients (pts) enrolled, 73 were randomised and treated (Arm V+A: 49; Arm A: 24; median age: 69.5 y [36.8; 87.8]), BMI ≥30 kg/m^2: 45%). PS ECOG was 0 (48%) and 44% of randomised pts were chemotherapy naïve; 12% previously received hormonal therapy. At the end of the safety run-in, no major safety concerns were reported. At the end of Simon' Stage II, centrally assessed PFR-8W was 67.3% (33/49 [95% CI unilateral: 54.7; -]) for A + V arm and 39.1% (9/23 [[95% CI unilateral: 22.2; -[) for arm A. Median PFS was 5.2 months (95% CI: 3.4-8.9) and 1.9 months (95% CI: 1.6-8.9) for A+V and A arms, respectively. One complete response and 11 partial responses (PR) were observed (ORR: 24.5 % (CI 95% [13.3 – 38/9%]) in the combination arm and 4 PR in arm A (ORR: 17.4% [CI 95%: 5-38.8%]). Fatigue, lymphopenia, hyperglycaemia and diarrhoea were the main (≥10%) Grade ≥2 adverse events related to V. Overall survival and translational research are ongoing. **Conclusions:** The A+V combination demonstrated clinically and meaningful improvement in 8w-PFR and median PFS with manageable toxicity. PI3K pathway remains a key target for new therapies in endometrial cancer and translational research must help to better select pts benefiting from these targeted therapies. Clinical trial information: NCT02730923. Research Sponsor: French NCI (INCA) and Fondation ARC.

5508 **Oral Abstract Session**

Pertuzumab plus trastuzumab (P+T) in patients (Pts) with uterine cancer (UC) with *ERBB2 or ERBB3* amplification, overexpression or mutation: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Hussein Moustapha Ali-Ahmad, Michigan Cancer Research Consortium, Lansing, MI*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of UC pts with *ERBB2 or ERBB3* amplification, overexpression or mutation treated with P+T are reported. **Methods:** Eligible pts had advanced UC, no standard treatment options, measurable disease, ECOG PS 0-2, and adequate organ function. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts matched to P+T had UC with *ERBB2 or ERBB3* amplification or overexpression or a pre-specified *ERBB2* mutation. Recommended dosing was P at an initial dose of 840 mg intravenously (IV) over 60 minutes (m), then 420 mg IV over 30-60 m every 3 weeks (wks), and T at an initial dose of 8 mg/kg IV over 90 m, then 6 mg/kg IV over 30-60 m every 3 wks until disease progression. Simon 2-stage design tested the null disease control (DC) - defined as partial (PR), complete response (CR) or stable disease at 16+ weeks (SD 16+) - rate of 15% vs. 35% (power = 0.85; $\alpha = 0.10$). If $\geq$2 of 10 pts in stage 1 have DC, 18 more pts are enrolled. If $\geq$7 of 28 pts have DC, the null DC rate is rejected. Secondary endpoints are progression-free survival (PFS), overall survival (OS) and safety. **Results:** Twenty-eight female pts were enrolled from August 2017 to November 2019; all pts were evaluable for efficacy and toxicity. Demographics and outcomes are summarized in Table. Twenty-two pts had tumors with *ERBB2* amplification (21) or overexpression (1); 4 tumors had *ERBB2* mutations; 1 tumor had *ERBB3* amplification; 1 tumor had both an *ERBB2* amplification and mutation. Two PR and 7 SD16+ were observed in pts with *ERBB2* amplification, and 1 SD16+ was observed in a pt with *ERBB2* V842I mutation only (no amplification) for DC and objective response (OR) rates of 37% (95% CI, 21% to 50%) and 7.1% (95% CI, 0.8% to 24%), respectively. One pt experienced grade 3 muscle weakness at least possibly related to P+T. **Conclusions:** P+T demonstrated evidence of anti-tumor activity in heavily pre-treated UC pts with *ERBB2* amplification or certain mutations. Additional study is warranted to confirm the efficacy of P+T in this pt population. Clinical trial information: NCT02693535. Research Sponsor: Genentech.

5509 **Clinical Science Symposium**

Evaluation of bintrafusp alfa, a bifunctional fusion protein targeting TGF-β and PD-L1, in cervical cancer: Data from phase 1 and phase 2 studies. *First Author: Julius Strauss, Laboratory of Tumor Immunology and Biology, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: The accelerated FDA approval of pembrolizumab validated the efficacy of anti–PD-(L)1 therapy for pts with recurrent/metastatic cervical cancer; however, the objective response rate (ORR) with pembrolizumab was 14.3% in pts with PD-L1 expressing tumors. HPV infection is implicated in $>$ 95% of cervical cancers and is linked to upregulation of TGF-β signaling. Bintrafusp alfa is a first-in-class bifunctional fusion protein composed of the extracellular domain of the TGF-βRII receptor (a TGF-β "trap") fused to a human IgG1 mAb blocking PD-L1. We report pooled safety and efficacy in pts with immune checkpoint inhibitor–naive, recurrent/metastatic cervical cancer treated with bintrafusp alfa in phase 1 (INTR@PID 001; NCT02517398) and phase 2 (study 012; NCT03427411) studies. **Methods:** Pts with pretreated, immune checkpoint inhibitor–naive, recurrent/metastatic cervical cancer received bintrafusp alfa 0.3-30 mg/kg (phase 1 dose escalation) or 1200 mg Q2W (phase 1 expansion/phase 2) until progressive disease, unacceptable toxicity, or withdrawal. Treatment past progression was allowed. Primary endpoints were safety for the dose-escalation part of the phase 1 study and best overall response per RECIST 1.1 for the expansion part of phase 1 and phase 2 studies. Secondary endpoints for the expansion part of the phase 1 and 2 studies included safety. **Results:** As of May 15, 2020 (phase 1) and December 22, 2020 (phase 2), 39 pts had received bintrafusp alfa for a median duration of 2.8 months (range, 0.5-19.3). The median follow-up to data cutoff was 35.0 months and 24.1 months for the phase 1 and phase 2 studies, respectively. All pts had received prior anticancer therapy; 16 pts (41.0%) had received $\geq$3 prior anticancer regimens. There were 2 complete responses and 9 partial responses (PRs; ORR per RECIST 1.1, 28.2%). Median duration of response was 11.7 months (range, 1.4-41.2), and 5 pts (45.5%) had ongoing responses (duration 1.5-41.2 months). An additional delayed PR was observed (duration 23.7 months). Reponses occurred irrespective of tumor histology or prior bevacizumab or radiation treatment. Median overall survival (mOS) was 13.4 months (95% CI, 5.5 to not reached); 24-month OS rate was 33.2%. Any-grade treatment-related adverse events (TRAEs) occurred in 33 pts (84.6%). Grade 3 TRAEs occurred in 8 pts (20.5%; anemia, colitis, gastroparesis, upper gastrointestinal hemorrhage, keratoacanthoma, cystitis noninfective, hematuria, pneumonitis, rash macular [n = 1 each]); 1 patient (2.6%) had a grade 4 TRAE (asymptomatic hypokalemia related to the above grade 3 gastroparesis). No treatment-related deaths occurred. **Conclusions:** Bintrafusp alfa had a manageable safety profile and demonstrated clinical activity in pts with heavily pretreated, immune checkpoint inhibitor–naive recurrent/metastatic cervical cancer. Clinical trial information: NCT02517398, NCT03427411. Research Sponsor: Merck KGaA, Darmstadt, Germany, and GlaxoSmithKline.

5510 **Clinical Science Symposium**

Clinical activity and safety of simlukafusp alfa, an engineered interleukin-2 variant targeted to fibroblast activation protein-α, combined with atezolizumab in patients with recurrent or metastatic cervical cancer. *First Author: Antoine Italiano, Early Phase Trials Unit, Institut Bergonié, Bordeaux, France*

Background: Simlukafusp alfa (SIM; FAP-IL2v) comprises an interleukin-2 variant (IL-2v) moiety and an antibody against fibroblast activation protein-α (FAP). The binding of SIM to FAP, expressed on cancer-associated fibroblasts, accounts for retention and accumulation in malignant lesions. The engineered IL-2v moiety has an abolished binding to IL-2Rα while the affinity to IL-2R$\beta\gamma$ is retained, resulting in activation of immune effector CD8 T and NK cells, but not of regulatory T cells, and therefore may augment activity of PD-(L)1 inhibitors. **Methods:** The clinical activity and safety of the SIM and atezolizumab (ATZ) combination in patients with recurrent or metastatic (R/M) cervical squamous cell carcinoma (SCC) were evaluated in a phase 2 basket study (NCT03386721). Patients (pts) were treated with SIM 10 mg IV and ATZ 1200 mg IV once every 3 weeks. The primary endpoint was objective response rate (ORR) by RECIST v1.1 assessed by investigators. Secondary endpoints were: disease control rate (DCR), duration of response (DoR), progression free survival (PFS). **Results:** 47 Pts with ECOG $\geq$1 and median age of 53 years (range: 25-69) were enrolled. All pts were checkpoint inhibitor naïve and 40 (85%) had $\geq$ 1 previous lines of therapy in the metastatic setting. The median number of cycles was 6 (range: 1-29). The ORR was 27% (90% CI: 18, 39) and DCR was 71% (90% CI: 58, 80) in 44 response-evaluable patients: 2 (5%) had complete response, 10 (23%) partial response, and 19 (43%) stable disease. Responses were observed across PD-L1 subgroups (SP142 assay, IC/TC cut-off $\geq$ 1%) with 8/22 and 4/18 responders in PD-L1$^+$ and PD-L1$^-$ patients, respectively. Responses were durable, the median DoR was 13.3 months (95% CI: 7.6, 14.7). PFS probability at 6 months was 0.4 (95% CI: 0.27, 0.59). The most common adverse events (AE) (reported in $>$ 30% patients), irrespective of relatedness to treatment and severity, were pyrexia (74.5%), anemia (48.9%), asthenia (48.9%), AST increased (44.7%), nausea (42.6%), ALT increased (42.6%), vomiting (36.2%) and diarrhea (31.9%). Grade 3 and 4 AEs related to SIM were observed in 63.8 % and 29.8 % of pts, respectively, while serious AEs (SAE) related to SIM were reported in 40.4%. The most common SAEs (reported in $>$ 5% pts) irrespective of relatedness to treatment were infusion related reaction (14.9%), pyrexia (6.4%) and hydronephrosis (6.4%). One Grade 5 event occurred, which was unrelated to treatment. **Conclusions:** SIM in combination with ATZ demonstrated an acceptable safety profile in pts with R/M cervical SCC. The anti-tumor activity compares favorably to the approved PD-1 inhibitors in this setting and supports further exploration of IL-2v and checkpoint inhibition in this patient population of high unmet medical need. Clinical trial information: NCT03386721. Research Sponsor: Roche.

5511 **Clinical Science Symposium**

Efficacy and safety results of GX-188E, a therapeutic DNA vaccine, combined with pembrolizumab administration in patients with HPV 16- and/or 18- positive advanced cervical cancer: Phase II interim analysis results (KEYNOTE-567). *First Author: Jong Sup Park, Genexine, Inc., Seongnam, South Korea*

Background: Pembrolizumab was approved for the treatment of recurrent or metastatic cervical cancer, based on 14.3% of objective response rate (ORR) in patients with PD-L1 expression (CPS$\geq$1). GX-188E vaccination has been shown to induce human papillomavirus (HPV) E6- and E7-specific T-cell responses. We aimed to investigate whether a combination of GX-188E (Tirvalimogene teraplasmid) therapeutic DNA vaccine plus pembrolizumab showed antitumor activity against recurrent or advanced cervical cancer. **Methods:** In this open-label, single-arm, phase 2 trial, patients with recurrent or advanced cervical cancer, who were aged over 18 years with ECOG PS of 0 or 1, HPV-16 or HPV-18 and histologically confirmed positive cervical cancer, and who had progressed after standard-of-care therapy were recruited from nine hospitals in South Korea. Patients received intramuscular 2 mg GX-188E at weeks 1, 2, 4, 7, 13, 19, and optional dose at week 46, and intravenous pembrolizumab 200 mg every 3 weeks for up to 2 years or until disease progression. The primary endpoint was the Best Overall Response Rate assessed by the investigator using RECIST version 1.1. **Results:** To date, a total of 52 patients have been enrolled and received at least one study treatment, and this interim analysis was performed after obtaining at least one post-baseline tumor assessment data from 48 patients. Median age was 52 (range, 27-79) years and 46.2% had ECOG PS 1. At the data cutoff date on January 11, 2021, median follow-up duration was 6.2 months (range; 1.7- 24.2 months). According to investigator evaluation, 15 (31.3%) of 48 patients achieved best overall response; 5 (10.4 %) patients had a complete response (CR) and 10 (20.8 %) had a partial response (PR). Especially, this combination treatment showed higher response rate, 48.0 %, in patients with PD-L1 positive, HPV-16 and squamous cell carcinoma. Median PFS was 4.1 months (range; 1.3-24.2) and median OS was 16.7 months (range; 1.7-24.2). In this clinical trial with cervical cancer patients, GX-188E in combination with pembrolizumab has shown an improved median PFS and OS than the monotherapy of pembrolizumab (KEYNOTE-158). 17 (32.7%) of 52 patients had treatment-related adverse events of any grade and two (3.8%) had grade 3 or 4 treatment-related adverse events; increased aspartate aminotransferase or alanine aminotransferase. No treatment-related deaths were reported. **Conclusions:** GX-188E vaccine combined with pembrolizumab in recurrent/advanced cervical cancer was safe and tolerable, and showed an enhanced clinical response rate compared with pembrolizumab alone in particular in patients with PD-L1 positive, HPV-16 and squamous cell carcinoma. The combination therapy could represent a new potential treatment option for this patient population. Clinical trial information: NCT03444376. Research Sponsor: National Onco Venture, Pharmaceutical/Biotech Company.

5512 **Clinical Science Symposium**

Phase IIa study of BVAC-C in HPV type 16 or 18 positive recurrent cervical carcinoma. *First Author: Chel Hun Choi, Samsung Medical Center, Seoul, South Korea*

Background: BVAC-C is a B cell- and monocyte-based immunotherapeutic vaccine transfected with recombinant HPV E6/E7, which was well tolerated in HPV positive recurrent cervical carcinoma in phase I study (J Clin Med . 2020 Jan 5;9(1):147). This phase IIa study sought to determine the antitumor activity of BVAC-C. **Methods:** Twenty-one patients with HPV 16 or 18 positive recurrent cervical cancer who had experienced recurrence after one prior platinum-based combination chemotherapy were enrolled. They were allocated to 3 arms; Arm 1, BVAC-C injection at 0, 4, 8 weeks ($1x10^8$ cells/dose); Arm 2, BVAC-C injection at 0, 4, 8, 12 weeks ($5x10^7$ cells/dose); Arm 3, BVAC-C injection at 0, 4, 8, 12 weeks ($5x10^7$ cells/dose) with topotecan at 2, 6, 10, 14 weeks (0.75 mg/m2 for 3 days). **Results:** The overall response rate was 21% (Arm 1: 29% (2/7), Arm 2: 25% (1/4), Arm 3 : 0 % (0/3)) among the evaluable patients (N = 14), and the median duration of response was 18 months (range, 9 – 26 months). The disease control rate was 43% (Arm 1: 29% (2/7), Arm 2: 50% (2/4), Arm 3 : 67 % (2/3)) and the median duration of stable disease were 12 months (range, 6 - 26 months). The median progression-free survival in all patients was 4 months (95% CI, 2 to Infinite months). Immune responses of patients after vaccination were shown to be correlated with clinical responses of them. Consistent with Phase I study, all evaluated patients showed not only inflammatory cytokine responses (IFN-γ or TNF-α), which might be mediated by the activation of natural killer cells and natural killer T cells, but also potent E6/E7-specific T cell responses upon vaccinations. **Conclusions:** BVAC-C demonstrated a durable antitumor activity with an immune response in HPV 16- or 18-positive recurrent cervical carcinoma patients who failed 1st line platinum based chemotherapy. Clinical trial information: NCT02866006. Research Sponsor: Cellid.

Evaluation of a RAD51 functional assay in advanced ovarian cancer, a GINECO/GINEGEPS study. *First Author: Felix Blanc-Durand, Institut Gustave Roussy, Villejuif, France*

Background: Homologous recombination deficiency (HRD), defined as *BRCA1/2* mutation (*BRCA*mut)or high genomic instability, is currently used to identify patients (pts) with epithelial ovarian cancer (EOC) most likely to benefit from PARP inhibitors. While these genomic tests are useful, they are imperfect: some *BRCA*m EOC demonstrate primary PARPi resistance and some HR-proficient benefit. Another approach to evaluate HRD is to measure the capacity of tumor cells to recruit nuclear RAD51 foci during S/G2 phase in the presence of double strand DNA damage using multiplexed immunofluorescence (IF) for RAD51, geminin (GMN) and yH2AX. We aimed to describe for the 1st time HRD using this RAD51 functional assay in EOC and correlate RAD51 status to platinum response and *BRCA*mut. **Methods:** Tumor samples and clinical data were collected prospectively from pts in the randomized CHIVA trial of neoadjuvant platinum chemotherapy +/- nintedanib. IF for RAD51, GMN, and DAPI was performed on a 3uM slide from FFPE blocks, where feasible, yH2AX was positively scored on a consecutive slide. Tumors were considered RAD51-deficient if $<$ 10% of gem+ tumor cells (TC) had $>$ 5 RAD51+ foci. *BRCA*mut were identified by NGS. **Results:** 155 baseline chemotherapy naïve EOC samples were available. All were advanced stage (IIIC/IV), 75% were G3, 7% G2, 2% G1, and 16% grade UK. A contributive RAD51 result was obtained for 90% (139/155) of samples. Contributive NGS results were available for 130 samples. Overall, yH2AX scores were high (median % TC+: 86%, IQR: 56%-100%) confirming the presence of significant basal DNA damage in high grade EOC. Only 8 samples were yH2AX-low, including two of the three G1 tumors. In contrast, 55% (76/155) of samples were considered RAD51-deficient (score $<$ 10%). With regard to outcome, pts with RAD51-deficient tumors had significantly higher overall response rates to neoadjuvant platinum (68% vs 37%, p = 0.04) and significantly longer median progression-free survival (HR 0.50, IC95% 0.25-0.98, p = 0.02). Considering BRCA status, 15% of tumors harbored a deleterious *BRCA*mut and 67% of these were RAD51-deficient. Importantly among *BRCA*mut EOC, the RAD51-proficient tumors had significantly poorer response to neoadjuvant chemotherapy (RR = 17% vs 75%, p = 0.02). **Conclusions:** We evaluated a novel functional assay of HR functionality in advanced EOC. The assay requires minimal tissue and yields contributive results in 90% of cases. Overall, EOC demonstrate high levels of basal DNA damage, yet 55% fail to recruit RAD51 foci during S/G2 cell cycle phase. These RAD51-deficient EOC have improved outcome after neoadjuvant platinum. Conversely, the RAD51 assay also identified a small subset of RAD51-high *BRCA*mut tumors with poor platinum response. Whether this RAD51 functional assay may also predict PARP inhibitor benefit is currently being investigated. Research Sponsor: ERAPerMed European Grant, Arcagy Gineco.

5514 **Poster Discussion Session**

Progression-free survival (PFS) and second PFS (PFS2) by disease stage in patients (pts) with homologous recombination deficiency (HRD)-positive newly diagnosed advanced ovarian cancer receiving bevacizumab (bev) with olaparib/placebo maintenance in the phase III PAOLA-1/ENGOT-ov25 trial. *First Author: Patricia Pautier, Institut Gustave Roussy, and GINECO, Villejuif, France*

Background: In the Phase III PAOLA-1/ENGOT-ov25 trial (NCT02477644), the addition of maintenance olaparib to bev in pts with newly diagnosed advanced high-grade ovarian cancer (HGOC) resulted in a significant PFS benefit, particularly in HRD-positive (HRD+) pts (hazard ratio [HR] 0.33; 95% CI 0.25–0.45) (Ray-Coquard *et al.NEJM* 2019). We explored efficacy in HRD+ pts by disease stage. **Methods:** Pts with newly diagnosed, FIGO stage III–IV HGOC in response after platinum-based chemotherapy + bev received bev (15 mg/kg q3w for 15 months [mo]) + either olaparib (300 mg bid for 24 mo) or placebo (pbo). This exploratory analysis evaluated PFS (data cut-off [DCO]: Mar 22 2019) and PFS2 (DCO: Mar 22 2020) in HRD+ pts (tumor *BRCA1/BRCA2* mutation [tBRCAm] or genomic instability score [Myriad myChoice HRD Plus] ≥42) by FIGO stage. **Results:** 387/806 randomized pts (48%) were HRD+; 272/387 (70%) had stage III disease and 115/387 (30%) had stage IV disease. 153 (56%) HRD+ stage III pts and 61 (53%) HRD+ stage IV pts had a tBRCAm. Among HRD+ stage III pts, 172 (63%) had upfront surgery (51/172 [30%] had residual disease) and 90 (33%) had interval surgery (19/90 [21%] had residual disease); 52 (45%) HRD+ stage IV pts had upfront surgery (34/52 [65%] had residual disease) and 55 (48%) had interval surgery (18/55 [33%] had residual disease). Median follow-up for PFS and PFS2 was respectively 24.8 and 37.2 mo in HRD+ stage III pts and 24.0 and 37.0 mo in HRD+ stage IV pts. Median PFS, PFS2 and HRs are in the Table. Among HRD+ stage III pts, 36-mo PFS2 (olaparib + bev vs pbo + bev) was 74% vs 60%; among HRD+ stage IV pts, 53% vs 30%. Among HRD+ stage III pts with no residual disease after upfront surgery, HR (95% CI) for PFS was 0.15 (0.07–0.30) and for PFS2 was 0.22 (0.06–0.67). Among HRD+ stage III pts with residual disease after upfront surgery or who received neoadjuvant chemotherapy, or HRD+ stage IV pts, HR (95% CI) for PFS was 0.38 (0.27–0.53) and PFS2 was 0.68 (0.46–1.03). **Conclusions:** In the PAOLA-1 study, maintenance olaparib + bev provided a PFS and PFS2 benefit over pbo + bev in HRD+ pts, irrespective of FIGO stage and residual disease after upfront surgery. Clinical trial information: NCT02477644. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

PFS and PFS2 by FIGO stage in HRD+ pts in PAOLA-1.

	Olaparib + bev	Pbo + bev	HR (95% CI)
Median PFS, mo (95% CI)			
Stage III	39.3 (36.0–NE) (n=182)	19.9 (17.7–23.4) (n=90)	0.32 (0.22–0.47)
Stage IV	25.1 (22.0–37.2) (n=73)	12.8 (10.4–15.8) (n=42)	0.32 (0.20–0.52)

5515 **Poster Discussion Session**

Olaparib treatment (Tx) in patients (pts) with platinum-sensitive relapsed ovarian cancer (PSR OC) by BRCA mutation (BRCAm) and homologous recombination deficiency (HRD) status: Overall survival (OS) results from the phase II LIGHT study. *First Author: Cara Amanda Mathews, Program in Women's Oncology, Department of Obstetrics and Gynecology, Women and Infants Hospital, Brown University, Providence, RI*

Background: LIGHT (NCT02983799) evaluated olaparib Tx in pts with PSR OC in cohorts with known BRCAm and HRD status. We report the final OS analyses. **Methods:** We conducted anopen-label, non-randomized, multicenter study of pts with PSR OC and ≥1 prior line of platinum-based chemotherapy (CTx). Pts were assigned to one of 4 cohorts: germline (g) BRCAm; somatic (s) BRCAm; HRD +ve (non-BRCAm); and HRD -ve. Genomic instability score (GIS) and gBRCAm status were determined by Myriad myChoice and BRACAnalysis CDx tests, respectively. HRD +ve tumors were defined by a GIS ≥42. Pts received olaparib Tx (starting dose 300 mg bid) until disease progression or unacceptable toxicity. OS was a secondary endpoint and was analyzed at 12 months (mo) after the primary analysis and 18 mo after the last pt was enrolled. Safety was assessed in pts who received ≥1 dose. **Results:** Data cut-off (DCO) was Aug 27, 2020. Of 272 enrolled pts, 271 received olaparib; of these, 270 had measurable disease at baseline and were included in efficacy analyses (Table). At DCO, 40% of pts had died (maturity) with a median follow-up in censored pts of 26.3 mo. Kaplan–Meier 18-mo OS rates were 86%, 88%, 79%, and 60% in the gBRCAm, sBRCAm, HRD +ve (non-BRCAm), and HRD -ve cohorts, respectively. Platinum-based CTx was the most common first subsequent Tx and was received by 39% pts after olaparib discontinuation. At DCO, the median duration of Tx was 7.4 mo and 244 pts had discontinued treatment, mainly due to disease progression (72%); 5% discontinued due to treatment-emergent adverse events (TEAEs). The only TEAE leading to discontinuation in >1 pt was nausea (2 pts). Serious TEAEs were reported in 25% of pts. The most common serious TEAE was small intestinal obstruction (6%). Three adverse events of special interest occurred, each in 1 pt (<1%): acute myeloid leukemia (post discontinuation), pneumonitis, and pulmonary fibrosis. **Conclusions:** In the final OS analysis, 18-mo OS ranged from 60–88% across the 4 cohorts. Consistent with the primary analysis, the 18-mo OS rate was highest in the BRCAm cohorts (similar OS in g and sBRCAm); among pts without a BRCAm, 18-mo OS was highest in the HRD +ve cohort. No new safety signals were observed compared with the primary analysis and with prior olaparib studies. Clinical trial information: NCT02983799. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

OS and subsequent Tx summary.

	gBRCAm (n=75)	sBRCAm (n=25)	HRD +ve (non-BRCAm) (n=68)	HRD -ve (n=89)	Overall (N=270)*
Deaths, n (%)	20 (27)	5 (20)	24 (35)	51 (57)	107 (40)
Alive at 18 mo (%) (95% CI)	86.4 (76.2–92.4)	88.0 (67.3–96.0)	78.6 (66.6–86.8)	59.6 (48.6–68.9)	74.3 (68.5–79.1)
Received subsequent Tx, n (%)	27 (36)	8 (32)	38 (56)	50 (56)	128 (47)

Combination of PARP and ATR inhibitors (olaparib and ceralasertib) shows clinical activity in acquired PARP inhibitor-resistant recurrent ovarian cancer. *First Author: Stephanie L. Wethington, Johns Hopkins University, Baltimore, MD*

Background: Following multiple blockbuster studies demonstrating long-term progression free and overall survival benefits with poly(ADP-ribose)polymerase inhibitors (PARPi), they have become an integral component of high grade serous ovarian cancer (HGSOC) treatment. Unfortunately, tumors ultimately acquire resistance and thus therapies that overcome PARPi-resistance are urgently needed. Preclinical studies show the addition of ataxia telangiectasia and Rad3-related kinase inhibitors (ATRi) to PARPi overcome PARPi-resistance. We present results of an investigator-initiated study of the combination PARPi (olaparib) and ATRi (ceralasertib) in patients who were on a PARPi and experienced disease progression. **Methods:** We conducted a non-randomized trial (NCT03462342) in platinum sensitive HGSOC immediately following prior PARPi treatment of a 28 day cycle of olaparib 300mg orally twice daily and ceralasertib 160mg orally once daily on days 1-7. Eligibility required a germline or somatic BRCA1/2 mutation, other homologous recombination deficient (HRD) mutation, or positive HRD score (>42 on Myriad My Choice). Clinical benefit from prior PARPi was required (> 12 months on treatment for 1st line maintenance, > 6 months for ≥2nd line maintenance, or treatment of recurrence with response by CA-125 or imaging). No intervening treatment between the PARPi and enrollment was permitted. The primary objectives were safety and objective response rate (ORR). **Results:** Thirteen patients (pt) of median age 60 years (range 43-78) were enrolled. 9 pt (69%) had germline *BRCA* mutations, 3 (23%) somatic *BRCA* mutations and 1 (8%) a positive HRD score. Median time on prior PARPi was 13 months (range 4-60). Prior PARPi indication was 1st line maintenance in 8% (n = 1), 2nd line maintenance in 38% (n = 5) and recurrence in 54% (n = 7). Nine pt (69%) had received olaparib prior to enrollment. The time from prior PARPi to cycle 1, day 1 was 34 days (range 22-311). The ORR was 46% (n = 6); all 6 demonstrating a PR. Pt received a median of 8 (range 3-23) cycles of olaparib and ceralasertib. 4 pt remain on study (4-14 months). 4 pt (31%) experienced grade 3 toxicity: 23% (n = 3) thrombocytopenia, 16% (n = 2) anemia, and 16% (n = 2) neutropenia. There were no grade 4/5 toxicities. There were 4 dose reductions (3 olaparib, 1 ceralasertib). No pt discontinued treatment due to toxicity. **Conclusions:** The combination of olaparib and ceralasertib is well tolerated and shows clinical activity in in a cohort of patients with recurrent HRD HGSOC who have progressed on prior PARPi thus warranting further investigation. This study is the first to suggest the potential of ATR inhibitors to overcome PARPi resistance in an HRD patient population. Molecular profiling studies are underway to identify potential biomarkers associated with response to guide future clinical trial design. Clinical trial information: NCT03462342. Research Sponsor: Astrazeneca, Other Government Agency.

5517 **Poster Discussion Session**

Subgroup analysis of rucaparib versus chemotherapy as treatment for BRCA-mutated, advanced, relapsed ovarian carcinoma: Effect of platinum sensitivity in the randomized, phase 3 study ARIEL4. *First Author: Amit M. Oza, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: In ARIEL4 (NCT02855944), rucaparib significantly improved the primary endpoint of progression-free survival (PFS) vs chemotherapy (CT) in patients with advanced, relapsed ovarian carcinoma (OC) harboring a deleterious *BRCA1/2* (BRCA) mutation (median PFS 7.4 [95% CI 7.3–9.1] vs 5.7 [5.5–7.3] months; hazard ratio (HR) 0.64 [95% CI 0.49–0.84]; *P*=0.001). This prespecified exploratory analysis investigated the effect of platinum sensitivity on the efficacy of rucaparib vs CT in ARIEL4. **Methods:** Patients were randomized 2:1 to oral rucaparib 600 mg twice daily or CT and stratified based on progression-free interval (≥1 to <6 months = platinum resistant; ≥6 to <12 months = partially platinum sensitive; ≥12 months = fully platinum sensitive). In the CT group, patients with platinum-resistant or partially platinum-sensitive disease received weekly paclitaxel 60–80 mg/m^2; patients with fully platinum-sensitive disease received investigator's choice of platinum-based CT (single-agent carboplatin or cisplatin, or platinum doublet). Patients could crossover from CT to rucaparib following radiologic disease progression. Efficacy endpoints were explored in patients with a confirmed BRCA mutation (patients with a reversion mutation were excluded), based on the randomization strata of platinum sensitivity. **Results:** The visit cutoff date was September 30, 2020. PFS and objective response rates (ORR) per RECIST v1.1 for rucaparib vs CT across subgroups are presented in the Table. The most common treatment-emergent adverse events in the rucaparib group were anemia/decreased hemoglobin (platinum-resistant patients: rucaparib 47% vs CT 40%; partially platinum-sensitive patients: 63% vs 27%; fully platinum-sensitive patients: 58% vs 20%) and nausea (52% vs 21%; 51% vs 23%; 60% vs 68%). In the intent-to-treat population, 74/116 (64%) patients in the CT group crossed over to receive rucaparib: 39/59 (66%) with platinum-resistant, 25/31 (81%) with partially platinum-sensitive, and 10/26 (38%) with fully platinum-sensitive disease. **Conclusions:** Results from this exploratory subgroup analysis suggest that rucaparib is a reasonable treatment option for heavily pretreated patients across all platinum sensitivity subgroups. Safety was consistent with prior rucaparib studies. Clinical trial information: NCT02855944. Research Sponsor: Clovis Oncology, Inc.

Niraparib efficacy and safety in patients with *BRCA* mutated (*BRCA*m) ovarian cancer: Results from three phase 3 niraparib trials. *First Author: Antonio Gonzalez Martin, Grupo Español de Investigación en Cáncer de Ovario (GEICO) and Medical Oncology Department, Clínica Universidad de Navarra, Madrid, Spain*

Background: Niraparib has been approved for the maintenance treatment of patients with advanced ovarian, fallopian tube, or primary peritoneal cancer after front-line chemotherapy (CT) and in the recurrent setting. Here, we summarize niraparib efficacy and safety in patients with *BRCA*m OC across three phase 3 trials: PRIMA/ENGOT-OV26/GOG-3012 (PRIMA; NCT02655016), ENGOT-OV16/NOVA (NOVA; NCT01847274), and NORA (NCT03705156). **Methods:** Patients enrolled in the PRIMA trial had newly diagnosed advanced ovarian, fallopian tube, or primary peritoneal cancer. All patients had stage III or IV high-grade serous or endometrioid tumors and had a complete or partial response to their first-line platinum-based CT treatment. Subgroup analysis by tumor *BRCA*m status was prespecified. Patients enrolled in the NOVA and NORA studies had platinum-sensitive, high-grade serous ovarian, fallopian tube, or primary peritoneal cancer. Patients had already received at least 2 lines of platinum-based CT regimens. In both studies, subgroup analysis by germline *BRCA*m status was prespecified. The primary endpoint in all trials was progression-free survival (PFS) by blinded independent central review. **Results:** The *BRCA*m populations from each trial are as follows: 223 (148 *BRCA1*m and 75 *BRCA2*m) from the PRIMA trial, 203 (128 *BRCA*1m, 69 *BRCA*2m, and 13 *BRCA*1/2m) from the NOVA trial, and 100 (78 *BRCA*1m, 21 *BRCA*2m, and 1 *BRCA*1/2m) from the NORA trial. PFS results are shown in the Table. Across the 3 trials, the most common treatment-emergent adverse events were thrombocytopenia, anemia, neutropenia, and hypertension. **Conclusions:** Patients with *BRCA*m OC derived a significant PFS benefit from niraparib maintenance treatment across all 3 trials. No new safety signals were identified. Clinical trial information: NCT02655016, NCT01847274, NCT03705156. Research Sponsor: GlaxoSmithKline, Pharmaceutical/Biotech Company.

Molecular results and potential biomarkers identified from MILO/ENGOT-ov11 phase 3 study of binimetinib versus physicians choice of chemotherapy (PCC) in recurrent low-grade serous ovarian cancer (LGSOC). *First Author: Rachel N. Grisham, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Lower responses to chemotherapy and the unique molecular profile of LGSO led to the adoption of MEK-inhibitors for this disease. Updated analysis from the MILO/ENGOT-ov11 phase III study of binimetinib vs PCC in recurrent LGSOC showed response rate of 24% in those treated with binimetinib (JCO, 2020; NCT01849874). Here we present results of the post-hoc tumor tissue biomarker analysis performed with MILO/ENGOT-ov11. **Methods:** Mutational/copy number analysis was performed via Foundation Medicine on archival tissue obtained prior to randomization. Unbiased univariate analysis was used to test association between mutation status and outcomes in binimetinib and PCC treated patients. Outcomes examined were progression free survival (PFS), binary response by local RECIST 1.1 (complete or partial response [CR/PR] vs. stable [SD] or progressive disease [PD]), and ordinal response. Kaplan-Meier was used to estimate PFS. Cox regression, binary logistic regression, and ordinal logistic regression were used to examine relationship between mutation status and outcomes. **Results:** MILO/ENGOT-OV11 enrolled 341 patients from June, 2013 to April, 2016. Patients were randomized 2:1 to binimetinib or PCC. Based on January 1, 2020 data cut-off the data is as-is, amongst those patients treated with binimetinib with molecular results available, PFS data is available for 144 and response rate (RR) data for 135. There were 47 mutations detected in ≥5% of patients, most commonly *KRAS* (33%). Patients harboring a *KRAS* mutation had 3.4 times the odds of responding to treatment with binimetinib as patients without *KRAS* mutation (95% CI 1.57,7.67; p-value 0.002). There was no difference in effect of *KRAS* G12V mutation vs other *KRAS* mutation on PFS (PFS HR 1.06; 95% CI:0.53, 2.12; p value 0.9). In the 135 patients with binimetinib RR data, other MAPK mutations were identified as follows; *NRAS* in 11(8.1%), *BRAFV600E* in 8(5.9%), *RAF1* in 2 (1.5%), *NF1* in 7 (5.2%). In patients with MAPK mutation (as defined above) the RR was 41% vs 13% in those without MAPK mutation. PFS was significantly better in patients treated with binimetinib harboring MAPK mutation vs those without (HR 0.5; 95% CI 0.31, 0.79; p = 0.003). In patients treated with PCC there was a nonsignificant trend towards improved PFS in those with MAPK mutation vs those without (HR 0.82; 95% CI 0.43,1.59; p = 0.6). A test for interaction between treatment and MAPK pathway was not significant by Cox regression model (p = 0.32). **Conclusions:** While this hypothesis generating analysis is limited by multiple testing, higher response rates and longer PFS were seen in those patients with LGSOC treated with binimetinib who harbored MAPK mutations, most commonly in *KRAS*. Somatic tumor testing should be routinely performed in patients with recurrent LGSOC to aid in clinical decision making. Clinical trial information: NCT01849874. Research Sponsor: Array Biopharma/Pfizer.

5520 **Poster Discussion Session**

An umbrella study of biomarker-driven targeted therapy in patients with platinum-resistant recurrent ovarian cancer (KGOG 3045, AMBITION). *First Author: JUNG-YUN LEE, Institute of Women's Life Medical Science, Yonsei University College of Medicine, Seoul, South Korea*

Background: Heavily treated platinum-resistant ovarian cancer remains a therapeutic challenge. Although standard therapy includes non-platinum single agent chemotherapy (CT), prognoses are very poor in this setting. Anticancer therapies based on molecular biomarkers have improved dramatically. We report data from an umbrella study of biomarker-driven targeted therapy (olaparib, O; cediranib, C; durvalumab, D; tremelimumab, T) in platinum-resistant recurrent ovarian cancer (NCT03699449). **Methods:** Patients with platinum-resistant ovarian cancer with ≥ two lines of prior chemotherapy and ECOG 0/1 were eligible for this study. In the screening phase, archival tumor samples were tested for HRD and PD-L1 status. Treatment arms were allocated according to the test results. For HRD+ patients, we tested the synergistic effects of O with other agents: patients were randomly allocated to arm 1, O+C (O 200mg bid + C 30mg qd); or arm 2, O+D (O 300mg bid + D 1500mg q4w). For HRD- patients, we tested the role of biomarker-driven immunotherapy according to PD-L1 expression: arm 3, D+CT (D 1500mg q4w + PLD or topotecan or weekly paclitaxel [6 cycles]) in patients with high PD-L1 expression; arm 4, D+T75+CT (D 1500mg q4w + T 75mg q4w [4 doses] + PLD or topotecan or weekly paclitaxel [4 cycles]) in patients with low PD-L1 expression; or arm 5, D+T300+CT (D 1500mg q4w + T 300mg [1 dose] + weekly paclitaxel [60mg/m^2 D1,8,15 q4w for 4 cycles]) in patients with low PD-L1 expression. Recruitment to arm 5 was initiated after completion in arm 4. The primary endpoint was objective response rates (ORR) according to RECIST 1.1. **Results:** Between Dec 2018 and Oct 2020, 70 patients were allocated to treatment as follows: arm 1 (n = 16), arm 2 (n = 14), arm 3 (n = 5), arm 4 (n = 18), and arm 5 (n = 17). Median age was 57 years (range 34-77) and median prior lines of treatment was 3 (range: 2-10). Among all patients, the ORR was 35.7% (25/70, 95% CI: 24.6%-48.0%); complete response was observed in two patients. The ORRs (95% CI) for each treatment arm were shown (Table). Treatment-related grade 3/4 adverse events were reported in 37.5%, 35.7%, 20%, 66.7%, and 35.3% of patients in each treatment arm, respectively. No treatment-related adverse events (TRAEs) leading to discontinuation of treatment and no grade 5 TRAEs were observed. **Conclusions:** This is the first biomarker-driven umbrella study conducted in patients with platinum-resistant recurrent ovarian cancer. This umbrella study provides preliminary evidence on the clinical benefit of biomarker-driven targeted therapy. All regimens were manageable, without unexpected toxicities. Clinical trial information: NCT03699449. Research Sponsor: Severance Hospital Research Fund for clinical excellence, Pharmaceutical/Biotech Company.

	Drug	Biomarker	ORR, % (95% CI)
Arm 1 (N = 16)	O+C	HRD+	50 (24.7-75.4)
Arm 2 (N = 14)	O+D	HRD+	35.7 (12.8-64.9)
Arm 3 (N = 5)	D+CT	HRD- & PD-L1+	20 (0.5-71.6)
Arm 4 (N = 18)	D+T75+CT	HRD- & PD-L1-	33.3 (13.3-59.0)
Arm 5 (N = 17)	D+T300+CT	HRD- & PD-L1-	29.4 (10.3-56.0)

5521 **Poster Discussion Session**

Dendritic cell vaccine (DCVAC) combined with chemotherapy (CMT) in patients with newly diagnosed epithelial ovarian carcinoma (EOC) after primary debulking surgery (PDS): Biomarker exploratory analysis of a phase 2, open-label, randomized, multicenter trial. *First Author: Lukas Rob, Third Faculty of Medicine, Charles University and University Hospital Kralovske Vinohrady, Prague, Czech Republic*

Background: Most patients with EOC relapse despite PDS and CMT. Autologous DCVAC can present tumor antigens to elicit a durable immune response. We hypothesized that adding DCVAC to CMT stimulates antitumor immunity and improves clinical outcomes. **Methods:** Key eligibility criteria were FIGO stage III EOC (serous, endometrioid, or mucinous), post-PDS with < 1 cm maximal residuum, no prior systemic therapy, and ECOG 0-2. In part 1, patients were randomized up to 6 weeks after PDS, 1:1:1, into arm A (A; DCVAC concomitant with CMT), arm B (B; DCVAC sequential after CMT), and arm C (C; CMT). Patients were stratified by tumor residuum (0 or < 1 cm). CMT consisted of 6 cycles of carboplatin (AUC 5-7) and paclitaxel (175 mg/m^2). Patients in A and B received up to 10 doses of DCVAC (1×10^7 DCs/dose). The primary endpoint was radiologically assessed progression-free survival (PFS). The key secondary endpoint was overall survival (OS). Results presented refer to a protocol-defined modified intention-to-treat population (mITT) including patients who received ≥1 CMT dose in C or ≥1 DCVAC dose in A and B. **Results:** Between November 2013 and March 2016, 99 patients were randomized. At the final analysis, the mITT included 31 patients in A, 29 patients in B, and 30 patients in C. Key baseline characteristics and DCVAC exposure were comparable across treatment arms. Median PFS was 20.3 months in A, not reached in B, and 21.4 months in C, with corresponding HRs (95% CI) compared to C of 0.98 (0.48-2.00) in A and 0.39 (0.16-0.96) in B. The PFS benefit in B was statistically significant (p = 0.034) This was supported by a non-significant trend in OS in A and B. Median OS was not reached in any arm at the time of median follow-up of 66 months (34% of events). Patients with low CD8+ T-cell counts (CD8^{Lo}) in tumor samples in A and B had significantly improved clinical outcomes compared to patients in C with CD8^{Lo}: median PFS gain of 6 months (19 vs 13 months) and a more robust OS gain (median not reached vs 31 months), with minimal difference between A and B. This effect could not be attributed to statistical differences in high CD8+ T-cell counts (CD8^{Hi}) density patients. These findings indicated the best clinical outcome in DCVAC patients with immunologically "cold" tumors in both DCVAC arms. DCVAC showed a good safety profile with only 8 DCVAC-related adverse events (Grade 1-2). **Conclusions:** DCVAC improved PFS and OS outcomes in patients with newly diagnosed EOC, predominantly in patients with immunologically "cold" tumors, thus representing a promising treatment option in this patient population. Clinical trial information: NCT02107937. Research Sponsor: SOTIO a.s.

Pembrolizumab in combination with bevacizumab and pegylated liposomal doxorubicin in patients with platinum-resistant epithelial ovarian cancer. *First Author: Judith Michels, Gustave Roussy Comprehensive Cancer Center, Villejuif, France*

Background: There is a medical unmet need for effective treatments in platinum resistant ovarian cancer patients. We assessed the safety and efficacy of a combination of pembrolizumab with bevacizumab and pegylated liposomal doxorubicin (PLD). **Methods:** This is an open-label phase 1b trial in patients ECOG 0 or 1 with platinum-resistant epithelial ovarian, fallopian tube, or primary peritoneal cancer. The safety of the dual combinations of pembrolizumab with bevacizumab or with PLD were previously evaluated in 6 patients respectively. In the absence of dose limiting toxicities (DLT) the triple combination was evaluated at a maximum tolerated dose (MTD)-1 for PLD in 3 patients and in the absence of DLT at MTD. The sample size was calculated according to the modified toxicity probability interval design. The primary evaluation criteria was the safety, the secondary endpoint was the outcome. Pharmacokinetics of the flat dose of bevacizumab will be evaluated. **Results:** 22 patients were enrolled from September 2019 until June 2020 in six French centers. 3 initial patients have been treated at 20mg/m^2 of PLD (MTD-1) and 19 patients were treated at the dose of 30mg/m^2 of PLD (MTD) combined with 200mg of pembrolizumab until progression, unacceptable toxicity, or withdrawal of consent and 400mg of bevacizumab for a total of six cycles. The patients' characteristics are reported in the table. No DLT occurred. Grade 3 palmar-plantar erythrodysesthesia were reported in 4 patients. The recommended phase II dose of PLD was 30mg/m^2 in combination with pembrolizumab and bevacizumab. For patients treated at MTD, the overall response rate was 32% (6 partial responses) with 74% of clinical benefit with a durable response in 10 patients (53%). Median number of cycles was 7.5 (2 to not reached). Two patients are still on treatment. Correlative studies are ongoing. **Conclusions:** The combination was well tolerated and demonstrated clinical benefit in 74% platinum resistant ovarian cancer patients with durable response (>6 months) in 53% of patients. Clinical trial information: NCT03596281. Research Sponsor: MSD, Other Foundation.

A phase II evaluation of pembrolizumab in recurrent microsatellite instability-high (MSI-H) endometrial cancer patients with Lynch-like versus *MLH*-1 methylated characteristics (NCT02899793). *First Author: Dana M Roque, Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD*

Background: Microsatellite instability (MSI-H) is a biomarker for response to immune-checkpoint inhibitors (ICIs); however, these neoplasms are heterogenous including Lynch (germline), Lynch-like (somatic) and sporadic (*MLH1*-methylated) tumors. Whether mechanisms underlying MSI alter responses to ICIs is unclear. We report data from a phase II pilot study (NCT02899793) of pembrolizumab in recurrent MSI-H endometrial cancer (EC) patients and potential mechanisms of primary/secondary ICI resistance. **Methods:** Patients with measurable, MSI-H EC confirmed by immunohistochemistry and polymerase chain reaction were evaluated by next-generation sequencing and received pembrolizumab 200 mg intravenously every 3 weeks for up to 2 years. The primary end point was objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. **Results:** Twenty-five patients (24 evaluable) were treated. Six (25%) patients harbored Lynch/Lynch-like tumors while 18 (75%) had sporadic EC. Tumor mutational burden (TMB) was higher in Lynch-like (median 2939, IQR:867-5108) versus sporadic tumors (median 604, IQR:411-798) (P= 0.0076). Median follow-up was 25.8 months with an ORR of 58% (95% CI, 36.6-77.9%). ORR was 100% in Lynch/Lynch-like patients but only 44% in sporadic patients (P= 0.024). The 3-year progression-free (PFS) and overall survival (OS) proportions were 100% versus 30% (P= 0.017) and 100% versus 43% (P= 0.043), respectively. Grade 3/4 treatment-related adverse events (6.8%) occurred in 12 patients. Defective antigen processing/presentation and deranged induction in interferon responses served as mechanisms of resistance in sporadic MSI-H EC. **Conclusions:** Our study demonstrated prognostic significance of Lynch-like versus sporadic MSI-H EC on ORR, PFS and OS when treated with pembrolizumab. Clinical studies evaluating separate subtypes of MSI-H EC treated with ICIs are warranted. Clinical trial information: NCT02899793. Research Sponsor: Merck.

Anlotinib plus sintilimab in patients with recurrent advanced cervical cancer: A prospective, multicenter, single-arm, phase II clinical trial. *First Author: Qin Xu, Fujian Cancer Hospital, Fuzhou, China*

Background: It is difficult for patients with recurrent advanced cervical cancer to obtain clinical benefits after the failure of standard chemotherapy. However, anti-angiogenic therapy combined with immune checkpoint inhibitors have become a promising strategy for advanced cervical cancer. Anlotinib is a novel multi-target tyrosine kinase inhibitor, inhibiting tumour angiogenesis and proliferative signalling. Sintilimab is a fully humanized, high-affinity monoclonal antibody against programmed cell death-1 (PD-1). This phase II, single-arm study (ChiCTR1900023015) aims to evaluate the efficacy and safety of anlotinib plus sintilimab in patients with recurrent advanced cervical cancer. **Methods:** Patients who have received at least once platinum-based chemotherapy, histopathologically confirmed recurrent advanced cervical cancer (including squamous cell carcinoma, adenocarcinoma or adenosquamous carcinoma), more than 1% PD-L1 expression, ECOG 0-1 were considered eligible for enrollment. Anlotinib was taken orally (10mg mg qd, d1-14, 21 days per cycle), and sintilimab was administered intravenously (200mg once every 3 weeks). The treatment was continued until disease progression, death or intolerant toxicity. The primary endpoint was objective response rate (ORR) and the secondary endpoints included disease control rate (DCR), progression free survival (PFS), overall survival (OS) and safety. **Results:** Between September 2019 and February 2021, 42 patients with a median age of 52 years (range:47-58), FIGO histopathological stage I (11.9%), II (31.0%), III (33.3%), IV (9.5%) and undiagnosed (14.3%) were enrolled. 39 of these patients were evaluable. In the efficacy-evaluable population (n = 39), the therapeutic evaluation showed that 2 and 20 patients achieved complete response and partial response respectively, yielding the ORR of 56.4% (22/39, 95% CI:40.2 to 71.5). The DCR was 94.9% (37/39, 95% CI:80.7 to 98.8). The median response time was 1.6 months. The median PFS was not reached. The most common adverse events (AEs) were grade 1 or 2, which included hypothyroidism (33.3%), hypertension (23.8%), AST (21.4%), diarrhea (19.0%), ALT (16.7%), hand-foot syndrome(14.3%), hypertriglyceridemia (14.3%) and anemia (11.9%). The grade 3 AEs were hypertension (4.8%), hyponatremia (4.8%), immune pneumonia (2.4%) and immune myocarditis (2.4%). No higher AEs and treatment-related death were observed. **Conclusions:** Anlotinib plus sintilimab showed a promising efficacy with a favorable toxicity profile for patients with recurrent advanced cervical cancer. We will report more data in the future. Clinical trial information: ChiCTR1900023015. Research Sponsor: None.

Parametrial evaluation in cervical cancer by magnetic resonance imaging and clinical examination: Analysis of data from the prospective Leipzig School MMR study. *First Author: Benjamin Wolf, University of Leipzig Medical Center, Department of Gynecology, Leipzig, Germany*

Parametrial evaluation in cervical cancer by magnetic resonance imaging and clinical examination **Background:** In cervical cancer patients, assessment of parametrial tumor extension is important for staging and treatment planning. The 2019 cervical cancer guideline published by the Féderation Internationale de Gynécologie et d'Obstétrique (FIGO) for the first time includes recommendations for usage of magnetic resonance imaging (MRI) in this setting. However, valid data regarding the accuracy of this method, especially in patients with advanced disease, are sparce. The objective of this investigation was to compare the accuracy of parametrial assessment in cervical cancer patients using MRI and clinical examination under general anesthesia. **Methods:** A retrospective cohort study based on data from the prospective monocentric observational Leipzig School Mesometrial Resection study was conducted. Cervical cancer patients staged FIGO IB1 to FIGO IVA who underwent primary surgery between 1999 and 2017 were included. Data from pathological specimen of these patients was compared to the MRI findings and the results from clinical examination under general anesthesia. The gynecological oncologist had access to the MR images during clinical assessment. We calculated sensitivities, specificities, and predictive values for both examination methods. We performed logistic regression modelling to determine factors influencing the accuracy of either method. **Results:** 400 women were included. Pathologically proven parametrial tumor invasion was present in 165 (41%) patients. Examination under anesthesia augmented by intraoperative display of MR images exhibited a higher accuracy (83%) as compared to MRI alone (76%; McNemar's odds ratio = 2.0, 95%CI 1.25 – 3.27, $p = 0.003$). While accuracy was not affected by tumor size in clinical examination, MRI was associated with a significant drop in accuracy in tumors $\geq$ 2.5 cm (univariable logistic regression, OR for a correct diagnosis compared to smaller tumors 0.22, $p < 0.001$). This association remained significant in a multivariable model. There was also a significant decrease in specificity when evaluating parametrial invasion by MRI in tumors $\geq$ 2.5 cm in diameter ($p < 0.0001$). Body mass index had no influence on performance of either method. Accuracy was significantly higher when test results were concordant (OR 7.5 and 6.0 on univariable and multivariable regression modelling, respectively, $p < 0.0001$ in both cases). **Conclusions:** Clinical evaluation of the parametrium by pelvic examination under anesthesia in conjunction with intraoperative presentation of MR images leads to more accurate staging in cervical cancer patients as compared to magnetic resonance imaging alone. Clinical examination should therefore remain an integral part of parametrial assessment in cervical cancer patients. Research Sponsor: None.

Discovery and validation of novel methylated DNA markers of cervical cancer. *First Author: Jamie Nadine Bakkum-Gamez, Mayo Clinic, Rochester, MN*

Background: HR-HPV DNA testing, with or without cervical cytology, provides excellent sensitivity for detection of cervical cancer (CC) and its precursors; negative test results indicate that risk of disease is extremely low and enable women to undergo reduced screening with safety. However, management of women who screen positive remains challenging as many will prove to have self-limited HR-HPV infections. DNA methylation is an early event in carcinogenesis that could enhance CC screening specificity. **Methods:** For discovery, DNA from 70 FFPE CC (36 squamous, 34 adenocarcinoma) tissues that were reviewed microscopically, 18 fresh frozen benign cervicovaginal (BCV) tissues collected at the time of benign hysterectomy, and 18 buffy coats from cancer-free women underwent reduced representation bisulfite sequencing (RRBS) to identify MDMs associated with CC. Candidate MDM selection was based on area under the receiver operating characteristic curve (AUC) discrimination, methylation fold change, and low background methylation among benign controls. Candidate MDMs were re-tested using methylation-specific PCR (MSP) to confirm performance. Blinded biological validation was performed using MSP on DNA extracted from independent FFPE CC (38 squamous, 43 adenocarcinoma) and BCV (40) tissues. The performance of CC MDMs was also tested in DNA extracted from cervical dysplasia (36 adenocarcinoma in situ (AIS), 32 cervical intraepithelial neoplasia (CIN) 2/3, 11 CIN 1) FFPE tissues. **Results:** From RRBS discovery and technical validation via MSP, 30 candidate MDMs showed marked methylation fold changes (10 to >1000) across both CC histologies compared to BCV tissue from cancer-free women. Each of the 30 MDMs highly discriminated CC from BCV tissue with 9 MDMs having an AUC >0.90 (Table). CC MDMs also highly discriminated AIS from BCV but did not perform well in CIN 2/3 and CIN 1 (Table). **Conclusions:** Whole methylome sequencing, stringent filtering criteria, and biological validation have yielded outstanding candidate MDMs for CC that highly discriminate CC from BCV, notably with high specificity. Performance in cervical dysplasias varied with higher positivity rates in AIS than in CIN 2/3 and CIN 1. Translation to testing these novel MDMs in lower genital tract biospecimens and the addition of HR-HPV to the CC panel are warranted. Research Sponsor: The V Foundation, Mayo Clinic Transform the Practice Grant.

A phase II trial of bevacizumab and rucaparib in recurrent carcinoma of the cervix or endometrium. *First Author: Camille Catherine Jackson, Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Treatment options for patients with recurrent cervical and endometrial cancer remain limited. Even with optimum care, median survival has stalled at 12-17 months. The PARP inhibitor rucaparib has demonstrated activity in both *BRCA* wild-type and mutant cancers. Furthermore, preclinical studies suggest a synergistic effect of PARP inhibitors and antiangiogenic agents. We hypothesized that the combination of rucaparib and the VEGF inhibitor bevacizumab would yield a clinically-significant anti-cancer effect in patients with persistent or recurrent cervical or endometrial carcinoma. **Methods:** NCT03476798 is a phase II trial of adults with histologically-documented carcinoma of the cervix or endometrium. Patients with evaluable lesions who had undergone at least one prior line of systemic therapy, had adequate performance status and organ function, with a life expectancy of at least three months were eligible. Biopsies were obtained prior to treatment initiation for assessment of baseline tumor biomarkers, including *ARID1A* mutation status. Each cycle comprised 21 days. Rucaparib was administered orally at 600 mg, twice daily. Bevacizumab was administered by IV at 15 mg/kg on day 1 of each cycle. The primary objective was to estimate the proportion of patients with persistent or recurrent cervical or endometrial cancer who survive progression-free for at least six months (PFS6). Kaplan-Meier analysis was used to estimate progression-free survival. **Results:** There were 28 evaluable patients; six had cervical and 22 had endometrial cancer. Median age was 60.5 years (range, 30-74). Self-reported patient races were White (82.1%), Black (10.7%), and Native American (7.1%). Self-identified Hispanic or Latina patients comprised 3.6% of the cohort. Twenty-two of 28 patients had progressive disease by six months [survival distribution function estimate = 0.214 (lower CI, 0.087; upper CI, 0.378)]. Of the six patients who achieved PFS6, one had cervical and five had endometrial cancer. Six patients had a mutation in the *ARID1A* gene and those patients achieved PFS6 at a rate of 66.7%. **Conclusions:** The study hypothesis was evaluated in a two-stage design, and the interim analysis occurred once 28 evaluable patients were enrolled. In order to move on to the second stage, at least seven patients needed to remain progression-free at six months, but only six did. Thus, the study was ended after the interim analysis. The combination of rucaparib and bevacizumab did not provide the expected clinical benefit in this cohort of patients, but may warrant further exploration in patients with *ARID1A* mutations. Clinical trial information: NCT03476798. Research Sponsor: Clovis Oncology.

5528 **Poster Session**

Defective mismatch repair associated mutational signatures, a prognostic and predictive biomarker in endometrial cancer. *First Author: Yifan Emily Chang, Yale School of Medicine, New Haven, CT*

Background: Mismatch repair (MMR) deficiency is the distinguishing molecular feature of a significant portion of endometrial cancers (UCEC), and tumors with MMR deficiency have been identified as candidates for immune checkpoint blockade therapy. We studied MMR deficiency in UCEC using defective mismatch repair associated mutational signatures (MMRd-ams). **Methods:** WES-derived somatic mutation data of 531 UCEC samples from TCGA Pan-Cancer Atlas were analyzed. COSMIC mutational signatures for each sample were calculated using the R package *deconstructSigs*. MMRd-ams were correlated with clinical and molecular features for 507 TCGA samples (cBioPortal). Samples were divided into High MMRd-ams (n = 192) and Low MMRd-ams (n = 315) groups by the average of the representative MMRd-ams (0.2396). Fractions of tumor immune infiltrates were derived from CIBERSORT. **Results:** A significantly higher percentage of patients (47/192, 24.5%) in the High MMRd group had somatic putative driver mutations in at least 1 of the MMR genes (*MLH1, MLH3, MSH2, MSH3, MSH6, PMS1, PMS2* and *EPCAM*), compared with patients in the Low MMRd group (37/315, 11.8%, $p = 0.0003$). 15% (54/359) of tumors in the non-MSI subtypes expressed significant MMRd-ams and were categorized in the High MMRd-ams group. Patients in the High MMRd-ams group had longer progression-free survival (PFS) ($p = 0.0457$, log-rank). Analysis of the inferred composition of tumor immune infiltrates revealed that the High MMRd-ams group had significantly higher fraction of CD8+ T cells ($p < 0.0001$), higher fraction of T follicular helper cells ($p < 0.0001$) and lower fraction of M2 macrophages ($p < 0.001$). Tumors in the High MMRd-ams group also displayed higher mRNA expression levels of immune checkpoint genes: *PDCD1* ($p = 0.0013$), and *CTLA4* ($p = 0.0016$). **Conclusions:** MMRd-ams may be a prognostic and predictive biomarker with significant clinical impact. High MMRd-ams patients prognostically demonstrated longer PFS. Predictively, high MMRd-ams was associated with increased tumor immune infiltrates and elevated expression levels of *CTLA4* and *PDCD1,* known immune checkpoint genes exploitable by immune checkpoint therapies. MMRd-ams importantly characterized a subset of patients that were non-MSI but fit the MMR deficient phenotype by mutational signature. Together these findings open an avenue for recognizing and treating a previously unidentifiable group of patients. Research Sponsor: None.

5529 **Poster Session**

Differentiated activity profile for the PD-1 inhibitor balstilimab. *First Author: Cailin Joyce, Agenus Inc., Lexington, MA*

Background: The development and clinical application of immune checkpoint inhibitors has transformed the therapeutic landscape for cancer treatment in recent years. Balstilimab (AGEN2034) is a fully human, monoclonal IgG4 antibody that binds with high affinity to programmed death 1 (PD-1), thus preventing the interaction between this receptor and its ligands programmed death ligand 1 and 2 (PD-L1, PD-L2). Emerging evidence suggests that balstilimab exhibits a differentiated activity profile compared to currently approved anti-PD-1 agents, including pembrolizumab and nivolumab. **Methods:** Balstilimab as monotherapy was evaluated in a large phase 2 study in patients (pts) with recurrent/metastatic cervical cancer who had relapsed after a platinum-based treatment regimen for advanced disease. Pts were dosed at 3 mg/kg once every 2 weeks for up to 24 months and antitumor activity was assessed using RECIST v1.1. The tumor cell killing activity of balstilimab was evaluated preclinically in a human co-culture system of (1) primary T cells engineered to recognize NY-ESO-1 and (2) NY-ESO-1$^+$ cancer cell lines, including PD-L1 and/or PD-L2-deficient engineered lines. The co-culture system was maintained for ~ two weeks to drive partial T cell exhaustion; a state where cytotoxicity is compromised but recoverable with PD-1 blockade. Cytotoxicity of these partially exhausted T cells was quantified against PD-L1/L2 double positive, single positive, or double negative cancer cells in the presence or absence of PD-(L)1 antibodies. **Results:** In the second-line treatment setting for pts with advanced cervical cancer, balstilimab showed a numerically higher objective response rate (ORR) in subjects with PD-L1$^+$, squamous cell carcinoma (SCC) tumors (21%, 95% CI, 12.7-32.6%) than those reported for pembrolizumab. Unlike pembrolizumab, balstilimab showed activity in PD-L1(-) pts, and irrespective of tumor histology (ORR 7.9%, 95% CI, 2.7-20.8%). Despite lower overall PD-L1 positivity compared to SCC (41.7 v 72.9%), an ORR of 12.5% (95% CI, 5.9-24.7%) was observed in the subset of pts with a poorer prognosis, those with cervical adenocarcinoma. Concordant with clinical observations, balstilimab demonstrated superior rescue of antigen-specific T cell cytotoxicity *in vitro* relative to pembrolizumab, nivolumab, or atezolizumab. Balstilimab also induced cytotoxicity against PD-L1 and/or PD-L2 deficient target cancer cells. **Conclusions:** Taken together, these data suggest functional differentiation of balstilimab from other PD-1 inhibitors with potentially important implications for extending the therapeutic reach of anti-PD-1 therapy. Investigation of the underlying mechanistic basis for these findings is ongoing. Clinical trial information: NCT03104699. Research Sponsor: Agenus Inc.

Differential benefit from fractionated dose-dense first-line chemotherapy for epithelial ovarian cancer (EOC) according to KELIM-evaluated tumor primary chemosensitivity: Exploratory analyses of ICON-8 trial. *First Author: Benoit You, Institut de Cancérologie des Hospices Civils de Lyon (IC-HCL), CITOHL, EMR UCBL/HCL 3738, Lyon, GINECO & GINEGEPS, Lyon, France*

Background: ICON8 phase III trial did not show improvement in PFS or OS with first-line weekly dose-dense chemotherapy in EOC. This analysis evaluated the impact of tumor intrinsic primary chemosensitivity (assessed with modeled CA-125 ELIMination rate constant K (KELIM) based on the CA-125 kinetics during the first 100 days of chemo), on survival by treatment arms. **Methods:** Retrospective analysis of ICON8 where EOC patients were treated with chemo (Arm 1, standard (std) carboplatin AUC5-6 & paclitaxel 175mg/m2 q3weeks; Arm 2, carboplatin AUC 5-6 q3weeks and weekly paclitaxel 80 mg/m2; or Arm 3, weekly carboplatin AUC 2 & paclitaxel 80 mg/m2; ratio1:1:1) and debulking primary surgery (immediate (IPS), or delayed (DPS)). The association between standardized KELIM (dichotomized as favorable ≥ 1, or unfavorable < 1) and efficacy of treatment arms and surgery completeness was assessed univariate & multivariate analyses. **Results:** Of 1,566 enrolled patients, KELIM was calculated in 1,004 with ≥ 3 CA-125 available values. KELIM did not differ by treatment arm. Irrespective of surgical strategy, both KELIM and surgery completeness were significant prognostic factors, but treatment arms were not. In 354 IPS patients, 225 had unfavorable KELIM (63%). Weekly dose-dense carboplatin-paclitaxel (Arm 3) (compared to std chemo-Arm 1) was associated with improved survival in unfavorable KELIM patients (PFS:19.6 vs 11.0 months, HR 0.80 [0.54-1.17]; OS : 53.7 vs 40.1 months, HR 0.75 [0.50-1.14]), and worse survival in those with favorable KELIM (PFS: 26.7 vs 48.2 months, HR 1.27 [0.72-2.22]; OS: NR vs 69.2 months, HR 1.05 [0.53-2.06]). Maximum benefit was seen in highest-risk diseases (unfavorable KELIM + incomplete IPS; n = 116; PFS: 17.0 vs 7.4 months, HR 0.49 [0.29-0.82]; OS: 42.6 vs 27.0 months, HR 0.56 [0.33-0.96]). In 611 patients treated with neo-adjuvant chemo +/- DPS (279 unfavorable KELIM, 46%), the same trend for higher survival benefit from dose-dense carboplatin-paclitaxel was found in those with unfavorable KELIM (PFS: 10.8 vs 7.4 months, HR 0.84 [0.63-1.13]; OS: 26.4 vs 23.5 months, HR 0.80 [0.60-1.08]), and reversely. The higher KELIM, the higher the likelihood of complete surgery (OR 4.82 [3.21-7.37]). The prognostic impact of the surgery completeness was greater in unfavorable KELIM patients. **Conclusions:** In ICON8 trial, both the tumor primary chemosensitivity (by KELIM) and completeness of debulking surgery were major drivers of the prognosis & survival. Dose-dense fractionated chemotherapy in 1st-line setting may be beneficial for patients with lower tumor chemosensitivity, whilst it might be detrimental in those with highly chemosensitive disease. The greatest OS benefit (HR 0.56) from dose-dense chemotherapy was seen in highest-risk diseases (unfavorable KELIM and incomplete IPS). Research Sponsor: None.

An international, multicenter, real-world analysis of epithelial ovarian cancer treatment and outcomes. *First Author: Geoff Hall, Leeds Cancer Centre, Leeds Teaching Hospitals Trust, Leeds, United Kingdom*

Background: Few major studies have examined and compared the management and outcomes of patients from diagnosis to death between countries. We have established an international collaboration across Europe and South Korea to compare treatment and outcomes in Epithelial Ovarian Cancer (EOC). **Methods:** Patients diagnosed with EOC between January 2012 and December 2018 (age $\geq$18), were included for analysis. Data from medical records from five European and a single South Korean treatment centre were extracted, standardised to a common data model and analysed at each centre using a common script developed in R. Time to each progression/recurrence event (defined as time to next treatment) and overall survival have been estimated using Kaplan Meier methodology and outcomes stratified by categories of interest. Changes in the use of anti-cancer therapies over time and the incidence of BRCA mutations and incidence/timing of second breast cancers have also been examined. **Results:** A total cohort of 2925 patients was identified with a median age at each centre of 53 to 67 years. Advanced disease (FIGO stage III - IV) (range 57% to 84%) and high-grade serous morphology (38% to 70%) were most common at each centre. The timing of surgery (primary, interval debulking or delayed) and the proportion of patients undergoing surgery varied with stage. Patients with stage I disease where most likely to undergo surgery (range 73% to 100%) and stage IV the least (range 39% to 84%). Median overall survival for high grade serous cancers ranged from 1.9 to 4.9 years, and for the whole cohort from 2.1 to 5.5 years. Median time to next treatment at first relapse for the whole cohort ranged from 14 to 22 months. Second breast cancers were noted in 6 to 17% of patients and the majority of these occurred before the diagnosis of EOC at a median time of 96 to 118 months prior to diagnosis of EOC. Additional data on treatment pathways, BRCA status and outcomes by line of therapy for each centre will be presented. **Conclusions:** Preliminary analysis of results across this network suggests a variation in patient populations between sites and substantial differences in both treatments and outcomes. The establishment of a common data model and the use of a common analytic script between sites across six different countries allows for detailed exploration of the factors influencing differences in patient management and treatment outcomes in ovarian cancer patients. Metronomic cyclophosphamide and bevacizumab for the treatment of recurrent gynecologic carcinosarcoma: A multi-institution, retrospective study. *First Author: Sara Bouberhan, Massachusetts General Hospital, Boston, MA*

Background: The recent findings from the GOG 261 trial established carboplatin and paclitaxel as the standard first-line therapy for advanced gynecologic carcinosarcoma (GCS). Response rates to alternative regimens are limited, and the optimal chemotherapy for later line treatment of gynecologic carcinosarcoma has not yet been determined. The objective of this retrospective study is to report clinical response to treatment regimens for patients with GCS treated at 2 large academic referral comprehensive cancer centers. **Methods:** This multi-institution, retrospective analysis identified patients with recurrent GCS treated between January 1, 2015 and August 1, 2020 at the Massachusetts General Hospital and the University of Alabama O'Neal Comprehensive Cancer Center. All eligible patients received platinum/taxane as their first-line treatment regimen and were subsequently treated for recurrent disease. Subsequent treatment strategies were investigated. Objective responses were determined based on the clinical radiologist's interpretation. Time on treatment (TOT) and treatment toxicity were identified for each subject. Given the small number of patients in this series, descriptive statistics were employed. **Results:** 29 patients met inclusion criteria. 15 patients had recurrent uterine carcinosarcoma, and 14 patients had recurrent ovarian carcinosarcoma. The most commonly used treatment regimens were: liposomal doxorubicin (PLD)/bevacizumab (ORR: 13%; Range TOT: 2-7 months), metronomic oral cyclophosphamide (MOC)/bevacizumab (ORR: 17%; Range TOT: 1-18 months), weekly paclitaxel/bevacizumab (ORR 60%; Range TOT: 3-18.5 months), liposomal doxorubicin (PLD) (ORR: 0%; Range TOT: 1-3 months), and weekly paclitaxel (ORR: 33%; Range TOT: 4.5-5.5). All regimens were generally well tolerated, and only 3 patients discontinued treatment due to toxicity concerns. **Conclusions:** In summary, in our cohort of gynecologic carcinosarcoma patients, the most active regimen (defined by mean TOT) was paclitaxel/bevacizumab, but prolonged TOT was also observed in the patients treated with MOC/bevacizumab. Given the rarity and aggressive nature of this tumor, further studies into optimal second line chemo (and beyond) are warranted; although, the combination of MOC/bevacizumab should be considered given the tolerability and the duration of treatment in this patient population. Anlotinib plus pemetrexed as a further treatment for patients with platinum-resistant ovarian cancer: A single-arm, open-label, phase II study. *First Author: Jueming Chen, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Department of Gynecologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Non-platinum chemotherapy is widely used in platinum-resistant recurrent ovarian cancer treatment but with limited efficacy. Combing chemotherapy with angiogenic inhibitors is a new therapeutic choice. Anlotinib is a novel tyrosine kinase inhibitor targeting multiple receptors involved in tumor proliferation, vasculature, and tumor microenvironment. The study aimed to further assess the efficacy and safety of anlotinib combined with pemetrexed in platinum-resistant ovarian cancer. **Methods:** Patients who had received at least two different chemotherapy regimens (including the first line platinum-based regimen), with histologically proven recurrent platinum-resistant or platinum-refractory epithelial ovarian cancer (including salpingocarcinoma and peritoneal carcinoma), ECOG 0-2, were considered eligible for enrollment to receive six 21-days cycles of anlotinib (12 mg QD from day 1 to 14; 21 days per cycle) orally plus pemetrexed intravenously (0.5 g/m^2 on day 1; 21 days per cycle). Subsequent maintenance treatment was anlotinib monotherapy (12 mg QD from day 1 to 14; 21 days per cycle) till disease progression or intolerant toxicity. The primary endpoint was objective response rate (ORR), and the secondary endpoints included disease control rate (DCR), progression-free survival (PFS) and safety. **Results:** As of Jan 2021, 27 patients were enrolled. The median number of chemotherapy was 4 (range, 2-10) and 51.9% (14/27) of patients had ever received antiangiogenic therapy. The ORR was 36.4% (partial response (PR) in 8 patients; 95% CI, 17.2-59.3). The DCR was 100.0% (PR in 8 patients and stable disease (SD) in 14 patients; 95% CI, 73.5-100). The median time of the first response was 1.6 months (range, 1.3-4.4). The median PFS was 9.3 months (95% CI, NE-NE). Furthermore, the ORR of patients with and without prior antiangiogenic therapy was 16.7% (95%CI, 2.1-48.4) and 60.0% (95%CI, 26.2-87.8) respectively (P = 0.074). Any grades of adverse events (AEs) were observed in 92.6% (25/27) of patients, containing allergic eruption (33.3%), hand-foot syndrome (29.6%), hypertension (25.9%), and fatigue (25.9%). The grade 3-4 adverse events were only observed in 5 patients, including 1 with grade 3 proteinuria, 1 with grade 3 ascites, 1 with grade 3 fatigue, 1 with grade 3 edema limbs and 1 with grade 4 anemia. **Conclusions:** The treatment of anlotinib plus pemetrexed showed a promising antitumor activity with tolerable toxicity for patients in platinum-resistant and refractory ovarian cancer. Clinical trial information: ChiCTR2000029654. Research Sponsor: Beijing Medical and Health Found.

Efficacy of niraparib maintenance therapy in Chinese women with platinum-sensitive recurrent ovarian cancer with and without secondary cytoreductive surgery: Results from the NORA trial. *First Author: Lingying Wu, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: NORA is the first, phase III, randomized controlled trial (RCT) that demonstrated individualized starting dose regimen of niraparib, which significantly improved PFS in Chinese patients with platinum-sensitive recurrent ovarian cancer (PSROC). This sub-group analysis evaluated the efficacy of niraparib maintenance therapy with and without secondary cytoreductive surgery (SCS) in PSROC. **Methods:** The NORA phase III RCT included adult (≥18 years) Chinese women with PSROC who were randomized in a 2:1 ratio to receive oral niraparib (n = 177) or matched placebo (n = 88). This retrospective subgroup analysis was based on the progression-free survival (PFS) of niraparib maintenance therapy in these two groups of patients with PSROC, patients with SCS, and patients without SCS. The PFS was assessed by blinded independent central review. The Kaplan-Meier (KM) estimator and log-rank test were performed to calculate the median PFS time. **Results:** Of the 265 evaluable patients, 69 (26.0%) patients received the SCS (niraparib, n = 48; placebo, n = 21), and 196 (74.0%) patients were without SCS (niraparib, n = 129; placebo, n = 67). Among patients with and without SCS, baseline characteristics for BRCA mutation were 26.1% vs 41.8%, complete response to last platinum-based chemotherapy were 68.1% vs 43.9%, time (6-12 months) to progression after penultimate therapy were 23.2% vs 34.7%, respectively. Treatment with niraparib led to a significant reduction of risk to disease progression compared with placebo in patients with SCS (Hazard ratio [95% CI]: 0.32 [0.13–0.78]; P = 0.0102) and without SCS (0.34 [0.23–0.50]; P< 0.001). Moreover, in the subgroups of patients who received SCS, niraparib maintenance therapy had a significantly longer PFS compared with placebo (Median [95% CI]: not reached [18.33 – not estimable] vs 5.75 months [3.68 – not estimable]; P = 0.0102). This trend was also similar in the subgroup of patients who did not receive SCS (Median [95% CI]: 10.28 months [7.49 – 18.37] vs 4.90 months [3.71 – 5.52]; P < 0.0001). **Conclusions:** The results from this retrospective sub-group analysis revealed that niraparib maintenance therapy provided significant clinical efficacy in patients with PSROC, irrespective of SCS. Clinical trial information: NCT03705156. Research Sponsor: Zai Lab, Other Foundation.

Safety assessment of niraparib individualized starting dose in patients with platinum-sensitive recurrent ovarian cancer: A randomized, double-blind, placebo-controlled, phase III NORA trial. *First Author: Jing Wang, Hunan Cancer Hospital, The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China*

Background: To present the safety profile of niraparib maintenance therapy in patients with platinum-sensitive recurrent ovarian cancer (PSROC) included in the NORA trial. **Methods:** The double-blind, randomized, placebo-controlled, multicenter, phase III NORA trial (NCT03705156) included adult (≥18 years) Chinese women with PSROC who received ≥2 prior lines of platinum-based chemotherapy. Post ≤8 weeks of the last chemotherapy, patients were randomized (2:1) to receive oral niraparib (300 mg/day or 200 mg/day for patients with bodyweight <77 kg or platelet count <150 × 10^3/μL) or matched placebo. The primary endpoint was progression free survival, reported previously. Safety was assessed in terms of treatment emergent adverse events (TEAEs) related to hematologic toxicity (anemia/platelet count decreased and neutrophil count decreased) and non-hematologic toxicity (nausea/vomiting/constipation/insomnia/palpitations/hypertension). Adverse events (AEs) were graded using the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) v4.03. The data cutoff was February 1, 2020. **Results:** Of 265 patients included, the first 16 patients were given oral niraparib or matched placebo at a fixed starting dose of 300mg while 249 patients received individualized starting dose of niraparib (n = 166) or matched placebo (n = 83) based on baseline bodyweight and platelet count. The incidence of any TEAEs and grade ≥3 TEAEs was 100% and 50.8%, respectively in niraparib group, while 95.5% and 19.3%, respectively in placebo. Incidence of all grades of hematologic toxicity, gastrointestinal adverse events (nausea, constipation and vomiting), insomnia, palpitation and hypertension were highest in the first month after treatment with a gradual decrease in the further months. The median time to onset of grade ≥3 anemia, decreased neutrophil count and decreased platelet count were 87, 28, and 22 days, respectively, in the niraparib group. In niraparib group, any TEAEs that lead to dose reduction was observed in 59.9% of patients. Only 2 (1.1%) patients discontinued the treatment due to platelet count decreased and no patients discontinued niraparib treatment due to anemia or neutrophil count decreased. Overall, only 4% of patients in the niraparib group and 5.7% in the placebo group discontinued the treatment due to TEAEs. **Conclusions:** The lower incidence of TEAEs and the discontinuation rates indicate improved safety profile of niraparib with individualized starting dose in PSROC. Clinical trial information: NCT03705156. Research Sponsor: Zai Lab, Other Foundation.

Association of homologous recombination deficiency in ovarian cancer with neoantigen load and expression of immune checkpoints. *First Author: Kathleen Fenerty, Department of Medicine, UCLA, Los Angeles, CA*

Background: Immune checkpoint blockade (ICB) is being explored as a treatment option in ovarian cancer, but objective response rates for single agent ICB are modest at around 10-15%. Validated biomarkers are needed to predict which patients will respond to ICB. BRCA mutations and homologous recombination deficiency (HRD) status are the only validated integral biomarkers in ovarian cancer. HRD tumors exhibit defective DNA repair mechanisms that promote increased mutational burden, which we postulate may correlate with higher neoantigen load and increased expression of targetable immune checkpoints. **Methods:** The Cancer Genome Atlas (TCGA) ovarian cancer dataset was evaluated and previously published, well annotated samples were obtained for HRD status. HLA type was determined with OptiType. Nonsynonymous mutations were annotated with Ensembl VEP. pVAC-Seq using NetMHCpan algorithm predicted neoepitopes 9 amino acids in length for MHC class I, reporting only those with a predicted IC50 less than 500 nM. Immune checkpoint gene expression counts were normalized with TCGAbiolinks. Correlation between HRD status and neoantigen load was assessed by Wilcoxon test. After log2 transformation, Wilcoxon tests evaluated for association between HRD status and expression of immune checkpoints. The relationship between HRD status and PD-L1 protein abundance with reverse phase protein array was measured. **Results:** Data from 154 HRD positive and 198 HRD negative tumors were analyzed. HRD positive status correlated with higher neoantigen load ($p = 0.038$) and increased expression of the immune checkpoints CTLA4 ($p = 0.024$), TIGIT ($p = 0.027$), and PVR ($p = 0.002$), but not PD-L1 ($p = 0.238$), LAG3 ($p = 0.583$), HVEM ($p = 0.805$), GAL9 ($p = 0.750$), NECTIN2 ($p = 0.874$), VSIG3 ($p = 0.438$), PSGL1 ($p = 0.205$) or VISTA ($p = 0.531$). TIM3 ($p = 0.064$) and B7H3 ($p = 0.052$) both demonstrated a trend towards increased expression in HRD tumors. Interestingly, HRD status showed a negative association with PVRIG ($p = 0.028$). There was no association between PD-L1 protein abundance and HRD status. **Conclusions:** HRD positive ovarian tumors demonstrate higher neoantigen load than HRD negative tumors, as well as increased expression of certain immune checkpoints. This supports the hypothesis that increased neoantigen load leads to compensatory induction of immune checkpoints, and suggests that HRD status may predict response to ICB, particularly to drugs that target CTLA4, TIGIT, PVR, TIM3 and B7H4. Clinical and molecular characteristics of ARIEL3 patients who derived exceptional benefit from rucaparib maintenance treatment for high-grade ovarian cancer (HGOC). *First Author: Tanya Kwan, Clovis Oncology, Inc., Boulder, CO*

Background: ARIEL3 is a placebo-controlled randomized trial of the PARP inhibitor (PARPi) rucaparib as maintenance treatment in HGOC patients (pts) who responded to the latest line of platinum therapy (NCT01968213). Rucaparib improved progression-free survival (PFS) across all predefined subgroups. Here, we present an exploratory analysis of clinical and molecular characteristics associated with exceptional benefit from rucaparib. **Methods:** Pts were randomized 2:1 to receive rucaparib 600 mg BID or placebo. At the data cutoff of Dec 31, 2019, 33/375 (9%) and 1/189 (0.5%) pts were still ongoing and receiving rucaparib or placebo, respectively. Molecular features (genomic alterations, *BRCA1* promoter methylation) and baseline clinical characteristics were compared between pts who derived exceptional benefit (PFS ≥2 yrs), and those with disease progression on first scan (≈12 wks; the short-term [ST] subgroup) within each treatment arm. **Results:** Of 564 pts, 83 (15%) showed exceptional benefit: 79/375 (21%) in the rucaparib arm and 4/189 (2%) in the placebo arm. Within the rucaparib arm, exceptional benefit pts had more favorable clinical prognostic factors at baseline compared with the ST subgroup (Table). While BRCA mutations were enriched in the rucaparib exceptional benefit subgroup, 34/79 (43%) of these pts were BRCA wild type. Among other biomarkers, *RAD51C/D* mutations were associated with exceptional benefit; low genome-wide loss of heterozygosity was enriched within the ST subgroup; and high *BRCA1* methylation was present at similar fractions. Trends were similar in the placebo arm (Table). **Conclusions:** Exceptional benefit in ARIEL3 was more common in, but not exclusive to, pts with favorable clinical characteristics and known mechanisms of PARPi sensitivity. Our results suggest that rucaparib can deliver exceptional benefit to a diverse set of HGOC pts. Clinical trial information: NCT01968213. Research Sponsor: Clovis Oncology, Inc.

LIO-1: Lucitanib + nivolumab in patients with advanced solid tumors—Updated phase 1b results and initial experience in phase 2 ovarian cancer cohort. *First Author: Erika P. Hamilton, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: The phase (Ph) 1b part of LIO-1 (NCT04042116; ENGOT-GYN3/AGO/LIO) assessed the oral antiangiogenic, multikinase inhibitor lucitanib + immune checkpoint inhibitor nivolumab, confirming the recommended Ph2 dose (RP2D) of lucitanib as 6 mg QD + nivolumab (480 mg IV every 28 days). To maximize lucitanib exposure and potential clinical benefit of the combination, individualized lucitanib dose titration is being explored in a Ph2 part, across 4 recurrent gynecologic malignancies (endometrial, cervical, ovarian, and ovarian/endometrial clear-cell cancers) using a Simon 2-stage design. We present updated Ph1b data and describe initial experience for the first 24 patients (pts) enrolled in the Ph2 ovarian cancer (OC) cohort. **Methods:** In Ph1b, pts with advanced, metastatic solid tumors received lucitanib at 6, 8, and 10 mg QD + nivolumab (in a 4+3 dose escalation). In the Ph2 OC cohort, pts with recurrent high-grade epithelial ovarian, fallopian tube, or primary peritoneal cancer (excluding clear-cell histology) with ≥2 prior chemotherapy regimens (including ≥1 platinum doublet) received the combination at RP2D; lucitanib dose was escalated from 6 mg to 8 mg and then to 10 mg QD for pts who met safety-based titration criteria. Visit cutoff was Feb 1, 2021. **Results:** In the Ph1b part (N = 17), median treatment duration was 109 days (range 14–505+). There has been 1 confirmed complete response (CR; anal cancer) and 1 confirmed partial response (PR; cervical cancer) per RECIST v1.1 with durations of 7.1 and 12.8 months, respectively. Ten pts had stable disease (SD), 3 had progressive disease, and 2 were nonevaluable; 3 pts remain on treatment. Overall disease control rate (CR + PR + SD ≥16 wk) was 47.1%. One dose-limiting toxicity (DLT; grade [G] 3 proteinuria) was observed in a pt receiving lucitanib 6 mg, leading to lucitanib discontinuation; no DLTs were seen at 8 or 10 mg. G ≥3 treatment-emergent adverse events (TEAEs) reported in ≥2 pts included hypertension (HTN; n = 4), fatigue (n = 2), and proteinuria (n = 2). Of the first 24 pts enrolled in the Ph2 OC cohort, 13 (54%) remain on treatment (median duration 59 [2–167+] days). Most frequent any-grade TEAEs were HTN (n = 10), fatigue (n = 8), nausea (n = 7), and proteinuria (n = 6). The only G ≥3 TEAE experienced in ≥2 pts was HTN (n = 4); 1 pt discontinued due to G4 HTN/G2 angina pectoris and 1 pt to G2 colonic perforation. To date, 21 pts have completed ≥1 cycle; 11 met safety-based dose-titration criteria, 10 of whom escalated to the 8 mg lucitanib dose. Of these, 5 pts subsequently escalated to 10 mg. One pt required dose reduction from 6 mg to 4 mg lucitanib. **Conclusions:** Ph1b data suggest that lucitanib + nivolumab has promising signs of antitumor activity. A safety-based dose-titration strategy appears feasible with manageable toxicity, based on experience from the Ph2 OC cohort to date; efficacy data from this cohort will also be presented. Clinical trial information: NCT04042116. Research Sponsor: Clovis Oncology, Inc.

Underutilization of germline BRCA testing in commercially-insured women diagnosed with ovarian cancer. *First Author: Stephanie Cham, Brigham and Women's Hospital, Boston, MA*

Background: Germline BRCA (gBRCA) testing has prognostic, therapeutic, and familial implications for patients with ovarian cancer. Since 2010, national guidelines have recommended universal genetic testing, but few data are available about rates and timeliness of testing or factors associated with testing. **Methods:** We examined rates of gBRCA testing and the time from index procedure to testing among commercially-insured women aged 18 to 64 with claims for ovarian, fallopian tube, or primary peritoneal cancers cancer who received cytoreductive surgery and chemotherapy between 2008-2018. We used logistic regression to assess patient-, clinician-, and practice-level characteristics associated with testing. **Results:** Overall, the rate of g*BRCA* testing was 33.9%, increasing from 14.7% in 2008 to 46.4% in 2018; the median time to testing decreased from 280.0 to 72.5 days. Patients who were tested were younger than those who were not (mean [SD] 54.7 [9.9] years vs. 58.1 [11.8] years, $P<.001$) and had fewer comorbidities (Charlson score ≥2: 3.7% vs. 9.5%, P=0.01). There were no differences in testing rates by US region, rurality of practice location, or medical vs. gynecologic oncology providers. However, testing rates were higher in academic and NCI-designated cancer centers (36.2% and 32.5%, respectively), compared with community practices (25.5%; $P<0.001$) (Table). In adjusted analyses, lower test rates were associated with older age (aOR=0.97, 95%CI=0.96-0.98), more medical comorbidities (Charlson score ≥2: aOR=0.77, 95%CI=0.61-0.97), and community practices vs. NCI cancer centers (aOR=0.64, 95%CI=0.46-0.88). **Conclusions:** While the rates and time to testing for gBRCA in patients with new diagnoses of ovarian cancer have improved over time, testing remains underutilized, even among well-insured populations. Future studies should examine barriers to timely genetic testing and identify scalable strategies for increasing testing in women with ovarian cancer, particularly for women treated in community practices. Research Sponsor: None.

Postoperative adjuvant dose-dense chemotherapy with bevacizumab and maintenance bevacizumab after neoadjuvant chemotherapy for advanced ovarian cancer: A phase II AGOG/TGOG trial. *First Author: Wei-Chun Chen, Chang Gung Memorial Hospital of Linkou Main Branch, Taoyuan, Taiwan*

Background: The objective of this study is to evaluate the safety and efficacy of adding bevacizumab to dose-dense adjuvant chemotherapy with bevacizumab maintenance after neoadjuvant chemotherapy (NAC) and interval debulking surgery (IDS) for stage III/IV ovarian, tubal, and primary peritoneal cancer. **Methods:**This phase II clinical trial using Simon's minimax two-stage design was conducted. At the first stage, 13 subjects were enrolled, and the trial would proceed to second stage if ≤3 subjects discontinued treatment for study-defined significant adverse events (AEs). Patients with stage III/IV ovarian, tubal, and primary peritoneal cancer deemed not feasible for primary cytoreductive surgery were enrolled after 3 to 4 cycles of NAC and IDS without disease progression. NAC could be either weekly paclitaxel (80mg/m^2) (dose-dense) plus 3-weekly carboplatin (AUC5-6) or 3-weekly conventional schedule. After IDS, postoperative dose-dense adjuvant chemotherapy for 3 cycles at least (best to 6 cycles), and 3-weekly bevacizumab 15mg/kg was given since postoperative cycle 2. Further 3-weekly maintenance bevacizumab 15mg/kg was given intravenously for 17 cycles. **Results:** Of the 22 enrolled subjects, 13 (59.1%) had no gross lesion after IDS. Of the 13 subjects enrolled on the 1st stage, one study-defined significant AE occurred, therefore the trial proceeded to the 2nd stage (n = 9). The median progression-free survival (PFS) was 22.1 months (95% confidence interval [CI], 13.7 – 30.5), and the median overall survival (OS) was 49.2 months (95% CI, 33.8 – 64.6). Peritoneal Cancer Index score at entering abdomen during IDS was significant for PFS (>12 vs ≤ 12: p = 0.003). One of the 22 subjects did not receive any study treatment. In the safety analysis (n = 21), grade 3/4 AEs included thrombocytopenia of 38.1%, neutropenia 71.4%, and anemia 28.6%. Study-defined significant AEs of bowel perforation, poor-healing wound, and hypertension were found in 1 case each, respectively. **Conclusions:** This phase II trial demonstrated adding bevacizumab to dose-dense adjuvant chemotherapy with bevacizumab maintenance after NAC was feasible with tolerable toxicity and comparable PFS/OS as compared to other studies using bevacizumab in the NAC phase or dose-dense scheduling throughout. Clinical trial information: NCT02022917. Research Sponsor: Ministry of Health and Welfare, Taiwan, Other Foundation.

Patient self-reporting of tolerability using PRO-CTCAE: A randomized double-blind placebo controlled phase II trial comparing gemcitabine in combination with adavosertib or placebo in women with platinum resistant epithelial ovarian cancer. *First Author: Ainhoa Madariaga, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: A 4 month improvement in OS was demonstrated when Wee1 inhibitor adavosertib (Ad) and gemcitabine (G; arm A) was compared to G and placebo (P; arm B) in a phase 2 trial in recurrent ovarian cancer (NCT02151292). The patient reported outcome version of the CTCAE (PRO-CTCAE) was used to capture self-report of the frequency, severity and/or interference (scored 0-4; higher scores indicating worse symptomatic adverse events [syAEs]). **Methods:** Ad/P was given orally on D1-2, D8-9, D15-16 with G D1, D8, D15 in a 28-day cycle. English speaking pts in 2 centres completed PRO-CTCAE items electronically in clinic at baseline, D1 and D15 of each cycle and off treatment. An exploratory objective was to characterize syAEs in the first 3 months of therapy. We calculated 12-week area under the curve (AUC12w) as a measure of syAE over time and incremental AUC12w (iAUC12w) for adjustment to baseline syAEs and compared arms A and B using an independent samples t-test. We assessed proportion of scores 3-4 at 6 time-points and compared them using Fisher's Exact Test at each survey. **Results:** 51 pts were enrolled and completed ≥1 survey, 47 were evaluable for primary outcome (arm A: 28, B: 19). ECOG status was ≤1 in 44/47 pts. Median number of cycles of therapy were 5 (1-16) in arm A, and 2 (1-16) in B. Survey completion rates were high (arm A 93%, B 95%). Mean AUC12w fatigue severity (A 152 [standard error 9] vs B 112 [10]; p = 0.005) and interference (A 144 [11] vs 98 [15]; p = 0.018), diarrhea frequency (A 70 [12] vs B 33 [9]; p = 0.014), mucositis (A 23 [6] vs B 6 [3]; p = 0.012) and difficulty swallowing severity (A 10 [3] vs B 2 [2]; p = 0.023) were higher in arm A (any grade). There were no statistically significant between-arm differences in abdominal pain, bloating, nausea, vomiting and anxiety. The iAUC12w was significantly higher in arm A vs B for difficulty swallowing severity (A 10.1 [3] vs B -2.7 [4.7]; p = 0.02), mucositis severity (A 19.9 [6.6] vs B -3.1 [6.9]; p = 0.02) and fatigue severity (A 35.2 [8.2] vs B -3.1 [9.8]; p = 0.005). Proportions with high scores (3-4) were only significantly higher at C1D15 for fatigue severity in arm A (A 55% vs B 19%, p = 0.044). No significant differences were seen in other 3-4 scores per survey time. **Conclusions:** This is the first study evaluating pts self-reported toxicity with adavosertib in a randomized setting, allowing pts self-evaluation of toxicity in the context of improved PFS and OS. Greater fatigue, diarrhea, mucositis and difficulty swallowing were experienced by pts receiving adavosertib and gemcitabine, but score 3-4 reached significance on C1D15 fatigue only. No significant differences were detected in syAE profile for nausea, vomiting, abdominal pain, bloating and anxiety. This approach allows objective assessment of pts perception of toxicity with complex therapy. Clinical trial information: NCT02151292. A phase I study of mirvetuximab soravtansine (MIRV) and gemcitabine (G) in patients (Pts) with selected frα-positive solid tumors: Results in the ovarian cancer (EC) cohort. *First Author: Mihaela C. Cristea, City of Hope, Duarte, CA*

Background: Mirvetuximab soravtansine (MIRV) is an ADC comprising a FRα-binding antibody, cleavable linker, and the maytansinoid DM4, a potent tubulin-targeting agent. MIRV has promising single agent activity in FRα-positive medium/high expression epithelial ovarian cancer (EOC), at 6 mg/kg, based on adjusted ideal body weight (AIBW) IV every (q) 21 days. This study evaluated MIRV and G in recurrent EOC, endometrial and triple negative breast cancer. The recommended phase 2 dose (RP2D) was established at MIRV 6 mg/kg AIBW IV, day 1 and G 800 mg/m2 IV, d1, 8 q21 days (J Clin Oncol 37, 2019, Abs. #3009). Here we report the results from the EOC cohort. **Methods:** Patients (pts) with FRα-positive platinum resistant EOC with ≤4 prior chemotherapy (CT) regimens, were eligible. FRα positivity was initially defined as ≥ 25% of cells with PS2+ staining intensity (low to high FRα expression) and was subsequently revised to require medium/high FRα expression (≥50%/ ≥75% of cells with PS2+ staining intensity). **Results:** From 10/2017 to 12/2020, 113 EOC pts underwent FRα screening, with 74 FRα-positive results. Thirty total EOC pts (with median 3 prior lines of therapy) were treated; 8 pts during dose escalation and 22 EOC pts at the RP2D (all evaluable for response). Fifteen (50%) pts had high FRα, 10 pts (33%) medium FRα, and 5 pts (17%) low FRα expression. Eleven (36%) of the 30 EOC pts achieved a partial response (PR), 15 pts (50%) had SD and 4 pts (13%) progressed. Among the 11 responders, 5 pts had high FRα, 4 pts medium FRα and 2 pts low FRα expression. Non-heme clinically significant adverse events (AEs) included: G2 sensory neuropathy (4 pts) G3 diarrhea (3 pts), G3 fatigue (2 pts), G3 pneumonitis (2 pts), and 1 pt with G5 respiratory failure (secondary to pneumonia but drug-induced pneumonitis could not be ruled out). **Conclusions:** MIRV in combination with G has promising clinical activity in late line platinum resistant FRα-positive EOC, with best responses observed in high FRα expression. The regimen is well tolerated with expected AEs based on the known toxicities of each agent. This study was approved and funded by the National Comprehensive Cancer Network (NCCN) Oncology Research Program from general research support provided by ImmunoGen Corp and Cancer Center Support Grant P30CA033572. Clinical trial information: NCT02996825. Research Sponsor: NCCN.

The correlation between BRCA status and surgical cytoreduction in high-grade serous ovarian carcinoma. *First Author: Rachel Soyoun Kim, University of Toronto Division of Gynecologic Oncology, Princess Margaret Cancer Centre/University Health Network/Sinai Health Systems, Toronto, ON, Canada*

Background: High grade serous ovarian cancers (HGSC) with BRCA mutation are biologically unique, with distinct molecular and clinical behaviour from sporadic cases. It is unclear if these biological differences translate to favorable outcomes at the time of primary cytoreductive surgery (PCS). The aim of this study is to compare the amount of residual disease following PCS in BRCA-mutated (BRCAm) and wildtype (BRCAwt) HGSC, and to assess whether BRCA status is an independent predictor of residual disease. **Methods:** We conducted a retrospective analysis of patients with HGSC with known germline and somatic BRCA mutation status, treated with PCS from 2000 to 2017. We compared the cytoreduction outcomes between the BRCAm and the BRCAwt cohorts and built a predictive model to assess whether BRCA status was associated with amount of residual disease at the time of PCS. **Results:** Of 355 women, 144 harbored germline or somatic BRCA mutations (41%) and 211 were BRCAwt (59%). BRCAm women tended to be younger (54 vs. 59; $p < 0.001$), but there were no differences between the two groups in stage, disease burden at presentation, surgical complexity score, length of surgery, or perioperative complications. The BRCAm group had a higher rate of complete cytoreduction to no residual disease (0mm) [75% vs. 54%], and a lower rate of optimal cytoreduction (1-9mm) [16% vs. 34%] or suboptimal cytoreduction (≥10mm) [9% vs. 12%] ($p < 0.001$). In our predictive model, after accounting for length of surgery, CA-125 level, stage, disease scores and surgical complexity scores, BRCAm status was predictive of complete cytoreduction to 0mm residual disease (OR 4.78; 95% CI 2.32-9.85; $p < 0.001$). **Conclusions:** BRCA status is predictive of complete cytoreduction at time of PCS in HGSC. Timely availability of BRCA testing is paramount as it may aid in the therapeutic decision making between PCS or neoadjuvant chemotherapy in women with newly diagnosed HGSC. Research Sponsor: None.

Nanoanalysis of plasma volatile organic compounds using novel DNA-decorated carbon nanotube vapor sensors to noninvasively distinguish ovarian and pancreatic cancer from benign and control samples.

First Author: A. T. Charlie Johnson, University of Pennsylvania Department of Physics & Astronomy, Philadelphia, PA

Background: All cells release volatile organic compounds (VOCs) which emanate from body fluids. Our previous preliminary proof of concept study demonstrated that VOCs released from tissue and plasma from ovarian cancer patients are distinct from those released from samples of patients with benign tumors and controls. We seek to create a sensitive and specific, high-throughput screening test for cancer based on analysis of VOCs using novel nanosensors, first targeting cancers with limited clinical screening modalities. In this study we use these sensors to distinguish vapor characteristics in plasma samples from patients with ovarian and pancreatic cancer from benign specimens and controls. **Methods:** VOCs emanating from .5 mL of thawed, previously banked plasma samples from 93 total individuals were analyzed using a 10-channel nanoelectronic olfaction ("e-nose") system based on single-stranded DNA-decorated single-walled carbon nanotube (DNA-NT) vapor sensors. Analysis was performed on samples from 20 patients with ovarian cancer, 20 with benign ovarian tumors and 20 age-matched women as well as 13 patients with pancreatic cancer, 10 patients with benign pancreatic disease, and 10 age- and sex-matched controls. All ovarian cancer patients and comparators were non-smokers, while 1 pancreatic patient and 1 corresponding control were current smokers. The sample set included cancer patients with both early- and late-stage disease. All cancer specimens were obtained proximal to initial diagnosis and prior to initiation of therapy. With a test time of approximately 20 minutes per sample, the array output for each individual sample creates a vector in a 10-dimensional sensor space. The ability of the nanosensor array to discriminate between malignant, benign, and healthy groups was investigated using linear discriminant analysis (LDA), support vector machine (SVM), *k*-nearest neighbors (KNN), and random forest classification algorithms. Each algorithm was trained and tested according to leave-one-out and repeated stratified *k*-fold cross-validation methods. **Results:** Compared to their corresponding benign and control specimens, the DNA-NT sensor array was able to discriminate the VOCs from ovarian cancer with 95% accuracy and pancreatic cancer with 90% accuracy. Plasma samples from patients with early-stage ovarian and pancreatic cancers were correctly identified by the algorithms. **Conclusions:** Nano-enabled DNA coated vapor sensors were able to distinguish the VOC pattern between cancer, benign and control samples in both ovarian and pancreatic cancer. We provide strong evidence that ovarian and pancreatic cancer alters the VOC pattern emanating from plasma. Our results provide optimism that a diagnostic approach based on vapor detection of ovarian and pancreatic cancer is achievable. Research Sponsor: Klyberg Foundation.

Olaparib maintenance monotherapy for non-germline BRCA1/2-mutated (non-gBRCAm) platinum-sensitive relapsed ovarian cancer (PSR OC) patients (pts): Phase IIIb OPINION primary analysis.

First Author: Andres Poveda, Initia Oncology, Valencia, Spain

Background: In the Phase II Study 19 trial (NCT00753545; Ledermann *et al Lancet Oncol* 2014), maintenance olaparib improved progression-free survival (PFS) vs placebo in PSR OC pts, including non-BRCAm pts. A significant PFS benefit was also seen with maintenance olaparib vs placebo in gBRCAm PSR OC pts in the Phase III SOLO2 trial (NCT01874353; Pujade-Lauraine *et alLancet Oncol* 2017). To investigate olaparib maintenance monotherapy in non-gBRCAm PSR OC pts who had received ≥2 prior lines of platinum-based chemotherapy (PBC), we performed the Phase IIIb, single-arm, OPINION study (NCT03402841). **Methods:** Pts had high-grade serous or endometrioid OC and were in complete response (CR) or partial response (PR) to PBC. Pts received maintenance olaparib (tablets; 300 mg bid) until disease progression or unacceptable toxicity. The primary endpoint was investigator-assessed PFS (modified RECIST v1.1). Secondary endpoints included PFS by homologous recombination deficiency (HRD) and somatic BRCA mutation (sBRCAm) status determined by central Myriad tumor and germline testing; and time to first subsequent treatment (TFST). The primary analysis was planned for 18 months (mo) after the last patient was enrolled. **Results:** 279 pts were enrolled from 17 countries (mean age: 64 years); 253 pts (90.7%) were confirmed non-gBRCAm. At data cut-off (Oct 2, 2020), median PFS was 9.2 mo (95% CI 7.6–10.9), with 210 PFS events (75.3% maturity). 65.3%, 38.5% and 24.3% of pts were progression-free (PF) at 6, 12 and 18 mo, respectively. The Table shows PFS in key subgroups. Median TFST was 13.9 mo (95% CI 11.5–16.4). Median exposure to olaparib was 9.4 mo (range 0.0–31.9). Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 29.0% of pts and serious TEAEs in 19.7% of pts. TEAEs led to dose interruption, dose reduction and treatment discontinuation in 47.0%, 22.6% and 7.5% of pts, respectively. **Conclusions:** Our findings support the use of olaparib maintenance therapy in non-gBRCAm PSR OC pts, consistent with our interim analysis and previous trials in this setting. Clinical trial information: NCT03402841. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Feasibility of an adapted schedule of carboplatin plus paclitaxel in elderly women with advanced ovarian cancer: A retrospective cohort.

First Author: Benjamin Nicaise, Department of Medical Oncology, European Georges-Pompidou Hospital, APHP. Centre, France; Paris University, Faculty of Medicine, Paris, France

Background: The EWOC-1 trial compared Carboplatin monotherapy (C mono) to two different Carboplatin + Paclitaxel (CP) regimens (weekly or 3-weekly) in vulnerable elderly patients treated for advanced ovarian cancers (OC). This study was closed prematurely because of a worse outcome in the C mono group. Both CP regimens were equivalent in terms of feasibility and efficacy with different toxicity profiles. Optimal CP regimen in elderly patient is still unknown. Here we propose a study of another adapted regimen of CP (aCP) performed in elderly patients in our institution. **Methods:** We retrospectively analyzed OC patients ≥ 70 years who received a Carboplatin AUC 4-5 d1q3week + Paclitaxel 80 mg/m^2 d1-d8 q3week regimen between 2015 and 2019. Primary endpoint was treatment feasibility according to the EWOC-1 standard: completion of 6 courses of chemotherapy without early stopping for disease progression, death or unacceptable toxicity (adverse event (AE) related to chemotherapy or treatment procedure leading either to early treatment stopping, to an unplanned hospital admission or to death or to a dose delay lasting more than 14 days or more than 2 dose reductions). **Results:** We identified 36 pts with a median age of 79 years (table). All patient but one had an ONCODAGE-G8 score ≤ 14, 30.6% of patients had a comorbidity Charlson's index > 4 and 52.5% had an albumin rate < 35 g/L. The feasibility endpoint was met in 58.3% of patients (IC95% = [25.6; 57.8]). Main causes of treatment failure (TF) were early discontinuation because of toxicity in 6 patients (16.7%) and progressive disease in 3 patients (8.33%). Median PFS was 35.3 months (IC95% = [22.7; NR]) and median OS was 62.1 months (IC95% = [31.4.0; NR]). The most frequent AE were asthenia (all grades = 94.4%, grade 3-4 = 13.9%), anemia (all grades = 94.4%, grade 3-4 = 27.8%), neutropenia (all grades = 66.7%, grade 3-4 = 38.9%) and neuropathy sensory (all grades = 61.1%, no grade 3-4). Non high-grade-serous histological type and a poor Charlson's score were associated with a higher rate of TF (100% and 63.6%, respectively). **Conclusions:** These results are consistent with the findings of the EWOC-1 trial in both CP regimens and suggest that aCP could be non-inferior with an acceptable toxicity profile. Further prospective and comparative studies are mandatory to confirm this trend and to better identify predictive factors of TF in OC elderly patients. Research Sponsor: None.

Stage I Sertoli-Leydig cell tumors: An interim report from the International PPB/*DICER1* & OTST Registry.

First Author: Alexander Nelson, University of Minnesota Medical School, Minneapolis, MN

Background: Sertoli-Leydig cell tumors (SLCT) are rare ovarian sex cord-stromal tumors which occur primarily in adolescents and young adults and are associated with *DICER1* pathogenic variants. **Methods:** Informed consent for participation in the International PPB/*DICER1* or OTST Registry was obtained. When available, pathology was centrally reviewed. Staging was evaluated by Registry review using the International Federation of Gynecology and Obstetrics (FIGO) classification system. **Results:** Eighty-three patients with stage I SLCT were enrolled. Median age at diagnosis was 15 (range 1-60) years. Most (57/83) patients had germline *DICER1* testing; 35/57 (61%) had germline pathogenic variants. Fifty-six patients had Ia and 27 had Ic SLCT. The distribution of patients receiving chemo based on histology and stage is displayed in Table. One patient with poorly differentiated stage Ia SLCT with sarcomatous elements and no chemo at diagnosis recurred 6 months after surgery and died of disease. Three patients with local diagnosis of stage Ia SLCT, with data unavailable for Registry confirmation of stage, developed a subsequent SLCT 33 to 74 months after diagnosis; of these, 2 died, and 1 remains in treatment for recurrence. Available records and molecular testing in these 3 cases have not provided a distinction between recurrent and metachronous disease. Excluding the latter 3 patients, 3-year overall survival was 97.3% for stage Ia SLCT. Six patients with stage Ic SLCT recurred (Stage Ic1=5 and Stage Ic2=1) with a median time to recurrence of 25 (range 3-53) months. In stage Ic1, 18% (2/11) recurred after upfront chemo compared to 33% (3/9) after surgery alone. Of the 5 patients with stage Ic1 disease that recurred, 4 had intermediate and 1 had poorly differentiated SLCT. One patient had sarcomatous elements and 2 received upfront chemo. Two of the 5 patients are alive, neither received upfront chemo. One patient with poorly differentiated stage Ic2 SLCT with sarcomatous elements and no upfront chemo recurred and died of disease. Three-year event free and overall survival were 86.9 and 88.6% for stage Ic SLCT. Four patients had metachronous SLCT in the contralateral ovary confirmed by clinical review or somatic testing at a median time from diagnosis of 33 (range 28-104) months. All 4 have germline pathogenic variants and no evidence of disease at last follow-up. **Conclusions:** Individuals with early stage SLCT generally fare well, however, ongoing surveillance for recurrence and metachronous disease is indicated. Novel therapies are needed to address recurrent SLCT. Research Sponsor: Pine Tree Apple Tennis Classic Fund and Children's Internal Research Funding.

Circulating tumor DNA as a noninvasive marker of resectability in ovarian carcinomas. *First Author: Roxane Mari, Department of Medical Oncology, Institut Paoli Calmettes, Marseille, France*

Background: Ovarian cancer is the leading cause of death by gynecological cancer. Complete surgery remains one of the main prognostic factors. Laparoscopic exploration is mandatory to assess surgical resectability at diagnosis or after neoadjuvant chemotherapy. However, there is no clinical or biological marker that can correctly predict resectability and may be able to avoid a second laparoscopic exploration for initially unresectable diseases. Our aim was to assess circulating tumor DNA (ctDNA) value as a predictive non-invasive marker of evolution towards resectability for patients with epithelial ovarian cancer receiving first-line chemotherapy. **Methods:** We explored in this work one of the secondary objectives of the CIDOC study (NCT03302884). CIDOC is a multicenter prospective study aiming to explore ctDNA value as early marker of disease relapse after first-line treatment for epithelial ovarian cancer. Patients with mucinous histology or early stages not requiring chemotherapy are excluded. Plasma samples are collected at diagnosis, during neoadjuvant chemotherapy, and during follow-up. After DNA extraction, panel-based next generation sequencing is performed on both tumor samples and germline DNA, and somatic mutations of interest are selected for ctDNA monitoring. ctDNA analyses are conducted using droplet digital PCR (BioRad QX200) by measuring the variant allele fraction (VAF) of previously identified mutations. **Results:** This intermediary analysis has included 47 patients diagnosed between March 2017 and December 2019. Median age was 69 years old (48 – 84). Most of the patients had advanced disease (89.4% stage FIGO III or IV), serous histology (94.8%), and high grade tumor (92.3%). Most of the patients underwent complete interval cytoreductive surgery (76.3% vs 17.4% complete upfront surgery). Most of the tumors had *TP53* mutations (85.1%), following by alterations involving DNA repair genes (38.3%). Median cell-free DNA concentration at baseline was 0.38 ng/µL (0 – 12.8). ctDNA was identified in 92.1% of patients at baseline with a median VAF of 1.84% (0 – 42.52%). ctDNA VAF was correlated to the peritoneal dissemination (p= 0.039) assessed with the peritoneal cancer index. ctDNA clearance after preoperative chemotherapy tended to be correlated to achievement of complete interval surgery for patients receiving neoadjuvant chemotherapy (p= 0.108). **Conclusions:** ctDNA may be a promising non-invasive marker to assess peritoneal cancer spreading and to predict surgical resectability after neoadjuvant chemotherapy. If confirmed in larger populations, this may enable to avoid additional surgical explorations for patients who remain ctDNA positive after chemotherapy. Clinical trial information: NCT03302884. Research Sponsor: AstraZeneca.

5549 **Poster Session**

Health-related quality of life (QoL) in platinum-resistant ovarian cancer patients treated with olaparib and pegylated liposomal doxorubicin (PLD), a multicenter single-arm phase II clinical trial (ROLANDO, GEICO-1601). *First Author: José Alejandro Perez-Fidalgo, Department of Medical Oncology, Hospital Clínico Universitario de Valencia, Valencia, Spain*

Background: The prognosis for patients with platinum-resistant/refractory ovarian cancer (PROC) is poor, and the aim of treatment is focused primarily on symptom control and maintenance of QoL. The objective of this study was to assess the impact on QoL of the combination of pegylated liposomal doxorubicin (PLD) with olaparib (OLA) in PROC patients (pts). **Methods:** ROLANDO is a single arm phase II trial that enrolled pts with high-grade serous or endometrioid and at least one previous PROC recurrence (between 28 days - 6 months after last platinum). Up to 4 previous lines (up to 5 in *BRCA*-mut) were allowed. Pts received 6 cycles of PLD 40 mg/m2 intravenously every 28 days + OLA 300 mg b.i.d. followed by OLA 300 mg b.i.d. monotherapy until progression or unacceptable toxicity. QoL was measured by European Organization for Research and Treatment of Cancer QLQ C30 questionnaire evaluating functional status, and symptom intensity and QLQ OV-28 ovarian cancer specific module, both filled out by pts every 4 months (mo) regardless of disease progression. Questionnaire compliance was reported as percentage of the initial number of pts. Changes between baseline and subsequent visits (Wilcoxon rank test) were evaluated. P values < 0.05 were considered significant. **Results:** From 2017 to 2020, 31 pts were recruited. Median age was 57 y.o., ECOG 0/1: 32.3%/67.7%. Median of prior lines was 2 (range 1-5) and pts were on study treatment for a median of 5 mo (range 1.4-19.5) for OLA and 5 cycles (range 2 - 6) for PLD. QoL information was available at baseline for 30 (97%) pts and decayed to 22 (71%), 13 (42%), 6 (19%) and 4 (13%) pts at 4, 8, 12, and 16 mo respectively. Global health status measured by QLQ C30 and QLQ OV-28 scores was maintained throughout all time points with no significant differences. Significant transient improvement was seen in social functioning after 12 mo ($p = 0.013$). Nausea-vomiting ($p = 0.02$), hair loss ($p = 0.012$) and constipation ($p = 0.037$) showed a significant increase at 4 mo overlapping with PLD administration, and returned to baseline levels afterwards. This was in line with the reported adverse reactions frequency of nausea (58.1%) and vomiting (45.2%). Dyspnea showed a transient significant increase at 12 mo ($p = 0.012$), whereas insomnia ($p = 0.038$) and attitude towards disease ($p = 0.007$) improved at 16 mo. Symptoms such as appetite and constipation did not change after 12 mo. Most functional scales (physical, role, emotional, cognitive, body, sexuality) and symptom scales (fatigue, pain, appetite loss, diarrhoea, neurologic, hormonal and economic burden) had no statistically significant changes. **Conclusions:** Pts treated with OLA+PLD combination reported no signs of clinically relevant deterioration of QoL while on treatment. All QoL items changes were transient in no more than 1 time-point. Clinical trial information: NCT03161132. Research Sponsor: AstraZeneca.

5550 **Poster Session**

Phase 1 dose-escalation study of STRO-002, an antifolate receptor alpha (FRα) antibody drug conjugate (ADC), in patients with advanced, progressive platinum-resistant/refractory epithelial ovarian cancer (EOC). *First Author: R. Wendel Naumann, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: STRO-002-GM1 is a Phase 1, open-label study in patients (pts) with advanced, platinum resistant or refractory EOC. STRO-002 is a novel FRα-targeting ADC with a precise DAR of 4 using site-specific conjugation technology to circumvent limitations of current ADCs. STRO-002 induces immunogenic cell death and contains the tubulin-targeting 3-aminophenyl hemiasterlin warhead SC209, a potent cytotoxin that is a weak substrate for P-gp. **Methods:** STRO-002 is given IV on Day 1 of each 21-day cycle until disease progression. Ocular exams are performed at baseline and every other cycle. Prophylactic corticosteroid eyedrops are not administered. FRα expression was not required for eligibility and retrospective analysis of FRα expression in archival tumor tissue is ongoing. **Results:** Enrollment has been completed with 39 pts treated at 9 dose levels (0.5 to 6.4 mg/kg). Data cut-off is Jan 30, 2021. Median age was 61 years (range 48-79). Median number of prior systemic therapies was 6 (range 2-11). 86% of treatment emergent adverse events (AEs) were Grade 1-2. The most common treatment related Grade 3 and 4 AEs were reversible neutrophil count decreased (36%) and neutropenia (33%), Grade 3 arthralgia (12.8%) and neuropathy (7.7%). Two pts developed neutropenic fever that resolved with antibiotic therapy. 34 pts were treated at clinically active doses ($\geq$ 2.9 mg/kg) and 31/34 are evaluable for RECIST 1.1 response. Objective responses were seen in 10/31 pts - 1 CR, 4 confirmed PR, and 5 unconfirmed PR (imaging studies under review in 1 pt with uPR). Disease control rate (CR+PR+SD) is 74% at $\geq$ 12 weeks and 61% at $\geq$ 16 weeks. 5 pts remain on treatment with 3 ongoing at $>$ 74 weeks. FRα-expression results are available in 14 pts treated at $\geq$ 2.9 mg/kg with 50% low, 21% medium and 29% high FRα-expressing tumors per PS2+ scoring algorithm. 12/13 pts with H-scores of $\geq$ 105 achieved disease control with PR or SD. Maximum plasma concentrations of STRO-002 were achieved at the end of the 1 hour infusion and exposure increased in an apparent dose proportionate/linear manner. **Conclusions:** STRO-002 is a novel FRα-targeting ADC with an encouraging emerging safety and efficacy profile in heavily pretreated relapsed/refractory EOC. No ocular toxicity signals have been observed. Durable responses and anti-tumor activity have been demonstrated across a broad range of FRα expression levels in evaluable pts treated at $\geq$ 2.9 mg/kg. 48% (15/31) of pts were on treatment without disease progression for $\geq$ 24 weeks and 13% (4/31) remain on treatment for over a year, suggesting that STRO-002 is well tolerated in long-term responding patients. A randomized expansion cohort comparing STRO-002 at 4.3 mg/kg vs 5.2 mg/kg dose levels in less heavily pretreated EOC pts is ongoing. Clinical trial information: NCT03748186. Research Sponsor: Sutro Biopharma.

5551 **Poster Session**

Serum-based assay for adnexal mass risk of ovarian malignancy. *First Author: Daniel Ure, Aspira Women's Health, Trumbull, CT*

Background: A Deep learning neural network was developed to assess ovarian cancer risk in women presenting with adnexal mass into risk categories. The algorithm shows potential to improve on the performance of CA-125 as the standard biomarker to monitor women as a clinical management metric to trace increased risk of malignancy. **Methods:** Serum specimens from an enriched biobank (N = 2688) were collected during previous clinical studies from women presenting with an adnexal mass at risk of ovarian cancer. Protein biomarker data from these specimens were used to develop a novel neural network for binary stratification of ovarian cancer risk assessment. These specimens were divided between training and testing data sets using 5-fold cross validation during training. A randomized, separate sample set was withheld from use in training and testing the algorithm for independent validation purposes. As algorithm inputs seven biomarkers are used in the network: cancer antigen 125, human epididymis protein, beta-2 microglobulin, apolipoprotein A-1, transferrin, transthyretin, and follicle stimulating hormone. In addition to these biomarkers, the patient's age and menopausal status are used. Menopause was defined as the absence of menses for $\geq$12 months. The algorithm uses supervised learning with known histopathology diagnoses as the labels for training. The algorithm is a classification deep feedforward neural network. The neural network is regularized using node dropout to reduce overfitting. The final layer of the neural network has two nodes and uses the softmax function to assign a binary classification of low or high-risk of malignancy. **Results:** Algorithm performance metrics are also shown comparing predicted results from the algorithm to the known malignancy diagnoses. The performance metrics are also compared below to the standard of care biomarker test, cancer antigen 125 (CA125), reporting increased sensitivity by 26.1%, and failure to reject the null hypothesis of equivalent specificity. **Conclusions:** The algorithm detected 91% of malignancies in the independent validation data. This high sensitivity in malignancy detection paired with the failure to reject the null hypothesis of equivalent specificity (Pearson's chi-squared test p-value of 0.281) and negative predictive value (NPV) suggest the algorithm could be used two-fold. First, surgical referral to gynecological oncologists for women classified in the high-risk cohort. The second as a goal with future clinical validation, is that women with a low risk of malignancy might be able to delay surgery and enter into a serial monitoring clinical management care pathway. Research Sponsor: None.

	Neural Network	CA125
Malignancy detection rate	21/23 (91.3%)	15/23 (65.2%)
Count of malignancies not detected	2	4
Count of false positives	64	52
Positive predictive value	21/84 (25.0%)	15/67 (22.4%)
Specificity	509/573 (89.0%)	521/573 (90.9%)
Negative predictive value	509/511 (99.6%)	521/529 (98.5%)

Disparities in ovarian cancer treatment and overall survival according to race: An update. *First Author: Deanna Huffman, Allegheny Health Network, Pittsburgh, PA*

Background: It has long been identified that black women with ovarian cancer have worse overall survival when compared to white women. Disparities in the adherence to NCCN guideline-directed treatment and socioeconomic characteristics may be responsible for the differences in these outcomes. **Methods:** A retrospective review of National Cancer Database (NCDB) was performed to identify patients diagnosed with ovarian cancer from 2012-2016. We defined adherence to NCCN (National Comprehensive Cancer Network) guidelines as having stage and year-appropriate chemotherapy and surgery. Differences in guideline adherence, socioeconomic characteristics and survival outcomes were assessed. **Results:** In total, 32,163 were identified meeting the study criteria; 27,744 identified their race as "white" and 2,204 identified their race as "black". Characteristics associated with higher likelihood of black race were advanced stage of disease- stage III (OR = 1.1869, CI = 1.03-1.37) or stage IV disease (OR = 1.4495, CI = 1.23-1.70) and treatment in a comprehensive (OR = 1.5757, CI = 1.16-2.15) or academic (OR = 2.3023, CI = 1.70-3.12) treatment facility. Variables associated with a lower likelihood of black race were higher education level (OR for high school degree $<$ 6.5 % = 0.2501, CI = 0.21-0.30) and higher median household income (OR for income $>$ $63,333 = 0.4218, CI = 0.36-0.49). Whether the care received was adherent to NCCN guidelines did not seem to be associated with black race (OR for adherence = 1.0021, CI = 0.89-1.13). 5-year overall survival for patients who received adherent care was 58% for white patients vs. 49% for black patients. Among those who didn't receive adherent care, the outcomes were 49% among white patients vs. 38% among black patients. **Conclusions:** Overall survival remains worse for black patients, regardless of whether their care adhered to NCCN guidelines as defined by our study. This suggests that while receipt of care that is not adherent to NCCN guidelines seems to be negatively associated with overall survival, we must consider and evaluate other socioeconomic, environmental and system factors that are contributing to this continued survival discrepancy in women being treated for ovarian cancer. Next generation sequencing in ovarian cancer patients: Does personalized medicine improve oncological outcomes? *First Author: Tamar Safra, Sackler Faculty of Medicine, Tel Aviv, Israel*

Background: Ovarian cancer (OC) is the second most common gynecologic malignancy and the most common cause of gynecologic cancer mortality in the United States. Homologous recombination deficiency (HRD), including the *BRCA* mutations, are found in 50% of OC tumors. Next generation sequencing (NGS) provides understanding the underlying molecular and genetic patterns to improve OC treatment. This study examines the prognostic and predictive biomarkers identified with NGS in hopes to improve OC patients outcomes. **Methods:** The patient cohort included 890 consecutive OC patients treated between 2002 and 2020,at the Tel-Aviv Medical Center. We retrospectively evaluated patients with histopathologically confirmed OC. Cox models were used to analyze the clinical impact of various mutations and biomarkers among OC patients with and without FoundationOne CDx NGS testing, by assessing overall survival (OS), progression free survival (PFS), and physicians' timing preferences for referral to NGS testing. **Results:** Among the 890 OC patients, 103 (11.57%) completed NGS molecular testing. The median OS among patients with and without NGS testing, adjusted for age, stage and recurrence status, was 73.36 and 68.50 months, respectively (P = .02). The median PFS was 17.23 and 17.43 months, respectively (P = .77). We also evaluated physicians' preferences regarding timing of molecular profiling, upon diagnosis, after first recurrence and at advanced line of treatment in 31.95%, 36.08% and 26.8% of practitioners, respectively. Of the patients who completed NGS, 48 (52.75%) harbored actionable mutations, and 21 patients (43.75%) received matched targeted therapy. Forty-five patients were microsatellite stable (MSS) (45%), 55 with undetermined status (55%) and 0 patients with MSI-H. Forty-one (71.93%) patients had low ($<$ 5) tumor mutation burden status (TMB), 16 (28.07%) intermediate (5-15) and none with high ($>$ 15) TMB. There was no noticeable survival difference when comparing low with intermediate TMB (P = 0.3). Loss of heterozygosity (LOH) was a significant prognostic biomarker. Patients with high LOH (hLOH $>$ = 16%) had longer OS compared to low LOH (ILOH $<$ 16%), 99.02 vs. 50.23 months, respectively (P $<$ .005). Patients with hLOH and BRCA mutations (BRCA+) had longer OS compared to hLOH/BRCA WT (BRCA-), ILOH/BRCA+, and ILOH/BRCA-, with an unreached median OS of 91.5 vs. 60.48 vs. 45.21 months, respectively (P = .005). **Conclusions:** Our work demonstrates the clinical benefit of NGS personalized medicine as a cornerstone of future treatment strategies in OC. Our study suggests an OS benefit among the NGS tested cohort. We identified LOH as a prognostic biomarker. Prospective studies evaluating larger cohorts are necessary to generate a more extensive evaluation of additional prognostic and predictive biomarkers among OC patients. Research Sponsor: None.

Symptom identification and management in epithelial ovarian cancer. *First Author: Ashley Deanelle Hickman, Mayo Clinic Department of Internal Medicine, Rochester, MN*

Background: A better understanding regarding the burden of treatment side effects in patients with gynecological malignancies could help guide symptom interventions and oncologic therapy decision-making. We aim to inform understanding of symptom burden in epithelial ovarian cancer (EOC) by analyzing patient-reported symptom data from patients treated for this condition over a 16-month period. **Methods:** Patients receiving medical oncology care at Mayo Clinic Rochester and at Midwest Mayo Clinic Health System community sites have received symptom-focused surveys prior to each medical oncology visit since March 28, 2019 through the Enhanced Electronic Health Record Facilitated Cancer Symptom Control Study (E2C2). These surveys, administered either through the electronic medical record portal or on a clinic tablet prior to each oncology office visit, no more frequently than every 2 weeks, include six linear analogue scales measuring sleep disturbance, pain, anxiety, emotional distress, and fatigue (SPADE), as well as physical dysfunction on a scale of 0 (none) to 10 (as bad as you can imagine). Scores of 0-3 were considered mild symptoms, 4-6 moderate symptoms, and 7-10 severe symptoms. We collected survey results from March 28, 2019 to July 20, 2020 for patients with EOC and reviewed the number of surveys per patient in addition to the average symptom scores. **Results:** From March 2019 to July 2020, for patients with EOC, there were 2974 encounter-based surveys from 762 patients. The number of surveys completed by each patient ranged from 1-20. The following number of patients returned the correlating number of surveys: 1 survey:240 patients; 2 surveys:145; 3 surveys:79; 4 surveys:56; 5 surveys:58; 6 surveys:45; 7 surveys:38; 8 surveys:27; 9 surveys:22; ≥10 surveys:52. The average score from all surveys for each symptom was: 2.41 for sleep disturbance, 2.03 for pain, 2.32 for anxiety, 1.97 for emotional distress, 3.26 for fatigue, and 2.50 for physical dysfunction. Please see the table for the proportion of surveys that reported symptoms as mild, moderate, or severe. **Conclusions:** Fatigue and physical dysfunction were reported most frequently in patients with EOC, while emotional distress and pain were reported least frequently. 20% of surveys reported moderate to severe emotional distress, while 40% reported moderate to severe fatigue. A targeted approach to symptom management is needed for patients undergoing EOC evaluation and treatment. Our next steps in this analysis include an assessment of potential predictors of greater symptom burden (e.g., specific treatments, age, and other clinical and sociodemographic characteristics). Clinical trial information: NCT03892967. Research Sponsor: U.S. National Institutes of Health.

	Sleep Disturbance	Pain	Anxiety	Emotional Distress	Fatigue	Physical Dysfunction
Mild (0-3)	71.8%	77.9%	74.9%	79.6%	60.0%	69.4%
Moderate (4-6)	20.5%	16.3%	18.7%	15.5%	27.8%	22.7%
Severe (7-10)	7.7%	5.8%	6.4%	4.9%	12.2%	7.9%

Association of the Khorana Score with development of venous thromboembolism in ovarian cancer. *First Author: Ellen Marcus, Albert Einstein College of Medicine and Montefiore Medical Center Department of Obstetrics, Gynecology & Women's Health, Bronx, NY*

Background: The Khorana score is a previously validated method to identify patients at high risk of VTE during chemotherapy who would potentially benefit from thromboprophylaxis. The objectives of our study were to evaluate risk factors and timing associated with VTE in a large cohort of ovarian cancer patients and to assess the predictive ability of the Khorana score in this population. **Methods:** After IRB approval, a retrospective analysis was performed of all patients with ovarian cancer in the Albert Einstein Tumor Registry who received treatment between 2000 and 2020. Demographic, clinical, surgical and histologic data and information regarding timing of VTE were abstracted from the medical record. Khorana scores were retrospectively calculated for all patients who received chemotherapy based on their pre-chemotherapy laboratory indices. Bivariate analysis and multivariable logistic regression were used to examine the association between Khorana score and VTE. **Results:** A total of 472 patients were included over a median follow-up time of 33.7 (13.3, 61.1) months of whom 142 (31%) underwent diagnostic imaging to rule out VTE. A total of 62 patients (15%) were diagnosed with VTE with a median time from presentation to VTE of 8.7 (2.7, 30.3) months. Individual covariates which were significantly associated with VTE included stage III-IV disease, epithelial histology, open surgery, radical tumor debulking, and presence of residual disease after surgery. Of the 254 patients who received chemotherapy for their disease, 36 (14%) developed VTE within 3 weeks of receiving chemotherapy. Patients with Khorana scores of 2 (OR 1.73 95% CI 0.88-3.42) or 3 (OR 0.89 95% CI 0.33-2.44) were not significantly more likely to develop VTE during chemotherapy compared to patients with a score of 1. However, patients with a score of 4 were 6.74 times more likely to develop a VTE during chemotherapy (95% CI 1.39 - 32.73). Overall, a Khorana score of 2 or higher conferred no significant increased risk of developing VTE during chemotherapy than a score of 1 (OR 1.61 95% CI 0.85- 3.02). In a multivariable model, the Khorana score was not significantly associated with risk of VTE and a Khorana score of 2 or higher could explain only 0.86% of the variability in predicting VTE. The only variables significantly associated with VTE after adjustment were stage III-IV disease and hyperlipidemia. **Conclusions:** Patients with ovarian cancer are at high risk of developing VTE many months after diagnosis and initiation of chemotherapy. Current ASCO and SGO guidelines recommend thromboprophylaxis for those initiating chemotherapy with a Khorana score of 2 or higher, however our study found that these patients are not at increased risk compared to those with a score of 1. Future models should be developed and validated in large population-based cohorts to determine if there is a more accurate strategy to identify women with ovarian cancer who are at risk for VTE. Research Sponsor: None.

5556 **Poster Session**

Does aggressive surgery only benefit patients with less advanced ovarian cancer? *First Author: Shinichi Tate, Departments of Reproductive Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background: The recent SCORPION trial showed that aggressive primary debulking surgery (PDS) did not improve survival outcomes in patients with advanced ovarian cancer and was associated with a high incidence of perioperative morbidity. We compared survival outcomes and morbidity between patients who underwent highly aggressive and less aggressive surgery at our hospital; patients with high tumor loads were treated with neoadjuvant chemotherapy (NACT), followed by aggressive surgery. **Methods:** This retrospective study included 209 patients with a surgical complexity score (SCS) ≥8, who underwent aggressive surgery between January 2008 and December 2018. PDS, followed by chemotherapy was performed in this study, and NACT followed by interval debulking surgery (IDS) was performed in patients with excessively high tumor loads, a poor general condition, or unresectable lesions in whom PDS was contraindicated. Based on the median SCS, patients were categorized into highly aggressive surgery and less aggressive surgery groups, and we performed an intergroup comparison of progression-free survival (PFS), overall survival (OS), and perioperative morbidity. **Results:** The median SCS was 13 in all cohorts. The less aggressive surgery group (SCS $<$ 13) and the highly aggressive surgery group (SCS≥13) included 83 and 126 patients, respectively. The peritoneal cancer index in the highly aggressive surgery group was higher than that in the less aggressive surgery group (20 vs. 9). Notably, 52 patients (63%) underwent PDS in the less aggressive surgery group, and 104 patients (83%) underwent IDS after NACT in the highly aggressive surgery group. No intergroup difference was observed in patients without any residual disease (less aggressive surgery group: 74 patients [89%] vs. highly aggressive surgery group: 118 patients [94%], p = 0.245). The median PFS in the less- and highly aggressive surgery groups was 32 months (95% confidence interval [CI] 24–45) and 31 months (95% CI 27–34) (log-rank test, p = 0.622; Wilcoxon test, p = 0.926), respectively. The median OS in the less- and highly aggressive surgery groups was 99 months (95% CI 59–not reached) and 75 months (95% CI 56–106) (log-rank test, p = 0.390; Wilcoxon test, p = 0.799), respectively. Severe perioperative complications (Clavien-Dindo grade ≥IIIb) occurred in 4 patients (4.8%) and 8 patients (6.4%) in the less- and highly aggressive surgery groups, respectively (p = 0.767). **Conclusions:** Aggressive surgery benefits both patients with less advanced and advanced ovarian cancer. Selection of the optimal timing of debulking surgery may lead to better survival outcomes without an increase in perioperative morbidity in patients with high tumor loads, who undergo highly aggressive surgery. Research Sponsor: None.

Anlotinib in combination with TQB2450 in patients with recurrent ovarian cancer (ACTION): A multicenter, single-arm, open-label, phase Ib trial. *First Author: Chunyan Lan, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Combination of antiangiogenic therapy and immune checkpoint inhibitor therapy is reported as an effective antitumor strategy. TQB2450 is a humanized IgG1 monoclonal antibody against programmed death-ligand 1 (PD-L1). We aimed to assess the activity and safety of TQB2450 plus the antiangiogenic multi-target tyrosine kinase inhibitor anlotinib in patients with recurrent advanced ovarian cancer. **Methods:** The study with ClinicalTrials.gov identifier NCT04236362 is an open-label, multicohort, and multicenter phase Ib trial evaluating the efficacy and safety of anlotinib combined with TQB2450 in patients with advanced gynecologic cancer. The present study (ACTION study) reports the ovarian cancer cohort. We enrolled patients aged 18–70 years with platinum-resistant or platinum-refractory epithelial ovarian cancer, fallopian tube cancer, or primary peritoneal cancer, an Eastern Cooperative Oncology Group performance status of 0 or 1, and measurable disease according to the Response Evaluation Criteria in Solid Tumors (RECIST). Eligible patients received anlotinib 12 mg per day orally on days 1 to 14 and TQB2450 1200 mg intravenously on day 1, every three weeks. Treatment continued until disease progression, unacceptable toxicity, and withdrawal of consent. The primary endpoint was objective response rate (ORR) assessed by investigators according to RECIST version 1.1. Secondary endpoints included progression-free survival (PFS), duration of response (DOR), overall survival (OS) and safety. **Results:** Between 21 Feb 2020 and 15 Jan 2021, 33 patients with a median age of 55 years (range, 26-71) were enrolled and received study treatment. Patients had received at least once platinum-based chemotherapy, and the median number of previous chemotherapy lines was 3 (range, 1–6). 30.3% patients had bevacizumab therapy before enrollment. At data cutoff (15 Jan 2021), the median follow-up was 5.1 months (range, 0.1–10.8). In the 25 efficacy-evaluable patients, 13 of them achieved partial response, yielding the ORR of 52.0% (95% CI, 30.4%–71.6%). The median PFS was 6.7 months (95% CI, 4.5 months to not reached). The median duration of response and the median OS were not reached. The treatment-related grade 3 or 4 adverse events (AEs) occurred in 54.5% patients, and the most common ones were palmar-plantar erythrodysesthesia syndrome (21.2%) and hypertension (18.2%). The most potential immune-related AEs included grade 1 to 2 hypothyroidism (24.2%) and fatigue (9.1%). No treatment-related death was recorded. **Conclusions:** Anlotinib plus TQB2450 showed encouraging antitumor activity and tolerable toxicity in patients with recurrent advanced ovarian cancer. Clinical trial information: NCT04236362. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Improving the prediction of surgical outcome at secondary cytoreduction in patients with ovarian cancer: Results from retrospective part of HELP-ER study NOGGO TR2/ENGOT OV47-TR. *First Author: Ioana Braicu, North-Eastern German Society of Gynecological Oncology (NOGGO) and Department of Gynecology with Center for Oncological Surgery, Charité–University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: Complete resection at secondary cytoreductive surgery is associated with prolonged progression free and overall survival for patients with relapsed ovarian cancer. Secondary cytoreductive surgery has no impact on survival rates, if macroscopically tumor clearance cannot be achieved. Therefore, in order to avoid unnecessary perioperative morbidity and mortality, selection of patients who will undergo secondary tumor debulking is crucial. This study aims to improve upon the contemporary Arbeitsgemeinschaft Gynäkologische Onkologie (AGO) score by including additional clinical variables like circulating HE4 and CA125 levels to predict surgical outcome at secondary cytoreduction. **Methods:** A total of 90 patients underwent secondary cytoreductive surgery and were retrospectively assigned a positive AGO score. Of those patients, 62 (68.9%) achieved optimal surgical outcome at secondary debulking with 28 (31.1%) patients retaining residual tumor mass ($>$ 0mm). Utilizing clinical variables including circulating HE4 and CA125 levels, we implemented a machine learning workflow to predict suboptimal surgical outcome in patients despite a positive AGO score. **Results:** We elucidated significantly lower levels of circulating HE4 (p = 0.0038) in patients with optimal surgical outcome compared to patients that retain macroscopic residual tumor at secondary cytoreductive surgery. Moreover, machine learning algorithms trained on clinical variables (e.g. serum HE4 level, serum CA125 level, age, Risk of Ovarian Malignancy Algorithmus (ROMA) score and occurrence of peritoneal carcinomatosis) achieved a mean area under the curve (AUC) of 78.4% based on 100 consecutive executions with randomized training and test sets. **Conclusions:** The application of machine learning allows to further improve the prediction of patients with high likelihood of achieving optimal surgical outcome at secondary cytoreduction. In turn, it might identify patients that would benefit from amplified treatment efforts. However, machine learning relies on large amounts of data to account for biological and clinical variation and produce predictions of sufficient/adequate quality. Given this limitation, we would validate this data within the prospective multicentric cohort of patients collected within NOGGO/ENGOT HELP_ER Trial. Research Sponsor: Roche Diagnostics.

Real-life data of niraparib maintenance treatment in patients with recurrent platinum-sensitive ovarian cancer. *First Author: Bente Vilming, Oslo University Hospital, Oslo, Norway*

Background: PARP (poly adenosine diphosphate [ADP]–ribose polymerase) inhibitors are the new standard for maintenance treatment in platinum sensitive recurrent ovarian cancer (PSROC), independent of germline (g-BRCA) or somatic *BRCA* mutation status. Real-life data after the introduction of new anti-neoplastic agents are needed to evaluate whether the benefit observed in phase III trials can be translated into clinical practice. The aim of this study was to provide real-life data on efficacy and safety of niraparib in non-gBRCA PSROC. **Methods:** This retrospective multi-center cohort study included patients with PSROC who were enrolled in a national individual patient access program in Norway. Efficacy and safety data were collected from the patients´electronic medical records. The primary outcome was time from start of niraparib treatment to first subsequent treatment (TFST). Secondary endpoints included prevalence of dose interruption and -reduction, as well as adverse events. **Results:** The study included 106 patients with median age of 64 years (range 38-81). After median follow up of 15.3 months (95% CI 12.1-18.5), 71 patients (67%) had progressed, 64 (60%) had started a new line of treatment, and 25 (24%) had died. 25 (24%) patients were still receiving niraparib. Median duration of niraparib treatment was 7.6 months (0.4 to 27.3 months). Median TFST was 11.7 months (95% CI 9.2 -14.2). Patients with elevated CA125 after chemotherapy prior to start of niraparib had shorter progression-free survival (PFS) compared to patients with complete serological response (6.5 months (95% CI 5.7 – 7.3) vs 12 months (95% CI 6.2 – 17.9, ($p < 0.001$)). Grade 3-4 hematologic and non-hematologic events occurred in 25% and 17% of the patients, respectively. The most common grade 3/4 hematologic events were anemia (15%), thrombocytopenia (11%) and neutropenia (8%). Adverse events led to dose interruption in 38% and dose reduction in 44% of the patients. Patients with individualized dosing based on baseline weight and platelet counts had fewer dose reductions ($p < 0.001$) and -interruptions (p = 0.042) than patients whose dose was not adjusted to those baseline values. **Conclusions:** In a real-life setting, niraparib maintenance treatment in patients with non-gBRCA PSROC showed efficacy comparable with the published phase III data and an acceptable safety profile. Individualized dosing at start of treatment minimized adverse events. The prolonged PFS in patients with CA125 normalization after last chemotherapy, suggests that these patients in particular benefit from maintenance treatment but warrants confirmation in a larger sample. Research Sponsor: GSK.

Characteristics		(n, %)
gBRCA status	Non-mutated	96 (91%)
Previous lines of chemotherapy	2	73 (69%)
	≥3	33 (31%)
Response of chemotherapy preceding niraparib[2]	CR	14 (13%)
	PR	80 (75%)
	SD	7 (7%)
	Non-evaluable[3]	5 (5%)

Role of CD10 expression in endometriosis-associated mesenchymal stem cells on the progression of endometriosis-associated carcinoma. *First Author: Huda Atiya, University of Pittsburgh, Pittsburgh, PA*

Background: Endometriosis-associated carcinomas (EACs) such as ovarian clear cell cancer (OCCC) are rare, aggressive, chemo-resistant malignancies. While endometriosis is a known chronic inflammatory condition, the molecular mechanisms for the malignant transformation of endometriosis is unknown. Mesenchymal stem cells (MSC) are a critical component of the ovarian cancer microenvironment. Cancer cells reprogram MSCs to form carcinoma-associated MSCs (CAMSCs), which promote cancer growth, chemotherapy resistance, and metastases. MSCs are also found within the endometriotic microenvironment. CD10, a surface protein expressed by endometrial stromal cells, is also expressed on endometriosis-associated MSCs (enMSCs). Preliminary data demonstrate CD10 expression is lost in a subset of enMSCs and this loss is correlated with the acquisition of tumor-promoting properties. We hypothesized that the CD10 negative subset of enMSCs behave similarly to CAMSCs and support the growth of OCCC. **Methods:** EnMSCs were isolated from primary human benign endometriosis deposits involving the ovary or fallopian tubes. Flow cytometry was used to measure surface CD10 expression. We investigated the role of low CD10 enMSCs versus high CD10 enMSCs on OCCC tumor cell growth, chemotherapy resistance and stem-like cell properties in vitro and tumor cell engraftment, growth, and metastases in vivo. Luciferase-expressing OCCC cells were (1) used alone, (2) mixed with low CD10 enMSCs, or (3) mixed with high CD10 enMSCs and injected orthotopically into the ovarian bursa of NSG mice. In vivo imaging system was used to follow tumor progression and metastasis. **Results:** Our results demonstrated that enMSCs have variable CD10 expression. EnMSCs with low CD10 expression significantly enhanced OCCC proliferation, resistance to cisplatin, and sphere formation compared to OCCC alone. In contrast, high CD10 expressing enMSCs significantly reduce OCCC proliferation and sphere formation. Interestingly, low CD10 enMSCs selectively enhanced OCCC cell growth and had no effect on high grade serious ovarian cancer cell growth. Moreover, a reduction of CD10 expression was observed over time when high CD10 enMSCs were co-cultured with OCCC cells. Our results also showed enhanced tumor engraftment when OCCC cells were co-injected with low CD10 enMSCs to 100% one week post-injection, compared to 40% with OCCC and high CD10 enMSCs and 60% with OCCC alone. Further, mice co-injected with low CD10 enMSCs demonstrated increased metastasis and decreased survival compared to mice co-injected with high CD10 enMSCs. **Conclusions:** Our results indicate there is a sub population of enMSCs, marked by decreased CD10 expression, which selectively enhances OCCC growth. This highlights the existence of a tumor-promoting stromal cell within endometriosis which may be critical to the formation and propagation of EACs. Outcomes of ovarian cancer patients treated with platinum or non-platinum based chemotherapy after PARP inhibitor maintenance. *First Author: Ralynn Brann, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: PARP inhibitors (PARPi) are approved for maintenance treatment of platinum sensitive ovarian cancers either after front-line therapy or after treatment for recurrence. Current recommendations include retreatment with platinum-based chemotherapy (PC) after progression on maintenance PARPi. There exists a theoretical concern that progression of disease (POD) on PARPi is indicative of the development of platinum resistance due to similar DNA targets of platinum chemotherapy and PARPi. Our objective was to evaluate the response to subsequent chemotherapy in patients who progressed on PARPi maintenance. **Methods:** All patients with ovarian, fallopian tube, or primary peritoneal cancer treated with PARPi treatment from 2017 to 2021 at two academic tertiary care centers were retrospectively identified. Patients were assessed for treatment time on PARPi, time to POD on PARPi (PFS), type of chemotherapy regimen following PARPi maintenance, and time to disease progression on subsequent therapy following PARPi (PFS2). Comparative statistical analyses were performed with appropriate two-sided statistical tests. Time to progression on chemotherapy after PARPi was calculated using the Kaplan-Meier method. **Results:** A total of 83 ovarian cancer patients treated with PARPi were identified, and of these, 61 (73.5%) were treated with PARPi in the maintenance setting. Among the patients treated with PARPi maintenance, 22 (36.1%) remain on treatment. 19 (31.1%) patients were started on PARPi maintenance after front-line chemotherapy. While on PARPi maintenance, 63.9% discontinued PARPi, the majority due to POD, and 26.2% due to patient intolerance of side effects. Following POD, 21/29 (72.4%) received subsequent PC and 8/29 (27.6%) received non-platinum based chemotherapy (NPC). Treatment time, PFS, and PFS2 are listed in Table. Of the patients who received PC, 14/21 (66.7%) had a PFS2 of over six months and 5/21 (23.8%) had a PFS2 of over 12 months. Of the patients who received NPC, 7/8 (87.5%) had a PFS2 of over six months and 2/8 (25.0%) had a PFS2 of over 12 months. **Conclusions:** Following POD on PARPi, patients responded to both PC and NPC. Time to progression on subsequent chemotherapy after treatment with PARPi does not differ significantly between PC and NPC regimens. Many patients continue to see benefit from PC after PARPi maintenance. Retreatment with PC following POD on PARPi maintenance should still be considered. Research Sponsor: None.

Time outcome (months)	PC after POD on PARPi maintenance	NPC after POD on PARPi maintenance
Median treatment time	9.0 (1.0-31.0)	5.5 (1.0-8.0)
Median PFS	14.4 (1.0-60.0)	5.5 (1.0-8.0)
Median PFS2	7.0 (0.0-23.0)	8.5 (2.0-40.0)

Patient care and clinical trials in gynecological oncology: Implications of the COVID-19 pandemic. *First Author: Sara Nasser, North-Eastern German Society of Gynecological Oncology (NOGGO) and Department of Gynecology with Center for Oncological Surgery, Charité–University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: This is a prospective international Survey to evaluate the impact of the COVID-19 Pandemic on the management of patients with gynecological malignancies from the multidisciplinary physicians' perspective, with particular focus on clincial infrastructures, and trial participation. **Methods:** The anonymous online survey consisted of 53 COVID-related questions. It was sent to all healthcare professionals in gynaecological oncology centres across Europe and the Pan-Arabian region from April 2020 to October 2020. All healthcare professionals treating women with gynecological cancers were able to participate in the survey. **Results:** A total of 243 answers were collected from 30 different countries. The majority (73%) of participants were gynecological oncologists from university hospitals(71%) with at least an Intensive care unit with cardiopulmonary support available at their institutions. Most institutions continued to perform elective surgeries only for oncological cases (98%). Patients had to wait on average 2 weeks longer for their surgery appointments compared to previous years(range 0-12 weeks). Cases that were prioritised for surgical intervention across all tumors (Ovarian, Endometrium, Cervical) were early stage disease (74%), primary situation (61%), and good ECOG status (63%). The radicality of surgery did not change in the majority of cases (78%) across all tumor types. During the pandemic, only 38% of clinicians stated they would start a new clinical trial. 45% stated the pandemic has negatively impacted the financial structure and support for clinical trials. 79% do not routinely screen patients included in trials for SARS CoV2. Overall, approx. 20% of clinicians did not feel well informed regarding clinical pathways for COVID-19 patients throughout the pandemic. The majority preferred regular updates and training via Webinars (75%), followed by tumorboards and interdisciplinary conferences (45%). 30% of clinicians stated that they are currently experiencing difficulties in providing adequate medical care due to staff shortage. **Conclusions:** Despite well-established guidelines for patient care and performing clinical trials in gynecological oncology, the COVID-19 pandemic has impacted clinical research, and financial structures. Longer waiting times for operative interventions, less support for clinical trials and concerns regarding provision of adequate medical care and triaging patients are very real. This survey underlines the necessity for building robust emergency algorithms tailored to gynecological oncology patients in the future. Research Sponsor: None.

Selinexor in combination with weekly paclitaxel in patients with advanced or metastatic solid tumors: Results of an open label, single-center, multiarm phase 1b study. *First Author: Shannon Neville Westin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Selinexor is a first-in-class novel, oral potent selective inhibitor of nuclear export (SINE) which blocks Exportin-1 (XPO1) leading to nuclear accumulation and activation of tumor suppressor proteins and prevention of translation of proto-oncogenes. Weekly paclitaxel is a standard chemotherapy regimen used in various tumor types. Preclinical models show that selinexor with paclitaxel exerts antitumor activity against multiple solid tumors. Our objective was to determine the maximum tolerated dose (MTD) and recommended phase II dose (RP2D) of selinexor and weekly paclitaxel. **Methods:** This was an open label, single-center, multi-arm phase 1b study utilizing a "3 + 3" design and a "basket type" expansion. Selinexor (twice weekly orally) and weekly paclitaxel (80mg IV 2 week on, 1 week off) was employed as one of 13 parallel arms. Two dose levels (DL) of selinexor were explored: DL1 selinexor 60mg; DL2 selinexor 80mg. Patients (pts) with advanced or metastatic solid tumors were eligible if they had adequate bone marrow and organ function. There was no limit on prior lines of therapy. Efficacy was evaluated using RECIST 1.1. Progression free survival (PFS) was defined as time from treatment until disease progression or death. **Results:** Of 35 pts treated, all were evaluable for toxicity, and 31 (88%) were evaluable for response. Pt diagnoses included ovarian (n = 28), breast (n = 4), prostate (n = 2), and cervical (n = 1) cancer. Pts had a median of four prior therapies (range 1-10), and 47% had a prior taxane. All pts with ovarian cancer had platinum resistant/refractory disease; high grade serous histology was most common. There were no DLTs and DL1 was chosen as the RP2D given its long term tolerability. 97% of pts had at least one treatment-emergent adverse event (TEAE) and the most common TEAEs were anemia (74%), nausea (57%), fatigue (51%), leukopenia (51%), neutropenia (49%), thrombocytopenia (46%), and vomiting (31%). The most prevalent grade $\geq$ 3 TEAE were neutropenia (46%), anemia (31%), leukopenia (17%), and fatigue (9 %). Partial responses (PR) were noted in 4 pts (13%); 10 pts (32%) achieved stable disease for $>$ 4 months for a clinical benefit rate (CBR) of 45%. 16 pts (47%) had prior exposure to a taxane, including 1 pt who achieved PR. Among 24 evaluable pts with ovarian cancer, response rate was 17%, CBR was 58%, and PFS was 6.83 months (95% CI 3.73, not reached (NR)). Median duration of clinical benefit in ovarian cancer was 7.57 months (95% CI: 4.43, NR). **Conclusions:** Oral selinexor in combination with weekly paclitaxel demonstrated promising clinical activity with manageable toxicity, and further evaluation with once weekly selinexor is warranted. This combination should be considered for further exploration in a randomized study, especially in ovarian malignancies. Clinical trial information: NCT02419495. Research Sponsor: Karyopharm, U.S. National Institutes of Health.

Phase 1b study of GAS6/AXL inhibitor (AVB-500) in recurrent, platinum-resistant ovarian carcinoma. *First Author: Katherine Cynthia Fuh, Washington University in St. Louis, St. Louis, MO*

Background: AVB-500 is a first-in-class Fc fusion protein that binds the GAS6 ligand thereby inhibiting AXL signaling. Both GAS6 and AXL are highly expressed in high-grade serous ovarian cancer (HSGOC). This study evaluated safety, tolerability, and preliminary efficacy of AVB-500 in combination with pegylated liposomal doxorubicin (PLD) and paclitaxel (Pac) and determine the recommended Phase 2 dose (RP2D). **Methods:** Patients were enrolled in escalating dose cohorts of AVB-500 10mg/kg to 20mg/kg q2 weeks in combination with weekly Pac 80mg/m^2 D1, 8, 15 q28 days or PLD 40mg/m^2 D1 q28 days and assess for safety, pharmacokinetics, pharmacodynamics, and response by investigator, via RECIST v1.1. **Results:** A total of 53 patients with platinum-resistant HGSOC (PROC) were enrolled. A total of 23 patients received Pac + AVB-500 and 30 patients received PLD + AVB-500. Grade 3 or 4 treatment-related adverse events were observed in 4/23 (17%) and 2/30 (7%) PAC and PLD, respectively. No patients discontinued therapy due to an adverse event. Most events were related to known chemotherapy side effects. RP2D was identified as 15mg/kg. Confirmed overall response rate (ORR) with Pac+AVB-500 was 35% (8/23) including 2 CRs and 11% (3/28) in the PLD+AVB-500 subgroup. ORR was 19% (3/16) in patients with platinum free interval (PFI) of $<$ 3 months versus (vs) 23% (8/35) in patients with PFI of 3-6 months. ORR was 11% (2/18) in patients with 1 prior treatment vs 27% (9/33) in patients with 2-3 prior lines of therapy. ORR in patients without prior bevacizumab was 33% (9/27) vs 8% (2/24) in those with prior bevacizumab. Patients treated with Pac combination and whose AVB-500 trough levels were above the minimal efficacious concentration (MEC) of 13.8mg/L achieved the greatest benefit with ORR, median PFS, and median OS of 43% (6/14), 3.9 months, and 17.8 months vs 22% (2/9), 2.8 months, and 8.7 months observed in those whose trough was below the MEC. Among the Pac treated subgroup, the ORR was 47% (13% CR) vs 0% for those with sAXL/GAS6 ratios $>$ 0.773 compared to ratios $<$0.773. 67% of patients had baseline sAXL/GAS6 $>$ 0.773. **Conclusions:** AVB-500 is a novel Fc fusion protein that binds the GAS6 ligand and inhibits AXL signaling. AVB-500 was well-tolerated in combination with Pac or PLD. This Ph1b trial suggested a higher ORR in the Pac treated subgroup, with C1D15 trough levels $>$ 13.8mg/L (most consistently achieved at the 15mg/kg dose level). Exploratory analyses suggested that improved ORR may be observed in patients who have not been exposed to bevacizumab. The serum sAXL/GAS6 ratio may be a potential biomarker of pathway activation and identify patients who most benefit from Pac+AVB-500. The ORR in patients with PFI $<$ 3 months or who had $>$ 1 line of prior therapy were similar to those with 3-6 months PFI or $\leq$1 lines of therapy. Further development of AVB-500 15 mg/kg q2 weeks in combination with Pac is warranted in PROC. Clinical trial information: NCT03639246. Research Sponsor: Aravive, Inc.

Assessment of predictive biomarker prevalence in molecularly defined adult-type ovarian granulosa cell tumors. *First Author: Robert Tyler Hillman, MD Anderson Cancer Center, Houston, TX*

Background: The FDA has separately approved pembrolizumab for all advanced solid tumors with either microsatellite instability or high tumor mutational burden ($\geq$10 mutations per megabase), and homologous recombination deficiency is an established biomarker for response to poly ADP ribose polymerase inhibitors in epithelial ovarian cancer. The detection of these predictive biomarkers in adult-type ovarian granulosa cell tumors could identify novel treatment strategies in this rare disease. The primary objective of this study was to determine the prevalence of established predictive biomarkers among molecularly defined adult-type ovarian granulosa cell tumors. **Methods:** With institutional review board approval, we performed a cross-sectional study examining de-identified FoundationOne companion diagnostic molecular profiles for 423 women with molecularly defined (FOXL2 c.C402G positive) adult type ovarian granulosa cell tumors. The dataset was comprised of coding variants for up to 406 genes as well as genomic signatures including microsatellite instability, tumor mutational burden, and genome wide loss of heterozygosity. PD-L1 expression by immunohistochemistry was also available for a subset of tumors. Descriptive statistics were used for comparison between groups and all statistical tests were two-sided. **Results:** Women in this cohort had a mean age of 57 years (range 24-87) at the time of sample submission for molecular profiling. The median tumor mutational burden was 1.3 mutations per megabase [mut/Mb] (range 0-8.8 mut/Mb). TP53-mutated aGCT had a higher tumor mutation burden than TP53 non-mutated tumors (median 2.4 mut/Mb, 95% CI 1.7-3.0 mut/Mb vs median 1.3 mut/Mb, 95% CI 1.5-1.9 mut/Mb; P=.02). All 384 tumors with available microsatellite instability testing were microsatellite stable. Sixty-seven tumors had PD-L1 expression measured and of these 94% (63/67) were negative with the remainder "low positive." No tumors were positive for genome wide loss of heterozygosity. Apart from FOXL2 c.C402G, the most frequent short variants were TERT promoter mutations (-124C$>$T: 190/423, 45.0%; -146C$>$T: 39/423, 9.2%). Other frequently observed variants included truncating mutations in KMT2D/MLL2 (71/423, 16.8%), pathogenic TP53 mutations (35/423, 8.3%), CDKN2A/B deletions (43/423, 10.2%), and activating PIK3CA mutations (23/423, 5.4%). **Conclusions:** No women with molecularly defined adult-type ovarian granulosa cell tumors in this large cross-sectional study would be eligible for FDA-approved pembrolizumab based on either microsatellite instability or high tumor mutational burden. No tumors exhibited evidence of homologous recombination deficiency and molecularly targetable mutations were rare. The development of novel precision treatment options remains a critical unmet need for this rare disease. Research Sponsor: Cancer Prevention and Research Institute of Texas (CPRIT).

Correlation of HRD status with clinical and survival outcomes in patients with advanced-stage ovarian cancer. *First Author: Travis T. Sims, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Nearly 50% of patients with high grade ovarian cancer (HGOC) harbor a germline or somatic mutation in BRCA1/BRCA2 or have tumors characterized by homologous recombination deficiency (HRD). HRD is associated with response to poly(ADP-ribose) polymerase inhibitors (PARPi) in HGOC. Although PARPi show great promise, there is interest in investigating how HRD status affects outcomes and can be used to objectively tailor other treatment strategies. We aimed to compare clinical and survival outcomes in HGOC stratified by HRD status. **Methods:** We performed a retrospective analysis of all advanced HGOC from April 2013 to June 2019. Patients were included if germline BRCA and HRD status was known. Clinical outcomes were analyzed and stratified by (1) germline BRCA+ (2) germline BRCA - and somatic BRCA/HRD+, or (3) BRCA-/HRD-. Progression free (PFS) and overall survival (OS) were estimated using Kaplan-Meier methods stratified by HRD status and modeled via Cox proportional hazards regression. **Results:** 1271 patients with advanced HGOC presented during the study period of which 187 met inclusion criteria. 106 patients had germline BRCA mutation, 26 somatic BRCA/HRD+, and 55 BRCA/HRD-. Patients who had HRD- tumor had older median age at diagnosis (63 vs. 54 and 60 years, p$<$0.001), white race (89% vs. 74% and 68%), non-serous histology (20% vs. 6% and 0%, p=0.04), required more NACT chemotherapy cycles (4 vs. 3 and 3 cycles, p=0.03), and less complete gross resection (R0) at tumor reductive surgery (TRS) (60% vs. 83% and 77%, p=0.02). Patients who had BRCA/HRD- tumor had worse PFS (14.9 months) compared to germline BRCA+ (23.5 months) or somatic BRCA/HRD+ (20.2 months, p$<$0.001). Patients with BRCA/HRD- disease also had worse OS (42.3 months) compared to germline BRCA+ (68.8 months) or somatic BRCA/HRD+ (69.2 months). Multivariate analysis for PFS revealed that age (HR 1.02, 95% CI 1.00-1.04), p=0.01), stage (HR 5.7, 95% CI 1.39-23.4, p=0.02), R0 resection at TRS (HR 0.41, 95% CI 0.21-0.83, p=0.01), and BRCA/HRD-status (HR 1.63, 95% CI 1.07-2.48, p=0.02) were significant factors impacting PFS. Multivariate analysis for OS revealed that age (HR 1.07, 95% CI 1.03-1.10, p$<$0.001) and R0 resection at TRS (HR 0.19, 95% CI 0.08-0.44, p$<$0.001) were significant factors impacting OS. **Conclusions:** Germline BRCA-mutant, somatic BRCA/HRD+ HGOC was associated with improved PFS and OS regardless of primary TRS or NACT. BRCA-/HRD- was a negative prognostic factor for survival in HGOC. Research Sponsor: MD Anderson Cancer Moonshot, U.S. National Institutes of Health.

5569 **Poster Session**

Final results of phase 1 evaluation of the safety and clinical activity of sapanisertib in combination with serabelisib and paclitaxel in patients with advanced ovarian, endometrial, or breast cancer. *First Author: David Starks, Avera Cancer Institute, Sioux Falls, SD*

Background: Evidence suggests that activation of the PI3K/AKT/mTOR pathway by paclitaxel may play a role in the development of taxane resistance. Conversely, PI3K inhibitors have been shown to sensitize tumors to the effects of paclitaxel. Therefore, the link between taxane resistance and activation of the PI3K/AKT/mTOR signaling pathway suggests inhibition of this pathway in combination with antimitotic drugs like paclitaxel may improve treatment outcomes in many malignancies. To further investigate this hypothesis we combined the TORC 1/2 inhibitor sapanisertib (TAK-228), the PI3Kα isoform inhibitor serabelisib (TAK-117), and paclitaxel in a phase I trial of heavily pretreated patients to determine the safety, efficacy, and RP2D. **Methods:** This is an open label, cohort study of sapanisertib (TAK-228) and serabelisib (TAK-117) given on days 2-4, 9-11, 16-18, and 23-25 with paclitaxel on days 1, 8, and 15 of a 28-day cycle. A traditional 3+3 dose escalation design with a maximum of 5 dosing cohorts was used. All 5 cohorts plus an expansion cohort are presented. **Results:** Enrollment has been completed and the overall results are summarized. Nineteen patients were enrolled; the majority were heavily pretreated with the average number of prior regimens exceeding 4. Based upon ITT, the ORR is 37%. The ORR is 47% in patients that completed at least 3 cycles. The clinical benefit rate is 73% and the PFS currently stands at approximately 11 months. Two patients with endometrioid endometrial adenocarcinoma achieved a complete response. All patients received comprehensive genomic profiling and 7 patients received prior mTOR inhibitor. Overall, the combination was well tolerated, except by patients in cohort 5. One DLT occurred in the last patient enrolled. The most common non-laboratory AEs were nausea (6%), fatigue (5%), and mucositis (5%). There were 45 (9%) grade 3 or 4 events, and the most common were decreased WBC and non-febrile neutropenia. Hyperglycemia was common in patients with a history of diabetes mellitus. **Conclusions:** Overall, the combination of sapanisertib, serabelisib, and paclitaxel was safe and efficacious throughout the first 4 cohorts. There were few serious adverse events, and most side effects were managed with routine supportive care interventions. Preliminary clinical results appear very promising, especially for patients with PI3K/AKT/mTOR pathway mutations. The positive effects of the combination were routinely seen in the lowest dosing cohorts and clinical benefit was even seen in patients that had previously failed everolimus or temsirolimus. All patients were either resistant or refractory to paclitaxel at time of enrollment, so further exploration of this combination to elucidate the mechanism of benefit is warranted. Clinical trial information: NCT03154294. Research Sponsor: Takeda.

5570 **Poster Session**

Health-related quality of life (HRQoL) in advanced endometrial cancer (aEC) patients (pts) treated with lenvatinib plus pembrolizumab or treatment of physician's choice (TPC). *First Author: Domenica Lorusso, Gynecologic Oncology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS and Scientific Directorate, Rome, Italy*

Background: In Study 309/KEYNOTE-775, lenvatinib + pembrolizumab (L+P) demonstrated significant and clinically meaningful improvement in OS, PFS, and ORR compared with TPC in aEC pts following prior platinum-based systemic therapy. Given the medical complexity/age of EC pts, QoL analyses are critical, but often under-reported. We present results of pt-reported HRQoL for Study 309/KEYNOTE-775. **Methods:** Pts were randomized 1:1 to receive lenvatinib 20 mg QD PO + pembrolizumab 200 mg IV Q3W (n=411) or TPC (n=416; doxorubicin 60 mg/m^2 IV Q3W or paclitaxel 80 mg/m^2 IV QW, 3 wks on/1 wk off). Pt-reported HRQoL was assessed at cycle 1 day 1, day 1 of each subsequent cycle and at time of discontinuation using EORTC QLQ-C30, its EC module QLQ-EN24, and EQ-5D-5L in treated pts who had ≥1 HRQoL assessment available. Higher scores indicate better functioning/QoL (EORTC QLQ-C30, EQ-5D-5L) or worse symptom severity (QLQ-EN24). Changes in EORTC QLQ-C30 global health status (GHS)/QoL was a secondary endpoint. This was analyzed from baseline to the latest timepoint at which overall completion was ≥60% and overall compliance was ≥80%, using constrained longitudinal data analysis; other HRQoL analyses were exploratory. **Results:** Completion and compliance rates of EORTC QLQ-C30 were >95% in both groups at baseline. Primary analysis was conducted at wk 12 as completion rate was 80% for L+P and 62% for TPC; compliance rate was 93% for L+P and 87% for TPC. Baseline GHS/QoL scores were similar between the L+P group and TPC group: mean (SD) of 65.74 (21.87) vs 65.69 (22.71), respectively. Over 12 wks of follow-up, pts in both groups had slight decreases in GHS/QoL. Similar decreases were observed for pts receiving L+P vs TPC: -5.97 (95% CI: -8.36, -3.58) vs -6.98 (95% CI: -9.63, -4.33). The between-group difference in least-squares (LS) mean score change from baseline to wk 12 for L+P vs TPC was 1.01 points (95% CI: -2.28, 4.31). Over time, QoL scores were generally similar across treatments. Results were similar for other HRQoL endpoints (Table). **Conclusions:** No significant differences were observed in HRQoL scores between treatment groups. With no standard treatment approach following failure of platinum-based therapy, these data along with previously reported efficacy and safety findings from Study 309/KEYNOTE-775 further support that L+P has an overall favorable benefit/risk profile compared to chemotherapy. Clinical trial information: NCT03517449. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Race-related disparities in patterns of uterine cancer recurrence. *First Author: Camilla Dagum, Montefiore Med Ctr-Albert Einstein College of Medcn, Bronx, NY*

Background: Racial disparities in uterine cancer outcomes are present, as Black patients with uterine cancer have markedly higher mortality when compared with White patients. Potential etiologies of this discrepancy have been investigated, including implicit bias, histopathologic factors and stage at presentation, molecular and genetic factors, and socioeconomic factors. The purpose of this study is to explore if non-White patients with uterine cancer are more likely to experience distant cancer recurrence compared to White patients. **Methods:** A single-institution retrospective cohort study was performed examining all patients diagnosed with uterine cancer from 2006-2016. Data regarding patient demographics, medical co-morbidities, histology, stage, treatment course, and disease recurrence were abstracted from the medical record. Race was categorized based on how a patient was registered in the medical record. The primary outcome was location of recurrence, with local recurrence defined as vaginal/cuff recurrence and distant recurrence representing nodal, intraperitoneal, or distant recurrence. A multivariable regression model was built in a backwards stepwise fashion to examine the association of individual covariates with distant recurrence as opposed to vaginal recurrence. **Results:** A total of 1205 patients with uterine cancer were included for analysis. Three hundred eighteen (26.5%) patients were White, 472 (39.2%) Black, 319 (26.5%) Hispanic, 91 (7.6%) Asian, and 4 (0.3%) other. A total of 223 (18.5%) patients experienced disease recurrence. Black women experienced a statistically significant increased risk of recurrence compared with non-Black women [OR 1.99 (95% CI 1.37-2.88), $p < 0.01$]. Additionally, Black patients were significantly more likely to experience nodal, intra-peritoneal and distant recurrences relative to White patients ($p < 0.01$). When adjusting for covariates including race, histology, grade, stage and adjuvant treatment, non-White race [OR 3.87 (95% CI (1.42-10.54), $p < 0.01$] was associated with significant increase in risk of distal recurrence. **Conclusions:** The findings of this study suggest that non-White race is potentially contributory to distant recurrence of uterine cancer, even when accounting for histopathologic differences, stage at presentation, and other traditional covariates. These findings suggest that the disparate outcomes experienced by non-White patients are likely multi-factorial in nature and highlight the need for efforts focused on optimizing treatment and improving outcomes of non-White women with uterine cancer. Phase II trial assessing niraparib with or without dostarlimab (anti-PD-1) in recurrent endometrial carcinoma. *First Author: Ainhoa Madariaga, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Treatment options in recurrent endometrial carcinoma (EC) are limited. Endometrioid EC shows alterations in PTEN, a possible biomarker of response to PARP inhibitors (PARPi). Similarly, homologous recombination deficiency (HRd), a biomarker of response to PARPi in ovarian cancer, is associated with serous EC harbouring *TP53* mutations. Preclinical EC models have shown synergy between combining a PARPi and immune checkpoint inhibitor (ICI). **Methods:** A pilot multi-centre, non-randomized, phase II trial enrolled patients (pts) with recurrent serous or endometrioid EC in two consecutive cohorts (NCT03016338). In the first cohort (C1) pts received niraparib 200 or 300 mg qd, based on baseline body weight and platelet count, in 4 week (w) cycles. In the second cohort (C2) niraparib was given with dostarlimab 500 mg q 3 w for 4 cycles, followed by 1000 mg q 6 w thereafter. There was no limit on prior lines of therapy. Prior ICI was not allowed in C2. Primary endpoint was clinical benefit rate (CBR; complete, partial response or stable disease ≥16w). Secondary endpoints included toxicity assessment and ORR. CT scans were performed q 8 w. Potential biomarkers were assessed in archival tissue by IHC (PTEN, p53, MMR, PDL-1 [threshold 1%]) and a NGS panel (including *TP53*, *PTEN*, *POLE* and other HRd genes). Tumour mutational burden-high (TMBh) was defined as top 20% mutation load. **Results:** In C1, 25 pts were enrolled (23 evaluable for response). Median age was 69 years old, 64% had serous EC, 72% were platinum resistant (PlatR) and median prior therapies was 2 (range 1-4). Median number of cycles was 3. The CBR was 20% (95% CI: 9-39) and median clinical benefit (CB) duration was 5.3 (1.8-7.2) months. The ORR was 1/23 (4%; 0-20). Related grade (g) ≥3 AEs ≥10% were anemia (24%), fatigue (16%) and thrombocytopenia (16%). In C2, 22 pts were enrolled (all evaluable) and two continue on-treatment. Median age was 64 years old, 46% had serous EC, 68% were PlatR and median prior therapies was 2 (1-6). Three pts had MMR deficient (MMRd) tumors (14%) and one pt a *POLE* mutation (5%). Median number of cycles was 3. The CBR was 31.8% (16-53) and median CB duration was 6.8 months (3.7-9.5). The ORR was 3/22 (14%; 3-35), out of the three responders one had MMRd and one a *POLE* mutation. Related g≥3 AEs ≥10% were anemia (27%) and neutropenia (14%). No significant correlation was detected between CB and IHC markers (PTEN, p53, MMR, PDL-1), or NGS (*PTEN*, *TP53*, HRd TMBh) in C1 and C2. **Conclusions:** Niraparib as single agent for treatment in a PlatR enriched recurrent EC population showed modest activity with clinical benefit rate at 16w of 20%. The combination of niraparib and dostarlimab showed a clinical benefit rate at 16w of 31.8% in a predominantly PlatR recurrent EC. PTEN loss by IHC or NGS, and alterations in HRd genes did not correlate with clinical benefit. Clinical trial information: NCT03016338. Evaluating the role of aromatase inhibitors (AIs) in the treatment of endometrial stromal sarcomas (ESS). *First Author: Fionnuala Crowley, Mount Sinai Morningside and West, New York, NY*

Background: Endometrial stromal sarcomas (ESS) account for < 20% of uterine sarcomas. They usually express estrogen and progesterone receptors (ER/PR) and are considered hormone sensitive. Due to the rarity of these tumors, large clinical trials studying optimal treatment have not been possible. This study represents the largest retrospective study of ESS treated with AI. **Methods:** The clinicopathological variables and outcomes of patients (pts) with pathologically confirmed low grade ESS treated with AI at our institution between 1998-2020 were recorded. **Results:** 48 pts with ESS treated with AI were identified. They had a median age of 54 years (range 23-84) and BMI of 27 (range 20-50). 79% were white. 6 (12%), 9 (19%), 14 (29%) and 19 pts (40%) had stage 1,2,3,4 ESS, respectively. 37 (77%) were ER+/PR+; 2 (4%) ER+/PR- and 9 pts (19%) had unknown ER/PR status. All pts were postmenopausal at AI initiation. 12 pts (25%) had a synchronous cancer (5 of these had breast cancer {3 of the 5 presented post tamoxifen}). 23 pts (48%) received megestrol acetate and 25 (52%) an AI as first line hormonal manipulation. During their disease course, 35 pts (73%) received letrozole, 21 (44%) anastrozole and 19 (39.6%) exemestane. 22 pts (46%) were treated with more than one AI. 28 pts (58%) reported side-effects; arthralgia (33%) being the most common. 10 pts (21%) discontinued AI due to toxicity; 12 pts (25%) switched AI for toxicity (with improved tolerance in 67% of these pts). Among the 24 pts (50%) with measurable disease there were 2 partial responses (objective response rate of 8.3%). 1-year disease control rate (DCR) was (79%) for all pts and 58% in stage 4 disease. Median PFS for 1st line AI was 161.6 months (95% CI 48.5 to 274.7). **Conclusions:** This study represents the largest study of AI use in ESS to date. We found the ORR to be more modest than previously reported. The majority of pts had prolonged stable disease with a DCR of 58% even in stage 4 disease. Pts who progress on one AI may benefit from trial of a 2nd AI. A phase 2 study of interruption versus maintenance AI in locally advanced/metastatic ESS is currently underway (NCT03624244). Research Sponsor: U.S. National Institutes of Health.

Open-label, multicenter, phase 1b/2 study of rebastinib in combination with paclitaxel to assess safety and efficacy in patients with advanced or metastatic endometrial cancer. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Rebastinib is a first-in-class investigational, orally administered, potent and selective switch-control kinase inhibitor of tunica interna endothelial cell kinase (TIE2). This is a 2-part open-label, multicenter Phase 1b/2 study of rebastinib in combination with paclitaxel. Here we provide updated results (ASCO 2020) from the fully enrolled endometrial cancer (EC) cohort of the study. **Methods:** Part 2 of the study has five disease-specific cohorts (EC, platinum-resistant ovarian cancer, gynecological carcinosarcoma, TNBC and inflammatory breast cancer). Patients were treated at the RP2D and evaluated for efficacy (RECIST v1.1) and safety (CTCAE v5.0). **Results:** As of Jan 8, 2021, 38 EC patients were enrolled (median age of 66 years); 42% were of grade 2/3 endometroid histological subtype. All patients received at least 1 prior line of paclitaxel in combination with carboplatin and 79% of patients received ≥3 prior anti-cancer regimens. Sixteen of 38 patients were initially treated with a starting dose of rebastinib 100 mg BID, 11 of which dose reduced to 50 mg BID, and 22 patients were treated with a starting dose of rebastinib 50 mg BID, in combination with paclitaxel 80 mg/m^2 IV weekly (days 1, 8, 15 of 28-day cycle). In 33 evaluable patients with median follow-up of 5.9 months, the ORR was 33% and clinical benefit rate at 8 and 16 weeks was 70% and 55%, respectively, including 11 PRs (8 confirmed) and 12 SDs. Treatment-emergent adverse events (> 20% of patients; mostly ≤ grade 2) included fatigue (n = 18), constipation, peripheral edema (each at n = 16), peripheral sensory neuropathy, nausea (each at n = 15), dyspnea (n = 13), alopecia, hypokalemia (each at n = 11), diarrhea, hypomagnesemia (each at n = 10), dry mouth, dysgeusia (each at n = 9), arthralgia, hypertension, dehydration, GERD and muscular weakness (each at n = 8). Serious adverse events (SAE) at least possibly related to rebastinib included muscular weakness (n = 2 at 100 mg BID, n = 1 at 50 mg BID), nausea (n = 2), acute myocardial infarction, atrial flutter, dehydration, non-infective encephalitis, peritonsillitis, and stress cardiomyopathy (each at n = 1) and were resolved after dose interruption. **Conclusions:** The updated results of rebastinib at 50 mg BID in combination with paclitaxel showed encouraging preliminary anti-tumor activity and an acceptable safety profile in heavily pretreated EC patients, and supports further development in patients with EC (NCT03601897). Clinical trial information: NCT03601897. Research Sponsor: Deciphera Pharmaceuticals, LLC.

High prevalence of actionable germline variants in unselected endometrial cancer (EC) patients. *First Author: Monica Levine, The Ohio State University Wexner Medical Center and James Cancer Hospital, Columbus, OH*

Background: The use of upfront germline genetic testing for cancer patients to identify hereditary syndromes and to aid in treatment decision making has increased dramatically. Recent evidence suggests that such testing should be considered for all solid tumors. In EC, mismatch repair deficiency (MMRd) has emerged as an important molecular marker for treatment with checkpoint inhibitors. MMRd is the hallmark of Lynch syndrome (LS), the most common hereditary cause of EC. Therefore, identifying LS not only affords opportunities for cancer prevention but also for making treatment decisions for women who already have EC. Although tumor-based screening is highly effective, some LS diagnoses will be missed. Upfront multi-gene panel testing (MGPT) for EC has been evaluated as an alternative approach to identifying LS with the potential to simultaneously find actionable germline variants in other cancer susceptibility genes (CSGs). Our objective was to determine the frequency and types of actionable germline variants in a large, unselected group of women with EC. **Methods:** Prospective germline MGPT for 47 CSGs was performed for 961 unselected EC cases. Patients diagnosed from 2017-2020 were enrolled at nine different institutions. Clinicopathologic data were abstracted from patients' records. **Results:** 101 likely pathogenic (LP) or pathogenic variants (PV) were identified in 98 women (10.2%). LP/PVs in LS genes were most common: 29 LS cases were identified (3.02%, 95% CI 2.1 - 4.3%). MGPT found 9 cases (one-third of LS cases) that were not identified by tumor screening: 6 were from institutions that do not perform tumor screening and 3 had normal immunohistochemistry. There were 72 LP/PVs found in 17 different CSGs. 21 patients (2.1%) had LP/PVs in high penetrance CSGs other than the LS genes, 19 of which were in genes associated with breast and/or ovarian cancer (4 in *BRCA1*, 6 in *BRCA2*, 6 in *BRIP1*, 2 in *PALB2*, 1 in *RAD51C*). *BRCA1/2* PVs (1.04% of the study population, 95% CI 0.6 - 1.9%) were significantly more frequent in women with type II cancers than the rest of the cohort (P = .005, HR 2.00, 95% CI 1.16 - 4.75). 21 additional LP/PVs were found in moderate risk CSGs (*ATM, CHEK2, NBN, NF1*). **Conclusions:** Upfront MGPT in an unselected EC population improved LS diagnosis and identified an additional 2% of patients with LP/PVs in highly penetrant CSGs. The enrichment of germline BRCA1/2 PVs in type II cancers is consistent with prior reports that non-endometrioid tumors are frequently deficient in homologous recombination. Germline BRCA mutation is a known predictive biomarker in ovarian cancer and an attractive therapeutic target in EC. Knowing germline status at the time of diagnosis facilitates further delineation of germline/phenotype associations, and it defines a genetic syndrome allowing for cancer prevention. Upfront MGPT in EC provides clinically impactful information and should be adopted into routine clinical care. Clinical trial information: NCT03460483. Research Sponsor: The Ohio State University Comprehensive Cancer Center-James Statewide Cancer Impact Award.

Trends in the incidence of endometrial cancer among young women in the United States, 2001 to 2017. *First Author: Fangjian Guo, University of Texas Medical Branch at Galveston, Galveston, TX*

Background: Endometrial cancer at this time is predominantly being looked at as a disease of postmenopausal population. Increased obesity has been identified as an important risk factor for endometrial cancer. An overall increase incidence of endometrial hyperplasia and endometrial carcinoma in obese premenopausal women has been reported. A close examination of the relationship between trends in endometrial cancer incidence and obesity prevalence in young women will provide important information for prevention and early screening of the disease and its precursors. This study was to assess current trends in endometrial cancer incidence in women ages 20-29 and 30-39 years in relationship to obesity in the US. **Methods:** We used data on US adult women 20-39 years old from the National Program for Cancer Registries and Surveillance, Epidemiology, and End Results Incidence–U.S. Cancer Statistics 2001–2017 database. This database covered essentially all young female population between 2001 and 2017 in the US (Puerto Rico not included). Incidence was age adjusted to the 2020 U.S. standard population. We also examined the trends in obesity prevalence among females 18-34 years old using data from the National Health and Nutrition Examination Survey (NHANES) III and NHANES 1999-2014. **Results:** There were 24,446 cases of endometrial cancer among young adult women aged 20-39 years during 2001-2017. Endometrial cancer incidence increased from 0.6 per 100,000 in 2001 to 1.2 per 100,000 in 2017 (APC 3.6, 95% CI 2.9-4.4) among young women 20-29 years old, and increased from 4.6 per 100,000 in 2001 to 7.5 per 100,000 in 2017 (APC 3.0, 95% CI 2.7-3.3) among women 30-39 years old. Obesity prevalence also increased significantly from 1988-2014 among females 18-34 years old. Incidence of endometrial cancer and obesity prevalence were both higher in Hispanics than in other racial/ethnic groups. **Conclusions:** The significant increasing incidence in endometrial cancer among young adult women is in accordance with the concurrent increasing prevalence in obesity in young girls and women in the US. This indicates that endometrial cancer screening might need to be considered at much earlier age among patients with abnormal bleeding and certain ethnic populations. Research Sponsor: U.S. National Institutes of Health.

Exploring molecular profiles and survival in hormone receptor-positive uterine serous carcinoma. *First Author: Amaranta Craig, Fox Chase Cancer Center, Philadelphia, PA*

Background: Hormone receptor (HR) positivity has been reported as a good prognostic indicator in endometrial cancer. This study investigated estrogen receptor (ER) and progesterone receptor (PR) positivity as indicators of platinum response and improved survival in uterine serous carcinoma (USC), and determined differences in molecular profiles between these tumors and hormone receptor negative tumors. **Methods:** Tumor profiling was done with immunohistochemistry (IHC), next generation sequencing (NGS), and whole transcriptome sequencing (WTS). PD-L1 expression was determined by IHC using SP-142 (cut-off >1%). Microsatellite instability (MSI) status was evaluated with IHC and NGS, and tumor mutational burden (TMB) by totaling somatic mutations per tumor (high if > 10 mutations/ MB). Immune-cell fraction was determined with QuantiSeq. We used insurance claims data to calculate Kaplan-Meier estimates for overall survival (OS). Statistical significance was determined with chi-square and Wilcoxon rank sum test and adjusted for multiple comparisons. **Results:** 2806 USC tumors were available for molecular profiling with 717 HR+/966 HR-, 1559 ER+/1059 ER- and 805 PR+/1809 PR-. Median OS for HR+ patients was longer than patients who were HR- regardless of treatment (1152 v 797 days; hazard ratio 0.68, 95% CI 0.58-0.80, p < 0.01). This OS benefit of HR positivity remained for patients receiving platinum therapy (1134 v 889 days; hazard ratio 0.75, 95% CI 0.58-0.98, p < 0.01). HR+ status trended towards improved OS in those treated with hormone therapy (407 vs 771 days, hazard ratio 0.78, 95% CI 0.59-1.02, p = 0.07). In addition to increased androgen receptor expression (54.2 vs 6.2%, p = < 0.001), PTEN mutations were more common in the HR+ group (10.3 vs 5.1%, p = 0.016). This resulted in in more frequent alterations of the PI3K pathway when compared to HR- tumors 64.5 vs 52.2%, p = < 0.001). PD-L1, TMB, and MSI status were similar between the two cohorts. Checkpoint inhibitor gene expression was notable for higher IDO expression in the HR+ group, but lower CD80, CD86, HAVCR2, IFNG, and PDC1 expression. The immune micro-environment was notable for less B-cells and M1 macrophages, but more M2 macrophages. Breaking the ER and PR positive cohort down to individual expression of each gene resulted in similar OS and molecular findings. **Conclusions:** HR positivity is associated with improved survival in allcomers with USC and those treated with platinum therapy, and there was a trend to improved OS with hormone therapy. More data is needed to determine if HR status is a prognostic marker for IO treatment response. This cohort had a distinct molecular profile compared to HR- tumors. Research Sponsor: None.

HER2 in uterine serous carcinoma: Testing platforms and implications for targeted therapy. *First Author: Tenley Klc, University of Minnesota Physician's Oncology Clinic-Masonic Cancer Clinic, Minneapolis, MN*

Background: HER2 is an emerging prognostic and therapeutic target in uterine serous carcinoma (USC). Testing algorithms and platforms in breast and gastric cancers are well studied and validated, but optimal HER2 testing in uterine cancer is not yet established. We aimed to assess the concordance of chromogenic in situ hybridization (CISH), immunohistochemistry (IHC), and next generation sequencing (NGS) platforms to aid in the development of USC specific testing guidelines. We also evaluated the rate of downstream mutations that may affect response to HER2 directed therapy. **Methods:** A total of 2,192 USC tumors were analyzed using NGS (NextSeq, 592 Genes and WES, NovaSEQ), a subset of 1,423 tumors were also tested by IHC and CISH (Caris Life Sciences, Phoenix, AZ). HER2 positivity through IHC (4B5, Ventana) and CISH (INFORM DUAL HER2 ISH Assay, Ventana) was determined based on 2007 and 2018 ASCO/CAP HER2 breast cancer guidelines. PD-L1 expression was tested by IHC using SP142 (Spring Biosciences) (positive cut-off >1%). Microsatellite instability (MSI) was tested by fragment analysis (FA), IHC and NGS. Tumor mutational burden (TMB) was measured by totaling somatic mutations per tumor (TMB-high cut-off > 10 mutations per Mb). Statistical significance was determined using chi-square. **Results:** Rates of HER2 positivity were comparable using the 2018 and 2007 breast cancer guidelines (19.5% vs 17.5%; p=0.25). Based on 2018 guidelines, the concordance between IHC and CISH was 98.9%. Specifically, 229/1423 patients (16%) were IHC+/CISH+, 5 patients (0.4%) were IHC+/CISH- and 11 patients (0.8%) were IHC-/CISH+ (Table). Common pathway alterations in HER2+ USC include TP53, RTK RAS, PI3K, NOTCH, chromatin remodeling and cell cycle genes. Single gene alterations in HER2+ tumors that may implicate HER2 therapy resistance (based on pathway analyses in other tumor types) included PI3K (36%), KRAS (2.6%), and PTEN (2.1%). HER2+ tumors had low immunotherapy biomarker profiles (0.3% MSI-H, 0.8% TMB, 17.1% PD-L1). **Conclusions:** High concordance rates were observed between CISH and IHC. Ultimately these testing platforms need to be validated by response to HER2 targeted therapies in order to develop USC specific HER2 testing guidelines. Research Sponsor: None.

Concordance of IHC and CISH in determining HER2 positivity by 2007 and 2018 breast cancer guidelines.

ASCO/CAP Guidelines (Breast Cancer)	IHC+/ CISH+	IHC-/ CISH-	IHC+/ CISH-	IHC-/ CISH+	Concordance (%)	Sensitivity (%)	Specificity (%)	PPV (%)
2007	164	1160	2	8	99.3	98.8	99.3	95.3
2018	229	1178	5	11	98.9	97.9	99.1	95.4

Treatment patterns and outcomes among patients with microsatellite stable (MSS) advanced endometrial cancer in the United States: Endometrial Cancer Health Outcomes (ECHO) retrospective chart review Study. *First Author: Shelby Corman, Pharmerit-an OPEN Health Company, Bethesda, MD*

Background: Traditional platinum-based systemic chemotherapy continue to be the SOC for aEC in the first line. Phase 2 clinical trials of chemotherapy (GOG 129 series) and some targeted therapies (229 series) for second line advanced endometrial cancer (aEC) have proved disappointing. Recently the treatment landscape for aEC patients has significantly changed with newer targeted therapies focusing on the microsatellite instability (MSI) status of endometrial tumors. The objective of the ECHO study was to describe real-world treatment patterns and outcomes in non-MSI-high or DNA mismatch repair proficient (pMMR) aEC patients in clinical practice in the United States (US) prior to 2019. **Methods:** The ECHO study is a multicenter, retrospective chart review study in women diagnosed with aEC in the US. Data were obtained from medical records of adult women (≥18 years) diagnosed with advanced or inoperable aEC (stages III or IV) with known MSI status, who had received at least one prior systemic therapy and progressed between July 1, 2016 – June 30, 2019. De-identified patient data extracted by treating oncologists included patient demographics, clinical and treatment characteristics, and clinical outcomes. Kaplan-Meier analyses were performed to estimate real-world progression-free survival (rwPFS) and overall survival (OS). **Results:** A total of 124 non-MSI-high or pMMR aEC patients who had progression following first line therapy were included in this interim analysis. Average age was 63 years, 62.9% White/Caucasian, 16.9% Hispanic/Latino, and 86% had ECOG ≤1. Metastases were observed in 70% of patients at diagnosis, with the most common metastatic sites being lung (47.6%), liver (32.3%), and distant lymph nodes (29%). As 2nd line therapy, 69% of patients received mono or combination chemotherapy (primarily with doxorubicin), 13% hormonal therapy, and 18% targeted therapy ± chemotherapy. Median duration of 2nd line therapy was 4 months. The majority (86.3%) discontinued 2nd line therapy , with disease progression the most common reason (66.4%). A quarter (26.6%) of patients initiated an additional line of therapy. Median rwPFS from initiation of 2nd line therapy was 5 months (95% confidence interval [CI]: 4-9). Median OS from initiation of 2nd line therapy was 12 months (95%CI: 9-18). Estimated OS rates from initiation of 2nd line therapy at 6, 12, and 24 months were 66%, 47%, and 30%, respectively. **Conclusions:** In this retrospective, chart review study, patients with non-MSI-high/pMMR aEC in the US who failed at least one systemic therapy had poor prognosis on subsequent therapies. There continues to be a significant unmet need in this group of women. Novel therapies are needed that delay progression and/or improve overall survival and further research is indicated to explore this. Molecular determinants of response to immune-oncology therapy in uterine carcinosarcoma. *First Author: Annelise M. Wilhite, University of South Alabama, Mobile, AL*

Background: Uterine carcinosarcoma (UCS) is subtype of endometrial cancer (EC) with aggressive behavior and poor prognosis. UCS has not traditionally been included in EC clinical trials and treatment options are limited. Immune-oncology (IO) therapy has shown promise UCS, but it is unknown which patients benefit most. We sought to identify immunogenic markers in UCS and explore treatment response to IO therapy. **Methods:** Tumor samples were analyzed using Nex-Gen sequencing of the DNA (NextSeq, 592 genes or NovaSeq, whole exome sequencing) and RNA (NovaSeq, whole transcriptome sequencing) and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ).PD-L1 IHC used SP-142 (cut-off >1%). MSI was tested by FA, IHC and NGS. TMB was measured by totaling somatic mutations per tumor (high > 10 mutations per MB). Immune cell fraction was calculated by QuantiSeq. Overall survival (OS) information was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined patient cohorts. Statistical significance was determined using chi-square and Wilcoxon rank sum test and p values adjusted for multiple comparisons (q) to be <0.05. **Results:** A total of 1,144 UCS tumors underwent comprehensive tumor profiling. 68.4% of samples were obtained from primary tumors and 31.6% from metastatic sites. 21.6% of tumors expressed PD-L1, 8.5% were TMB-H and 6.8% were MSI-H/MMRd. UCS patients treated with IO had longer median overall survival than those not treated with IO (months: 31.2 vs 19.4; HR(95% CI): 0.39 (0.17-0.76) p=0.005). Median OS was also increased for dMMR/MSI-H (OS not yet reached vs 18.9 months); HR(95% CI): 0.56 (0.36-0.92) p=0.019) and TMB-H (OS not yet reached vs 18.9 months); HR(95% CI): 0.62 (0.38-0.99) p=0.047). More patients are needed to determine if these markers predict response to IO therapy. The most common mutations in UCS led to pathway dysregulation in the PI3K, RAS, chromatin remodeling, HR, and WNT pathways. dMMR/MSI-H tumors have distinct molecular profiles compared to MSS tumors (table). Additionally, dMMR/MSI-H tumors had higher TMB (96.9% vs 2.2%, q<0.01) and increased frequency of PDL-1 (23.6% vs 13.8%; q=0.04). Immune checkpoint genes were more often expressed in MSI-H tumors, though this was non-significant except for IFNG (4.66-fold increase; q=0.01). **Conclusions:** IO therapy is associated with improved survival in USC. MSI and TMB are markers of improved OS in patients with UCS. MSI tumors have a distinct molecular profile compared to MSS tumors, and they appear to be more immunogenic, which could contribute to the improved survival seen in patients who received IO therapy.
